	(18)	- Recyclable solid wastes storage facilities and separate collection of 6 or more: 58.33% - Separate collection of 6 or more: 33.33% - Separate collection of 5 or more: 8.33%
	(19)	Installation of hydro-extracting equipments for food wastes: 100.00%
	(20)	Reduction rate of city water use: average 27.4%
	(21)	Installation of rainwater harvesting systems of which capacities are equivalent to 5% or more of needed service water: 25.00%
	(22)	Water permeable pavement ratio: average 53.4%
Ecological environment	(27)	On-site topsoil reuse ratio: average 5.46%
	(28)	- Alternative green retaining wall ratio: average 36.75% - Green roof ratio: average 1.21% - Green wall ratio: average 31.28% - Green fence ratio: average 55.56% - Green retaining wall ratio: average 34.87%
	(29)	Garden-to-site area ratio: average 36.62%
	(31)	- Biotope for aquatic life-to-site area ratio (on the natural ground surface): average 0.44% - Biotope for aquatic life-to-site area ratio (on the artificial ground surface): average 0.66%
	(32)	- Biotope for terrestrial life-to-site area ratio (on the natural ground surface): average 0.81% - Biotope for terrestrial life-to-site area ratio (on the artificial ground surface): average 1.27%
Indoor environment	(33)	- No use of UFFC (Urea Formaldehyde Foam Cavity) insulation: 41.67% - Number of low or no VOCs materials applied: average 4.25
	(34)	- Installation of heat recovered and controllable ventilation system per room: 25.00% - Installation of controllable ventilation system: 50.00% - Openable window-to-floor area ratio: average 17.53%
	(35)	Installation rate of thermostat per each room or zone: average 98.33%
	(36)	Thickness of the walls between units: average 199.17mm
	(37)	Green space-to-balcony area ratio: average 9.72%
Extra	(39)	Noise level difference between the values of complex and environmental standard: average -5.62dB (daytime), -4.96dB (nighttime)
	(40)	Installation of photovoltaic system for 20% or more of street lamps and solar collector with capacity equivalent to 20% or more of domestic hot water demand for common place (welfare center, community center and so on): only 1 apartment complex
	(41)	Grey water-to-total drained water ratio: average 2.74%
	(42)	Preservation of existing natural resources ratio: average 1.64%
	(43)	- Lightweight impact sound: 50.00% (1st grade), 41.67%(2nd grade) - Heavyweight impact sound: 41.67% (3rd grade)
	(44)	Continuous sun-shined unit ratio at least for 2 hours from 9am to 3pm on the winter solstice: average 81.18%

3.3.5 Indoor environment

Among the allotted items with high points, item 34 (design for natural ventilation) is grouped under the D class (55.00%/3 points). Among the allotted items with low points, item 37 (green space-to-balcony area ratio) comes under the E class (35.00%/2 points).

While ventilation is essential for indoor air quality, in the cold season uncontrolled natural ventilation through open windows may result in a significant amount of heat loss. Thus, it is recommended that the heat recovery ventilation system is applied for the item 34. Item 37 is excluded from the assessment items of the revised GBCS.

3.3.6 Extra

The extra category consists of items that either require significant cost or are difficult to be implemented practically. Every item in the extra category is grouped under the D or E classes, with the exception of item 44.

In the case of item 40 (use of alternative energy), there are problems that equipments' efficiencies are too low to be applied widely to the apartment complex. Item 41 (installation of grey water system) may increase the maintenance cost as well as the construction cost. Moreover, the city water rate is very low. However, it is recommended that these items be applied to common facilities such as a community center, etc., considering the demand for a reduction in the use of fossil fuels and the conservation of water resources. Because residents are significantly influenced by the item 43 (sound insulation performance of the floor), it is essential to apply a sound-insulated floor structure. Measures of the increase in the thickness of the floor structure, the insertion of the impact-absorbing material, etc. may be applied.

4. Summary and Conclusions

In Korea, the GBCS (Green Building Certification System) has been in force since 2002. A total of 6 types of buildings are dealt in the GBCS. In particular, it is anticipated that the number of applications for GBCS for apartment complexes in Korea has increased continuously due to financial incentive programs that have been offered since 2006 for certified apartment complexes. In this study, we aim to pick out the items requiring improvement for the green apartment complex. Existing 12 certified apartment complexes were selected. GBCS assessment results and actual conditions of design and construction were investigated and analyzed. Among the 23 items with high allotted points, 11 items were grouped under either the D (worse) or E (worst) classes, including gross floor-to-site area ratio, Energy Performance Index, reduction of CO_2 emission, application of artificial landscaping methods considering ecological environment, garden-to-site area ratio, design for natural ventilation and extra items, with the exception of the percentage of sunshine entering into the unit. Among the 21 items with low allotted points, 7 items were grouped under the D (worse) or E (worst) classes, including interference to the right to sunshine of adjacent properties, the connection of an on-site pedestrian walkway to the outside public walkway, minimal use of furniture through the built-in wardrobe, use of rainwater, on-site topsoil reuse ratio, connection to the outside green space and the green space-to-balcony area ratio. It is expected that the relevant specifics regarding these items will be helpful for future design works.

Summary

The main goal of the research project, GLITNE, is to produce knowledge on how environmentally effective buildings can be made more competitive. Extended Producer Responsibility (EPR) is an environmental policy approach in which a producer's responsibility, physical and/or financial, for a product is extended to the post-consumer stage of a product's life cycle. The superior idea is that trough the introduction of EPR in the building industry, including environmental considerations the building project will become profitable. This may be realised though a clear documentation of the environmental properties of products and constructions, to advance environmental product development, and an EPR model, ensuring that environmentally effective buildings also are the economically most favourable.

Based on the experience with the different models for EPR in other industries and the special challenges connected with the building industry, a model were an independent third party is responsible for the product after use on behalf of the producer seems interesting (one of three models for EPR). This will be a target of further investigation.

The EPR model will be linked to a tool, designed as a model checker towards an intelligent Building Information Model (BIM). A building model may then automatically, at different stages in the building process, be checked with respect to its environmental properties.

The article presents the preliminary results for this innovating project, including the first steps towards finding a suitable valuation method.

1. Introduction

The research project, short name GLITNE[1], is financed by the Norwegian research Council, Norwegian Housing bank and National office of Building Technology. Snøhetta AS is the owner of the project, and SINTEF Building Infrastructure the research partner. Partners involved in different degrees in the project are Snøhetta, SINTEF Building infrastructure, Norwegian financial Services organisation, Entra eiendom, Teknobygg, National office of Building Technology and Administration Norway, Norwegian steel association, Wood Polymer Technology, The Norwegian Association for Ventilation and Energy Technology, NCC, Veolia miljø, OSO Hotwater, Protan and Bellona. Together they represent all phases in the building lifecycle, many stakeholders and liable actors in a buildings lifespan.

The main goal of the project is to provide knowledge about how environmentally effective buildings can become more competitive. This is underpinned by the following sub goals:

[1] GLITNE ("The glowing") is in the Norse mythology the house of "Forsethe" in "Aasgaard". The hall had a roof of silver and pillars of gold. "Forsete" is the god of justice, and was the son of "Balder" and "Nanna". He sat by the "hov" (place of worship) of the gods, and was a lawmaker and judge in difficult cases. Most often he managed to come to an agreement in all difficult cases.

- Based on existing knowledge produce a method and a tool to show the environmental consequences of a building, for the user, government and business.
- Produce knowledge on how the partners in the project may use the method in environmental product development and therein innovative solutions.
- Suggest a model for extended producer responsibility that will benefit the construction/ building industry.
- Provide facts as a input to national and international standards, laws and regulations on the area.

The results of GLITNE are mainly:

1. An established weighting principle/method to calculate the environmental load from a building
2. A structure to follow the initial environmental goals for a project, though design, construction, operation and demolition
3. A tool to make the method and structure above useful to all partners in the project, and hence the construction/building industry
4. An EPR model to make environmentally efficient buildings also the most cost effective one

In this paper it is discussed how EPR might be a solution for the building industry to anticipate environmental challenges, including a discussion of existing models for EPR. Does a suitable economic weighting method for the purpose of EPR exist? Different weighting methods are looked into an evaluated by defined criteria. And finally, some conclusive elements in adjusting an environmental tool such as GLITNE to the building process are presented. This is discussed due to important milestones in the building process and last, outlined due to a suitable tool for the participants in the building process.

2. Background

Nationally it has been a topic in Norway if EPR could be an effective policy instrument to move the building industry in a more environmentally friendly direction. For now it is concluded that "*today the knowledge base is too weak to possibly estimate what the intended and unintended consequences of system like this may be. An improved knowledge basis is a premise for an eventual recommendation of EPR as a suitable system for buildings*" (NOU, 2005).

The basic principle of EPR is that the producer is made responsible for the environmental effects concerning their products throughout the lifetime of the product, the intention of producer responsibility being tripartite:

- Increase recycling and recovery of wasted products, like e.g. building products.
- Awarding of products with high environmental standard, e.g. a construction.
- Stimulate consumers to select products, including buildings, with high environmental standard.

The building industry represents a large share of the environmental load form the society in the respect of resource use, generation of waste, emission of gasses with global warming potential, use of toxic substances etc. The consumption in the dwelling- and building industry are increasing and presumably not consistent with sustainable development. In Norway stricter requirements in terms of environmental programs, substitution of hazardous chemicals, polluted soil, control with hazardous substances in demolition, waste plans etc. are implemented. The largest contribution will most likely come from the new energy labelling program for buildings, probably in the course of 2009-10 (NVE, 2008).

The increasing focus on the significance of building with regard to the environmental loads from our society will most likely lead to stricter requirements. Norway has introduced EPR for several products that represent a significantly lower environmental impact than a building represents throughout its lifetime, e.g. milk cartons and electric products. Today environmentally friendly buildings are not favoured neither towards consumers or when considering business profitability. To build with less environmental load is considered more expensive, at least initially. This is a great hindrance for realising environmentally friendly concepts within the industry.

For the industry it is important to be an active partner, or perhaps also the driving force, in these changes. This active participation will be crucial for the success of any action for change both for the industry and for the resulting environmental improvements. This is a part of the motivation behind GLITNE. The partners want to show the government how EPR may work for the building industry and what conditions that must be fulfilled before such a system is a success. The success depends not only on the environmental effect but also on how it is received and implemented in the industry and in the market.

An important motivation for the partners is to clarify their own premises and make sure that their processes are optimal. They all mean that they have a potential to deliver products and services with lower environmental loads. The most important obstacles to realise this potential are price and demand. They also state that environmentally conscious choices depend on:

- Environmentally consciousness being rewarded
- The availability of tools to ensure these choices
- Improved information throughout the industry

The most important prerequisite to prevent poor environmental decisions that lead to bad solutions are official regulations that are follow-up by enterprise controls and public supervision. Public requirements are the triggering factor on internal follow up in the enterprises (Ovesen, 2008).

3. About EPR as an instrument for sustainable buildings

OECD has defined Extended Producer Responsibility (EPR) as "*an environmental policy approach which a producer's responsibility physical and/or financial, for a product is extended to the post consumer stage of a product's lifecycle*". This approach is based on that the producer has the biggest influence on improving a products environmental properties through production of components (for construction), fabrication (of the building) and waste treatment, reuse and recycling possibilities (of the components of the building) (USEPA, 1997).

3.1 Purpose of EPR

According to NOU (2005:12) the basis for EPR is giving the objective producer responsible liability. The producer has the responsibility for the product from production to waste treatment. This responsibility involves the producer being submitted to duties during the building process, the lifecycle and waste treatment. In this context EPR defines the producer as responsible for the building's environmental load throughout its lifetime. This would involve attaching responsibility for subjects also earlier in the cause-effect chain when a condition of responsibility occurs.

The purpose of an EPR model is to stimulate the market rewarding environmental awareness with increased profit throughout the value chain. Three important elements should be pointed out:

1. The placement of the responsibility of the product environmental load throughout the lifecycle of the product.
2. Rewarding products that are environmentally preferable.
3. Rewarding consumers that select environmentally preferable products.

A good model for EPR, that also takes into account all socioeconomic environmental costs, will also stimulate the reduction of material, resource- and energy use for all processes, elimination of the use of toxicants, reduction of waste production and increasing possibilities for reuse and recycling, and also adjustment and optimisation of the durability of composed products

There are three principally different models for EPR (Spicer et al. 2004):

1. The producer is directly responsible for the product after the user phase
2. A group/trade/industry assumes a collective responsibility for the product after the user phase
3. An independent third party assumes responsibility for the product after use on behalf of the producer. This can be accomplished through different financial mechanisms.

There are many factors in favour of alternative three. One of these, the need for adequate and predictable economic framework for reclaiming and recycling of products with a long service life, is very important to the building industry. How this may work in the Norwegian building industry will be studied further in GLITNE. Scenarios for the different partners in the project will be one of the methods in describing the consequences for the different alternatives.

3.2 How can EPR be a solution for the building industry?

Extended producer responsibility in the building industry as a voluntary arrangement is valuated as less realistic because of the structure of the industry, a major difference compared to the products that already have this type of mechanism implemented. Many small companies, the long lifespan of the product, changing owners, many partners (also from different companies), involved in the lifecycle, are some of the complicating aspects. A relatively fast implementation in the building industry must be done trough official rule.

Initially the producer responsibility is best taken care of though a defined producer buying the right to pollute. The capital will be used to compensate for the harm caused on the environment. In practise the money can be placed in a fund that pays for example for documented appropriate waste treatment in the future. As a public system this would resemble the pension scheme, and could contribute to good marked based arrangements based of free competition and minimal costs (Mysen, 2007).

There are mainly three principally different models identified as feasible dependent on who is responsible:

- The producer of a building product buys the right to pollute per product - a deposit to a fond when importing /producing
- The liable owner of the building initiative buys the right to pollute per object with the application duty according to the Planning and building act.
- Owners buying the right to pollute - paid as an annual insurance.

These three arrangements are possible by themselves or in combination. The main task in GLITNE towards the fall of 2009 is to test these possibilities in close cooperation with the partners, and to analyse the consequences for the industry. The results will be a recommendation regarding EPR as a possible solution for the building industry and if so how could the system be designed to suite the industry and the environment.

4. Survey of monetary based weighting methods

One of the goals of the GLITNE project is to find a monetary based principle for weighting of environmental effects. Monetary valuation is used to improve the basis for decision because:

- effects on environment and health expressed in monetary units can be used to negotiate environmental duties/taxes that internalise external costs
- decision makers, as for example public authorities, will put into action measures that should not cost more than it gains the general public

Environmental valuation is based on peoples willingness to pay a certain amount of money to avoid environmental damage or willingness to accept a compensation if environmental damage occur. The wish to include environmental effects is based on a "market failure", meaning that the market don't reflect the real social value of the environment (Damigos, 2005).

Through monetary valuation environmental effects traditionally regarded as externalities are included and form a basis for better decisions. It is important to remember that monetary valuation only is useful as a basis for decision; the intention is not to estimate a price that someone actually will pay or a real value of e.g. a specie. The social value of environmental good also exceeds the marked price for tree reasons (Brüer, 2003):

1. Lack of scientific knowledge means that there will always be undiscovered and non-valued values related to the functions of an ecosystem.
2. A functioning ecosystem is more worth than the sum of its components.
3. Any ecosystem has a primary value because of it use and non-use values. These primary values cannot be measured by the use of conventional economical terms (consumer preferences).

There are many opponents to monetary valuation of environmental effects, and their primary resistance is based on general resistance against weighting, based on ethical or moral reasons, resistance against the ranking of risks or uncertainty in the primary data.

In GLITNE the partners tends towards monetary based weighting, mainly because it provides a basis for them to make cost effective measures to improve their products, and an understandable and communicative measure of environmental effects related to their activities.

4.1 Important criteria for a suitable weighting method or tool

The goal of the survey was to find existing methods and tools for environmental evaluation of buildings preferably using monetary evaluation. It was also relevant to find tools that had other aspects relevant to the development of the GLITNE tool, e.g. IFC (Industrial Foundation Classes) based tools, tools that is used to any extent, that have a good user interface or structure. Both the internet and article databases were searched to find relevant information. The amount of material available on the two subjects is almost inexhaustible, the resulting report cannot cover all findings, but the most interesting findings are presented in Strand-Hanssen (2008).

The methods and tools found were subjected to a coarse evaluation, to find those relevant to form a basis for GLITNE. It is important that the method developed is based on the relevant standards, including those under development.

In LCI (Life Cycle Inventory) and EPD's it is mostly mid-point effects that are quantified. In monetary evaluation it is mostly the endpoint effects that are valued, this provides a challenge. In addition the aspects listed horizontally in Table 1 were considered important regarding the GLITNE method, based on discussions with the partners and literature:

4.2 Recommended weighting methods for the GLITNE project

The principles of economic weighting evaluated are listed in Table 1, together with a qualitative evaluation of the suitability of the methods in GLITNE.

Table 1: Summary of the evaluation it the different methods for monetary valuation (Strand-Hanssen, 2008)

Method	Theoretical validity	Market validity	Resource needs	Communication	Environmental effects	Flexibility	Total evaluation
Change in productivity	+	+	0	0	÷	?	Not suited
Loss of income	0	+	0	+	÷	?	Not suited
Preventive measures	+	+	÷	+	0	+	Not suited
Recovery measures	0	0	0	+	+	+	Further evaluation
Relocation	?	?	+	÷	÷	÷	Not suited
Travel cost	0	?	÷	?	÷	÷	Not suited
Hedonic pricing	÷	0	÷	+	÷	÷	Not suited
Wage differences	÷	+	÷	÷	÷	?	Not suited
Environmental taxes	?	?	+	+	?	0	Further evaluation
CV	+	0	÷	0	+	+	Further evaluation
Trade off game	+	0	÷	0	+	+	Further evaluation
Priority-evaluation	+	0	÷	?	+	+	Not suited
Artificial markets	+	?	÷	÷	÷	?	Not suited

+	Good
0	Neutral
÷	Poor
?	Not possible to evaluate

The methods found to be suitable for further evaluation in GLITNE were:

1. Costs for recovery measures
2. Environmental taxes
3. Contingent valuation (CV), (existing studies)
4. Trade off game (existing studies)

CV are subjected to substantial critique (presented e.g. in Howarth et al. (2006) og Sagoff (2004), mostly directed towards difficulties the respondents have understanding what they are actually assigning a value. important aspects related to GLITNE is that it is expensive to produce data and difficult to maintain them. In addition results strongly depend on how the survey is designed and carried out. There is a high risk of misleading answers because of misinterpretation of questions or the person answering giving misleading or strategic answers. There are no studies in Norway that can be used in GLITNE, and it is seen as less likely that the industry will accept studies in other countries as a basis for decisions in the Norwegian building industry.

Two interesting studies were found that uses environmental taxes as a basis to valuate willingness to pay, Green tax (Wu et al, 2005) and Ecotax (Eldh, 2003). They both use the principle that the taxes represent the shadow price of the willingness to accept that environmental damage using this principle. There are several taxes in Norway that are completely or partially environmentally motivated, as e.g. tax on the emission of CO_2, tax in the petroleum sector on the continental shelf, Environmental tax on pesticides, tax on HFK and PFK, natural resource tax on power etc.

Recovery measures are considered to represent a conservative value of willingness to pay. It is also considered difficult to assign value to natural resources. There are some existing studies that could provide values to be used also in GLITNE, e.g. cost of the measures necessary to reach the Kyoto targets. Dependent on which political targets selected and the inherent perspective, the price of CO_2 per tonne reduced is found to vary from 183 to 600 NOK (2007). There are also available costs for NOx, SO_2, nmVOC and NH_3 based on damage and recovery costs.

The selection of weighing principle is in the end a choice of value, depending on the view on nature, humans and on the society, including view on equity in time and between generations, belief in market economy and the market ability to solve environmental problems etc. The strategy to reach a conclusion GLITNE is to involve the partners in this discussion. The methodology-group within GLITNE will be presented with the alternatives and challenged to reach a conclusion. The method as such will also be presented to the industry beyond the partners, allowing them to express their views on the method.

5. Some success criteria for an environmental evaluation method for buildings

There are many aspects to consider for an environmental evaluation method to be a success. At this stage we have found that a close relation to the building process and the existing milestones are important, together with a format that will enable the complicated trade-offs necessary to construct an environmentally efficient building.

5.1 Suited to the building process

According to the partners (Ovesen, 2008), the most important phase in the building lifecycle for implementation of environmental measurements are the design phase. But almost everyone involved in the building process are responsible when it comes to setting environmental requirements at some level, including government, investors, developers, planners, architects and engineers, those involved in constructions, client, owners, consumers and insurance. Good environmental information is most important for the architects and the consulting engineers. The GLITNE method and tool must therefore be well suited for their needs in the design process. In programming the client/developer is the important user, in a user/demolition phase the owner would be very important (Ovesen, 2008).

The environmental design process begins with the developer (client or owner) of a building project deciding on an environmental strategy, often defined in an Environmental program. The goals in this program are further developed into requirements, measures in design phase, and realisation through construction and finalisation. Follow up in the user phase and demolition is also important.

Important milestones in the building process related to the Norwegian Planning and Building Act(PBL) are listed in *Table 2*. The GLITNE-EPR check will be linked to the PBL milestones, but the GLITNE method and tool will be in use from strategy phase to demolition.

Table 2: Phases of the building process, PBL milestones and GLITNE-EPR milestones.

Phase	PBL/milestone:	GLITNE- EPR
1. Strategy		
2. Programming		
3. Design		
a) Sketch	Application	→ GLITNE check
b) Pre-project		
c) Detailed project	Permission to start project	→ GLITNE check
4. Construction and completion	Certificate of completion	→ GLITNE check
5. FM		
6. Demolishing and disposal		

The tool will consist of several layers covering the relevant environmental aspects as they develop throughout the process and as build, this may be thought of as a three dimensional matrix (time or phases in the process, the environmental aspects and the measures taken in each phase for each aspect). The challenge is to link measures in the design phase to the resulting environmental effects as e.g. hazardous substances and CO_2 emissions. What happens to the total environmental load of the building if it is designed with a different type of exterior wall? This is among other things what the GLITNE method and tool wants to answer.

5.2 IFC based tool for environmental evaluation of buildings

The literature survey also included a survey of existing tools for environmental evaluation of buildings, about 100 tools were found, and about 30 of them are briefly evaluated in the survey. The goal was identifying relevant aspects to include in the GLITNE method and tool. Of special interest were the tools linked to CAD, especially if they were on IFC format. Interesting tools were LCAdesign, CSIRO, Australia, and BSLCA, Granlund, Finland. These tools have linked LCA and CAD models using BIM (Building Information Model) and IFC. In terms of methodology however they bring few new aspects as they use existing LCA methods. The GLITNE tool will be programmed in IFC, the details of this part of the project is described in Holthe et al. (2008).

The GLITNE tool will be designed as a model checker towards a BIM, communicating using IFC format. The checker will be linked to a BIM to calculate the environmental load at different stages in the building process, also listed in *Table 2*. To include also the energy aspects it must be linked to an energy simulation program. The data on the building materials, EPD's after ISO 21930, could be included in the checker or provided by an exterior database as illustrated in Figure 1. At this stage in the project the tool is split into modules, as e.g. Material, Energy and Transport. Monetary valuation is used to value some of the environmental load, and risk criteria is developed to include other aspects, and forms the basis for placing the building e.g. in different classes of "environmental risk".

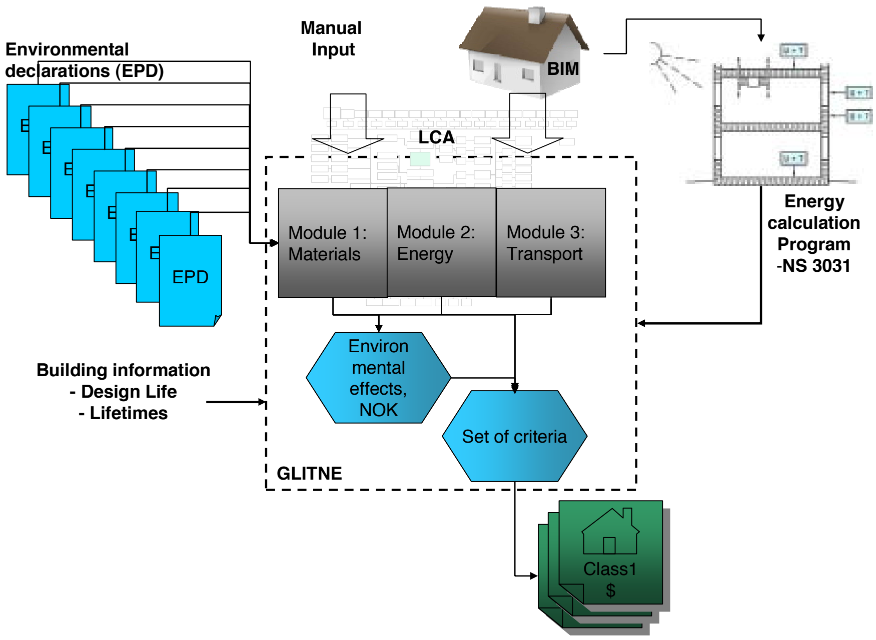

Figure 1: Schematic illustration of the GLITNE tool.

6. Conclusion and further work

An EPR model for the building industry is questionable, but it has solved the problems for other industries. The bottom-line question is whether or not the market alone can solve the problems the industry and the society are facing – that environmentally effective buildings are too costly to produce. Will the public respond to the increasing environmental awareness and invest more money in better buildings? It is seen that the market for ecological food has in some areas exploded. The same increased demand of environmentally efficient buildings is less likely simply because there are less obvious and direct effects, the environmental consequences may be to far away in time or in geography for the investor to acknowledge them. Assuming the market being unable to solve the problems, regulations must be implemented, one suggestion being EPR.

Three possible EPR models are identified, one of them managed by an independent third party assuming responsibility for the product, accomplished through different financial mechanisms e.g. as a fund, where any surplus may be used to find solutions for or reduce the environmental load from the industry. This may be thought of as a system of quotas, where e.g. the owner of the building initiative buys the right to pollute per object beyond a certain defined level.

A suitable weighting principle for the evaluation method could be based on environmental taxes or costs for remediate action. So far it seems like economic valuation alone cannot be used to define the EPR level. There is probably a need for supplementary criteria to be able to cover all relevant environmental aspects. Another possibility is to select and define quotas for some environmental aspects like CO_2, ozone depletion waste to deposit etc. Each building could then be allowed a certain pollution level within these aspects and the owner (or the responsible part according to the selected EPD model) pays for any emissions above these quotas. The money could be used to implement measures to reduce the environmental load in the industry both in direct measures, innovation and research.

A close relation to the existing processes and milestones in a building project is necessary for a tool/method to be a success. Application, permission to start project and certificate of completion are identified as relevant EPR evaluation milestones. The method and the tool must be valid in all phases of the building process and also include all relevant environmental aspects.

The survey of methods for weighting of environmental aspects and assessment methods for buildings, provides a basis for the further development of a GLITNE method and tool. According to the partners in the project it would be an advantage if the method was scientifically correct, but the findings in the survey amongst the partners reviled that this is not a prerequisite for the method to be a success. Factors like usability/user friendliness and advantage are valued as just as important. It is also argued that critique from some groups will arise irrespectively of the method (Ovesen, 2008). These aspects become very important when developing the interface of the tool. The details of the method, structure and tool will be further developed in close relation to the partners of the project. Some partners provide test cases, and some will assist to ensure that the result is well adapted to their needs. The project will be finalized at the end of 2009.

Summary

CASBEE (Comprehensive Assessment System for Building Environmental Efficiency) has been revised and updated in order to be utilized more effectively in the building market. This progress includes introduction of new assessment item "Measures for Global Warming," the development of CASBEE for Home and the development of CASBEE for Urban Development. A number of local authorities now introduce CASBEE into their building administration as a part of sustainable building reporting system. Incentives based on the CASBEE rating are now provided. For instance, the maximum floor-area ratio of the building can be increased if the rating reaches the B+ class, the third of CASBEE's five grades. The city of Osaka subsidizes residential buildings that are A-ranked by CASBEE. Financial sector, such as banks, utilizes such information to offer better interest rates to the consumers who buy environmentally high performance residential units. The assessment of building environmental performance is prevalent among the building industry, in other words, among professionals. On the other hand, the results published by a municipal suggested that social recognition may have more influence on sustainability in the building market.

1. Introduction

CASBEE (Comprehensive Assessment System for Building Environmental Efficiency) is a method for assessing and rating the environmental performance of buildings. In recent years, several local authorities introduced CASBEE into their building administration. Consequently environmental performance assessment of buildings is now carried out in many buildings in Japan. The system appears to have become a very strong driving force towards market transformation of the building industry. This paper firstly explains the change in CASBEE as a system in order to be utilized more effectively in the building market. Then it describes administrative use of such assessment system, and discusses the effects on the building market.

2. Progress of CASBEE Intending Utilization in the Building Market

2.1 The Outline of CASBEE

CASBEE is a comprehensive assessment ranked in five grades: Excellent (S), Very Good (A), Fairly Good (B+), Good (B-) and Poor (C). It has been developed under a committee established within the Institute for Building Environment and Energy Conservation, under the guidance of the Ministry of Land, Infrastructure and Transport. The first assessment tool, CASBEE for Office, was completed in 2002, followed by CASBEE for New Construction in July 2003, CASBEE for Existing Building in July 2004 and CASBEE for Renovation in July 2005. CASBEE assessment tools were developed on the basis of the following three principles: [1] Assessment can continue through the lifecycle of the building. [2] Assessment can consider both the "Environmental quality of the building (Q)" and the "Environmental load of the building (L)." [3] The idea of environmental efficiency can be employed to assess on the basis if Building Environmental Efficiency (BEE), a newly-developed indicator. CASBEE comprises the four basis tools, tailored to the building lifecycle, and expanded tools for specific purposes (Japan Sustainable Building Consortium, 2008a, 2008b). These are collectively called as the "CASBEE Family," as shown in Figure 1.

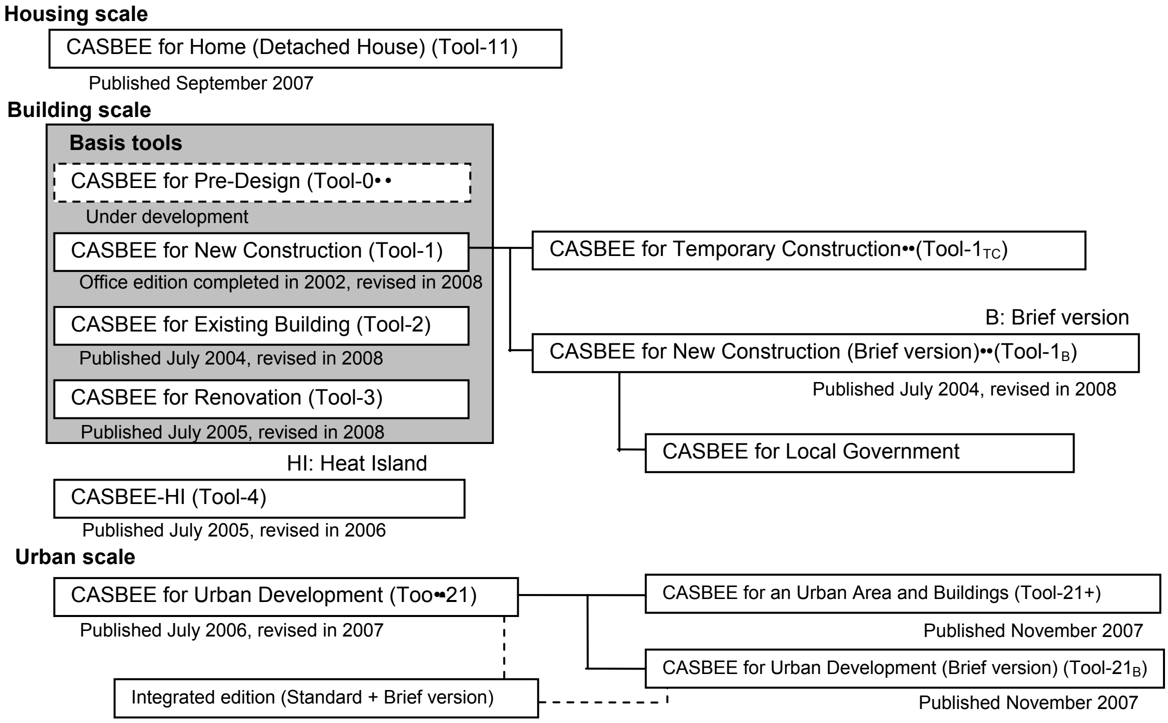

Figure 1 Structure of CASBEE Family

2.2 Incorporation of LCCO2 Assessment to CASBEE and New Assessment Item "Measures for Global Warming"

CASBEE (version 2006) is already capable of assessing efforts to reduce the energy needed to operate buildings, utilize existing building structural frames and recycled construction materials, and extend the service life of buildings. Such efforts can reduce CO2 emissions from the production of construction materials (embodied CO2), and reduce a building's Life Cycle CO2 (LCCO2) emissions, respectively. But Lifecycle CO2 was not directly counted in BEE (Building Environmental Efficiency) and CASBEE Rating.

New CASBEE (version 2008) incorporated a new item, "Measures for Global Warming," that can be rated by LCCO2 emissions. LCCO2 emissions are assessed in the simplified manner and reflected in the item "Measures for Global Warming" under "LR3: Off-site Environment." These results also affect the radar chart, Building Environmental Efficiency (BEE), and CASBEE ranking directly. CASBEE has changed to explicitly assess measures for global warming. This new assessment items has been introduced to all the CASBEE tools since the publication of CASBEE for Home in 2007. Further efforts to prevent global warming are expected to be promoted by the building sector (Sato, 2008).

2.3 Development of CASBEE for Home

In Japan, about 500 thousand detached houses have been constructed per year. To improve the quality of those houses, CASBEE for Home was developed in 2007. There are various stakeholders surrounding housing construction industry such as clients, designers, contractors, and builders. Therefore "CASBEE for Home" especially focuses on making users easy to understand. Among CASBEE tools, CASBEE for Home first introduced five-star indicator as a new expression of the five BEE ranks in addition to the BEE chart.

Structure of "CASBEE for Home" is similar to other tools in the CASBEE family. Both quality and environmental loads are evaluated. They include 54 sub-criteria that are modified from the other standards in Japan. These assessment items for comprehensive assessment consider not only house itself but also outdoor space of the house, home appliances, provided information to the occupants from house suppliers and the environmental strategies at the material produce stage and the construction stage•(Seike, 2008).

2.4 Development of CASBEE for Urban Development

2.4.1 The Purpose of Developing CASBEE for Urban Development•(CASBEE-UD)

Previous CASBEE tools assessed individual buildings, but, as a general rule, CASBEE for Urban Development•(CASBEE-UD) covers groups of buildings. The purpose is that "When a project is planned and implemented that comprises multiple buildings and other elements on a single, large-scale site under a unified design concept, assessment can go beyond the environmental design of each building, to identify new or expanded environmental measures, and their effects, that are made possible by the building group, and thereby contribute to the comprehensive improvement of environmental performance in urban renewal."

For convenience, previous CASBEE versions is referred as "CASBEE (building scale)," to distinguish them from CASBEE for Urban Development, which considers building groups (urban scale).• CASBEE-UD carries on the concepts of CASBEE (building scale), and it is one of the expanded CASBEE tools, developed with reference to the Q-3 (Outdoor Environment on Site) and LR-3 (Off-site Environment) assessment items of CASBEE for New Construction. However, CASBEE-UD is an environmental performance assessment tool for whole groups of buildings (urban scale), focusing on the phenomena that can accompany the conglomeration of buildings, and the outdoor spaces around the buildings. It is also a standalone system, independent of the previous building-scale CASBEE. CASBEE-UD excludes the interior of buildings from assessment (although there are exceptions in some assessment items), as shown in Figure 2.• Therefore, this configuration makes it possible to use [1] CASBEE-UD to assess an area of development as a whole, while [2] CASBEE (building scale) assesses the environmental performance of individual buildings within the designated area• (Japan Sustainable Building Consortium, 2008c).

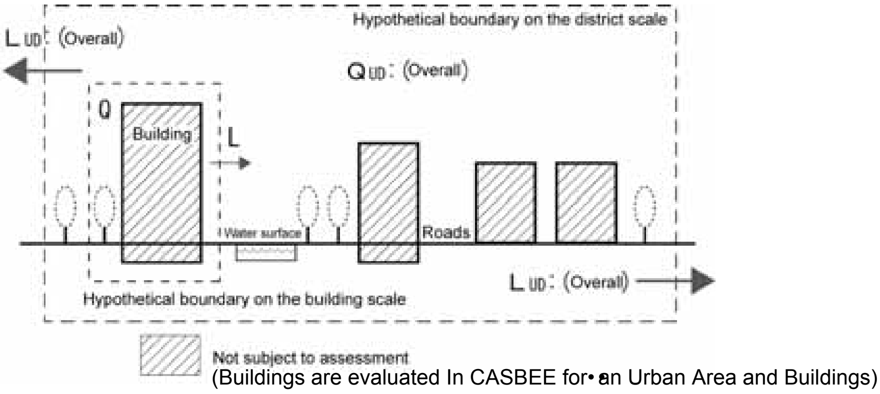

Figure2 Concept of Assessment subjects for CASBEE for Urban Development

The following are four examples of ways in which CASBEE-UD is used.

1)•• As a tool for environmental consideration in area development projects.
2)•• As an environmental labeling tool.
3)• As a planning and assessment tool for energy-saving remodeling plans on the urban scale.••••

4)• As a tool to support city planning with a view to sustainable urban development.

The first three applications, taken together, are expected to act as an incentive for environmental consideration in area development projects.• Following the pattern of CASBEE for New Construction, a brief version has been developed to enable easy application from the preliminary stages of a plan.

2.4.2 The CASBEE for an Urban Area and Buildings

Now the overall indication format for assessment results [1] and [2] in 2.4.1 is defined separately as CASBEE for an Urban Area and Buildings (abbreviated below to "Urban + Building"), to meet demand for assessment of the urban area as a whole, including buildings. Also, as the assessment items for CASBEE-UD includes important elements of the city and regional planning fields, which may not extend down to the building scale, we recommend that Urban + Building be applied to projects which are individual buildings but have high levels of public interest (major social impact). That approach enables assessment using CASBEE-UD together with building-scale assessment. Figure 3 shows an example of the BEE of an Urban Area and Buildings.

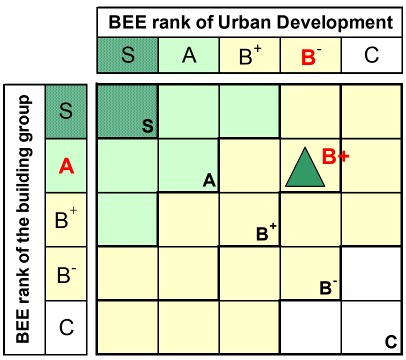

Figure 3 An example of BEE of an Urban Area and Buildings

3. Measures to Spread Environmental Performance Assessment for Buildings by Public Sector

3.1 Administrative Use of CASBEE by Local Governments

Public sector has been playing a major role in spreading environmental performance assessment of buildings in Japan. In recent years, many major cities and prefectures in Japan have been adopting “Sustainable building reporting systems• (SBRS)” as an environmental policy in their building administration. To operate this system, these local authorities utilize an environment performance evaluation method for buildings as policy instruments. Under required ordinances and guidelines, building owners are asked to carry out comprehensive assessment of their buildings’ environmental performance when a building above a certain size is newly constructed. These results must be reported to the authority and the authority must publish the submitted assessment results of environmental performance. Figure 4 shows the number of reports assessed by CASBEE published by the local authorities.• Over 2,000 CASBEE results have been submitted to the local authorities by Sept. 2007. Most authorities use the Internet to disclose the results and the summary of environmental measures taken by the building owner to improve environmental performance.• •

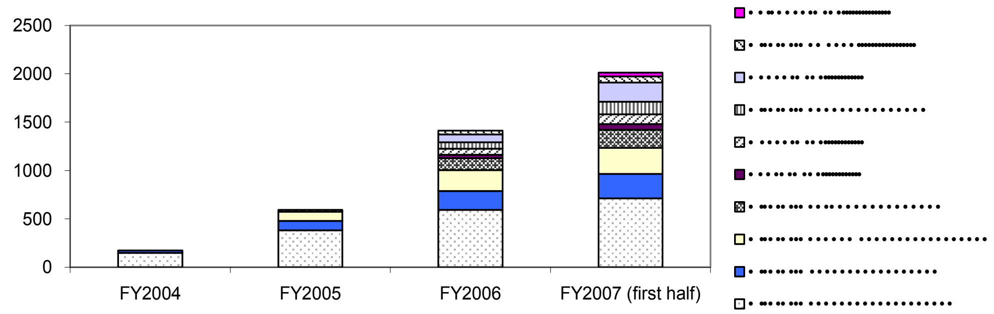

Figure 4 Number of CASBEE results submitted to the local authorities (as of Sept. 2007)

The reporting system is designed to promote voluntary actions by building owners for the environment through information disclosure to the local residents, by showing which building owners are active in environmental measures.

3.2 Localization of CASBEE

CASBEE is also intended to take regional conditions into consideration as background for the assessment. To promote environmental assessment for buildings, localization is one of the important processes to meet social demand of the region where the building market exists.

Local characteristics such as infrastructure, local economy, climate and history may be different. Local authorities that use this tool can tailor it to local conditions, such as climate and prioritized policies. Changes are generally made by modifying the weighting coefficients. Flexible response to regional character is a common feature of all elements of CASBEE.• CASBEE-Nagoya has its own scoring guidelines that instruct some criteria in relation to local contexts, such as materials from local industry, and that define some excluding criteria (Noda, 2004). Another example is CASBEE-Osaka that altered weighting coefficient from the original to reflect the high priority they give to heat island policy. They changed the weights of Q-3 Outdoor environment on site from 0.3 to 0.4• (City of Osaka).

3.3 Advanced Application of CASBEE to Promote Sustainable Buildings in the Building Market

3.3.1 Incentives by the Municipals

Further, it is possible to provide incentives to buildings which gain high ratings with CASBEE, as shown Table 1. In city of Osaka, the rating should at least reach the B+ class, the third of CASBEE’s five grades, if the approval for an administrative scheme, called “Planned design system (sougou sekkei seido),” is given to the building being assessed. The maximum floor-area ratio of the building can be increased in this scheme. In Nagoya, 250% maximum floor-area ratio will be given if the buildings are S-ranked by CASBEE, whereas 200% will be given to the A-ranked buildings.

Financial support can be provided for high score buildings assessed by CASBEE. The city of Osaka subsidizes residential buildings that are A-ranked by CASBEE. The city of Nagoya also subsidizes the residential buildings selected in order of BEE value by CASBEE.

3.3.2 Utilization of the Assessment by Financial Sector

Financial sector, such as banks, may utilize such information to offer better interest rates to the consumers who buy environmentally high performance residential units.• In Kawasaki, developers who are selling multi residential units must publish CASBEE results in their advertisements to inform consumers about the environmental performance of the buildings (City of Kawasaki). This scheme is called “Environmental Performance Indication System for Apartment Buildings.” Up to 1.5 % reduction in the interest rate is available for the consumers who bought units assessed as S-ranked by CASBEE-Kawasaki.

Table 1 Administrative use of CASBEE by local governments

Municipality	Started	Subject building scale (total floor area)	Adoption of Localized CASBEE	Incentives by government Extra floor	Subsidy	Awards
City of Nagoya	2004.04	> 2,000 m^2	CASBEE-Nagoya	yes	yes	
City of Osaka	2004.10	> 5,000 m^2	CASBEE-Osaka	yes	yes	yes
City of Yokohama	2005.07	> 5,000 m^2	CASBEE-Yokohama	yes		
City of Kyoto	2005.10	>= 2,000 m^2	CASBEE-NCb*			
Kyoto Pref.	2006.04	>= 2,000 m^2	CASBEE-NCb*			
Osaka Pref.	2006.04	> 5,000 m^2	Osaka’s own indicator + CASBEE-NCb *			yes
City of Kobe	2006.08	>= 2,000 m^2	CASBEE-Kobe			
Hyogo Pref.	2006.10	>= 2,000 m^2	CASBEE-NCb*

City of Fukuoka	2007.10	> 5,000 m^2	CASBEE-Fukuoka			
City of Sapporo	2007.11	> 5,000 m^2	CASBEE-Sapporo			
City of Kitakyushu	2007.11	>= 2,000 m^2	CASBEE-Kitakyushu**			

* CASBEE-NCb; Standard version of CASBEE-NCb
** Under development

4. Discussion

4.1 Increased Number of Professionals

The number of accredited professional CASBEE assessor is increasing year by year. Those who aiming to become assessor must attend an assessor training course, pass the assessor examination, and then complete registration. Applicants must be the first-class architects to be qualified. Even though the requirements of becoming CASBEE accredited assessor seem very demanding, the number of applicants increases rapidly because of the SBRSs introduced by many major municipalities. This suggests that assessment of building environmental performance is prevalent among the building industry, in other words, among professionals.

4.2 Environmental Performance of Buildings

It is crucial to investigate how the environmental performance of buildings improved because of the SBRSs using environmental performance assessment of buildings. The assessment results published by a municipal are shown in Figure 6. The SBRS of the municipal subjects buildings of total floor area above 5,000 m^2. This shows that apartment building accounts the largest part in new construction by building type. Many factories are low ranked in comparison to the other building types.

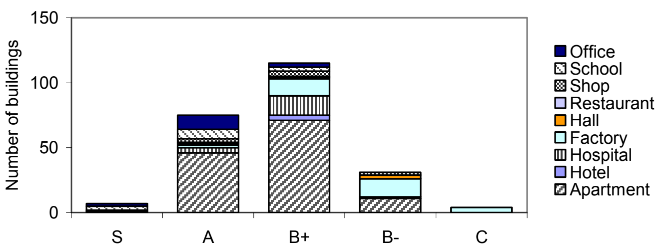

Figure 6 Assessment results of CASBEE in a municipal by building type.

Figure 7 describes variation of the environmental performance of reported buildings in the municipal from 2005 to 2007. Factories are excluded in this figure. This figure suggests that improvement in environmental performance of buildings can not be seen between 2005 and 2007 for both apartments and commercial buildings. It is also said that very few buildings are S-ranked since 2005. This also applies to other municipalities.

Tokyo metropolitan government (TMG) is the first municipal that adopted the SBRS and Environmental Performance Indication System for Apartment Buildings. TMG does not use CASBEE but operates its own assessment system. Since the indication system has started in 2005, TMG (2007) suggested that there was a slight improvement in environmental performance among apartment buildings. By comparing the assessment results between 2005 and 2006, the percentage of the top scored, so called “three stars,” building, increased from 12% to 25% in insulation, from 32% to 42% in energy saving, from 8% to 9% in durability and from 48% to 51% in outdoor planting. However TMG also reported that commercial buildings were not improved in terms of CO2 emission.

To make a conclusion, further accumulation of data is required. However, one reason for the improvement of environmental performance in apartments in TMG may be because of Environmental Performance Indication System for Apartment Buildings. The indication system directly sends information on the environmental performance to the end consumers in the building market. And the results can be far more easily compared by the end customers to utilize for their decision making. This situation encourages developers to improve environmental performance of buildings they provide. Social recognition seems to have a very important role in improving sustainability of the building market.

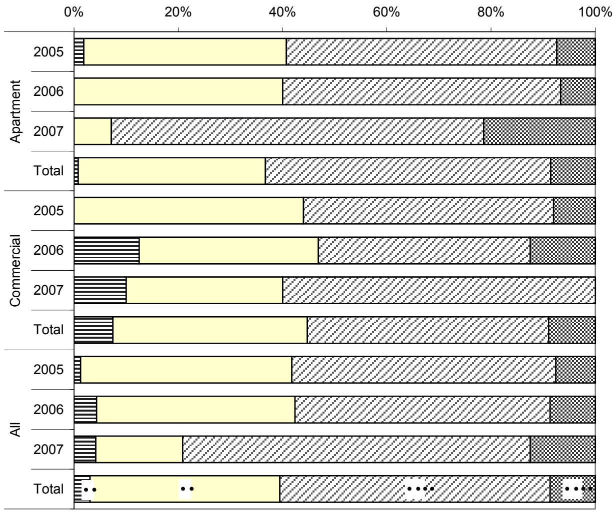

Figure 7 Percentage of BEE rank in a municipal from 2005 to 2007 (excluding factories)

5. Conclusion

1. CASBEE has been revised and updated intending wide use of assessment in the building market. This progress includes introduction of new assessment item "Measures for Global Warming," the development of CASBEE for Home and the development of CASBEE for Urban Development.

2. CASBEE has been seen as one of the most useful policy instruments by local governments. Together with incentives, administrative use of CASBEE is the most effective in spreading assessment of building environmental performance, so far.

3. The recognition of environmental performance of buildings has been widely spread among professionals in the building industry. However the social recognition, especially among the last consumers, of environmental performance of buildings may have more influence on sustainability in the building market.

STRATIFIED CHILLED WATER THERMAL STORAGE SYSTEMS IN QUEENSLAND

Eric L PETERSON PhD, PE, RPEQ[1]
Frank SCHULZE, RPEQ[2]

[1] School of ACME and Institute of Sustainability and Innovation, Victoria University, Melbourne MC, VIC, Australia eric.peterson@vu.edu.au

Keywords: stratified chilled water storage, thermal storage; energy efficiency; demand side management

Summary

Following the lead of Universities in the Northern Territory, Western Australian, and North Queensland, the Queensland Department of Public Works have installed a stratified chilled water thermal storage system at Runcorn to take advantage of lower electricity prices at night. This paper documents the thermal storage renovation of the Queensland State Archives at Runcorn (QSA2) and the oral presentation will also review thermal energy storage infrastructure at James University Cairns and Townsville campuses. In all these facilities there is a new focus on energy and water conservation improvements to existing heating, ventilation, and air-conditioning (HVAC) beyond minimal construction cost in compliance with building codes of Australia. These should be classed as environmentally sustainable design (ESD) integrations into the pre-existing traditional HVAC systems. The present draft focuses on the Runcorn QSA2 case study, but analogous examples will be provided from the James Cook University campuses as soon as operational trend logs are available. Three case studies are discussed, in Cairns, Townsville, and Brisbane. First was a 3 million litre tank at the Cairns campus of James Cook University, then a similar installation on the Queensland State Government Archives expansion at Runcorn, and most recently a 14 million litre tank at the Townsville Campus of James Cook University to replacing several ice storage systems with a district cooling system.

1. Off-peak chilled water storage

Chilled water plant within QSA Runcorn Stage 1 will be extended to meet the total load of both Stages 1 & 2. This involves provision of a new chiller and a new cooling tower within the space available within existing stage 1 plantrooms. This report also recommends the optional additional capital investment in an outdoor chilled water storage tank with larger centrifugal chiller capable of generating all of the cooling capacity 8 hours each night when electricity is cheap and energy and water are used more efficiently. The payback will be about 10 years based on the current cost of power, but may be sooner if demand for electric power increases faster than the provision of new power stations. Advantages of the proposed additional capital investment include lower energy costs, increased chiller life, reduced maintenance costs, and 16 hours cooling load storage capacity in-case of daytime power failure. The preferred option upgraded chiller installation will serve 70% more air handling loads, all the while reduce greenhouse gas emissions associated with the stage 1 + 2 chilled water plant by 28% below stage 1 only.

There were alternative-options for the dimensions and location of the outdoor chilled water tank: the arrangement of the design development at the rear of QSA2 at RL 80m; verses a wider and shorter arrangement amongst trees up hill at RL 86 m. In both cases the tank needs 3,000 kL effective chilled water storage capacity, and in any case the top of the tank is tied to the height of the building. Other alternative tank configurations with lower elevation overflows were excluded due to unacceptable increases in payback and operational risks. Dimensions of the thermal storage tank have now been determined to be either 14.696 m diameter × 19.60 m high if based at RL 80 m above sea level; or 18.564 m diameter × 13.84 m high if based at RL 86 m above sealevel. In either case the top working level of the tank shall be at least 98.6 m above sealevel, plus overflow and freeboard.

The advantages of placement at RL80 m are the minimum capital cost of connected chilled water piping and economical pumping that results in the payback analysis documented in the present report.

The pipework associated with siting the chilled water storage tank based at RL 86 m would have required substantially more underground trenching, and crossing under/over many other buried services such as watermains, sewers, power, and data/telecom. Furthermore the hillside tank location at RL 86 m would require the clearing of a number of mature trees and the excavation and leveling of reactive soils. From an engineering perspective it would be preferable to fix the location at RL 80 according to the design development, but it is understood that aesthetic impact of the large tank could be better in the hillside. With an ideal location on-top of the hill at RL 89 m, but that would depend on re-negotiation of a 287 m² Lands Lease held by Telstra in the SE corner of the 8 ha State Archives site. Perhaps our engineers and Telstra could collaboratively redesign our tank 11 m high x 20 m diameter to accommodate the Kuraby tower, but such was far beyond the scope of the project management constraints. Also be warned that Telstra have outsourced infrastructure design and maintenance to various parties, so it would have been unclear who to work with even if timelines were not a concern.

This report assesses the performance of existing air handlers, chillers and cooling towers and to provide design development guidance for stage 2, with particular attention to finding added cooling capacity with thermal storage. Water and greenhouse gas emissions impacts are also estimated in this report.

The original stage 1 facility included sufficient plantroom space to provide additional chiller and cooling tower capacity sufficient for stage 2 air conditioning loads. ESD initiatives considered in the present report are focused on air-conditioning systems to be installed in Stage 2, and necessary changes to the existing chilled water plant that serves both the Stage 1 and Stage 2 facilities. The chillers are water cooled with cooling towers that use a substantial amount of town water, and so water requirements and recycling opportunities are reviewed.

1.1 Thermal storage with centrifugal chiller

As another ESD initiative, the present report considers an off-peak thermal storage tank run at night, exploiting the tendency of cold water produced by chillers to sink while warmer spent water is drawn off the top. A rising boundary layer thermocline about 300 mm thick is established between the two zones as the tank is charged with chilled water by chillers running full load at the time of lowest electricity cost and highest efficiency.

Thermal storage tanks must have the strength to withstand the pressure of the chilled water, and corrosion-resistant. Aboveground outdoor tanks must be weather-resistant. Buried tanks must withstand the weight of their soil covering and parked cars. Tanks should be insulated to minimize external condensation and limit thermal losses to 1%.

Large steel tanks, with capacity of up to several million litres, are typically cylindrical in shape and field-erected of from plate steel. Epoxy coating is usually required to protect the tank interior, and may colour the exterior for aesthetic appeal. Southern Cross Encon has an economical unpressurized modular system of hot-dip galvanized steel panels manufactured in Toowoomba, and assembled on site before insertion of foam insulation and rubber bag liner. It is reported that there is a cheaper competitor on the Gold Coast who has had some failures in Sydney. The Encon system has a free surface that must be positioned a couple of meters above the highest cooling coil served.

Concrete tanks may be cast in place. Concrete tanks are sensitive to thermal shock. Large tanks are usually cylindrical in shape, while smaller tanks may be rectangular or cylindrical, and may be integrated into building foundations. Concrete tanks may be operated as pressure vessels, and so may be positioned below cooling coils. The cost of concrete tanks are 2 to 3 times the cost of the modular system offered by Encon.

This report was originally commissioned to assess the capacity and efficiency of the chillers and cooling towers to meet the increased load of the Stage 2 extensions, all the while maintaining spare capacity for breakdowns and routine service. The coefficient of performance (COP) of existing chilled water plant are not very high, owing to the intermittent cycling of plant to meet demand for the various cooling coils in the facility. Substantial improvements in operating efficiency and reliability is possible in the context of a thermal energy storage tank with newer larger higher-efficiency chiller.

Thermal energy storage, by way of stratified chilled water, provide the opportunity to allow chillers and cooling towers to run continuously at peak efficiency at night when electricity is cheaper and causes a lower greenhouse gas impact. Nightly full load chiller operation reduced wear and tear, and provides steadier temperature control of air-conditioning systems. Payback is considered by considering the likely cost of daytime electric power in the near future, as population growth is not being matched by increased power generation capacity.

"Design Guide for Cool Thermal Storage" by Dorgan & Elleson 1993 introduces key engineering concepts and economics of cool storage with both chilled water and phase-change media (ASHRAE Research Project 592). This was consulted during the detailed design of diffusers and controls. This reference advocates dual use of a single thermal storage tank for fire protection. This guide also discusses the advantages and disadvantages of "empty tank systems", comprised of two or more vessels where one is always empty at the start of charging so that warm water is processed by chillers and pumping into the empty tank. During discharging, stored chilled water is drawn for cooling and warm water pumping into another empty tank. In such systems the usable volume is reduced by the empty tank volume, and they require complex piping and controls to ensure pumps work correctly against varying dynamic head. Multiple tank systems increase first and maintenance costs, but one may be taken out of service while others continue to provide service.

2. Scope

The HVAC services covered in this report are the air-conditioning chilled and condensing water systems serving the existing Stage 1 and the proposed Stage 2 extensions to the Queensland State Archives. The study includes chillers and cooling towers, as well as associated pumps. Three existing chillers (#1, #2, & #3) and three existing cooling towers (#1, #2, & #3) will be supplemented by additional capacity to meet the Stage 2 extension (chiller #4 & cooling tower #4). A freestanding thermal energy storage tank is also considered together with the efficiency improvements now available in large centrifugal chillers.

The payback calculation for the proposed tank at Runcorn was based on a full-storage strategy, also called load shifting, that shifts the entire on-peak cooling load to off-peak hours (11PM-7AM). The system is designed to operate at full capacity during all off-peak hours to charge storage on a hot "design day". On rare occasion of extreme heat, the chillers must continue working after 7 AM to finish recharging the tank.

3. Investigation – existing service

The HVAC services covered in this report are the air-conditioning chilled and condensing water systems serving the existing Stage 1 and the proposed Stage 2 extensions to the Queensland State Archives. The study includes chillers and cooling towers, as well as associated pumps. Three existing chillers (#1, #2, & #3) and three existing cooling towers (#1, #2, & #3) will be supplemented by additional capacity to meet the Stage 2 extension (chiller #4 & cooling tower #4). A freestanding thermal energy storage tank is also considered together with the efficiency improvements now available in large centrifugal chillers. The original building was built in 1992 with two reciprocating chillers (#1 & #2) located in the basement plantroom and two cooling towers in the third floor plantroom. Space was made available in the plantrooms for an additional two chillers and two cooling towers. In 1996 a new screw chiller and cooling tower were added to provide more efficient operation and spare capacity for breakdowns and routine service. Each of the three chillers has a cooling capacity of 550 kW, but the newer screw chiller (COP up to 6) is twice as efficient as the older reciprocating machines (COP up to 3). The three cooling towers each have a condensing water flow capacity of 29.5 L/s at 35°C-29.5C°, capable of rejecting 2000 kW in total, 95% of installed chiller capacity. Chiller #1 & #2 each reject up to 733 kW, while the newer chiller #3 rejects no more than 641 kW. The cooling towers share common headers and a common sump level, working together to cool any combination of chillers that maybe required at one time.

The coefficient of performance (COP) of the existing three chillers logged over the 5 months September 2005 – February 2006. Estimated demand of condensing water pumps and cooling tower fans were added into the logged chiller motor loads before determining these COPs. The overall COP of the gang of machines was 3.3, owing to the large percentage of the time that machines were partloaded. This reinforces the advantage of providing a thermal storage tank, as all chillers perform more efficiently at full load.

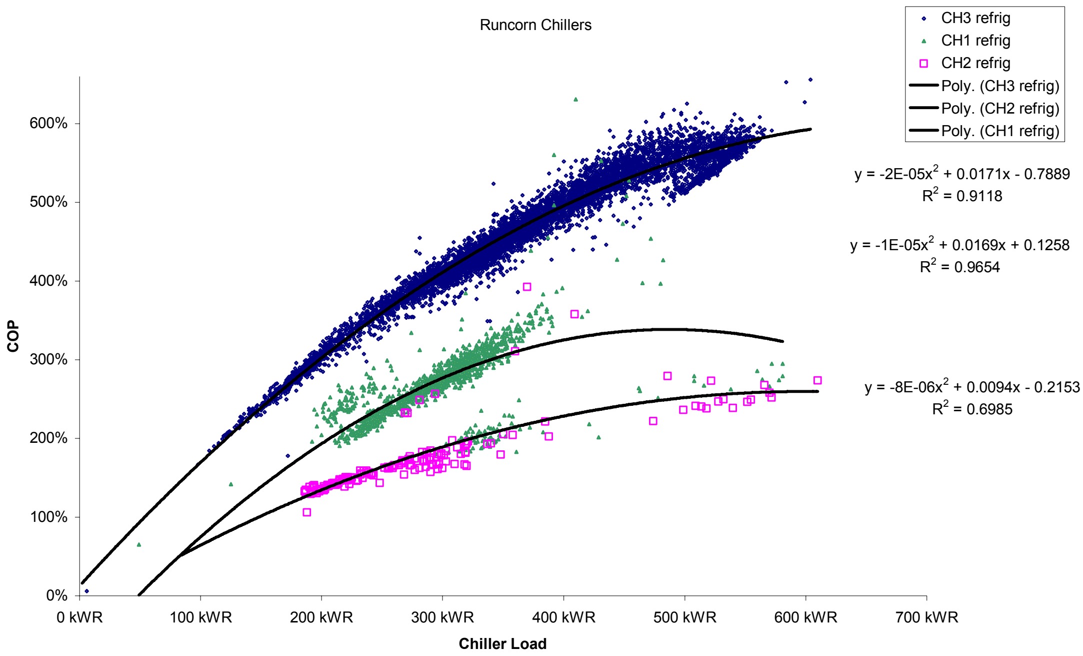

Figure 1 Part-load performance of existing Stage 1 chillers.

Figure 1 shows polynomial trendlines of best fit to summarize the partload COPs of each of the three existing chillers. The screw chiller (#3) has substantially better coefficient of performance (COP) than the older reciprocating chillers (#1 & #2), even though all three machines each have 550 kW refrigeration capacity. Chiller #1 was running more efficiently than chiller #2, even though the two are identical twins with sequential serial numbers. Leadership among the three chillers is manually switched seasonally by the decision of various human operators. From the above results it should be argued that chiller #3 be set as leader at all loading levels.

Chiller logs indicate that the Stage 1 building load did not exceed 950 kWr this past summer. Given that outdoor temperatures in that time exceeded nominal design conditions by 3°K, 1000 kWr capacity amply serve the stage 1 facilities.

The detailed study of chiller logs since late 2005 has been useful in the present report since this has been a warmer than average summer, as compared to the cooling degree days over the past 30 years, and so we are confident benchmarking the existing stage 1 load with the limited chiller log sequence that we have at hand. The chillerlogs are a record of entering and leaving water temperature and the cooling energy output and electric power input to each machine every 10 minutes for a period of over 5 months. These timeseries were converted into COP of each machine and total chilled water flow rate to represent the building load of Stage1. The time series of power into the three chiller motors was factored into an analysis of 30-minute power demand for Stage 1 as recorded by the power retailer Energex. Now it is possible to model and project chiller power requirements of state 1 back into history as far as Energex can provide load profiles, but in the present study the year 2005 and early 2006 were considered.

Slow and difficult liason with Energex lead to not exploring earlier load profiles, but the current season's weather pattern may be justified as a benchmark because it is warmer than usual and the local climate is trending towards a warmer regime.

3.1 Existing cost structure for electric power

In the past three years the cost of peak power has been increasing, but it may level after new power stations are brought onto line. Recent past tariff structure shows that off peak charges are very constant, but that "peak" consumption charges have been accelerating upwards. Future electricity pricing structures are not guaranteed, as the client regularly calls for tenders from contestable power retailers such as Energex. Figure 2 shows the recent trends in power purchase at Runcorn Archives.

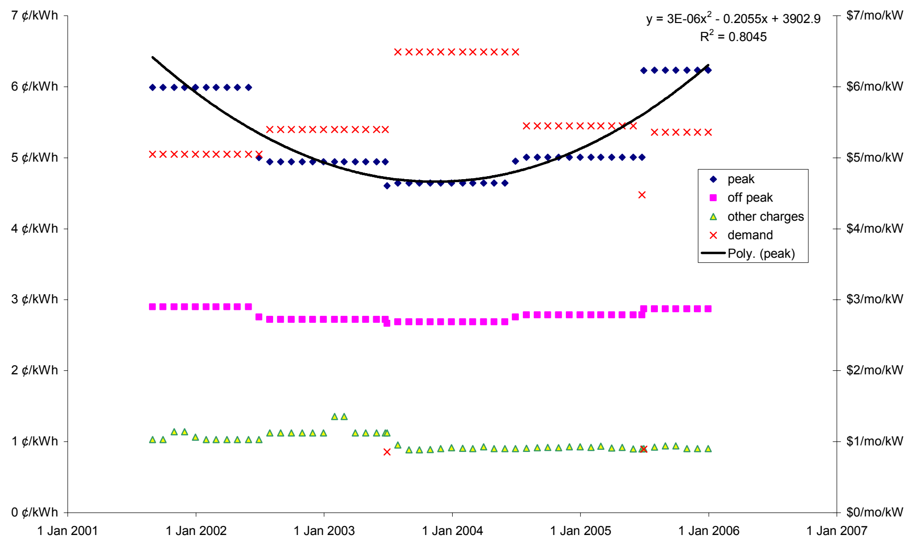

Figure 2 Recent Power Cost Structure.

In terms of market economics, it should not be surprising if the cost of peak daytime power consumption increases in the future as demand is growing faster than the construction of new power stations. Increasing demand for daytime power is certainly a direct effect of rapid population growth in southeast Queensland, as an increasing number of homes and businesses come on line. Indirect effects are the conversion of once cooler bushlands in suburban landscapes covered by dark coloured roofs and bituminous pavements, creating a local "heat island" that adds to "global warming" to increase a dependence on air conditioning throughout the general community. In terms of sustainability, the initiatives of QSA2 can lead the community by an example of "demand side management", reducing and shifting electric loads to the early hours of the morning when power stations and transmission networks have better efficiency.

4. Option selection

Design development proceeded to allow selection of two options (A) add a 550 kW screw chiller just to meet increasing load; or (B) to invest in a 1650 kW centrifugal chiller AND off-peak thermal storage tank. Option A without any storage tank, but a new 550 kW screw chiller lagged by one of the existing 550 kW screw chillers and the older 550 kW reciprocating chiller as last in demand was simulated as illustrated in the following graphic based on load profiles since September 2005, detailing 1st week January 2006 in figure 3.

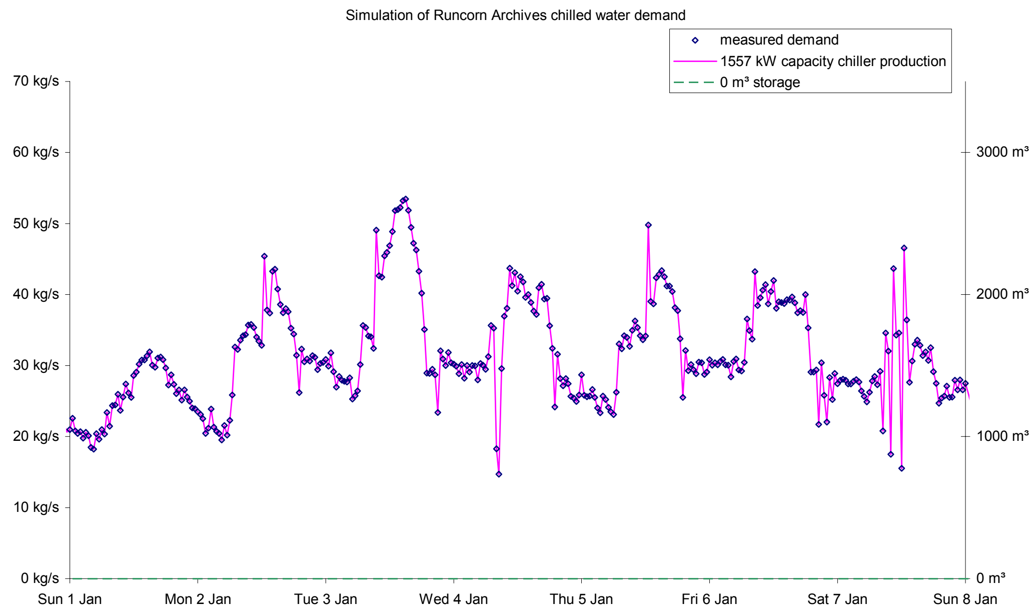

Figure 3 Simulation of Option A (not recommended)

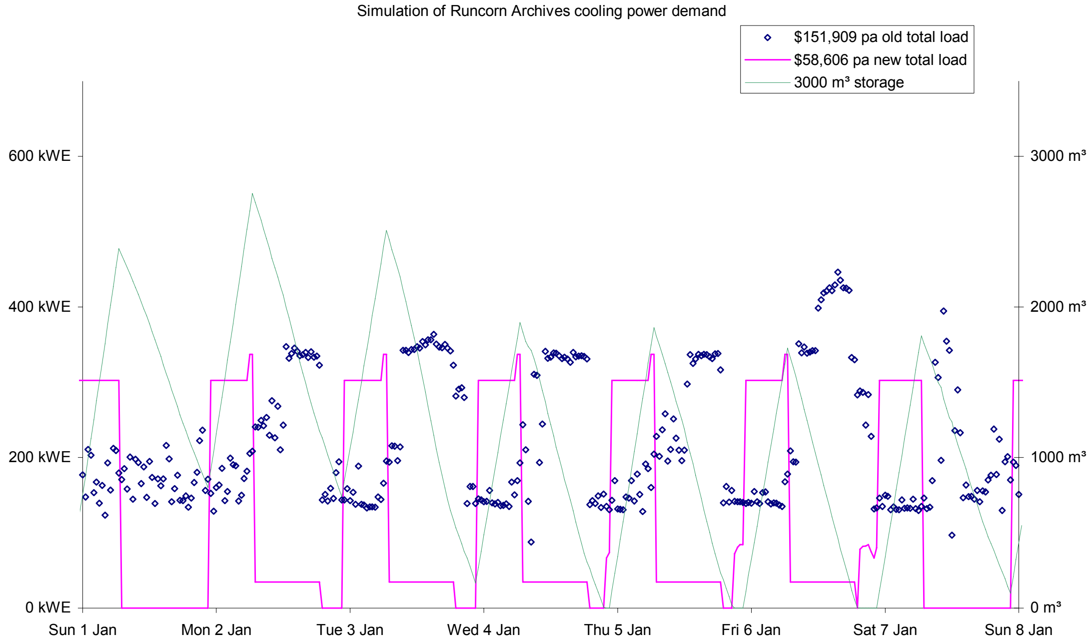
Above is one week detail of over 5 months of measured cooling load in Stage 1, scaled up to represent the total of Stages 1 and 2. If the new chiller #4 were similar to the most recent existing screw chiller #3, then there would be some improvement of performance owing to their coefficient of performance. But none the less there would be times when either of the old reciprocating chillers #1 or #2 would need to be used, and so power use intensity would continue as has been the case in Stage 1. The existing mix of reciprocating and screw chillers provides part load control, but not very efficiently. Many reasons may contribute to the poor baseline performance of the Stage 1 chillers, as no significant correlation could be found in an analysis of 4 years of cooling degree days (weather data) and monthly power invoices.

Rather than Option A, it was decided a thermal storage tank be provided to exploit chiller efficiency. Option B was decided upon with 3000 m³ storage tank and new 1650 kW centrifugal chiller lagged by existing 550 kW screw chiller and the older 550 kW reciprocating chillers as backup was simulated as illustrated in the figure 4.



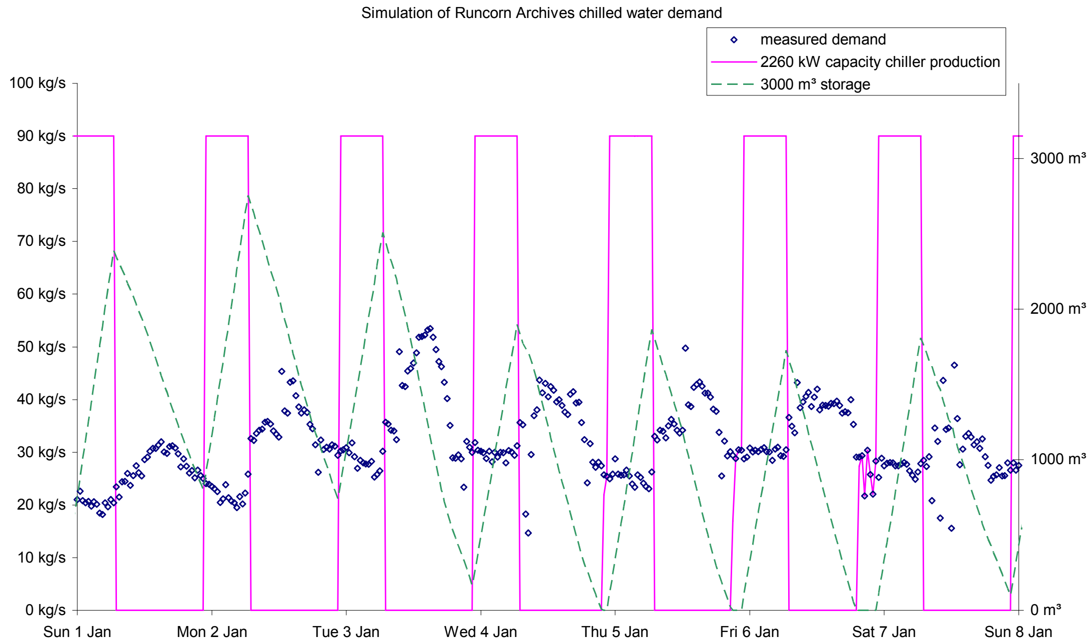


Figure 4 Simulation of proposed option B (accepted for construction)

The above are one week of detailed simulation results with 3000 m³ storage tank with new 1650 kW centrifugal chiller lagged by existing 550 kW screw chiller. The older 550 kW reciprocating chillers are provided only as backup, and so we have modelled the system to perform at high coefficient of performance at all times. In the above example illustration, the chillers run full load 8 hours per night, and the storage tank meets the load 16 hours per day, except for a couple hours late one Friday evening– being a special case of weather 35.5° the previous Monday exceeded the 34° outdoor design conditions, and caused the storage tank charge to only recover to 2ML. Storage capacity fully recovered over the following weekend, and a small penalty was paid for partload operation of the screw chiller until the 11 PM the Friday night.

Option B would produce half the greenhouse gas emissions of Option A (800 tonnes rather than 1750 tonnes p.a.).

If the design for Stage 2 extensions were driven entirely by the lowest capital cost without concern for maintenance and energy costs, then there would have been only one additional 550 kW screw chiller installed to meet the additional Stage 2 building load in the event that one of the older chillers were to fail. But there is a substantial power savings payback available, so the additional capital investment was made in a larger high efficiency centrifugal chiller and freestanding thermal energy storage tank in Figure 5.

Allowing $70,000 capital cost of increasing the new chiller specs and $720,000 for the chilled water storage tank, the building tenant is rewarded with annual cost savings of $79,000 p.a. based on current electricity price structure: Maximum demand penalty $5.359/kW/mo; plus "peak" consumption 7AM to 11PM Monday through Friday charged at 7.1332 ¢/kWh; plus off-peak consumption charged at 3.7704 ¢/kWh. Note that various charges may be added into both peak and off peak charges, so the key index is the net price difference between the two. The client would be advised to contact their power supplier to discuss forward contracting of electricity supply since they may be interested in rewarding off-peak thermal energy storage.

The thermal storage system with larger centrifugal chiller results in a simple payback period of ten years, but the payback is one year sooner for each one cent (1¢) per kW-hour increase in the difference between peak and off-peak charges.

Because this is a 7 day-per-week 24 hours-per-day facility, the economics of thermal storage are more favourable than in daytime-only facilities. The proposed concept would be to provide and operate a high efficiency/capacity centrifugal chiller almost entirely during off-peak times (11 PM until 7 AM the following morning) to serve the facility load and to regenerate the thermal storage tank. The chillers and cooling towers remain idle each day from 7 AM until 11 PM, while the thermal storage tank provides all of the State Archives cooling load for 16 hours each day. All that would be required operate during the day would be the chilled water pump and fans in air handling units, easily provided by the emergency generator in case of power failure. The chilled water storage tank and it's associated pump would be treated as the fifth machine for the Queensland State Archives "Chiller #5" with a capacity of 2200 kWr.

5. Completed installation

Figure 5 Queensland State Archives Stratified Chilled Water tank under construction

The installation was completed in early 2008 and commissioning was in progress in May/June 2008.

An inadvertent shutdown of chillers over one weekend in May was discovered the following Monday, all the while the chilled water storage tank fully maintained stringent temperature and humidity conditions in the facility for 72 hours. This was an inadvertent, but useful test of the installation. Operational trend-logs will be presented in the poster version of this paper to be presented at SB08, complete with discussion and preliminary conclusions. But the final report on this installation should wait until after the next summer.

EDUCATIONAL RIFT IN ARCHITECTURE – SUSTAINABLE VERSUS MODERN

Elżbieta RYŃSKA Associate Professor PH.D. Eng. Arch.

Faculty of Architecture, Warsaw University of Technology, Poland, 105dr@arch.pw.edu.pl

Keywords: sustainability in architecture, education, investment decisions

Summary

In the second half of the 80-ties, representatives of many disciplines participated in research involved with the implementation of the sustainable development philosophy. It was stated that "…*there exists a requirement for a better understanding of the resource values on which our lives depend. If we want the human mankind to change its way of thinking and accept the need to include the environmental issues, we have to start at the educational level…*". In 1999 this idea was undertaken by the Norwegian Government within a redevelopment of their education program. In 2002-2005, this issue became a task theme between Warsaw University of Technology and University of Norway. This international participation, brought forth a SureBuild Program, developing a strategy to include sustainable issues within the modernization process of school buildings in Poland.
In 2006, Warsaw University of Technology and NTNU Trondheim received a grant from the Norwegian Mechanism source. The current project is STEP, and its general aim is a scientific and research support allowing to achieve a better quality energy performance of the public buildings in Poland. The direct aim – is delivery of support tools for the decision making within the curricula of technical solutions used in new and existing public buildings, including initiation of changes in traditional building techniques, in favor of more optimized solutions.

1. Architecture and Environment

Sustainable development deals with each and every sphere of our everyday life. Our senses are constantly bombarded by external incentives. Some everyday phenomenon – such as intensively urbanized city areas, skyscrapers or electric energy – have become a part of our life to such an extent, that we do not pause over them, but accept them as something obvious. Above elements are part of the designer's workshop. Hence, if other solutions will be introduced, they will be accepted as a standard,. Therefore architectonic creations will act as one of the medias implementing the environmental policy.
The issue of sustainability in education was first raised in Chapter 36 of Agenda 21. Promotion of a wider scope of environmental knowledge means that each nation must accept uniform values. This aim may be achieved through reorientation of the formal education and definition of common goals. Additionally, it is required that every person will posses an adequate level of knowledge sufficient to understand the complex environmental issues.
The search for a harmony between men made and natural environment is not a new one. Until the beginning of the 20th Century the development of the economy and civilization depended on existing climatic and environmental conditions. Only industrial revolution and rapid growth of various technologies, wide access to a seemingly cheap energy and mass transport, conviction in the ineffability of new techniques, assumption as to the inexhaustible supply of resources, as well as promotion of the anthropocentric strategies - caused radical changes, both within the design process and construction industries.
This had high influence on the learning program introduced into various schools and was concerned directly or indirectly with building processes. This was especially evident in European schools of architecture, where two educational paths were taken – artistic, dealing with the philosophy aesthetic form and outlook of the designed volumes, and - engineering, dealing both with the aesthetic and construction issues. Leaving aside the first path, within the second - a certain status quo was established. It was the architect, who chose the location on the site and form of the building. His choice was then supported by a civil engineer and later various other technical engineers. Little care was taken as to the existing state of environment. Globally used building materials were – reinforced concrete, glass and stone cladding. Construction techniques and HVAC systems became similar all over the world. The appearance of buildings also became uniform. When seeing a picture of a single building or a complex of buildings, without any additional references to surroundings or traditional architecture – it was impossible to state the location or the country where the photograph was

taken. Modern aesthetic characterized by a high contempt of historic details and features – became part of the educational systems. Each and every decade of the 20th Century brought new Modern style, and each new style became further removed from the vernacular from which it had sprung.
Sustainable development appeared in the 60-ties[1] of the former decade – at first it was a pro-ecologic design only, promoted by a social group, who discarded the consumptive way life and accepted the need to limit the economic growth.
For most representatives of the environmental route, economic growth and profits became acceptable only after the introduction of sustainable development described in the Rome Club Report under the heading of "Factor Four" [2], where the concept described a possibility of both economic growth and environmental protection. It included doubling of the present standard of living with the use of half of the contemporary supply of stock materials. Authors proposed technological optimalisation, better performance of production without higher costs, lower volume of waste, lower use of oil products, as well as construction of low energy buildings.
Above changes can be perceived in the construction sector, where presently 50% of the total world energy is used for the construction and maintenance, including 40% of the output of the non-renewable stock. Additionally 50% of the world water requirements (including 26% during the construction process itself), is used for the same purposes. Transport of people and various supplies also use next 25% of the total energy production. Many scientists state, that large quantities of waste are produced during the construction and demolishing.
Application of the sustainable development is closely connected with three areas:

- human requirements
- renewing, or at least sustaining, of existing environmental parameters
- economic effectiveness and environmental management, also within the construction and derivative sectors.

Sustainable buildings have to be accessible to each member of society and should be created with the participation of designers and consultants of different disciplines, as well as final users. Hence, it should be assumed that harmony between architectonic solutions, technologies and costs, is possible only with the use of a clear management strategy. This is a holistic treatment of the relation between men and environment, or rather – built and natural environment.
This approach is only very rarely discussed within the education curricula of Architects. The knowledge that design should be conducted in accordance with the limited accessibility to natural resources and limited space, is very often not even mentioned. The issue of recycling - is often treated as an oddity, maybe a fashion to be soon forgotten. The same applies to the context of development of urban areas where planners should foresee a high need to transform areas already used, limiting the impact of the urbanised on natural environment.
From the time of the Rio Summit, application of environmental parameters within the planning and design processes has been accepted by nearly all European countries, but this does not mean that it has been implemented as part of the basic or even supplementary architectonic education in each of the existing Schools.
The new generation of designing Architects which appeared in the past fifteen years – is usually a group of self taught designers. Yet, this class of sustainable creators, already knows that during the design process they have to apply various procedures and program strategies allowing to calculate required maintenance energy and the impact of buildings on natural environment. Each and every parameter is inserted as an integral part already at the concept stage. Both – form and the function – are closely connected with particular location and requirements of the future user. Certainly, the issue of sustainable building has become a cultural phenomenon – widely used by the politicians, and economists – more and more knowledge also becomes part of the general education.
This state can be especially perceived in Germany – it dates back as far as 70-ties of the 20th Century – and it is closely connected with the importance of the Green Party. Presently, sustainability – has become one of

[1] Some researchers of Architecture argue that this movement appeared already in the 30-ties of 20th Century in USA, and was represented by George Fred Keck. In his design he used details analogous to those found in present environmental buildings – wide eaves and movable external shutters (1953 - Cahn House, Lake Forest, Illinois), large glazed façade used as sun collectors (1941 – Duncan House, Flossmoor, Illinois) , and heating with heat gains (1945 – a prototype Solar House, Rockford, Illinois). Duncan House was also monitored during the first year of use. Data was never used by later designers [3]

[2] Factor Four – described by Ernst Ulrich von Weisäckera and energy consultants Amory B. Lovins and L. Hunter Lovins, published in 1995 in Germany

the alternatives both for the German designers as well as contractors – especially after the enforcement of new laws and the Low Energy[3] and Passive Building Acts[4].
Cities such as Freiburg im Bresgau and Stuttgart were the first to introduce pro-ecologic requirements into the urban planning. Further research disclosed that approximately 30% of the consumer market is interested in sustainable issues. Over 58% of Germans assume that the government does not undertake sufficient measures to stop the climatic changes and over 94% accept higher initial construction costs in order to have environmentally friendly buildings. These statistics are characteristic to more developed European countries, unfortunately – those which have joined EU lately are in a less advanced phase of development and therefore consider the issue of sustainable development as an economic hindrance
In countries such as Poland – sustainability is a catch word only. Here, the designers are aware of the fact that the area of their influence is much wider than the design process itself. They are aware that there is a need for a multidisciplinary approach, definition of a network of influences allowing for a potentially sustainable development. Non existence of integration between each of construction areas produces high energy losses and building material waste. It has been stated in some academic and scientific papers and books that the *"…limits of contemporary sustainable investment process starts with the initiation of the building's idea and ends with the life of the building"* (change of function or demolishment). Still – the idea accepted by the scientists and many students of Architecture has not until now, been accepted into the education curricula of any of the Schools of Architecture in Poland.
Detailed research[5] conducted in early 90-ties at the Faculties of Architecture and Construction, only confirmed that Polish engineers are not well prepared within such educational fields as economy, management and environmental issues. Further investigations conducted in 2000 and 2003 – showed similar conclusions, including the need for further education at a post diploma level (80% of the students).
It is only due to high interest of some of the Polish researchers that any sustainable programs are conducted within the scope of construction industry at all; STEP program being one of them.
In 2006 Warsaw University of Technology in participation with the NTNU Trondheim received a grant from the Norwegian Mechanism source. The name of the project is STEP and its general aim is scientific and research support concerned with the achievement of a better quality energy performance of the public buildings in Poland.
The direct aim – is the delivery of support tools indispensable for the decision making in the curricula of technical solutions in new and existing public buildings, which will initiate the changes in traditional building techniques in favor of the more optimized solutions in accord with accepted criteria. Public buildings have a very special place in the Polish building substance. They are used by the local councils and national administration for the statutory purposes such as: education, health safety, cultural events etc. Energy performance of the existing buildings is low, and modernization processes are very limited. Those buildings are very often the local construction key elements and should be treated as demo cases - showing possible use of low energy technologies.

- Collecting and compiling of data in a table format – various functions – educational, office and cultural - constructed during 1990-2003 in European countries according to energy saving rules. The tables will disclose basic layouts, cross sections, elevations, known technical parameters as well as basic information as to the design conditions of the functions and layouts.
- Preparation of a diagram showing characteristic areas which can be distinguished in each phase of the construction investment process, pointing out the role and position of the Designer within the integrated design process. The Concept Design Phase plays one of the most important roles, especially in the case of the Client's and technical designers' s energy saving education. The Designers should therefore, prepare an integrated Brief - to be performed "for" and "in the Name" of the Client. The scope of tasks depends on the Client's expectations, Project's quality, assumed time schedule and accessible finance. The Design Data should include all information being the outcome of the Client's and design team requirements, site location, time and work schedules, energy saving and aesthetic effects, maintenance costs and existing budget.
- Additional data on the public buildings constructed or being under construction in accordance with energy saving requirements during 2004-2007 in European countries
- Co-operation with other task leaders in order to exchange technical data concerning chosen buildings

---

[3] Published in 1982 laws define the upper coefficient of energy use allowed in new buildings as 150kWh/m^2. In 1995 this parameter was lowered for single housing as 100kWh/m^2 (analogous rules were accepted in Sweden in the 80-ties).
[4] A Passive Standard Building was for the first time introduced in Germany, Hessia Land, in 80-ties. The main aim was to limit the heating energy to 15kWh/m^2/annum. First four buildings were constructed in 1991 in Darmstadt – Kranichstein. In 2001, similar residential buildings were also constructed in Austria and Switzerland.
[5] First research was conducted in 1986 by ORGBUD, next one by the academic staff of the Faculty of Architecture, Warsaw University of Technology, Team of Economic design

- Definition of the scope of influence of energy saving issues on the massing and aesthetic features of the designed building
- Definition of the most important “demise” areas between the architectural knowledge and other engineering branches participating within the construction investment processes,

The best case catalogues will be a summary of research conducted within some of the work tasks, data will contain information for the designers or investors helping them to undertake investment decisions. Prepared education materials will be used in faculties and post diploma courses conducted at the Warsaw University of Technology and other didactic centers
Educational output data from each of the work groups will be used as schooling materials for post diploma courses destined for general use within the scope of this task.

2. Foreseen role of an Architect in the process of sustainable education

Some assume that the highly organized nature of Architecture is an aentropic form, where the constructed and maintained buildings act as a counterbalance for the growing level of entropy. This is a high simplification of the whole issue [1]. A living organism is an open system characterized by a constant level of entropy. It absorbs high energy matter, later transforming the energy in its cells and emitting less complex substances into the environment hence not allowing for any additional growth of the entropy. If we treat the environment as a holistic set of areas, then a total exchange of energy in the organic systems and the environment will always take place in accordance with the second law of thermodynamics.
Processes such as growth, decay and death – are constant elements within the slow exchange of energy taking place in the environment. The second law of thermodynamics still applies within a holistic acceptance of the organism treated as an open system existing within the environment, including a marginal constant growth of the entropy.
Therefore, this is a clear indication that when preparing a location analysis, the designers should widen the presently limited ecologic concept of the environment with this holistic analysis. Ecologists postulate that urban environment should be analyzed with the areas surrounding the actual site which is being developed. Each individual ecosystem should be analyzed in relation to all Earth ecosystems. Hence the term “environment” – should be understood in a global context.
A holistic sustainable building process does not mean therefore that the environment is protected from the human intervention, but that it formulates relations between the effects of the human intervention in the ecosystem and the environment, finding of ways to limit those interventions and acceptance of the volume limits of each of the ecosystems.
Sustainable design solutions are usually multidisciplinary. Definition of negative influences of constructed buildings and their possible limitation already within the concept stage, depends on the skills and education of the design team.
From the very beginnings of civilization, human kind had a tendency to be surrounded with objects of beauty. The idea of beauty fluctuated in time and place – but the idea was always similar regardless of other influences. Hence, if a building will be designed and constructed in accordance with the low energy and environmental strategies only, but the aesthetic parameters are not existent, only very few will choose it as a place of inhabitation. Unfortunately, since environmental issues are still regarded as a novelty, the load bearing elements are usually very heavy, facades are devoid of details and color, whereas interiors are dark and gloomy. Too often environmental solutions – such as solar or wind chimneys, solutions supporting passive heating and cooling of the building – are perceived as something additional, attached to the building after the original thought of the designer has been already formulated.
There are some contemporary buildings which have been designed and constructed according with the sustainable principles maintaining harmony between the environment and user requirements. Hence, one of the tasks to be provided by the Architect - a teacher in the issues if sustainability – is such introduction of detail, that it will be perceived as an integral and widely accepted feature of the newly constructed buildings.
Still the connections with the environment reach further than the Architecture itself. Designers, developers, financial and public organizations have their own priorities, not necessarily in accordance with the sustainable aims. Each of those participants should participate in the actions to protect our environment. In order to achieve this, following actions should be widely undertaken:

- a better level of general education accessible to all age groups;
- preparation of a frame educational network – to be taught at every level of education;

All designers, not just architects should participate in both of the above described areas.
There is no better way to educate the society, than through constant existence of certain solutions and characteristic features. Hence - a wide possibility to use them in the architects’ professional life – the use of

aesthetics' and creations as an integral part of the educational programs. Their subconscious influence on the human actions and functioning of surrounding environment. It may be therefore accepted that outside the residential areas, it is the educational buildings that can be used as support education tools – and simultaneously co-operation of designing teams should become the main aim of the Architects – acting as Tutors.
The issue of a higher awareness, has been stated already within the text of this paper – it has been pointed out that the differences between "environmental" and "architectonic" quality should be removed. It is the Architect, who has the best possibility to integrate local societies into the design process already at the concept level, and then include their requirements and needs. This co-operation should result in following outcomes:

- a higher level of ownership, and at the same time a higher acceptation and level of belonging to the place of residence;
- a higher level of environmental protection;
- preservation and revalorization of local eco-systems;
- limitation of transport distances – as part of the inhabitants choice, not legal requirements;
- limitation of the noise level emitted within the urban areas.

Above processes have been in most cases included in the legal acts and are being enforced in many European countries.
The area where the Architects have most influence to create the awareness of sustainable development – is educational buildings. Designing teams can actively participate in the realization of two teaching methods:

- "see" and "touch" method
- "stating questions" method – "why", "where", "who" and "what".

These solutions can be easily provided with the use of a limited access to the internal building systems e.g. partially glazed HVAC system elements - teaching the children that their building is not just a classroom and playground area, but have additional elements allowing to preserve correct environmental and living standards.
The demands for designing low energy sustainable buildings call for a new way of designing, as it is no longer sufficient to improve the technical parameters only. One of the main issues is the requirements to accept the issue of Integrated Design Process - by all parties involved in the design. This participation should appear already in the initial stages of design. Hence a certain awareness will be created allowing for a better understanding of the impact of the architectural and technical decisions – already at the sketching level. The first step in the process is therefore the introduction of a core design team – to discuss the basic targets and directions regarding the site and function. Participating actors are: the building owner, user, architect, urban planner, as well as environmental specialist, energy specialist and biology consultant. Initial discussion should cover such data as the form and program of the building and site, energy issues, internal and external environment parameters, potential building materials as well as the level of financing.
It is rather unfortunate that most of the contemporary designers does not have sufficient scope of knowledge dealing with ecology, biology and climatology as well as building physics – indispensable for the design and construction of sustainable buildings. This further means, that such knowledge should be incorporated into the scope of education taught in the faculties of architecture as well as other technical disciplines directly or indirectly connected to the construction industry,
Architecture is not only one of the Art disciplines, but also a social practice connected with various areas. Creation of urban environment within the natural environment is a basic example of human influence on the transformation of the natural ecologic systems. Education of architects within the scope of issues concerned with environment and provided by the outcome of the STEP Project should prove to be very valuable.

"Identifying Sustainability Priorities and Engaging Stakeholders" - The Hong Kong Housing Authority's Experience
(ID Code SB430)

Ada Y S Fung[1]

[1]Housing Department, HKSAR Government, Hong Kong, China, ada.fung@housingauthority.gov.hk

Summary

The Hong Kong Housing Authority (HA) provides affordable and sustainable public housing for those in need. To achieve our vision of sustainable housing, we try to balance and integrate the environmental, social , economic and aesthetic concerns of the community. We have been contributing to the broader sustainability of Hong Kong by providing affordable quality housing and a healthy living environment for about 30% of the population in subsidised rental flats and improve their quality of life. As a public sector client, we have been driving sustainability initiatives through the value chain in the public housing sector, in collaboration with all stakeholders from planning, design, construction to occupation stages. Sustainability means getting the best use out of our housing stock by prolonging the life of our buildings, engaging our community in our development proposals and their subsequent operation, and building effectively through an environmentally aware approach. This paper gives an overview of our approach, whereas the details are contained in a family of papers submitted to SB08 by my colleagues.

Keywords: public housing, sustainability, stakeholder engagement, environment,

1. Introduction

The primary role of the Hong Kong Housing Authority (HA) is to provide subsidized public rental housing to low income families who cannot afford private rental accommodation. The public housing programme has evolved to meet public expectations, from an emergency housing programme in the 1950's, into the more sophisticated public housing services that we provide today, covering planning, design, construction, management and maintenance. Over the years, we have been working to ensure the implementation, maintenance and sustainability of an effective housing programme that will not only meet Hong Kong's requirements but also contribute towards a stable and happy community. The improvements we make are a direct response to public demand as society has prospered and as public expectations and the demographics of Hong Kong have changed. At the end of March 2007, about a third of Hong Kong's population was living in 680 000 public rental housing flats.

One of our key missions is to provide affordable quality housing with a healthy living environment, thereby improving the quality of life in Hong Kong. This, we believe, allows our tenants to contribute more effectively to the community and the local economy, and allows the HA to contribute to the overall sustainability of Hong Kong. As a public sector client, we have been driving sustainability initiatives through the value chain, in collaboration with all stakeholders from planning, design, construction, maintenance and estate management fields in the public sector. We continually work to improve our operations with the full integration of environmentally friendly, user friendly, functional and cost effective considerations. We have put this vision into action through our *Strategy for Sustainable Housing*, and I shall give an overview of our approach as follows –

a) We identify our sustainability priorities in three aspects: environmental, social, economic;

b) We engage our stakeholders with overarching policies and systems;

c) We work hand in hand with stakeholders throughout the three major stages of the estate life cycle: planning and design stage, construction stage and occupation stage, integrating the environmental, social and economical initiatives in a holistic manner.

2. Identifying Sustainability Priorities

Sustainable development goals are now major considerations in the development of Hong Kong. We are progressively exploring ways to improve our performance, balancing the priorities in three aspects: environmental, social and economical. The best results can be achieved through the full integration of the needs for economic and social development with those of conserving the environment. We have to find ways to maintain prosperity and improve the quality of life, while reducing the environmental impact of our activities and help to preserve common resources and so create a sound basis for future generations. We cannot achieve this alone and we need to collaborate with our stakeholders in the value chain, to ensure that we will achieve sustainable development goals.

2.1 Environmental Priorities

Given the high-density, high-rise environment in Hong Kong with its enormous political, technical, time and cost constraints, we need to build efficiently and act in an environmentally friendly manner through effective design, construction and management to the benefit of our tenants and the community at large. We are committed to properly managing and reducing our consumption of resources in our day to day activities, in particular the reduction of waste and energy consumption. We are always looking for better construction methods to decrease our environmental footprint and reduce the overall impact of our development, occupation, management and maintenance processes.

2.2 Social Priorities

Social sustainability enhances the well-being of people. Low rents in public housing represent a subsidy to low income families and consequently the housing programme promotes social stability, economic prosperity and harmony in the community. The HA wants to see public housing estates as safe, healthy and secure places to live, so that our tenants enjoy a satisfying and good quality living environment.

We must therefore prioritize the demands on us according to our policy pledges, by providing public housing to those who need it most. Our goal of providing a safe and healthy living environment applies not only to our tenants, but also in the working environment, safety and protection for those who are engaged in our construction, maintenance and property management services. Our policies are geared to enhancing social cohesion and contributing to the well-being of the community as a whole.

2.3 Economic Priorities

The economic performance of an organisation is the key to its success and hence its ability to continue in business. Cost effectiveness is critical to the HA because decisions on the housing programme, whether design, construction, or operations and maintenance will have an impact on the public purse. We achieve cost-effectiveness through a number of measures, including the public listing of some of our assets and the constant review of management measures to get the best returns out of HA resources and sustain the useful life of our buildings. Enforcing tenancy controls is critical to reduce abuse of public housing. Refurbishment programme and allocation policies reduce vacancies in flats. We prolong the service life of our stock by providing efficient maintenance and upgrading our housing blocks through the Total Maintenance Scheme.

3. Engaging Stakeholders: Overarching Policies and Systems

Sustainability in housing cannot be achieved without engaging each and every one of its stakeholders. Our stakeholders include planners and designers, building, maintenance and property services experts, tenants, users and workers, as well as the community at large. To achieve this balance, we have formulated and applied our policies on sustainability across all our activities and communicated them to our staff, tenants, and business partners. Sustainability is embedded in our operating procedures, planning and design guidelines, tendering, contracting, and our tenancy agreements, and guides our stakeholders on all fronts. We monitor the application of our policies and systems regularly, and measure against established targets, and backed-up by training and promotion so that our expertise meets our needs and tenant's awareness is raised.

3.1 Partnering with the Industry

Improvements in the way that we work, both in construction and property management operations have only been possible with the collaboration of our business partners. As we develop new initiatives we involve our partners, so that we can be sure that they are practicable, and that they too, own the decision. The HA has been instrumental in driving improvements in the industry, in safety, health & environment, working conditions, and the protection of wages. Dialogue with the industry and efforts to promote partnering are critical to the success of new initiatives in the delivery of housing services. We tap the expertise of our partners through regular meetings or ad hoc groups, to develop the operational details more effectively.

Since 2001, we have run project partnering workshops in all building, piling and some maintenance contracts, to promote effective communication amongst our contractors, subcontractors, our staff and consultants. With six years' experience, many project teams have reported communication benefits with problems being solved more promptly on site, less paper work, smoother progress and improved quality of work. Partnering means that we are more open and we build rapport in working towards our common project objectives of quality, safety, environmental performance and customer service with synergistic and reliable results.

In mid 2006 we took partnering a step further and embarked on a Modified Guaranteed Maximum Price Contracting model in a pilot project at the Eastern Harbour Crossing site Phase 4. This contract arrangement requires the contractor to commit to a maximum price based on his design proposals at the contract award stage. It allows for design development and the sharing of cost savings between the employer and the contractor from alternative design proposals that are made after contract award, hence providing financial incentives, integrating the contractor's expertise and enhancing design and build-ability.

3.2 Communication with Residents

Clear communications is essential in HA activities, so that everybody is fully informed of our plans, that they understand and respond to initiatives and so help ensure their success. In 1995 we launched the "Estate Management Advisory Committees" (EMAC), which allow our tenants to contribute to management of our estates, by acting as bridges between the HA and the residents (Photo 1). Each Committee consists of the Housing Manager, a District Councillor of the constituency, and representatives from Mutual Aid Committees and residents associations. They act as an advisory body and make suggestions on day-to-day management issues, assess the performance of contractors and allocate funds for minor improvement works. In 2005/06, we issued more than 260 editions of a half-yearly EMAC newsletter, helping to keep the two million public housing tenants in touch with important housing issues and local estate news. The EMAC Scheme has made a significant contribution to building partnership between the managers of estates and the tenants.

The "Housing Channel", launched in 2004, has been extended to cover over 850 residential blocks in almost 130 estates. Video programmes are broadcast on LCD monitors installed in the ground floor lift lobbies of our blocks. The channel enhances communication with the tenants and keeps them informed of new services and developments within their estates. Over 50 videos were produced, including topics on developments in the Review of Domestic Rent Policy, the Total Maintenance Schemes, the Rent Assistance Scheme, the promotion of green practices in estates, and even news and weather information.

Photo 1: Event Organized by the EMAC Play a Vital Role in Stakeholder Engagement in HA Estates.

4. Engaging Stakeholders: Planning and Design Stage

We motivate our planners, project managers and designers who play a crucial role in the "embryonic stage" of our estates during the planning and design work, which will ultimately affect the construction and occupation phases throughout the life of the buildings. It therefore follows that we must positively engage this group of creative people and align their thoughts with our corporate vision and values, through design reviews, experience sharing sessions, and promulgation of design guidelines.

4.1 Adopting Micro-climate Studies for Environmentally Responsive Design

Since 2004, we have employed micro-climate studies for all new estates designs, to verify environmental performance. We do this by applying computational fluid dynamics techniques, so that our designers may refine their scheme designs to maximize the advantages of the form, orientation and disposition of buildings and thereby optimize the benefits of local wind patterns, natural ventilation, dispersion of pollutants, day-lighting, thermal comfort, and ultimately help to improve energy efficiency during the occupation stage.

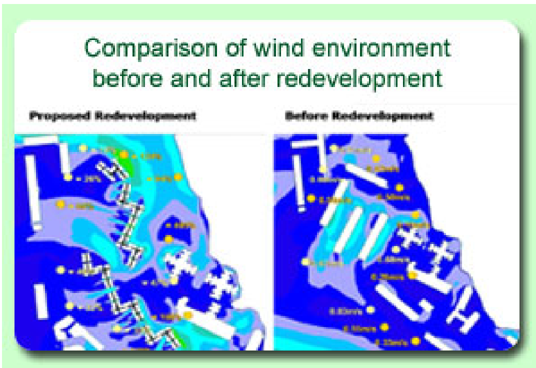

Photo 2: Micro-climate Studies are used in development of all designs, and this is for Upper Ngau Tau Kok

The studies help us to provide a healthier, more natural and more user-friendly living environment. We have already applied these modelling techniques on 26 projects. The first project employing these techniques, Upper Ngau Tau Kok Phases 2 and 3, which is due for completion in 2008, has been assessed under the Hong Kong Building Environmental Assessment Method (HK-BEAM) and has achieved the provisional top-level Platinum Rating.

We have also researched into the detailed design of the facades of our buildings by addressing orientation and sun-penetration for better thermal comfort, reduced glare or more natural lighting, depending on the location of each flat. A pilot project at the Eastern Harbour Crossing Site Phases 3 and 4, in Eastern Kowloon, will be completed soon.

4.2 Developing a Common W-trap System for Drainage Works

The SARS outbreak also led to the re-appraisal of soil and waste drainage systems to address the risk of transmission of disease through dried-up traps to floor drains. We worked with the City University of Hong Kong to develop a common W-trap system so that floor traps always provide an adequate seal. A number of plumbing suppliers have expressed interest in manufacturing the traps for use in HA projects and they will be used on all new developments where practicable, at first in Eastern Harbour Crossing Phases 3 and 4.

4.3 Community Participation in the Design and Planning Processes.

Engaging The Community has become a vital process in our delivery of public housing. Comprehensive design approval processes, and a mature feedback system, ensure estate planning and design match with tenants and community needs. We consult Government Departments as a start and then District Councils to gauge the community needs. Public and media briefings on new proposals and a range of communal activities such as meetings with residents groups, art promotions, exhibitions and planting activities all play an important part in securing public support to development proposals.

We have explored several models of user-oriented neighbourhood design. At Yau Tong Estate, Ma Hang Headland, Upper Ngau Tak Kok Estate and Lam Tin Estate, we have worked with a variety of interest groups; academics, residents, schools and NGOs in a series of facilitated workshops, where they were briefed on the constraints and opportunities of the project, and help them to articulate the concerns and aspirations in the neighbourhood. We ran drawing and mural painting competitions to strengthen public awareness and appreciation of local heritage. We succeeded in drawing up a design brief to meet common objectives and will continue this work to integrate community aspirations in future designs. The experience gained will be invaluable in future projects.

Photo 3: A Workshop held with the participation of local schools in the development of Yau Tong Estate

4.4 Life Cycle Costing and Life Cycle Assessment

In view of our large stock of buildings and large customer base, we have a culture of using simple designs and materials that are long-lasting, easy to care for and environmentally friendly. In 2002 to 2005, we commissioned consultants to study the life-cycle costing and assessment on typical domestic buildings. The study confirmed that the materials that we use achieve an optimum environmental performance and life-cycle cost effectiveness (Photo 4). Designers are now using this tool to help their decisions on the choice of new materials in future designs and thereby reduce our maintenance burden in future.

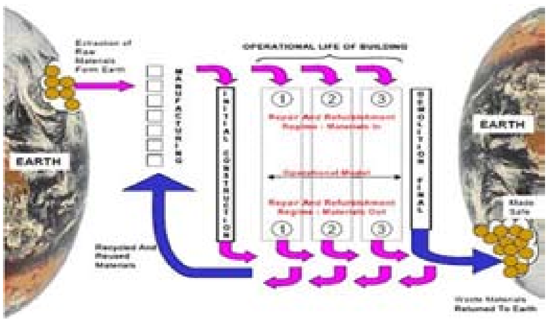

Photo 4: Life Cycle Process Of Building Materials From Extraction, Through Manufacture To Final Disposal.

4.5 Regenerating the Public Housing Stock

While the majority of our housing stock consists of modern blocks built after a Comprehensive Redevelopment Programme in 1988, we continuously maintain and evaluate our older estates, which we define as over 40 years old. Comprehensive structural survey of nine estates has just been completed according to technical criteria developed in consultation with local and international specialists. Options of protection, restoration and structural strengthening are studied. As a result of these investigations, we announced in March 2006 that So Uk Estate would be demolished. While the 16 blocks of this estate built in the 1960's are all structurally sound, the extensive repairs required would not be cost-effective, and there would be considerable nuisance and disturbance to tenants. For all other estates where they are not beyond economic repair, we would prolong their further use by 15 years.

5. Engaging Stakeholders: Construction Stage

The construction stage can have a huge impact on the community and if not properly managed can lead to complaints and delay to projects. To motivate our contractors, subcontractors, suppliers and workers, we have introduced contractual provisions to require our contractors to develop best practice including safe and green building practices. They in turn, cascade the message down through the supply chain to workers on site. We conduct rigorous site inspections and have implemented thorough Performance Assessment Scoring Systems (PASS) to monitor performance so that they meet their obligations by strict compliance with specified standards.

5.1 Applying Pre-casting and Mechanized Construction Methods

With labour shortage in Hong Kong in the late 1970's, we started construction of housing blocks with various mechanized forms. Mechanized construction can make the process simpler, safer, quicker and cleaner. By 1990's these techniques were widely used and became mandatory contractual requirements. Our teams worked with contractors to perfect the use of large panel formwork systems, pre-fabrication techniques for a wide range of building components (Photo 5). Our latest pilot project sees an increase in the extent of prefabrication from our usual 20% of the concrete work, to approximately 60%. There are social, economic and environmental benefits, most notably in quality, in site safety, waste reduction and so a reduced impact on the environment.

Photo 5: Increased Use of Pre-cast Concrete and Prefabricated Elements in Building Construction Works

5.2 Applying Hard Paved Construction for Building and Piling Works

A further enhancement to reduce the impact of our works and improve conditions at site level has been the requirement for temporary paving in all of our construction sites. We have specified "hard paved construction" for use in all building and piling contracts since June 2005. The practice has provided healthier and cleaner sites with much better dust control, material storage and handling, and surface water runoff.

Photo 6: Hard Paved Construction Sites now used, this one at Eastern Harbour Crossing Phase 4

Some builders have gone further with the use of re-usable pre-cast concrete slabs instead of in-situ concrete. "Hard paved construction" has been shown to be effective, not only in minimizing the environmental impact but also in improving site safety, and gradually changing the behaviour and culture of the workforce where more clean and green working practices are becoming the norm.

5.3 Applying Hydraulic Crushers for Demolition and Jack Piles for Piling Works

Demolition and piling works are usually noisy and dusty activities which have the greatest impact on the community. We have been working with the industry to reduce noise emissions, and introduce efficient, safe and environmentally friendly demolition and piling techniques. Since 2001, we have carried out trials of hydraulic concrete crushers in demolition works rather than using traditional pneumatic breakers. In 2004 we published guidelines and specifications to facilitate their use by project teams for works close to noise sensitive receivers, such as domestic buildings, schools and hospitals. We have conducted a comprehensive study in 2003, and after consultation with the Buildings Department, we have applied the use of "jack piles", which is a new type of more environmentally friendly piling technique.

5.4 Safety Management Means Business

We have been progressively introducing measures to improve site safety, increase safety awareness and promote best practices beyond basic regulatory requirements. These included the Silver Card advanced safety training scheme, Housing Authority Safety Auditing System, Pay for safety, environment and hygiene scheme. These systems have been instrumental in improving safety management and the overall awareness of the managerial staff engaged in projects, by setting objective safety standards on sites. The HA has a good record for site safety with 9.9 accidents per 1000 workers in 2007 (provisional), compared to about 60 accidents per 1000 workers in the industry as a whole, (Figure 1).

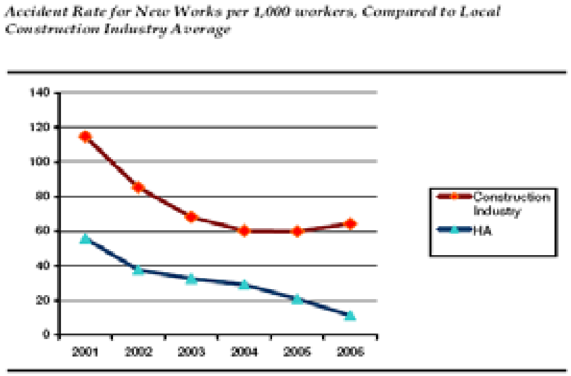

Figure 1: The decline in the accident rate in HA projects by comparison with the Industry as a whole.

5.5 Securing and Monitoring Wages Payment to Workers

With the multi-layered subcontracting in Hong Kong, construction workers have often suffered from wage arrears. Commercial disputes between contractors and sub-contractors may lead to late payments or non-payment at the lower levels of subcontracting and if wage arrears occur, then as a public sector client, the HA may be criticised, even though the contractors may have been paid for the work done. Labour disputes between contractors and sub-contractors and their workers also affect quality of service and cause delays.

In response to some serious incidents on building contracts in late 2005 to early 2006, we consulted the industry, including sub-contractors and workers, and developed improvement measures to secure and monitor the payment of wages to workers. These have been adopted in our building contracts and nominated sub-contracts from May 2006. The measures include employing Labour Relations Officers to conduct on-site checks and verify records of workers in employment, records of attendance; payment of wages and acknowledgement of receipt; monitor the situation and identify any anomalies. The Labour Relations Officers will also receive, acknowledge and record complaints and inquiries from workers.

6. Engaging Stakeholders: Occupation Stage

Throughout this occupation stage we engage our tenants, property managers and the community to foster a green and healthy living habitat in harmony, making effective use of housing resources and prolonging the useful life of buildings.

6.1 Green Delight in Estates

Through education campaigns and outreach programmes with "green groups", we have collaborated with tenants, staff and service providers to reduce domestic waste, promote schemes to save energy and water, and clear hygiene black spots. Working with our tenants is the most effective way of spreading the environmental awareness message to a large proportion of the Hong Kong public.

In 2005, we have launched a long-term community environmental programme, called "Green Delight in Estates", to promote environmental awareness among our tenants through educational and community activities (Photo 7). Various activities are being organized with local "green groups" where they have implemented green initiatives for 30 estates in 2005/06. The programme was extended to a further 30 estates in 2006/07 and will be progressively rolled out to all public rental housing estates. A tenants survey conducted at the end of the first year concluded that the programme has raised environmental awareness and the green groups are working with us to promote waste reduction and recycling campaigns. We have also started energy saving campaigns with the green groups and the Electrical and Mechanical Services Department to promote energy conservation amongst our tenants.

Photo 7: Partnering with Green Groups to as part of the "Green Delight in Estates" Programme.

6.2 Reducing Domestic Waste

In 2006 to 2007, residents of HA estates generated 0.74 kg per person per day compared to 0.82 kg per person per day in 2003. Waste recovery has also been a concern, both from the perspective of recycling and for disposal of potentially toxic waste such as used rechargeable batteries. Our residents also make significant contributions to environmental protection by using the recycle bins provided in each block. Recovery rates for recyclables in the past year have increased and in total, 12.36% of paper, 28.31% of aluminium cans and 6.19% of plastic bottles were recovered for recycling from our estates.

6.3 Estate Landscaping and Greening

Landscaping and planting schemes in public housing estates have long been an HA priority (Photo 8). In 2005/06, the HA professional and Horticulture Teams have continued their work to improve the standards of landscaping, both in new developments and improvements to existing estates. About 4,100 trees, 527,400 shrubs and 92,000 annuals were planted during the year. We set ourselves five targets on greening works for 2005/06, which have all been achieved, which have upgraded of the landscaping in selected estates and promoted the benefits of a green environment through the EMAC. Theme gardens have been set up to enhance awareness of greening, with Rhododendron Gardens at Lei Muk Shue and Nam Shan Estates and every year we organize tree planting days to help to raise awareness of our efforts and achievements.

Photo 8: HA Estates have extensive Landscape Facilities, with this example in Tseung Kwan O New Town.

6.5 Customer Satisfaction

We have been conducting customer satisfaction surveys with our residents for many years, to gather feedback on new estates and compile statistical data. We use this to review our designs, our space standards and specific requirements for estate facilities and communal areas. Latest survey results in 2007/08 indicated that less than 1% was dissatisfied with the estate and our services, whereas 74% of households were either very or quite satisfied. These surveys are invaluable in our drive for improvements and we apply the findings to refine our standards, management services and project administration.

6.6 Community Participation After Occupation to Meet Users Needs

In May 2006, we conducted a community workshop at Lei Muk Shue Estate to explore how best to respond to feedback and refine the design to meet user and estate management needs that arose after intake. The workshop proved to be an effective platform in gauging community opinion. The open forum allows people to voice their concerns and propose improvements. We have since then conducted post occupation review workshops at various estates. These were well received by residents and we believe through these workshops trust was established between tenants and management. By showing that we are sensitive to the well-being of residents and respond to their concerns, we encourage a sense of ownership as the community develops.

6.7 Healthy Life Styles and Obligations to Neighbours

Healthy living became a major concern in Hong Kong after the SARS crisis in 2003. High-density, high-rise living imposes obligations on all of us. Our behaviour directly affects our neighbours and our recognition of our obligations builds a more harmonious relationship between residents and the estate management teams. Clean Neighbourhood Campaigns are organized in our estates every year. In parallel, we introduced a Marking Scheme to address the problems caused by the unsociable behaviour of a minority of our residents that could affect hygiene and public health. Infringement of accepted public hygiene standards such as littering, spitting, urinating in public areas, mosquito breeding, smoking in lifts, throwing rubbish and objects from height, will all attract severe penalties. For serious threats to estate hygiene, we adopt a zero tolerance policy and allot demerit points to offenders, who will receive verbal and written warnings, and eventual termination of their tenancies if 16 or more demerit points are accumulated within two years. In October 2005, this scheme was reviewed in response to feedback from the public and cases which result in injury to a person, will lead to the immediate termination of tenancy.

6.8 The Total Maintenance Scheme

In February 2006, we implemented a new Total Maintenance Scheme. This was a major innovation in the maintenance of our estates, by proactively identifying maintenance needs and responding promptly to emergencies and requests for repairs, and at the same time strengthening publicity on maintenance issues. The scheme makes use of “In-flat Inspection Ambassadors” who visit all households, inspect flats thoroughly to identify maintenance needs and immediately rectify any problems. It aims to complete the inspection of 30 estates in a year and of all rental flats in a five-year cycle. The scheme will set up of a maintenance database on individual flats, strengthen research and development in maintenance and diagnostic methodology, and establish a maintenance hotline, as well as map out a comprehensive promotion and education plan.

7. The Future

Public housing in Hong Kong has made an enormous contribution towards the well-being of the community. While the sustainability of our housing estates requires tremendous dedication from our stakeholders, our sustained driving force as a public sector client also requires tremendous steer and support from top management. We define our sustainability priorities very clearly, develop and maintain a sound strategy for the future which will not only achieve our goals but also respond to the changes that may arise from time to time.

The sustainability of our programme is inextricably linked to economic, social and environmental performance. We need adequate budgets to enforce cost effective and meaningful applications. To enlist support and be accountable to the public, we prove our work through objective indicators, and monitor results for continuous improvement. We set achievable initiatives on sustainability with a firm vision. We demonstrate through our day to day actions that our vision and mission are credible; and our provision of services is cost-effective. Last but not least, we spend relentless efforts in engaging people, engaging our community in all stages of work. We must continue to engage all stakeholders to gain their support as we articulate our strategies and set out our plans for driving further sustainability initiatives. With this momentum, we build a healthy, harmonious, eco-friendly neighbourhood to be enjoyed by our tenants of all ages and abilities, at all times in the years to come.

Keywords: construction products, concrete, wood, zinc, environmental assessment, leaching behaviour

Summary

In order to satisfy the Essential Requirement n° 3 of the Construction Products Directive (Hygiene, Health and Environment), in 2005 the European Commission mandated CEN to prepare tests with which construction products can be tested with respect to the potential release of dangerous substances to indoor air, soil, groundwater or surface water (local environmental impact). A horizontal approach is considered the best route for such test development. Horizontal approach means it is product independent, so applicable to one or several relevant families of construction products. In this context, the aim of this work is to study the release of substances from construction products into water – a phenomenon called "leaching behaviour". The present research has been carried out on three different (especially from leaching behaviour point of view) construction products: the concrete paving slabs (an inorganic porous product), the wood duckboards (an organic porous product) and the zinc gutters (a metallic non – porous product). The research was conducted at two experimental scales: laboratory scale (exposure to controlled conditions) and pilot scale (exposure to non-controlled / outdoor conditions). A comparison of data from the two scales testing showed that a simple transfer of laboratory data to outdoor conditions (or service conditions) is not possible. An alternative approach to the direct transfer of data is provided: the use of the tests results to feed models that describe and simulate the product leaching behaviour.

1. Introduction

The Essential Requirement (ER) n° 3, "Hygiene, Health and Environment", of the Construction Products Directive (CPD, 89/106/EC) states that the construction works must be designed and built in such way that they will not be a threat to the hygiene or health of the occupants or neighbours, nor to the environment [EC, 1989]. So far, the compliance of this ER is not integrated into the construction products CE marking process, due to lack of harmonised methods allowing the assessment of environmental and health characteristics of products. Thus, in 2005, the European Commission mandated CEN to set up methods with which construction products can be tested with respect to the potential release of dangerous substances to indoor air, soil, groundwater or surface water (local environmental impact).This kind of assessment method represents a complementary approach to the Life Cycle Assessment (LCA) which refers to the global scale environmental impacts for generic scenarios, but does not take into account the local scale impacts and specificities. An overall (global and local) environmental assessment approach will be a more relevant decision - making tool for the impact assessment of the construction products. The LCA approach is well developed and adapted for the construction products assessment and serves to the Environmental Product Declarations (EPDs) establishment. Several EPDs are already available in different databases as for example the French National database named INIES [INIES, online].

In this context, the goal of this work is to contribute to the development of a local environmental impact assessment approach. The aim of the research is to study the release of substances from construction products into water – a phenomenon called "leaching behaviour".

The European Commission considers that a horizontal approach is the best route for products assessment [EC, 2005]. Horizontal approach means it is product independent, so applicable to one or several relevant families of construction products. In order to comply with this requirement the research has been carried out on three different (especially from leaching behaviour point of view) construction products: the concrete paving slabs (an inorganic porous product), the wood duckboards (an organic porous product) and the zinc gutters (a metallic non – porous product). The study was conducted at two experimental scales: laboratory (exposure to controlled conditions) and pilot (exposure to non-controlled / outdoor conditions) scales, in order to establish correlations between the two kinds of exposure conditions.

2. Materials and Methods

2.1 Materials

The concrete paving slabs were manufactured by using a CEM I – based concrete, supplied by a concrete mixing plant (ready-mix concrete). The concrete was cast in rectangular moulds of 16x13x4cm^3 and cured in bulk form at room temperature in a humid environment for 28 days. The wood duckboards are a pine wood type (Pinus Sylvestris) industrially preserved with some active substances based on boron-copper-propiconazole, for outdoor use in risk class IV (i.e. wood placed horizontally outside, wood in contact with fresh water etc.). The zinc gutters is made of a zinc alloy with 0.13% Cu and 0.05%Ti. The target elements that will be monitored during different tests are: Al, B, Ca, Cu, K, Na, Si, Zn, Cl^-, SO_4^{--}, DOC for the concrete slabs; B, Ca, Cu, K, Zn, Cl^-, SO_4^{--}, DOC for the wood duckboards and Zn for the zinc gutter.

2.2 Laboratory Scale Experiments

2.2.1. Physico – chemical characterization and static leaching tests

The physico-chemical characterization of the products consisted in the determination of the: 1) moisture content, porosity and pore-water composition of the two porous materials (concrete and wood), 2) total content in target elements, 3) pH influence on target elements release and 4) the buffering capacity of the material called "Acid / Base Neutralisation Capacity (ANC / BNC)". These determinations were carried out and reported in previous works [Schiopu *et al.*, 2007; Schiopu, 2007]. Here, it is briefly presented the static leaching test (i.e. equilibrium conditions are reached during the test) based on the European standard TS 14429 [CEN, 2004]. This test allows the determination of the pH influence on release and the ANC / BNC of the product. The test consists of a series of extractions on separate samples with pre-selected amounts of acid or base, in order to obtain eight final pH values, covering the range pH 4–pH 12. The obtained solutions (called "eluates") were analysed for pH and targets elements (ICP–AES for the metals, by using a Dionex Ionic Chromatograph 25 for the anions, and a COT-meter 5000A Shimadzu for the DOC).

2.2.2. Dynamic leaching tests

In order to study the leachant hydrodynamics influence on the release, two types of dynamic leaching tests were carried out: the Continuous Monolithic Leaching Test (CMLT) and the MultiBatch Test (MBT).

The CMLT is a dynamic test with continuous flow of the leachant, based on a protocol developed by Polden / Insavalor [Polden, 2005]. The monolithic sample(s) was (were) placed in a reactor and completely submerged in demineralised water (the leachant) all along the test period (64 days), at a L/A ratio of 5 cm^3/cm^2 (the L/A ratio means the ratio between the volume of leachant and the geometric surface of the sample) and a renewal rate of 0.52 cm^3/cm^2/hour. In the reactor, the local homogenization of the leachant was assured by an efficient stirring. This stirring was performed by a loop recirculation of the leachant with a peristaltic pump at a flow rate of 18L/hour. The eluate was collected in separate fractions after a fixed period of time: 2, 4, 8 hours, 1, 2, 4, 9, 16, 36 and 64 days. Two types of eluate sampling were carried out: 1) a punctual sampling (a minimum quantity of eluate (~25mL, needed for analysis) collected at the end of the fixed periods of time) and 2) an average sampling (all eluate collected during the fixed period). The eluate parameters (pH, conductivity, redox potential) and the concentration in the targets elements were monitored.

The MBT is a dynamic test with sequential total renewal of leachant. The protocol is based on the Dutch standard NEN 7345 [NNI, 1995]. As for the CMLT, the monolithic sample(s) was (were) placed in a reactor and completely submerged in demineralised water at L/A ratio of 5 cm^3/cm^2 but without any stirring. A total renewal of leachant was carried out at the same fixed period of time as for the CMLT sampling (2, 4, 8 hours, 1, 2 etc. days). All the eluate was collected and analysed at the end of each fixed period. The parameters of two dynamic tests (leachant nature, L/A ratio, sampling period, etc.) were chosen as similar as possible, in order to make pertinent comparison of their results. The main protocol differences between CMLT and MBT consist in the reactor type (open - i.e. matter exchange with the exterior - or closed) and in the eluate hydrodynamics (continuous or sequential renewal).

2.3 Pilot Scale Experiments

The products were exposed outdoor for one year, on a test field at Scientific and Technical Centre for Building Industry (CSTB), in Grenoble, France. The products were placed horizontally in order to reproduce two scenarios (Figure 1): "run -off" and "stagnation" scenario. In "run-off" scenario, the rainwater ran - off over the products and went into the leachate collector (run-off leachate). In "stagnation" scenario, the concrete paving slabs and the wood duckboards were immersed into the leachant, which accumulated up to a maximum volume imposed by the set-up design (stagnant leachate) and may overflowed into a leachate collector through an overflow pipe fixed at 20 mm above the upper surface of the product (overflow leachate). In the case of the zinc gutter, the leachant accumulated directly into the gutter up to maximum depth of 40 mm. After each "efficient" rainy event (i.e. a minimum of 2 mm/day), the different types of leachates and a rainwater sample (from a blank setup) were collected in polyethylene barrels whose contents were measured and analysed. For "stagnation" scenario the volume of the stagnant leachate was calculated and the sampling was done directly into the product tank or into the gutter, respectively. The local meteorological parameters (rain, temperature, relative humidity of the air) were monitored every ten minutes by a meteorological station located on the test site.

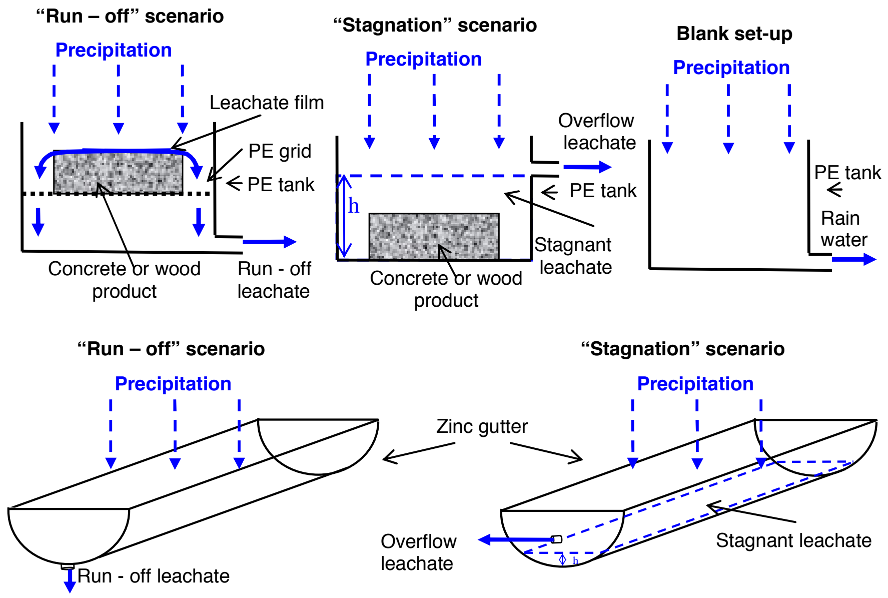

Figure 1 Pilot scale experiments scheme

3. Experimental Results

3.1 pH influence on release and the Acid / Base Neutralisation Capacity (ANC / BNC)

The pH at which the leaching takes place is one of the most influent parameter and depends on: 1) the pH of the leachant, 2) the pH induced by the matrix of the product (its "own natural pH") and 3) the ANC/BNC of the material ("resistance" to external influence on pH).The ANC/BNC is given by the amount of acid / base per kg of material (moles acid/base per dry kg of material, moles OH^- are expressed as "- moles H^+") needed to obtain a certain pH of the eluate.

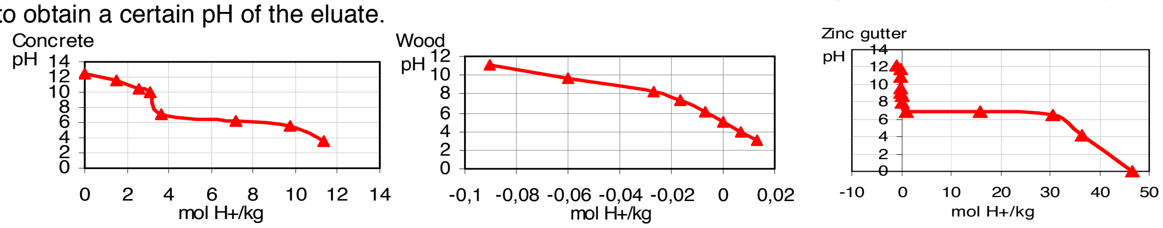

Figure 2 Acid / Base Neutralisation Capacity (ANC / BNC) curves

The ANC/BNC of the three studied materials are very different (Fig. 2). In the case of concrete, a high ANC is observed: a steady pH is maintained even if 6 moles of acid/kg of material have been added. This high ANC is mostly due to the carbonates which are major constituents of concrete. The wood presents a very weak BNC due to its own acidic pH and no ANC. In the case of the zinc gutter, the plateau observed at pH 7 can not be assigned to an ANC because the steady pH is due to the dissolution reaction of the zinc (the "matrix" is the target element in itself). Hence, the material does not "resist" to external influence on pH. Thus, among the three studied matrices, the concrete based product presents the highest resistance to external influence on pH.

The results of the pH influence on the release behaviour are expressed in mg/L of constituent as a function of the final pH of the eluate. The Fig. 3 shows the pH influence on Zn release from the three materials.

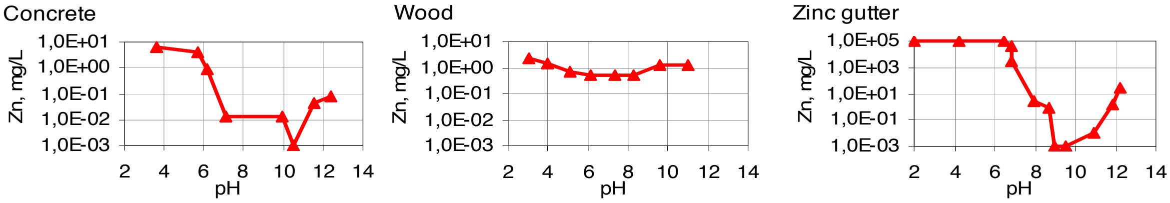

Figure 3 pH influence on the release behaviour

As expected, for the zinc gutter (metallic matrix), the pH is an extremely influent parameter for the Zn release. Its solubility changes by orders of magnitude as a function of pH (3 log units per pH unit). In the two other studied matrices (a non-metallic inorganic and an organic matrix), the zinc is present in a cationic form and its behaviour is different from the one of the zinc gutter case. Moreover, between an inorganic and an organic matrix, some differences occur, due especially to the dissolved organic matter (DOC), which is a crucial factor in the release of metals. Thus, in the organic matrix (i.e. wood), an increase of release is observed in alkaline medium compared to the behaviour in inorganic matrix. This could be explained by the high DOC concentration and availability in this medium. For the same element, release curves are similar; only the absolute level differs between different materials. This implies that the release controlling factors are the same but the relative importance of the influence differs from one matrix to another (buffering effect). For the other target elements (not shown here) the same conclusion could be drawn [Schiopu, 2007]. The results also showed that although same tests could be used for different products in a horizontal approach, some of them, such as TS 14429, do not bring essential information if they are applied to "simple" products such as zinc gutter (99,8% metallic zinc). Indeed, the results are as expected in line with the Pourbaix diagram for zinc [Pourbaix, 1966]. Thus, the physicochemical characterisation of a product could be more or less complex and must take into account the knowledge already available.

3.2 Laboratory / Pilot Comparison

The release behaviour observed at laboratory scale through the two dynamic tests (CMLT and MBT) is compared to the release observed at pilot scale. At laboratory scale, for each of the three products, over 64 days of continuous exposure to leachant, the cumulated L/A ratio (leachant volume to product surface ratio) was 800cm^3/cm^2 in the case of the CMLT and 50cm^3/cm^2 in the case of the MBT. At pilot scale, over one year of outdoor exposure, the total rainfall was 800mm and different L/A ratios were registered. In "run-off" scenario the L/A ratios were 50cm^3/cm^2 for the concrete slab, 44cm^3/cm^2 for the wood duckboards and 45cm^3/cm^2 for the zinc gutter. In "stagnation" scenario, the L/A ratios were 27cm^3/cm^2 for the concrete slab, 23cm^3/cm^2 for the wood duckboards and 30cm^3/cm^2 for the zinc gutter. Hence, the L/A ratio depends on the exposure conditions and product type (geometry, water absorption capacity etc.). 34 "efficient" rainy events (> 2 mm/day) were registered over the duration of test. The pH of the rainwater ranged between 5.7 and 7.9 (mean value 6.7). The air temperature varied between -9℃ and +38℃ (mean value +15℃) and 33 days registered below zero temperatures.

The Fig. 4 shows the pH evolution and for some of the target elements, the evolution of surface-related cumulative release (quantity of element released cumulatively per surface unit of the product sample, mg/m^2) as a function of product/leachant contact time. The contact time (and not the exposure time) was chosen for the representations because unlike laboratory tests, in field conditions, the products were not continuously in contact with the leachant (see 4.1).

In the case of the concrete slabs, figure 4 shows an increase of pH during MBT up to 10 days of leaching, followed by a slightly decrease afterwards. During the CMLT and "stagnation" scenario the pH evolution seems equivalent. Nevertheless, the causes are different: during the CMLT a depletion of alkaline and high soluble elements (i.e. Na, K) in pore water is registered, whereas during the "stagnation" scenario the carbonation effects could be the principal cause of the pH decrease; this is in agreement with Ca behaviour where the release is less important in out-door exposure conditions. For the "run-off" scenario, the pH evolution is dependent especially of the rain and inter-rain periods duration. At both experimental scales, the Zn (amphoteric element) behaviour is correlated especially with the pH evolution: the release decreases with the pore water pH decrease. For the wood duckboards, at both experimental scales the release rate of boron (coming from the preservative treatment of wood, based on B-Cu-propiconazole) is higher initially when exposure is started and gradually reduces as time (and L/A ratio) goes. This element is available to leaching up to total content release. In "stagnation" scenario, after 2 months of contact time the release increases probably due to a physical degradation of wood matrix. It must be noted that in the case of this product some artefacts could be assigned to the high heterogeneity of treated wood. For the zinc gutters, the Zn release increases during CMLT and the release is still under significant progress at the end of the test, whereas in the case of the MBT, the release rate decreases along time. This could be explained by the gradient effect which lessens during the MBT (the leachant is not continuous renewed). In outdoor conditions (pilot test), the release is under significant progress after one year of exposure and the release rate is controlled by a complex set of parameters: rain intensity and duration, air humidity, air pollution (SO_2, NO_X), product's surface state (e.g. patina formation/degradation).

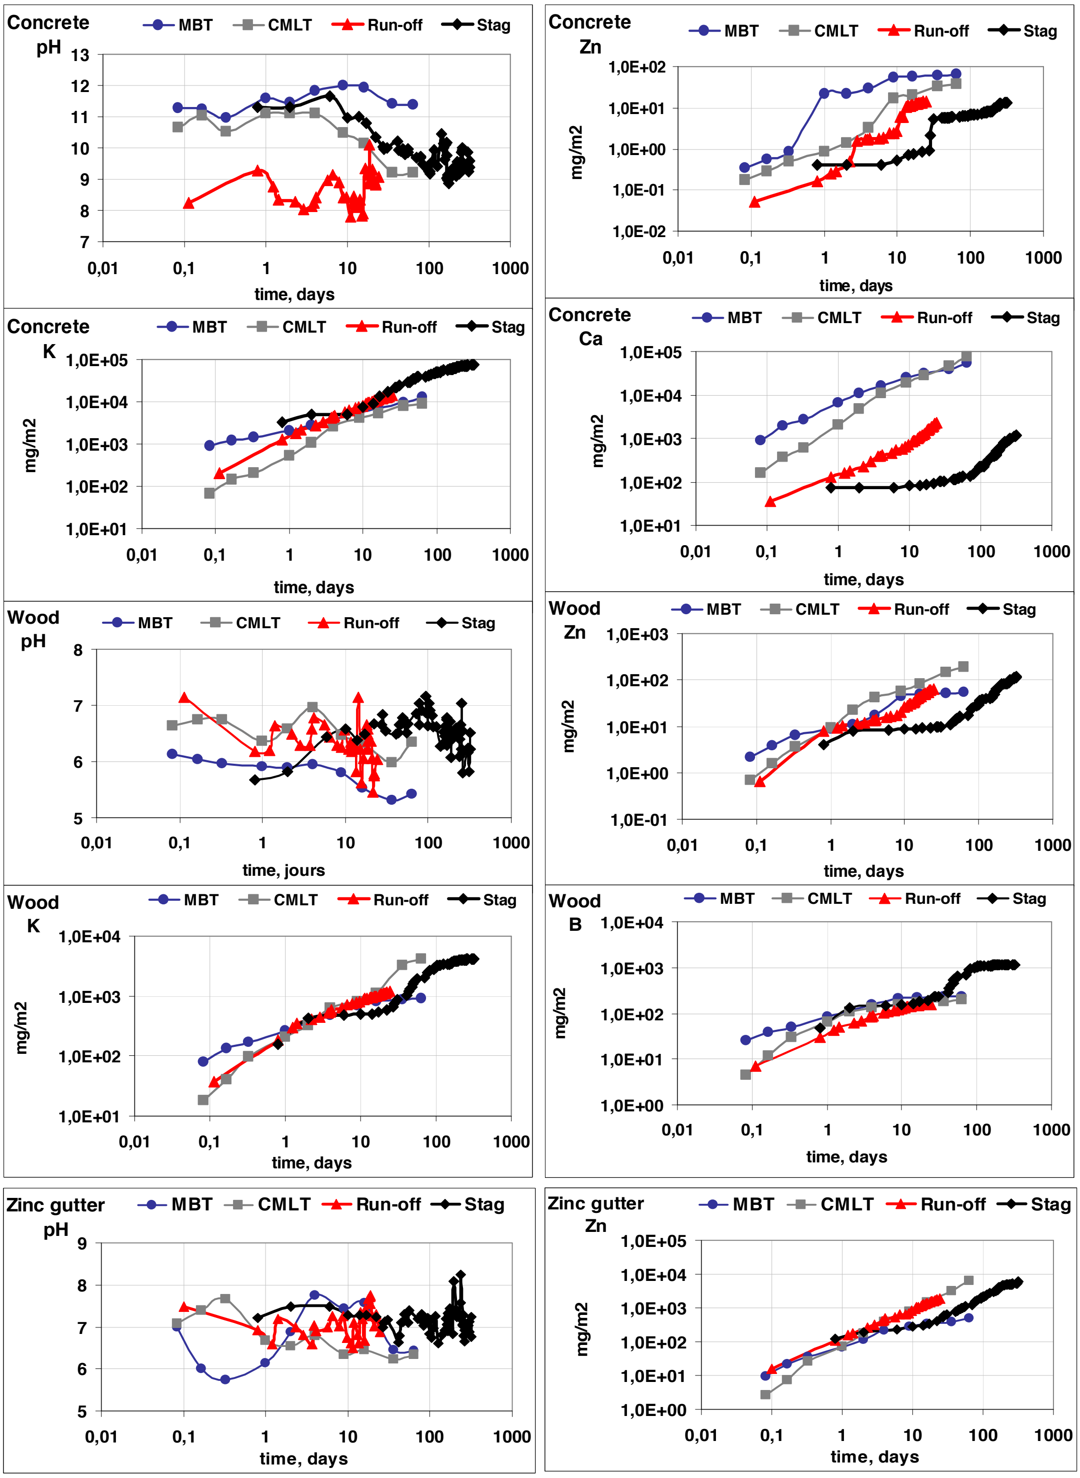

Figure 4   Evolution of pH and cumulative release as a function of product/leachant contact time

Comparisons of data obtained from the laboratory tests with data from pilot tests show that a simple transfer of laboratory data to service conditions is not possible. Indeed, even if release behaviour of some elements could appear as equivalent, the causes may be different. An alternative approach to the direct transfer of data is given hereafter: the use of the tests results to feed models that describe and simulate the product leaching behaviour. Such a model (chemical / transport) was developed for the case of the concrete slabs.

4. Coupled Chemical / Transport Model

4.1 Model Development

Several steps could be distinguished in the model development process: 1) the chemical model development, 2) the transport model development, 3) the coupled chemical-transport model development and 4) the model validation.

The chemical model consists of a combination of the mineralogical phases and chemical reactions occurring during the product / leachant contact. From the experimental data (especially the static leaching test TS14429) and by using PHREEQC software coupled with the LLNL data base, it is possible to identify the mineralogical phases which may control the target elements release. Three principal steps can be identified in the development of the chemical model:

1) the first step consists of the identification of all mineralogical phases in which the target elements could be found, based on DRX results [Schiopu, 2007], on literature and by using PHREEQC/LLNL. All the mineralogical phases identified in this first step are not necessary the most reactive during leaching. Thus, identification of phases controlling the leaching phenomena was carried in a second step.

2) the approach for identification and quantification of phases controlling the leaching phenomena was to find by simulation the leachates composition obtained experimentally at various pH values (TS 14429 test). The influence of phases that are not integrated in the LLNL data base was taken into account based on literature data. This was the case for the calcium-silicate-hydrate gel (CSH) and the iron oxides which may control the Ca and the Cr release, respectively [Schiopu, 2007]. Some indications about the nature of phases controlling the leaching are given by the saturation index (SI) calculated according to the formula: SI = log ($\Pi a_i v_i$ / Ks), where a_i is the activity of the target element, v_i is the stoichiometric coefficient and Ks is the solubility product equilibrium constant. The phases being in a near equilibrium state with the leachate (i.e. SI close to zero) are considered as controlling phases.The quantification of phases was made based on experimental data obtained at pH values for which the release was maximum (very acid pH, in general) and / or total content.

3) the improvement of chemical model all along the model development process, including during the coupled chemical-transport model step and model validation step by simulating the pilot test.

In a porous monolith as the concrete slabs, the main mechanism of transport is the diffusion. The one-dimensional diffusion equation is used, by considering an equivalent sheet geometry with the same monolith volume ($V_{concrete}$) and the same contact surface area ($A_{concrete}$). The monolith is considered exposed to leachate by only one face and this equivalent sheet is of thickness h = $V_{concrete}$ / $A_{concrete}$. In the leachate comportment, in the case of the open reactors (i.e. CMLT and leaching under outdoor exposure conditions), the transport is realized both by diffusion (coming from the porous monolith) and convection (due to the leachate hydrodynamics).

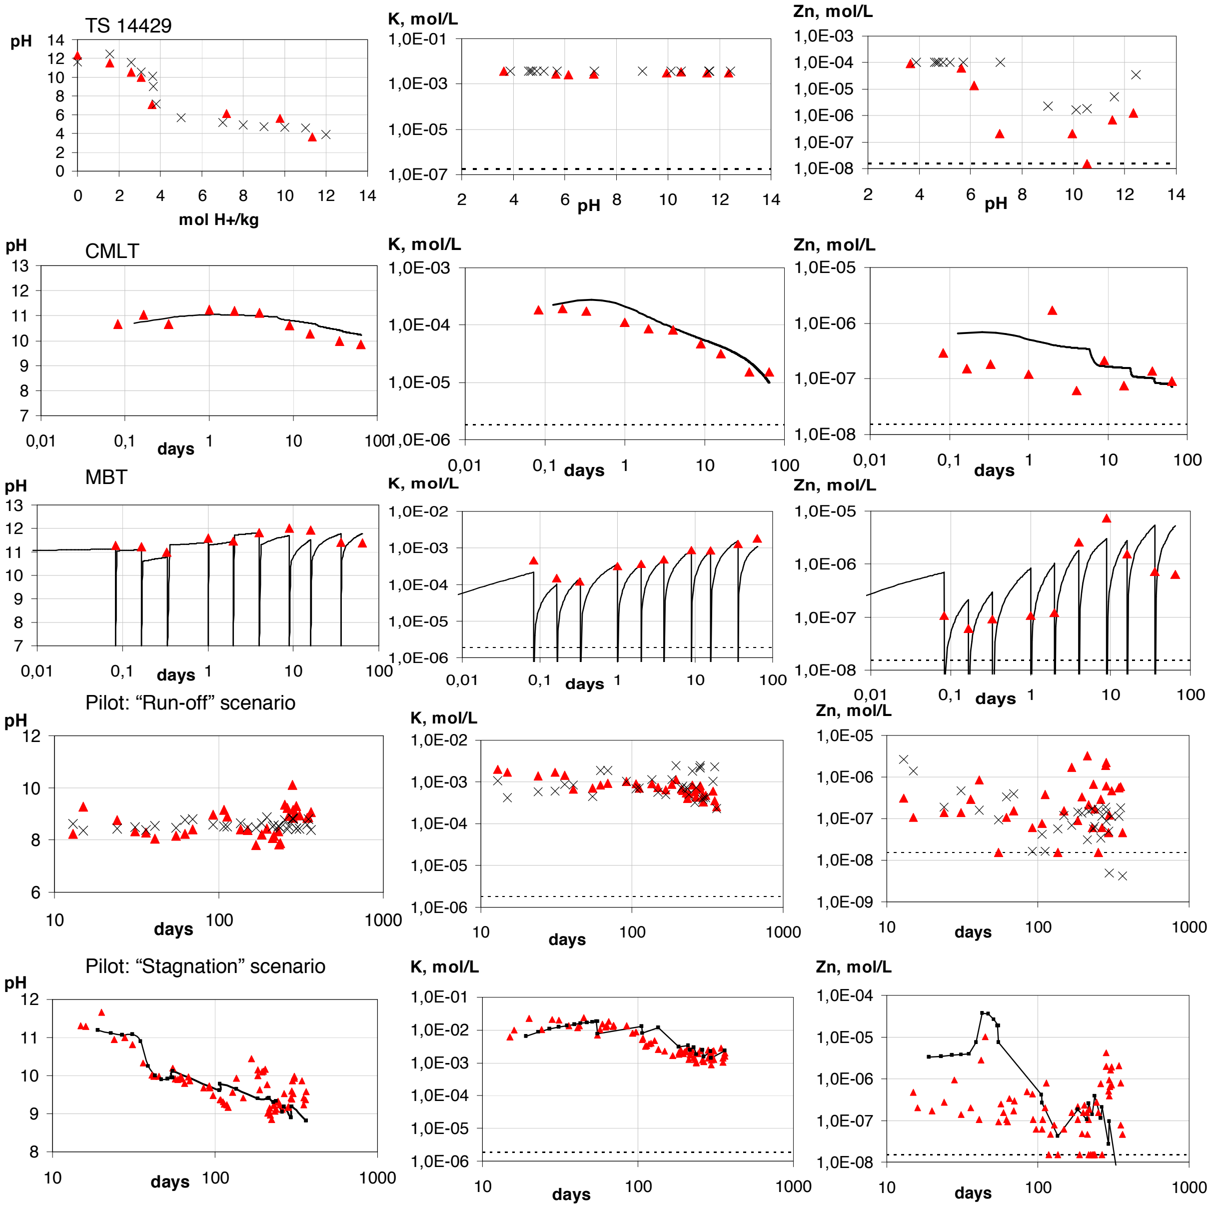
The coupled model chemistry-transport takes into account the physicochemical phenomena as well as the transport phenomena. The development approach consists in an iterative process of comparing the experimental and simulated results obtained for TS14429 and the two dynamic tests (MBT and CMLT), up to an acceptable fit. The chemical model is improved by integrating a kinetic model of dissolution for the CSH and portlandite phases which are major constituents of the matrix. For these two phases, the general kinetic model implemented in PHREEQC is used [Parkhurst and Appelo, 2003]

The model validation was done by simulation of concrete leaching under outdoor exposure conditions. The chemical model developed at laboratory scale was used and improved by integrating the rain water composition and the carbonation effect. The transport model developed at laboratory scale was used (the same diffusion coefficient and the same transport mechanisms) with the specific hydrologic balance of the field test. As function of the scenario type (i.e. "run-off" or "stagnation") the contact conditions were different. The approach adopted for the modelling was to discretize the exposure time according to these conditions. For both scenarios, two main types of conditions were identified: 1) exposure conditions which do not allow substance transfer and 2) conditions which allow and generate substance transfer. The first category (13 % of the exposure time) corresponds to the initial 14 days of exposure without any precipitation (dry conditions) and to the freeze periods (33 days in all, spread over 100 days in winter). The second category (i.e. substance transfer) is dependent on the scenario type. Thus, in "stagnation" scenario, the periods named "1s conditions" (85% of the exposure time) correspond to the stagnation and evaporation of the stagnant leachate. The periods named "2s conditions" (2% of the exposure time) correspond to the strong rain duration, when the stagnant leachate overflows into the collector. In "run-off" scenario, the periods named "1r conditions" (7% of the exposure time) correspond to the rain duration, when the rainwater runs off over the product and goes into the leachate collector. The periods named "2r conditions" (80% of the exposure time) correspond to inter - rain duration, when the diffusion continues into the saturated concrete matrix (intern diffusion). For the « stagnation » scenario simulation, the exposure time was discretized in 15 periods: 8 periods correspond to "1s conditions" and 7 periods to "2s conditions". The freeze periods were taken into account only in the exposure time duration. No structural modification of the concrete was considered. For the « run-off » scenario simulation, the exposure time was discretized in 67 periods: 34 periods correspond to "1r conditions" and 33 periods to "2r conditions".

The conceptual coupled chemical/transport model implemented in PHREEQC is explained elsewhere [Parkhurst and Appelo, 2003]. PHREEQC has not a dedicated module to simulate the open stirred reactor (complex boundary conditions for the diffusion equation). An extension of its application field for modelling the dynamic leaching tests and scenarios was realized and explained in previous works [Schiopu, 2007; Tiruta – Barna, 2008]. The mass balance equation has been written for all elements existing in the leachate. The results are the concentrations of elements in each phase and leachate, including the pH. To couple chemical and transport models, PHREEQC uses the split operator approach. To solve the model, the methods are the Newton-Raphson algorithm for the equilibrium equations, the Runge – Kutta algorithm for the equations describing the kinetics reactions and the finite differences method (explicit scheme) for the transport equations.

4.2 Results

For each target element and pH, the tests simulation results are compared with the experimental results on the same graph (Fig.5). For all tests, the simulated results are of the same order of magnitude as the experimental data. For the Zn, the simulated patterns are in agreement with the experimental data but some deviations are registered; they were assigned especially to very weak concentrations closed to the detection limit (high experimental uncertainty). In the model, the concrete slab was represented by an assembly of 3 very soluble elements considered completely dissolved in the pores water, i.e. Na, K, Cl-, and 8 reactive mineralogical phases, i.e. calcite, Cr-ettringite, CSH, ettringite, portlandite, tenorite, zincite and iron oxides. The effective diffusion coefficient was identified to be $6 \cdot 10^{-12}$ $m^2 \cdot s^{-1}$.



Legend: ▲ experimental x or ▬ simulation - - - detection limit

Figure 5 TS 14429 experimental and simulation results

Figure 5 highlights the variable conditions imposed by the sequential renewal of the leachant during MBT (pH curve). These disturbances generate physicochemical phenomena (e.g. dissolution/ precipitation of the various phases, variation of concentration gradient), artificially induced by the sequential renewal of leachant, which strongly influence the release (strong fluctuations of the leachant / leachates composition). This is not the case for the CMLT when the leaching conditions are constant; the continuously renewal assures the same characteristics of leachant during the test. Hence, the CMLT experimental curves are better representations of the physicochemical phenomena taking place during the test. The MBT experimental curves represent only the leachate composition at the end of each leaching sequence and therefore they are dependent on the sequences duration. At pilot scale, for such complex system as a concrete product exposed to natural/not-controlled conditions the simulated results are in good agreement with measured concentrations.

5. Conclusion

The main results show that in order to assess the substances emission from construction products into water, in a « horizontal » approach framework, the following steps are required and must take into account the product and the exposure conditions specificities:

- physicochemical characterisation of the product, which could be more or less complex, depending on the product and on the knowledge already available ;

- characterisation of leaching behaviour, under static (equilibrium) and dynamic conditions, which must take into account the use of the product during its service life. The Continuous Monolithic Leaching Test (CMLT) seems more suitable for release dynamic assessment;

- modelling of the products behaviour in a specific exposure scenario. The laboratory data cannot be directly transferred to service conditions but they are essential for the modelling of environmental behaviour. The static leaching test TS 14429 is essential for the chemical model development, i.e. the identification and quantification of mineralogical phases controlling the elements release. The dynamic leaching tests, CMLT and MBT allow the transport model development and the coupled model calibration. The model was validated by application at field scale over 1 year of exposure. The simulated results are in good agreement with experimental results.

Keywords: deciduous climbing plant, shading device, shading coefficient, bioclimatic

Summary

Strategic integration of vegetation to reduce heat gain and to improve environmental quality is increasingly being adopted by building designers. One option to reduce solar gain is to grow climbing plants on a supporting framework external to a building. This is a relatively recent design feature that has little data available to predict its shading performance. This issue is being investigated through a collaborative research project between University of Brighton (UK) and Kasetsart University (Thailand). A thermal model which integrates the shading effects of different leaf layers and their coverage has been developed and experimental investigation started at the University of Brighton. Experiments were set up to collect the environmental and physical growth data of a deciduous climbing plant canopy. The results enabled the development of dynamic shading coefficients which represent the shading efficiency of the plant canopy at different time of its growing cycle. Similar experimental studies were performed at Kasetsart University but with non-deciduous plants. This paper reports on the work carried out at Brighton. It summarises the development of the thermal model, the experimental measurements and analyses to establish a time series function representing the dynamic shading coefficient. The dynamic coefficients were applied to a computer simulation programme to predict the effect of different percentage areas of the climbing plant canopy to indoor thermal conditions.

1. Introduction

In response to the global awareness of environmental impact of buildings, more designers are adopting 'bioclimatic' principles to regulate the indoor thermal environment. One such design is the use of live plant canopies as external shading devices, which can not only regulate the solar gains, air temperature and humidity, but also improve air quality and the aesthetic of the building. As climbing plants grown on an external framework is a recent design feature, knowledge on their performance is scarce. This research project, in collaboration with Kasetsart University, explores and validates, through experimental investigation, an appropriate methodology for evaluating the thermal and environmental performance of climbing plant canopies. This paper reports on the outcomes of the experimental studies on the shading performance under the UK climate. The thermal studies by Kasetsart University including the air quality evaluation are reported in separate publications.

2. Bioshading device

The shading device consists of one or more vertical climbing plants that trail on a metal framework which is located in front of the building façade as shown in figure 1. The climbing plant for the experiment was selected based on a number of established criteria that include: plant height, growing cycle, façade orientation, leaf coverage, soil type and local climate. To take advantage of winter solar gain in the UK, only deciduous plants were considered. Virginia Creeper was selected for the study after a detailed evaluation process (Lam, 2007).

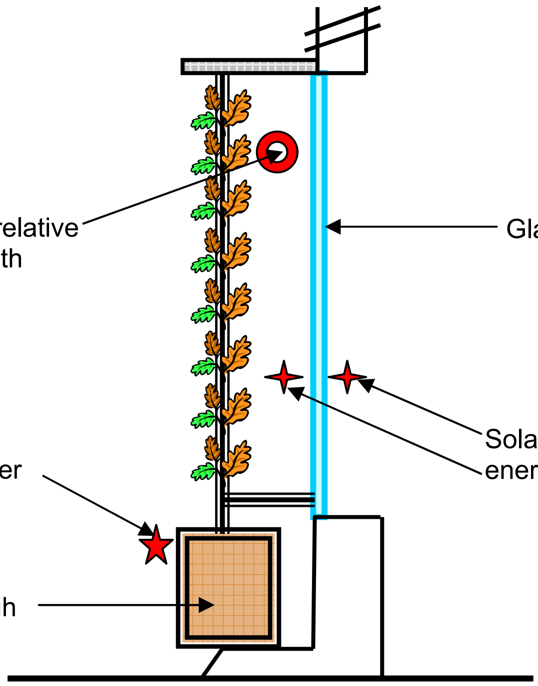

Figure 1: Vertical climbing plant shading device

3. Bioshading coefficient

Unlike a static shading device, the shading coefficient of a climbing plant canopy is not constant but changes with growth behaviour of the plant. A new term 'bioshading coefficient' is proposed to represent this dynamic shading performance (Ip et al., 2004) as:

$$BSC(s) = \frac{Q_{bioshader(s)}}{I_{0(s)}\left(\sum_{k=0}^{n} L_k\right)_{(s)}} = \frac{Q_{bioshader(s)}}{I_{0(s)}\left(A\right)_{(s)}} \tag{1}$$

The solar gains behind the bioshader canopy $(Q_{bioshader})$ can be broken down into three main components; they are: the amount of transmitted radiative heat transfer through the bioshader (I_{trans}), the long wave radiation between the leaves and the building facade (I_{l-w}), and the amount of direct radiation passing through the open gaps of the bioshader.

These three components of radiation received behind the bioshader can be expressed as:

$$\begin{aligned} Q_{bioshader(s)} &= \left(L_0 I_0\right)_{(s)} + \left[L_1 I_0 T_1 + L_2 I_0 T_2 + \ldots\ldots L_n I_0 T_n\right]_{(s)} \\ &\quad + \left[L_1 I_{(l-w)(1)} + L_2 I_{(l-w)(2)} + \ldots. L_n I_{(l-w)(n)}\right]_{(s)} \\ &= \left(L_0 I_0\right)_{(s)} + \left(I_0 \sum_{k=1}^{n} L_k T_k\right)_{(s)} + \left(\sum_{k=1}^{n} L_k I_{(l-w)(k)}\right)_{(s)} \end{aligned} \tag{2}$$

Applying this result to equation 1, the bioshading coefficient at time s becomes:

$$BSC(s)=\frac{(L_0I_0)_{(s)}+\left(I_0\sum_{k=1}^{n}L_kT_k\right)_{(s)}+\left(\sum_{k=1}^{n}L_kI_{(l-w)(k)}\right)_{(s)}}{\left(I_0\sum_{k=0}^{n}L_k\right)_{(s)}}=\frac{(L_0I_0)_{(s)}+\left(I_0\sum_{k=1}^{n}L_kT_k\right)_{(s)}+\left(\sum_{k=1}^{n}L_kI_{(l-w)(k)}\right)_{(s)}}{(I_0A)_{(s)}} \quad (3)$$

Where:

s = Time (in days) starting from the beginning of the year

$BSC(s)$ = Bioshading coefficient at time s

$Q_{bioshader(s)}$ = Solar gain measured behind the bioshader canopy at time s $[W]$

$I_{0(s)}$ = Ambient solar radiation perpendicular to the bioshader at time s $[Wm^{-2}]$

$A=\sum_{k=0}^{n}L_k$ (Area of the façade shaded by bioshader) $[m^2]$

L_k = Area of multi-leaf layer k $[m^2]$

k = Number of leaf layer

s = Time (in days) starting from the beginning of the year

T = Leaf solar transmission coefficient

n = Maximum number of leaf layers

$I_{(l-w)}$ = Radiation exchange per unit area between leaf and facade $[Wm^{-2}]$

The above equations are mathematical representations showing the key variables and their relationship in the bioshading coefficient. They enable the identification of parameters to be measured and monitored in the experimental investigation.

4. Experimental investigation

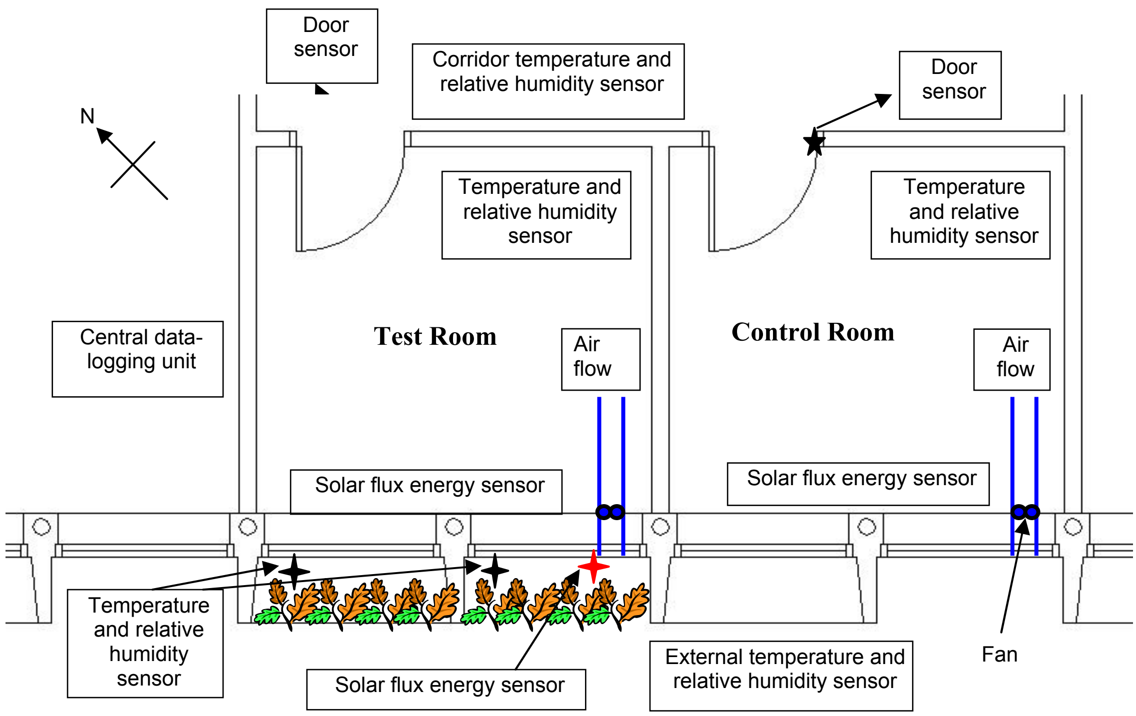

Figure 2: Plan showing locations of sensors and monitoring equipment

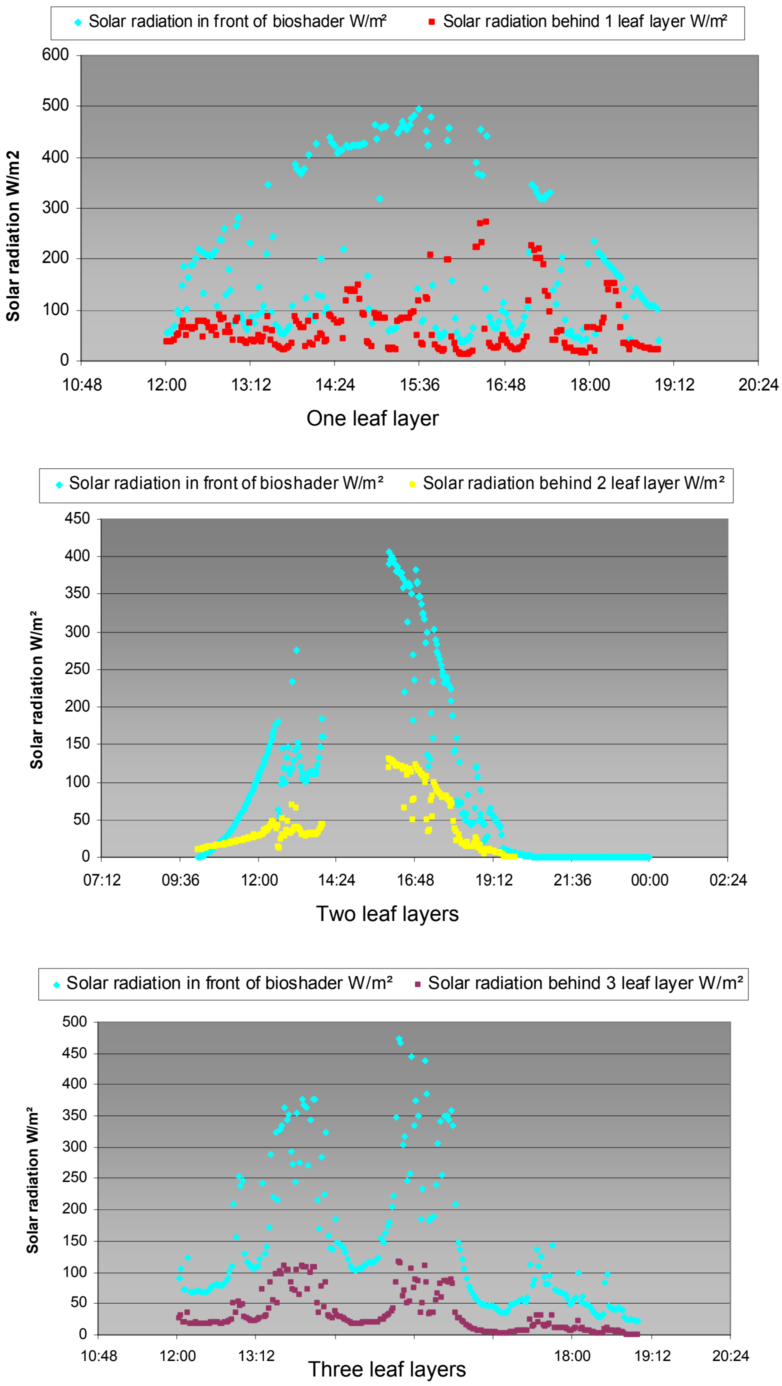
Two offices, one for the test and the other for control, on the first floor of a university building were used for the experiment. Two proprietary metal trellis were installed external to the test room. Monitoring equipment and sensors were employed to measure the parameters identified in the thermal model these include: temperature and relative humidity sensors, solar flux sensors, a dome solarimeter, air velocity sensors, door sensors, a data-logger and a personal computer. Figure 2 shows the locations of these sensors and equipment in the offices.

5. Results and analyses

5.1. Solar reduction of leaf layers

Examples of solar radiation data measured over one day behind one to four layers of Virginia Creeper leaves are summarised in figure 3. The corresponding horizontal solar radiation is plotted for reference. These data were collected on different days with different weather conditions. Scattered data distribution indicates more varied solar radiation levels as happened on cloudy days.



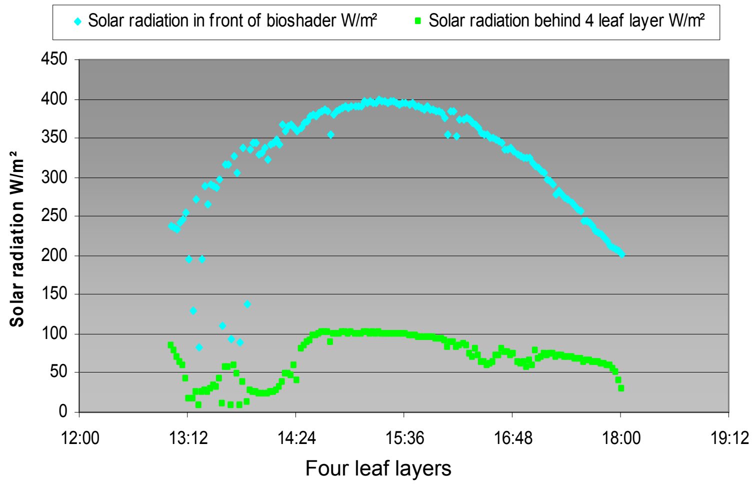


Figure 3: Solar radiation measured in front the canopy and behind 1 to 4 leaf layers

5.2. Leaf coverage

The change in leaf layers and their corresponding area on the plant canopy were extracted from digital images taken at regular intervals. The results for Window A in the test room are summarised in figure 4. Similar results were recorded for Window B. Pruning was necessary as the plant had reached its maximum coverage and overgrown due to the restriction of the window.

5.3. Bioshading coefficient

Taking the results of the leaf solar reductions and their corresponding coverage, a series of bioshading coefficients were established based on the concept of bioshading coefficient developed in section 2. A best fit curve was plotted to provide a continuous mathematical representation of the bioshading coefficients.

The R-square value of this curve is over 0.87 which shows very good fit between the day of the year and the bioshading coefficients. The time-series equation to represent the shading performance of the bioshader is expressed as:

$$BSC_{(s)} = 6 \times 10^{-5} s^2 - 0.027s + 3.5324 \qquad (4)$$

Where:

$BSC_{(s)}$ = Bioshading coefficient on day s

= 1 if $s \leq 133$

= 1 if $s \geq 316$

s = Day of the year ($1 \leq s \leq 365$)

The bioshading coefficient time-series in figure 5 shows the cycle shading performance which corresponds to the three growing phases over the year between April and October.

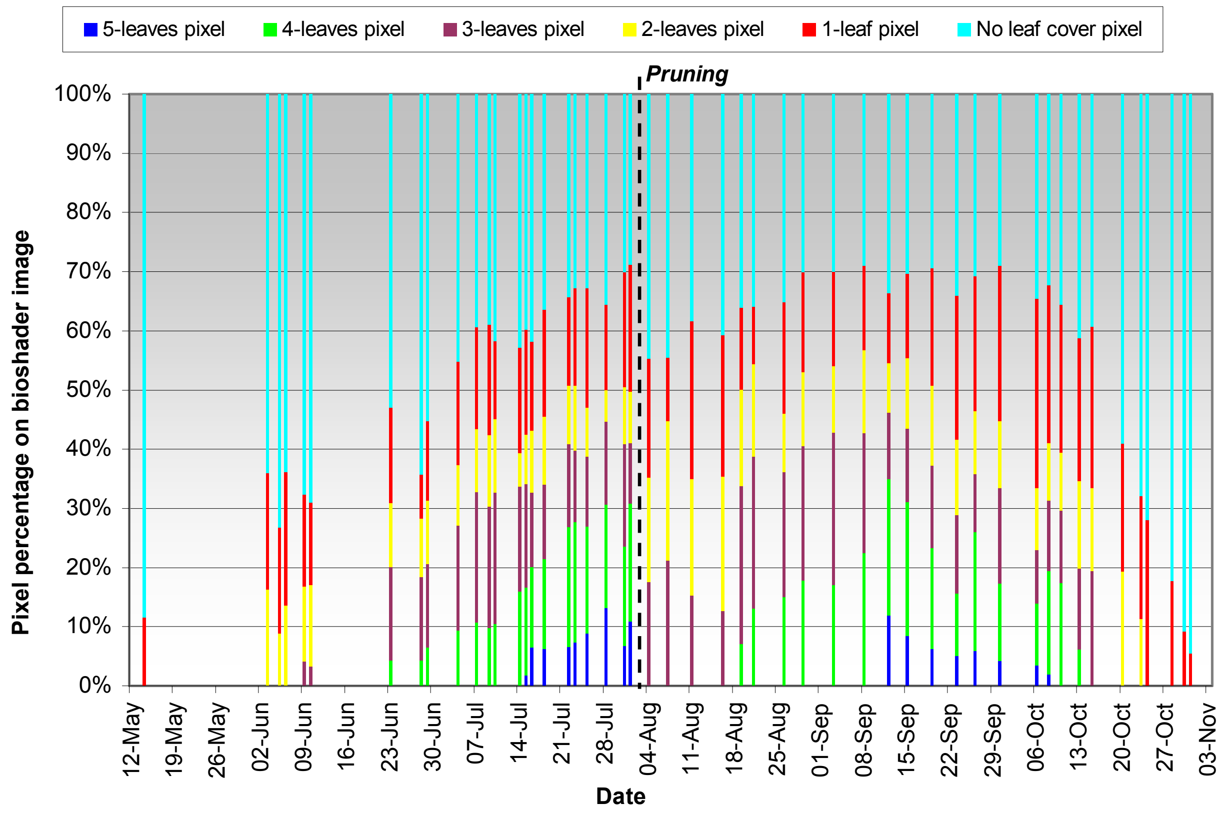

Figure 4: Coloured pixel distribution showing coverage by different layers of leaf on Window A of test room

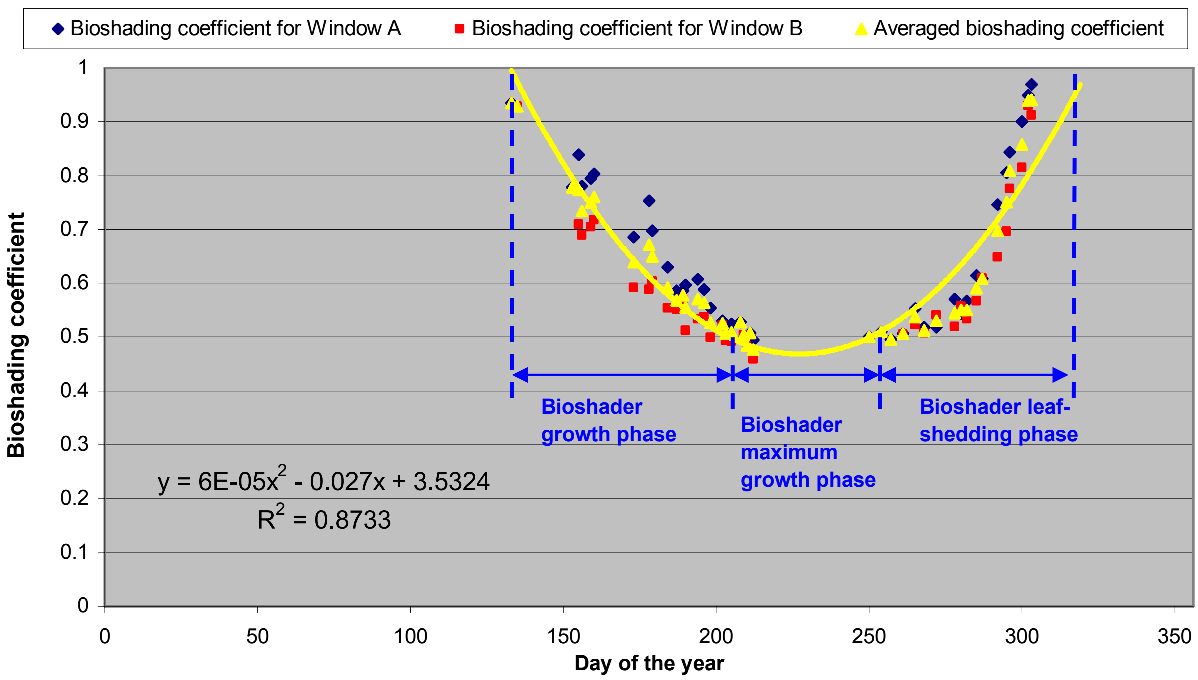

Figure 5: Bioshading coefficients and the best-fit curve

6. Computer simulation

Bioshading coefficients were applied to a dynamic thermal simulation IES VE (IES, 2007) software to predict the shading effect to the indoor thermal condition. The building model, image shown in figure 6 together with the simulation weather profile, is constructed to meet the minimum standard of the current building regulations in the UK. The south facing façade of this naturally ventilated building is shaded by the vertical climbing plant canopies. Four percentages (20%, 50%, 70% and 90%) of glazed window areas shaded by the external climbing plant were studied. Results for the south facing middle office on the first floor are illustrated in figure 7 to demonstrate the shading effect. Each graphs in figure 7 shows the resultant temperatures with and without the shading devise. The results show the shading effect is more pronounce in the summer as the leaf cover increases. The indoor temperatures during the peak summer in August were significantly reduced even the glazed area is as high as 90%. Taking the first of August as an example the average resultant temperature for all cases with the shading device is below 24°C while the temperature can be as high as 35°C without shading. The drop in temperatures ranges from 6°C for 20% and 50% glazing, to 10° and 11°C for 70% and 90% glazing.

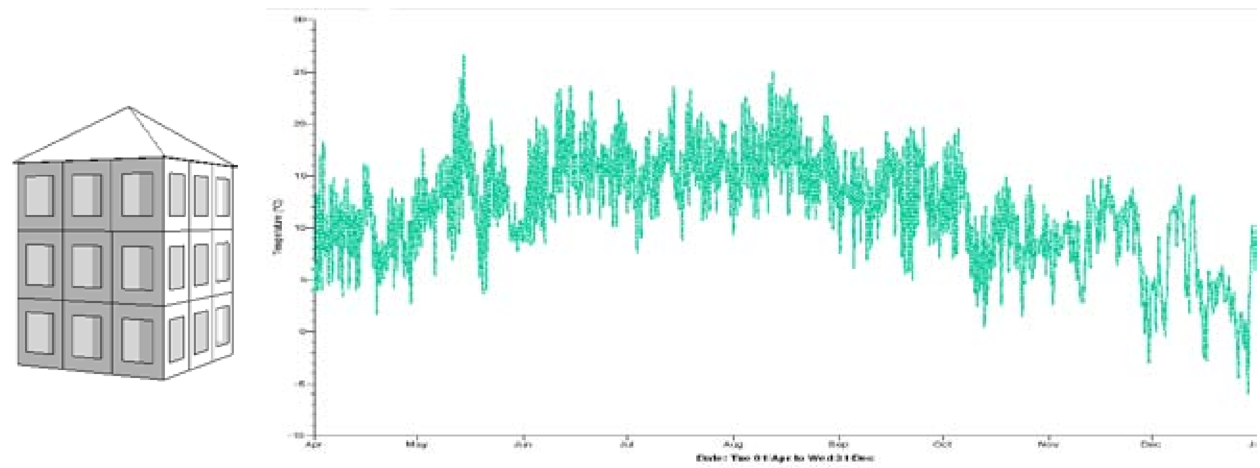

Figure 6: Simulation model and weather profile (IES, 2007)

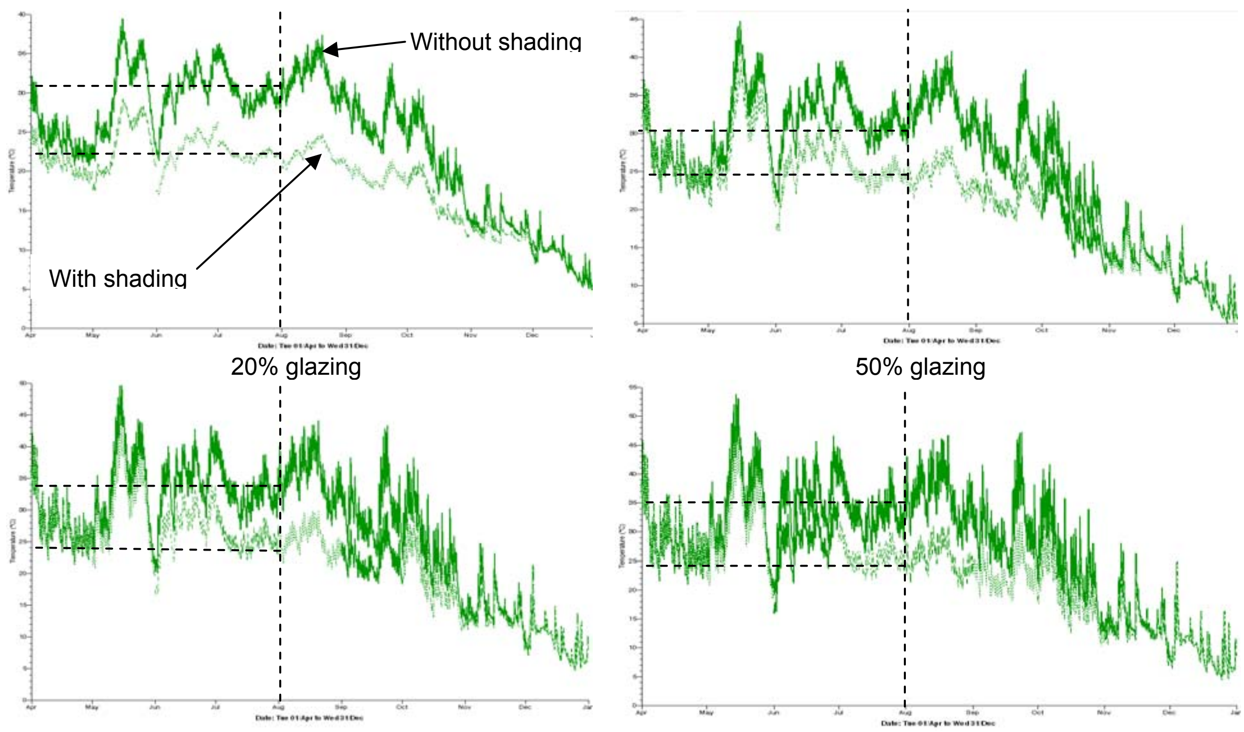

Figure 7: Effect of climbing plant shading to the indoor resultant temperatures with different percentage glazed areas

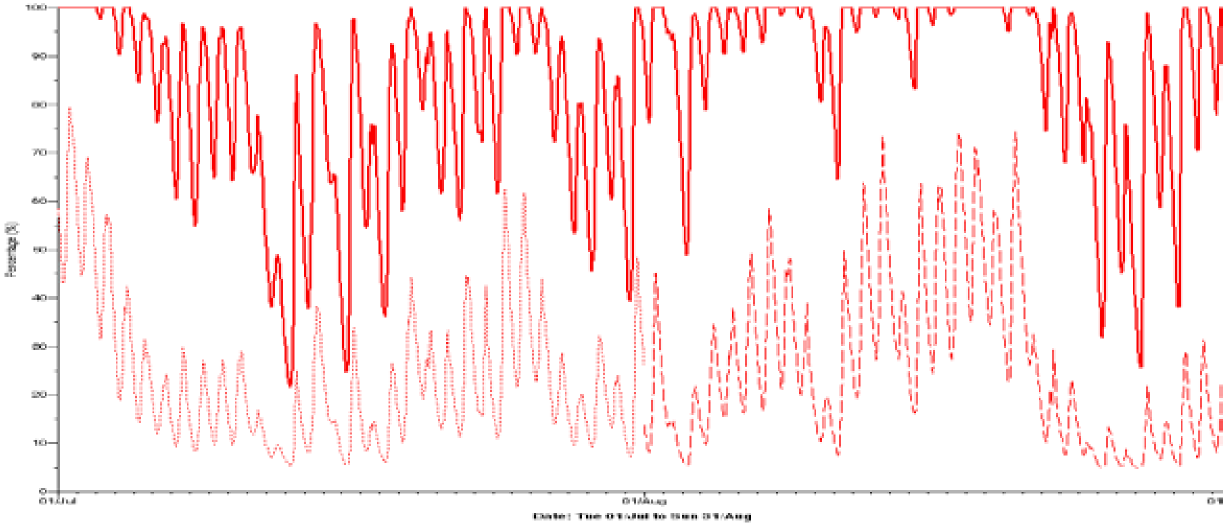

Figure 8: Percentage dissatisfied with 90% glazed area shaded by the climbing plant canopy

Figure 8 shows the predicted percentage of occupants dissatisfied with the thermal comfort for July and August for the case of 90% glazing. The dissatisfaction has significantly reduced from an average of around 80% to an average of about 30%.

7. Conclusion and future work

This research has successfully developed a methodology to quantify the shading performance of an external deciduous climbing plant shading device. The mathematical model has identified the key parameters related to the shading performance. Through an experimental setup at the University of Brighton, these parameters were measured and applied to establish the daily bioshading coefficients and subsequently a continuous function of a best fit time-series equation. This equation provides the shading performance data for the simulation program and enables the climbing plant shading device to become an integral component of the thermal model in the dynamic thermal simulation of the building. The current work can only be considered as embryonic yet revealing to the broad range of further and future work in this field. The collaboration with Kasetsart University in Thailand will continue to explore measurement of wider range of regional plants; to develop the scientific techniques to measure and quantify the dynamic heat and mass transfer of plants; and to include other parameters, such as air quality, that improves the environmental quality due to the integration of plant in the built environment.

Summary

The environmental load due to the building industry has become a main issue for Italy. In the last few years, Italian regions and iiSBE Italia worked together to develop a tool to assess the environmental performance of new residential buildings, called Protocollo ITACA, to become a common reference to verify the environmental performances of buildings. Eventually this tool went public, being mentioned in a great number of design competitions and becoming increasingly well known by building designers as well as constructors.

Protocollo ITACA assesses a list of criteria concerning various different aspects related to the building and its impact on the environment (such as materials, water and energy consumption, indoor air quality, etc). The scores achieved in each of the criterion will contribute to determine the environmental performance level of a building. Such environmental assessing system can become an useful support to design, to be used during the creative phase, proposing a precious aid to the systematic control of the achievement of the performance thresholds required. Once set a target minimum environmental performance, the designer should be able to assess and monitor the effectiveness of the different design options in order to satisfy the performance required.

In order to define a way to gradually lead the designer through the integration of environmental assessment and design process, two different experiences have been carried out, each one of them reflecting a particular approach: the first test, on the Piano Casa of Liguria Region, involved the designers directly through a self-assessment process; the second test, on the Sustanaibility Meta Distretto of Treviso, involved the designers only in the collection of significant data, while the assessment phase was carried out by a technical department. Strengths and weaknesses of the two procedures will be compared.

1. Protocollo ITACA

1.1 Introduction

In an economical and social context where the environmental topics have become increasingly more relevant, due to an increased awareness on the effect of our actions on the near future, it has become necessary for the building sector to question its responsibilities and to set new targets. The building sector is one of the main actors in the increase of resources consumption and the related environmental loadings.

Some designers which in the last years have tried to apply a sustainability-oriented design, considering the building as a complex system interrelated to its environmental context, have found themselves confused by the absence of clear reference points, while being on the other hand confused by different and mixed information – due to the recent proliferation of manuals, guidelines, and training courses. The excess of available data can lead to misinformation, falling short of the expectations and good will of those who try, with their work, to contribute to improve the built environment, aiming at higher performance standards.

Protocollo ITACA represents an effective solution to define sustainability targets, while providing a method to clearly assess the design efforts made to satisfy such targets.

1.2 What is Protocollo ITACA

Protocollo ITACA is an assessment system developed by the ITACA workgroup (Istituto per la Trasparenza degli Appalti e la Compatibilità Ambientale – Institute for Transparency and Environmental Compatibility in Contracts) which allows to assess the energetic and environmental quality level of a building, measuring its performance against a number of assessment areas and criteria, following the structure suggested by the iiSBE Method.

1.3 Protocollo ITACA – Synthetic

Protocollo ITACA, in its first edition, was composed by 70 criteria grouped in 7 main areas, to approach the theme of sustainability in an ample and diverse way. To aid the actual application of the system a more compact version became necessary. This need led to the draft of a Synthetic version of the Protocol which reduced the number of criteria and areas, while keeping the same underlying structure. Up to this day, the main applications of the Protocollo ITACA by the public administrations have been based on the Synthetic version.

1.4 Application of Protocollo ITACA

Protocollo ITACA was designed as an assessment system of the energetic-environmental performance level of a building. It is thus used wherever it proves necessary to define the environmental sustainability level of a building, through a codified process.

Protocollo ITACA is becoming a strong reference for private and public bodies, which need to define classifications or threshold levels of the environmental quality.

The version of the Protocollo discussed in this paper is aimed at the assessment of the performance of residential buildings.

1.5 Technical specifications of Protocollo ITACA

Protocollo ITACA is based on a requirements matrix, organized in single criteria depending on various assessment areas. To each requirement corresponds a performance indicator and a reference scale. Through the processing of the design data, it is possible to obtain the value of the performance indicator for each requirement, to be confronted with its reference scale. The output is a number of scores which represent the performance levels obtained. These scores, suitably aggregated, will concur to the definition of the global performance level of the building. The term “performance” indicates the response to a precise need, which in this case is the improvement of the sustainability level of the building.

For each criteria, the Protocollo ITACA gives the following information :

the *intent*, defining which environmental quality target was set; the *performance indicator*, or the parameter used to assess the performance level of the building under the criterion; this parameter can be a number or a scenario; the *measurement unit* – for numerical indicators only; the *verification method*, defining the procedure to establish the performance level of the building under the criterion; the *performance scale*, defining the score obtained by the building based on the performance indicator level obtained through the verification method; the *legislative references*, i.e. the laws or regulations in the area; the *reference standards*, i.e. the technical regulations used to set the performance scales and the verification methods; the *required documentation*, i.e. the information to be provided to justify the attributed score; the *notes*, to clarify doubts on the criterion verification.

Following the instructions specified in the *verification method*, it is possible to calculate for each criteria the *performance indicator* value. Through a comparison with the *performance scale*, this value is related to a score expressing the improvement achieved by the building over the minimum acceptable performance.

During the assessment the building can obtain, for each criterion and sub-criterion, a score ranging from -1 to +5, based on the performance level achieved.

-1 represents a sub-par performance, lower than common building practice;

0 represents the minimum acceptable practice, based on laws, standards or common building practice (when no regulation is available);

3 represents a significant improvement of the performance, compared to regulation or common building practice. It corresponds to the best building practice;

5 represents a significant improvement of the best bulding practice. It corresponds to experimental practices.

The scores achieved in each criterion or sub-criterion are weighted and aggregated to determine the scores of each area. The weighted output of the area scores is the global score.

2. Case Studies

2.1 "Piano Casa" of Liguria Region

The first testing started in July 2007, in the Social Housing Incentive Program promoted by Liguria Region, aimed at increasing the social housing apartments to be rented. The target of this initiative was to give a concrete answer to the detected need of the various types of social housing solutions. It has been decided to attribute financing benefits to the projects that proved to reach a set environmental performance level.

2.1.1 Test targets and restrictions

To estimate, in a transparent and objective way, the effectiveness of the sustainable design solutions of each project applying to the program, a point-based assessment system was need. Thus the system prepared by the ITACA workgroup was selected as reference, with some changes to the basic scheme.

The project's environmental performance level was asked to be calculated directly by the designer, following the indications of the assessment system.

2.1.2 Structure of the test

Each designer received a series of documents to support the self-assessment phase. Such documentation was aimed at explaining the contents of the assessment system, to calculate in an autonomous and semi automatic way the performance level obtained by the building, and to prepare the documentation needed in the validation phase.

The designers received:

the *Assessment System*, i.e. the document explaining each criteria through which the building was to be assessed, and their verification methods;

the *Calculation Tool* to self-assess the project, i.e. an electronic-format document through which the designer could calculate the final score achieved by the building;

the *Data Gathering File*, i.e. a synthesis document which had to be filled with the main data used in the performance indicator calculation for each criteria.

After calculating the performance indicator for each criteria, the designers filled out the *Calculation Tool* for the self-assessment of the project. Through this tool, the designers inserted the calculated values of the performance indicators, and obtained automatically the final assessment value.

2.1.3 Results

Regarding the Assessment System, the verification procedure was not always applied correctly, partly due to errors in the interpretation of the requirements of the Protocollo partly to the absence of reference standards and regulations. Moreover, the design documentation provided was in some cases not adequate and sufficiently detailed to verify the adequateness of the given data and the correctness of the calculation of the performance indicator. This implied, for almost every design team, the request of further documentation integration. On the other hand, the functioning of the *Calculation Tool* for the self-assessment of the design proved to have been understood in most cases.

2.2 "Meta Distretto Bioedilizia" of Treviso City

A further chance to test the integration of an energetic-environmental assessment tool in the design process was offered by a consulting and collaboration project with the City of Treviso and its "Meta Distretto Bioedilizia" (Sustainable Building Meta District).

2.2.1 Test targets and restrictions

The requirement of the Meta Distretto was to develop a system which could be able to aid quality in buildings, while avoiding the need for prescription in the local regulations. The aim was to introduce the option to attach to the technical and graphic design documentation a new document, certifying the level of the environmental performance of the building. The Meta Distretto wanted to define a tool which could be able to perform the assessment automatically.

2.2.2 Structure of the test

An electronic tool was prepared in order to support both the designer to collect the relevant building information and the technical department – performing the assessment of the projects – to assign automatically the final score. The electronic tool to self-assess the projects was divided in two distinct and complementary modules.

The first module (Module A) collected all the project data to be used in the assessment, processing them to obtain the value of each performance indicator. Module A was filled by the designers by inserting the required data or selecting the appropriate scenarios. The second module (Module B) was formed by the weighting system, the performance scales and the algorithm which processed the results of Module A, to output automatically the final score. Module B was managed by the technical department.

2.2.3 Structure of the Modules: Module A

To perform self assessment of the project, the designer used the data input module to collect the significant project data. This module, called Module A, was to be filled out in each section, dived as follows:

Context and site input: a file collecting data on the context and the site (Note: some context data can cancel the applicability of the performance criteria in which they are involved, and thus causing an automatic redistribution of the final weights of the criteria); *Building input*: a file collecting data on the building in general; *Indoor environment input*: a file collecting data on the indoor zones of the building; *Materials and building elements input*: a file collecting information on materials and building elements; *Technical systems input*: a file collecting information on the components of the technical systems; *Scenarios:* a file collecting the scenarios of the qualitative criteria, among which the designers had to select the best scenario describing the specifics of the project; *Calculation sheet*: a file collecting the simplified tools prepared to calculate the indicators of the criteria; *Summary output table*: a file containing the indicator values to be confronted with the reference values of the performance scales in Module B.

Module A had to be filled out in all its sections, inserting the design values or selecting the scenarios. The data obtained was processed and transformed automatically into the performance indicators required by the assessment system. The designer had no direct access to the spreadsheets, but could only read the results of the process in the Results sheet. The output data in this sheet constituted the values required to complete the assessment through Module B.

2.2.4 Structure of the Modules: Module B

Module B, to which the designers had no access, was a Tool reserved to the technical department. It was linked to the results obtained by Module A, from which it extracted – for each criterion – the performance indicators and compares them to the performance scales.

Through a weighting process of the values and their aggregation, a summary output table was obtained, showing the area scores and the final assessment score.

2.2.5 Results

This tool can be considered as an innovation which allows designers to assess the energetic and environmental performance of a building in a guided, simple way. Also the technical department personnel found in it a strong support to the final score processing, without the need of specific training.

On one hand, the automation of the calculation procedures allowed to quicken the assessment process and to reduce errors in the interpretation of the verification methods. On the other hand the designers were unable to see the direct effect of the design choices, useful to improve the overall performance of their projects. This is a direct consequence of the thematic areas composing Module A, which had no clear correspondence between the inserted data and the assessment system criteria, giving to the designers no perception on when and how such data were processed to define the final score.

2.3 Conclusions

The merits of the environmental assessment systems such as Protocollo ITACA have been the schematic organization of the requirements, the definition of reference performance levels, and the development of specific methods to assess the performance of buildings. It is thus possible to define in a transparent, measurable and shared way the sustainability targets which have been selected. Such assessment systems can become an useful support to design, to be used during the creative phase through which control the performance thresholds achieved.

The Italian experiences described in this paper aimed at testing different approaches in integrating the use of the environmental assessment system within the design process. The advantages given by the assessment tool prepared for the Sustainable Building Meta Distretto of Treviso turned out to be helpful to avoid calculation errors and diversity of data, as found during the test carried for the Liguria Region, but on the other hand it created a gap between the designer and the assessment tools of the project. In our opinion understanding the connections between the design choices and their effect on the environmental themes is fundamental to give consciousness to the designer on its actions, and to further stimulate his creativity. Thus the next challenge is to define a tool which can combine the two different approaches described.

BUILDING ENVELOPES WITH CONTROLLED THERMAL RESISTANCE

Keywords: controlled thermal resistance, energy performance, low energy buildings

Summary

The paper is devoted to the analysis of possibility for construction of low energy buildings with envelopes controlled for minimization of energy consumption by air conditioning systems. It describes the possibilities to reduce energy consumption of large public buildings mainly in summer time when there are the highest electricity demands for cooling. Energy consumption depends on parameters of outdoor and indoor air, energy performance of the envelope and inside heat and moisture emissions. The paper gives a complex mathematical model for controlled envelope's thermal resistance depending on outdoor parameters. It proposes constructive suggestion to create buildings whose walls, roofs and glassed surfaces have changeable thermal characteristics and methodology of control for separate elements (double skin facades, multiple films on windows, ventilated curtain walls, automated venetian blinds). The paper analyses the impact of building envelope thermodynamic characteristics on the parameters of supply air in air conditioning systems. It describes the change modes of thermal resistance, resistance to water vapour transfer and resistance to solar radiation considering the different states of inside and outside air conditions. As the result the paper gives theoretical algorithm of regulation of building envelope thermodynamic characteristics in ideal conditions based on minimization of energy use by air conditioning systems

1 Introduction

Traditionally low energy buildings are supposed to have maximally big thermal resistance of building envelope. In reality big thermal resistance is justified only in coldest winter days in countries with cold climate or in hot summer days with intensive solar radiation. In other periods buildings with full air conditioning would have to have different properties of building envelope that could allow heat flow in one or another direction. There are also periods when minimal resistance to vapour transfer is required. Sometimes the building envelope is needed only to prevent from rain, insects or to give the intimacy and it is not needed from the point of energy efficiency, as it does not have to form the shield against the heat or vapour flow(Todorovic 2004).

The fact is known to the scientists who use simulation of building energy performance during the whole year. Building energy performance simulation models allow choosing optimal characteristics of building envelope on the basis of annual heat consumption. The model described in this paper would help to optimise building energy performance even more on the condition that we can change the properties of building envelope.

The properties of real building envelope allow:

1) to minimize heat flow from the inside space to outside environment and vice versa;
2) to minimize or completely prevent vapour transfer across the building structures;
3) to minimize or prevent the influence of solar radiation on the inside space conditions.

The abilities of building envelope to prevent heat flow arousing due to the temperature differences of inside and outside air is characterized by thermal resistance of building stricture R_T, m^2K/W.

The ability of building structure to prevent water vapour transfer is characterized by the resistance to water vapour transfer R_V, m^2 h·Pa/mg.

Speaking about the solar radiation there is no common parameter for characterization of the building envelope ability to resist the influence of solar radiation. But this property of building envelope may be shown as resistance to solar radiation R_R. The resistance to solar radiation:

$$R_R = \frac{\Phi_R - \Phi_I}{\Phi_I}, \qquad (1)$$

where: Φ_R is heat flow from solar radiation coming to the outer side of building envelope, W; Φ_I is the solar radiation heat flow that got inside, W.

2 Modelling of air conditioning system working regimes

In order to ensure optimal comfort conditions of indoor air quality in dwelling buildings the air conditioning system has to consist of the following main parts: heating devices, humidifier, air cooler, control equipment for the automatic regulation of heating devices and air humidity. For the comfortable air conditions the supply air temperature has to be in the *comfort zone* confined in area of temperatures θ_{Smin} ... θ_{Smax} and air humidity φ_{Smin} ... φ_{Smax}. This zone is shown at the *H-x* diagram (Figure 1) and represents the calculated climatic conditions that can be ensured by the previously mentioned regulation facilities of ventilation system(Kreslins 1976).

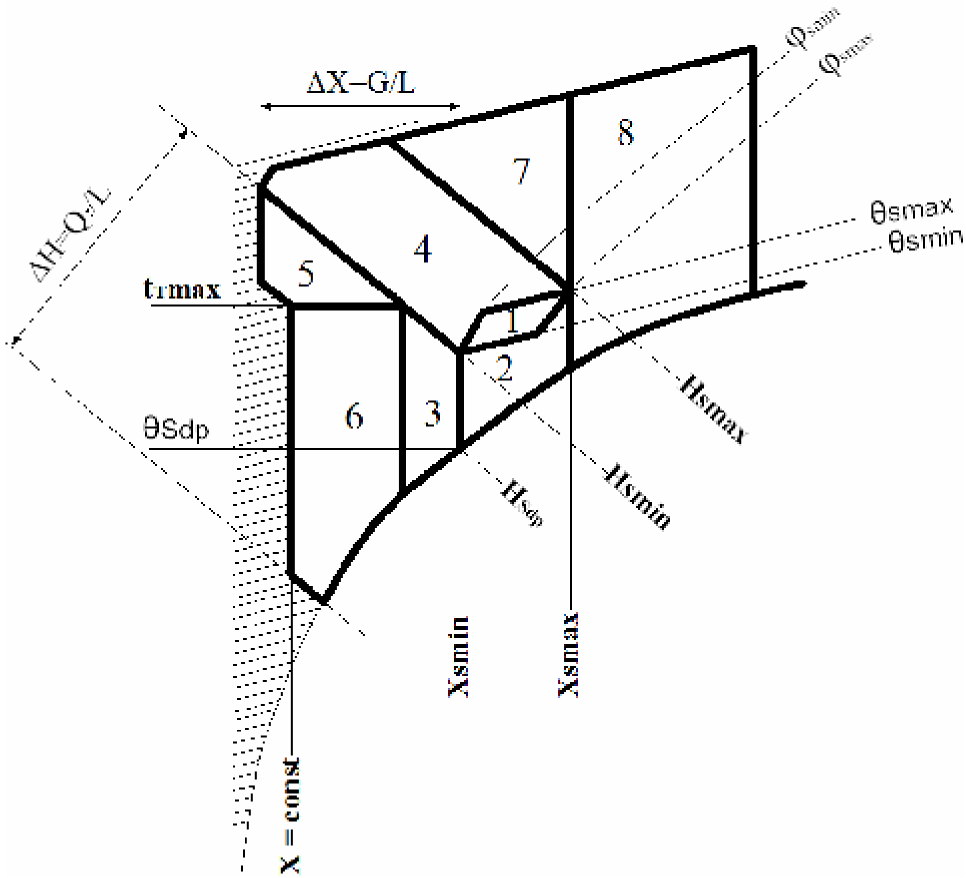

Figure 1 The indoor air comfort zone and regulation regimes on H-x diagram(H – enthalpy, kJ/kg; x – moisture content, g/kg; θ – temperature, °C; φ – relative humidity; Q_T – heat source capacity, kW; G – humidifier capacity, g/s; L - air quantity, kg/s)

There are eighth system regulation regimes depending on the conditions of the outdoor air and required indoor air parameters:

- in the 1st zone the outdoor air parameters match required indoor air parameters so the heating devices and air humidifier are switched off;
- in the 2nd zone the air is heated by the convector till the minimal required temperature θ_{Smin} if φ_{Smin} ... φ_{Smax} or till maximal relative humidity φ_{Smax} if θ_{Smin} ... θ_{Smax};
- in the 3rd zone the air is heated by the convector till enthalpy is H_{Smin} and then it is moisturized till φ_{Smax};

- in the 4th zone the air is only moisturized till the comfort zone upper level - till φ_{Smin} if θ_{Smin} … θ_{Smax} or till θ_{Smax} if φ_{Smin} … φ_{Smax} ;
- in the 5th zone the air is moisturized till moisture content is x_{Smin} and then additionally heated by other heating devices till θ_{Smin};
- in the 6th zone the air is heated till the maximal possible temperature $\theta_{Tmax}= t_{Tmax}$; moisturized till moisture content is x_{Smin} and then additionally heated by other heating devices till θ_{Smin}
- in the 7th zone the air is cooled till comfort zone minimal temperature, θ_{Smin} or less in case, when internal heat gains are too high;
- in the 8th zone air is cooled till X_{Smax} or till X_{Smax} and then additionally heated by heating device till θ_{Smin}.

There are four main temperatures that are usually distinguished in air conditioning. Two of them are widely used in all other calculations: the temperature of outside air θ_e, and the temperature of inside air θ_i,. Two others are connected to the thermodynamic processes in the air of inside space and may be higher or lower than inside and outside air temperatures (Kreslins 1984). These temperatures are: the temperature of supply air and temperature of exhaust air (Figure 2).

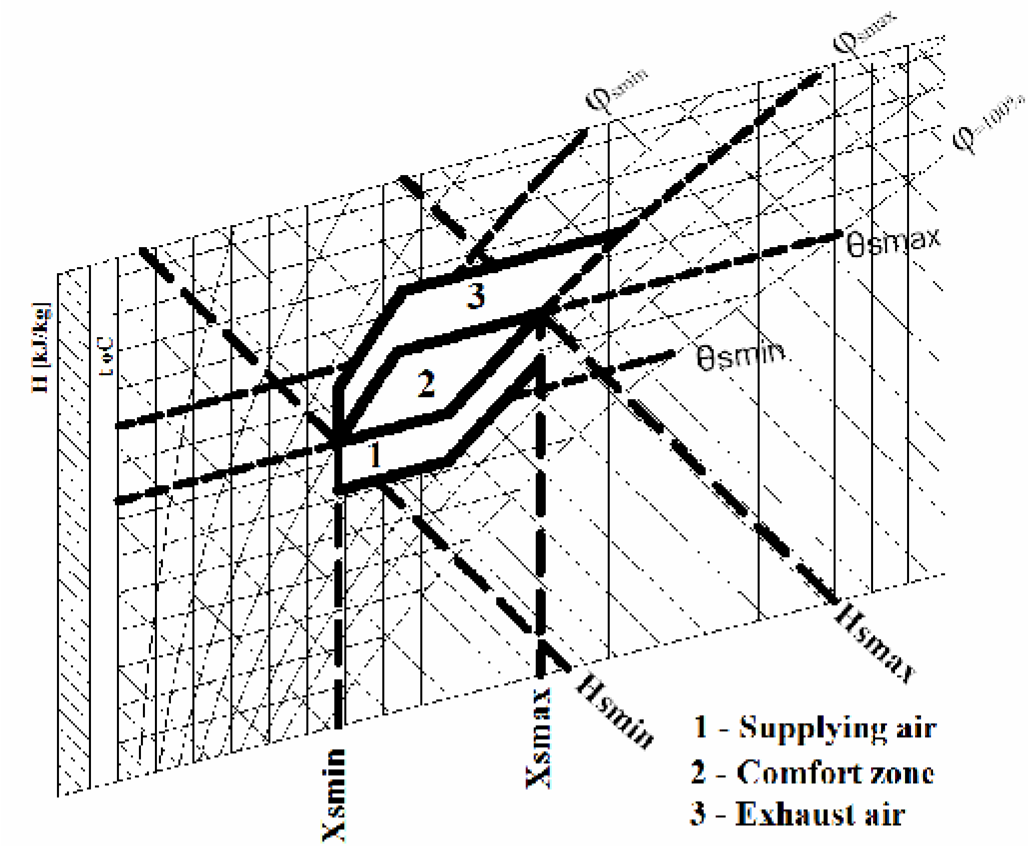

Figure 2 The air parameters in air conditioning system

3 Possibilities to improve performance of air conditioning system using building envelopes with controlled thermal resistance

Building envelopes with controlled thermal resistance can be efficiently used in hot summer periods, when the outside air temperature is much higher than inside air temperature. In such case the classic air conditioning system should work in 8th regime (Figure 3).

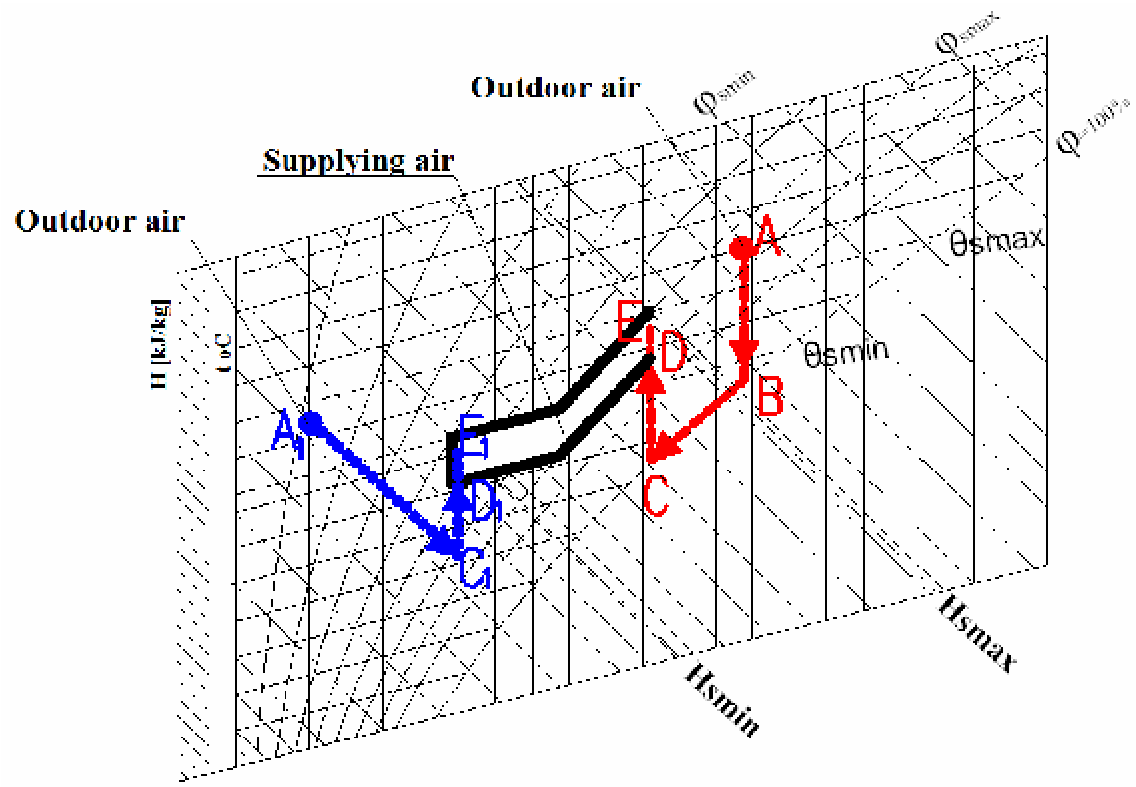

Figure 3 Typical air conditioning working regimes ("dew point regime")

In that working regime after the outdoor air cooling (process A-B-C) the heating device heats up supply air till minimal required temperature (C-D) and internal heat gains further heat air till comfort zone (D-E). Although it is possible to reduce heating loads using solar radiation and heat transfer from outside air to inside thought the building envelope in order to heat up outdoor air till minimal required supplying air temperature. For that purpose it is necessary to reduce thermal performance of building envelope and resistance of glazing surface to heat radiation.

In general the capacity of air conditioning system could be calculated using the following equation:

$$Q_{total} = \Delta H_{cooling} + \Delta H_{heating}, kWh \qquad (2)$$

where: ΔH_c – energy consumption for outdoor air cooling, kWh; ΔH_h – energy consumption for supplied air heating, kWh.

In case when external heat gains could be used for supply air heating the energy consumption of air conditioning system for air heating will be equal to external heat gains:

$$\Delta H = Qe.g \qquad (3)$$

The simplified external heat gains could be calculated as follows (ASHRAE 2001):

$$Q_{e.g} = \frac{1}{R} A(\theta_i - \theta_e), kWh \qquad (4)$$

where: R - thermal resistance, m^{2}K/W; A – area of building envelope, m^2; θ_i – indoor air temperature, ^{0}C; θ_e – outdoor air temperature, ^{0}C;

On the basis of the before mentioned equation the thermal resistance of building envelope could be calculated:

$$R = \frac{A(\theta_i - \theta_e)}{Q_{e.g}} \text{ m}^2\text{K/W} \qquad (5)$$

4 The algorithm of thermal resistance and radiation resistance regulation in ideal building envelope

If there are heat sources in the inside space and outside air temperature θ_e is lower than inside air temperature θ_θ, to ensure constant inside air temperature the building envelope heat losses has to be equal to the internal heat gains. In that case the thermal resistance of building envelope structures has to be:

$$R_T = \frac{(\theta_i - \theta_e)A}{\Phi}, \text{ m}^2\text{K/W} \quad (6)$$

where A is area of building envelope structures in m^2; Φ is heat gains or heat losses in W.

If in the same situation with internal heat gains (Φ>0) outside air temperature is higher than internal air temperature, thermal resistance of structures has to be as big as possible (∞), but in case when $\theta_i=\theta_e$, the value of thermal resistance does not matter and it may have any value.

The similar analysis of other possible situations gives an algorithm of change and optimal values of thermal resistance and resistance to solar radiation. The algorithm of changes in values of thermal resistance and resistance to solar radiation is shown in Table 1.

Table 1 The algorithm of changes in values of thermal resistance

Outdoor air position	Difference in air parameters	Thermal resistance of building envelope
1	$\theta smin \leq \theta_e \leq \theta smax$	any
2	$\theta smin \leq \theta_e$ and $Xs_{min} \leq X_e \leq Xs_{max}$	∞
	$\theta smin \leq \theta_e \leq \theta smax$ and $Xs_{min} \leq X_e \leq Xs_{max}$	any
3	$\theta smin \leq \theta_e \leq \theta smax$	∞
4	$\theta_e \geq \theta smin$ and $\varphi_e \leq \varphi s_{max}$	∞
	$\theta smin \leq \theta_e \leq \theta smax$ and $\varphi_e \leq \varphi s_{max}$	any
5	$\theta_e \geq \theta smin$ and $X_e \leq Xs_{min}$	0
6	$\theta_e \geq \theta smin$ and $X_e \leq Xs_{min}$	0
	$\theta_e \leq \theta smin$ and $X_e \leq Xs_{min}$	∞
7	$\theta_e \leq \theta smin$ and $\varphi_e \leq \varphi s_{max}$	∞
8	$\theta_e \geq \theta smax$ and $X_e \geq Xs_{max}$	0
	$\theta_e \leq \theta smin$ and $X_e \geq Xs_{max}$	∞
	$\theta smin \leq \theta_e \leq \theta smax$ and $X_e \geq Xs_{max}$	any

5 The algorithm of vapour resistance regulation in ideal building

Similarly to the analysis of thermal and radiation resistance regulation we can analyse the regulation of the resistance to water vapour transfer.

If there are moisture sources in the air of inside space characterized by moisture production rate G, kg/h and water vapour pressure of outside air is lower than water vapour pressure of inside air (p_e<p_i), the resistance to water vapour transfer has to be:

$$R_v = \frac{(p_i - p_e)A}{G}, \text{ m}^2\text{s·Pa/kg} \quad (7)$$

In case when both pressures are equal the resistance to water vapour transfer can have any value, but when p_e>p_i, the resistance has to be as big as possible (∞).

The algorithm of water vapour resistance regulation is shown in Table 2. It takes into account also moisture content x in grams in the kg of dry air.

Table 2 The algorithm of vapour resistance regulation

G	x_e	R_V	x_{ex}	x_s	x_I
>0	$>x_i$	∞	$> x_s$	$< x_I$	$> x_s$
	$= x_i$	any	$> x_s$	$< x_I$	$> x_s$
	$< x_i$	$\frac{(p_i - p_e)A}{G}$	$= x_s$	$= x_I$	$< x_s$
=0	$>x_i$	∞	$= x_s$	$= x_I$	$= x_s$
	$= x_i$	any	$= x_s$	$= x_I$	$= x_s$
	$< x_i$	∞	$= x_s$	$= x_I$	$= x_s$
<0	$>x_i$	$\frac{(p_i - p_e)A}{G}$	$= x_s$	$= x_s$	$> x_s$
	$= x_i$	any	$< x_s$	$> x_s$	$< x_s$
	$< x_i$	∞	$< x_s$	$> x_s$	$< x_s$

R_V- resistance to water vapour transfer, m^2 h·Pa/mg;G -moisture production rate, kg/h; x_e – outside air moisture content, g/kg; x_{ex}- exhaust air moisture content, g/kg; x_I - internal air moisture content, g/kg; x_S- supply air moisture content, g/kg

6. Conclusions

In practice the choice of the regulation mode depends on the level of technical development and economical considerations.
Some of the regulation decisions, such as shutters or solar reflectors, are known for generations. They are in compliance with the model described in the paper but they were known long before and without it. On the other hand the given algorithm shows all possible directions of technical development in order to minimize annual heat consumption of buildings.
At the present stage of scientific and technical development it is naturally to expect fast progress of technology toward the building structures with changeable characteristics. For example, even now it is possible to imagine inflatable buildings with changeable thickness' insulation air layers, or regulation of structures' vapour permeability by perforation with changeable dimensions.
The paper gives the algorithm of regulation for hypothetical ideal constructions, which can be used as the guide for the future development of building structure technique.

Summary

The open international standards for exchange of information (Information Foundation Classes, IFC) and the definitions of what to be exchanged (International Framework for Dictionaries, IFD) are emerging as the new standards in building information modelling. Together with an emerging third standard (Information Delivery Manual, IDM), these standards set the premises for electronic exchange of building specific information in the business process. IFC, IFD and IDM facilitate the use of a wide range of model-based applications in the building industry, included future tools and applications for environmental assessments of buildings. Today, only a few such environmental assessment model-based applications exist. The information flow propounded by the use of IFC, IFD and IDM depends on clearly defined data in the information package to be exchanged. With the new ISO 21930, Environmental declaration of building products (EPD), a standardized way of defining life cycle based environmental information on building products is established. An EPD is intended to provide information for environmental planning, design and assessment of buildings, by giving information that verifiable and accurately, and ensuring that any environmental impacts are completely accounted for. A template based on ISO 21930 is an optimal information package (schema) for environmental information to be exchanged in building information modelling. The template should also be incorporated in the IFD Library.

1. Introduction

The ongoing research project GLITNE (2006-2009) is a joint project of major actors of the Norwegian building sector. The main target is to produce knowledge on how environmentally effective buildings can be made more attractive and financially competitive. A method is being developed based on Life Cycle Assessment (LCA) and economic weighting of environmental effects. This is further described in Strand-Hanssen et al. (2008). The method will be integrated in a computerized tool to be used in the building process by relevant actors. It is of major importance that this method and tool are suited for use in the design process of a building. This requires that the tool present necessary information on a suitable level for the actors in the building process (client, architect, technical consultants), integrated with the working processes. This can be accomplished by making the tool communicate with a Building Information Model (BIM).

All environmental assessment tools, such as the forthcoming GLITNE tool, are depended on the quality of input data. To assure this, the input data should be based on LCA standards, be verifiable and accurate. International Standard Organization (ISO) 21930:2007 'Environmental declaration of building products' (EPD) defines EPD as *environmental declaration providing quantified environmental data using predetermined parameters and, where relevant, additional environmental information.* ISO 21930 is based on the LCA standards. Thus, when e.g. performing an environmental assessment of different building products, such as a wall or a window, the assessment should be based on data from EPDs.

The increasing use of building information modelling in the building industry opens the use of a wide range of model-based applications. Industry Foundation Classes (IFC) is emerging as an open international standard that makes it possible to exchange building information between a BIM (Building Information Model) and different tools, databases, CAD software etc. International Framework for Dictionaries (IFD) will, together with IFC, describe which building information that actually is being exchanged. IFD is an open digital library, where concepts and terms are semantically described and is given a unique identification number. The forthcoming standard Information Delivery Manual (IDM) set the premises for electronic exchange of building specific information in the business processes.

The building information flow made possible by IFC, IFD and IDM, depends on clearly defined data in the information package to be exchanged between a BIM and a model based application. This can be defined as an exchange schema (IFC schema).

In this paper, the following is discussed; what environmentally relevant information for a building product should be exchanged between an IFC based BIM and an IFC based environmental model-based application? This is discussed due to the content of EPDs and ISO 21930. How could such environmental building specific information be exchanged between a BIM and a model-based application? Two existing LCA/IFC based tools are presented and the use of IFD Library is discussed.

2. Environmental decision making in the building process

The foundation of environmental qualities is defined in the strategic phase of the building process. It is important that environmental goals are set in the strategy phase for the building project to secure that initial environmental goals are pursued also later on in the process. The building process includes a broad spectre of participants; such as project manager, architects, contractors, constructers, users etc, and these participants are involved in a variety of roles, actions and communications. To achieve environmental goals set in the early stages, it is important to present the necessary environmental information to the relevant participant in order to obtain informed and suitable decisions.

2.1 Present situation

Numerous methods and tools exists for environmental assessment of buildings, from green product guides and checklist, building assessment and rating schemes to LCA based tools of various kinds (Environment Australia 2001, Strand-Hanssen 2008). In environmental management, the principles and framework of life cycle assessment (LCA) has grown to be widely used, based on international standards. As defined in ISO 14040 Environmental management – Life Cycle Assessment – Principles and framework, LCA is *compilation and evaluation of the inputs, outputs and the potential environmental impacts of a product system throughout its life cycle*. The method assess the impact on the environment of a product (including buildings) from "cradle to grave", i.e. from acquiring raw materials for product manufacture to its disposal at the end of its useful life.

Despite the huge amount of developed environmental assessment tools, they are only seldom used. There could be several reasons for this. Two major explanations are that the developed tools are not suited for a specific need in the building process nor addressed to the right decision maker. The end users will only use a specific software tool repeatedly if it is helpful (Bazjanac 2004). There are several practical problems related to the use of LCA as well. As stated by Melby Strand (2003), this is primarily related to the time needed to perform an assessment, but also the lack of agreed methods for the final assessment steps. And finally, there is a lack of satisfactory input data on building products composed in available databases. The lack of data is one of the largest obstacles of bringing assessment systems into use. Because of this, there is little knowledge of the environmental consequence of different design alternatives in buildings, especially regarding the building construction. As a consequence, the environmental evaluation is delayed until late in the design phases when it is too late to consider any changes in the basic design decisions, if considered at all. Evidently, it is an initial choice of level of complexity, between a complex tool that provide detailed information of environmental impacts associated with different design decisions, ore a simple tool (merely checklists) that provides guidance only.

2.2 Future situation – if BIM based?

The increasing use of digital building information modelling in the building industry opens for the use of a wide range of model-based applications, so also for methods and tools for environmental assessment of building performance.

Building Information Modelling (BIM) is the term used for the creation and use of coordinated, consistent, computable information about a building project in design, in construction, in building management and operation (Wix et al. 2007). A BIM is the collection of objects that describe a building. It covers geometry, spatial relationships, geographic information, quantities and properties of building components. Quantities and properties of materials and elements can be extracted for use in model based applications, and the BIM can also be used to store results of e.g. environmental calculations.

As stated in Haagenrud et al. (2008) it may also include building processes undertaken during design, construction and operation/maintenance, related to the people and organizations involved. For the different participants in the building process, the use of BIM makes it possible to insert, extract, update or modify information on different stages in the building process to support and reflect the needs of any given participant.

The exchange and sharing of data between a BIM and an application require interoperability. This is the key idea of buildingSMART that supports open interoperability between BIM based software applications by using open interoperability standards such as IFC, IFD and IDM. The processes of the brand buildingSMART are driven by the organization International Alliance of Interoperability (www.iai-international.org). These standards will give a series of opportunities; e.g. for easier updating of data and tracking changes, that can be time-consuming and a source of errors. Further, a great benefit is the possibilities of more information based decisions for the participants involved when using suitable environmental applications on different stages in the building process. The environmental impacts and some of its content are shown in figure 1, divided in different building information models reflecting the process (requirement, design, production, commissioning and operation). Other aspects of sustainability are also included. Because of the possibility of interoperability (standards within buildingSMART) some of these models may be as one model.

	REQUIRED	DESIGNED	CONSTRUCTED	DELIVERED	ACHIEVED
PERFORMANCE IN USE	• user requirements • desired performance in use	• designed technical solutions • estimated performance	• constructed building	• validated conformity	• user satisfaction • performance in use
ENVIRONMENTAL IMPACTS	• targeted environmental impacts over the life cycle	• estimated environmental impacts over the life cycle	• environmental impacts during construction	• estimated environmental impacts in use	• environmental impacts of building and its use
ECONOMIC IMPACTS	• targeted whole life costs • targeted business benefits and value of the facility	• estimated life cycle costs	• construction costs	• estimated running costs	• running, maintenance and refurbishment costs, recycling, reuse, demolition and waste disposal costs • value of facility
OTHER	• targeted social, cultural and institutional impacts		• construction safety • construction ethics		• social impacts in the neighbourhood • impacts to the cultural heritage

Figure 1 Aspects within sustainability, included environmental impacts and some of its contents in different phases of the building process (Haagenrud et al. 2008, Huovila et al. 2007). The different models reflect the phases of the process.

One major challenge yet to be overcome is the lack of relevant environmental data to be used in software applications. Another aspect to consider is the need for clearly defined environmental data in the information package to be exchanged between a BIM and a model based application.

3. Environmentally relevant building-specific information

Simulating the environmental performance or impact of a building requires detailed information of the design and operating conditions. The amount and accuracy of the data required vary depending on the purpose of the simulation and in which stage of the building process the simulation is performed. This section it is focused on the exact data needed for defining the environmental qualities in materials and products in the building process.

3.1 Environmental Product Declaration (EPD)

One of the key aspects in a LCA is the quality of the input data; weather the data is generic or specific, their relevance and accuracy etc. With poor or insufficient data quality, the result of a LCA will be significant reduced. Participants involved in building design, users, owners and manufactures of building products have shown increased interest for environmental product declaration, and several national initiatives lead to the standardization work done in ISO/TC 59, Building construction, Subcommittee SC 17 Sustainability in Building Construction. The work in this standardization group has now resulted in a new standard for environmental declaration of building products; ISO 21930:2007. The standard is expected to form the basis for Type III environmental declaration programmes leading to Type III environmental declarations of building products (EPD). The principles and procedures for Type III declarations are described in ISO 14025.

In ISO 21930, EPD is defined as *environmental declaration providing quantified environmental data using predetermined parameters and, where relevant, additional environmental information.* An EPD is intended to provide information for planning, design and assessment of buildings, by giving information that is verifiable and accurate, and ensuring that any environmental impacts are completely accounted. The EPD are based on the LCA standards, but an EPD may also include only a certain life cycle stage. In these cases, the EPD becomes an information module.

When a building product is declared e.g. only for the product stage, the EPD is expressed per declared unit. When declared for the entire life cycle (cradle to grave) the EPD is based on a full LCA and the unit is expressed as a functional unit. The distinction between declared and functional unit is crucial, as the declared unit gives the quantity of a building product (e.g. mass, volume, square meter) and the functional unit gives the performance of a product system for a building product (e.g. m^2 glass wool insulation with heat resistant R = 1 m^2K/W and 60 years). When comparing and assessing building qualities, the environmental information should be based on EPDs with functional units.

3.2 EPD schema as a basis for environmental data to be exchanged

Because EPDs are based on LCA and consider all important environmental aspects, they are ideal to form the basis of an exchange schema between a BIM and e.g. a tool for selection of environmentally preferable materials and products. EPDs should also form the basis of e.g. whole buildings LCA. The mandatory and additional environmental aspects in ISO 21930 are given in table 1.

Table 1: Mandatory and additional indicators in ISO 21930.

MANDATORY:
• Environmental impacts:
  ○ Climate change (greenhouse gases)
  ○ Depletion of the stratospheric ozone layer
  ○ Acidification of land and water sources
  ○ Eutrophication
  ○ Formation of tropospheric ozone (photochemical oxidants)
• Use of resources and renewable primary energy:
  ○ Depletion of non-renewable energy sources
  ○ Depletion of non-renewable material sources
  ○ Use of renewable material resources
  ○ Use of renewable primary energy
  ○ Consumption of freshwater
• Waste to disposal
  ○ hazardous waste, or
  ○ none hazardous waste

DECLARED IN ACCORDANCE WITH NATIONAL STANDARDS AND PRACTICE: • Emission to water • Emission to soil • Emission to indoor air
ADDITIONAL ENVIRONMENTAL INFORMATION, e.g.: • Biodiversity • Human toxicity • Environmental toxicity • Geographical aspects • Product performance • Hazard and risk assessment on human health and environment • Preferred waste management option for used building products
USE OF RESOURCES IN ALL PHASES OF THE BUIDLING PROCESS SHOULD BE DIFFERENTIATED IN: • Water/ wind power • Fossil energy • Bio-energy • Nuclear power • Other energy • Secondary fuels • Non-renewable resources

There exist a number of EPD programmes worldwide, covering several product categories (www.gednet.org). In Norway, a system called EcoDec has been developed by SINTEF Byggforsk over a period of 10 years. EcoDec is aimed specifically at building products. The content of the EcoDec system is fully based on ISO 21930.

Despite the interest for environmental declarations in the international building industry, so far, only a few has been produced and are available. The accelerating use of BIM and model based applications on international open standards provides the manufactures of building materials and products with an opportunity to disseminate their product relevant information in a format that software tools will be able to import directly. This will enable the end user to select products for their advantage, based on environmental considerations. Depending on where in the building process design alternatives are compared, there is a need for generic and product specific data, both which may by produced by using the new international standard ISO 21930.

3. Exchange of building specific information with open standards

3.1 IFC, IFD and IDM

In order to enable the sharing of information and data and interoperable flow between a BIM and a software application, three pillars in the buildingSMART context form the basis. This is (Haagenrud et al. 2008, Bell and Bjørkhaug 2006):

- An exchange format that define how to share the information, IFC
- A reference library to define what information that are being shared, IFD
- Information requirements that define which information to share when, IDM

IFC is an international open standard (ISO/PAS 16739) and a data format for exchange of data between a building information model and a software tool. Tucker et.al. 2003 state that *the IFCs are a set of electronic specifications representing objects that occur in constructed facilities (including real things such as doors, walls, fans, etc. and abstract concepts such as space, organisation, process etc.). These specifications represent a data structure supporting an electronic project model useful in sharing data across applications.* Each specification is called a class, and is used to define things that have common characteristics. The latest IFC version, IFC 2x3, was published in 2006 (http://www.iai-international.org/Model/R2x3_final/index.htm). The purpose of an IFC schema is to facilitate the exchange and sharing of information. It is not a software application, but may be used by a programming language and in this way be included in a software tool.

IFD (ISO 12006-3) is an open library, where concepts and terms are semantically described and given a unique identification number. Cooperating with IFC, the IFD standard will define the building information that is actually being exchanged. Thus, IFD is not an alternative, but a supplement to IFC. IFD is implemented in Norway, the Netherlands, Canada and USA. What is interesting about IFD is that it offers a 'Globally Unique Identifier', the so called GUID. The GUID can be compared with e.g. a personal identification number. When the user adds the properties in an IFD Library, it is done once (and for all) and may be used repeatedly and by other users as well (http://dev.IFD-library.org).

In the standardization group ISO TC59/SC 13 work has been started to set the premises for the electronic exchange of building specific information in the business processes, IDM, and will specify (http://idm.buildingsmart.com):

- A defined activity in the building process (why it is relevant);
- Who are the actors involved in the activity (and the information flow between them);
- What is the information created and consumed in the activity;
- How this information should be supported by software solutions.

IDM consists of three parts: i) exchange requirements, defining the set of information within IFC that needs to be exchanged in a defined business requirement in the relevant stage of the building process, ii) functional parts, being the technical content required by software developers to support the exchange requirements, and finally iii) process maps, that capture the connection between exchange requirements and business processes. To illustrate a simple process map, the case of environmental selection of a window is used (fig. 2).

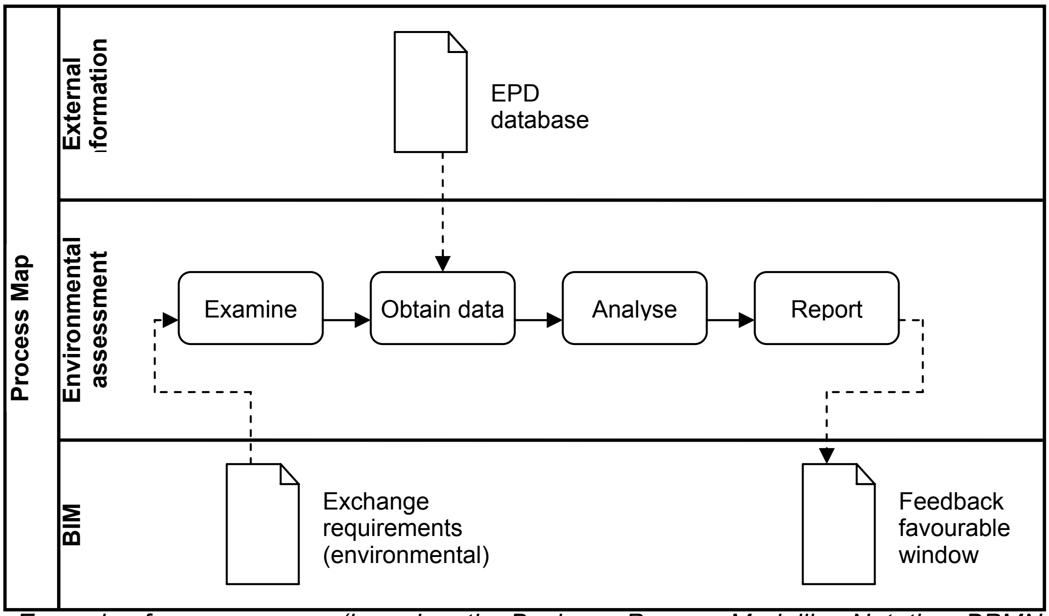

Figure 2 Example of a process map (based on the Business Process Modelling Notation, BPMN, www.bpmn.org).

The environmental assessment is undertaken in four steps; examine, obtain data, analyze and report. This is made possible by defined exchange requirements from the BIM, as defined in section 3.2 as an IFC based EPD schema. By obtaining external information from an EPD database, an analysis is accomplished and a report sent back to the BIM.

3.2 IFC and environmental specific information

What exchange does the existing IFC model enable; environmental data, environmental assessment and/or environmental indicators? In the IFC standard the 'Environmental Impact Value' was first defined in the IFC 2x2 version of the standard. From IAI the Environmental Impact Value is defined as *an amount or measure of an environmental impact or a value that affects an amount or measure of an environmental impact.* Further, the IfcEnvironmentalImpactValue could represent the volume of carbon dioxide emission, amount of operational energy or mass of aluminum used in a product. There are also given examples of impact types that may be applied, such as CO_2-emmisions, embodied energy, mass of aluminum, operational energy, resource and water pollution. This environmental impact value may be attached to any object as defined by the IFC standard. Thus, there is no environmental information in the IFC standard today, only suggestions to what this value might be.

The ongoing STAND INN project (scheduled to end late 2008) addresses new manufacturing processes based on IFC standards, and performance based standards for sustainable construction, in order to create new and more efficient business processes in the construction sector (Haagenrud et al. 2008). One of the objectives in STAND INN is to integrate environmental indicators with BIM/IFC following the scheme of elements presented in international standards dealing with environmental aspects of buildings. In STAND INN it is stated that environmental impacts should be expressed in terms of life cycle inventory (LCI) or LCA following the formats agreed in ISO. The final results from environmental assessment should be enclosed as environmental impact indicators to BIM (Wix et al. 2007). This means that the IFC standard to some extent provide support for capturing data to calculate environmental indicators. It also means that the IFC model only exchange rudimentary environmental data, such as environmental indicators that may be the result of a numerous environmental assessments done by other applications.

This is where the IFD standard complements IFC. By combining the IFC and IFD standard, the opportunities of unique identification are possible by the earlier mentioned GUID. By identifying in the IFD Library, all indicators, definitions, units etc. as stated in ISO 21930 with a unique GUID, these properties may be connected to an object. When using an (future) assessment tool for environmental assessment of building products or whole buildings LCA, the application to is able to 'talk with a BIM' and request just the right properties. The result of such an assessment may be stored in the BIM connected to the object (material or building product) in question. This is further discussed in section 5.

4. Interpretation of existing LCA & IFC based tools

In Wix (2007) several sustainable projects are studied. The study reveals that two thirds of the responses used CAD rather than BIM, and this is considered to reflect the fact that BIM use is not yet widespread in the building construction industry. The most widely supported application was energy performance declaration. The third major application supported was environmental analysis, and the findings showed that there were some useful applications supporting environmental impact analysis, but as yet not linked with BIM. One exception was the Redhill project, that showed that with a well structured material database and data collection within the BIM, an environmental impact analysis could be done both easy and highly effective. Strand-Hanssen (2008) found two tools that perform an LCA of whole buildings by using IFC compatible building information models where found, being BSLCA (Finland) and LCADesign (Australia). These applications where further studied by Sivertsen and Surnflødt 2007. In this section it has been focused how the exchange of building exchange seems to be done, and what environmental data that form the basis for the LCAs.

4.1 BSLCA

BSLCA is developed within the company Olof Granlund Oy (Finland). The background for developing the tool being that the existing LCA tools are missing the links to other designs tools (Laine et. al. 2001). BS LCA is a database solution with a Windows interface, and handles environmental impacts of the building envelope and building service system (e.g. HVAC). The tool consists of four modules, Structures (building envelope), Systems Design (building services such as HVAC, electrical, building automation, kitchen and hospital equipment), Networks and Energy. Only the first module (Structures) is IFC compliant.

The environmental assessment starts with importing building structures related geometry data from architectural CAD systems. BSLCA consist of a product library (such as HVAC) and a construction library (typical building constructions). Both libraries are connected to the material database. The environmental data in the libraries have been published by the Helsinki University of Technology (more environmental data may be added to the database when available). It is uncertain whether the data are based on environmental declarations. The various objects from the IFC architectural model are automatically labelled with environmental data. BSLCA is depended on information input from other applications, such as RIUSKA, used to calculate the energy consumption.

For the LCA, different characterisation and/or valuation methods are used (DAIA, EcoIndicator 95, EPS-96). It is open for adding several methods. In Laine et. al. 2001 it is pointed out that the contents of the IFC standard limit the possibilities to build all data transfer requirements based on IFCs. Sivertsen and Surnflødt 2007 show that only the building construction is imported.

4.2 LCADesign

LCADesign is an Australian tool, and is developed due to satisfy the needs of 'environmentally conscious design' (Tucker et. al 2003) and facilitate the assessment of environmental impact of a building construction by automatically exchange from 'intelligent' 3D CAD drawings. The tool enables the comparisons between different design alternatives.

LCADesign performs the LCA in the following steps; first the application extract information (including dimensions, location, building products, etc) from a 3D CAD to provide component quantities (automated take-off) by using IFC. Then the user of the application must tag the objects from the CAD model with the environmental information on products selected from the database within LCADesign. A generic database and set of reasoning rules for component composition are used to calculate quantities of resources and emissions for each product. The final step is to select measures (impact category and single values) so that different profiles may be compared. The LCA methods used for environmental impact calculation are CML, EPS and Eco-indicator 99.

The life cycle inventory (LCI) database in LCADesign is based on the so called Boustead model, and consists of environmental product declarations and data for various products through modelling their process of manufacture, from raw material extraction, manufacturing, use and final disposal (and consequently to the associated environmental impacts).

The interpretation of BSLCA and LCADesign is summarized in table 2. It shows that both applications automatically import the architectural model from a 3D CAD system by using IFC. In BSLCA the objects are automatically given their environmental characteristics, in LCADesign, the objects must be tagged manually. Both applications are using internationally known LCA methods. Both applications use input based on national environmental data, LCADesign using EPDs.

Table 2 Interpretation of BSLCA and LCADesign.

Characteristics / application	BSLCA	LCADesign
LCA based	Yes. Ecoindicator 99, DAIA	Yes. Ecoindicator 99
Use of IFC	Yes. Import of architectural model	Yes. Import of architectural model
Identifying environmental characteristics in objetcs	Automatically	Manually tagged
Input data (environmental)	National	National, use of EPDs

5. Discussion and conclusions

The possibilities of the buildingSMART standards in environmental assessment of buildings are huge, and it is a unique opportunity for software developers to create future applications for decisions support in building information modelling. The challenge in integrating BIM and environmental simulation of any kind has several components; i) environmental calculation methods, ii) data exchange and iii) user interaction, defining when the simulation should be done and the graphical user interface.

As stated in Melby Strand (2003) and shown in section 4, different LCA methods are developed. International consensus on which weighting method to be used is non-existent. On the other hand, this is not necessary due to the consensus on the input data basis; LCA and thus ISO 21930. LCA has grown to be a widely accepted method for assessment of environmental building qualities and there are several tools worldwide. The content of ISO 21930 is well suited as a foundation for an exchange schema for automatically exchange between a BIM and a model based environmental application:

- LCA based information, thus all relevant environmental aspects is included (without double accounting)
- Detailed and accurate
- Enables the possibilities of both generic and specific data
- Basis for environmental planning, design and assessment

If the basis for the data exchange between a BIM and an application is based on ISO 21930, any LCA based IFC application may be used. By using the terms in IDM, this is called exchange requirements. An IFC schema should contain all the environmental aspects, units for input and out put etc. What also makes IDM a suitable tool is that it e.g. defines when a simulation should be carried out. In environmental assessment, it is utterly important that a given stakeholder gets the needed information in time for the right decision to be made. Thus the use of BIM and IFC-based applications are especially suitable for all the actors involved in the building process. By making process maps, the information flow between the actors is identified in connection with a certain decision, and this reassure the right information to be incorporated in the exchange requirements.

In order to calculate an EPD based on the rules in ISO 21930, an application is required. Several EPD programmes and applications exist worldwide, but the lack of databases containing EPDs or similar LCA based information is striking. This is a huge challenge but also a great opportunity for manufactures of building products to describe their products in such a way that existing and future software tools will be able to import it directly. This again enables the end user to select the best suited products for their purpose. If such databases existed, with both generic and specific (Type III) declarations, the basic input for environmental assessments would have been in place.

A template from the EPD standard for building products should be incorporated in the open ISO standard IFD, giving a GUID to every environmental impact, definitions of different emissions (such as CO, CO_2), units etc. When this is defined in an IFD Library, these GUIDs make it possible for a model based application to know what information to exchange with a BIM in a standardized way. Already developed LCA and IFC based tools for automatically exchange of environmental relevant building specific information use automatically import of the architectural model from a 3D CAD system by using IFC. The environmental characteristics of the objects are shown to be tagged both automatically and manually. With a GUID from IFD Library there would be no doubt in which environmental characteristic a given object would have.

The relevance and potential of IFC/BIM for the different users/actors in the building process are areas of great interest in further research and development.

Keywords: sustainability, performance indicators, assessment criteria

Summary

The environmental sustainability of buildings is at present involving ITC-CNR and iiSBE Italia at both national and international level with a formal convention aimed at performing and calculating the environmental sustainability level of buildings by the permanent use of SBTool, the GBC tool managed by iiSBE International. It is a second generation scoring system that allows the evaluation of the building environmental sustainability with regard to a high number of criteria and that can be updated depending on the building local context.
The system, realized for buildings located in the province of Treviso, was conceived for new residential buildings or relevant refurbishments and it is available in two versions depending on the number of housing units in the building. It was created in MS Excel, in order to make its diffusion and application simple and immediate, and it calculates the building performance with regard to a certain number of criteria.
The system final output is the sustainability level score of the building resulting from the weight and aggregation of the criteria scores. The scores are assigned through methods and tools described and explained in specified guidelines which have been defined for each evaluation criterion.
The innovative aspect of the system is its self-sufficiency: it integrates (even if hidden to the user) the tools for the calculation of each criteria indicator through a user-friendly interface, for which the biggest effort was the definition of the input screens layout.
Some case studies were carried out in order to demonstrate the effectiveness of the assessment tool thus supporting the designers towards the definition of a green building and the assessors in the control of the actual performances of the applied technical solutions.

Preface

ITC-CNR and iiSBE Italia have collaborated for a long time on the subject of energy-environmental sustainability of buildings in order to use in a permanent way, either directly or indirectly, the SBTool, the reference tool of the GBC methodology.
This methodology is essentially based on a score system which allows the assessment and certification of the environmental sustainability level of the building based on a high number of criteria and which is adaptable to the territorial context.
Starting form SBTool and according to the assessment criteria included in the Simplified Protocollo ITACA (" with 28 technical sheets"), ITC-CNR and iiSBE developed a verification tool for the environmental sustainability of residential buildings, realized for the "Metadistretto Veneto per la Bioedilizia" and promoted by CNA of the Province of Treviso. [1]
The assessment system involves the design of new residential buildings or important refurbishment interventions; it was developed in Excel language in order to make its diffusion and application simple and immediate, and it is aimed at the assessment of the environmental sustainability of a building by measuring its performance with regard to thirty-three criteria grouped in five assessment areas: energy and resources consumption, environmental loadings, indoor environmental quality, service quality, context quality.
Each criterion is associated to an either quantitative or qualitative indicator: in the former case a specified calculation procedure is implemented within the tool while in the latter case the user is proposed a certain number of possible scenarios. Actually, the tool directly integrates the calculation tools which process the data included in the project documentation in order to set the performance indicators values for the assessment.

Assessment tool features

The main features of the assessment tool are:

- Simplicity of the interface: to simplify the approach to the environmental sustainability assessment for technicians and professionals; to this end, the topics that characterize the environmental sustainability verification were re-interpreted and put into a language common to the actors of the design process.
- Thoroughness of the contents: to respect the holistic nature of the sustainability verification of buildings, considering the context where the buildings are located; among the numerous performance criteria proposed by the SBTool, the most suitable to the territory were chosen by using the usual methodological approaches of the design process, if present.
- Objectivity: quantitative and qualitative performance indicators were defined; the former were defined together with the relevant referenced calculation procedures (regulations, technical-scientific literature), the latter together with detailed scenarios in order to minimize the interpretations.
- Self-sufficiency regarding the analysis tools: this is a very complex aspect which involved a thorough analysis of the performance indicators for the criteria, in consequence of which proper simplified calculation methodologies were developed. The choice of the indicators themselves was strongly influenced by the different calculation methodologies. The effort was trying to use, when possible, indicators that didn't require any further elaboration, i.e. already provided in the technical design documentation as provided for by the law.
- Transparency: the methodological approaches (benchmarks and verification procedures), normative and legislative references and input/output relations were made explicit.
- Flexibility: it is possible to modify criteria weight and benchmark values.

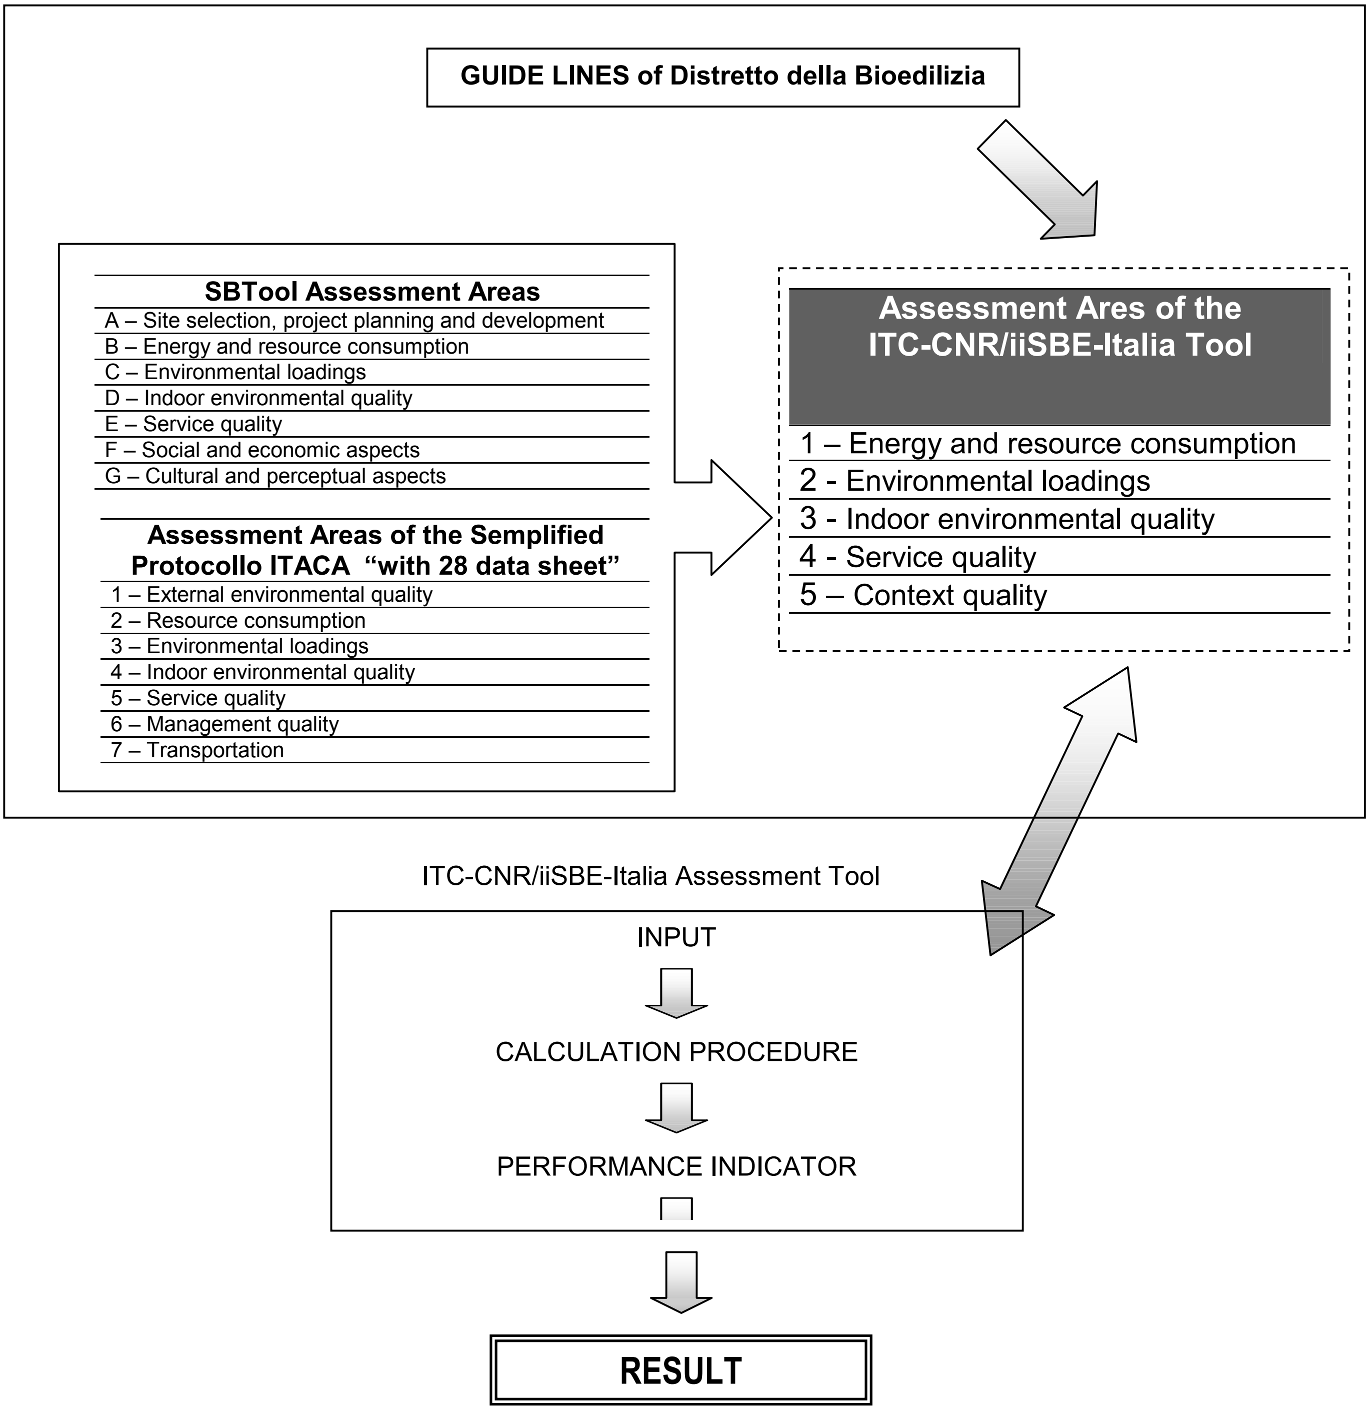

Figure 1 Scheme of the assessment tool

1.1 Assessment areas and criteria

The assessment areas were chosen starting form the Guide Lines for the Diffusion of the Environmental Sustainability and for the Promotion of the Living Quality of the Distretto della Bioedilizia of the Province of Treviso, by keeping the SBTool setting and adapting it to the needs of the building type and to the specific territorial features. Also, the effort was trying to be as consistent as possible with the Simplified Protocollo ITACA, by taking into account all the difficulties that it implied, in fact:

- the Protocollo itself is currently being updated;
- the assessment of each criterion is connected to the difficulty of implementing and integrating the specific calculation procedures.

In the assessment tool developed by ITC-CNR and iiSBE Italia the assessment areas E, F from SBTool and the assessment areas 5, 6 from the Simplified Protocollo ITACA were grouped into the area named “Service Quality”; instead the area G from SBTool and the area 7 of the Semplified Protocollo ITACA are part of the area named “Context quality”.

A certain number of criteria and sub-criteria, whose main features are listed below, was chosen for each assessment area:

- they have a relevant economic, social and environmental value; -
- they can be either quantified or defined as qualitative, in the latter case they correspond to predefined performance scenarios;
- they have a holistic approach;
- they have a proven scientific value;
- their special properties are of public interest.

For each criterion, the following aspects were defined:

- requirement, i.e. the environmental quality objective to be reached;
- performance indicator: it measures the building performance level with regard to the assessment criterion;
- unit of measurement, defined only in case of quantitative criteria;
- verification procedure: it defines the procedure for the calculation of the performance indicator of the assessment criterion;
- input data, i.e. the data needed for the calculation of the performance indicator;
- performance scale, i.e. the reference benchmark to which the performance indicator has to be compared in order to calculate the assessment criterion score;
- legislative reference, i.e. the mandatory legislative provisions;
- normative references, i.e. the reference technical regulations used to define the performance scales and the verification procedures.

For each criterion, and sub-criterion, if any, the building is assigned a score that can vary from –1 to 5 by comparing the calculated indicator with the performance scale benchmark.
Zero represents the standard reference related to the current building practice, in accordance with the regulations in force.
In particular, the meaning of the performance scale scores is described in the Table 1.

Table 1 Interpretation of the assessment area scores of the performance scale

-1	It represents a **performance below the standard** and the current practice.
0	It represents the **minimum acceptable performance** defined by laws or regulations in force; in case they do not apply it represents the **current practice.**
1	It represents a light performance improvement with respect to the regulations in force and to the current practice.
2	It represents a moderate performance improvement with respect to the regulations in force and to the current practice.
3	It represents a significant performance improvement with respect to the regulations in force and to the current practice. It is considered as the **best current practice**.
4	It represents a moderate performance improvement of the best current practice.
5	It represents a **substantially advanced performance** with respect to the best current practice, of an experimental nature.

A weight is assigned to each assessment area, category, criteria and any sub-criteria according to the importance they have within the assessment process. Weights are editable and updatable depending on the features of the building to be assessed. (Table 2)

Table 2 List of criteria and relevant weights

Assessment Areas and Categories	**Weights (%)**
1. Energy and resources consumption	**30**
1.1. Total non renewable energy used during the life-cycle	40
1.1.1. Expected energy embodied in the construction materials (yearly basis)	20
1.1.2. Expected primary energy required for heating during operation	50
1.1.3. Expected solar gains during summer	30
1.2. Renewable energy	25
1.2.1. Expected energy use from renewable resources	100
1.2.1.1. Expected solar thermal energy production	40
1.2.1.2. Expected solar photovoltaic energy production	60
1.3. Materials	20
1.3.1. Intended use of recycled materials	33
1.3.2. Intended use of natural materials (from renewable resources)	33
1.3.3. Intended use of recyclable materials and materials that can be disassembled	33
1.4. Potable water	15
1.4.1. Intended use of potable water for irrigation	50
1.4.2. Intended use of potable water for internal use	50
2. Environmental Loadings	**30**
2.1. Greenhouse gases emissions	45
2.1.1. Expected annual greenhouse gas emissions produced by different forms of energy used for the annual operation of the building	100
2.2. Water	30
2.2.1. Effluents	50
2.2.2. Expected rainwater recovery	50
2.3. Impact on the site	25
2.3.1. Heat island effect– external areas	25
2.3.2. Heat island effect– coverings	25
2.3.3. Soil permeability	25
2.3.4. Impact of the building on the solar radiation accessibility of adjacent buildings.	25

3. Indoor environmental quality	**25**	
3.1. Indoor air quality		20
3.1.1. Pollutants control		100
3.1.1.1. Pollutants control: VOC		50
3.1.1.2. Pollutants control: VOC: radon		50
3.2. Ventilation		20
3.2.1. Design strategies to maximize the ventilation efficiency in naturally ventilated environments		100
3.3. Air temperature and relative humidity		15
3.3.1. Design strategies to keep air temperature and relative humidity acceptable in naturally ventilated environments		25
3.3.2. Design strategies to avoid the air overheating during summer in the absence of air conditioning systems		50
3.3.3. Design strategies to minimize the air temperature by keeping high comfort conditions		25
3.4. Natural and artificial lighting		15
3.4.1. Design strategies to ensure a sufficient natural lighting in the main environments		80
3.4.2. Direct beam solar radiation penetration		20
3.5. Noise and acoustics		25
3.5.1. Strategies for noise reduction through envelope components		100
3.6. Electromagnetic contamination		5
3.6.1. Magnetic fields with industrial frequency (50 Hertz)		100
4. Service quality	**10**	
4.1. Controllability		60
4.1.1 Operation efficiency of the technological systems		100
4.2. Performance maintenance during operation		40
4.2.1. Availability of building technical documentation		50
4.2.2. Development and implementation of a maintenance plan		50
5. Context quality	**5**	
5.1. Proximity to public transport		20
5.2. Control of private vehicles use		20
5.3. Support to the use of bicycles		20
5.4. Proximity to occupational centres (offices)		20
5.5. Proximity to commercial and cultural centres		20

The system was defined for the assessment of dwellings of different size and it is available in two versions depending on the number of housing units. In the first working-sheet, where the general building data are collected, it is possible to choose the reduced version (1) or the full version (2) whether the building has got two or more housing units respectively.
Each version is composed of two parts:

- one to collect the input data, to be filled in by the designer (Form A);
- one to carry out the assessment; in this part all the criteria performance indicators previously calculated or gathered from the project documentation are compared with the scale performance benchmarks. Benchmarks are defined according to the regulations in force, the technical literature and the current building practice. (Form B).

Once Form A has been filled in with the building data, in Form B all the criteria indicators are automatically calculated through the integrated calculation tools and they are assigned a score.
The obtained scores are weighted and aggregated in order to define those of the categories, which are in turn combined to assign those of the assessment areas. The weighted aggregation of the assessment areas scores will return the final building score.
In addition to the global building score, the systems provides, as further outputs, some indicators related to absolute significant performances of the building; they allow a comparison also beyond the specific context of the performance scales (Table 3).

1.2 Assessment tool validation

The validity of the assessment tool launched by the collaboration between ITC-CNR and iiSBE Italia was internally proven through the assessment of a case-study building with residential/commercial destination of use located in the province of Mantua while an external feedback form the CNA of Treviso is still expected: actually, the tool was given out to the municipalities of the Province of Treviso, which will contribute to the process validation by providing the results of their assessment carried out on a certain number of buildings. Testing in still in progress.

	AREA DI VALUTAZIONE	Punteggio	Peso	Punteggio Pesato
1	**Energia e consumo di risorse**	**2.3**	30%	**0.69**
2	**Carichi ambientali**	**2.3**	30%	**0.68**
3	**Qualità ambientale interna**	**1.2**	25%	**0.31**
4	**Qualità del servizio**	**2.2**	10%	**0.22**
5	**Qualità del contesto**	**3.4**	5%	**0.17**
	Punteggio Totale dell'edificio		2.07	

	Prestazioni assolute	Per area	Unità di misura
1	Previsione dell'energia primaria contenuta nei materiali da costruzione annualizzata	**6.97**	GJ/m^2
2	Previsione di fabbisogno di energia primaria utilizzata per il riscaldamento in fase operativa	**55.00**	kWh/m^2 anno
3	Previsione degli apporti solari durante il periodo estivo	**9.05**	kWh/m^2 anno
4	Uso di acqua potabile per irrigazione	**0.00**	m^3/m^2
5	Uso di acqua potabile per usi interni	**118.50**	m^3/m^2
6	Previsione delle emissioni annue di gas effetto serra dovute alla climatizzazione invernale dell'edificio	**11.25**	kg/m^2

Figure 2 Example of the provided outputs

1.3 Remarks on the assessment tool

The specifications which steered the realization of the tool and its development environment (Microsoft® Excel), which was chosen due to its wide diffusion, called for some compromise in order to balance the need of a user-friendly interface with the need of guaranteeing the thoroughness of the contents and the integration of calculation procedures for the different performance indicators.
Data to be provided for the assessment can be found in the project documentation and they do not imply any further processing. This makes the use of the system remarkably easier, but it does not leave out of consideration the fact that the user must be able to understand and manage the methodological approach by evaluating the order of magnitude of each indicator and by deciding about the soundness of results.
As a matter of fact, the simple development environment of the system does not allow to introduce accurate and detailed controls regarding the consistency of the entered input data and it therefore requires an adequately aware use of the assessment tool. This is one of the reasons for deciding to highlight in red the negative scores: in this way the attention of the user is drawn to any mistakes in the design choices or in filling the input datasheet which may cause one or more performance criteria to remain unfulfilled.
The choice of including the negative score in the performance scale was justified by the fact that not all the criteria refer to standards and laws; in this case the benchmark scale does not refer to specific legislative limits, but is defined by the analysis of case-studies through calculation methods derived from technical-scientific literature.
Whoever has developed a project without considering those theoretical bases and without a proper performance target, might have indeed chosen building and technological solutions which do not satisfy the minimum sustainability requirements.

Another important aspect is the compatibility with the Simplified Protocollo ITACA which results from the meaningful correspondence between the results yielded by the two tools. In expectation of an updating of both the assessment tools, in the next future the system realized for the Metadistretto della Bioedilizia will converge into the Protocollo ITACA according to the most recent changes of the regulations in force.
Nevertheless the possibility of adapting the assessment tool to the specific territorial features and to the local regulations (when more restrictive than national ones) remains its most peculiar aspect.
At last, thanks to the amount and type of criteria introduced into the assessment tool and to the performance-based methodological approach, the tool would be easily adaptable also for the evaluation of existing buildings.

1.4 Conclusions

At present, the developed assessment tool is the only one to integrate the calculation procedures therefore allowing to automatically transform the information normally included in the project documentation (that can be easily entered in the input datasheet) into the final result, that is the building environmental sustainability level.
Also, thanks to the User Manual, which specifies the relations between input parameters and performance criteria indicators, the designer can increase his awareness about the consequences that may derive from the defined building and technological choices.
The complexity of each calculation engine is hidden to the user in order to maximize the interface simplicity and manageability, though the methodological approaches and the normative and technical references are clearly specified in the tool manuals.
The achieved goal of facilitating the diffusion of the environmental sustainability topics for the realization of green-buildings with a low impact on the environmental and territorial context could be further proven by the results of the ongoing assessment of a certain number of case-study buildings.

Notes

[1] In addition to the authors of the article, the assessment tool has been developed with the contribution of:

- B. Barozzi, L. Danza, M. Orlandi: ITC-CNR;
- Valentina Colaleo: iiSBE Italia.

SUSTAINABILITY ASSESSMENT OF URBAN SOCIAL HOUSING: A FIRST MODEL FOR NORTHEAST REGION OF BRAZIL

Keywords: sustainability, assessment, indicators, social housing

Summary

Sustainability assessment of buildings is an important tool to verify and to demonstrate which route to follow in order to achieve sustainable development. Some methods, for sustainable building evaluation, can be found in the literature and are currently being used as, for instance, BREEAM, HK-BEAM and LEED. These methods, however, almost exclusively takes into account only environmental issue. On the other hand, a wider concept of sustainability includes, at least, two others dimensions: economic and social. Regarding social housing in developing countries, this kind of evaluation has also to be based on local priorities and to consider local technical and cultural values. This article deals with indicators for sustainable housing in order to develop a tool for social housing assessment. The set of indicators proposed in SBTool is taken as initial reference, once it includes some social and economical indicators, suggesting the beginning of building evaluation from the sustainability point of view. Moreover, it is designed to handle regional-specific issues and consists of an initiative that aggregates international experiences that contributes for developing new systems. The objective of this paper is to apply this tool to two social housing settlements situated in the cities of Recife and Olinda, Brazilian northeast region, taken as study case. These settlements have different building typologies: (i) multi-familiar dwelling, three-story building; and (ii) isolated houses and two-story building for two distinct families. The results show that, beyond collecting and evaluating data, this approach allows drawing guidelines to overcome the developing countries challenges. For example, decrease housing deficit and improve building performance without compromising the environment. In other words, sustainable housing designs have to consider improvement of inhabitant's quality of life, economic and technical feasibility; and environmental compatibility.

1. Introduction

In general, methods for assessing sustainability of built environments are based on quantitative and qualitative indicators, defined and measured on the basis of the comprehension of sustainable development concept and the role of the built environment in this context. Hence, the diversity of methods proposed reflects these different interpretations, yet marked by regional specificities that induce values and relevance of what should be measured (DING, 2008). The complexity of assessing sustainability is inherent in its very concept still evolving (AZEVEDO et al, 2007).

Developing countries, like Brazil, demand social housing, destined to meet the shortfall of stock of habitations, intended to a populace with low (or no) income and low level of education. These needy populations commonly originate irregular human settlements[1] in urban areas close to major Brazilian cities, as a result, mainly, of the search for better alternatives to generate income and reduce costs with transport. The precarious life conditions in these spontaneous settlements are even sharper due to the lack of minimum urban infrastructure, which also contributes to the degradation of the area irregularly occupied, requiring its recovery. Initiatives to meet this specific demand, usually provided solely by public resources, involve large numbers of housing units, and require the adequacy of the whole infrastructure for water supply, sanitation, energy and transport, and also need to provide options for generation of income. These ventures, in fact, consist of construction of human settlements, where the types of housing are heavily influenced by financial constraints and availability of spaces, and whose quantity is still pushed by demand. However, to be sustainable, they must be environmentally compatible, socially acceptable and economically viable.

Sustainability of social housing is admittedly an issue of significant importance for developing countries. The global Agenda 21 (UN, 1992) and Habitat II Agenda (UN, 1996) as well as Agenda 21 of the state of Pernambuco[2] (PERNAMBUCO, 2002) denote the relevance of social housing / human settlements, treating them as one of the factors to be prioritized in the search for a more sustainable world. In the search of understanding on sustainability in the construction industry were established the Agenda 21 for Sustainable Construction (CIB, 1999) and the Agenda 21 for Sustainable Construction in Developing Countries (CIB,

[1] *Cadernos MCidades Habitação, Volume 4 – Política Nacional de Habitação, Ministério das Cidades, 2006.*
[2] *Brazilian state located in the northeast region of Brazil - zwww.ibge.gov.br/ibgeteen/povoamento/constrterrit/mapapolitico.htm*

2002). The second agenda was due to the particularities of these countries not fully addressed in the first one, more targeted the reality of developed countries.

In Brazil, sustainability assessment of built environment is beginning to receive attention. This work is a result of the construction process of a tool for assessing sustainability of social housing, oriented to the specific characteristics of the Metropolitan Region of City of Recife - MRR, capital of the state of Pernambuco. This paper summarizes the procedure employed in the construction of the tool, highlighting some of its indicators. It will also be shown the results obtained with the tool in two case studies.

2. Objective

Aspects related to sustainability of social housing in the Brazilian context have been object of study (SATTLER, 2007). However, in Brazil, it is not yet available a set of indicators of sustainability oriented to social housing and systematically organized to allow some kind of assessment.

This work aims to contribute to the conception and systematization of indicators enabling the start of a tool for assessing sustainability of built environments, initially targeted to social housing in MRR. With the application of this tool to two case studies, this paper contributes not only to validating the tool but also to a comparative analysis between these two projects, whose results may steer potential opportunities for improvements.

In a broader approach, it is understood that the method in development for assessing sustainability of built environments can help guide decision-making, providing guidelines for the design of new more sustainable social housing in the MRR.

3. Method

Initially a set of indicators for built environment sustainability is chosen as a base reference: SBTool (version 2007). This choice is based on the differentiated approach adopted by SBTool, that distinguishes it among other available tools: is an initiative that adds the international experience in which Brazil also participates; presents character of scientific research, allowing the inclusion of regional specificities, contributing to the development of new systems, provides an assessment in a broader view of the concept of sustainability, with the inclusion of social and economic indicators, and the availability of information[3].

A critical analysis of all indicators proposed by SBTool for residential buildings was carried out, prioritizing those for design and occupation phases. This analysis sought to verify: understanding, applicability, relevance and technical feasibility of the indicators, focusing on social housing and the specific conditions of MRR. Other indicators, not included in SBTool, have also been proposed. The same form of scores (scale of -1 to +5) was maintained, seeking also reduce the level of subjectivity inherent to SBTool. The legislation was taken as reference to acceptable practice (scores 0). It was also included a weighting criterion, according to the degree of importance/feasibility assigned to each indicator.

Aspects related to developing country, as discussed by GIBBERD, 2002 and REFFAT, 2004, have also been taken into account, helping to understanding the emphasis given to each indicator.

Once constituted the base of indicators, technicians from city halls of Recife and Olinda (MRR), who are responsible for management and development of social housing projects in these municipalities, were asked to make another analysis of the indicators in order to verify their applicability and feasibility, providing also values for weights and benchmarks. Note that, at this stage of the research, it is more important to evaluate the relevance and applicability of the proposed indicators than the final result obtained with the tool.

3.1 General structure of indicators

The same general structure, presented below, was defined to the conception of each indicator:

- Indicator: definition of the indicator itself (what is to be measured).
- Understanding: explanations about the indicator and its context for better understanding and other considerations for its quantification.
- Intention: designates the purpose of the evaluation.
- References: indication of legislation, technical standards or instructions, booklets and other documents that should be taken as reference in the quantification of the indicator.
- Quantification/score: Definition of parameters for measuring and the resulting assessment of each indicator. The division and scores follow the SBTool model, as indicated below:
  - Negative practice: when minimal specifications are not followed (score: -1).
  - Acceptable practice: specifications defined in the legislation or considered as minimal (score: 0).
  - Good practice: specifications above the minimal requirements and therefore give the indicator a higher grade from the sustainability perspective (score: +3).
  - Best practice: Most demanding specifications, considered as the highest degree from the point of view of sustainability (score: +5).

[3] *www.iisbe.org – Nils Larsson*

- Degree of importance in the context of social housing /weighing: Establishment of weights, which can be adjusted in order to consider the local context, depending on the technical and economical feasibility, and relevance of each indicator, as explained below:
  - Not applicable: weight 0 (when the proposed indicator is not adequate to the kind of project).
  - Still far from the local reality / Non-existence of financial or technological resources: weight 1.
  - Little importance / It is not priority: weight 2.
  - Important / Ought to be considered and resources should be provided: weight 3.
  - Very important / It is already possible to be considered: weight 4.
  - Indispensable / Must be considered: weight 5.

3.2 Indicators

The set of indicators was divided following the basic dimensions of sustainability, depending on the emphasis given to each, so the final result expresses the performance of the project, according to these dimensions.

Table 1 Sustainable Indicators

Environmental Indicators	Area destined to the project	Vulnerability to flooding
		Vulnerability to sliding of hillsides
		Proximity to water courses
		Proximity of the sewerage system to water courses
		Proximity of the sewerage system to water reservoir
		Employment of environmentally compromised area
		Recovery level of the environmentally compromised area
	Project Planning	Environmental impact report
		Availability of treated water
		Controlled exploitation of water
		Recycled and reused materials
		Biodegradable materials
		Material with less negative environmental impact
		System for monitoring electricity, gas and water individual consumption
		System to capture and use of rainwater
		System to capture and use of gray water
		System for the use of solar energy
		Infrastructure for selective collection and storage of solid waste
		Infrastructure for composting of organic solid waste
		Planned demolition of buildings
	Reuse and recycling[4]	Use of pluvial water
		Reuse of gray water
		Selective collection of solid waste
		Reuse of organic solid waste
	Rationalization of natural resources[4]	Treated water consumption
		Electricity consumption
		Electricity consumption from renewable sources in the project itself
		Solid waste production
		Liquid effluents production
	Landscape	Provision of green common area
		Use of native plantings
		Provision of trees with shading potential (and for CO_2 sequestration)
	Indoor environment quality	Heat Island – floors
		Heat Island – roofs
		Thermal transmittance - external walls
		Thermal transmittance - roofs
		Natural ventilation
		Building orientation
		External noise

[4] *Estimates obtained from the specifications of the project, at design phase, to help the development of guidelines.*

		Internal noise
		Internal noise – bedroom
		Internal noise – lounge
		Natural lighting
		Artificial lighting
Economic Indicators	Economic insertion and local development	Proximity to public transport
		Proximity to centres of employment - job opportunities
		Mixed use – activities for income generation
		Garage for bicycles
		Use of materials produced by local companies
		Use of goods and services provided by local businesses
		Costs with use and maintenance
	Planning and development in long terms	Compatible projects
		Adaptability of structural system and envelop to spatial adequacy
		Adaptability to changes in water, energy, sewage systems
		Adaptability to the use of other energy and water sources
		Performance of buildings envelop
		Documentation handed to the dwellers
	Technical and financial feasibility	Resource for technical and financial studies
		Results of technical and financial studies
		Percentage increase in the cost of a more sustainable construction
Social Indicators	Project localization	Proximity to basic commerce centre
		Proximity to public medical centre
		Proximity to public educational centre
		Proximity to options for cultural entertainment
		Proximity to public green space
	Accessibility	Adequacy of sidewalk to disabled (reduced mobility)
		Adequacy of sidewalk to visually handicapped
		Adequacy of horizontal circulation to disabled (reduced mobility) – External and internal common areas
		Adequacy of horizontal circulation to visually handicapped – External and internal common areas
		Adequacy of vertical circulation to disabled (reduced mobility) – Common areas
		Adequacy of vertical circulation to visually handicapped – Common areas
		Adequacy of bathrooms to disabled (reduced mobility) – Common areas
		Adequacy of privative area (residential unit) to physical handicapped
	Environmental education and social integration	Area for social events
		Area for physical activities
		Area for children entertainment
		Social and environmental education programs for dwellers
	Safety	Sentry box
		Security system against the entrance of strangers
		Fire safety
	Privacy	Private parking
		Residential unit privacy
		Private external area
	Conservation of the local culture	Compatibility with the local urban context and its cultural values
		Conservation of the cultural and historical heritage
	Participation	Dweller's participation
		Evaluation of dweller's satisfaction

4. Case Study

The case studies are social housing ventures (state housing), to be constructed in the cities of Recife and Olinda (MRR). These cities were chosen because they are fairly representative of the urban context of Brazilian northeast region. And, yet, present challenges related to the sustainability of residential buildings typical of developing countries, for example, reduce the high housing deficit, recovery of degraded area due to irregular occupation, increase durability of buildings, development of activities to generate income for the people, increase the use of recycled materials and with less negative environmental impact, among others. These initiatives are intended to needy populations that gave origin to irregular spontaneous settlements.

4.1 Characterization of State Housing V8 e V9 in Olinda

The project, called ***State Housing V8 and V9***, consists of the re-urbanization of a spontaneous irregular settlement, which also occupied part of an area originally reserved for environmental protection, and includes the construction of housing units of two types: detached single-family ground floor houses and double-storey houses (for two families). The first type sum a total of 43 units, the second reaches a total of 524 units. Each resident has an area of approximately 27m^2 to 31m^2 with living room, a bedroom, bathroom, kitchen and service area, and an area planned for future expansion, whose foundation will be built by Olinda City Hall. In addition to the residential units, it will be deployed 46 business units, once that many of the current residents have small businesses (commerce or service) on the spot, which guarantee them income.

There will be improvements in urban infrastructure, such as re-structuring the access routes for moving and transport, paving, micro-drainage, deployment and recovery of water, sewage and public lighting systems, improvements in solid waste collection, deployment and rehabilitation of parks/squares for community activities and leisure (track of cooper, gymnastics, and ramp to skate, bicycle paths and sports court). It is also planned deployment of social facilities (school, kindergarten and acoustic shell). Environmental and social education is also planned.

Recovery of the environmentally degraded area is also expected, including means to avoid possible disorderly re-occupation in the future, as the urbanization of the river bank, with parks, squares and gardens.

4.2 Characterization of State Housing *Abençoada por Deus* in Recife

The project, called ***State Housing Abençoada por Deus***, consist of the construction of a residential condominium destined to shelter some communities that originated spontaneous irregular settlements. Four-storey buildings (ground floor plus 3 upper floors) are employed to accommodate 428 apartments. Each housing unit has an area of 39m^2 with living room, two bedrooms, bathroom, kitchen and service area.

The system for the treatment and final disposal of sanitary sewage, through anaerobic reactors and filters, will be installed in the condominium. Day care centre and playground for children are expected to be built, and also community centre and square favouring dwellers social living. Also planned is the rehabilitation of environmentally degraded area, after the removal of families for the new residential area, including ways to prevent another disorganized occupation, with the urbanization of the river bank through with parks, squares, and gardens. Replanting of forest and swamp is also expected.

An important difference between these two cases is that in Recife the project provides the recovery of the local originally occupied irregularly with transfer of families to a new residence in another area, while in Olinda the project provides the continuation of the families in the occupied area, after its recovery.

5. Results

Due to limited space, only a few indicators will be discussed. The chart presented below summarizes the results, which consist of weighted averages from the values assigned to the indicators and weights established by designers and managers of public municipalities of Recife and Olinda. Information was obtained from documentation of the projects.

5.1 Economical sustainability

Under the economic dimension, it is given emphasis to streamlining the economic resources, to promoting income generation and to the development of local economy.

- Proximity to public transport

The easy access to legal public mass transport (bus, subways, trains, etc.) is a basic requirement for the social housing dwellers as a result of a strong dependence upon it. Both projects are set in urban area, facilitating the access to the main available public transport in MRR, which is the bus. Weight: 4.

Olinda - Score: +3	Recife - Score: 0
Mean distance among bus stop and building is between 100m e 260m.	Distance among bus stop and condominium entrance is approximately 500m.

- Proximity to centre of employment - Job opportunities

For social housing it becomes indispensable the existence of job opportunities in its vicinity, facilitating the access to formal labour market, also contributing to the reduction of costs with transport. Weight: 5.

Olinda - Score: +5	Recife - Score: +5
Both projects are set in urban area, favouring the access to labour market and public transport.	

- Mixed use – activities for income generation

The existence of infrastructure in the project to enable its users develop income generating activities, is an important guideline for social housing. This also contributes to reducing costs with transport and to the achievement of these activities in an orderly way, minimizing the possibility of irregular improvisations that can compromise safety and quality of public space. Weight: 3.

Olinda - Score: 0	Recife - Score: -1
The project provides for buildings for commercial use, close to the	No area aimed to activities for income

housing units, aimed at activities for generating income for the dwellers, whose built area is around 5.36% of the total built area.	generation for the dwellers are available in the project.

- Documentation handed to the dwellers.

Refers to availability to the dwellers, before the occupation of habitation, of information documents on the proper use and maintenance of the property, including drawings of the projects (as built). Weight: 3.

Olinda – Score: -1	Recife – Score: -1
It is not provided for availability of information on the use and maintenance of the property to the dwellers.	

- Technical and financial feasibility.

Use of renewable energy, reuse of water, use of materials with less environmental impact, efficiency in the use of energy, among other examples, are solutions of unconventional buildings design, tending not to be accepted initially. This indicator stimulates the achievement of technical and economic studies that justify these solutions (including computer simulations of natural and artificial lighting, and thermal comfort that provide better efficiency in the use of energy). Weight: 2.

Olinda – Score: -1	Recife – Score: -1
There are no technical and financial studies for providing solutions to more sustainable project.	

5.2 Environmental sustainability

The environmental indicators are those preferably related to a rational use of natural resources in order to promote equilibrium between development and environmental preservation.

- Use of material with less negative environmental impact.

It is not yet available, on a consolidated basis for the MRR, data regarding to embedded energy and gas emissions associated with building materials, so this indicator takes as a reference the project specifications, with respect to the restriction of materials that do not contain contaminants agents, such as CFCs, asbestos, etc, or those acquired irregularly (unauthorized) such as wood, or aggregates and ornamental stones extracted from irregular deposits. Weight: 2.

Olinda – Score: +3	Recife – Score: -1
Ornamental stones will not be used. Aggregates will be extracted from the local itself or from legal deposits. Only certified wood will be used.	Reference is made only to legalization of deposits of material used in re-embankment.

- Vulnerability to sliding of hillsides.

The area considered as adequate is that presents less risk of damage to property and dwellers with the occurrence of the sliding hillsides. Weight: 5.

Olinda – Score: +5	Recife – Score: +5
Both projects are not situated in areas near to hillsides.	

- Controlled exploitation of water.

It is common in the MRR supplementary water supply through the use of wells when the public water supply system does not meet demand. However, the indiscriminate use of wells does not favour the rational use of water and can cause problems such as salt water intrusion (salinization of aquifers - in coastal region), subsidence, etc. The use of wells, deep or not, shall be monitored by the Water Resources Company of Pernambuco (CPRH), the authorized governmental agency responsible for water management. Weight: 3.

Olinda – Score: +5	Recife – Score: +5
Both cases provide for the exclusive use of public system of water supply.	

- Infrastructure for selective collection and storage of solid waste.

This indicator is based on the existence of infrastructure enabling the selective collection and storage of solid waste, in order to facilitate recycling. Weight: 4.

Olinda – Score: -1	Recife – Score: -1
In both cases there is not any infrastructure appropriated to selective collection and storage of solid waste.	

- Thermal transmittance - external walls.

The thermal transmittance is calculated based on the Brazilian Standard (ABNT, 2003), according to the materials that compose the external walls. Weight: 3.

Olinda – Score: +3	Recife – Score: +3
The calculated thermal transmittance of the external walls corresponds to 2.34 W/(m².K).	The calculated thermal transmittance of the external walls corresponds to 2.65 W/(m².K).

- External noise.

The external noise reduction is measured according to the Sound Transmission Class (STC) of the windows, pursuant to the classification given in Table 4 of the Brazilian Standard NBR 10821 (ABNT, 2000). Weight: 2.

Olinda – Score: +3	Recife – Score: +3

The Sound Transmission Class reaches 28, considering glass of 6mm, according to the program BD Acustica 1.2[5].

5.3 Social sustainability

As for social sustainability, the indicators are preferably related to the socialization, welfare and the quality of life, promoting the appreciation of cultural and communitarian aspects.

- Proximity to educational centre

When it comes about social housing, educational centres in the vicinity contribute to access to education favouring also transport costs reduction. Weight: 4.

Olinda – Score +3	Recife – Score: 0
The project envisages construction of municipal school, from infant education until 8th year of elementary school, within the radius of at least 1000m.	The project envisages the construction of a school only for early childhood education (day care), within the radius of at least 1000m.

- Adequacy of privative area (residential unit) to physical handicapped

Prediction of residential units adapted to physical handicapped, based on the specifications of Brazilian Standard NBR 9050 (ABNT, 2004). Weight: 3.

Olinda – Score: -1	Recife – Score: -1
In both projects there is no prediction of housing units adapted to the physical handicapped.	

- Areas for physical activities

Corresponds to provision of infrastructure for physical activities, promoting also welfare and social conviviality. Weight 4.

Olinda – Score: +3	Recife – Score: -1
It is planned the deployment of soccer fields, sports courts, bicycle paths, apparatus for gymnastics, and a skate ramp.	There is no prediction of facilities for physical activities.

- Socio-environmental education programs for dwellers

It is common for dwellers of these state housing present low education and little experience in condominium conviviality. In addition, alternatives such as rational use of energy and water, waste recycling, among others, require awareness of the users so that, in fact, they may be employed effectively. Thus, it becomes necessary social and environmental training for dwellers. Weight: 4.

Olinda – Score: 0	Recife – Score: 0
It is expected, in both projects, social assistance, provided by the municipal managers, during a short period of time, but environmental issues are not prioritized.	

- Residential unit privacy

Takes up, as reference for privacy of housing units, the minimum distance between buildings, provided for in the legislation, in addition to positioning of openings, use of appropriate windows and glass and the existence of external elements (vegetation, for example), which promote privacy. Weight: 4

Olinda – Score: 0	Recife – Score: 0
It was not identified, in both projects, other alternatives to promote the internal privacy than the minimum setbacks between buildings established in the legislation.	

The following graphic resumes all the results obtained for the several indicators.

6. Conclusions

This paper proposed some indicators that are systematized in order to provide a tool for assessing sustainability of social housing in the Metropolitan Region of Recife, oriented to design phase.

Two case studies are evaluated using this tool. It is necessary to remark that the information contained in the documentation of the projects (specifications and budget spreadsheets, for example) do not always allow accurate results, requiring some estimates. On the other hand, it is emphasized that more important than the final result is the contribution of the work to a methodology for evaluating sustainability of built environment able to steer the market to more sustainable solutions in architecture and construction.

It is also important to point out that what is predicted in a state housing project is not always accomplished, due mainly to lack of financial resources, influenced by social housing policy. The precocious deterioration of state housing in the Metropolitan Region of Recife questions these housing policies. So, results obtained on the basis of design phase may not reflect the real level of sustainability of a state housing project at its concluison.

The continuity of the work will allow the improvement of the tool and the methods employed in the measurement of indicators. An experimental prototype (*Sustainable Built Environment Assessment Tool*) of the proposed method is being elaborated to be accessed via internet, allowing the participation of stakeholders with suggestions for new indicators and adaptations.

Keywords: BREEAM, sustainability, low/zero carbon, school design, capital costs

Summary

The drive for more sustainable development is one of the defining issues of the early 21st Century. This is at odds with the often perceived view that the short-term costs of sustainable practices are too high to justify their application within buildings. Research was undertaken by BRE and Faithful+Gould to identify real cost data for a broad range of sustainability technologies and design solutions for a primary and secondary school. The capital cost for each design or specification adjustment was assessed and compared with a Building Regulation compliant base case study school building. This outlined the additional cost associated with achieving the BREEAM Schools 2006 ratings and a zero carbon school. The results show that major performance improvements can be achieved at little extra cost and even at no cost at all. Reaching the highest standards and striving for zero carbon performance does incur some cost premium, but the research shows that careful consideration of the design and specification at an early stage can minimise these cost premiums.

1. Introduction to BREEAM

BREEAM has become a benchmark of environmental responsibility for buildings in the UK, and has gained international recognition for objectively and holistically assessing the environmental performance of all building types. BREEAM was devised by BRE in 1990 and has become a highly sought after label that demonstrates the environmental credentials of all building types and developments. Credits are awarded for implementing environmental aspects within the building design. Each credit is weighted according to its importance and the resulting points are summed to give a total BREEAM score and rating.

BREEAM Schools forms part of the BREEAM buildings portfolio and was funded by the Government Department for Education and Skills. The scheme forms the basis of an independent and credible certification scheme against which the UK Government have set targets for new build and major refurbishment projects.

2. The Approach

The capital cost for each design or specification adjustment was assessed and compared with a base case study school built to comply with Building Regulations. The cost of each design solution was determined using real and recent project data collected by sustainability and cost consultants Faithful+Gould. By using BREEAM Schools credits as a measure of environmental improvement, it was possible to identify the additional capital cost associated with each incremental improvement in environmental performance. This made it possible to identify 'quick wins' and design initiatives that need to be built into the specification at the earliest opportunity for no extra cost or relatively little cost. Whole life costs were not assessed in this study because specific information about the site, maintenance methods and the future energy costs were not available.

2.1 Location related issues

In BREEAM Schools several credits are dependent on the location of the school and other details relating to the site. These include proximity to public transport, existing ecological value and whether the site is greenfield or brownfield. In this study, two location scenarios were assessed:

- ***Greenfield site*** with poor transport links and no location credits are achieved.
- ***Brownfield site*** with good transport links and a selection of location-based credits are achieved.

This places each building within a site-specific context that relates to the BREEAM Schools 'Land Use & Ecology' and 'Transport' associated credits.

Some credits could not be assessed in this study as the costs were very site-dependent. These included improving the acoustic performance of the school, sourcing recycled aggregate and improving the ecology of the site. As these credits could not be assessed, more innovative and potentially costly technologies, such as renewable technology, were incorporated. This may not always represent the most cost-effective means of achieving a BREEAM Schools 'Excellent' rating and for a real building the site-dependent credits could be achieved at a lower capital cost.

3. Case studies – achieving BREEAM Schools ratings

3.1 Primary school

The Building Regulation compliant 'base case' primary school building has the following attributes:

- Construction capital cost is £1570/m^2 including preliminaries and contingencies but excluding furniture, fittings and equipment, external works and fees.
- New build, single-storey building with a gross floor area of 1367 m^2 and accommodating 210 students and staff.
- Utilises natural ventilation and thermal mass as its sole form of cooling. Each classroom has a full-height glazed window and a ventilation stack. The ventilation stack on top of each classroom allows air to flow throughout the room. Brick and blockwork cavity walls, concrete ground-floor slab.
- No mechanical ventilation is used except where required by regulation/functional requirements (eg toilet and kitchen facilities).
- Radiators served by condensing gas boiler, low-temperature hot water heating.
- Nylon carpet and vinyl flooring in circulation area. Standard fluorescent electric lighting.
- Double-glazed aluminium windows with softwood rooflights.

The following measures were included and costed for a good location:

- Pass: Insulation with a global warming potential (GWP) of less than 5; external lighting in compliance with the Institute of Lighting Engineers' guidance; water-saving appliances.
- Good: Energy-efficient external lighting; registration for Considerate Constructors' Scheme; mains leak detection system; energy-efficient internal lighting.
- Very Good: Water meter with pulsed output; recycling facilities; mains-fed water coolers; *Green Guide* 'A'-rated floor finishes; cyclist facilities; building user guide; proximity detection shut-off system.
- Excellent: Sub-meters; site investigation; *Green Guide* 'A'- rated external hard landscaping; renewable and low emissions energy feasibility study; low carbon renewable energy system (eg biomass boiler).

3.1.1 Primary school BREEAM Schools ratings

Table 1 % increase in capital cost for a primary school to achieve Pass, Good, Very Good and Excellent BREEAM Schools rating in a good and poor location

Location	BREEAM score and rating for a base case school	Pass	Good	Very Good	Excellent
Good	19.3 Unclassified	0.0	0.7	1.8	5.9
Poor	11.0 Unclassified	0.3	1.1	3.0	9.85

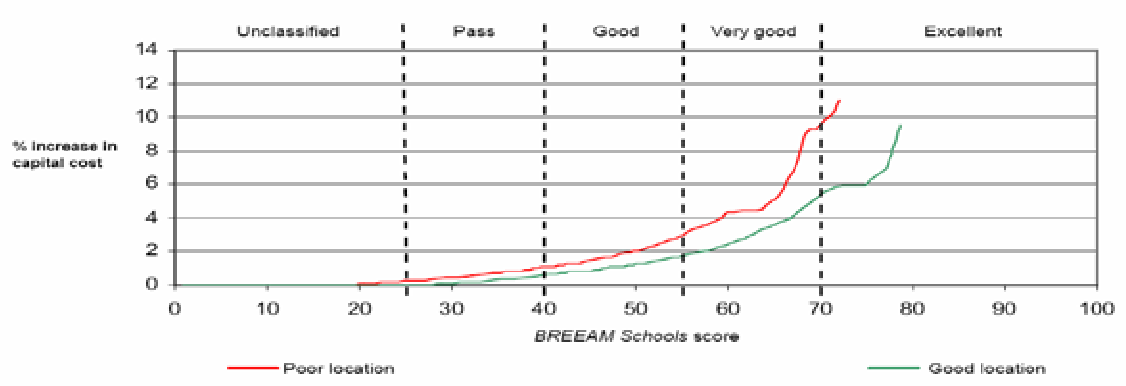

Figure 1 Cost versus environmental performance for a primary school in a good and poor location

3.2 Secondary school

The Building Regulation compliant 'base case' secondary school building has the following attributes:

- Construction capital cost is £1711/m^2 including preliminaries and contingencies but excluding furniture, fittings and equipment, external works and fees.
- New build, 3-storey building with a gross floor area of 3116 m^2 and accommodating 500 students and staff.
- Utilises natural ventilation and thermal mass as its sole form of cooling. Brick and blockwork cavity walls, concrete ground-floor slab.
- A central corridor divides the floor in two lengthways, and classrooms are located either side of the central corridor.
- No mechanical ventilation is used except where required by regulation/functional requirements (eg toilet and kitchen facilities).
- Radiators served by a condensing gas boiler, low-temperature hot water heating.
- Nylon carpet and vinyl flooring in circulation area. Standard fluorescent electric lighting.
- Double-glazed aluminium windows.

The following measures were included and costed for a good location:

- Pass: Insulation with a GWP of less than 5; external lighting in compliance with the Institute of Lighting Engineers' guidance; water-saving appliances.
- Good: Low NOx boiler; energy-efficient external lighting; registration for Considerate Constructors' Scheme; mains leak detection system; water meter with pulsed output.
- Very Good: Recycling facilities; mains-fed water coolers; *Green Guide* 'A'-rated floor finishes; building user guide; proximity detection shut-off system; whole life cost model; site investigation.
- Excellent: Cyclist facilities; sub-meters; *Green Guide* 'A'-rated external hard landscaping; renewable and low emissions energy feasibility study; lowcarbon renewable energy system (eg wind turbine).

3.2.1 Secondary school BREEAM Schools ratings

Table 2 % increase in capital cost for a secondary school to achieve Pass, Good, Very Good and Excellent BREEAM Schools rating in a good and poor location

Location	BREEAM score and rating for a base case school	Pass	Good	Very Good	Excellent
Good	21.1Unclassified	0.0	0.2	0.8	3.9
Poor	12.8 Unclassified	0.1	0.5	2.7	4.4

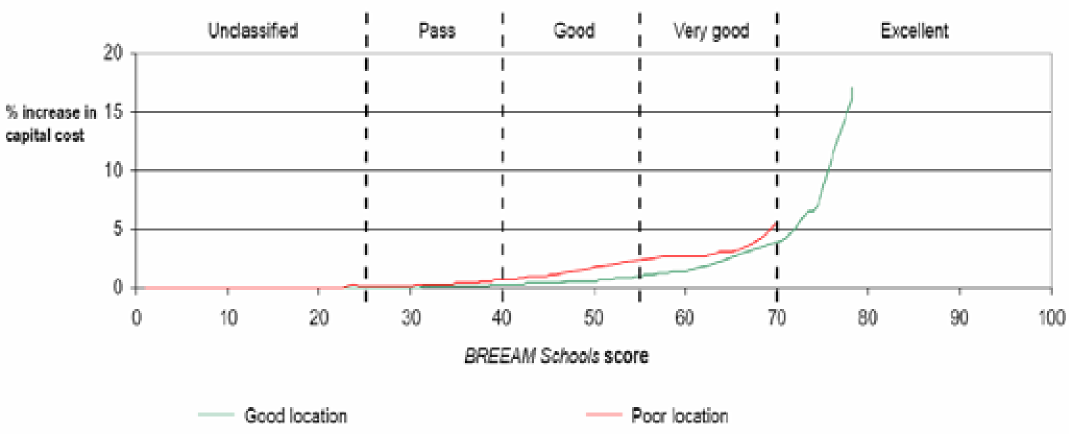

Figure 2 Cost versus environmental performance for a secondary school in a good and poor location

4. Case studies – achieving a low/zero carbon school

Having considered the cost implications for achieving the BREEAM Schools ratings, the study sought to understand the improvements that would be required to achieve a zero- or low-carbon school over and above a base case Building Regulations compliant school. A zero-carbon school is defined as one where the net CO_2 emissions are zero (ie energy used to power, heat, cool, ventilate and illuminate the building using standard hours of use). This includes small power services such as computers and appliances. Carbon emissions were reduced using low-cost measures such as increasing insulation levels, reducing infiltration rates and maximising the use of daylight before applying renewable energy technology. Renewable energy systems were then applied as a means to reduce further the carbon emissions.

4.2 Primary school results

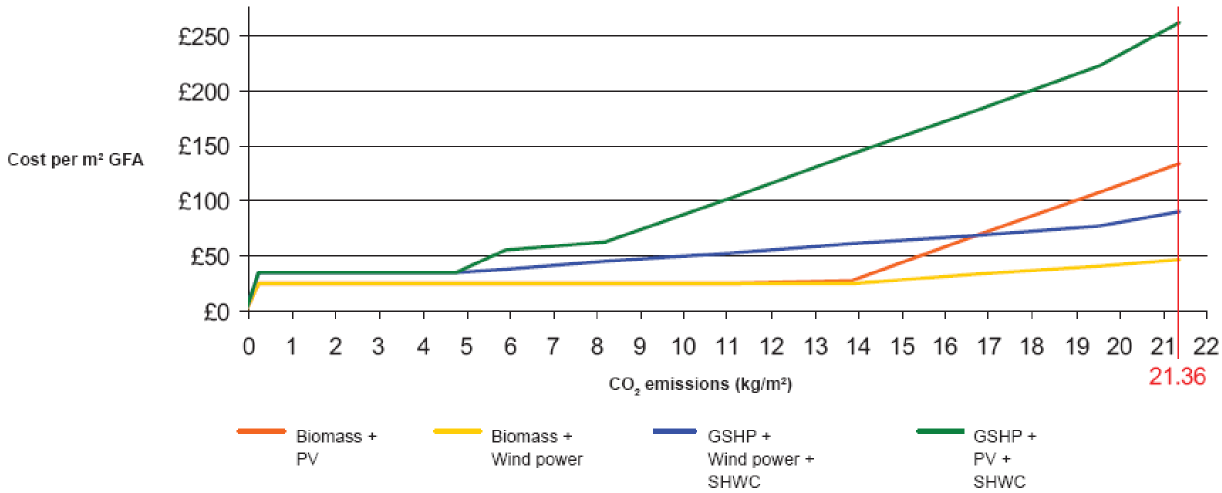

Figure 4 Cost (£/m²) to reduce carbon emissions for a secondary school addressing a combination of renewable and low-carbon emission technologies

4.1 Discussion of results - achieving a low/zero carbon school

The primary and secondary schools demonstrated that lighting controls yield the greatest reduction in carbon emissions. Improving the U-value is the next best option but provides significantly less savings than the lighting controls. The reduction of air infiltration from 10 to 5 $m^3/m^2/hr$ provides the least reduction in carbon emissions.

4.1.1 Carbon footprint of electricity use

The base case primary school had carbon emissions due to electricity consumption of 3.29 $kg/CO_2/m^2/year$ while the secondary school had carbon emissions of 7.77 $kg/CO_2/m^2/year$.

The energy modelling process suggests the most significant means of reducing carbon emissions is through the installation of automatic daylight-controlled dimming. This is particularly apparent within the two case-study schools which had high daylight factors and consequently enabled electric lighting to be switched off for much of the time. As schools are mainly operated within daylight hours, electric lighting should only be required at the beginning and end of the day in winter. In practice, lights are left on even if daylight is sufficient unless the designer also takes care to improve the uniformity of the daylight distribution and can provide glare-free daylight suitable for viewing electric whiteboards without having blinds down and lights on. The carbon emissions for electricity are fairly low due to the savings on electric lighting with high daylight factors. If it was not possible to make such large savings on lighting the achievement of zero carbon would be much more difficult as the 'on-site' generation of electricity through renewable technology is more demanding than for heat.

4.1.2 Carbon footprint of space heating and hot water

The base case primary school had carbon emissions due to space heating of 7.24 kg/CO_2/m^2/year while the secondary school had carbon emissions of 10.55 kg/CO_2/m^2/year. Both schools had carbon emissions from hot water of 2.7 kg/CO_2/m^2/year.

While improved U-values and lower infiltration rates reduced the carbon emissions associated with the heating load of school buildings, the introduction of daylight dimming lighting controls increased heating-related carbon emissions by reducing the indirect contribution of heat from the lighting load.

4.1.3 Application of renewable and low emission technology

The heat and electricity demand were targeted separately to reduce the net carbon emissions to zero with on-site renewables and low emissions technologies such as:

- ground source heat pumps (GSHP) for heating,
- biomass for heating and hot water,
- wind and photovoltaics (PV) for electricity,
- solar hot water collectors (SHWC) for domestic hot water demand.

It would not be possible to supply all the heat demand using solar hot water alone and therefore this has only been considered to supply hot water. These paths to zero carbon may simply not be available to some schools as these costs assume:

- good ground conditions suitable for good efficiencies of GSHP,
- a sufficient wind resource for wind power,
- sufficient suitable roof area for PV/solar hot water collectors, and
- fuel availability for biomass.

It should be noted that in some circumstances low/zero carbon will be difficult to implement and will have a major impact on the costs presented in this section. The following scenarios outline the low-emission and renewable technologies that were applied in the order listed until net carbon emissions in the base case schools became zero.

5. Conclusion

This study illustrates that many sustainability measures can be implemented at little cost and a limited number of items are available at no additional cost. It should be noted that costs may significantly increase if sustainability advice is received too late. Ensuring that sustainability is considered broadly at the outset (and in detail at appropriate stages in the development of the design) will minimise cost and maximise environmental performance. Other broadly applicable findings are as follows:

- Development location and site conditions have an impact on the costs associated with achieving higher (ie Very good or Excellent) *BREEAM Schools 2006* ratings. Any estimates of the cost of achieving a BREEAM rating should include a thorough review of site conditions.
- Effective management of the development process is critical to ensuring that all low-cost options are identified and achieved. Costs can rapidly increase once all the low-cost options have been implemented or exhausted. To enable environmental performance to be maximised at lowest cost, sustainability must be considered at the earliest possible stage of the design process and every effort should be made to incorporate all the possible low cost items.
- The case studies in this report assume that solutions are implemented at the design stage, rather than retrofitted. Identified low- or no-cost options include:
    - specifying water-efficient appliances,
    - ensuring all timber is procured from appropriate certified sources,
    - committing to good construction practice (such as through the Considerate Constructors' Scheme),
    - providing low-energy lighting,
    - enhancing thermal performance through increased insulation levels,
    - avoiding air-conditioning where possible. Not only does this help to reduce energy use and associated CO_2 emissions, but the use of a passive or mechanical system also avoids the need for expensive refrigerants (particularly those with a high global warming potential) and refrigerant monitoring systems.
- Providing technologies such as photovoltaic panels or rainwater harvesting is still relatively expensive compared with most other sustainability options and has significant maintenance implications.
- While outside the scope of this study, good controls and commissioning can lead to significantly lower energy consumption making it more likely that design aspirations will be achieved.

Although initial capital costs may be higher, purchasing or procuring an energy-efficient school can result in significant cost savings on energy bills. If the mains water consumption is metered, implementing low water-use facilities will also have a positive effect on reducing operational expenditure.

Appendix A. BREEAM

BRE's Environmental Assessment Method (BREEAM) is used to measure a building's environmental performance. The main objectives of the scheme are:

- to differentiate buildings that meet higher levels of environmental performance from the rest of the market,
- to encourage, reward and promote best environmental practice,
- to raise awareness of the benefits of building to best environmental practice standards.

BREEAM considers broad environmental concerns such as climate change, resource use and impacts on wildlife, and balances these against the needs for a high quality, safe and healthy internal environment. They identify those projects that improve environmental performance through good management, design and specification, and credits are awarded where specific performance levels are achieved in each category. The credits are then weighted according to the relative importance of the environmental issue that they address to give a point score. The weightings were established through a large and varied stakeholder consultation and are revised periodically as priorities change.

Table 5: The following BREEAM 2006 ratings are awarded on a scale of achievement: Pass, Good, Very Good and Excellent based on the scores given below.

BREEAM rating	BREEAM score
Unclassified	< 25
Pass	≥ 25 – < 40
Good	≥ 40 – < 55
Very Good	≥ 55 – < 70
Excellent	≥ 70

Keywords: housing projects, sustainable assessment methods

Summary

To improve the quality of the building construction environment, developed countries have designed methodologies to assess sustainability both of building constructions and urban areas. In developing countries the situation is somewhat more complex, considering that the fast and disordered urban growth has generated several environmental and mainly social problems. Among other problems, São Paulo, with almost 11 million inhabitants, has a significant housing deficit, both owing to the insufficiency of housing units to meet the existing demand and the low quality of existing units. In the context presented by the authors, the purpose of this article is to analyze some sustainable assessment methods existing internationally, applying them to a housing agglomerate project that was designed in light of sustainable urban planning principles such as differentiated design, use of solar energy for water heating, and participation of the community in the project development, among others. With such analysis, the authors intend to review the situation of housing agglomerates in regard to sustainability and, at the same time, analyze the applicability of international methods to the Brazilian reality, identifying the main difficulties and contributing to build an overview of the situation of housing agglomerates with a view to implementing a national method to assess building construction and urban area sustainability.

1. Urbanization in developing countries

Urbanization is an important issue to be addressed, considering the constant demographic growth of large cities. Current cities are not self-sustainable organisms but rather large consumers of agricultural and industrial inputs and natural resources, without however recycling or reusing them (ANDRADE, 1998; WALSH, 2006).

If on the one hand the urbanization process has contributed to the evolution and development of modern societies, on the other, it has significantly modified the natural space therefore generating extremely negative environmental and social impacts, mainly in developing countries. In developing countries, the urbanization process was fast and intense, and was characterized by the absence of organization or planning on the part of the local government and a spontaneous development whose rules were dictated by real-estate speculation. This mainly benefited the development of services infrastructure for the nobler areas of the cities intended to the high- and middle-income classes, whereas other less appreciated areas that were occupied by classes with a lower purchasing power remained almost or even completely without urban infrastructure (ANDRADE, 1998).

In Brazil, in spite of decreasing urban growth rates, large cities such as São Paulo still suffer as a result of that spontaneous urbanization (ANDRADE, 1998; WERNA, 2001). The growth that was uncontrolled for years now represents a difficulty to be overcome by urban management, both in environmental and economic terms, and mainly in social terms (BONDUKI, 1994).

In social terms one might say that the low-income population is excluded from the right to decent housing because it is not able to get access to the formal housing unit market. The solution found by that extremely poor population goes from the production of squatter settlements to the establishment of an informal sector of small real-estate promotion (for example, renting rooms in tenement buildings). They are always settled in disagreement with official regulations with precarious dwellings in risk areas – for example, hills – or areas of water supply source protection deprived from comfort or services infrastructure (ROCHEFORT, 1998).

Gibberds (2001) states that housing conditions in developing countries do not achieve even the minimum standard to meet the basic needs of quality of life such as access to water/sewage and energy, which makes the possibility to achieve higher environmental quality levels even more remote.

2. The context of Brazilian housing agglomerates

Generally speaking, Brazilian housing agglomerate projects do not present features relating to environmental concerns or any other principle relating to sustainable development (FREITAS, 2001). Moretti (1997) states that the Brazilian laws are extremely restrictive, limiting the use of differentiated designs and inducing to the development of some project typologies with high infrastructure implementation cost, such as:

- Single-family units isolated in the tract of land – making the land use coefficient extremely low and raising the cost of infrastructure;
- Mesh-type roadway system, without a hierarchy of roadways generating high paving costs and large impermeable areas;
- Execution of large land movements to adapt the land to the housing agglomerate that is often designed for practically leveled soils, increasing erosion and sedimentation and compromising soil stabilization.
- Negative impacts such as: sunlight obstruction and neighborhood disturbance during construction.

To improve that situation, in recent years, the CDHU – Companhia de Desenvolvimento Habitacional e Urbano do Estado de São Paulo (Housing and Urban Development Company of the State of São Paulo), responsible for the development of housing programs intended to low-income classes – adopted some actions regarding the improvement of socially-oriented housing conditions. From 1998 to 2002, the CDHU designed a project called Ecodesign that consisted of an initiative among the company's technical professionals for environment management training. The product of that project was called Project Manual for EHIIS – Empreendimentos Habitacionais Integrados de Interesse Social (Integrated Socially-Oriented Housing Projects). Its purpose is to apply social and environmental management concepts, guidelines and procedures called Integrated Socially-Oriented Housing Projects.

The greatest challenge to be overcome by the Manual is to incorporate social and environmental sustainability principles into urban and socially-oriented housing projects through an integrated view of products and processes, and the adoption of environmental principles and criteria.

In 2001 the actual application of the Ecodesign concept in a CDHU project was started (FIGUEIREDO, 2002). The purpose was to address variables such as ecology and use of land, a healthy community life, materials selection and specification, water and energy conservation, maintenance and operation management.

The application of those principles occurred in the implementation of a housing agglomerate in partnership with the Municipal Government of Atibaia – the Atibaia D housing agglomerate that will be detailed in the case study below.

3. The Atibaia D housing agglomerate

The housing agglomerate under study is located in the City of Atibaia, 67km far from the City of São Paulo, outside the Metropolitan Area. In the Master Plan prepared by the municipal government the estimated population was 126,851 inhabitants for 2005 according to IBGE (Brazilian Institute of Geography and Statistics) data. The population income of the housing agglomerate's area corresponds to US$ 400.00/month.

Before the construction of the housing agglomerate the soil had low vegetation and had no trees or buildings. The declivity is approximately 12% towards the existing creek.

Figure 1 Two views from GoogleEarth: first in 2002 and second 2008

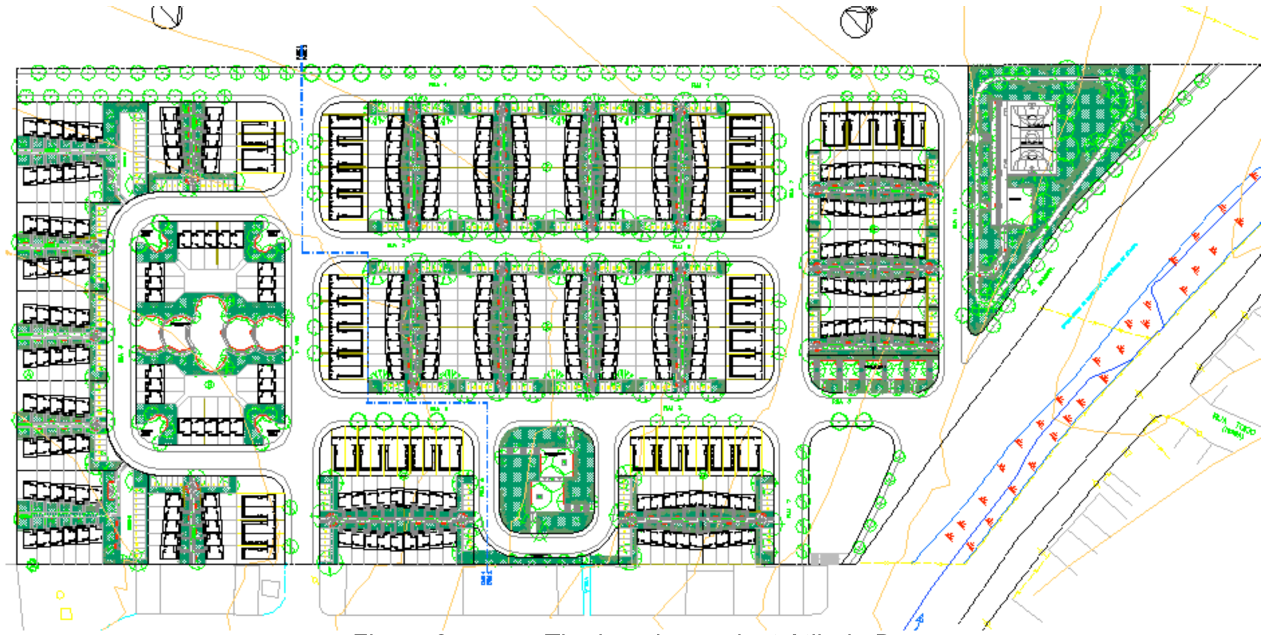

Figure 2 The housing project Atibaia D

The Atibaia D housing agglomerate project is differentiated not only for its design but also for its Ecodesign principles used in its development. In relation to design, unlike traditional housing agglomerates, the Atibaia D has groups of townhouse-type housing units for better use of the urban infrastructure.

Hierarchical use of roadways not only takes advantage of the infrastructure and reduces paving costs but also configures a more pleasant and not monotonous outdoor environment.

The project was designed in the form of small villas, where the access to the housing units occurs on foot through a narrower and entirely tree-planted street. The parking space is perpendicular to the housing unit access way. Some principles to be followed were defined and are mentioned below:

- Population participation in the project, engineering works planning and production of the public space
- Creation of the housing agglomerate's natural resource management system (water, vegetation, energy and solid waste)
- Priority in the use and preservation of local resources
- Technology suited to the local labor/users
- Reduction, minimization or elimination of waste generation.

Programs provided to reduce the housing agglomerate's environmental impact include:

- Basic sanitation
- Landscaping (denser green areas/recomposing the original vegetation)
- Selective Garbage Collection
- Use of solar energy to heat water in some units
- Minimizing waste in the engineering works.

The urbanization and building construction studies prepared by CDHU estimated 369 housing units to be built, part of them on a global contractor's work basis and another part of them through self-help housing production (housing bees). The housing agglomerate has two typologies: 208 two-story houses and 61 one-story houses. Of the one-story houses, 12 are intended to physically disabled individuals.

All future residents are being trained for construction, maintenance and landscaping activities of the housing agglomerate that will remain under the responsibility of users, including implementation and maintenance. The civil engineering works started in 2004 and are expected to end in the first half of 2008.

4. Assessing of housing agglomerate through different methods

For its differentiated project, the Atibaia D housing agglomerate was selected for the purpose of verifying the applicability of international methods to housing agglomerates with a differentiated project and also to analyze its sustainable performance according to international parameters.

Through the case study, the Atibaia D housing agglomerate was evaluated using five methods chosen according to the criteria below:

- Methods already studied internationally and with already-published bibliographical analysis;
- Methods prioritizing urban areas;

- In the case of being specific for assessment of buildings that included categories of assessment of the surroundings and of the building with its neighborhood;
- Methods that made access available to its files and structure, such as spreadsheets, checklists, etc.
- Possibility for the method to be used for self-assessment.

The methods were obtained via the Internet, through file download. The methods chosen according to our criteria were:

- Building Research Establishment – Ecohomes (United Kingdom),
- Sustainable Building Assessment Tool – SBAT (developed in South Africa)
- Sustainable Building Tool – SBTool (an international initiative involving several countries)
- Leadership in Energy and Environmental Design – LEED-ND (United States)
- Category 01 of the AQUA method adapted to Brazil from the French method: NF Batiment Terciare – Haute Qualité Environnementale – HQE.

The LEED-ND method is the only one of the selected methods whose purpose is to assess urban areas using specific indicators. Other methods were studied to be compared with the LEED-ND. Although they are intended to building constructions and are not specific for neighborhoods, districts or urban areas, all of them have indicators to assess, for example, the impact of the project on its surroundings, in relation to sunlight and winds, in addition to verifying the services available, such as hospitals, schools, parks, access ways, transportation systems, and infrastructure existing in the surrounding area.

Those indicators would serve to supplement the project assessment, making its evaluation possible through methods that are not specific for urban areas. The housing agglomerate's assessment using those methods was performed based on the construction projects and guidelines provided by the CDHU. That work did not follow through the construction phase of the housing agglomerate

5. Analysis of assessment results using sustainable methods

Table 1 EcoHomes results

EcoHomes - Categories	**Score/Total %**	**%**	**Classification**	
Energy	2.75/22	12.5	Pass	36%
Transport	5/8	62.5	Good	48%
Pollution	4.55/10	45.5	Very Good	58%
Materials	0/14	0	Excellent	70%
Water	5/10	50		
Land use and Ecology	4/12	33		
Heath and Wellbeing	0/14	0		
Management	3/10	30		
Not pass	**24.29**			

ECOHOMES (BRE, 2006) - The housing agglomerate did not achieve the minimum scoring to be approved by the system because the method is restricted to United Kingdom or European Union standards that do not exist or do not have a Brazilian standard equivalence, in addition to being intended to building construction assessment, leaving few indicators for the assessment of the project and location and its surroundings. Only 15% of indicators account for project location and its surroundings.

Table 2 SBAT results

SBAT	**Score/Total**	**%**	**Classification**	
Economic	3.9/5	78	Very poor	0-1
Environmental	1.5/5	30	Poor	1-2
Social	1.9/5	38	Average	2-3
			Good	3-4
Average	**2-3**	**46**	Excellent	4-5

SBAT - Its indicators are very general allowing for the assessment of a large project as a whole, considering that it is not restrictive to specific building construction items. The Atibaia D project gives great emphasis to economic factors, which makes sense considering that the resources are scarce and the construction has to be economically viable. The social aspect assessment had a low score, showing that the housing agglomerate did not meet the indicators proposed by the social category. The environmental aspect assessment had the lowest score of the three categories, once the Atibaia D housing agglomerate project does not provide for any of the environmental requirements of the system, such as: implementation of a vegetable garden and orchards, water treatment and reuse, and use of recyclable materials. The only requirements met by the housing agglomerate are: use of renewable energy for water heating, selective garbage collection provided by the municipality and the policy of non-wasting during engineering works.

Table 3 - SBTool results

SBTool - Categories	Score/Total	%	Classification	
Site Selection, Project planning and development	3/5	50	Acceptance practice	0
Energy and resource consumption	1.2/5	10	Good practice	3
Environmental loadings	1.7/5	15	Best practice	5
Indoor environmental quality	0/5	0		
Service quality	0/5	0		
Social and economic aspects	4/5	15		
Cultural and perceptual aspects	3/5	5		
Acceptance practice	**2.6/5**			

SBTool (Larsson, 2008) - In general, the system is extremely complex, but also malleable. The weight of indicators may be changed or disconnected according to the reality in question. As mentioned before, the system is a generic tool but may be adjusted to different realities. It was not possible to perform the assessment of the following categories: indoor environmental quality and service quality, whether for lack of data or even for not being applicable to the urban configuration of the housing agglomerate. Several other indicators of other categories were not applied for the same reason.

Table 4 Aqua results

Aqua – category 1	Performance
Sub-category 1.1	Average
Sub-category 1.2	Good
Sub-category 1.3	Good
Final performance	**Average**

The AQUA method has a quite different configuration from the other methods for establishing a profile rather than a scoring classification. In this case, we did not use the entire system, but the first of the 14 categories, which generated an assessment using the indicators applicable to that category only. Unfortunately the housing agglomerate did not have a better performance because a requirement for superior performance is the rational use of water and energy concomitantly, and this is not the case of Atibaia D.

Table 5 LEED-ND Pilot version results

LEED-ND - Categories	Score/Total	%	Classification	
Smart Location % Linkage	19/30	63	Certified	40-49
Neighborhood Pattern & Design	27/39	70	Silver	50-59
Green Construction & Technology	5/31	16	Gold	60-79
Others	3/6	50	Platinum	80-106
Silver	**54**	**51**		

The pilot version (USGBC, 2007) was the one which best adapted to the Atibaia D housing agglomerate, first for being a specific method for urban areas and second for having indicators more easily adaptable to the Brazilian reality. A differentiating characteristic of the system is that it combined sustainability indicators with geo-processing information, something that has already been used in urban planning issues in developed countries (NOBREGA, 2006).

As a whole, the Atibaia D housing agglomerate performance was considered medium using the methods that assess building constructions and their surroundings only. In spite of the good performance using indicators related to the urban context such as infrastructure and services, the housing agglomerate does not present any initiative regarding the efficient use of potable water, there is no project for collecting rainwater or reuse of served water applied in the project and it does not present any initiative regarding the use of recyclable or recycled materials.

5. Final remarks

In terms of environmental practices, the Brazilian civil construction industry has recently started to address sustainable construction procedures, and most construction processes do not have a significant environmental impact.

Brazil does not have laws on water reuse or provisions for locally produced excess energy that may be thrown in the network; this makes the implementation of small alternative energy stations difficult, because they become economically unfeasible.

Indicators relating to daylight or natural lighting and sunlight achieved maximum level, for the fact of Brazil being a tropical country unlike the countries where the methods were developed, with a lower rate of sunlight.

Indicators relating to greater local density and location of the land close to services and transportation were met at their highest level: the housing agglomerates are located in dense areas and assisted by some services; the problem is more complex services such as hospitals and mainly employment centers that are usually located in downtown areas quite distant from the housing agglomerate.

Construction materials are a significant obstacle to be overcome, because there are almost no data about raw materials and manufacturing processes.

The social issue has to be addressed more deeply both in relation to labor and the local community.

In some methods that assessed the effective consumption of water and energy, the housing agglomerate performance was excellent, mainly because there is no purchasing power for greater consumption. The average consumption of a low-income family of a housing agglomerate is less than 18% of the consumption of an American family (EIA – Energy Information Administration, ANEEL – Agência Nacional de Energia Elétrica (Brazilian Agency of Electric Energy).

An important aspect to be pointed out is the difficulty faced by designers when creating a sustainable land development project. That type of project requires a systemic view and the constant work of a team, unlike the traditional method whereby projects are implemented in line. The project has to be designed to be highly efficient during use and operation, which sometimes means higher spending in the project and construction than the land developer wants to invest.

The comparison among the methods and their indicators reveals that all of them use practically the same indicators to asses the performance of their building constructions or urban areas. The comparison also shows that, in general, there are indicators that may be applied to different realities, because they are essential to demonstrate a good environmental or sustainable performance. What differentiates a system from another is its organization and structure, that is, how it organizes, assesses and weighs the criteria to provide the final classification to the project.

In general, the methods are applicable to the Brazilian reality. However, several indicators must be adjusted to the Brazilian reality for the certification of a sustainable project to be real on all levels, whether on the more general level that is the international level where all provide for the effective use of water and energy, responsible consumption of resources, etc., or on more specific sustainability levels that are the national, regional and local levels, which require compliance with specific needs.

Summary

In this paper we examine a process to provide designers information about the “Importance,” or ranked correlation of design decisions to explicit multi-criteria performance metrics. Historically, the Architectural, Engineering, and Construction (AEC) industries have relied on prescriptive requirements and experience-based precedent to promote building performance. The increasing complexity of building performance today, however, requires confronting multi-dimensional trade-offs across a wide range of performance metrics. With rapidly expanding goals and options competing with limited time and resources, designers struggle to frame, manage and extract value from data-rich simulations and analyses. The Importance process uses systematic exploration of problem and solution spaces to identify performance drivers. It builds upon building information modeling, model-based analysis and optimization, and decision analysis methods including sensitivity analyses, to systematically generate information about the impact of various design decisions on overall building performance according to a defined value function. In this paper we use a simple test case to demonstrate the Importance process and to highlight the design guidance created. Future work will test the usefulness of the Importance process by evaluating its ability to enable creativity in performance-based design.

1. Introduction

Buildings are a major source of demand for energy and materials and are currently responsible for approximately: 39% of carbon emissions, 65% of electricity consumption and 30% of raw material use in the United States (USGBC 2008). Managing and reducing these impacts has become a high priority for businesses and government. The American Institute of Architects (AIA) in the 2030 Challenge, and the Federal Government in the Energy Independence and Security Act, for example, call for 0% estimated annual fossil fuel energy consumption for new building designs by the year 2030. Throughout the industry, sustainable design is being defined using a variety of existing and emerging metrics, such as carbon footprint, energy cost savings, indoor environmental quality and embodied energy, to name a few. The complex nature of sustainability, however, forces trades-off between multiple and competing objectives. Whole-building energy simulation and optimization are important tools for facing the challenges of performance-based design. While building energy modeling capabilities currently lag behind multi-disciplinary analysis and optimization activities in other engineering disciplines such as aerospace (Mavris et al, 1998) or structural engineering (Ghobarah, 2001), researchers are currently working to automate collections of building performance simulations to model interactions among combinations of options, and to optimize for single or multivariate criteria (Ellis et al, 2006.)

Typical results of multi-criteria building optimization support Pareto-optimal design solutions, where a set of equally-ranked optimal solutions are identified (Grierson and Khajehpour, 2002). Such analyses serve as powerful and efficient filters of a given solution space, and rigorously identify a sub-set of “best” solutions that meet a prescribed set of constraints according to an implicit or explicit value function. Key to such an exercise and to multiple attribute decision making (MADM) in general, is the selection of a solution or set of solutions from a finite number of alternatives (Mavris et al, 1998.) As a result, the design guidance provided by either single or multi-criteria optimization is restricted in domain to the solution space modeled, and, as such, the process may be limited in its ability to enable creativity.

Creativity in design is a sought-after yet often ill-defined goal. More than 80 definitions exist in literature (Dasgupta, 1994). Frequently, the solution space for creative design is considered unbounded. Some have ascribed the unrestrained nature of creativity to the “co-evolution” of problem space and solution space, stating that the creative design process, unlike optimization, is not restricted to the search for a satisfactory solution within a fixed problem space. Rather, creative design is about parallel problem formulation and solution generation through constant iteration, synthesis and evaluation between spaces (Dorst et al, 2001). Central to many definitions of creativity are the concepts of usefulness and uniqueness. In the context of performance-based building design, we here define usefulness as generating value according to a prescribed value function, and uniqueness as lacking equivalent alternative(s) within the prescribed solution space.

Our proposed Importance process builds on the work of others who are automating building performance simulation tools as well as those who evaluate performance's sensitivity to decisions using either decision analysis or design of experiment techniques (Howard, 2007, Giunta et al, 2003). Our work generates a ranking of the numerical correlation of simulation inputs (problem space elements) to simulation outputs (solution space elements) for buildings. We prioritize design decisions according to specified building performance metrics using a defined value function. Our test case is a simple building that characterizes the trade-offs implicit to maximizing building performance. As practiced today, energy simulation analyses tend to fall short of providing satisfactory design guidance, and can be non-systematic and error-prone. Current research in building simulation is providing reliable ways to improve building analysis through (semi-) automation, parametric modeling and optimization; new developments in interoperability are providing greater flexibility in data exchange between software allowing a greater number of performance trade-offs to be assessed (Maile, 2007). Our Importance Process is a synthesis of various techniques with an additional post-processing step that presents designer information about the nature of the relationship of their design decisions to expected value. Future work will test the effectiveness of such a process on the usefulness and uniqueness of the solutions generated.

1.1 Points of Departure

Several key points of departure form the building blocks of our Importance process, including building information modeling, building simulation, process modeling, and decision analysis methods. Table 1 summarizes the level of assistance provided by these points of departure toward the six steps essential to our process. These steps are 1. identify problem space / define metrics; establish solution space / define value function 2. systematically generate options, 3. analyze options according to assigned metrics, 4. use value function to evaluate options, 5. prioritize decisions with regard to the value function / establish Importance 6. iterate problem and solution spaces. An “X” indicates the step is achieved; a “P” indicates the step is partially achieved using an existing method.

Table 1: Points of Departure, and their ability to assist with the 6 proposed steps in our process

Elements of design guidance	Establish problem and solution space	Systematically generate options	Analyze options according to assigned metrics	Use value function to evaluate options	Prioritize decisions with regard to the value function	Iterate and synthesize problem and solution spaces
Points of Departure						
Building Information Modeling (BIM)		P	P			
Building Performance Simulation			X			
Parametric Modeling	P	X	P			
Optimization	P	X	X	P		
Decision Analysis	X	P	P	X	X	P
Design of Experiment	X	X	P	X		P
Multi-attribute decision-making	X		X	P	X	

Table 1 shows that no one method currently supports all six of the steps necessary to create a strong decision basis in AEC industries to advance sustainable decision-making in buildings. Existing barriers may include erroneous inputs or limited accuracy of simulation engines (Judkoff et al., 2008); the complexity or computation challenges of probabilistic modeling (Grierson, Khajehpour, 2002); or the diversity of preferences of the stakeholders involved (Haymaker, Chachere 2005). While much pertinent and significant work exists in each area, further work is needed to fully integrate the various tools and theories into a new process that will allow AEC designers to better leverage building performance analyses to enable creativity and generate more useful and unique solutions according to an assigned value function.

1.2 Test Case

To create a test-bed for this investigation we adopted the Relocatable Classroom as a model. While simple, it serves to emulate the basic challenges in performance-based design: unknown building science relationships, uncertain assumptions, and competing performance trade-offs. The Relocatable Classroom model represents any portable or modular classroom in use across the United States. The structure is a simple rectangular box with typical dimensions of 24 feet wide, 40 feet long, and 12 feet high, limits which ensure it can be transported on the back of a flatbed truck. Detailed professional energy analyses have already been performed for this building type (Apte et al., 2005; DEG 2000) and California High Performance Schools has published a best practices manual for the Relocatable Classroom (CHPS, 2006). Figure 1 shows the basic geometric form: a single room outfitted with two windows with overhangs, one door, lighting, heating and cooling, a plenum. Since floor level is raised, insulation can be placed on all six sides of the structure.

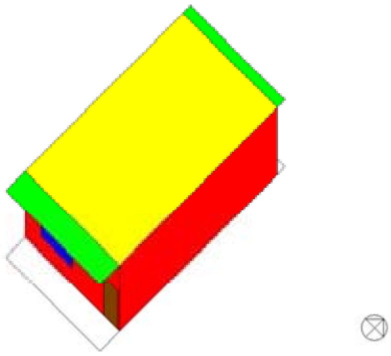

Figure 1 A Relocatable Classroom DOE-2 model represented in DrawBDL

Using the Relocatable Classroom we present the following challenge: to identify the set of design decisions that result in the most cost effective, energy efficient, and thermally comfortable Relocatable Classroom possible. To meet this challenge and investigate our Importance process, we developed a software tool to automate simulation runs and assess the Importance of available decisions. Our prototype tool is a vertical decision support model created as a wrapper to the building simulation tool DOE-2 (Winkelmann et al., 1993.) using Analytica modeling software (Henrion et al., 1996).

For our test case, we modeled seven design decisions: 1) Roof Color (white or metal) 2) Roof Construction (high, medium, or low insulation) 3) Wall Construction (heavy-weight construction, mid-weight construction, or light-weight construction) 4) Floor Construction (high, medium, or low insulation 5) Window Glass (clear, low-e or grey tint) 6) Lighting Power Density (1.66 w/sf or 1.22 w/sf) 7) Packaged Heating and Cooling (heat pump, indirect evaporative cooling, or none). Keeping everything else in the model fixed, we evaluated building's performance using three metrics: first cost, annual energy consumption and hours outside the range of thermal comfort. Finally, we calculated the sensitivity of a linearly weighted value function to these seven decisions. The following section outlines how our prototype software performs the Importance process on the Relocatable Classroom test case.

2. The Importance Process Applied

The Importance process assesses the correlation of individual design decisions to expected building performance. To identify key performance drivers on our simple test case, we exhaustively modeled all possible combinations of the seven decisions. For more complex building designs, we will rely on statistically significant sampling techniques to evaluate performance across an exponentially increasing solution space (Giunta et al, 2003). However, for the Relocatable Classroom model, in collaboration with software engineers at Lumina Decision Systems Inc., we developed a custom prototype, which automatically executes exhaustive simulation of building performance in DOE-2 and performs deterministic sensitivity analysis on the results within Analytica modeling software. Figure 2 diagrams the information flow in the evaluation of Importance in our test case. Note that in preliminary testing, we fixed all design decisions and uncertainties outside the seven decisions analyzed. We named our prototype tool Decisions Assistance Using Importance System (DAIS).

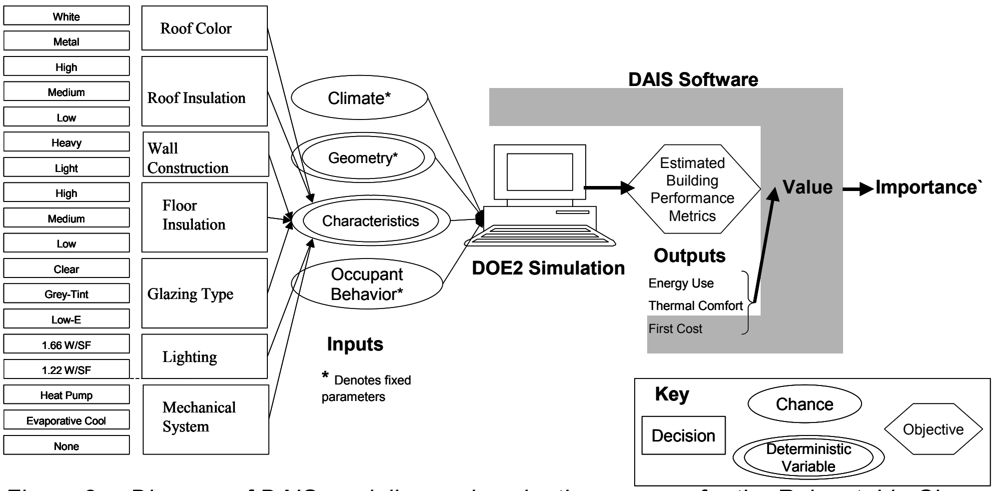

Figure 2 Diagram of DAIS modeling and evaluation process for the Relocatable Classroom

Figure 2 illustrates how DAIS wraps an existing building simulation tool to systematically evaluate the modeled solution space and assess the relative importance of the decisions considered. While several process integration tools exist (Noesis, 2004), little work has been done to date to use such wrappers in conjunction with building performance simulation. The following section outlines the structure of our DAIS prototype software.

2.1 DAIS Structure

In general, DAIS v. 1.0 automates the transfer of information from a user-selected design decision to an existing simulation engine, runs a statistically significant set of simulations, and returns the results to a vertical decision support model environment. Specifically, DAIS runs DOE-2 to estimate energy use and thermal comfort; it tabulates first cost directly in a look-up table; it calculates value using pre-defined value function; it performs a deterministic Importance analysis ranking the impact decisions inputs to assessed value; finally it presents this information to the designer in an Importance chart enabling the designer to better iterate problem and solution space. The following discussion outlines how DAIS v. 1.0 performs these 6 steps:

2.1.1 Step 1: Establish goals, identify metrics and define a value function

Systematic problem space exploration requires definition of project specific goals, metrics and value. We currently, define our problem space by selecting the performance metrics energy use, thermal comfort and first cost. We hard-coded the first cost associated with each option into DAIS. We defined and coded a linear weighted value function in DAIS using the select metrics.

The metrics selected for our test case represent the fundamental nature of performance trade-offs: improving one performance metric by adjusting one parameter may diminish the performance of a second metric. For example, a low cost, low energy building may result in unacceptable thermal comfort; a low energy building that maintains a high level of thermal comfort may result in a high first cost, etc. While a variety of metrics may be critical, (e.g.; indoor environmental quality, maintainability, acoustical environment, carbon emissions . . . etc.), for our test case we constrained our value function to depend on just three. As previously noted, this significantly bounds the problem and makes full analysis of the solution space achievable for our test case.

We normalized the metrics into units of dollars and used a single utility value function to assess value. Thermal comfort, for example, is calculated by the potential loss in productivity ($) for a given number of hours outside of a predetermined thermal range. Other research explores the plurality of AEC design decisions (Haymaker, Chachere 2005) or the qualitative nature of design judgments (Papamichael, 1993.) While, we will continue to develop and hone our value function as our research progresses, we currently use the following equation:

$$\text{Value} = \text{Thermal Comfort}(\$)*\text{Weight}_1 - \text{Total Energy Use}(\$)*\text{Weight}_2 - \text{First Cost}(\$)*\text{Weight}_3$$

The goal of normalizing the metrics to units of dollars is to establish designer indifference to a given set of options. In other words, using a single utility function, decision makers will be indifferent to any design solutions of equal value. This is distinct from some multi-attribute decision making, where it can be difficult to objectively balance alternatives using incomparable metrics.

2.1.2 Step 2: Systematically generate options

DAIS automates the exchange of information to and from the building simulation program DOE-2 to a vertical decision support model environment. It does this by systematically 1) generating a DOE-2 "include" (.inc) file in Analytica; 2) executing a DOE-2 simulation run using this include file; and 3) returning the resulting data.

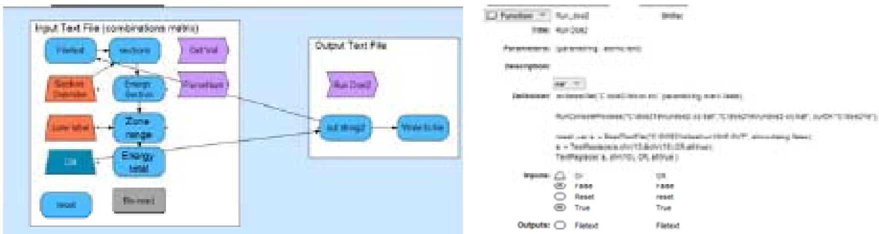

Figure 3 DAIS generates combinations (left), runs a console process in Analytic (right) and executes a DOE2 simulation. The results are fed back to DAIS (left)

Note that existing energy simulations tools do not necessarily successfully or accurately all model building design alternatives (Judkoff et al., 2008). While errors do not occur for our simple test case, future research will have to be prepared for and address a host of challenges related to simulating complex building designs.

2.1.3 Step 3: Analyze options according to assigned metrics

The simple test case of the Relocatable Classroom constrains the solution space to 972 possible design alternatives. In preliminary analysis, we fixed the uncertainties related to 1) climate and 2) occupancy schedule. In addition, we fixed the orientation of the building. Analysis was limited to varying the building performance characteristics for the following design decisions: 1) Roof Color 2) Roof Construction 3) Wall Construction 4) Floor Construction 5) Window Glass 6) Lighting Power Density 7) Packaged Heating and Cooling. Using the results simulated by DOE-2 for annual energy consumption and thermal performance, along with the first cost data tabulated within DAIS, DAIS evaluates value for each design alternative modeled using the defined value function.

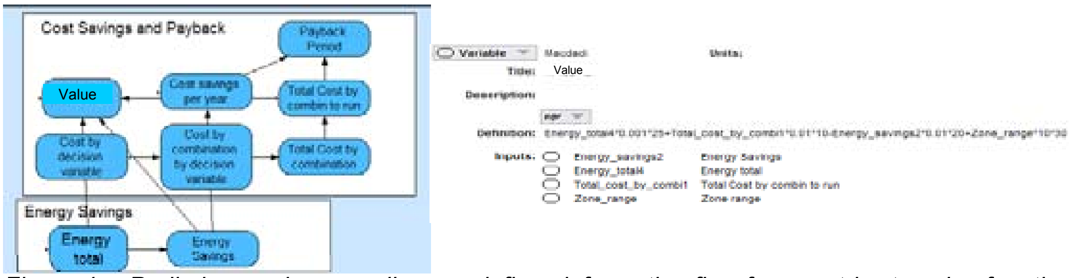

Figure 4 Preliminary relevance diagram defines information flow from metrics to value function, (left); Sample value function defines value in DAIS (right)

2.1.4 Step 4: Use value function to assess Importance

For the simple Relocatable Classroom model, DAIS calculates Importance using high-low sensitivity analysis over all 972 design alternatives.

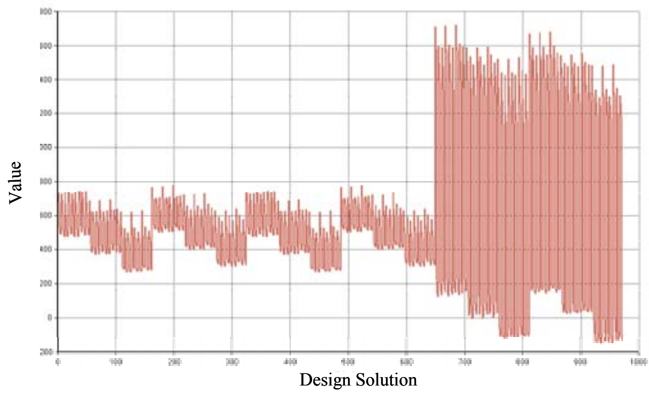

Figure 5: Value function assessment for all defined Relocatable Classroom design alternatives

Figure 5 illustrates the value function evaluated in DAIS over the entire solution space as defined by the seven design decisions modeled. This graph visibly demonstrates that certain decisions have significantly more impact on defined value than others.

2.1.5 Step 5: Prioritize decisions with regard to the value function

DAIS presents user information about the ranked correlation of design decisions to the expected value of building performance in the form of an Importance chart. Figure 6 shows such a chart for energy performance for the Relocatable Classroom in a cold climate. Starting at a given baseline, each decision can be "upgraded" to a higher performance option (e.g., R-11 to R-13 insulation) to the highest (R-19 insulation) option. Figure 6 shows the potential impact of the first upgrade according to the defined value function (in blue) and the potential impact of the second upgrade (in green.) In the case of windows, where the cost "upgrades" show a negative impact on performance for the given design scenario tested: a school building (winter schedule) in a cold climate, blocking increased amounts of solar heat gain results in an overall value function reduction.

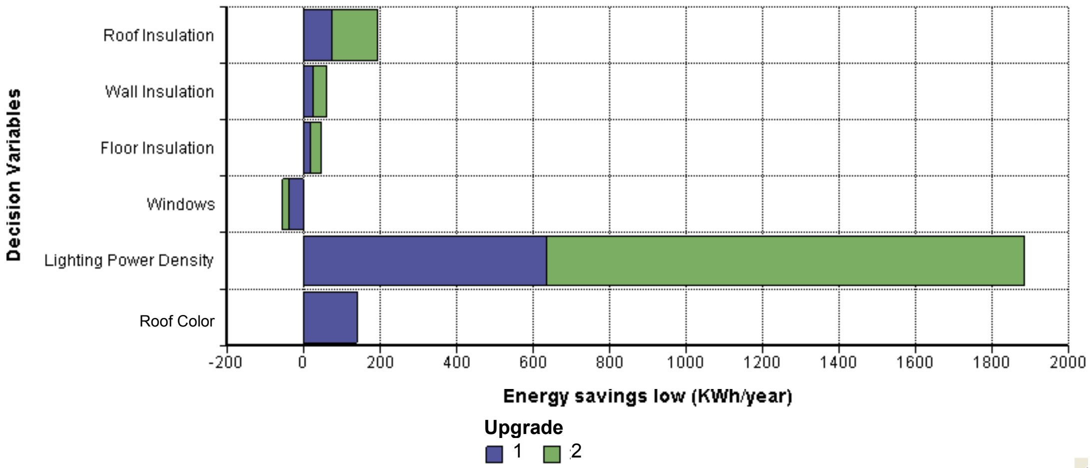

Figure 6: Chart showing "Importance" analysis results for the Relocatable Classroom in DAIS v 1.0

The Importance chart shown in Figure 7 represents post-processing of traditional optimization or design of experiment (DoE) performance results. It is made possible in DAIS by linking a vertical decision support tool, Analytica (equipped with sensitivity analysis functionalities) to a building performance simulation tools, e.g., DOE-2. Since systematic exploration of a problem space is required to evaluate sensitivity, optimum or pareto-optimum solutions are identified during the process. However, we propose that rather than ending with the identification of these generated optimum(s) within a fixed problem space, the addition of post-processed sensitivity analysis will be critical to promoting creativity in performance-based design for buildings.

2.1.6 Step 6: Iterate and synthesize problem and solution space

The design assistance provided by building simulation and analysis tools in performance-based design, ultimately, is a function of how well these tools help designers navigate performance trade-offs to promote creative, useful and unique, building designs of value. Existing challenges to optimization or design of experiment approaches include proper framing of the multi-dimensional problem spaces and accurate evaluation of the elusive solution spaces associated with complex building design. To the extent that the problem and solution space are properly characterized, the systematic search of optimization may leave little room for innovation. However, if characterization is imperfect, a computer generated "optimum" design may, in fact, be inferior to an unrealized alternative. To promote creativity, design exploration should maintain design freedom while supporting knowledge transfer (Mavris et al, 1998.) Our intuition is that the Importance process, building on systematic and automated computer-based search, may offer design guidance beyond the bounds of the modeled solution space and provide further opportunity to iterate and synthesize problem and solution spaces. Our on-going research will focus on cataloging the extent to which the Importance process enables creativity and generates unique and useful solutions as compared to traditional performance-based design methods.

3. Conclusions and Future Work

Today's AEC professionals are struggling to reconcile competing design trade-offs in performance-based design. Currently, trial and error techniques dominate while optimization applications are being developed. Building on modeling insights from other fields and as demonstrated by DAIS, the AEC community may be able to leverage existing building simulation tools using vertical decision support models. By applying the Importance process and presenting designers information about the correlations of their design decisions to building performance objectives, designer may be better equipped to understand the behavior of problem and solution spaces, and better able to transfer this knowledge beyond the bounds of what has been modeled to generate new, creative design solutions. Significant opportunities exist for improved design guidance in performance-based, sustainable design. Impacts on practice may include incentive for vendors to create new functionalities in energy-modeling software and motivation for designer to seek out Importance information when deciding how to allocate design resources. Future work will test the impact of the Importance process on enabling creativity by comparing the usefulness and uniqueness of design solutions generated with and without the assistance of the Importance process.

A REVIEW OF APPROPRIATENESS OF INTERNATIONAL ENVIRONMENTAL ASSESSMENT TOOLS FOR A DEVELOPING COUNTRY

Nosizo SEBAKE[1]

[1] CSIR, Built Environment, Architectural Sciences. P.O. Box 395, Pretoria, 0001. ssebake@csir.co.za

Keywords: Sustainable Building Assessment Tools, SBAT, assessment methods, rating tools

Summary

The World Green Building Council (WGBC) has 10 existing members including the United Kingdom, Taiwan, Australia and America. These members have adopted building rating systems, such as Building Research Establishment Environmental Assessment Method (BREEAM), Comprehensive Assessment System for Building Environmental Efficiency (CASBEE), Green Star and The Leadership in Energy and Environmental Design, respective in order to stimulate market demand for high-performance buildings.

The Green Building Council for South Africa (GBCSA) was established by the South African Property Owners Association earlier this year (May 2007) and aims to promote environmentally sustainable practices within the South African commercial and industrial property market.

As with the existing members, an appropriate rating system will be required by the GBCSA. The paper studies the implication of the use of any of the three aforementioned rating systems for South Africa's developing context and compares these systems against the South Africa's indigenous rating tool, Sustainable Building Assessment Tool (SBAT).

The paper suggests that the SBAT is a more appropriate tool for use within a developing country and presents findings for the study.

1. Introduction

The concept of sustainable development has been defined by the World Commission on Environment and Development (WCED) in their Brundtland Report as meeting the needs of the present without compromising the ability of future generations to meet their own needs (WCED, 1987). This was recognized as a balance between the environmental protection, economic growth and social development dimensions in 1992 at the Rio Declaration by the United Nations NGO Committee on Sustainable Development (UN, No date a).

According to Cole (2003) environmental assessments and labeling programs are currently undertaken on a voluntary basis, but are considered as having the potential to create market demand for green buildings.

Building environmental rating systems provide a way of showing that a building has been successful in meeting an expected level of performance in various declared criteria (Cole, 2003). Cole (2003) adds that it is in the adoption and promotion of such systems that contribute significantly to the shifting of the public's awareness and perceptions of what building quality is. This can be confirmed by the increasing number of people demanding information on environmental aspects of buildings, such as whether or not a building was good for their health or if it fit into a sustainable society (Carlson & Lundgren, nd) since the development of the very first building assessment tool, the Building Research Establishment Environmental Rating Assessment Method (BREEAM).

1.1 Relevance

Currently almost each European country, the United States of America, Canada, Australia, Japan, Hong Kong and South Africa have their own assessment tool (Silva, 2007). Da Silva adds that each of these tools shares a *"common goal to stimulate market demands for higher environmental performance levels"* and with "the remarkable exception of South Africa's SBAT," all of the existing tools *"deal exclusively with the environmental dimension of sustainability"* (Silva, 2007).

1.2 Scope of Research

The research focuses on the review of current literature and the review of the five rating tools used by the existing member countries of the World Green Building Council (WGBC).

1.3 Research Aim and Questions

The research aimed to review changes that have occurred globally within the sustainable development field. In light of the changes found, the research questions derived are as follows:

- How do the global changes within the field of sustainability affect the SBAT?
- How does the SBAT compare with the international tools used by national GBCs used?

1.4 Structure of the Paper

The paper is structured under the following heading; background, methodology, literature review, assessment framework, discussion and conclusions.

2. Background

2.1 South African Context

The Republic of South Africa is considered to be the most developed and modern country on the African continent. Since 1994, when the first democratic government was elected, South Africa has had positive economic growth (Knight, 2006). However, on the other side of this positive aspect is a country which still has major social and economic problems including poverty, inequality, unemployment, HIV/Aids and property and personal insecurity (Beall et al, 2005).

2.2 SBAT framework

The SBAT was developed to support the development of a more sustainable built environment within South Africa's developing country context. The tool draws on international best practices and has been refined through use in South Africa that reflects the local context and policy. The tool provides a robust framework/methodology that assesses the sustainability performance of proposed designs and existing buildings. The framework/methodology includes five criteria in all three sustainability aspects, namely:

- Economic – local economy, efficiency, adaptability and flexibility, ongoing costs, capital costs;
- Environmental – water, energy, waste, site, materials and components; and
- Social – occupant comfort, inclusive environments, access to facilities, participation and control, education, health and safety (Gibberd, 2001).

Each of the 15 criteria has a set of five sub-criteria linked to indicators that are used to measure the sustainability performance of a proposed design or existing building (see Table 1). The SBAT has been used to assess commercial, residential buildings.

Table 1 The Structure of the SBAT

Sustainability aspect	Criteria	Sub-Criteria	Indicator
EC ECONOMIC	EC1 Local Economy	EC1.1 Local Labour	Use of local (from within 50km of the site) labourers
		EC1.2 Local Materials	Building material sourced from within the country
		EC1.3 Local Materials and Components	Material and components sourced from within the country
		EC1.4 Local Furniture and Fittings	Furniture and fittings sourced from within the country
		EC1.5 Maintenance	Maintenance and repairs can be undertaken by local SMMEs (turnover of <R5m)
3 Sustainability aspects in total	15 criteria in total	75 sub-criteria in total	75 indicators in total

Source: Sebake and Gibberd, 2008

3 Methodology

Literature of global commitments to sustainable development was reviewed. This led to the development of an assessment framework which will be used to assess the GBC rating tools.

4 Literature Review

4.1 Global Commitments to Sustainable Development

4.1.1 Global Monitoring Report [2007]

The development of the Millennium Development Goals (MDGs) derived from the Millennium Declaration in 2000, at the United Nations Millennium Summit. The MDGs consist of eight goals, and 18 concrete targets for development; which outline the shared responsibilities of *“developing countries to pursue poverty reduction and good governance and of developed countries to support the efforts of developing countries; by increasing aid, opening trade to exports from developing countries, and providing debt relief”*. The MDGs fall within the three spheres of sustainable development, namely economic (poverty alleviation, development of global partnerships), environmental (ensure environmental protection) and social (achieve universal primary education, promote gender equity, reduce child mortality, improve maternal health and combat HIV/Aids and other diseases).

The World Bank’s Global Monitoring Report (GMR) 2007 is the fourth annual GMR. The report takes into account the progress taken toward the achievement of the MDGs. It further assesses the contributions of developing countries and other international institutions in their undertaking toward meeting the commitments.

The 2006 GMR (WB, 2006) showed that governance was needed as a core continuous part of the wider task of monitoring the progress of reaching the MDGs.

The current GMR highlights 2 areas that need more global attention, namely gender equity and fragile state (WB, 2007).

4.1.2 Global Reporting Initiatives third generation (G3) [2006]

A third generation of GRI Guidelines, G3, was released in October 2006 following several years of research, development, and consensus-seeking by multi-stakeholder technical working groups, each assigned to focus on different parts of the guidelines ending with a period of public participation and comment. The G3 replaces previous versions of the GRI Guidelines released in 2000 and 2002. The G3 Guidelines provide universal guidance for reporting on sustainability performance (including economic, environmental and social aspects). This means they are applicable to small companies, large multinationals, public sector, NGOs and other types of organizations from all around the world. It is the way that the guidelines are created (through the multi-stakeholder, consensus seeking approach) that enables them to be so broadly applicable. (http://www.globalreporting.org)

The guidelines provide a set of core indicators, which have been developed through GRI’s multi-stakeholder participatory processes. Additional indicators represent emerging practice that may only be relevant to some organisations. (GRI, 2006)

4.1.3 The Living Planet Report [2006]

The World Wildlife Fund (WWF) published the first Living Planet Report in 1998. The report still shows the state of the natural world and the impact of human activity upon it. It has been published biennially since the late nineties. The current report developed in collaboration with the Zoological Society of London and the Global Footprint Network corroborates that humanity is using the planet’s resources faster than they can be renewed – the latest data obtainable (for 2003) shows that humanity’s Ecological Footprint has more than tripled since 1961. Humanity’s footprint now surpasses the world’s ability to regenerate by about 25 per cent (WWF *et al*, 2006).

In addressing sustainable development the report requires that the world, on average, meets at a minimum of two criteria, which are well known accounting tools for measuring progress toward sustainability in the areas of the socio-economic and ecological imperatives. The tools are the Human Development Index (socio-economic) and Ecological Footprints (ecological) (WWF *et al*, 2006).

4.1.4 Strategic Framework for Sustainable Development in South Africa

The strategy was developed DEAT to articulate South Africa’s national vision for sustainable development and direct its planned participation to re-adjust South Africa’s development path towards sustainability. It provides the basis for a long-term process of integrating sustainability as a key component of the development dialogue and shows South Africa’s commitment to the principles developed at international summits, described above, and conferences in the economic, social and environmental fields

4.1.5 Johannesburg Securities Exchange [2004]

The Johannesburg Securities Exchange (JSE) has developed criteria to measure the ‘triple bottom line’ performance of companies in the FTSE/JSE All Share Index. In May 2004, it launched the first Socially Responsible Investment (SRI) Index, which is built on four pillars of sustainability, namely: corporate governance, the economy, the environment, and society (Figure 1. Source: Barron and Gauntlett (2002) and

Department of Environmental Affairs and Tourism (2006)). At present, only forty nine companies are listed on the SRI Index. For the reason that listing is voluntary, the sample population on which data are based is heavily weighted towards the leading performers in the field of corporate sustainability, and the results from a random sample of listed companies would produce lower, less positive results. It is known, however, that holding, property, and investment companies have extremely limited awareness of environmental impacts and issues and have no significant institutional structures in place to deal with them (DEAT, 2006).

Figure 1 Integrated Model representing sustainable development

Most companies dealing in the material economy (that is, those that handle, process, and transform materials/ substances) are addressing environmental concerns at some level and nearly three-quarters of the companies assessed on the SRI Index (71%) had protected environmental principles in a policy or formal mission statement. Only 55% of the companies listed, however, have formal policies in place to ensure that their suppliers are paying attention to sustainability, and there is little evidence that these policies are influencing supplier behaviour.

The majority of the businesses claim to have all the elements of environmental governance and management in place, but it was complex to assess their efficacy in practice. Of these businesses, 84% give responsibility for the environment to a senior executive and/or a board committee.

4.2 International Environmental Assessment Tools

In May 2007 the South African Property Owners Association (SAPOA) established a Green Building Council of South Africa (GBCSA). This was in order to promote environmentally sustainable practices in South Africa's commercial and industrial property industry (Creamer Media, 2007). Australia's Green Star was selected as a basis of a national rating system. The Australian rating system will be customised for South Africa (GBCSA, 2007).

South Africa is one of 17 countries in the process of forming a national Green Building Council. These national councils will be member countries of the existing World Green Building Council (WGBC) which was founded in 1999 following the prior existence of the United States Green Building Council. The goal of this world-wide council is to intensify the shift from convention to more sustainable practices within the global property industry.

The existing member countries include the United States, Australia, Emirates, Japan, Russia, Spain and United Kingdom. Table 3 presents the existing member countries and the rating systems used in each country. It is interesting to note that LEED and Green Star have been adapted for use in other countries and that the BREEAM, CASBEE and EEWH are only used nationally.

Table 2 WGBC Member Countries and the Rating Systems used

Country	Rating System Used
Australia	Green Star
Canada	LEED Canada N-C 1.0 (Adapted from GBC USA's rating system)
Emirates	LEED Green Building Rating System (Adapted from GBC USA's rating system)
India	LEED India (Adapted from GBC USA's rating system)
Japan	CASBEE
Mexico	LEED Green Building Rating System (Adapted from GBC USA's rating system)
New Zealand	Green Star NZ Adapted from GBC Australia's rating system)
Taiwan	Ecology, Energy saving, Waste reduction and Health (EEWH)
United Kingdom	BREEAM
United States of America	LEED

The rating systems used by the existing GBCs will be reviewed, together with the SBAT:

- The Building Research Establishment (BRE) developed BREEAM in 1990, which has been adapted for Canada, Emirates, India and Mexico (see Table 2). The method is available for offices, housing, courts, industrial units, prisons, retail and schools.

  BREEAM uses nine categories to assess building performance, including management, energy use, health and well-being, pollution, transport, land use, ecology, materials, water. (http://www.breeam.org/)
- The United States GBC (USGBC) developed the LEED (1993) tool, which has been adapted for Canada, Emirates, India and Mexico (see Table 2). LEED assessment tools are voluntary, consensus-based national rating system for developing high-performance, sustainable buildings.

  LEED uses six categories, including sustainable sites, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, innovation. (http://www.usgbc.org/LEED/)
- Comprehensive Assessment System for Building Environmental Efficiency (CASBEE, 2002), a labeling tool based on environmental performance of buildings developed in Japan by the Japan Sustainable Building Consortium (JSBC). The tool evaluates new, existing or renovated offices, schools and apartments.

  CASBEE uses four primary categories: energy efficiency, resource efficiency, local environment, indoor environment. (http://www.ibec.or.jp/CASBEE/english/index.htm)
- Australia developed Green Star (2003), which has been adapted for use by New Zealand. This environmental rating scheme evaluates the environmental design and achievements of buildings. Green Star drew from existing rating systems including BREEAM and LEED, but it is tailored to the Australian marketplace and environmental context. The rating scheme is used to assess new and existing offices.

  Green Star uses ten categories including energy, management, water, indoor environmental quality, transport, ecology and use, emissions, materials, innovation. (http://www.gbcaus.org/)
- Ecology, Energy saving, Waste reduction and Health (EEWH) System, is a green building certification system in Taiwan. It was launched in 1999. No information was available regarding the building types and building lifecycle stages assessed.

  EEWH comprises nine indicators that fall into four categories - ecology, energy saving, waste reduction and health (Wikipedia contributors, 2008).

5 Assessment Framework

6 Discussion

Table 4 presents a summary of the literature reviewed. This finds that since the broadening of the scope of sustainability in the early 1990s, a number of organizations have followed suite (i.e. the GRI and the Living Planet).

The framework for assessing the performance of buildings developed by ISO has, however, continued to concentrate on the environmental performance. This focus on environmental aspects can also be seen in the assessment tools reviewed (see Table 2).

It is interesting to note that although the JSE requires listed companies to report on all aspects of sustainability, including non-financial ones (social and environmental), the newly formed GBCSA's focus is solely on environmental issues (as derived from the council's use of the environmental assessment rating tool, Green Star).

Table 4 Summary of the international and local activities related to Sustainable Development

Year	Economic	Social	Environmental
2004	Johannesburg Stock Exchange (JSE) Securities Exchange – the Socially Responsive Investment Index		
2005	Strategic Framework for Sustainable Development in South Africa		
2005			ISO: Framework for Assessment of Environmental Performance of Buildings
2006	Global Reporting Initiative third generation (G3)		
2007			Green Building Council of South Africa
2007	The Living Planet Report		

Cole (2003) stated that assessment methods would need to broaden *"the scope of discussion beyond environmental responsibility"* by embracing *"the wider agenda of sustainability"* which equates social and economic aspects with environmental ones.

7 Conclusions

There have been some activities within the sustainable development field since the SBAT was completed in 2003; however none of these activities negatively affect the SBAT framework.

In contract, they serve to confirm that the SBAT reflects the progress of the wider field of sustainability performance measurement, which seeks to broaden *"the scope of discussion beyond environmental responsibility" by embracing "the wider agenda of sustainability"* (Cole, 2003).

The SBAT is currently the only assessment tool which assesses all three aspects of sustainability; however, it has not maintained its potency through the release of updated versions as suggested by Cole (2003).

SUSTAINABLE ASSET MANAGEMENT: REDUCING THE ENVIRONMENTAL EFFECTS RELATED TO MAINTENANCE AND PARTIAL REPLACEMENT OF FAÇADE COMPONENTS

Inge BLOM MSc[1]

[1] Delft University of Technology, OTB Research Institute for Housing, Urban and Mobility Studies, Delft, the Netherlands, i.s.blom@tudelft.nl

Keywords: façade, maintenance, replacement, life cycle assessment (LCA), energy, transport, service life

Summary

In this research, the factors that determine the environmental effects related to maintenance and replacement of façade components are analysed using an activity scenario analysis based on life cycle assessment.

A scenario consists of maintenance activities, such as painting, and replacements of façade components, such as glazing. Additionally, energy used for space heating which is influenced by the thermal insulation of the façade, and transportation of maintenance workers are taken into account. The scenarios are created for a reference apartment building.

The data used to calculate the environmental effects of the scenarios are from the IVAM LCA database. The contributions to nine environmental effects as described in the CML method are calculated. A calculation tool is developed to be able to calculate the environmental effects that are caused in each year of the scenario. With the tool, multiple building components can be defined and specific scenarios can be assigned to them. This way, components that are exposed to different local climate conditions can be treated differently, according to the need for maintenance. The results of the calculation show the accumulated environmental effects over the years. Scenarios of up to 150 years can be calculated in order to assess long term effects of strategic decisions.

The results of the research show that the use of energy for space heating is the factor that contributes most to the environmental effects. Therefore, improving the thermal insulation of glazing significantly reduces the environmental burden. Transport related to façade maintenance activities and replacement of components is another important factor. Other factors that influence the environmental effects of the activity scenarios are the materials of the façade components and the time intervals between activities.

1. Introduction

Buildings make a significant contribution to the human-induced environmental burden. This is not only due to construction and demolition; activities undertaken during the operational phase, such as building maintenance and energy use, also have environmental effects. In Europe, on average, about 100 times more houses are in use than are built annually, meaning that the existing housing stock is both slowly growing and ageing (Federcasa 2006; Itard *et al.* 2008). Moreover, the thermal quality of the existing housing stock is, on average, lower than that of new housing (Beerepoot 2007; Itard *et al.* 2008). Thus, in order to lessen the annual impact of housing on the environment, it would be more efficient to improve the existing housing stock than simply to focus on building new houses.

In this research, the focus is on the maintenance of existing buildings. 4 variables related to maintenance are assessed: the use of different materials for building components or during maintenance activities; the times at which maintenance activities and replacements take place; the transportation of maintenance workers during activities; and energy used for space heating.

The aim of the research is to:

- Assess which (combinations) of the variables mentioned above have the greatest potential to lessen the environmental impact related to building maintenance.
- Assess how maintenance scenarios can be made more sustainable, and how the knowledge acquired in the course of the research can be implemented in practice.

In the following section, a brief explanation of the methodology used is provided. Next, the results of the research will be shown. Finally, the conclusions of the research and the implementation of the findings into practice will be discussed.

2. Methodology

Life cycle assessment (LCA) can be used to quantify the contribution of products or activities to environmental problems, or environmental effects (ISO 1997). The following environmental effects are taken into account:

- abiotic depletion: a measure of the speed and rate at which non-renewable materials are depleted;
- global warming: a measure of the amount of greenhouse gases emitted to the atmosphere, which leads to heat radiation being kept in the atmosphere;
- ozone layer depletion: a measure of the amount of substances emitted which will break down ozone in the stratosphere, which reduces protection against harmful solar radiation;
- photochemical oxidation: a measure of the amount of substances emitted which will form ozone in the lower atmosphere, leading to health problems;
- human toxicity: a measure of the emission of substances which are toxic for human beings;
- fresh water aquatic ecotoxicity: a measure of the emission of substances to water, which are toxic for fresh water ecosystems;
- terrestrial ecotoxicity: a measure of the emission of substances to the soil, which are toxic for ecosystems on land;
- acidification: a measure of the emission of substances which will lead to damage to water and forest ecosystems;
- eutrophication: a measure of the emission of substances that will lead to a lower biodiversity.

The environmental effects are determined by first making an inventory of the flow of all substances to and from the environment over a building's complete life cycle. Each substance's potential contribution to pre-defined environmental effects is calculated. In order to do this, for each environmental effect, the impact of a particular of substance flow is compared with that of a reference substance. This process is called the impact assessment. The complete set of environmental effects is known as the environmental profile of a product or activity. This research used the CML 2000 LCA method to calculate the environmental profiles of maintenance activities and replacements (Guinée 2002). Once the environmental effects of a complete maintenance scenario have been calculated, the results can be interpreted.

A building's maintenance scenario describes the maintenance and replacement activities that take place during its operational phase. This research is limited to doors, windows and door and window frames. The activities taken into account in this research are: painting, replacing sealant, replacing hinges and locks, and replacing building components, such as frames, doors, windows and glazing. Each scenario starts with the replacement of all building components.

A maintenance scenario provides the following information:

- the types of activities taking place;
- the first occurrence and frequency of maintenance activities;
- the first occurrence of and time interval between replacements;
- the interdependence of the activities.

Figure 1 Floor plan (left) and side view (right) of the gallery flat reference dwelling (SenterNovem 2007).

For this research, an assessment is made of the maintenance activities specific to a Dutch reference building, a gallery flat built between 1966 and 1988(Novem 2001; SenterNovem 2007). Figure 1 shows the building's floor plan and a side view. The reference building consists of ten floors of seven dwellings each along and open gallery. Because maintenance activities are often performed simultaneously on multiple dwellings, the entire building of 70 dwellings is assessed.

3. Results

In this section, two sets of results will be dealt with. The first set contains scenarios in which the aspects of energy used for space heating and transportation of maintenance workers is taken into account. These factors are indirectly related to maintenance and replacement of building components. The second set of results contains scenarios in which different materials for building components and paint have been used, as well as scenarios in which the factor of time has been investigated.

The first set of results is shown in Figure 2 and Figure 3. On the x-axis, the environmental effects explained above are shown. Each of these environmental effects has its own unit, which is why the results are indexed. Additionally, the differences between the scenarios can be shown best by indices. Figures 2 and 3 contain comparisons between several maintenance scenarios. The first scenario is a reference scenario which is indexed at 100. It contains maintenance and replacement activities which take place at reference intervals. The glazing in the reference building is plain double glazing. Energy used for space heating and transportation of maintenance workers are not taken into account. The reference scenario is compared with a scenario in which transportation of maintenance workers over a 50km one-way travel distance is taken into account. The environmental impact of the total scenario increases by 5-110% when transportation is taken into account. Thus, taking transportation into account is important and reducing the environmental impact related to transportation is an effective measure in reducing the overall environmental impact. A reduction of environmental impact related to transportation can be realized by reducing the distance travelled, switching to fuels that are more environmentally friendly or switching to cars that use fuels more sparingly.

The third scenario in Figure 2 is a scenario in which energy used for space heating is taken into account. It shows that the environmental impact increases by 30-970%. This means that energy use has a much bigger influence on the environment than all maintenance activities combined. When the thermal quality of the façade improves, the energy used for space heating decreases. In the fourth scenario, the plain double

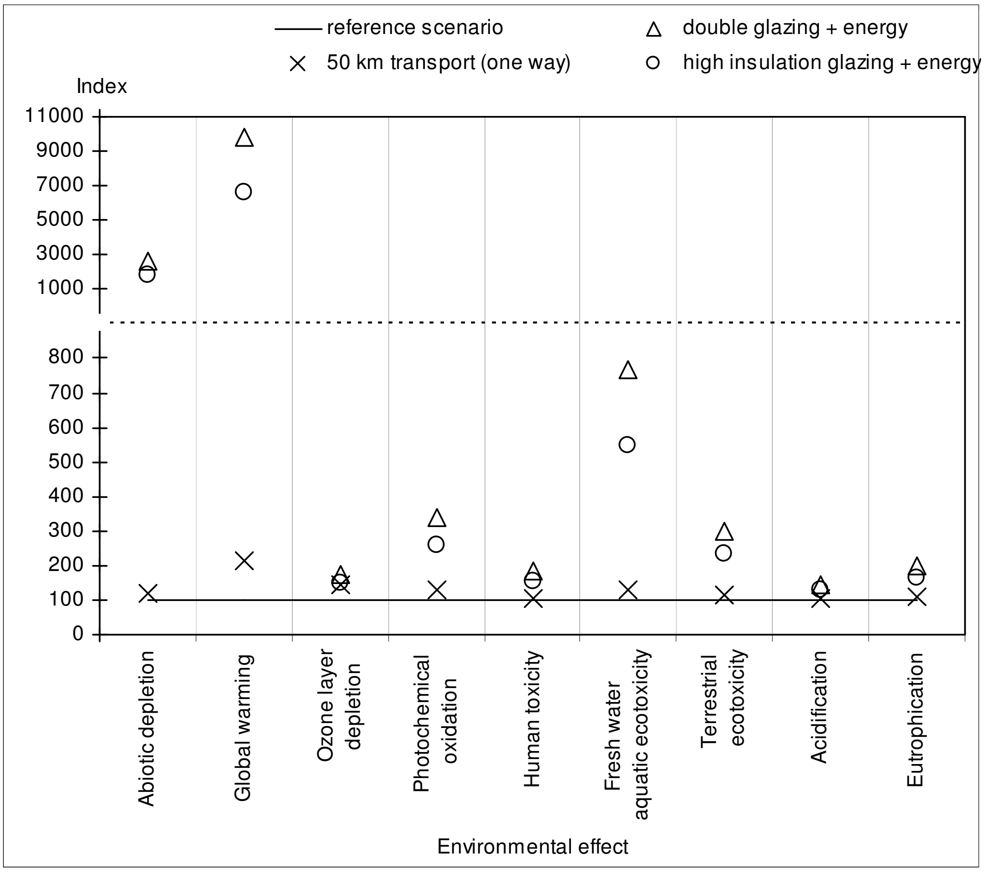

Figure 2 Comparison between the reference scenario and scenarios in which transportation of maintenance workers or energy used for space heating are taken into account.

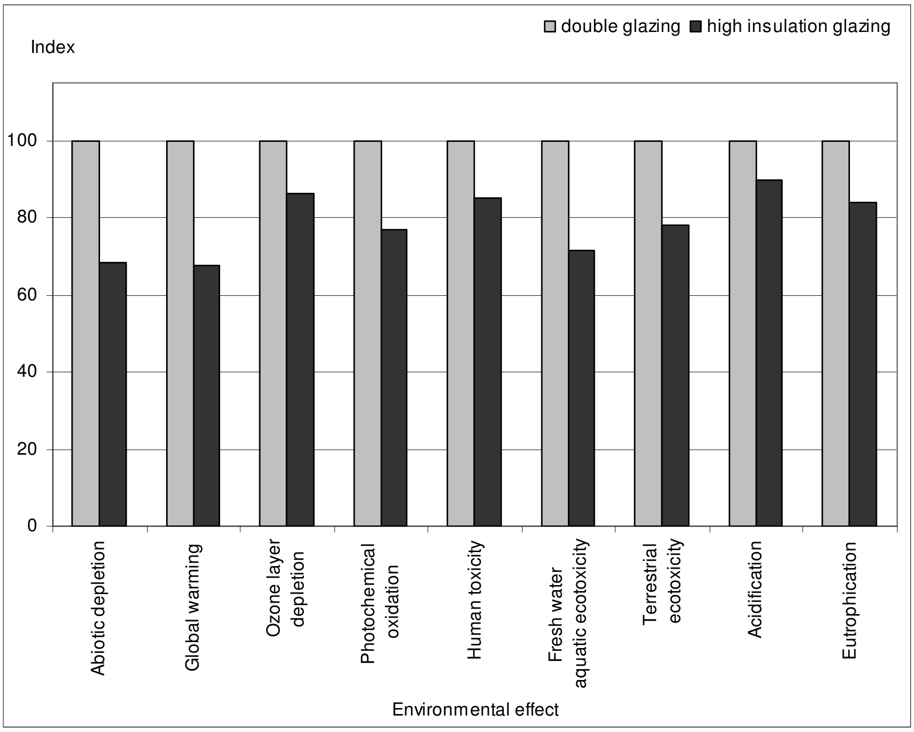

Figure 3 *Comparison between the reference scenario which contains double glazing and a scenario in which the glazing is replaced with high insulation glazing. Energy used for space heating is taken into account.*

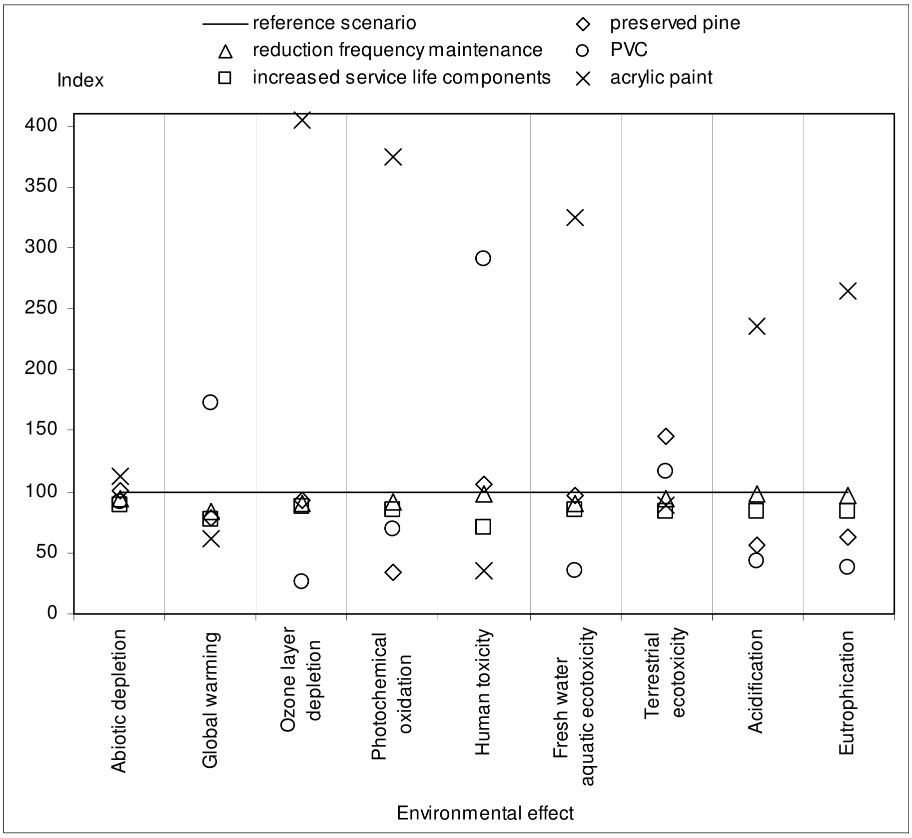

Figure 4 *Comparison between the reference scenario and scenarios in which different materials are used or different time intervals between activities.*

glazing is replaced by high insulation thermal glazing. As a consequence, the energy use for space heating decreases by 32.5%. Both Figure 2 and Figure 3 show the results of the third and fourth maintenance scenarios. In Figure three, the reference scenario including energy use is indexed at 100. The results show that replacing double glazing with high insulation glazing leads to an overall improvement of 10-30%. Moreover, the environmental effects that show the biggest improvement – abiotic depletion and global warming – are also the effects with which governmental policies are concerned. These policies aim at reducing CO_2 emissions and the use of non-renewable resources. Thus, replacements of building components which reduce the energy used for space heating are very effective in reducing environmental burden of existing dwellings.

The second set of results is shown in Figure 4. The reference scenario in that figure is the reference scenario of Figure 2, including transportation of maintenance workers. The reference building contains building components made of meranti FSC timber, painted with high solid paint. In all scenarios in Figure 4 transportation of maintenance workers is taken into account.

A comparison was made between the reference scenario and scenarios in which preserved pine or PVC building components are used. Figure 4 shows that the use of different materials leads to an increase of the contribution to some environmental effects and a decrease of the contribution to other effects. The same is true for the use of a different kind of paint, which is shown by a scenario in which acrylic paint is used.

In Figure 4, a comparison is also made between the reference scenario and two scenarios in which the service life of building components and the frequency of maintenance activities are lengthened and decreased respectively. Both measures show an improvement of all environmental effects, though the changes are not as big as when different materials are used. Figure 4 shows the results after 50 years of maintenance. The benefits of lengthening the service life of building components and decreasing the frequency of maintenance activities increase in time, because more replacements and activities will be avoided in a longer time period. Lengthening the service life of building components is more effective than decreasing the frequency of maintenance, but these aspects are related: the service life of a building component might be lengthened by increasing the frequency of maintenance. In that case, there will be a balance between the reduction of environmental impact realized by the lengthening of the service life and the increase of environmental impact by increased maintenance activity and related transportation.

4. Discussion

For all scenarios, a transportation distance of 50km one-way for maintenance workers has been taken into account. According to maintenance companies, this is a realistic estimate for the Netherlands. If the transport distance were to be altered, the conclusions of the research would remain the same. However, the differences between the scenarios might be less significant if the transport distance would be shorter.

This research does not take transportation of building components from the harbour in Rotterdam to the building site into account. If that would have been taken into account, then the environmental impact associated with replacing building components would increase equally for all scenarios. The positive impact of lengthening the service life of building components would thus increase. The overall conclusions of the research would not change considerably.

The true values for the service life of building components and maintenance intervals strongly depend on building design, quality of the technical details and the local climate. The reference values used in this research are a mean value for the Netherlands, based on information of producers of building components. In practice, the service life of building components can be much higher if it is designed well, but it can also be much lower if the building is designed poorly.

5. Conclusions and implementation

Of the four variables considered, reducing energy used for space heating by replacing building components proves to be most effective in reducing the environmental impact related to the maintenance of dwellings. This measure will lead to an improvement of all environmental effects, because the environmental effects caused by energy use are much stronger then the environmental effects that are directly caused by maintenance. Second, the use of alternative materials for building components is effective in reducing some of the environmental effects, but it may also cause an increase in some other environmental effects. There is no definitive answer to the question which material is best for building components: it depends on factors such as time (service life of building / length of the maintenance scenario), the local climate and the origin of the materials used. The decision to use solvent-based paint or water-based paint can be made by looking at other aspects than environmental impact. The differences in environmental impact for different kinds of paint are relatively small and the health effects of the paint during the application are more important in labour conditions law. Third, lengthening the service life of building components will lead to a reduction of environmental effects due to the fact that less building components are needed during the service life of the building. However, this measure cannot be reached without adjusting the frequency of maintenance. If more frequent maintenance is needed, the reduction of environmental impact may be counterbalanced by the negative effects of transportation of maintenance workers, which is the fourth measure to reduce the environmental effects related to maintenance of dwellings.

The implementation of the research findings in practice involves two actors: the building's owner and the maintenance company. Buildings' owners make the decision whether or not to replace existing building components with components with improved thermal insulation properties or made of a different material. Reducing the distance travelled by maintenance workers is a responsibility that is shared between the building's owner and the maintenance company. The former can specifically state a desire to limit travel in the maintenance agreement, while the latter can service employees efficiently and switch to more sustainable means of transport. Both actors, together, decide on the strategic maintenance plan for a building, in which is decided at what time activities take place and what is the policy regarding the lengthening of the service life of building components. Finally, the maintenance company decides on the materials used for maintenance activities, such as paint and sealant. Since the influence of these materials on the environment is not significant compared with a complete maintenance scenario – except when they need more transportation to be applied - the decision can be made based on other factors, such as costs and the health of maintenance workers.

6. Acknowledgements

This research was partly funded by SBR, the Dutch knowledge institute for building, and WVB, the Dutch association of real estate maintenance companies. The research was conducted in cooperation with W/E consultants.

INTERACTION BETWEEN EXTERNAL ENVIRONMENT AND BUILDING STIMULATED BY DYNAMIC ENVELOPE WITH INTER-SPACE

Dariusz HEIM Ph.D.[1]

[1] Department of Building Physics and Building Materials, Technical University of Lodz, Poland
dariusz.heim@p.lodz.pl

Keywords: heat transfer; buffer zone; building envelope; external environment

Summary

The presented study treats the problem of heat exchange between building space and external environment through transition space more generally. The main goal of this study is the estimation of the effects of external partition with inter-space on thermal behaviour of the adjacent building zone. The analysed wall consists of a transparent external part, ventilated air space and inner part. Heat exchange between solid volumes (walls) and air volume (inter-space) as well as heat storage potential play a significant role in energy balance. The following changeable thermophysical properties were considered in the presented work: convective heat exchange, radiation heat exchange, air heat storage potential, material heat storage potential. All analyses have been conducted using computational numerical techniques based on compound heat transfer model and advanced simulation software. For the purpose of this study hypothetical characteristics of external environment were defined in daily profile forms. The variable parameters were external air temperature and diffuse/direct solar radiation.

1. Introduction

An optimal solution of inter-space between outer and inner parts of a building envelope are currently well described for some particular, practical applications. The rules how to provide required, proper conditions and optimise the systems from thermal point of view were investigated e.g. for solar walls, double-skin facades, solar spaces etc. The first two of them are limited to a small scale building application. The third is rather used in modern, huge and tall buildings and has a wide range of options to control the effects between external and internal environment. Therefore, the use of active semi-translucent buffer zone (BZ) like double-skin façades (DSF) is very popular with architects at almost all latitudes. In majority of climatic conditions the main exploitation problem is summer overheating, not only in the gap of the façade but also in the adjoining room. On the other hand, the limitation of sun access (e.g. by vertical shading) results in deterioration in illuminance. The worst side effect is decreasing thermal or visual comfort. Sustaining such comfort is connected with increasing cooling or lighting energy requirements.

The results of a whole building simulation give not only energy efficiency of buffer space but also precise temperature distribution inside each part of the external partition. Recent works showed many different strategies in BZ design and solution to optimise the control strategy of shading systems, air flows or both. It means that the previous strategies were devoted rather to eliminate or protect against environmental effects, based on additional element like blinds or ventilation system. The presented work shows possible storage potential of each façade component and the potential of controlled heat exchange between air in inter-space and external and internal skin.

One of the main thermal problems during exploitation of double façades is considerable temperature fluctuation between day and night and temporary overheating or overcooling effects. In order to reduce these effects and sustain stable thermal conditions on the inner part of the façade shading devices with proper control strategies are generally applied (BBRI 2002, Leal et al. 2003, Gratia & DeHerde 2004, Stec et al. 2005). However, the main question is what should be the best solution for buffer space in the context of geometry, construction and control of internal parameters under different environmental conditions. For moderate climate of Central Europe the weather exceeds some extreme conditions in the middle of summer or winter. However, the temperature during the year usually varies from –25°C (winter) to +25°C (summer) with different daily fluctuations depending on individual locations, altitude or local conditions.

2. Boundary conditions

For the purpose of the presented study external weather conditions were assumed to be changeable according to the following assumptions:

- extreme temperature changes from –25°C in winter to +25°C in summer with possible daily fluctuations from 5 K to 25 K,
- diffuse and direct solar radiation is considered separately and is assumed to be minimum 100 W/m^2 or maximum 500 W/m^2 at noon.

These assumptions allowed to consider the behaviour of BZ under conditions representing different climates, locations, latitudes or local microclimate influences. The results of the presented analysis allowed to formulate more general conclusions. The set of climate data parameters (temperature differences ΔT, direct I_{dir} and diffuse I_{dif} solar radiations) for 20 hypothetical cases is presented in Table 1.

Table 1 Hypothetical climate conditions

Case	ΔT [K]	Idir [W/m^2]	idif [W/m^2]
1	5	–	100
2	5	–	500
3	5	100	–
4	5	500	–
5	10	–	100
6	10	–	500
7	10	100	–
8	10	500	–
9	15	–	100
10	15	–	500
11	15	100	–
12	15	500	–
13	20	–	100
14	20	–	500
15	20	100	–
16	20	500	–
17	25	–	100
18	25	–	500
19	25	100	–
20	25	500	–

Temperature function varies periodically from minimum and maximum values with assumed ΔT from 5 to 25 K. Solar radiation achieved maximum values at noon and the length of the periods depends on the season of the year. Figure 1 shows exemplary data for “the shortest” winter day in the year. Temperatures vary with ΔT=10K and solar radiation reaches maximum values 500W/m^2. Other climate files were done in the same way. For the purpose of numerical analysis the whole single type period was three weeks, including two weeks of start-up days and one week of analysis.

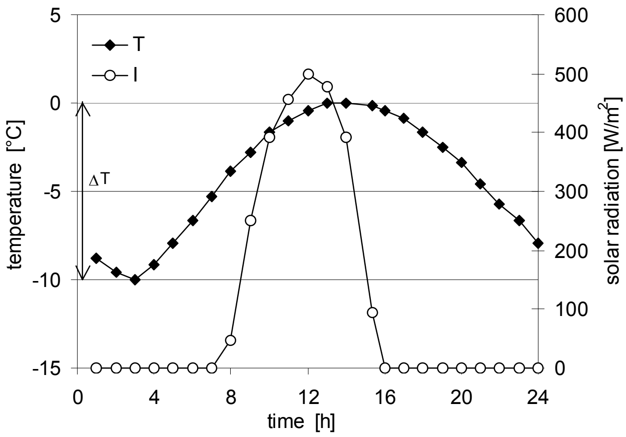

Figure 1 Demonstration of daily function for winter day

3. Analyzed construction

For the case studied herein the whole single glazed external partition is considered as an airtight envelope. The U value of this partition is 5.40 W/m^2K and optical properties are assumed as for "clear float" glass . The space gap is 0.5 m wide and represents a separate space on each floor. No additional shading system was applied in an inter-space. In the case under discussion different proportions between glazing and opaque part of second skin are considered: 20, 40 60, 80 and 100% of glazing. The heat transfer coefficient for opaque and transparent part is set to U = 2.70 W/m^2K (twice as small as the outer one U = 5.40 W/m^2K). The total area of the DSF is 9 m^2 (3 m × 3 m) with the volume of 4.5 m^3. The adjacent zone is 3 m wide and 5 m deep with the total volume 45 m^3. Three traditional opaque partitions (only specific heat capacity) were considered. All considered opaque walls have the same thickness (d=0,2 m), specific heat (c_p=1000 J/kg K) and conductivity (λ=0,75 W/mK). They differ in density as follows:

- lightweight (**L**) wall ρ=125 kg/m^3,
- average-weight (**A**) wall ρ=1250 kg/m^3,
- heavyweight (**H**) wall ρ=2500 kg/m^3.

Radiation heat transfer between air in buffer zone and the façade was considered by different thermophysical properties of the inner part. All of them were covered from the outside by thin coating with different values of absorptivity and emissivity (Table 2).

Table 2 Absorptivity and emissivity of the inner part.

CASE $a\varepsilon$	ABSORPTIVITY a	EMISSIVITY ε
99	0.9	0.9
91	0.9	0.1
59	0.5	0.9
55	0.5	0.5
19	0.1	0.9
11	0.1	0.1

Casual gains from equipment, lights and occupants were also set to zero in order to remove their impact on the simulations and so make the results of the interpretation easier.

Convection heat transfer depends on different air flow. In the case studied herein the most popular outdoor air curtain was chosen. For thermal analysis the air-flow rates of A – 1 ac/h, B – 5 ac/h and C – 10 ac/h were constant during the whole year. One-story high façade, completely tight from the surroundings and the adjacent room was chosen. It means that no air flow between following stores and between zone and the façade were assumed. The DSF space was defined as one, uniform thermal zone representing single control volume (Hensen et al. 2002).

The control volume approach was adapted to describe physical elements of the zones and networks. Spaces, described by geometry, construction and operational data are interconnected using network models that describe air and moisture flow paths. Construction components, surfaces and zones are represented by nodes for which energy and mass balance is performed. Conduction, convection and radiation exchanges are described in relation to other nodes systems (Clarke 2001).

4. Results

4.1 Boundary conditions

The effects of heat transfer between building and the environment are stimulated by the characteristics of the buffer space. The analysis has been conducted for several temperature fluctuations according to daily characteristics presented in figure 1. Five cases were considered where temperature fluctuations between day and night $\Delta T=T_d-T_n$ were respectively: 5K, 10K, 15K, 20K and 25K. The maximum external temperature T_{emax} was assumed to be +25°C and the minimum –25°C (for $T_{emax}–\Delta T_{5K}$ =20K–5K). During the day (8:00-16:00) diffuse solar radiation was assumed according to the layout presented in figure 1 with maximum values at noon 100 W/m^2. The results presented in figure 2 show the relationship between internal resultant temperature (T_{imax}) and external temperature (T_{emax}) for five amplitudes of external temperature. Internal air temperature was controlled at the level of 20°C.

The highest differences between different daily temperature fluctuations were noticed for maximum external temperatures above assumed internal temperatures. When external temperatures changes sinuously from 25°C to 20°C (T_d-T_n=5K) the internal resultant temperature exceeds 24°C. However, if external temperatures dropped to 0°C during the night (T_d-T_n=25K) the internal resultant temperature is below 21°C (~3.5K less). It means that for maximum external temperature 25°C, maximum external temperature fluctuations ΔT_e=25 are balanced during the day by solar heat gains. When daily fluctuation is only ΔT_e=5K (or less) solar radiation causes a significant overheating problem. For maximum diffuse solar radiation 500 W/m^2 internal temperature is almost 28°C. Below external temperature equalling 15°C the effect of daily fluctuations cause only slight differences of about 0.3K, while for sub-zero temperatures it becomes imperceptible.

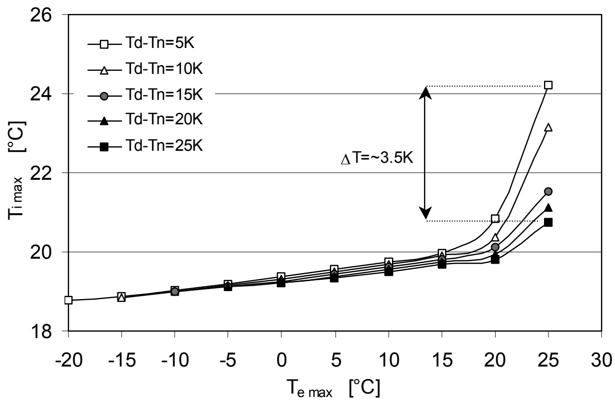

Figure 2 The effect of external temperature on the resultant temperature inside the building

4.2 Time lag

For the purpose of proper interpretations of further results, initial analyses have been conducted to show the effect of time lag. These analysis have been conducted for fully glazed façade with air changes in inter space 5ac/h. Exemplary results for ΔT=10K and solar radiation 500W/m^2 show the thermal dynamic of buffer space. Diffuse radiation gives higher differences in time when maximum temperature is noticed. The moment of maximum temperature in the buffer space is shifted by about 1.5 hours with reference to maximum ambient temperature and by 3.5 hours after maximum solar radiation. It means that reported extreme values of the analysed parameters appear at different hours.

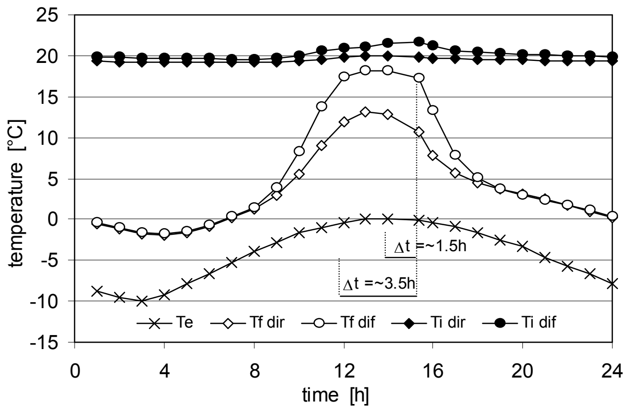

Figure 3 The time lag of thermal effects in the buffer space

4.3 Thermal mass

Thermal mass effect of the construction as well as mass flow effect (air flow) between the buffer space and external environment were also analysed. Air changes rates were assumed constant during the whole period and equal respectively: 1 ac/h and 10 ac/h. Thermal mass storage effect was considered on the basis of geometry (A_w/A) and material (cases L, M, H) of the inner skin. The A_w/A=1.0 means a fully glazed wall and 0.2 means 20% of glass. In winter internal air temperature was assumed to be more than 20°C (heating control point – hcp), in summer less than 24°C (cooling control point – ccp).

The results presented in figures 4 and 5 show the effect of thermal mass and air flow in winter. Analysing minimum resultant temperature (in winter – fig. 4) inside the heating zone the effect of thermal mass is really slight similarly to maximum resultant temperature (in summer – fig. 5). However, for a relatively low window/wall ratio 0.2 (20% of glass) temperature differences reach 0.5 K. The intensity of air flow in the façade space gives a similar small effect on resultant temperature inside the heated or cooled zones. Increasing air changes per hour from 1 to 10 indicate temperature changes of more or less 0.1 K.

4.4 Surface heat flux

The effect of solar energy absorption on inner part of the DSF was analysed for selected values of absorption and emission coefficients. All analyses were done for the zone with controlled air temperature (minimum 20°C in winter and maximum 24°C in summer).The differences (for medium weight wall) presented in figures 6 (for winter) and 7 (for summer) show a reliable effect of surface properties on internal temperature in summer. The recorded values in maximum resultant temperature differ by more than 1 K for little glazed wall. As expected, the highest differences were obtained between high and low absorptivity. In winter the highest temperature was for high absorptivity and low emissivity surface and the lowest for high emissivity and low absorptivity coefficients. However, the differences between extreme values were 3 times smaller than for the summer (3.5K).

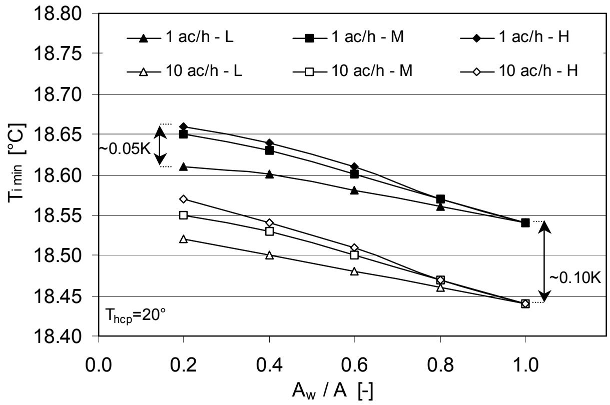

Figure 4 The effect of air flow and thermal mass on the minimum, internal resultant temperature

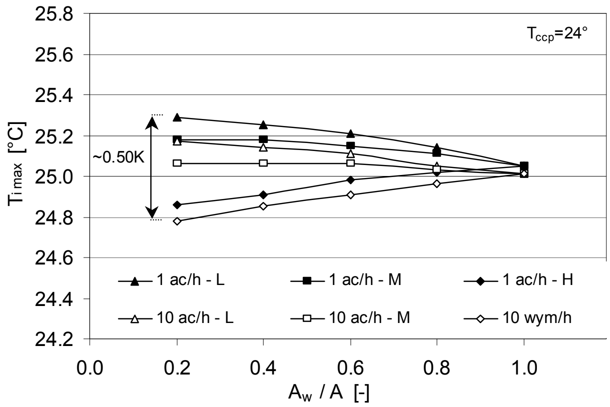

Figure 5 The effect of air flow and thermal mass on the maximum, internal resultant temperature

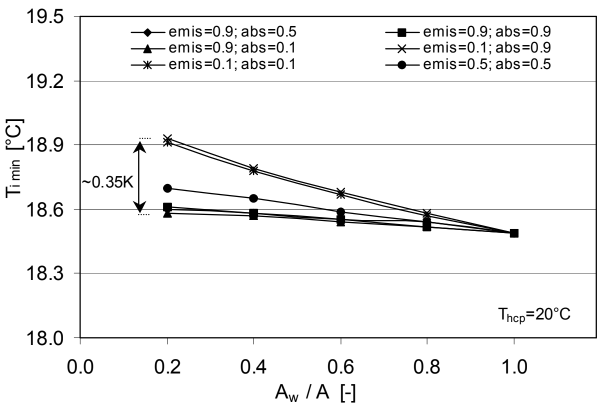

Figure 6 The effect of absorber properties on the minimum, internal resultant temperature

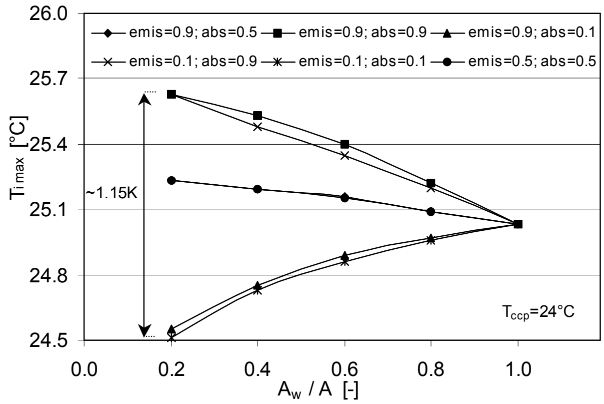

Figure 7 The effect of absorber properties on the maximum, internal resultant temperature

4.5 Energy efficiency

Energy performance of the DSF system was presented by Saelens & Hens in 2003 and Saelens et al. in 2005. This analysis is limited only to some discussion concerning the properties of opaque part within the first, inner part of the DSF.

Energy demands were analysed for different properties of inner part, because this parameter gives the largest temperature differences. The results obtained for medium mass wall "M" were shown in figures 8 and 9, for winter (heating) and summer (cooling) respectively. Possible savings in heating or cooling energy demands are not bigger than 10 kWhs per year. The savings of heating energy are about 7% between high absorptivity (A=0.9, ε=0.1) and high emissivity (A=0.1, ε=0.9) buffer side surface. In summer the anti-sun surface layer should have possibly low emissivity and absorptivity (A=0.1, ε=0.1) which can lead to reducing cooling energy by even about 70%.

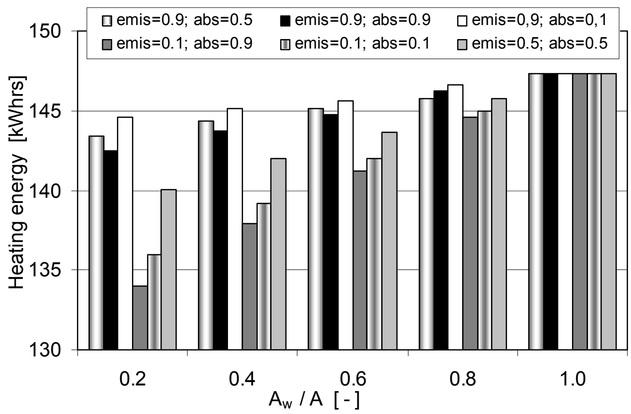

Figure 8 Heating energy demands

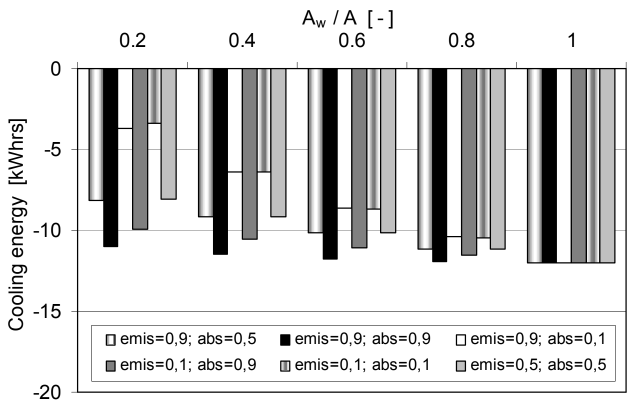

Figure 9 Cooling energy demands

All conclusions mentioned above concern the inner part of the wall with a small window (20% of glass). For a larger glass area the effect of surface properties becomes less noticeable.

Summary and conclusions

The first part of this study was devoted to show the effect of changeable climate parameters on the behaviour of a zone buffered from the outside by additional space. The effect of daily temperature fluctuations is noticed where maximum external temperatures are above assumed internal temperatures. The highest difference (~3.5K) was obtained in summer (T_{emax}=25°C) for daily temperature fluctuation ΔT_e=5K.

In the second part the effects of conduction and convection heat transfer between inter-zone and construction are discussed. Different properties of internal space were analysed to show the effect of ventilation rate, glazing opaque ratio and surface properties on thermal behaviour of the building. The greatest thermal effect on internal temperature was received for different surface properties (radiation heat exchange), especially surface absorptivity. The highest difference reported for summer is about 1.1K.

Energy analysis for surface properties parameters show saving potential in requirements by about 7% for heating and even 70% for cooling. However, cooling energy provides only 10% of the whole energy demands. It is also confirmed in other publications for Central Europe climatic conditions (Heim 2006).

Summary

This paper relates the study for environmental goals insertion in public procurement procedures for Brazilian large state company that is subordinated to Ordinance nº 2.745/98 that is a simple way of the Law 8.666/93, without standing back the isonomy and economy doctrine of the company. Motivated by the chapter 4 of the agenda 21: change of the consumption patterns; aided by the articles 37, 170 and 225 of the Brazilian Federal Constitution, this work aims to be an instrument to guide future procurement, by introducing criteria of environmental order such as: water consumption; energy consumption; pollutant emission; residues generation; toxins in the goods and durability, all aligned with the procedures of acquisition of goods and engineering services, as well as compatible with governmental politics, environmental legislation and certification ISO 14.001. The conclusion brings up to an end that these measures have legal base application and also appliance for future accounts rendered and they won't be impacting in the value of the final product, specially considering the life cycle analysis of the project in the operation and maintenance phase of the enterprise, besides being base to make possible the improvement of the environmental performance of the buildings.

1 Introduction

1.1 Contextualization

During the 1970's began the first demonstrations about the sustainable development and at the same time the environment exploitation in a large scale by the men (NSSD, 2003). During the 1980's the sustainable development aims have been defined during global convention as Montréal (1982), Rio de Janeiro (1992) and Kyoto (1997). This aims, up to that time implicit in many national politics, gained United Nations Convention on Climate Change (UNCED) compromising and recognition the carried out in the Rio de Janeiro in 1992 that turned in a global plan action for the XXI century. It was published the Agend 21, which was establishing a long term vision to balance the natural planet resources (UNITED NATIONS, 1992).

The Agend 21 was adopted by 178 governments and all the society sectors initiated a reinterpretation process of them into the specific contexts of several local Agends and Sectorial ones. Public policies started to impose environmental requisites to countless economical activities for environmental products demand less aggressive grew in parallel (CIB, 2000).

Changes in the public procurement processes were necessary for administrative routines in order the public administration were adapted to the environmental questions, particularly the Chapter 4 of the Agend 21. This chapter defines the change consumption standards of containing the next areas of programs: Examination of the unsustainable production and consumption standards and the development of politics and national strategies to stimulus to changes in these standards (UNITED NATIONS, 1992).

The establishment of objectives and environmental goals must take place mainly in the annual cycle of the administration strategic projection and they will be part of the objectives and strategies of the institution itself, turning in goals and/or criteria adopted in the public procurement processes.

The Public Administration is great natural resources consumer and user and have strategic paper in the promotion and indication of new standards production and consumption, and, therefore must be an example in the reduction of the socio-environmental negative impacts produced by its activity.

1.2 Objective

The paper purpose is to test the feasibility of inserting environmental goals by checking the legal bases for Public Procurement in Brazil, combating so, all the forms of natural resources waste and public goods; to contribute to an appropriate the public administration management, including socio-environmental criteria in the purchases and services employment of the government departments, moving the civil servants regarding the environmental aspects and the improvement of their environment quality work.

1.3 Methodology

The inquiry has descriptive characteristics, by bibliographical survey and from the point of view of the form of approach of the problem, it presents the results in accordance with a qualitative way.

2. Sustainable Public Procurement Process Evolution

The green procurement also known as eco-acquisition, or positive procurement or sustainable procurement is a solution to integrate environmental and social considerations in all the stages of the public agents and employment purchase process with the objective to reduce impacts on the human health, to the environment and on the human rights. It satisfies the final consumers specific necessities of through the product purchase that offers the biggest benefits number for the environment and the society. The discussion on the legality of the most sustainable option in the green procurement is the constant one in the whole world, and standards for incorporation changes proposed in this area with legislation limits in many countries realities. In the table 1 it can be visualized several countries data list about the sustainable public markets (FGV, 2006).

Table 1 Worldwide Experience on Green Procurement

South Corea	Environmental certification Government system and green label to identify products and sustainable services. Second country to approve green procurement federal law.
Japan	Governments and industries created jointly a private organization, which organizes sustainable initiatives consumption, which they include from trainings, publications, up to the development purchases catalogues on-line. The green procurement Japanese system is the world most complete and dynamic in use (GPN - Green Purchasing Network)
Switzerland	Implemented system and law ingoing. It developed products and services standards and it promotes government agents and educators trainings.
Sweden	Sustainable procurement program initiated into 2001 creating an enterprise composed by public entities and public and private enterprises that defines priorities of action for green procurement carrying out scientific life cycle studies and economical analyses.
México	Integrates a public green purchases group created in the context of the agreement of free commerce of NAPHTHA (North American Free Trade Agreement) and has environmental public program implemented management, which includes public servants qualification, recycling, economy of energy, among others. The Mexican law included green procurement principles, demanding energetic efficiency and economy in water use in the government contracts and acquisitions.
England and Wales	The governments has been practicing out sustainable procurement for more than a decade. There is an intense public workers training program. The trainings board explain what is sustainability, the necessity of creating a organization strategy, mapping the market impacts and risks focusing on the risks analysis in the products life cycle. These governments advanced in such a form, allowing wage compensation for good performance of the workers regarding the aims established in the green procurement procedures.

Adapted by the author based on FGV, 2007

In Brazil, up to the moment, the government initiatives in the Federal spheres are shy and punctual. The MMA-Ministério do Meio Ambiente (Environmental Protection Agency) sent alteration proposal of the procurement Auctions Law to the Congress, for environmental sustainability criteria inclusion in the public administration (BRAZIL, 2007). The federal government prohibited the consumption of products with use of CFC (destructive gas of the ozone layer) for the public departments. As Valéria Damico (2005), the Sao Paulo state Government published Decree to oblige the wooden from Amazon region legal origin use, in the works and public state contracts, which must promote the sustainable products market.

2.1 Sustainable procurement in Brazil

Recent estimations demonstrate that purchases and government employment represent around 10 % of the internal Brazilian product indicating that the public sector, through its purchase power must be an important inductor of sustainable practices in the society (FGV, 2007).

In Brazil, the Law 8.666/93 that treats general standards on procurement auctions and administrative contracts, which superficial reading establishes less price as predominant criterion can work like obstacle to the sustainability incorporation in the purchases and public employment, preventing in the country the public power being a great inductor of the sustainability practice.

Table 2 Some Brazilian sustainable practices

Decree 2.783 of September of 1998	Prohibits the acquisition of products or equipments that contain or use the substances that destroy the ozone layer for the Public Federal Administration.
Sao Paulo - Decree 48.138/2003	Sets up water consumption reduction and rationalization measures.
Sao Paulo - Decree 45.643/2001	Obliges the acquisition for the Public sector and Foundational: - Use of lamps of high performance, with the less mercury tenor of among the available ones in the market (base in technical decisions). - Use high efficiency cables and lines and low polychloride of vinila (PVC) and lead tenor.
Acre	Government favorizes wood certified in the Government Palace State renovation fase and furniture procurement.

Adapted by the author on basis on BRAZIL, 2004

2.1.1 Proposal the Federal Government Law 8.666/93 alteration

Proposal of the Government contained in Bill set out for the National Congress in January 2007 in constitutional urgency regime vote the Law 8.666 change, which regularizes art. 37, I incise XXI, of the Constitution (BRAZIL, 2007).

The proposed alterations aim to adapt the auctions and government employment to the present information new technologies in the Brazilian current scenery, as well as pay attention to the beginnings of government employment transparency, economy, competitiveness and celerity with sights to make the auction process concomitant with the best worldwide practices. The figure 3 demonstrates other public Brazilian administration proposals suggested.

Table 3 Propositions of the commission managing the A_3P (Public Administration environmental Agend)

Draft of proposal of Recommendation of the CONAMA	Insertion of the environmental dimension in the administrative activities of the government organs, including actions to reduce costs with the elimination of wastes, stimulate the training of workers on the environmental questions, support to the development of clean technologies, between others.
Draft of Entrance hall setting two-story impression up in the services of reprografy	from determined quantity, in the documents made by the Environmental protection Agency.
	Inclusion of specification for acquisition of new printers that prime on both page sides without necessity to re-put the paper.
Insertion of environmental criteria in the electronic auction.	The application of electronic procurement systems of, which up to certain limit dispenses auction.
Institution of a model of green and / or sustainable building for the new constructions in Federal Unities of Conservation	Partnership with the IBAMA, when there is taking into account the funcionality integrated to the environmental sustainability (using constructive materials with low rate of built-in energy. Photovoltaic panels, biodigestores, green ceiling, permaculture, recycling, rain roof catchments system, gray water re use, natural ventilation, day lighting, and so on.

BRASIL, 2004

3. Legal Bases for Brazilian Green Procurement

The Federal Constitution establishes that the economical order should be based on the increase in value of the human work and on the free initiative with objective to secure to all the citizens a worthy existence, according the social justice dictates. Regarding the employment of works, services, purchases and alienation, by public procurement means. Brazilian federal constitution defines that this process should secure conditions between all the bidders equality. The relative prices system force at present in the Brazilian economy do not notice the social and environmental subsidies which enterprises enjoy launching to the society and to the environment externalities of products or services processes. The criterion of less prices treats unequal way the equals, and, so, fall to a public administrator to establish sustainability criteria in the purchases and public employment that better qualify and differentiate products and services, so these distortions are corrected and equality of conditions must be offered (Nascimento, 2005).

The infraconstitutional legislation also reminds us that the search of the most advantageous proposal must be in accordance with the public administration principles among them the defense of the environment and the regional and social inequalities reduction. The Law 8.666 prohibits restrictions to the competitive character that are impertinent or irrelevant for the specific contract object and nothing indicates that the defense the environment and inequalities reduction are impertinent or irrelevant conditions (BIDERMAN et al., 2006). According to Dr. Silvia Nascimento (2005) the Public procurement Law interpretation must be coherent with the remainder of the national legal standards, in individual, with the precepts of the National Politics Environment Law (Law 6.938/81) that orients the State in the of the public interest environment subject management. The above-mentioned law establishes among his objectives, which it is necessary to make the social-economic development compatible with the environment quality preservation, to set environmental quality standards criteria and relative standards to the environmental resources use and handling, to develop inquiries and technologies for environmental resources rational use, to spread handling environment technologies and to bring up a public environmental quality preservation and ecological balance the necessity conscience, promoting environmental resources preservation and restoration. So, the public procurement should establish practices to respect these precepts.

3.1 Federal Constitution

Public Administration General Principles: Art. 37 of the Federal Constitution: Legality, impersonality, morality, publicity and efficiency (BRAZIL, 1988).

3.1.1 Administrative contracts

Art.37, XXI, Federal Constitution: order of works, services, procurement and alienation, by means of public auction, which secures equality of conditions between all the bidders and it takes the technical and economical qualification as an essential condition of the obligations fulfillment guarantee (BRAZIL, 1988).

3.1.2 The Environment

Art. 225 of the Federal Constitution: it imposes to the Public administration the environment defense and preservation duty for the present and future generations: To preserve and to restore the ecological essential processes and to promote the ecological ecosystems handling: To control the production, marketing and techniques that constitute a life risk, the life quality and the environment (BRAZIL, 1988).

3.1.3 Economical Activity General principles: Art.170 Federal Constitution

Economical order been based on the increase in the human work value and on the free initiative and it has how aim secure to all worthy existence, according the social justice dictates.

Principles: IV – free competition; VI – environment defense; VII - regional and social inequalities reduction (BRAZIL, 1988).

3.2 Legislation Infraconstitucional

3.2.1 Federal law nº 8.666, of 21.06.1993: General standards on public procurement and administrative contracts

Art.2º - Obligation of procurement auction: works, services, alienation purchases, concessions, permissions and rentals.

Art.3º - The equality observance principle and most advantageous proposal search, in accordance with the Public Administration principle.

3.2.1 The Environment National policies: Federal law nº 6.938, of 31.08.1981 – SISNAMA

Objectives – Art. 4

I – Make compatible social-economic development with the environment quality preservation and the ecological balance;

III – Establish environmental quality criteria and standards of relative to the environmental resources use and handling;

V - Environmental technologies of handling Diffusion and formation of a public conscience on the necessity of quality environmental preservation and the ecological balance;

VI – Environmental resources Preservation and restoration sighting rational use.

3.3 Auction - Proceeding

The process is divided in two phases: Competence (federal Law nº 8.666/93 Art.27) that is the bidder qualification examination (federal Law nº 8.666/93 Art.30); and proposal to examine the adaptation of the procurement requisites object.

3.3.1 Propositions Object-Prohibitions

For works and services the Art.7º, §5º prohibits that the procurement object includes goods and services without similarity of marks, characteristics and exclusive specifications, except when technically justifiably, under penalty of nullity and responsibility (§6º).

For purchases the Art.15, §7º demands the good complete specification, when the indication of mark or label was prohibited.

Works and Services:

Art. 12 – Regarding basic projects and executive of works or services will be considered the next requisites: Security with the adoption of technical standards of health and of security of the work adapted; functionality and adaptation to the public interest; the execution economy, conservation and operation; job for workers possibility, materials, technology and existent raw materials in the place; the execution easiness, conservation and operation, without damage for the durability of the work or the service; and environmental impact.

Object – Purchases

Art.15 – Align whenever possible to the standardization principle, which imposes technical specifications and performance compatibility, observed, when it will be the case, the maintenance conditions, technical back-up and guarantees offered [...].

4. Implementation and Recommendations

In the public authorities hands, the green procurement is a environmental protection powerful instrument. If this power be used to promote the goods production and the most sustainable services, it will be able to wait for improvements and considerable changes in the market structures in short and middle time. The administration shall:

a) create commissions and study groups involving different areas workers to carry out diagnosis of the situation, identify critical / real points and prepare an integrated projection, technical measures possible and operational efficiency proceedings, defining projects and activities, the actions cost and when goods/resource will be paid by the economy itself (pay back time);

b) To promote the continuous improvement for the systematic evaluation, proceedings projection, officials formation, new technologies introduction. Always evaluate and control the environmental performance, to identify improvement faults and benefits through the inclusion of specific clauses in the contracts elaborated with enterprises suppliers of services and goods supply, with sight to the education and environmental management capacity, for all the workers involved (ICLEI, 2003);

c) The results presented by the studies groups will have to produce activities to be proposed and implemented through training and diffusion of the knowledge by acting strategically in the decision political levels; making the workers aware of the problems; adopting new administrative proceedings, establishing partnerships; using rationally the available resources; establishing aims; appropriately materials disposal, recycling; and spreading the actions, advancements, indicators and sectors exchange experiences (BRAZIL, 2007);

d) Organize a “green procurement” guide containing an evaluation on products and services that provide environmental profits and resource economy, for product or products class, identifying the environmental aspects responsible for significant impact, in order to orient the taking decision process;

e) Determine aims and terms in order to respect them.

4.1 Environmental general criteria to guide the employment and acquisitions

There are several criteria that can be adopted in defining time the purchase or acquisition of goods or services classified as "green":

a) Natural resources Consumption: materials origin, energy in the production and in the transport;

b) Produce air and water pollution: phase of production; transport; use, operation and demolition;

c) Waste generation: Production; use (waste); and demolition (recyclable);

d) Building Performance: energy; durability; and indoor air quality.

The environmental impact resulting from natural resources use are treated in the level of definitions of the projects, when the definitions of engineering on institution politics basis, looking for technology of proved efficiency/profit in these resources use. The correct basic importance environmental aspects and impacts identification, as well as the evaluation and resulting actions for reduction or elimination (ECOCAMARA, 2007).

Inside these criteria, one classifies several visions, not forgetting that must be done in the global thinking life cycle analysis process (SILVA, 2007): First asking: Which source of energy is used in the process? And to last more? And will it cause any health harm?

4.1.1 General services

The bigger relevance third part services on cost like those of cleaning, vigilance, food and transport, will have to be standardized in manuals of compulsory use.

Actions that must be taken for services employment: the environmental legislation Compatibility and technical specifications alteration with water economy use practices, spills identification; energy efficiency; hard products consumption reduction for cleaning; use of less pollutant fuel in the vehicles used in the services execution (methanol or biogas); employees involved habilitation.

4.1.2 Works and engineering services procurement

Environmental supervision of the works and services by independent and co-responsible engineering; environmental conformity certification, containing the environmental attended demands, attended and not attended; certificate environmental agreement verification to the payment; and constructive methods revision, origin of inputs just like the certified wood by the BAD (performance evaluation report).

4.1.3 Materials acquisition

The enterprises must create materials catalogues previously selected when the specification and purchase are careless considering the environmental aspects and volume of purchases and must be selected and classified as strategic when the list is simplifying. In the Sao Paulo state today there are only 7.500 items in the materials catalogue versus 63.000 items in the conventional process (DAMICO, 2005).

4.1.4 Objective and goals

What is the environmental improvement waited through the green procurement implementation? The project of the entitled ICLEI "Relief" (Environmental Relief Potential of Urban Action on Avoidance and Waste Streams Detoxification Through Green Public Procurement) calculated the environmental potential of the contribution of the sustainable purchases. It demonstrated that a change for 100 % of consumption of organic production of wheat, meat and milk done by public authorities would produce a reduction in the eutrofization effects equivalent to the produced ones for 2,1 millions people by the pesticides use reduction, figure 4 (ICLEI, 2007).

What the price implications of a more sustainable alternative acquisition? In the cases where the most recent option applies for investments to the sight and offers economy during the operational phase, it is recommendable longer terms where future savings can finance the next investments.

What the appropriate terms are? To establish realistic terms the government can consider the principal purchases planned in the future and estimate the necessary time to integrate the criteria of in the budgets search and product specifications.

Table 4 Potential environmental impact reduction resulted from purchase option

Product	Category of Impact	Reduction of the environmental pressure for the option of green purchases	Equivalent-person middle emission
Bus	photochemical Formation of the ozone (t C2H4-equiv.)	-3.350	-3.350-113.110 (middle - emission European)
Bathroom suites	Consumption of water (liters)	-190.407.539	-3.086.387(middle - European consumption)
Computers	Emissions of gases of greenhouse effect (t CO2 - equiv.)	-835.320	-101.503 (middle - global emission)
Food	Euthrofization (t PO_4 – equiv.)	-24.044	-2.125.000 (middle - emission European)
Electricity	Emissions of gases of greenhouse effect (t CO2 - equiv.)-	-61.350.363	-7.481.752(middle - global emission

ICLEI, 2007

Where:

Bus – the new purchases subject standards of emissions of the EURO IV norm; hydraulic Equipments - substitution of basins of 9 liters for basins, with 6/3 liters with double flow of unloading and the installation of economical water tap; Computers - all new purchases attending the requisites of Energy-Star with monitors of TFT; Food-100 % of meat, wheat and milk produced organically; Electricity-100 % of use of renewable origin.

Equivalents – person - when European, the fact describes the middle emission of a citizen in the European Union. And when global, it describes the emission of a middle person living at any place in the world.

Taking as a reference the environmental profit quoted in the figure 4, the aims can be determined on basis of the resultant impacts of determined activities they are reduced through the determination of which up to determined date a definite percentage is reached like example: Up to 2009, secure that all the public acquired buses are fitted in the lowest gases emission standards.

4. Conclusions

This study indicates that there are legal sufficient bases to inspire of sustainable procurement initiatives in the country, lacking disseminate this information between the people in charge for the purchases and public employment, as well as the daring in testing this new practice.

Viability, in Brazilian legislation view, sustainable politics consumption introduction for the Public Administration (NASCIMENTO, 2005):

a) The object specification with requisites to meet the environmental conservation and preservation in the public procurement necessity;

b) Using environmental criteria in the public procurement according to the best type technique and technique and price possibility; and

c) Application, to a pollutant one, the administrative environmental impediment sanction to contract with the Public Administration for up to 3 years (Federal Law nº 9.605/1998 Art.72, § 8º).

As recommended strategy the progressive described criteria adoption, as soon as the change of the standard can bring resistances and/or technical difficulties.

The public procurement law interpretation must be coherent with the standards remainder, particularly with the Environment National Politics precepts Law (Law 6.938/81) that guide the State in the public interest management on the environment subject. The mentioned law establishes among his objectives, which the social-economic development has to be environment quality preservation compatible, to set up criteria and environmental quality standards and relative standards to the use and environmental resources handling, to develop inquiries and technologies for rational use of the environmental resources, to spread technologies of environment handling and to form a public conscience on the environmental quality preservation necessity and the ecological balance to environmental resources preservation and restoration. So, the public procurement should establish practices to respect these precepts (NASCIMENTO, 2005).

From a general vision, the practices look for consumption reduction, indicate also both of materials and of services cost reduction. The market is known when regulated by the relation between offer and demands what makes the state also responsible at the products final price and services that have collected value of echo-efficiency, since it will be able to stimulate this market, increasing the demand and consequently reducing prices.

4.1 Problems to be administered

a) Sustainability as prevalent criterion or decision criterion?

b) Relative "price": What is a less price? public procurement best type price Establishment, meaning more favorable conditions under the environmental optics in cheaper price detriment.

c) To value the positive biggest price ingoing or the cheaper price negative externalities?

d) The practiced option results and policies divergence;

e) Cost-benefit relation: the society and environment damages;

f) Quantification of the intangible ones;

g) lack of data book for the life cycle thinking culture and eco-design;

h) Product/service sustainability profile versus enterprise sustainability profile: approach in the product/service or coherence in the corporation integrated and systemic evaluation?

Keywords: erosion control, sediment control, LEED, sustainable building, soil stabilization

Summary

This paper relates the experience of implanting some BMPs for erosion and sedimentation control aligned to SS Pre-requisite 1- Construction Activity Pollution Prevention for LEED-NC 2.2 certification on 100.000m^2 of a large Brazilian State Company headquarters construction site. Presents a short project description, site, the method for environmental assessment proposed and main demands for the requirement fulfillment for the execution avoiding scope alteration as foreseen in the contract, Report of Urban Impact, Statement of environmental impact, projects and procedure manuals. It also relates how the brainstorm and workshops have happened with the disciplines involved teams. It shows the results after the plan established, concluding that the environmental goals should be defined in the development design phase of a project. In general there is no concern with basic actions that will be able to generate pollution in the water bodies receivers in Brazil. The solid particles or particulate matters risen by wind drags nearly always is neglected and finally it states that the necessary measures for being in conformity with the SS Pre-requisite 1 do not impact in the final cost of execution, but need be backed contractually for guarantee of its application.

1. Introduction

Any site where soils are exposed to water or wind can have soil erosion and sedimentation problems. Erosion is a natural process in which soil and rock material is loosened and removed. Sedimentation occurs when soil particles are suspended in surface runoff or wind and are deposited in streams and other water bodies.

Human activities can accelerate erosion by removing vegetation, compacting or disturbing the soil, changing natural drainage patterns, and by covering the ground with impermeable surfaces. When the land surface is developed or hardened in this manner, storm water can not seep into or infiltrate the ground. This results in larger amounts of water moving more quickly across a site which cam carry more sediment and other pollutants to streams and rivers (Berman, et al. 1991).

In addition, as stormwater runoff moves across surfaces, it picks up trash, debris, and pollutants such as sediment, oil, grease, and other toxics. Changes in ambient water temperature, sediment, and pollutants from stormwater runoff can be detrimental to aquatic life, wildlife, habitat, and human health. Soil exposed by construction activities is especially vulnerable to erosion. Runoff from an unstabilized construction site can result in the loss of approximately 35–45 tons of sediment per acre each year . Even during a short period of time, construction sites can contribute more sediment to streams than would be deposited naturally over several decades. Excess sediment can cloud the water reducing the amount of sunlight reaching aquatic plants, clog fish gills, smother aquatic habitat and spawning areas, and impede navigation in our waterways (USEPA, 2007).

The primary stormwater pollutant at a construction site is sediment. To control erosion at a construction site, it is important to understand the different types of erosion that can occur. Runoff carrying the soil particles becomes sheet erosion which eventually forms smaller rills and larger gullies. The best way to stop erosion is to keep the soil in place through vegetation, erosion control blankets, or other methods that prevent the soil from becoming dislodged during rain events. The erosion process is typically influenced by climate, topography, soils, and vegetative cover (Berman, et al. 1991).

1.1 The project and site characteristics

Designed to be the administrative Brazilian Oil Company headquarters in the Espírito Santo State (figure 1). One of the main directives of this project should be the reference for others projects in the Vitoria city by their energy and environmental performance, earning notoriety and the marketing recognition by the economic performance, environmental responsibility and the permanent compromise with the most modern concepts of environmental efficiency inserted in their architectural collection.

The Vitória city, Espírito Santo State capital, is the largest island of a group of 33 islands archipelago, and it is located on the southeastern region of Brazil, latitude 20º19'09" south and longitude 40º20'50" east of Greenwich located in Brazil Southeast which is the more developed Country Region (ARAUJO, 2007).

The site is situated on north of Vitória Island, the local climate is tropical humid, and maxim monthly average temperature is 30º C and minimum of 24º occurring most of rainstorm from October to January and the average is 1345 mm/year. November 1996 was the hardest rain 200,64 mm in the last 15 years (ARAUJO, 2007).

The chosen site was the last urban empty area in the city that could fit the project. Located in the most important avenue of the city, on a mix of residential and commercial neighborhood which becomes much more vulnerable and sensible.

The site is located over a solid rocky one with a small layer of superficial land, including some blocks emerged. Justified by the architectonics characteristics, to be implanted it was necessary a lot of activities such as clearing, grading, excavating, drilling and blasting operations what became larges unstabilized areas.

Figure 1 The original site aerial view, electronic perspective and the project implanted (electronic way).

1.2 Objective

Know the BMPs-Best management practices to erosion and sedimentation control, how and when they could be applied an know if LEED methodology is viable to apply on Vitória City constructions site analyzing by economic and environmental point of view.

1.3 Methodology

Based on its objectives this research is characterized as descriptive. All the practices was based on recommendations to NPDES–National Pollutant Discharge Elimination System and chosen to meet SS Pre-requisite 1- Construction Activity Pollution Prevention for LEED-NC 2.2 tool, The main author works on this site to implant the plan. Some workshops were organized to choose the best management practices where participated technical and engineers construction's builder stuff and the owner's technical body. From the technical procedures or research strategies point-of-view it assumes characteristics of survey and case study.

1.3.1 Evaluation tool and requirements

In the present paper LEED methodology will be used because the authors' choice for LEED was based on the fact that it is one of the most popular evaluation tools worldwide, and it has a simplified structure, assessing the sustainability of the whole building performance. Based on well-founded scientific standards, LEED method emphasizes strategies for the local sustainable development, water saving, energy efficiency, material selection and indoor air quality (USGBC, 2005).

Comprising a checklist that attributes credits to the fulfillment of pre-established criteria, each criterion is divided into credits that are basically project, construction or management actions that contribute to the reduction of the environmental impacts of the buildings. LEED results from a balance between prescriptive credits and performance specification, having as preference the environmental principles by norms and recommendations by accredited institutions (USGBC, 2005).

Is not a decision made that it will be a certificated Building, but the project manager decided that the construction time must be done aligned to the LEED-NC rating system that profess as prerequisite reduction pollution from construction activities by controlling soil erosion, waterway sedimentation and airborne dust generation. Since it the project was not registered on USGBC –United States Green Building Council, and it was not backed contractually, could not impact in the final cost of execution.

The requirements are create and implement an Erosion and Sedimentation Control Plan for all construction activities associated with the project. The ESC Plan shall conform to the erosion and sedimentation requirements of the 2003 EPA – Environmental Protection Agency Construction General Permit or local erosion and sedimentation control standards and codes, whichever is more stringent. The Plan shall describe the measures implemented to accomplish the following objectives: Prevent loss of soil during construction by stormwater runoff and/or wind erosion, including protecting topsoil by stockpiling for reuse; Prevent sedimentation of storm sewer or receiving streams. Prevent polluting the air with dust and particulate matter. The plan outlines the provisions necessary to comply with Phase I and Phase II of the National Pollutant Discharge Elimination System (NPDES) program. While the CGP only applies to construction sites greater than 1 acre, the requirements are applied to all projects for the purposes of the prerequisite (USEPA, 2007).

1.3.2 The Brazilian Legislation

To comply to The Brazilian legislation it was necessary a environmental research called DIA- Declaração de impacto ambiental (statement of environmental impact) and RIU–Relatório de Impacto Urbano (report of urban impact), besides de whole environmental ordinances. Based on DIA the local government establishes some mandatory rules and conditions that are going to be fulfilled for project Implementation permit be liberated. In this special case there is another permit for existing rocks blastering operations on site to locate the foundations. Some of them are about Wind erosion control, tracking of sediment off-site by vehicles leaving the construction area, Hazardous Waste Management, Contaminated Soil Management, Sanitary/Septic, Waste Management, Vehicle & Equipment Maintenance, Stockpile Management, Spill Prevention and Control, Solid Waste Management and so on.

Usually there is no environmental concern on the civil construction Industry in Brazil and because that, a high level of environmental performance was not written on legal contract signed between the building owner and consortium hired of builders. So, the operational site environmental manager had to look hard for find legal base and National Standards to meet the LEED SS prerequisite 1 requirement for guarantee of its application.

1.3.3 Brain storms, discussion and decisions

The decisions involved multidisciplinary knowledge, and some workshops were organized to choose the best management practices where participated technical and engineers construction's builder stuff and the owner's technical body.

The Operation site were planning for 3 different fases on DIA in order to detail each temporary installation like Hazardous Waste storage and the locating selective collection waste place and so on. None of the fases planed were followed. The contractor did not realize the necessity of planning the site and the decisions were made at local whenever needed or not. In case of being part of the permit, some of the requirements were done, but not monitored and no analyzed if were working or not.

The discussion focal point was always the drainage, runoff and others erosion control measures, because the site is on rock hill one, becoming difficult and not necessary to establish those measures on construction site on their mind.

Since erosion and sedimentation control was LEED requirement as prerequisite, it was necessary prepare the documentation to comply and evidence the historical site situation by maps, plans and photos and others drawings and reports. So the program started. But even the complete program to prevent erosion and sedimentation had been made it was not followed and applied (USGBC, 2005).

Figure 2 The mud flooded site outside situation shown on newspaper and mud situation inside the site.

In January 8th, a very hard storm occurred and serious consequences happened. Discharge of storm water from the construction site were likely to carry pollutants and sediments to neighborhood, impacting the buildings close to the site becoming headline on local newspaper's first page (figure 2).

Unfortunally, this event was the diverter from the non environmental responsible time and the necessity of program to prevent the stormwater pollution be implemented

First of all, it was made a soil analyses to know how much permeable it is and the runoff coefficient to compare how much local rainfall occurs to decide which measures should be taken. The summer time is worst for storm water and until January almost nothing had been done. At that time, it should be hurry, more rainstorms should be coming, and the measures must be applied.

The decision were restart from the beginning by the program using both permit as guidance to assist in developing the Stormwater Pollution Prevention Planed in order to follow the steps: Site assessment and planning, Selecting erosion and sediment control BMPs, Selecting good housekeeping BMPs, Inspection maintenance and recordkeeping in order to identify the potential sources of stormwater pollution at the construction site by attending the ten principles to erosion and sediment control by structural and non-structural practices used during the construction process to keep sediment in place (erosion control) and to capture any sediment that is moved by stormwater before it leaves the site (sediment control).

2. The erosion and sediment control program

2.1 Finding up the program requirements

Applicability—describing the geographic area covered and who is eligible to apply; Authorization—describing the types of stormwater (and non-stormwater) discharges that are covered; Permit requirements—outlines the elements that should to be addressed to prevent the contamination of stormwater runoff leaving the construction site; Implementation—BMP installation, inspection, and maintenance requirements; Other requirements—may include additional requirements such as spill prevention; Standard conditions—list of conditions that are applicable to most NPDES permits; Termination—lists conditions for terminating permit coverage after construction is complete (USEPA, 2007).

2.2 Site evaluation and data collection to selecting appropriate BMPs

First, it was necessary localize the site pollutants and the areas where it could come from or generate, aspects and impacts (figures 3, 4):

• Description of controls to reduce pollutants; Maintenance/inspection procedures; Records of inspections and follow-up maintenance of BMPs.

CONSTRUCTION SITE POLLUTANTS									
	Primary Pollutant	Others Pollutants							
Areas of Consideration	Sediment	Nutrients	Heavy metals	pH (acids & bases)	Pesticides & herbicides	Oil & grease	Bacteria & viruses	Trash, debris, solids	Other toxic chemicals
Clearing, grading, excavating, and unstabilized areas									
Paving operations									
Concrete washout and waste									
Structure construction/painting/cleaning									
Demolition and debris disposal									
Dewatering operations									
Drilling and blasting operations									
Material delivery and storage									
Material use during building process									
Solid waste (trash and debris)									
Hazardous waste									
Contaminated spills									
Sanitary/septic waste									
Vehicle/equipment fueling and maintenance									
Vehicle/equipment use and storage									
Landscaping operations									

Figure 3 Construction Site Pollutants Matrix (USEPA 2007).

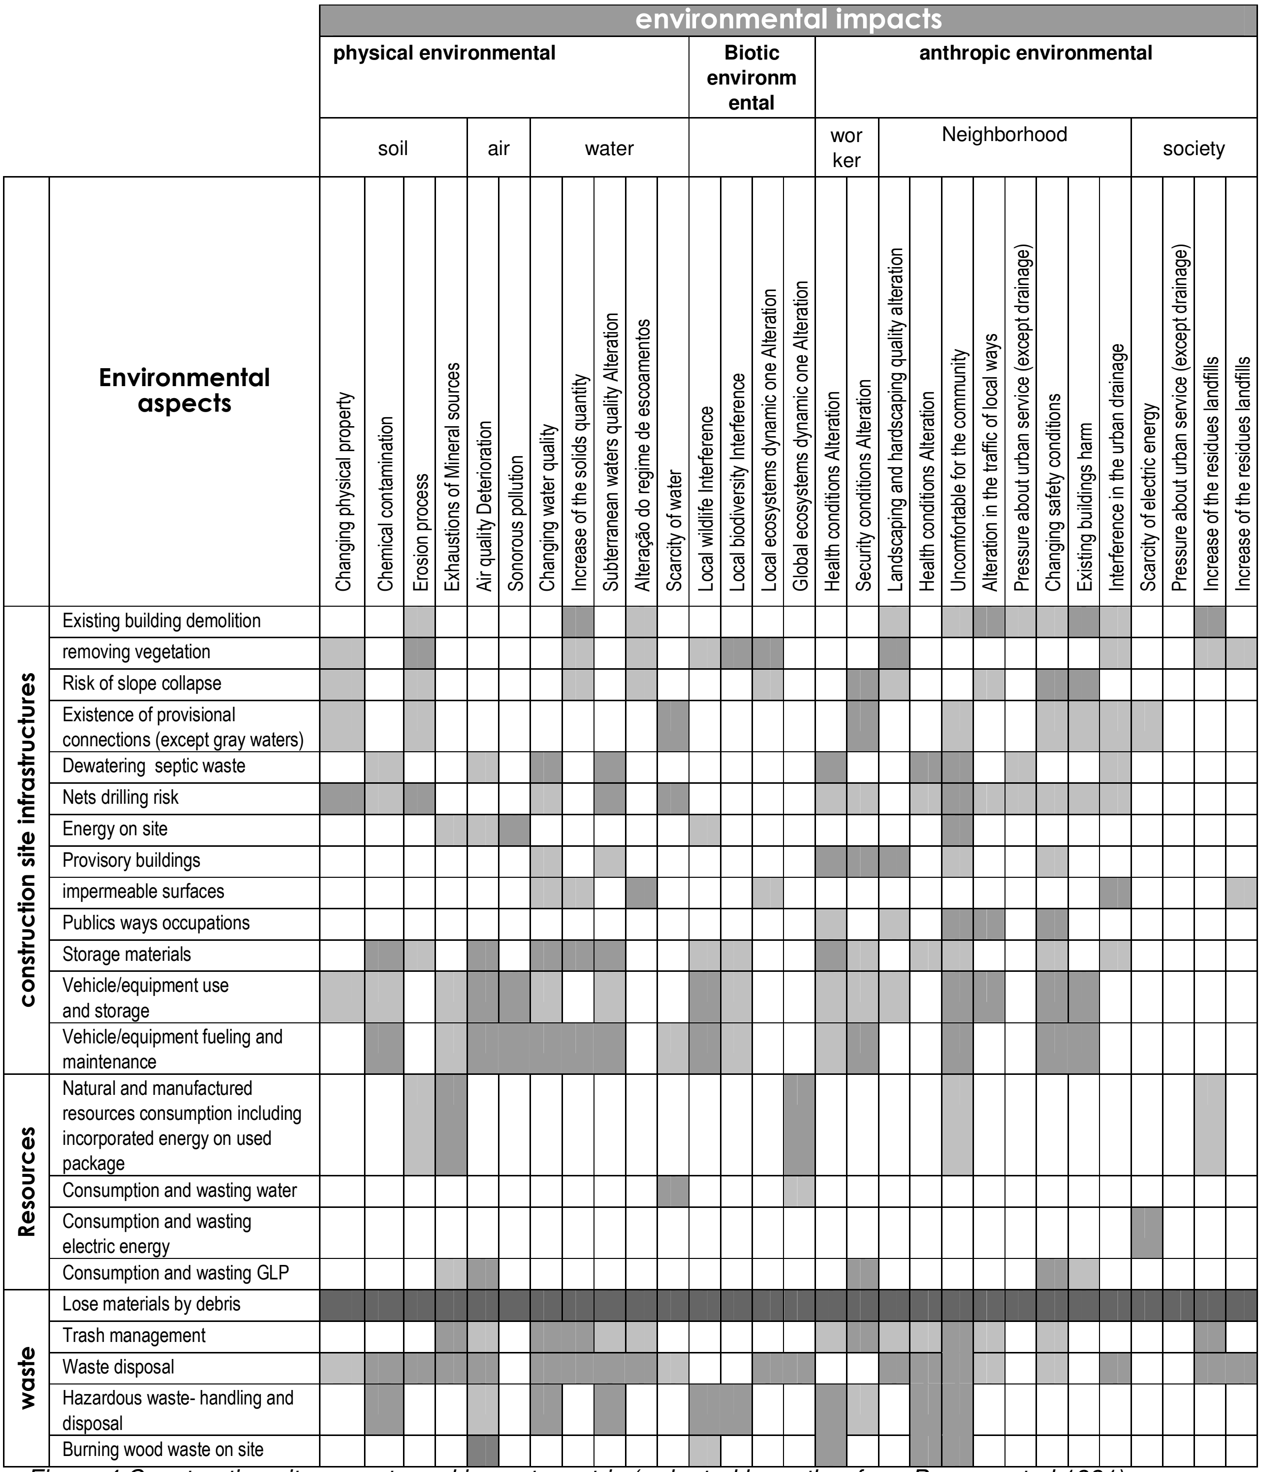

Figure 4 Construction site aspects and impacts matrix (adapted by author from Berman,et al 1991).

2.2.1 Minimize disturbed area protecting natural features and Control stormwater flowing onto and through the project

In spite of the Drilling and blasting Operations be the principal activity by that time and the whole site was revolved it was carefully considered the natural features of the site by carefully delineating and controlling the area that was been disturbed by grading or others construction activities, it was greatly reduced the potential for soil erosion and stormwater pollution problems. Limit disturbed areas to only those necessary for the construction of the project (figures 5). Natural vegetation was the best and cheapest erosion control BMP to protect and preserving topsoil. Another technique applied for minimizing the duration of exposed soil is phasing. By scheduling or sequencing your construction work and concentrating it in certain areas, it was minimized the amount of soil that was exposed to the elements at any given time. It was limited the area of disturbance to places where construction activities are underway and stabilizing them as quickly was possible.

Figure 5 Mapping the critical areas and preservation of existing vegetation (future public park).

Got site to final grade temporarily stabilized almost all bare soil areas as soon was possible and provided additional stabilization on erosion prone areas such as slopes and drainage ways. Areas needed for future roads, construction, or other purposes had been temporarily stabilized. Establishing a vegetated cover on as much of the site was possible did help to minimize erosion and sediment problems (figure 6).

Figure 6 the native vegetation growing evolution after have been removed.

2.2.2 Protected slopes and channels

Convey concentrated stormwater runoff around the top of slopes and stabilize slopes as soon as possible. This could be accomplished by using pipe slope drains or earthen berms that did convey runoff around the exposed slope, avoiding disturbing natural channels and the vegetation along natural channels (figure 14 16).

2.2.3 Establish perimeter controls to retain sediment onsite and control dewatering practices stabilized construction exits

Maintained natural areas and supplemented them it was installed controls on the downslope perimeter of the project to help prevent soil erosion and stop sediment from leaving the site. Sediment barriers was used can trap sediment from small areas, it was required, if consider using a temporary sediment trap or sediment basin. These practices detain sediment-laden runoff for a period of time, allowing sediment to settle before the runoff is discharged. It was Identified the best locations where vehicles will enter and exit the site. Wash racks and a hose-down system remove even more mud and debris from vehicle tires avoid Vehicles entering and leaving the site track significant amounts of sediment onto streets (figures 7, 8 and 9).

Figure 7 The outlet tire wash.

Figure 8 The outlet tire wash.

Figure 9 the sediment box view.

2.2.4 Inspect and maintain controls

Inspection and maintenance has been important as proper planning and installation of controls. So a checklist is applied every month, besides local daily visits to verify the site conditions. It was realized that without adequate maintenance, erosion and sediment controls will fail. Perform maintenance or corrective action as soon as problems were noted (California Stormwater Quality Association. 2004).

2.3 Housekeeping

Key Pollution Prevention Principles for Good Housekeeping were applied focused on construction projects generate large amounts of building-related waste, which can end up polluting stormwater runoff if not properly managed. Some of the best management practices applied are pollution prevention or good housekeeping practices that were designed to prevent contamination of stormwater from a wide range of materials and wastes at the site as: waste management system; proper building material staging areas; paint and concrete washout areas; The site doesn't have proper equipment/vehicle fueling and maintenance local and is necessary plan it soon and Develop a spill prevention and response plan as figure 10, 11 and 12.

Figure 10 equipment/vehicle fueling.

Figure 11 Grease spill.

Figure 12 fueling by biodiesel.

2.4 Dust and particulate matter control

Wind erodes soils and transports the sediments offsite, where they may be washed into the receiving water by the next rainstorm. Therefore, various methods were dust control needed to be employed to prevent dust from being carried away from the construction site. Localize how and where the dust is generate was necessary to decide how it should be treated by Identified the points critical and attack-them with more quickness; New opened accesses and do suppression of vegetation while the work was requiring; Dominant winds Mapping; Defined contingency plan for all grading process, including drilling and blastering operations and particulate control plan from it by watering (figure 20); In The phase of grading and excavations, verified manual of procedures and standards for safety slopes inclination and Material stock pile stabilization.

3. Results and Conclusions

Table 1 Results- before and after the Erosion and Sedimentation Control Plan

Before the plan situation	After plan results
 *Figure 13 The erosion process.*	 *Figure 14 Seeding the slopes and water velocity dissipation.*
 *Figure 15 The erosion process.*	 *Figure 16 Slope drains and Drainage swales.*

Before the plan situation	After plan results
 Figure 17 Flooded.	 Figure 18 Sediment basin and dewatering operation control.
 Figure 19 Dust by traffic.	 Figure 20 watering prevent dust by Soils storage piles and traffic.
 Figure 21 Dust by drilling.	 Figure 22 Watering prevent dust by drilling and blastering activities.

The results shown that the measures are very simple, cheap and efficient, but need be planed concluding that the environmental goals should be defined in the project development design phase, as well as the definition for guide the legal procurement processes. The level of detailing of the drawings for documenting the fulfillments of the SS Pre-requisite 1 is above the habitual Brazilian's design offices routine. Brazil has national laws to regulates the pollution prevention activities on the construction site but usually not followed.

The solid particles or particulate matters risen by wind drags nearly always is neglected finally it states that the necessary measures for being in conformity with the SS Pre-requisite 1 do not impact in the final cost of execution, but need be backed contractually for guarantee of its application. In general there is no concern with basic actions that will be able to generate pollution in the water bodies receivers and impacting the whole neighborhood.

Keywords: simulation methodology, high-rise office building, double-skin façade, computational fluid dynamic

Summary

A number of recent investigations and findings are reported in the literature pertaining to the used of double-skin façade for passive ventilation in buildings and the researches have revealed close link between natural ventilation design and the design of double-skin façade. It was found that significant energy saving is possible if natural ventilation strategy could be exploited with the use of double-skin façade. In this research, CFD was used to analyse the correlation between thermal comfort parameters and different double-skin façade orientations to be used in high-rise office buildings in hot and humid climate. A comprehensive methodology is proposed and results were presented.

1. Introduction

Extensive research has been carried in defining what is thermal comfort and the parameters that affecting it. All those findings had confirmed the importance of human factors and human influence towards the creation of a thermally comfortable indoor environment (Fanger 1970 and Ruck 1989). In more recent experimental studies concerning the effects of some human factors on the comfort conditions in particular geographical location, Dear, Leow and Foo (1991) found that people working in naturally ventilated buildings in hot and humid country could accept a temperature value of up to 3°C warmer than Fanger's values. This with other similar findings especially the newly published ASHRAE standard 55-2004 (2004) have given the opportunity in introducing natural ventilation for commercial buildings in the hot and humid region.

A number of interesting investigations and findings are reported in the literature pertaining to passive ventilation in buildings and the thermal performance of double-skin facades. Even though most of the researches are done mainly in temperate countries conditions but they have revealed close link between natural ventilation design and the function of double-skin façade. Grabe et al. (2001) developed a simulation algorithm to investigate the temperature behaviour and the flow characteristics of double facades with natural convection through solar radiation. Similar works on natural convection ventilation also reported by Ziskind et al. (2002, 2003), Bansal et al. (1994), Hamdy and Fikry (1998), and Priyadarsini et al. (2003). Most of them are using the idea of stack effect or the solar chimney concept and found that passive ventilation in summer is possible even for multi-storey buildings. In particular Priyadarsini et al. (2003) have concluded the energy efficiency of stack system used in residential of a hot and humid climate region.

Li Y and Delsante (2001) went a step further to investigate the effects of natural ventilation caused by wind and thermal forces in a single zone building with two openings. Ventilation graphs are plotted using the air change parameters (thermal air change, wind air change and the heat loss air change) for design purposes. Gratia and Herde (2004) attempted to look at the impact of double-skin façade facing southern direction in a temperate climatic condition. Thermal analysis using simulation software of different seasons of a year was done for a low-rise office building with and without double-skin façade. It was found that significant energy saving is possible if natural ventilation could be exploited through the use of double-skin façade.

This paper attempts to bridge the gap of looking into the possibilities of natural ventilation in high-rise office buildings specifically in the hot and humid climate region with the use of double-skin façade. The unique façade construction is thought to be able to act as a stack in providing required ventilation for the thermal comfort of the internal space. Airflow effects induced by wind and thermal forces on a high-rise office building are observed with all the thermal comfort parameters included are analysed.

2. Research Methodology

A virtual prototyping computational fluid dynamic (CFD) simulation software called Airpak (2003) is used in this research to model the complex energy transfer through the component layers of the multiplayer façade through the optimisation of the appropriate opening sizes on the glazing, the width of the intermediate space and the ventilation rate through the internal office space. The validation of the software has been carried out by comparing the experimental and simulation results from another commercial simulation software called FloVent which carried out by Manz H (2003). Both of the results are compared and analysed and it was found that the variation is within 5% of the acceptable error tolerance.

In view of the complexity of the problem at hand, the modelling of the computer model has been broken down into different 'levels'. The initial single office module in 3D is constructed with the geometrical dimensions of 3.5m x 5.0m x 3.5m in height. Numerous simulation runs have been carried out for the benchmarking purposes in which a typical curtain walling office module was observed and a simplified 'nomogram' has been established to define the initial parameters for thermal comfort in the tropical region. These results are compared with the simulation runs from the office module with double-skin façade construction. Following-up with the simulations analysis of a single office module discussed above, the computer model is 'extended vertically' to incorporate a 'concealed ground floor space' which usually used as shop front space for most high-rise office buildings. The office space is only starting at 1st level. Two different groups of modelling are constructed at this stage. First group is the benchmarking model with standard curtain walling system generally used in most modern high-rise office buildings (Figure 1). The other group is replaced with a standard vertically vented double-skin façade construction (Figure 2).

The strategy is to 'break-down' a very complex problem of simulating a multi-storey high-rise building into a '6-storey building block'. Simulations will be run for the 1st building block of 6-storey for the modelling of the office building from ground floor to 6-storey. Subsequently another 6-storey building block of the model will be constructed for modelling of the office building from 7-storey to 12-storey. The last building block will be the modelling of the office building from 13-storey to 18-storey. The building height of 18-storey or about 60m high will constitute the majority of the office buildings height in a medium to medium-dense modern city. This will give a good representation for investigating the problem at hand.

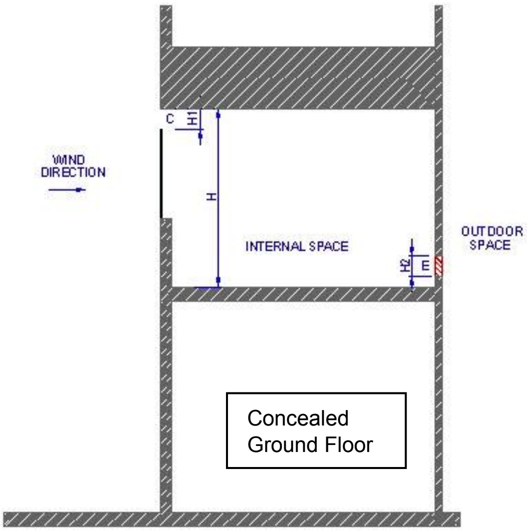

Figure 1 Standard curtain walling model.

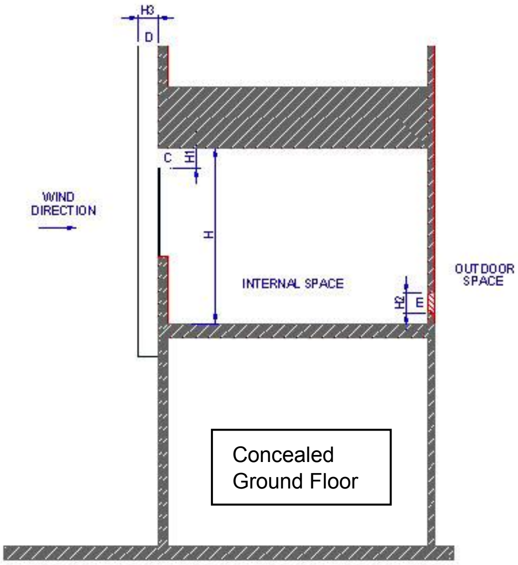

Figure 2 Double-skin façade model.

3. CFD Modelling

The first block (Stage 1) of the six-storey building (Figure 3) consists of a ground floor (which is not served by the double-skin façade, as this will be the typical design for any high-rise building) and 5 stories of office spaces above. The double-skin façade is a ventilated-shaft design which is 2.8m from ground level. In earlier findings it is a practical and economical option to introduce a shaft to improve the stack effect of the natural ventilation and in turn will improve the airflow rates required to reach thermal comfort level within the interior office space.

The heat sources for the CFD model will only be introduced at alternate floor, starting from 1st-storey. This was done to reduce the complexity of the model and computing time, but at the same time will be able to give a comprehensive view of the indoor thermal comfort of the office spaces. Each alternate floor will have two occupants, two computers and four ceiling lights, which are the same as the initial single office model. Each human model is assigned with 75 W/m^2 of heat generation with clothing value (clo) of 1.0 and metabolic rate (met) of 1.2 for sedentary office activities. Heat generated for the computers are 108 W/m^2 and 173 W/m^2 respectively and the heat flux of the lighting fixture is assumed to be 38 W/m^2 each.

Boundary conditions for wind velocity, external temperature and relative humidity were set to the ranges similar to the climatic conditions for Singapore. The ambient temperature in Singapore is hot with high humidity and relatively low wind velocity throughout most of the year. Only the optimum opening sizes on the inner pane and the air gap sizes of the double-skin façade (DSF) are being considered (as shown in Figure 4) for this stage of simulations, based on the findings from the preliminary modelling. The optimum vent size at the rear wall was found to be 300mm by 600mm from previous findings. The scope of the problem in investigation has been 'narrowed down' and carefully 'controlled' to find the 'optimum DSF configuration' for use in Singapore climatic conditions.

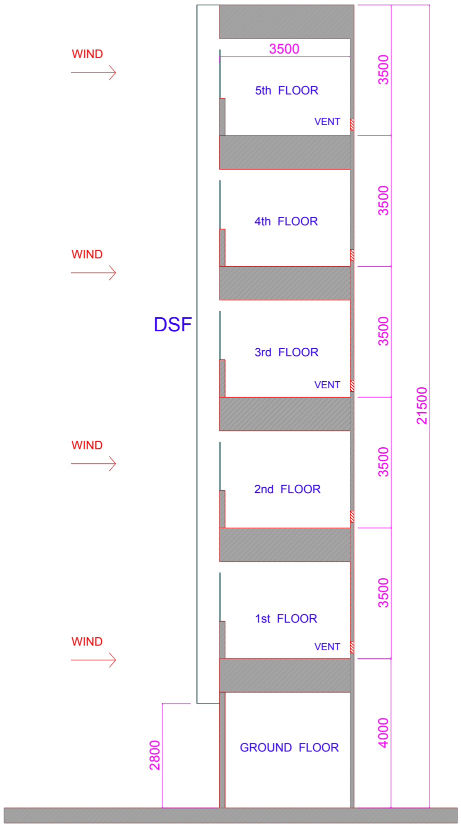

Figure 3 Model geometry of Stage 1 of the 6-storey office building.

4. Results

4.1 Comparison of results for single-skin and double-skin facades

The results obtained from the benchmarking simulations, which is a typical curtain walling system façade, are compared to the results from the proposed prototype double-skin façade.

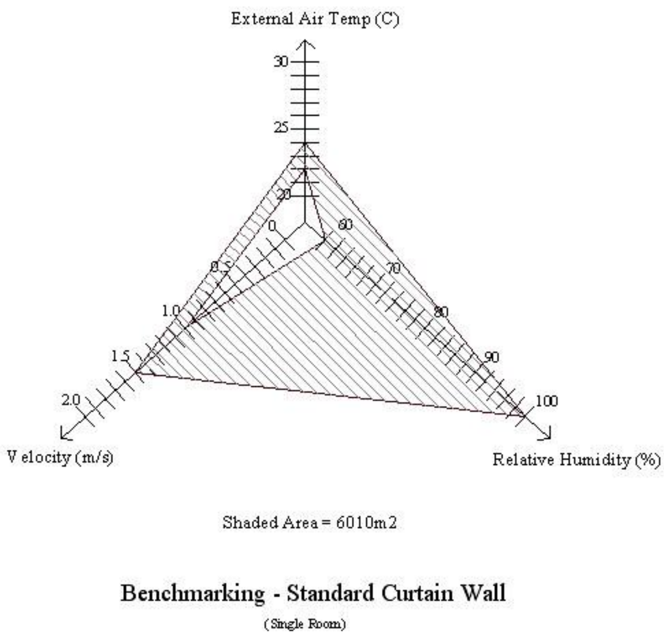

Figure 5 Nomogram showing the acceptable thermal comfort conditions (shaded area) for standard curtain wall system.

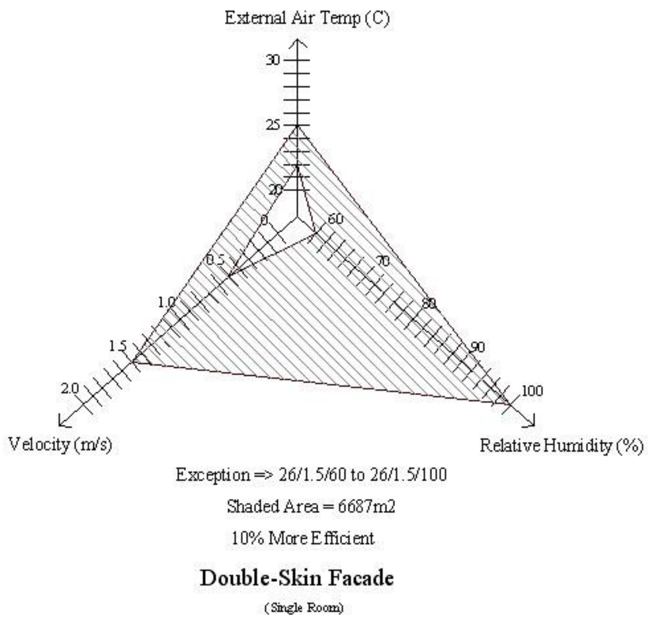

Figure 6 Nomogram showing the acceptable thermal comfort conditions (shaded area) for double-skin facade system.

The nomograms are formed by three axes, which represent the three important parameters in thermal comfort analysis, temperature, air velocity and relative humidity. Boundaries of thermal comfort are plotted onto the nomograms from the analysis of the simulation results and they are compared to see whether there are any advantages for using double-skin construction for an office building in the tropical climate.

Figures 5 & 6 above have shown that there are positive points in using the double-skin construction, as the 'shaded area' for the double-skin façade is larger than the normal curtain walling construction, even though this finding is only representing the low level results for the high-rise office building in study. The findings are encouraging as the double-skin façade construction does improve the internal thermal comfort for a naturally ventilated office space by as much as 10%, as compared to conventional curtain wall system.

4.2 Simulation results for South facing DSF system (Stage 1)

The first group of simulations is generated with the DSF system constructed at the south facing façade of the building only. The simulation periods are at 10 a.m. or 2 p.m. on either 15 January or 1 July of the month with wind direction perpendicular to the DSF wall and with wind velocities of 0.5 m/s, 1.5 m/s and 3 m/s. The external ambient temperatures were set from 26°C to 30°C with relative humidity ranging from 70% to 100%. The opening size for the inner pane of the DSF system used is 300mm. The air gap sizes used for the DSF are 300mm, 600mm, 900mm and 1200mm. The air vent size at the rear office wall is fixed at 300mm x 600mm.

There are a total of 18 location points being identified to record the simulation results on thermal comfort parameters. Six of those location points which are 0.8m above the office floor level and 0.2m away from the two human figures. These six points are chosen to monitor the thermal comfort conditions experienced by the occupants. Table 1 shows some of the comparative results for the simulation with different parameters used for the boundary conditions and DSF configurations taken at strategic locations. The indoor Operative Temperature (OT) calculated in the above table was using the formula stated in Figure 7 and the value was used to identify acceptable thermal comfort for naturally ventilated spaces in hot and humid climate using the graph given in the same figure.

4.3 Analysis of results and findings for Stage 1

Selected results for South facing DSF with external wind velocity of 1.5m/s and air humidity of 80% respectively are tabulated in Table 1. The variable parameters in consideration for this instance are external air temperature, the DSF air gap size and the time of the day. Results for S1-1, S1-2 and S1-3 (South facing DSF) as shown in Table 1 and Figure 8 indicated that the DSF air gap size of 300mm gives the best result for the particular conditions in a natural ventilated space. The findings are the same for the Northern orientation façade as presented in Figure 9. In most cases the lower floor of the office space would generate the lowest operative temperature due to the 'stack effect' provided by the DSF configuration. This has enhanced the natural ventilation strategy to provide better internal thermal comfort condition for the office spaces.

There is not much of a difference in terms of the internal thermal comfort conditions for either period of time in a given day (morning or afternoon) as seen in the results for S1-4 and S1-5 for South facing DSF. There is an internal temperature difference of 0.5°C for the mid-floor of North facing DSF and this could be due to the slower internal air velocity generated (Figure 9).

The South facing DSF configuration has produced an 80% Acceptability Limit for the 300mm air gap size for external temperatures between 26°C and 28°C, according to the Thermal Environment Conditions for Human Occupancy from ANSI/ASHRAE Standard 55-2004 as indicated in Figure 7. This is tabulated in accordance with the context that the office building is located in the Northern Hemisphere of tropical climate like the country of Singapore. The North facing DSF configuration did not produce any acceptable internal thermal comfort condition for the office space (Figure 9) as the operative temperatures for all the floors are above 30°C. This has again confirmed that the southern orientation is the best facing for buildings in the Northern Hemisphere.

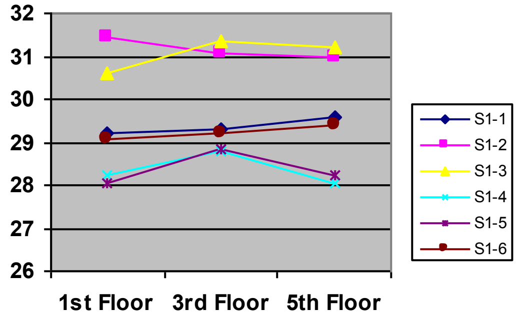

Figure 8 Comparison of Operative Temperatures (°C) for South facing DSF.

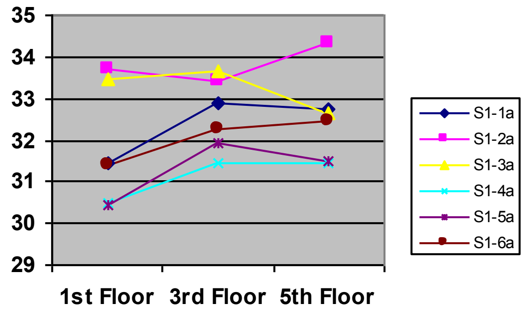

Figure 9 Comparison of Operative Temperatures (°C) for North facing DSF.

4.4 Analysis of results and findings for Stage 2

The selected results for both South and North facing DSF configurations are having similar parameters as Stage 1 for direct comparison. The external wind velocity is 1.5m/s and air humidity is 80% respectively and the variable parameters in consideration for this Stage are external air temperature, the DSF air gap size and the time of the day. South facing DSF with a DSF air gap size of 300mm gives the best result. The findings are the same for the Northern orientation façade. In most cases the lower floor of the office space would generate the lowest operative temperature due to the 'stack effect' provided by the DSF configuration.

There is not much of a difference in terms of the internal thermal comfort conditions for either period of time in a given day (morning or afternoon) as seen in the results for South facing DSF but for North facing DSF morning period has a higher operative temperatures compare to afternoon period. This could be due to the higher internal radiant temperatures generated during this particular period of time.

The South facing DSF configuration has produced an 80% Acceptability Limit for the 300mm air gap size for external temperature of 26°C up to 9th Floor. The North facing DSF configuration did not produce any acceptable internal thermal comfort condition for the office space as the operative temperatures for all the floors are above 31°C.

4.5 Analysis of results and findings for Stage 3

The selected results for both South and North facing DSF configurations are having similar parameters as Stages 1 and 2 for direct comparison. The external wind velocity is 1.5m/s and air humidity is 80% respectively and the variable parameters in consideration for this Stage are also external air temperature, the DSF air gap size and the time of the day. Results for South facing DSF indicated that the DSF air gap size of 300mm gives the best result for the particular conditions in a natural ventilated space, as in Stages 1 and 2. The findings are the same for the Northern orientation façade. In most cases the lower floor of the office space would generate the lowest operative temperature due to the 'stack effect' provided by the DSF configuration, as in Stages 1 and 2 also.

There is not much of a difference in terms of the internal thermal comfort conditions for either period of time in a given day (morning or afternoon) as seen in the results for South facing DSF.

The South facing DSF configuration has produced an 80% Acceptability Limit for the 300mm air gap size for external temperatures between 26°C and 28°C. The North facing DSF configuration did not produce any acceptable internal thermal comfort condition for the office space except for the lower floor for 300mm air gap configuration with external air temperature of 26°C during morning period.

4.6 Comparison results for different orientations

The simulation results for the three stages of the modelling have shown that the South-facing orientation provide a better outcome compared to the North-facing direction. The optimum air gap size for the double-skin façade construction is found to be 300mm and the best results were obtained during the morning period.

Figure 10 below recorded the comparison of selective results between the four major orientations for a double-skin façade installation for a typical high-rise office building. The results show that the South-facing façade has the best outcome followed by the East-facing façade during the morning period in the month of January. The North-facing and the West-facing façades do not provide an acceptable indoor thermal comfort for the purposes of office function in a high-rise building.

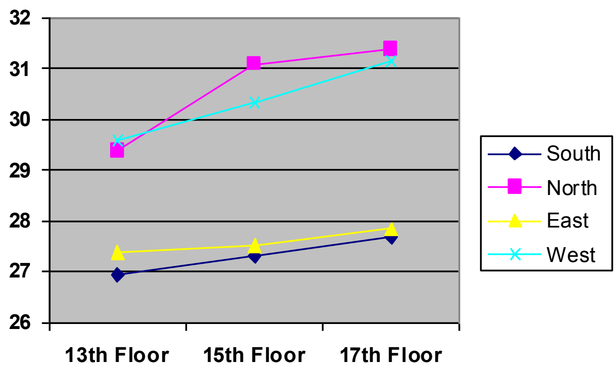

Figure 10 Comparison of Operative Temperatures (°C) for four major orientations.

5. Conclusion

Figure 11 below shows the complete 18-storey office building with typical multi-storey double-skin façade configuration. The proposed DSF starts from 1st storey at 2.8 meters from ground level up to the 17th storey with 1-meter parapet above the roof level. The office spaces are assumed to be divided into a number of small office usages and are tenanted out to various occupants. All office spaces are assumed to face the DSF at the front and facing open corridor at the rear.

With the completion of the three stages of simulations, numerous simulation runs had been carried out with various ambient temperatures, different external air velocities, different orientations of the double-skin façade, different periods of time during the day, etc in order to find out the appropriate window periods for acceptable indoor conditions for office workers in the Singapore context. These findings will be of outmost important as an indication whether double-skin façade is really possible to be used as a mean to introduce natural ventilation to the high-rise buildings in the tropics. The results and findings will also bear an important decision in how to carry out the optimization of the façade system for the whole high-rise office building.

The simulation methodology proposed is comprehensive in simulating a rather complex high-rise office building with accurate results. Further works could be carried out in developing a methodology to simulate office building with different combination of office sizes and usages in an efficient and accurate way.

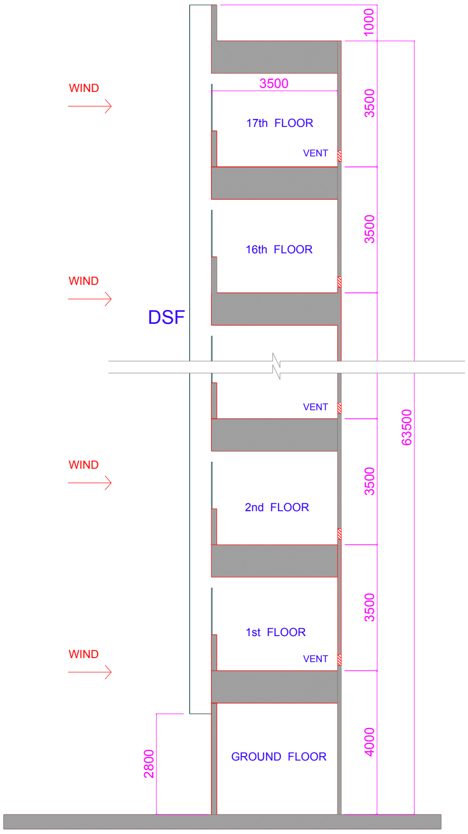

Figure 11 The model of the complete 18-storey office building.

Keywords: Sustainable Building, Malaysia, Labelling System, Office Buildings, Performance Criteria

Summary

The Green Building Mission launched recently by the Malaysian Government is an indication of a promising effort to ensure sustainable production and delivery of the construction industry products to fulfil these demands. The paper highlights the environmental issues faced by Malaysia and initiatives taken towards a cleaner environment. The development of a sustainable building label for the construction industry under these initiatives are described. Several existing building assessment methods were reviewed to examine their suitability for adaptation. The proposed labelling system takes into consideration of the local issues to provide a useful guide for the planning and construction of sustainable buildings in Malaysia and transformation of the construction industry into sustainable practices.

1. Introduction

The United Nations Framework on Climate Change Conference held in Bali Indonesia in December 2007 highlighted the potential of the building and construction sector in reducing global greenhouse gas emissions and carbon footprints through existing technologies and solutions. In this context, the adoption of sustainable buildings present key opportunities in regenerating the natural environment and community culture by enhancing the value of products and services to business, customers and society in general.

There is increasing public awareness and interest in Malaysia on how buildings affect the environment, worker productivity and public health. Both the public and private sector are beginning to demand buildings that optimize energy use; promote resource efficiency; and improve indoor environmental quality. Developers, owners, operators, insurers, and the public at large have started to value and market the benefits of sustainable buildings. These factors create new design, construction, and operation demands on building/urban facilities and the infrastructure which supports them.

Unfortunately, in Malaysia and in most developing countries, regulatory procedures to guide sustainable building and construction are still very limited. Additionally, in many cases, existing technologies for producing sustainable buildings are still poorly known across the building and construction spectrum and more often, these technologies are not being supported by existing policies and market signals (Shafii et al 2005, Shafii et al 2007, UNFCCC 2007, SBCI 2007, Marrakech Task Force 2007). In order to encourage the implementation of sustainable buildings, and setting a long term pathway to a low-carbon future for Malaysia, therefore a supporting building assessment framework is urgently required.

The paper describes the environmental issues surrounding Malaysian construction industry, and how these are addressed in the development of the buildings labelling system. A review of selected existing building assessment systems were undertaken for consideration of adaptation to Malaysia's requirement. The performance criteria of the adapted system is presented.

2. Environmental Issues in Malaysia

2.1 Energy Efficiency

The industrial sector has always been the biggest user of electricity, consuming about 54% of the overall electricity generated in 2001. The residential and commercial sector consumed 46% (18% Residential and 28% Commercial), while public lighting, mining and other sectors consumed about 1%. Peak demand in Peninsular Malaysia alone has grown from 3447 Megawatts in 1990 to 9712 Megawatts in 2000 and 10,060 Megawatts in 2001. A projection of these analysis indicated an increase by more than 117 percent, i.e.

21668 Megawatts by year 2010. In 2001, 76% of the electricity was generated using gas, 9% using coal, and 8% from Hydro power.

In Malaysia not much published data is available yet on the Energy Performance or actual annual energy consumption of buildings. However, the energy index (total energy used in a building for one year divided by the gross floor area of building) of typical office buildings is between 250-300 kWh/m2/year depending on the type and function of buildings. The breakdown of average energy consumption in an office building is 52% for air conditioning, 20% for lighting and 28% for general equipment *(Kristensen,2003).*

Although the shift of economy towards energy–intensive industries is a major reason behind the increased in energy demand, inefficient energy consumption by the public also account for the higher energy demands. Some office buildings and hotels maintain indoor temperatures as low as 18- 20 degrees centigrade against the thermal comfort range of 23-25 degrees C. Occupants have to wear sweaters at the work desk while energy is unnecessarily wasted for excessive cooling. The cost implication and continuous upward trend in energy consumption is a serious concern to the Malaysian government as this will eventually make energy supply over-costly and unsustainable. For environmental and economic reasons, initiatives have been taken by the Malaysian government for future buildings to be energy efficient in order to avoid depletion of fossil fuels whilst at the same time reducing the impacts upon combat climate.

2.2 Water

The growth in population and GDP over the last three decades has resulted in heavy demand for water. The problem of population growth is particularly felt in the urban areas, due to rural-urban migration and growing urbanization. The domestic and industrial water demand in Malaysia is expected to triple over the next 50 years. Estimation based on doubling the per capita water consumption by 2020, predicts that water shortages will occur within the next 5 years.

In general, the efficiency of water consumption in Malaysia is low. The amount of water consumed by the agriculture, industrial and domestic sector are approximately 62%, 21 % and 17% of the total water resources, respectively (Table 1). Table 1 shows the water consumption of OECD countries, including Malaysia. As irrigation water is charged on a per-area basis rather than on volume used and is relatively cheap, there is little incentive for farmers to use the water efficiently. Not surprisingly, Malaysia consumed a big share of their water resources in agricultural sector (Table 1).

In Malaysia, there is also a high proportion of unaccounted water in urban water supply systems, as one quarter to one third of the domestic and industrial water is lost before it reaches the consumers. These losses are the result of leaks in the distribution systems and illegal connections.

With increased demand from population growth and industrialization as well as competing for diminishing water availability, the optimization of water utilization must be dealt by the government urgently, in order to move towards efficiency, effectiveness of use conservation and sustainability.

Waste water is also an environmental issue in Malaysia. The 9th Malaysia Plan intensifies research and development on reuse of sludge for industrial, agricultural and landscape purposes as well as wastewater.

2.3 Solid Waste Management

Due to growing population and increasing consumption, Malaysia generates waste at 19,100 tons per day. In Kuala Lumpur waste generation is about 3,000 tons a day and forecasts shows that this will increase each year. In 2007, about 7.34 million tonnes of solid wastes were generated in Malaysia, enough to fill up 42 buildings of the same size as the world-renowned Petronas Twin Towers (Bernama, 2006). Whilst recycling has almost drawn universal acceptance as a means of waste disposal, Malaysia's domestic recycling rate still hovers at a mere five per cent.

The disposal of solid waste has been solely through open landfills. At this rate, more sanitary landfills and incinerator plants are needed in the future to prevent water contamination and environmental pollution. Although land in Malaysia is seemingly abundant, taking more and more land to be used as landfills is simply not a sustainable solution to this growing problem.

Table 1 Water consumption in OECD countries and Malaysia

Country	Water Use Share in Agriculture (%) [2000]	Country	Water Use Share in Industry (%) [2000]	Country	Water Use Share in Domestic (%) [2000]
Ireland	0.0	Greece	3.2	Netherlands	6.1
Iceland	0.1	New Zealand	9.5	Portugal	9.6
Austria	1.0	Australia	10.0	Germany	12.4

Spain	68.0	France	74.5	Iceland	34.0
Australia	75.3	United Kingdom	75.4	Austria	35.1
Portugal	78.3	Ireland	77.4	Sweden	36.7
Greece	80.5	Finland	83.7	New Zealand	48.5

3. Initiatives Towards a Cleaner Environment

The implementation of sustainable buildings in Malaysia will have to address major issues faced by the Malaysian construction industry, i.e. water conservation waste water reduction, energy efficiency and waste management. The Green Building Mission launched recently by the Malaysian Government is an indication of a promising effort to ensure sustainable production and delivery of the construction industry products to fulfill these demands.

The 9th Malaysia Plan (2006-2010) placed further emphasis on preventive measures to mitigate and minimise negative environmental effects, intensify conservation efforts and ensure sustainable development of depleted and renewable resources for a cleaner Malaysia.

The Malaysian Government is promoting and campaigning for the use of energy efficiency buildings like low energy case and zero energy case in demonstration buildings built for their own facilities. Their commitment to energy efficiency programme is further reflected in the development of Code of Practice on Energy Efficiency and Use of Renewable Energy for Non-Residential Buildings (MS 1525). Additionally, the government has also encourage the development and utilization of renewable energy whereby the Clean Development Mechanism (CDM) has been used to support the implementation of small renewable energy programmes (SREP).

The Ministry of Energy, Water and Communications of Malaysia runs the Water Conservation Awareness Campaign which is targeted to conserve 10% of water consumption by valuing it in reduction of domestic water usage by 10%. The government has started a campaign to construct green buildings. One of the suggestions being made is discouraging the use of treated water for washing cars, floors and gardening. As Malaysia received abundance of rain the collection of water through rain harvesting is encouraged. This untreated water is deemed to provide a better option for such activities (Bernama, 2006)

In addressing waste issues, the Government has focussed on the 3 R's principles - reuse, reduction and recycling of materials and promoting companies that undertake these activities. Meanwhile, the housing and local government is also drafting a master plan on solid waste management, which includes recycling campaigns, landfills and installation of incinerators. Eventually, waste reduction and recycling is no longer an option in Malaysia, but a necessity to protect both the environment and quality of life.

Guidance is needed in implementing these environmental measures and issues in buildings. The development of a building labelling system to take into consideration of these issues are described in the foregoing paragraphs.

4. Existing Sustainable Building Assessment / Labelling Systems

Sustainable Building Labelling Systems provide a common set of criteria & targets to achieve sustainable buildings. It also offers structured advice, including goals, strategies, and actions that are suitable for improving building performance. These systems also enable actors in the building industry to be more measured and accurate towards developing sustainable forms of designing, constructing and operating buildings. However, assessment systems vary with the requirements and priorities of the countries in which they were developed. After all, sustainability should be looked upon in the local context therefore for a fair evaluation and assessment of buildings, the system must address local issues. As assessment systems are unique for different countries, there has been considerable interest in developing robust and validated systems that can provide comprehensive performance assessments of buildings which encompass a broad range of physical conditions, cultural dimensions and environmental priorities occurring in different countries.

The development for a building assessment system/labelling system is crucial to address the issues mentioned in 2. and to guide sustainable development in Malaysia. As a first attempt, the Pro-tem Committee of The Malaysian Sustainable Building Council has focused on the development of an assessment system for new office buildings. Part of these development is described in section 4.

4.1 Comparison of Assessment Systems

Existing assessment systems namely, LEED (Leadership In Energy and Environmental Design, USA), BREEAM (Building Research Establishment Environmental Assessment Method, UK), SB Tool (Canada) and Green Mark (Singapore) were reviewed to study the respective scope of assessment, weights, scoring and reporting system. Of the four systems, Green Mark is the only one being developed within the tropical context. The information derived from these studies provide the basis for the development of an effective building assessment system in accordance to Malaysian requirements.

4.1.1 Scope of Assessment

Although many comparisons have been made by earlier researchers, this section is intended for summarising the important factors of the assessment methods and its relevance to the Malaysian context.

LEED (USA), BREEAM (UK), SB Tool (Canada) and Green Mark (Singapore) covered the essential critical criteria related to sites, resource use, ecological loading and indoor environmental quality (Table 2). Out of these systems, SB Tool is the most comprehensive, encompassing the broader context of sustainability which include social issues like amenities for the disabled and enhanced security measures as well as economic issues through life cycle costing (Ng, 2005). Security is an important issue addressed in current building development. The design and construction of safe and secure buildings continues to be the primary goal for owners, architects, engineers, and project managers.

LEED and Green Mark do not take into account of embodied energy. The absence of national database, made it difficult to precisely assess building life cycle environmental aspects, especially embodied energy (Scheuer and Keoleian, 2002). Buildings with short life spans will have relatively higher embodied energy compared to energy use during its operational service. Consequently, environmental impacts from construction work for buildings with shorter life cycle will be significant (Davies, 2001, SBCI 2007).The average lifecycle for Malaysian buildings varies from 30-40 years. Based on interpolation, from data by Jones 1998, the embodied energy of buildings with such lifecycle represents more than 20% of the energy used in its lifecycle.

Most assessment methods give credits for use of recycled materials in reducing environmental burdens. Although recycling saves landfill space, more energy may be used in the recycling process, producing negative impacts upon the air quality when compared to production from natural resources

SB Tool made substantial advances towards integrating LCA results and accepts input data for a very broad range of materials as part of its basic structure.

Amongst the assessment methods, BREEAM facilitates thorough studies on the life cycle environmental impact of buildings.

Table 2 Comparison of the scope of assessment between building Environmental assessment methods (Ng,2005)

4.1.2 Weights

Weights assigned to building assessments imply priorities of the performance criteria, respective basic attributes and features within the system. A comparison of the weights between systems are not as straight forward for the scope of assessments between system might be different, although most are based on common fundamental principles. The fundamental principles of the Whole Building Design Guide (wbdg.org) for sustainable buildings were used to facilitate comparisons of weights. The 'Whole Building' Design uses the integrated design approach based on the following principles:

(i) Optimize Site Potential
(ii) Optimize Energy Use
(i) Protect and Conserve Water
(ii) Use Environmentally Preferable Products
(iii) Enhance Indoor Environmental Quality (IEQ)
(vii) Optimize Operational and Maintenance Practices

A comparison of the weights of the various systems based on these scopes of assessments are shown in Table 3. The weights for BREEAM, CASBEE, SB Tool and Green Globe shown in Table 3 were extracted from Howard (2005).

Table 3 Comparison of Weights

	TECHNICAL CONTENT						
	Optimise Site Potential	**Optimise Energy Use**	**Protect and Conserve Water**	**Use Environmentally Preferable Products**	**Enhance IEQ**	**Optimise Operational & Maintenance Practices**	**Others**
BREEAM	15%	25%	5%	10%	15%	15%	15%
CASBEE	15%	20%	2%	13%	20%	15%	15%
SB TOOL	15% 12.5%	25% 20.8%			15% 16.7%	15% 16.6%	30% 33.4%
GREEN GLOBES US	11.5%	36%	10%	10%	20%		12.5%
LEED	20%	25%	7%	19%	22%		7%
GREEN MARK	12%	35%	15%	5%	15%	3%	15%

It is evident that optimizing energy use is the most sought after in many assessment methods. The Green Globes (36%) and Green Mark (35%) top the list in making energy efficiency their priorities. Recent development reported that Green Mark has revised the energy efficiency requirements to 50%.

The requirements for Sites and Indoor Environment Quality (IEQ) share equal importance at second place, ranging from 12%-22% (Table 3).

The priorities given to optimize site potential is not unexpected as the construction of sustainable buildings starts with proper site selection. The location orientation, and landscaping of a building affect the local ecosystems, transportation methods, and energy use. Siting for physical security has also become a critical issue in optimizing site design. The location of access roads, parking and lighting are essential elements that must be integrated into the design for a sustainable development.

The IEQ remain an important element in all assessment methods for its significant impact on occupant health, comfort, and productivity.

In many parts of the world, fresh water is an increasingly scarce resource. Green Mark gives high scoring to water conservation measures.

The use of Environmentally Preferable Products contribute to improved worker safety and health and achievement of environmental goals. This would minimize life-cycle environmental impacts such as global warming, resource depletion, and human toxicity. LEED gives high priority in the use of environmentally preferable product.

Operations and maintenance considerations will contribute to improved working environments, higher productivity, reduced energy and resource costs. Materials and systems which reduce maintenance requirements, consumed less water and energy are cost-effective and will reduce life-cycle costs. SB tool, CASBEE and BREEAM give high consideration to these factors.

4.1.3 Reporting Systems

One of the criteria of an ideal environmental assessment method is the ability of the assessment method to communicate the results effectively across to the different groups of users.

LEED, BREEAM, Green Mark presents the building evaluation results in an overall score /label indicating the level of performance achieved. The scores of each performance category can also be determined by the number of credits achieved in each category

GBTool presented the performance scores of the various performance categories in graphical form in which the performance level above the minimum acceptable standards is clearly visible, therefore in a better position to communicate the results more effectively across to users.

5. Proposed Malaysian Sustainable Building Labelling System

5.1 Considerations

The participants developing the Malaysian Sustainable Building Labelling System comprise of academic, mechanical engineers, civil engineers, architects, design consultants, building developer and members of professional associations (Association of Architects, Institution of Engineers, ASHRAE) who are experienced in the building construction practices and construction of green buildings in Malaysia. The team agreed on the first attempt to develop a labeling system for new office buildings. The green buildings in Malaysia so far, only address energy efficiency measures, which is only one part of the entire sustainable building assessment criteria. This industry driven initiative was the result of the much publicised promotions on sustainable buildings at the regional conference in Kuala Lumpur (SB07 South-East Asia) and support from construction stakeholders.

Various aspects appropriate to the needs and its pertinence were considered when developing the labeling system. Some of the key points being considered in the development of the system and leading to decision making are listed below.

a. The actors who will use and apply the system
b. Organizations which are involved in the system's development / delivery
c. Organizations support and or endorsement of the system
d. Organizations which are involved in the system's development / delivery
e. Organizations support and or endorsement of the system
f. Scoring system
g. Range of building performance aspects that are covered
h. Scope of environmental issues does the tool cover?
i. Extent of system to cover strategies for achieving desired performance levels
j. Is the system easy to adopt and implement?
k. Is it easy (real and perceived) to conduct an assessment?
l. Is it easy to access and understand the results?
m. Time required to gather data and conduct an assessment
n. The perceived value to different actors
o. The kind of market recognition offered for certification
p. Transparency of the process and results
q. Do the inputs and outputs serve as an educational tool about environmental issues?
r. Does the tool communicate emerging concerns and issues?

5.2 Adapted System

LEED and Green Mark are most commonly used to assess buildings in Malaysia. LEED is globally known and provides a complete framework for assessing building performance and meeting sustainability goals. Likewise, Green Mark is favoured for its tropical context and simplicity and effectiveness in transforming the building industry towards sustainable development. The new proposed system is a hybrid with the performance criteria addressing local issues and requirements. The proposed scope of assessment and performance criteria are listed in Table 3.

Table 3 Proposed Performance Criteria for Malaysian Requirements

SCOPE OF ASSESSMENT	Performance Criteria
Sustainable Sites	site selection, transport, landscape and exterior design, sloping sites, intensive brown field treatment
Water Efficiency	Water reduction, wastewater technologies, rainwater harvesting
Energy and Atmosphere	energy efficiency, renewable energy, ozone depletion, calculation , design for tropical climate
Materials and Resources	construction waste management, building and material reuse, resource recycling,

	diverting construction waste away from landfill, certified materials based on local certification.
Indoor Environmental Quality	thermal comfort, indoor air quality, pollution control, daylight and views, minimum IEQ Performance and relevant to MS1525
Innovation and Design Process	Innovation in design, tri-generation and thermal storage

All standardisation and certification issues will be in reference to local / Malaysian requirement.

The proposed scoring structure comprised pre-requisites items for minimum performance levels. The performance criteria shall be weighted accordingly with priorities to local issues on energy, water, waste and indoor environmental quality.

The system is still under development and expected for completion and trial use soon.

6. Conclusions

Sustainability is always seen in the local context. The consumption of energy and water and waste reduction are amongst the major environmental challenges for the implementation of sustainable buildings in Malaysia. The establishment of a sustainable building labelling system will provide a complete framework for guiding building and construction towards environmental performance and meeting sustainability goals. In order to be effective, the labelling system must be developed in the local context. The proposed scope of assessments and performance criteria reflect the prioritised issues in Malaysia.

Acknowledgement

The authors wish to acknowledge the contribution of members in Technical Committee 1 of the Protem Malaysian Sustainable Building Council for the initiatives and efforts in developing the sustainable building labelling system.

Keywords: sustainable buildings, tropics

Summary

An integrated approach is required in designing sustainable office buildings so as to come up with an optimal solution that balances all the important issues that have to be addressed. Various strategies have been identified for office buildings in the tropics. Daylighting has been identified as a potential source of energy efficiency measure because daylight is abundant in the tropics for most of the hours. Air-tightness of buildings to reduce energy required for dehumidification and use of energy efficient office equipment to reduce plug loads are also addressed. Rainwater harvesting has also been identified as the most practical and economical method for providing alternative water supply to substitute potable water use in the tropics. In addition, the management of construction waste and use of sustainable building materials have also been outlined. Source control to ensure good indoor air quality through selection of healthy materials as well as regulating the ventilation rate to balance indoor air quality with energy efficiency are also important considerations. Heat Island Effect is a greater concern in the hot tropics because the outdoor temperature is higher than desired. The impacts of transportation energy associated with office buildings are also highlighted so that measures can be taken to reduce the ecological footprint of the buildings.

1. Introduction

Sustainability in a building is more than just energy efficiency alone. There are many other important issues that have to be addressed in order to make the building sustainable. Designing sustainable buildings is an integrated process where the relevant issues have to be considered hand in hand in order to come up with an optimal solution. For example, more greenery is encouraged as an approach to reduce the heat island effect but more greenery may require higher irrigation demand so plants must be carefully selected. Designing for energy efficiency calls for more airtight building but the indoor air quality should not be compromised and so on and so forth.

The focus of this paper is primarily on office buildings in the tropical climate with examples mainly drawn from Singapore and Malaysia

2. Energy Efficiency

Energy saving is without doubt the quickest, most effective and most cost effective manner for reducing greenhouse gas emission and for helping countries to meet their Kyoto Protocol target. Energy efficiency in buildings is one area where important savings can be made.

In the tropics, designing office buildings for energy efficiency is less complicated than that for buildings in the temperate climate. In the tropical climate, only cooling and dehumidification are required but not heating. Air-conditioning takes up about 60% of the total building energy consumption. In order to improve the energy efficiency of the building, the first and foremost task is to reduce the cooling load and this is done by keeping the heat and moist air out and reducing the internal heat gain.

2.1 Daylighting

In the tropics there is a lot of potential in utilizing daylight for improving the energy efficiency of buildings. The tropics enjoy an abundance of daylight throughout most of the hours. In Malaysia, for example, the average horizontal diffuse radiation is 15,000 lux or higher between 8 – 17 o'clock and only 350 lux is required for indoor office lighting. A proper daylighting design can therefore greatly reduce the electrical light usage in the perimeter zone of tropical office buildings.

Daylight is free of charge and therefore does not contribute to the energy consumption of the building as artificial lighting does. Moreover, daylighting has a higher lumen efficacy (i.e. carries less heat per light unit) than artificial fluorescent lighting – and can have more than double the lumen efficacy when spectrally selective glazing is used. Spectrally selective glazing lets visible light pass through and in turn reflects infrared and UV light out. Hence, the use of daylighting translates into a lesser heat load from lighting and consequently a smaller energy consumption for the chiller. Numerous studies have also shown that people working in daylit environments work more efficiently and experience an improved well-being. In other words, there are several benefits of using daylighting in buildings.

2.2 Air Tightness

In the tropics there are no requirements for ensuring air-tightness of the building envelope, presumably because the temperature difference between indoors and outdoors is not very great. However, considerable energy can be saved by ensuring an air-tight building envelope, so that the hot and humid outdoor air does not infiltrate into the air-conditioned zone. Substantial energy is used by the air-conditioning system to dehumidify the hot and humid outdoor air if it gets into the air-conditioned building. In addition, air-tightness is a pre-requisite for using desiccant heat recovery on the air system (refer to section 2.3)

2.3 Desiccant Heat Recovery of Air

In tropical Malaysia and Singapore, about 50% of the outdoor air humidity content is removed to achieve a comfortable indoor climate. The latent cooling of outdoor air intake is considerably higher than the sensible cooling. Desiccant heat wheels allow the recovery of about 60% of the total cooling energy (latent and sensible) for the fresh air supply. For an efficient desiccant heat recovery to take place it is necessary to have an air-tight building so that the return air (dry and cool) can be directed through the desiccant heat recovery wheel and does not dissipate through a leaky building envelope.

2.4 Energy Efficient Equipment

Another potential area for energy consumption reduction is in the area of equipment energy use. Equipment energy use (plug loads) constitute a very big proportion of energy use in a typical office building. The energy consumption can be easily reduced by choosing energy efficient equipment in the first place. For example, a laptop only consumes 15-35W of power as compared to a PC with LCD monitor which consumes 70-90w of power. In addition, energy efficient printers, photocopiers, fax machines etc should also be chosen. Proper control of the usage of the equipment is also another way of reducing energy use. The equipments should only be used when necessary and should be switched off when not in use or put into sleep mode when they are on standby.

It is obvious that the selection of energy efficient equipment and proper control of usage require the cooperation of the client. The importance of the selection of energy efficient equipment to be put in the building has to be communicated to the client right from the start because this will affect the total building energy consumption.

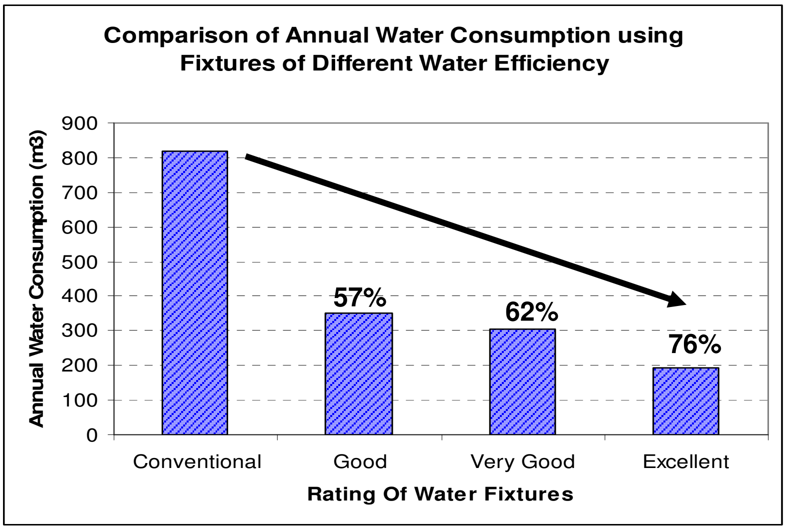
3. Water Efficiency

Other than energy resources, water is increasingly becoming a scarcity issue in many parts of the world, including Malaysia. Plentiful water resources in the past are no longer so in the context of modern water demand and increasing populations, industries and agricultural production. The cost of supplying safe and clean water is increasing and if this problem is not properly addressed, it could lead to a water crisis.

Sustainable water management principles need to be incorporated into the building. Sustainable water management means reducing the demand for water usage through the use of very water efficient fixtures and appliances where possible and identifying alternative sources of water supply to substitute the potable water use.

3.1 Water Efficient Fixtures

Increasing the efficiency of fixtures can lead to significant reductions in potable water demand from end users. In Singapore, the Public Utilities Board has launched the water efficiency labeling scheme for water fixtures. These fixtures include cisterns, taps, showers and urinals. The efficiency of the various fixtures are evaluated according to their flow rate. Figure 1 shows that 57-76% of potable water savings can be achieved when water efficient fixtures are used in the office building.



Note: Calculations based on flow rate specified in the different water efficiency rating from PUB, Singapore

Figure 1 Potable Water Savings from Use of Water Efficient Fixtures

3.2 Alternative Sources of Water Supply

3.2.1 Rainwater Harvesting

Rainfall is generally abundant in the tropical region and fairly consistent across the various months with occasional periods of drought. The average annual rainfall in Malaysia is around 2000 mm. Rainwater can be harvested from the roof or from other paved areas in the building.

3.2.2 Stormwater Harvesting and Management

Stormwater harvesting is the collection of water from the paved areas of the building. Stormwater harvesting helps to reduce surface runoff and relieve the load on the drainage system during heavy rain to lessen the possibility of flooding. Minimizing non porous areas will minimize surface runoff hence by having landscaped area helps to reduce surface run off and promote infiltration into the ground.

3.2.3 Greywater Recycling

Grey water is the wastewater collected from showers, sinks, floor drains which although no longer clean, is not as contaminated as toilet water (black water). By intercepting grey water before it goes to the septic tank or the municipal wastewater system, and providing some treatment (in certain cases, no treatment may be required) the water may be reused to irrigate plants. More complex treatment is required if the grey water is to be used for toilet flushing. Grey water from the kitchen sink is not recommended to be collected. This is because the grey water that comes from the kitchen sinks tend to contain more grease, oil and other food particles which will require a higher level of treatment to recycle the water.

3.2.4 Blackwater Recycling

Blackwater is the discharge from the toilet and the microbial contamination associated with blackwater means that the water needs to be treated to a very high level. This requires expensive technology like reverse osmosis.

3.3 Recommendations for the Tropics

Reducing the potable water demand should be the first step with the use of water efficient fixtures and promotion of user awareness. As rainfall is abundant in the tropics, rainwater harvesting is probably the most appropriate and perhaps less expensive alternative source to substitute the use of potable water for toilet flushing and irrigation.

4. Waste Management

Construction and demolition debris frequently makes up 10-30% of the waste received at many landfill sites around the world (Fishbein,1998). In the tropics, particularly the south east asian countries, recycling of construction and demolition waste is still not very widely practiced by the local contractors. In Malaysia, industrial and construction waste makes up almost 30% of the total solid waste generated. The recycling and reuse of construction and demolition waste can help to alleviate the pressure on landfills and natural resources. Waste minimization and avoidance must also cover the planning of the building such that wastes that are produced in the building during use can be separated and recycled.

4.1 Waste Reduction

The first step in a construction waste reduction strategy is good planning. Design should be based on standard sizes and materials should be ordered accurately. In addition, the use of high quality materials such as engineered products reduces rejects. The conventional construction method of extensive cast in-situ activities usually results in unnecessary waste hence new construction methods or technologies should be looked into. The adoption of prefabrication in construction is one way to reduce waste.

4.2 Re-use of Materials

Identify potential re-usable or salvageable materials from onsite or offsite sources. Re-usable or salvageable materials may include bricks, tiles, doors, windows, furniture, plumbing fixtures, steel etc. By re-using materials salvaged from demolition sites eliminates the need for new resources.

4.3 Recycling of Waste

For recycling of construction waste, the most important step is on-site separation. Initially, this will take some extra effort and training of construction personnel. Once separation habits are established, on-site separation can be done at little or no additional cost.

It is important to identify before recycling the waste, the people who will accept it. This helps to designate the type of waste to separate, and in making arrangements for drop-off or delivery of materials. Containers for material recycling must be set up on site and clearly labelled. Construction personnel must be trained in material sorting policy, and bins must be monitored periodically to prevent waste mixing as a result of crews or passersby throwing trash into the bins.

4.4 Waste Management Plan

A waste management plan has to be developed and should incorporate the following:

1. Types of waste materials produced as a result of work performed on the site
2. Estimated quantities of waste produced
3. Identification of materials with the potential to be recycled
4. Cost savings accrued by recycling rather than disposing of waste in landfills
5. On-site storage and separation requirements
6. Transportation methods
7. Destinations

5. Use of Sustainable Building Materials

Selection of sustainable building materials is one direct way of incorporating sustainable design principles into buildings. Selecting materials manufactured by environmentally responsible companies encourages their efforts at pollution prevention. In addition, by choosing products with recycled content (manufactured with post industrial or post consumer waste) helps to increase the resource efficiency of the building materials. The embodied energy content of recycled materials is much less than that of the virgin materials.

Sustainable materials should generally be non toxic, recycled and recyclable, obtained from local sources (to minimize transportation energy), durable and long lasting. Figure 2 shows an example of output from the BEES (Building for Environmental and Economic Sustainability) program developed by the National Institute of Standards and Technology in the United States. BEES is a program developed to help people select environmentally preferred materials. The output shows that it is better to choose the recycled PET(polyethylene terephthalate) carpet tiles over the nylon carpet tiles because the environmental performance of PET tiles is better even though the nylon carpet tiles were transported over a longer distance in the simulation. The BEES program is developed for use in the United States and may not be accurate for the other regions. There is currently no program developed for use in the tropics. However, as many materials might be imported from United States, BEES can still give us an indication of the performance between two alternative materials.

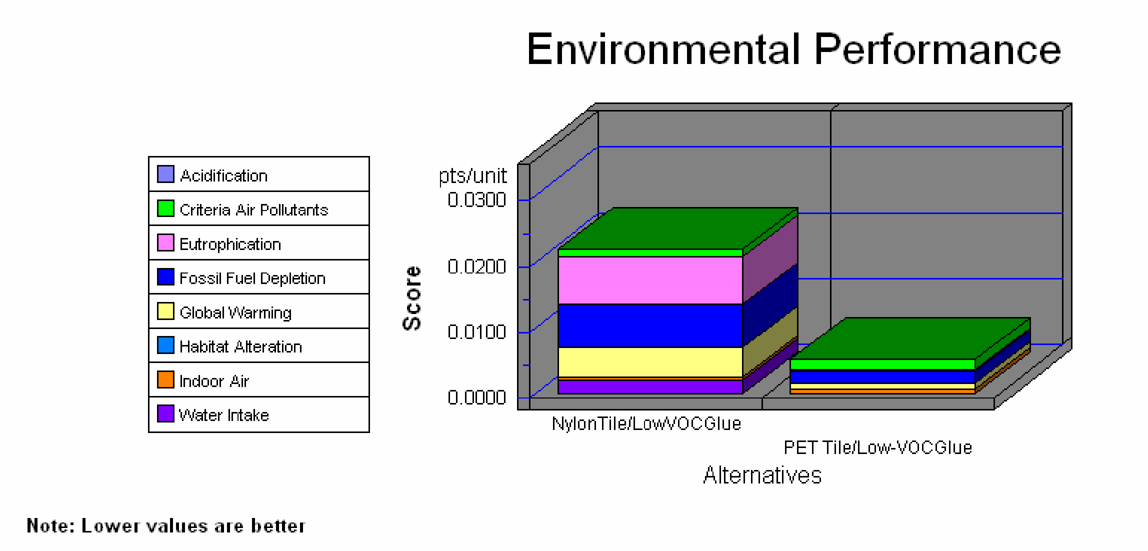


Figure 2 Selection of carpet tiles using BEES program (Example)

6. Indoor Air Quality

Indoor air quality (IAQ) has been increasingly gaining attention in office buildings due to its adverse effect on human health with the emergence of the Sick Buildings' Syndrome. The amount of pollutants in the office environment has a strong impact on IAQ performance as it can have an adverse effect on the health of the occupants. Source control for good indoor quality can be achieved by choosing healthy materials in the first place. Figure 3 shows that paints have great variation generally with high initial emissions that decay rapidly. Wool carpets have lower initial emissions but they persist over longer time. Particle boards have the lowest initial emissions but the decay is so slow that emissions can last for months or years.

To balance indoor air quality with energy efficiency, Carbon dioxide (CO_2) monitoring can improve indoor air quality and save energy when it is part of a demand control ventilation system. With CO_2 sensors connected to the ventilation system, the amount of fresh air supplied to interior spaces can be regulated to ensure that the CO_2 level does not exceed 1000 ppm (the threshold limit). More fresh air is supplied when there is increased occupancy demand, and when there are less people, ventilation will be reduced to reduce energy consumption.

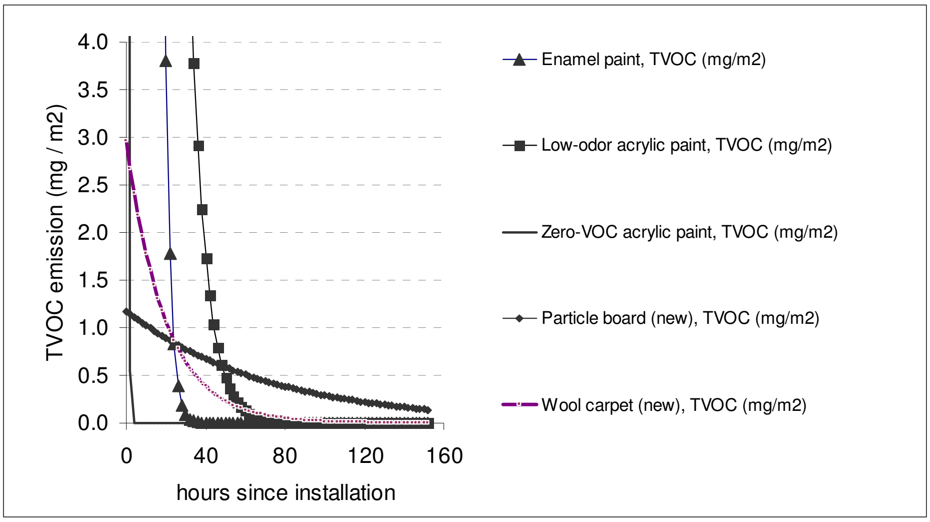

Figure 3 TVOC emissions from various indoor materials

7. Urban Heat Island Effect

Urban heat island is the built up of heat in the urbanized cities characterized with a higher temperature than the rural area. The high concentration of hard surfaces around the building could result in heat island effect due to the absorption of solar radiation by these surfaces in the daytime. This is a larger problem in the tropics because the outdoor temperature is already higher that what is preferred and any temperature increase in the cities is detrimental to outdoor comfort and also increases the cooling load.

Planting trees and vegetation is a simple and effective way to reduce heat islands. Trees and vegetation cool the air by providing shade and through evapotranspiration (the evaporation of water from leaves). A mature tree with 9m crown transpires approximately 150 litres per day and that corresponds to about 8000W of evaporative cooling or about 100W/m^2 of tree footprint. Shade reduces the amount of solar radiation transmitted to underlying surfaces, keeping them cool. Shaded walls may be 5° to 20°C cooler than the peak surface temperatures of unshaded surfaces. These cooler walls decrease the quantity of heat transmitted to buildings, thus lowering air conditioning cooling costs. Cooler surfaces also lessen the heat island effect by reducing heat transfer to the surrounding air.

Green plot ratio can be used as a measure of greenery provision in building developments since provision of greenery has been shown to be an effective way to reduce heat island effect. This ratio takes into the consideration the 3-dimensional coverage of the foliage by plants (Ong, 2003). Green Plot ratio is the average leaf area index (LAI) of the greenery on site and the LAI can be considered as the ratio of leaves to ground covered. The higher the green plot ratio, the larger the total area of leaves exposed to the sun as compared to the area of the ground itself. This reduces the ambient temperature because the plants are providing a lot of shade to the ground and they will also cool down the surrounding through evapotranspiration. The Green Plot Ratio is used as a rating criterion in Green Mark - a green assessment system developed by the Building Construction Authority of Singapore.

Another way to minimize heat island effect is to use high albedo surface materials. Materials that have a higher solar reflectance index help to reduce heat absorption. Solar reflectance index (SRI) is a measure of a material's ability to reject solar heat as shown by small temperature rise. Figure 4 shows the solar reflectance index of various roofing and paving materials (USGBC, 2005). It can be seen that darker materials generally exhibit low reflectance and consequently lower SRI. Lighter coloured materials have a higher reflectance and thus higher SRI which help to reduce heat absorption. However care must be taken to avoid glare from light coloured surfaces. High albedo materials are still not widely used in Malaysia and Singapore.

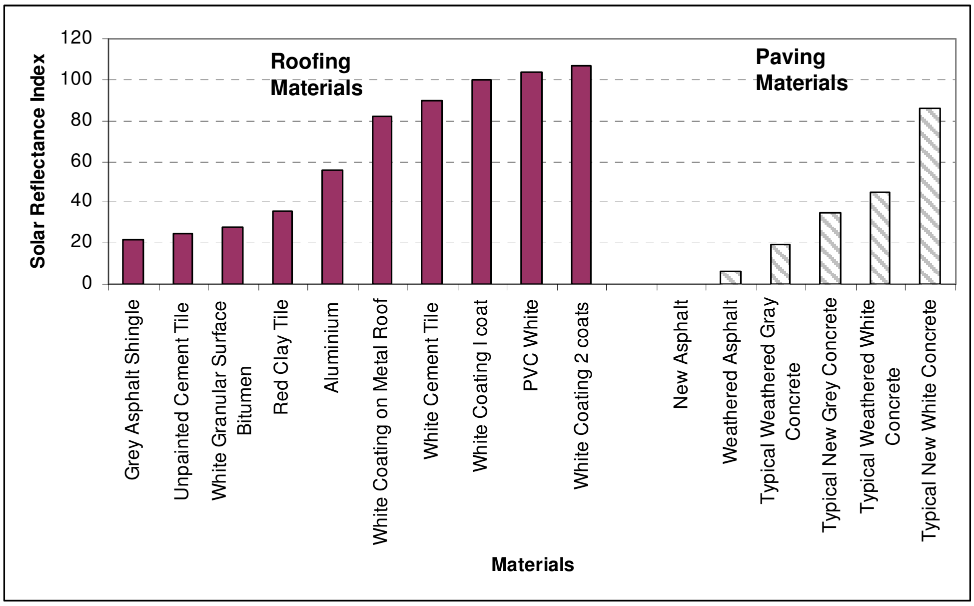

Figure 4 Solar Reflectance Index of Various Materials

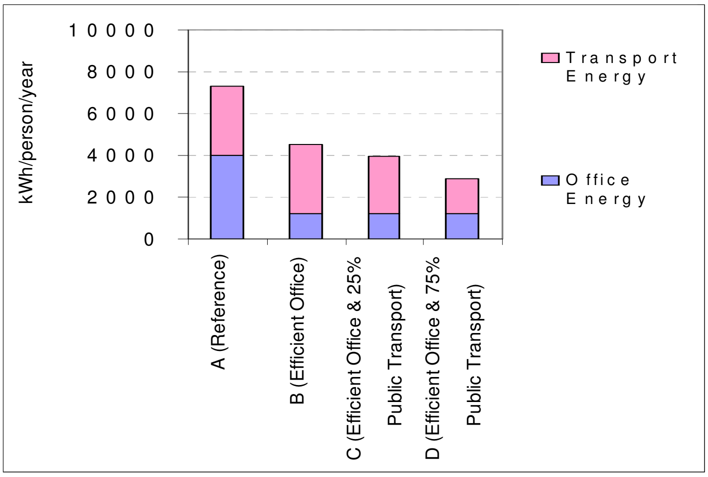
8. Transportation energy

As buildings are designed to become more energy efficient, the energy required to transport the occupants of the building to their workplace becomes significantly larger in comparison to the building energy consumption. For a building to be considered sustainable, the transportation energy associated with the building has to be considered and reduced as well. Figure 5 shows the breakdown of energy consumption using a calculation example for buildings in Kuala Lumpur. The calculations were based on results of study conducted by CETDEM (2006). Figure 5 shows that for a reference building in Kuala Lumpur with an energy efficiency index (EEI) of 250kWh/m^2/yr, the transportation energy amounts to 80% of the total building energy consumption. As the building becomes more energy efficient (EEI of 80kWh/m^2/yr), the transportation energy is about 2.7 times as much as the total building energy consumption. If 25% of the occupants take the public transport, the transport energy reduces to 2.2 times that of the building energy. And if 75% of the occupants take the public transport, the transport energy is almost the same as that of the building energy. It can be seen that the total energy consumed in the building and commuting to the building (transport energy) decreases significantly if commuting energy use is reduced.

The accessibility of the building to public transport is very important in reducing the need to drive. Sometimes the location is not within the control of the developer, the building owner can come up with various strategies such as providing company shuttle bus, offering incentives for carpooling etc.



Note: Assume transportation is by private car and public transport is by bus

Figure 5 Breakdown of energy consumption (example from buildings in Kuala Lumpur)

9. Building Environmental Assessment Systems

Building environmental assessment system facilitate as an objective yardstick for buildings to be rated according to various environmental criteria. Although no single system is perfect, each developed environmental assessment system seeks to quantify the performance so that buildings can be compared to one another in terms of their environmental performance.

There are currently no building environmental assessment systems developed for the tropics except Green Mark from Singapore. LEED (from USA) and Green Mark (from Singapore) are being adopted in Malaysia currently since Malaysia has not developed their own systems (but doing so at present).

Points chasing has become a phenomenon associated with building environmental assessment systems. It is common for people to want to pursue easy and cheap points which might not bring the best benefits for the building. However, the fault does not lie with the systems but rather the practitioners. It is thus very important for the consultants who are advising the clients to indicate the various aspects that are best for the building in terms of performance and associated cost effectiveness. Some criteria might have a higher initial investment cost (e.g. energy efficiency measures) but if they have a good payback due to good operational savings for the client, it is important that the consultants recommend and justify the measures to be implemented. It is also important for the consultants to advise the client so as to ensure the delivery of a building that is well-balanced in all the sustainable aspects.

Nevertheless, building environmental assessment system is still an effective tool to ensure that sustainable measures are implemented in the building design. However, using systems developed in other countries is not optimal because the priorities vary in different countries. Hence it is still important to develop or adapt systems to the local context.

10. Business Case for Sustainable Buildings

Going sustainable does not have to be very expensive, be it in the tropics or other parts of the world. A preliminary study conducted by Building Construction Authority (BCA) of Singapore showed that the green cost premium of incorporating green features in the building according to Green Mark is less than 10% with a payback of less than 10 years. The study indicate that there is no great disparity in the payback periods between Green Mark certified and Green Mark Platinum as the greater cost of higher level of rating can generally be recovered back through energy and water savings. The study also indicates that the trend of the local green cost premium in Singapore is generally quite consistent with the findings of green buildings in United States. It can be expected that the green cost premium will go down in future when there is greater demand and wider adoption of green technology.

BCA Green Mark Award Type	Green Cost Premium (%)	Payback Period (years)
Platinum	2% to 8%	2yrs to 8yrs
Gold Plus	1% to 3%	2yrs to 6yrs
Gold	1% to 2%	2yrs to 6yrs
Certified	0.3% to 1%	2yrs to 5yrs

(Source: BCA, 2008)

Figure 6 Range of green cost premiums & payback period vs levels of certification

11. Conclusions

Designing for sustainable office buildings in the tropics is less complicated as compared to designing for one in the temperate climate. The hot and humid climate in the tropics meant that only cooling is required, hence the hot and moist air had to be kept out of the building to reduce energy required to cool and dehumidify. Daylighting is found to be underutilized in the tropics because people generally associate heat gain and glare with daylight entry into the building. However, a good daylight design using diffused light helps to reduce the artificial lighting load and consequently translate into a lower cooling load for the building. Occupants working in daylit environment are also found to be more productive. Attention also needs to be given to air-tightness of the building and the use of energy efficient equipment in the offices. As the tropics has abundant rainfall, rainwater harvesting should be implemented in buildings which not only help to reduce potable water demand for toilet flushing and irrigation, but also reduces storm water runoff to mitigate flood risks. It is a greater challenge to bring in fresh air into the building in the tropics because of the humid air. Hence to maintain a balance between ventilation and energy consumption, source control through proper selection of healthy and non-toxic indoor materials is important to introduce as little contaminants into the building as possible. Regulating the fresh air intake with CO_2 sensor is also advisable. In addition, proper waste management, use of sustainable materials, reduction of heat island effect and focus on reducing commuting energy are all important aspects of designing for a sustainable office building.

SUSTAINABLE URBAN REGENERATION - A METHODOLOGY FOR URBAN SUSTAINABILITY

Stephen S.Y. Lau[1]

Wadu Mesthrige Jayantha[2]

Joyce Tai and Baharuddin[3]

ABSTRACT

The concept of sustainable development essentially calls for an integration of economic, social and environmental considerations in decision making. Yet, urban re-development activities over the last decade shows that most local re-developments were centered on economic initiatives and/or physical changes without given sufficient attention to social, environmental and community well-being. This is deemed a crucial reason for social dissatisfaction in the recent past over the people's objection to public sagas such as the on-going Queen Piers confrontation[4]. Further developments are at risk unless this conflict is addressed. Otherwise, this could lead to a huge loss of public resources, creating a human unfriendly urban environment; and badly affecting needs of future generations. Quantitative analytical tools such as CASET (Computer-Aided Sustainability Evaluation Tool) have been used by the planning authorities to evaluate the merits of proposed urban development projects. Apparently, these tools have overlooked the contribution and significance of public opinions that could overturn the success of a new proposal. The present study attempts to introduce a methodology, *i.e.* an integrated assessment approach, in which quantitative tools are supported by scenarios analysis (qualitative) with a built-in public participatory mechanism. This study will help to understand better the interrelated dynamics of ecology, economics and social values for an urban development and to identify policy interventions which could enhance human well-being, avoids conflicts of interest and thus saves resources immensely.

[4] Queen's Pier, named after Queen Victoria, is a public ceremonial pier in front of City Hall in Edinburgh Place, Central, Hong Kong. Following the controversy and the demolition of the Star Ferry Pier in Central in early 2007, public/activists declared their dissatisfaction over the conservation policy of the Government of Hong Kong. The criticism received over its handling of the Star Ferry Pier caused the Government to propose the idea of a piece-by-piece relocation of the Pier to a new location on the reclaimed waterfront. Thus, the government was compelled to postpone the demolition of Queen's Pier until a consensus could be reached on the course of action.

Sustainability, urban development, CASET, quantitative, qualitative, public participation, integrated assessment.

BACKGROUND OF STUDY

With the strong tendency that world development continues to move in an unsustainable direction, the integrity of life support systems has come under an increasing threat (Swart et al., 2004). Since the seminal report of the Brundtland Commission (WCED, 1987), creation of physically and socially sustainable cities is considered as the global policy objective of the sustainable development. While there are different definitions of sustainable development (Robinson, 2003), the term sustainable development goes beyond the boundaries of science and business development and trade to include human development, values, and differences in cultures. Thus, it is very important to maintain resilience in environmental and social systems by meeting a complex array of interacting environmental, social and economic conditions (Swart *et al*., 2004). This suggests that there are three imperatives for sustainable development: the ecological, the social and the economic, which are increasingly interdependent.

Sustainable urban development design is essentially based on a multidisciplinary approach. Experts from different areas such as economic, environmental and social aspects need to work interactively and closely in order to achieve sustainability principles of a project. Put in differently, a wide range of different experts and institutions should be involved in the formulation and implementation of national sustainable strategies. Sustainability science therefore studies how the interactions, behaviors and emergent properties of combined natural and social systems works effectively, and provides decision makers with better advice about the effects of various forms of behavior or intervention (Swart *et al*., 2004).

However, in Hong Kong urban development and or renewal has been narrowly understood as the physical redevelopment of land (Ng, 1998). In 1980s, while the government's efforts for comprehensive redevelopment have not been successful, some individual piece-meal redevelopments have been carried out by the private sector (Ng, 1998). These developments were a result of a series of property booms (Yeh, 1990). Such developments by the private sector have often led to an inefficient use of land, with few improvements to community facilities (Todd, 1985). Moreover, these developments offer little chance to provide much needed public open space or community facilities and renders comprehensive redevelopment of the surrounding block problematic in future (Adams and Hastings, 2000). Clearly, effort by the government on redevelopment was very insignificant with minimal financial commitment (Ng, 1998).

In the global arena in the 1980s, public–private partnerships emerged as a significant part of urban policy; especially in both Britain and the United States (Barnekov *et al*., 1989; O'Toole and Usher, 1992). This international experience was thought relevant to tackling the growing urban problems in Hong Kong. Thus government authorities early in the 1980s decided to promote partnership between the private and public sectors through the establishment of Land Development Corporations (LDC) (Adams and Hastings, 2001). LDC was established with the aim of increasing efficiency of coordination and implementation of development schemes. LDC was supposed to have both the merits of private sector and public sector (Ng, 1998).

Public-private partnership approach in Hong Kong also has not brought the intended sustainability goals of urban development due to various reasons. First, LDC did not have control over developments and no legal power of land resumptions. Second, many of the LDC's development proposals put much emphasis on commercial viability with less emphasis on potential of social well being (Ng, 1998). Finally, the most important reason was the ignorance of public inputs into the developments. Goals and objectives of different actors (government, private sector developers and community residents) of the society need to be compromised in order to achieve sustainable development goals (Ng, 1998). But, the history of redevelopments in Hong Kong shows that public participation, which is the most important actor in the scene, has been ignored due to some reasons. Instead, urban re-development activities over the last decade were centered on economic initiatives and/or physical changes without given sufficient attention to social, environmental and community well-being. This has been the case even in most recent developments in Hong Kong. This is deemed a crucial reason for social dissatisfaction in the recent past over the people's objection to public sagas such as the on-going Queen Piers confrontation.

From the beginning, the fate of the pier has been intimately linked with the central reclamation project. Following the controversy and the demolition of the Star Ferry Pier in early 2007, public/ activists started to show displeasure over the conservation policy of the government. The main reason behind this controversy is the adopted unbalance approach towards urban development in Hong Kong. On the one hand, government authorities argue that being overzealous in saving the past may hurt Hong Kong's competitiveness, and urge activists to take a more balanced view between economic benefits and conservation. On the other hand, activists accuse authorities for not being able to adopt an approach giving sufficient attention to conservation and environment. However, one thing is sure. That is, further developments are at risk unless this conflict is acknowledged and addressed. Otherwise, this could lead to huge confrontations between the general public and authorities, which will hamper future development activities.

There has been a widespread recognition that it is a range of issues that lead to the decline of major urban centers as desirable or acceptable places to live. Whilst there has been some evaluation of initiatives and schemes, there has been no real attempt to benchmark urban regeneration activity (Nicholas, 2004). Thus, urban redevelopment process in Hong Kong is in need of a proper guiding framework which meets sustainable principles of urban development. Moreover, Hong Kong needs a workable redevelopment model that achieves the necessary balance between commercial and social priorities.

Reasons for not reflecting public views / desires in the process of urban development need to be addressed soonest. One possible reason might be that wrong methodologies or frameworks adopted in the decision making stage of the development (sustainable assessment stage), which might not properly reflect the public ideas and interest into developments. Especially, too much dependent and belief on the usage of quantitative techniques may have over looked public inputs into the development. The purpose of this study is to shed light on a new integrated assessment (IA) approach with a significant public participatory mechanism (qualitative approach) for sustainable urban development, with the goal of exploring prevailing sustainability issues behind urban development projects in Hong Kong. In other words, it introduces an integrated assessment (IA) approach, in which quantitative tools and models are supported by scenarios analysis (qualitative) with a built-in extensive public-participatory mechanism. The proposed approach unfolds the pros and cons of a sustainable planning methodology that relates closely with a public-participatory process.

COMPUTER-AIDED SUSTAINABILITY EVALUATION TOOL (CASET)

A number of countries have attempted to develop integrated sustainability assessment tools. In 2001, the Hong Kong government has developed a sustainability assessment (SA) system, called CASET, developed under the Study on Sustainable Development in Hong Kong for the 21st Century (SUSDEV21). CASET is supposed to assist Government in evaluating new strategic initiatives or major programmes from a sustainable development perspective. This tool is built upon 42 sustainability indicators and eight guiding principles (economy, health and hygiene, society and societal infrastructure, biodiversity, leisure and cultural vibrancy, environmental quality, mobility and natural resources). Its purpose is to promote the integration of sustainability principles into the government's decision-making process, through assessing the impacts of proposals on the economic, environmental and economic conditions of Hong Kong in an integrated manner.

The assessment is based on eight guiding principles covering economy, health and hygiene, natural resources, society and social infrastructure, biodiversity, leisure and cultural vibrancy, environmental quality and mobility, and 42 associated quantifiable indicators. These guiding principles look very specific and broader enough to cover up sustainability aspect of a project. It is required to assess the impacts of proposals against the relevant indicators (only the relevant indicators would be selected for assessment). Apart from these 42 quantifiable indicators, the assessment also requires to evaluate other non-quantifiable yet important considerations in the process to ensure that the assessment is comprehensive.

In summary, the steps of assessment system can be summarized as follows (see Figure 1 for the Flow chart for a detailed description of the process):

1. Figure out the objectives and assumptions of the proposal;

2. A checklist of simple "yes" and "no" questions covering economic, social and environmental implications of the proposal;

3. An assessment of the possible impact of the proposal (development) against each and every affected indicators;
4. Cross-check the validity of the outcomes and consider possible alternative options, if necessary;

5. Summarizes the key findings of the assessment process, which includes an SA diagram to illustrate the positive and negative implications of the proposal.

Limitations of CASET

According to CASET, sustainability assessment (sustainability performance) is presented with scenario and without scenario. Both of them have been assessed against the baseline situation as recorded in the CASET. It should be noted that these baselines are derived based on the whole territorial figures, and not project specific. So here we compare project specific values against the overall territorial values, which itself is a controversial issue in the CASET. The summary of the sustainability assessment of the project is presented in the form of a table such as in Table 1. Accordingly, as shown in the table, very large improvement to current baseline situation is indicated through larger number (6 in this case) of '☑', while very large deterioration to current baseline situation is indicated through larger (6 in this case) of '☒' s.

However, there is a reasonable doubt that the CASET is able to absorb the social-human aspects in the assessment. CASET needs all qualitative variables to quantify in some form in its assessment, which is not an easy task and also not a sensible thing. The other important thing is that the outcome of the assessment is highly subjective: outcome may be manipulated or an arbitrary one. Unless parallel effective public participatory approach is adopted, the outcome may be biased in favor of the assessors.

However, there are some advantages of CASET as well. CASET can be used as a guiding mechanism and it is a good starter for a sustainable analysis. It will also help to analyze and discuss advantages and disadvantages of some quantitative aspects of a project.

INTEGRATED ASSESSMENT (IA) APPROACH - SCIENCE DRIVEN APPROACH TO SUSTAINABLE DEVELOPMENT

In a recent study, Swart *et al.*, (2004) emphasized the integration of science and scenario analysis in addressing the challenge of sustainability science, especially the core question of how to scan the future in a structured, integrated and policy-driven manner. In the literature, there have been many attempts to define IA. In one of them, integrated assessment (IA) is defined as

> "an interdisciplinary process of combining, interpreting and communicating knowledge from diverse scientific disciplines in such a way that whole cause-effect chain of a problem can be evaluated from a synoptic perspective with two characteristics: (i) it should have added value compared to single disciplinary assessment; and (ii) it should provide useful information to decision makers" (Rothmans and Dowlatabadi, 1997).

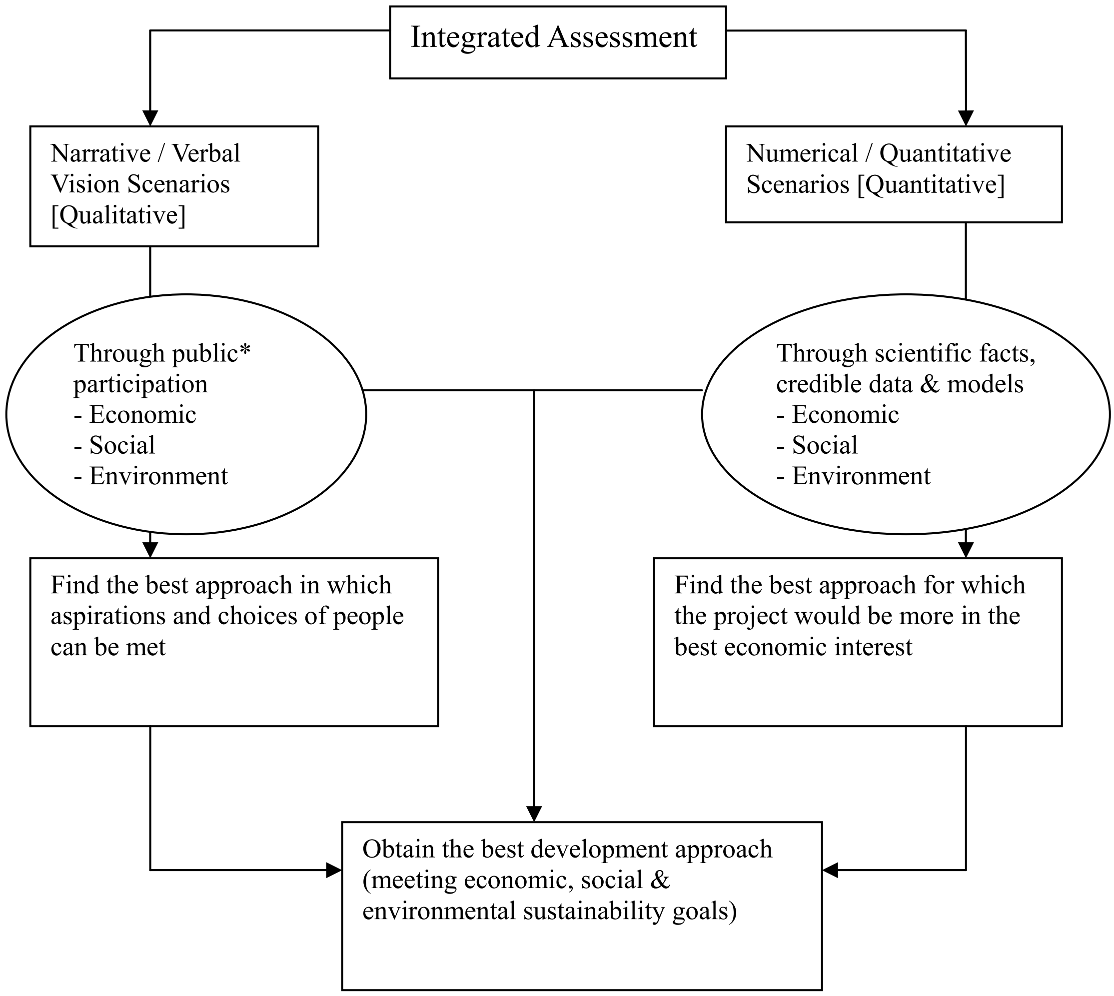
Therefore, IA is an effective mechanism that combines knowledge (science) and action (policy) in an effective way. While the link between science-driven research activities and sustainability policy development remains weak (Cohen *et al*., 1998), the call to strengthen the contribution of science to a sustainability transition has grown louder (Raven, 2002). Recently, Kates *et al*., (2001) proposed a framework for an emerging sustainability science for generating useful knowledge to support a transition to sustainable development. Integrated assessment is such an evolving field of research area, which is located in a territory between science and public policy (Tansey *et al*., 2002).

On the other hand, IA approach is typically of a more experimental character than traditional predictive approaches (Tansey *et al*., 2002), which is not based on present assumptions about choice and behavior of people. IA approach is seen to be capable of accommodating dynamics and fundamental character of interactions between nature and society.

Integrated assessment (IA) could accommodate a multitude of factors - conceptual (verbal), relational (models) and numerical (data) - that can be inter-linked in a logical manner. Broadly, it integrates two complementary components: verbal vision scenarios (narrative scenarios/qualitative analysis) and the use of numerical assessment models (quantitative analysis) (Figure 2). Lack of one or the other renders an IA analysis incomplete.

IA approach needs both ends to take effectively into consideration. On the one hand, it needs to explore possible alternative ways of the project based on scientific knowledge. Unless the alternative futures presented are documented as feasible and solidly taken into account based on scientific knowledge they will lack the required credibility. On the other hand, it also needs inputs from the public. Incorporation relevant values, perceptions and choices of societal actors about the future into research process are necessary to accommodate forms of knowledge normally not considered by analysts (Swart *et al*., 2004). Otherwise, it would miss aspiration of people into the development. If they are based solely on aspects of reality which can be illustrated through computer models and in numerical forms, they will not address important factors of society, political and individual aspirations and choices.

A METHODOLOGY FOR SUSTAINABLE URBAN DEVELOPMENT



*Public: representatives of NGOs, experts, government institutions, and the wider public

Figure 2: Relationship between qualitative and quantitative scenarios (Integrated Assessment Approach)

Therefore, what we need is an approach which can combine quantitative and qualitative analyses to elevate non-quantifiable cultural, institutional and value aspects of the society to avoid limiting the analysis to quantifiable aspects which are not necessarily the most crucial. Such an approach will make sustainability science more relevant to policy development and action through stakeholder participation (Swart *et al.*, 2004).

In an IA approach, scenario analysis (SA) plays an important role. SA helps to explore or identify a range of possible alternatives/futures in order to assess their desirability or feasibility. On the other hand, SA will help to understand better the inter-related dynamics of the economic, ecological and social systems, which is the most important issue in dealing with sustainability problems. This understanding is needed in order to identify policy interventions which could enhance human well being, while softening the adverse environmental effects of human activities. It ensures that the project achieves some measures of political and social relevance. Thus, the process to the development of the IA approach is very important. Scenario development is a result of the interaction between the choices of users and opportunities and constraints framed within the 'possibility space' created by the design approach to the modeling (Tansey *et al*., 2002). Scenario development process requires user input to make choices about possible alternative development paths of a project.

It shows that 'space' which the development model (methodology) is based on extends beyond domain of one discipline. It extends to a wider social context within which decisions are made. This indicates that design process of the methodology of sustainable development is a non-trivial exercise, and is a must in order to improve the quality of outcomes. Consequently, a significant effort should be made to research and develop an appropriate methodology encroaching aforesaid areas and disciplines in order to meet goals of sustainable development.

Advantages of IA

a) IA is based on a multidisciplinary sphere. It reaches beyond the bounds of a single discipline and address more than one aspect of the problem under consideration (Tansey *et al*., 2002).

b) It has a central purpose 'to inform policy and decision-making, rather than to advance knowledge.

.

c) In Hong Kong, present ways of consumption and living have led to problems like the overuse of ecosystem destruction, urban heat islands, pollution, growing inequality in cities and the degradation of human living conditions. Thus, Hong Kong has a special need to adopt an approach such as IA.

d) There is a greater role for public stakeholders in IA for both substantive and procedural reasons (Tansey *et al*., 2002).
   - Stakeholders may have a substantive role to play in providing context specific 'local' knowledge to researchers
   - Since stakeholders are likely to be affected by the policy under consideration in an IA exercise, they have an important procedural role to play
   - Thus, more relevant and effective policies can be designed through stakeholder participation and that they will be more successful in the implementation phase as a result.

e) IA – including new participatory and problem-oriented approaches – provides a powerful tool for integrating knowledge, scanning the future in an organized human choice into sustainability science (Tansey *et al*., 2002). Integrated assessment analysis is a process of analyzing possible future events by considering alternative possible outcomes (scenarios). The analysis is designed to allow improved decision-making by allowing more complete consideration of outcomes and their implications

CONCLUSION - EXPECTED OUTCOMES OF THE STUDY

- This methodology will lead to generate a planning mechanism/framework (a set of sustainable guidelines) that enhances sustainable development / redevelopment. It will help decision makers with better advice about the effects of various forms of behavior or intervention in the society.

- This framework will help to guide urban redevelopment process and facilitate comprehensive approach for urban renewal in Hong Kong SAR. Broad guidelines which may be considered as an alternative or supplementary framework to prevailing quantitative techniques may be derived from this methodology.

- This methodology would benefit the society with saving public money as it may suggest the best development approach for which the project would be in the best interest of Hong Kong (best way of investing resources in developments).

- The problems of uncertain futures and conflicting values can be managed through an essentially societal process, in which the computer models and quantitative techniques are tools for guiding discussions (Tansey *et al*., 2002). Present study/methodology will lead to produce a research methodology to operationalise precisely this kind of vision for the future of IA through combination of quantitative techniques and models and qualitative participatory approach.

- The policy implications that may be derived from this methodology will enable researchers to explore a number of critical research themes:

  - the role of quantitative techniques including computer models as a mediator between scientific and civic cultures
  - the role of hybrid process that combine expert analytical methods with participatory approaches in the context of policy development (Tansey *et al*., 2002).

Future research work
An extensive discussion and review / analysis will be carried out using this methodology based on a mini-case study focusing a past development project in Hong Kong.

Summary

The Computational Fluid Dynamics (CFD) techniques are currently widely adopted to simulate the behaviour of fire. The major shortcoming of the CFD is the requirements of extensive computer storage and lengthy computational time. In actual applications, although comprehensive field information of velocities, temperature, pressure, fraction of different constitutes etc. can be obtained from the CFD simulation, the user may be only interested in few important parameters which index the performance of the compartment design in the event of fire. Height of thermal interface (HTI) is one of the key indices. It is the average height above the floor level inside the fire compartment at which the temperature gradient is the highest. In practice, the fire compartment is considered untenable when the HTI descends lower than the respiratory level of the occupants. In the course of fire system design optimization, a series of CFD simulations is required for the parametric study. This approach is theoretically feasible but requires lengthy computational time. This paper proposes to apply Artificial Neural Network (ANN) approach as a fast alternative to the CFD models to simulate the behaviour of the compartment fire. A novel ANN model denoted as GRNNFA has been developed particular for fire studies. The GRNNFA model owns the features of removal of the noise embedded in the experimental fire data. It has been employed to establish a system response surface based on the knowledge of the available training samples. Since the available training samples may not be sufficient to describe the system behaviour especially for fire data, it is proposed to acquire extra knowledge of the system from human expert knowledge. The human expert intervened network training was developed to remedy the established system response surface. After the transformation of the remedied system response surface to the problem domain, Genetic Algorithm (GA) is applied to evaluate the close optimum set of the design parameters.

1. Introduction

Currently, the CFD is the most widely adopted approach to simulate the behaviours of fire systems. It is a sophisticated and useful technique to evaluate the behaviours of the systems. The CFD model divides the domain of a system into finite numbers of small volumes. The nonlinear system behaviour of the fire system is determined by solving a large set of differential equations describing the interactions between the small volumes. Extensive iteration steps and large size of matrices are usually involved in the CFD computation. The major drawback of the CFD is the requirement of extensive computer storage and lengthy computational time. Also, the results predicted by the CFD are flow field information of all small volumes (e.g. velocities, temperature, pressure, mass fractions of different species, etc.). These numerical results are still required to be further manipulated (i.e. post-processing) for telling the user the performance interpreted from the CFD simulation results especially when the user is not an expertise in fire. One of the examples is the height of the thermal interface in a single compartment fire. Even though the temperature field has been obtained from the CFD simulation, the field data is still required to be post-processed to determine the height at which the average temperature gradient is the highest.

Currently, ANN techniques were only applied to fire detection system. Many studies have confirmed the applicability of the ANN techniques to fire detection system. The superior performance comparing to other traditional models have also been addressed. However, application of the ANN techniques to determine the consequences of fire is still very limited. Lee et al. (2000) applied Feedforward MLP model for determination of sprinkler actuation. The prediction results are comparable to zone models. The FAM was employed by Lee et al. (2001) to determine the occurrence of flashover. The highest rate of correct prediction was determined to be 97.6%. Lee et al. (2002) have also developed a probabilistic inference engine (PEMap) based on the theories of maximum information entropy for treating the uncertainties embedded in fire data. It was also applied to determine the occurrence of flashover. The results show that the performance of the PEMap is competitive to the FAM but with a comparatively simple network structure and working mechanism.

These pioneer works have confirmed the applicability of the ANN techniques in determination of fire consequences.

A novel ANN model denoted as GRNNFA (Lee et al., 2004a) has been developed particularly for prediction of compartment fire. It has been proven to be a rapid alternative to the CFD simulation for predicting the height of the thermal interface in a single compartment (Lee et al., 2004b). The high speed computation of the GRNNFA facilitates the formulation of a soft computing based optimization model.

The next section of this paper introduces the development of a novel hybrid ANN model, denoted as GRNNFA, which was designed particularly for fire studies. The novel approach of network training by employing human expert intervention is also introduced to remedy the system response surface created by the GRNNFA model. Then, the optimization model by GA is also illustrated.

2. GRNNFA Model with Human Expert Intervened Network Training

2.1 Development of the GRNNFA Model

The structure of the original GRNN model developed by Specht (1991) is self-determined. Every sample presented to the GRNN is recruited as a kernel and stored inside the network. However, large set of kernels is resulted if the batch of the training samples is large. Specht (1991) proposed to introduce a clustering process to compress the total number of training samples to fewer number of kernels. Different clustering approaches for reducing the number of kernels of the GRNN model were proposed. The major shortcomings of the clustering schemes are the requirement of predefinition of number of kernels prior to the clustering process. The investigations Carpenter et al. (1991) and Moore (1989) also reveal the instability of these clustering models by using Euclidean distances for the similarity measurement. On the other hand, the FA (Carpenter et al., 1991) with guaranteed convergence in network training has been proven to be stable. As a result, the FA is used for clustering the training samples incrementally and stably into fewer numbers of kernels in the GRNNFA. The basic architecture of the GRNNFA model is shown in Figure 1.

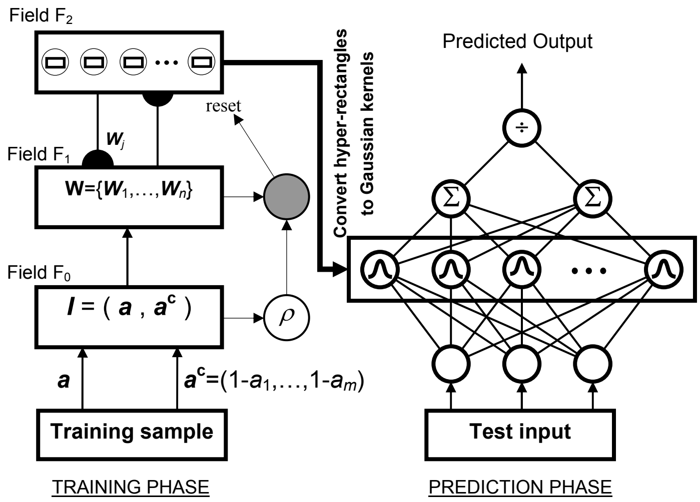

Figure 1 Architecture of the GRNNFA model

2.2 Human Expert Intervened Network Training

Most of the intelligent systems are designed to minimize the human intervention in network training phase for the purpose of automation. The knowledge of the system is solely recruited from the available training samples. However, when the number of training samples is limited, especially for the fire data, the knowledge recruited from the available samples may not be sufficient to describe the system behaviour. Human expert experience can provide the information missing from the limited training samples. It is proposed to simplify the prediction model by putting part of the nonlinearity of the decision action back to the human brains. Similar idea was successfully applied by Iba and Mimura (2002) to gene regulatory network by interactive evolutionary computing. The idea of applying the human intervention to ANN model is proposed. If the training samples are limited in size, human expert intervention is considered as the only way to further improve the performance of the prediction model. The human expert intervention facilitates the modelling of the expert knowledge into the system which can also be considered as a supervised tuning of the system to the 'preferences' of the expert. The trained model not only captures the system behaviour from the limited samples but also recruits the expert knowledge into the network. The human expert intervened network training algorithm consists of the following generic procedures:

a. Historical data of the system is recruited as training samples for network training.
b. The GRNNFA model is trained by the available training samples. A system response surface is created to represent the knowledge of the training samples.
c. Human experts are invited to examine the established system response surface and identify any 'defective' location at the surface.

d. If a defective location is found, CFD simulation will be carried out to create an extra sample at that location. It provides an extra knowledge of the system for further network training.
e. The GRNNFA model is trained again with the presence of the extra samples. The system response surface is hence remedied.
f. Repeat step c. to e. until the human experts satisfy the remedied system response surface.

3. System Design Optimization by Genetic Algorithm

The last section illustrates the approach of establishing the system response surface. This system response surface, according to the objective of the design optimization (i.e. the objective function), is transformed to the problem domain. GA can be applied on the transformed surface to arrive a close optimum solution. The genetic algorithm (GA) is a evolutionary optimization approach developed on the basis of the natural selection theory as described in the book of ‘On the Origin of Species by Means of Natural Selection or the Preservations of Favoured Races in the Struggle for Life’ written by Darwin (1859). Holland (1975; 1992) developed an algorithm to apply the natural selection theory on genetic chromosomes which is a string of Deoxyribonucleic Acid (DNA) of which four basic blocks are included (i.e. ‘A’, ‘T’, ‘G’ and ‘C’). In the traditional binary coding of the GA, the basic blocks are ‘1’ and ‘0’. Crossover and Mutation are the two basic operators developed from biological theories. They are used for breeding new chromosomes from one generation to the next generation. In each generation, the ‘best fit’ chromosomes are selected as parent chromosomes for breeding the next generation. The overall design optimization approach is described as follows. The GRNNFA creates a system response surface from the collected samples. During the network training, human expert knowledge is adopted to remedy the response surface. GA optimization is then applied to achieve the close optimum design parameters.

4. Applicatoin of the GRNNFA-GA Optimization Model

This section demonstrates the application of the GRNNFA-GA optimization model for determination of door width of a fire compartment. The fire experimental data for the GRNNFA model training was extracted from Steckler et al. (1982) experiments. It is a set of full scale steady state experiments of flow induced in a single compartment fire. A total of 55 experiments were performed that included different fire locations, fire intensities and window and door sizes. The height of the thermal interface was estimated from the room temperature profile data as the position of rapid temperature change between the lower cold layer and upper hot layer of the compartment. Owing to diffusion and mixing effects of the fluid flow, the thermal interface height could not be determined precisely. It was ascertained that the interface height could only be achieved within a range of ±8% to ±50% accuracy (Steckler et al., 1982). The values of the interface height recorded in the format of mean ± error were used to compare the GRNNFA predictions.

4.1 System Response Surface Establishment

Different controlled parameters were varied to result different measurements. Table 1 summarizes the parameters and measurements. The HTI was chosen to be the target output of the GRNNFA model. Since there are only total 55 numbers of samples available, the bootstrapping technique was adopted to evaluate a statistically justified prediction results. The value of K of the kNN and the vigilance parameter of the GRNNFA model were set to be 2 and 0.92 respectively

Table 1 Controlled parameters and measured results of the Steckler et al. (1982) Experiment

Controlled parameters	▪ Width of opening ▪ Height of the sill of the opening ▪ Fire Strength ▪ Distance of fire bed from the front wall ▪ Distance of fire bed from the centerline ▪ Ambient temperature
Measurements	▪ Air mass flow rate ▪ Neutral plane location ▪ Height of the thermal interface ▪ Average temperature of the upper gas ▪ Average temperature of the lower air ▪ Maximum mixing rate ▪ Air velocity profile at opening ▪ Temperature profile at opening

4.2 Human Expert Intervened Network Training

The above procedures established the system response surface the GRNNFA and the training samples adopted from Steckler et al. (1982). The system behaviour of the height of the thermal interface has been validated. In this step, the human expert intervention is involved in the network training. Five different cases which are unseen from the training samples were examined by the human expert. The five cases and the original sample distribution are shown in Figure 2 and Figure 3 respectively.

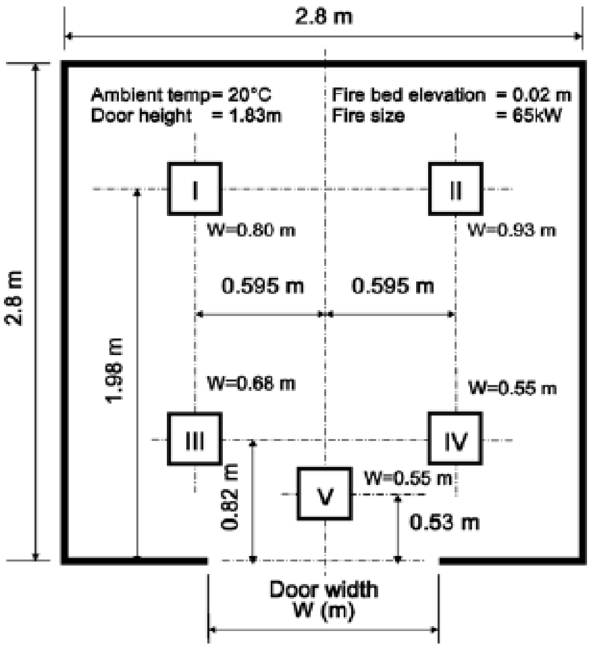

Figure 2 Distribution of the five cases to be examined by the human expert

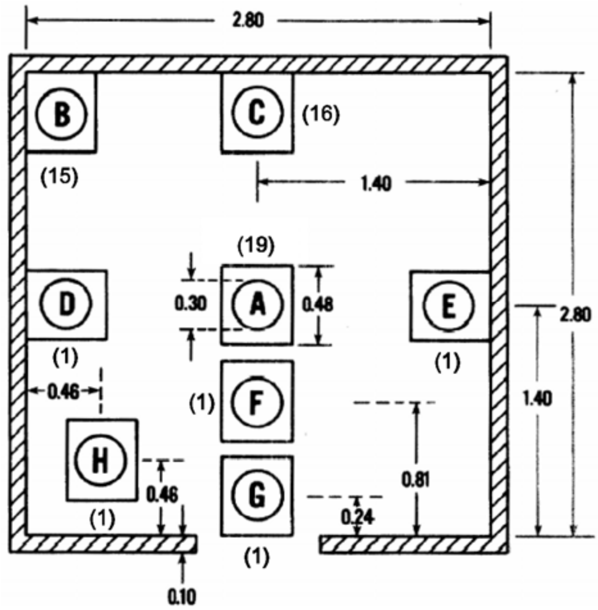

Figure 3 Distribution of the original samples in Steckler et al. (1982). Numbers of samples at the different locations are bracketed

The trained GRNNFA model was applied to the five cases to predict the corresponding HTIs. The predicted results are shown in Table 2. According to the validated conjectures which are considered as the human expert knowledge, the HTIs of the five cases should be ranked as: HTIII > HTII > HTIIII > HTIIV > HTIV. However, Table 2 gives a different ranking: HTIII > HTII > HTIIII > HTIV > HTIIV

The original data distribution is shown in Figure 3. The bracketed values shown in the figure indicate the number of samples in each fire location. It is seen that majority of the samples are located at ‘A’, ‘B’ and ‘C’. Comparing to the five test cases, test case I and II benefit from these samples.

For test case V, although most of the samples are remotely away from this location, there are still two samples (i.e. locations ‘F’ and ‘G’) contributing their knowledge to this fire location. For case III and IV, they receive less benefit from the remote samples. However, there is a sample at location ‘H’ contributes to case III. Although this sample also contributes to case IV (mirror at the center of opening), the door width of this sample (i.e. 0.74m) is closer to case III (i.e. 068m) than case IV (i.e. 0.55m). It was proven by Lee et al., (2002) that the accuracy of prediction is significantly affected by the data distribution density. This particularly applies in the knowledge distribution in the experimental results of Stecker (1982). Since the data distribution density at test case IV is less than that at test case V, it can be concluded that the available samples are not sufficient to describe the system behaviour at the test case IV.

Table 2 The HTIs of the five cases predicted by the GRNNFA

Case	Distance from door center (m)	Door Width (m)	HTI (m)
I	2.067	0.80	1.207
II	2.067	0.93	1.225
III	1.013	0.82	0.954
IV	1.013	0.55	0.897
V	0.530	0.53	0.913

An extra sample was created by applying CFD simulation on test case IV. Fire Dynamic Simulator (FDS) (McGranttan et al., 2000) was employed. The predicted HTI was 0.992m. The GRNNFA was re-trained by the original 55 numbers of samples together with the extra sample created by the FDS. The re-trained model is denoted as GRNNFA*. Figure 4 shows the ranking of the HTIs of the five test cases before (i.e. GRNNFA) and after (i.e. GRNNFA*) the network re-training. The error envelop indicated on Figure 4 was estimated by the FDS simulations on the five test cases with the minimum error range of the HTI as indicated on Steckler et al. (1982) incorporated. It shows that the network re-training with the extra sample drags the case IV back to fall within the error envelop. In fact, other cases has also benefited from the re-training since they have also been moved closer to the center of the error range. The above example demonstrates the remedy of the system response surface by the human expert intervened network training. The human expert knowledge was not required to be quantified but employed for identifying the defective location of the system response surface.

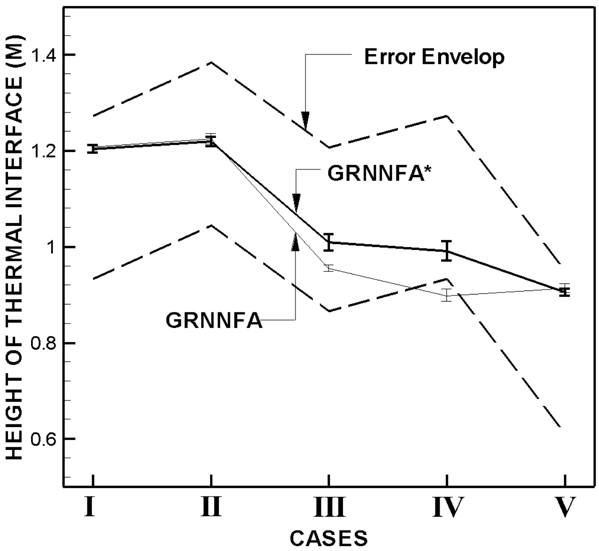

Figure 4 Improvement of the GRNNFA prediction by introduction of the extra sample

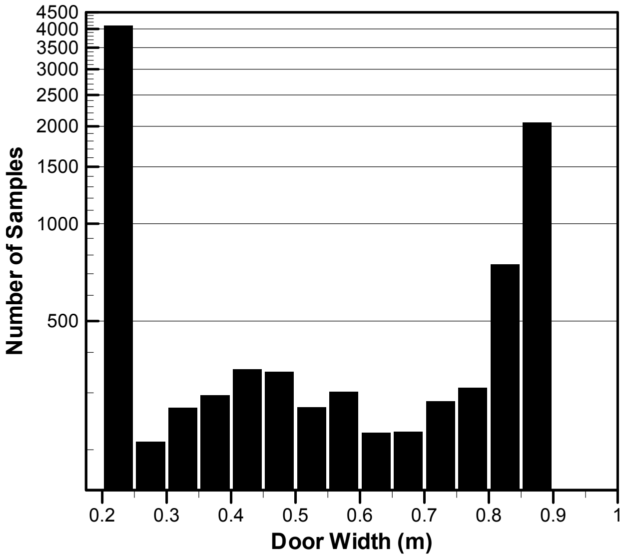

Figure 5 Distribution of the 10,000 door widths with which the HTIs were not lower than 1.0m above floor level

4.3 Optimization of Design Parameter by Genetic Algorithm

The remedied system response surface was ready to be used after the network training. The objective of this design parameter optimization is to determine the minimum door width with which the HTI would not lower than 1.0m above floor level disregarding the location of the fire. The objective function is defined in formula: arg{W, Min[$H(W,D_x,D_y)-1.0]^2$; $\forall(D_x,D_y)\in\Omega$} where H is the HTI resulting from the door width W, distances of the fire bed from room center D_x and from the front wall D_y. The physical domain of the fire bed location is defined as Ω.

The objective is to minimize the value of J. It was found that different set of $\{W,D_x,D_y\}$ may result the same value of HTI. In order to determine minimum door width irrespective to the location of the fire bed, Monte-Carlo simulation was carried out. Total 10 000 numbers of fire bed locations were randomly created within the physical domain Ω to arrive 10000 corresponding door widths with which the HTIs were not lower than 1.0m. The typical progress of the GA optimization is shown in Figure 23. It can be observed that the close optimum solution was reached by only 10 generations. Also, the objective function did not has further reduction over 200 generations. The distribution of the 10 000 door widths is presented by the histogram as shown in Figure 5.

By counting 99.9% of the 10000 samples (i.e. 9990 samples) from the leftmost, the door width of the 9990th sample falls into the range of 0.85–0.9m. The following conclusion can be drawn: There is at least 99.9% confidence level that the average height of the thermal interface induced by the fire (62.9kW) will not lower than 1.0m above floor level when the door width is 0.9m disregarding the location of fire inside the compartment identical to the experimental setup of Steckler et al. (1982) experiment.

5. Conclusions

This paper presented the development of a set of generic optimization procedures with applications of the GRNNFA model, the human expert intervened network training and GA. The GRNNFA model established the preliminary system response surface according to the information of the available training samples. Since the available samples may not be sufficient to describe the general behaviour of the system, human expert intervened network training was developed to remedy the system response surface by the implementation of the human expert's knowledge. Subsequently, the GA was applied on the remedied system response surface to arrive a close optimum solution.

This optimization approach was demonstrated by the application to determine the door width of a single compartment with which the HTI would not lower than 1.0m above floor level irrespective to the location of the fire bed. The Steckler et al. (1982) experimental results were adopted as the training samples. The trained GRNNFA model revealed the two conjectures of the HTI's behaviour (i.e. the HTI will be raised by placing the fire bed away from the door opening or increasing the width of the door opening). The conjectures were also validated theoretically and numerically. The established system response surface was examined by the human expert. The defective location of the surface was then determined by his knowledge. CFD simulation was carried out at that location to create the extra sample for the network re-training. The re-trained GRNNFA produced the remedied system response surface. It was shown that the human knowledge together with the CFD simulation significantly improve the system response. After the completion of the GA optimization applying on the response surface, the close optimum door width was found to be 0.9m.

Abstract

Improving statues of society's economic affects to change and destroy environment. During a building's existence, also affects the local and global environments via a series of interconnected human activities and natural processes. Studies in developed and developing countries show, to enhance environmental sustainability, a building must holistically balance and integrate all three principles: Sustainable Design, Economy of Resources, and Life Cycle Design in design, construction, operation and maintenance, and recycling and reuse of architectural resources. These principles comprise a conceptual framework for sustainable architectural design. The other fact that design management has been neglected in building design, which is a very difficult process to manage. Because, a large number of professionals involved, including architects, project managers, structural engineers and service engineers to build environment. Studies show, to achieve sustainability (controlling all affects) in building industry, the design process needs to be planned and controlled more effectively, in order to minimize the effects this industry in our environment. To achieve this goal (sustainable architecture), it requires holistic integration of all architectural activities into the design process throughout the life cycle of buildings.

To respond to this requirement some world universities developed a conceptual framework to educate architecture students to meet this goal of coexistence. This allows them to further and analyze specific methods architects can apply to reduce the environmental impact of the buildings they design.

In Iran, also like other countries building industry making a lot of environmental problem. Studies in this area show, to achieve sustainability in building industry, Iranian Universities need to establish special academic programme for this country. To achieve sustainable architecture education Shiraz University started to educate postgraduate architecture student about how can possible design and construct building regards to goal of sustainability for Iranian building industry.

This paper cited to define the method of education design for sustainability in master degree for architecture students in the Faculty of Art's and Architecture, Shiraz University and other fields which are related to building industry to achieve sustainability in Iranian building industry.

Introduction

In modern society, more than 70% of a person's lifespan is spent indoors. An essential role of architecture is to provide built environments that sustain occupants' safety, health, physiological comfort, psychological well-being, and productivity[1]. According to studies a large percentage of defects and environment in building arise through decisions or actions taken in the design stages. It is also widely known that poor design has a very strong impact on the level of efficiency during the production stage. The increasing complexity of modern buildings in a very competitive market – place in recent years, has significantly increased the pressure for improving the performance of the design process in terms of time and quality.

The fact that design management has been neglected understandable to some extent because, building design is a very difficult process to manage. It involves thousands of decisions, sometimes over a period of years, with numerous interdependencies, under a highly uncertain environment. The design process therefore needs to be planned and controlled more effectively, in order to minimize the effects of complexity and uncertainty. The lack of adequate design planning, results in insufficient information being made available to complete design tasks and inconsistencies within construction documents. Poor communication, lack of adequate documentation, unbalanced resource allocation, lack of coordination between disciplines, and erratic decision making have been pointed out as the main problems in design process management[2].

Studies show that in pursuit to achieve adequate planning and design, responsive to the above problems, sustainability concept of understanding needs to exist in almost all related specialties. In the architecture field, the subject has caught attention of many related specialists, in the recent years. To achieve the objectives and the concept of sustainability, it is required to teach the concept knowledge to architectural and related field college and university students. Educational curriculum and courses in this field are mainly to control and assess the factors effective in design and construction. According to studies, to enhance environmental sustainability, a building must holistically balance and integrate all three principles — Sustainable Design, Economy of Resources, and Life Cycle Design — in design, construction, operation and maintenance, recycling and reuse of architectural resources[3].

1. Development as the case for changing environment

Studies show that in the existing conditions, "development" in all sciences can ruin and destroy natural state of the earth and the species living on it. According to statistics the rate of destruction and degeneration is estimated at 27000 extinctions per year, which means 74 cases per day or three cases per hour. Specialists believe that global warming, Ozone layer reduction due to usage of various pollutants, increased environmental pollution and extinction of living species are all in all because of improper development in human societies. They believe that concern for environmental problems is essential for the future of human beings' life. Numerous reviews also reflected that construction and civil developments are one the most effective factors to degenerate and destroy natural environment and if the current pace of construction is not controlled or changed, irrecoverable or uncompensated damages may evolve.

2. Destroying the earth due to building construction

Architectural professionals like other specialists have to accept the fact that as a society's economic status improves, its demand for architectural resources-land, buildings or building products, energy, and other resources-will increase. This in turn increases the combined impact of architecture on the global ecosystem, which is made up of inorganic elements, living organisms, and humans. For instance, the energy and water used by its inhabitants produce toxic gases and sewage; the process of extracting, refining, and transporting all the resources used in have numerous effects on the environment. Other side during a building existence it affects the local and global environments via a series of interconnected human activities and natural processes. At the early stage, sit development and construction influence indigenous ecological characteristics. The procurement and manufacturing of materials impact the global environment[4].

3. How can we save the environment from continued devastation

As it was mentioned earlier development is known as one of the greatest needs of the human being as it alters and manipulates the environment. Construction is known as a high potential industry for man–power employment (hundreds of thousands of construction workers and related techniques), and also the main factor for ruining agricultural lands, eroding the soil, polluting the environment and providing hazard to health and well being of the people such that it has also brought with it energy crisis. This emergency in mid 1960's, along with increase in air pollution and environment pollution was a serious global warning that invoked environmentalist groups who supported the idea of protecting land against industrial pollutants world-wide and who followed the issue in its extended concept under title "sustainability". Therefore saving the environment from continued devastation by our built environment is the single most important issue for our tomorrow.

3-1. Sustainability (environmentalist view)

The new term sustainability that concerned environmental issues was first introduced in 1986 by the world committee on globalization of environment under the topic: (fulfillment of the current time needs without hazards to the future generations' resources in coping with their needs); the dimensions and scope of this issue increased daily so that proper strategies may be put forward world-wide. Architects, in line with other specialists, are pursuing, in their own profession, new approaches to provide for appropriate living conditions for people. Obviously, it must be reminded that living, working, entertainment and resting … all and all are the actions and activities taken in spaces designed by architects. Since weak and strong points of a building has direct effects on eco-system and environment, architects bear fairly sensitive duties in this concern. Application of sustainability and sustainable development concepts in architectural design has introduced a new terminology called "sustainable architecture" the most important topics of which were titled "eco-tech architecture, architecture and energy-green architecture".

3-1-1. Sustainable construction

Sustainable construction means: management of a clean and healthy area on the basis of effective exploitation of natural resources and ecological principles; its main objectives concerning mitigation of damage on environment, energy resources and the nature has three branches.

1- Reduced consumption of un-renewable energy resources
2- Development of natural environment
3- Deletion or reduction of toxic materials consumption that damage the nature through construction industry

Sustainable construction may therefore be defined as a building that has the least incompatibility and inconsistency with its own surrounding locality, and in a broader sense, with the region and the world. Studies show that construction techniques in a wide spectrum are in line to secure integrated quality, economically, socially and environmentally. Therefore, logical use of natural resources along with proper construction management may help protect limited natural resources and reduce energy which in turn helps improve natural precincts quality [5]

4. Role of architect to protect the environment

Design and building construction is usually carried out by architects and under his or her supervision in cooperation with the expertise of other specialists in the construction industry. Architectural college students however, get familiar with a number of related subjects such as principles of buildings, building techniques and materials, building structures, and environmental control, which are taught and exercised in an integrated manner with other courses of the curriculum program (such as Principles of Buildings Building Techniques and Materials, Building Structures and Environmental Controls) which are taught and exercised in an integrated manner with other courses of the degree programme. Hence, in a field originated on sustainability, the potential role of architecture is defined, in broad and comprehensive perspective, in terms of human natural habitat; all different samples of which, including urban areas, urban textures, livable hubs and finally, single abodes and open spaces are related to one another by the architecture. Such a comprehensive panorama draws "sustainable design" path so that it interferes and meets different lines of expertise and makes intra-expertise group activities (for different fields of structural and facilities design engineering and planning) essential and inevitable. In regard of this heavy responsibility of architects in design and control of all different specialties involved in the building industry, architects have a grossly sensitive role in optimum implementation of the above activities towards environmental protection.

5. Current methods of education fro architecture and sustainability in Iranian Universities

Studies and reviews on architectural education methods in the Iranian universities, with respect to the status of sustainability ideas show that:

- Educations are mostly carried out without considering to the interactive relationship and dependencies between human and its local habitat.
- Efforts and endeavors are scarce mostly in the context of conventional educational courses.
- Most of the solutions lead to short-term planning
- In the current educational methods, dissociation of fields provided with lack of interaction between study fields.

According to this status, current methods of higher education in most courses is emphasized on individual and competitive learning and not so much on participation and cooperation of different specialty branches; it therefore delivers to the society, managers and authorities who are not trained for group cooperation and participation. Some studies argued how and why our current design approach and perception of architecture must radically change if we are to ensure a sustainable future. Those studies also argued forcefully that this can only be achieved by adopting the environmentalist view.

6. Study on education of sustainable architecture in some universities around the world

Studies carried out on sustainable architecture in the foreign universities show that there is no specific sample institute that centers on or follows one particular and concentrated educational model. The training courses related to sustainable environment design, offered in universities and other educational centers are mostly part of a set of approaches and curricula predicted out of proposal or a combination of several educational approaches from a few educational models. Most of the trainings are concentrated on theoretical sustainability notion such that its non-practical specialized basics are more highlighted than its practical and empirical actions. The reason for such approach in specialized education is the fundamental notion that architectural students (environmental design majors in general) must get adequately mastered in the course of special training, on design skills and architectural doctrines. In fact, students of this major field are gradually educated to gain and realize their role and position in attaining sustainable society.
In sustainable architecture education, training is experienced in its limited form in a design workshop. This type of atelier design enjoys a better stance than the single-field one. In this composed atelier, only students with architectural background are absorbed, but on the side of design professors, they enjoy and take advantage of the presence of professors from other specialties related to the subject, especially those in fields related to environmental design (structure, facilities, planning, urban development and landscape design) and also those in environmental science. Therefore, students can experience all different aspects and dimensions of problem solving and can concentrate on the subjects as much as possible. In such atelier, smaller workgroups are generally formed. Each group is tasked to concentrate on a part of the problem. Finally findings of each group will put to discussion to achieve to agreed decision.

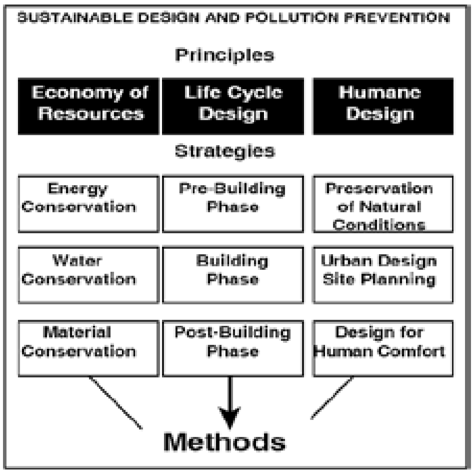
6-1. Curriculum sustainable architecture in the some world universities

The curriculum in the university of UTSOA for sustainable architecture offers two design-based and one scholarly program study on scholarly is about the relationship between the built and natural environments. In design-based curriculum offers for graduate students without a previous degree in architecture. In post professional program, they designed programme for students who already have an undergraduate professional degree. In Master of Science in Sustainable Design program, also they designed for students who wish to prepare for the Ph.D. or for employment in research, activism, or public policy. All program target increasing student and faculty interest in three areas of inquiry — natural systems, building systems, and cultural systems. The study of natural systems relies upon the disciplines of physics and ecology as they relate to architecture. The study of building systems includes investigation of those component technologies that are required to construct environmentally responsive architecture. The study of cultural systems requires that natural and building systems be investigated within the complex social and political context of architectural practice. In sum, the Sustainable Design Program is practical, technical, and philosophical in scope.

Another example of sustainability curriculum is the sustainable architecture graduate program in Architecture and Fine Arts College of the south London University, described as following: Attention and emphasis of the majority of curricula is paid today to environmental design. On the other hand, in order to gain special and specific skills like application of sustainability principles by students, many methods and technologies in the area of environmental design are available. Students who take part in such compact programs do not have much time to dig into the roots.

The graduate program on sustainable architecture emphasizes mainly on this aspect of the problem that instead of training architects who use up the existing prevailed set of proposed methodologies, graduate students must redirect themselves towards more research and innovative ideas and new think formation. To achieve this, authorities have made efforts to develop solid sustainability thinking foundation in students' minds, with the help of a set of theoretic courses and argument-and-discussion sessions or seminars. The main objective of this program is therefore, instead of design and computer modeling, set and emphasized on research and scientific argument and discussion.

The other university is Michigan University, which is established sustainable design programme to educate architects to meet this goal of coexistence. They have developed a conceptual framework in three levels of the framework (Principles, Strategies, and Methods) correspond to the three objectives of architectural environmental education: creating environmental awareness, explaining the building ecosystem, and teaching how to design sustainable buildings. The overall conceptual diagram for sustainable design is shown in figure 1.



They proposed three principles of sustainability in architecture.

- **Economy of Resources** is concerned with the reduction, reuse, and recycling of the natural resources that are input to a building.
- **Life Cycle Design** provides a methodology for analyzing the building process and its impact on the environment.
- **Humane Design** focuses on the interactions between humans and the natural world. These principles can provide a broad awareness of the environmental impact, both local and global, of architectural consumption.

Figure 1 *Principles, Strategies, and Methods sustainable architecture to educate in Michigan University*

6-1-1. List of sustainable architecture courses in Hong Kong University

The list of sustainable architecture courses in Hong Kong University, called "sustainable design" is offered in graduate program. The framework of the curriculum and the courses introduced as below:

- Understanding sustainability thought

- Maintaining balance among social, economical and environmental factors
- Internal energy and work energy
- Climatic and morphological details of the building
- Design of active envelop of the building
- Social aspect of sustainable technology
- - Renewable energy resources
- Recycling- based design

From the preceding discussions it is clear that in seeking sustainable architecture there is no unequivocal course of action that will suit all ethical stances all objectives and all situations. There is no class or style of design which will guarantee success if followed. Rather, there are difficult interrelated decisions to be made that are contingent on particular circumstances. This study show goal of sustainable design is to find architectural solutions that guarantee the well-being and coexistence of constituent groups [6].

6-2. Instructions to sustainable architecture

According to study sustainable design is the thoughtful integration of architecture with electrical, mechanical, and structural engineering. It addition to concern for the traditional aesthetics of massing, proportion, scale, texture, shadow, and light, the facility design team needs to be concerned with long term costs: environmental, economic, and human with the considering following points[7]:

- Principles of Sustainable Design
- Connecting with nature
- Understanding Environmental Impact
- Understanding People
- Understanding Place
- Understanding natural processes
- Embracing Co- Creative Design Processes

Therefore, sustainable architecture thus embraces a multi-value structure: aesthetics, environment, society and politics. In other word "design and construction" that is compatible with local environment. An architect shall cleverly consider a few factors: resistance, durability and life span of the building, proper materials and the concept. All sustainable architecture principles must materialize in a complete process that leads to development of safe and healthy environment.

6-3. How sustainable architecture principle influence design and planning

We have highlighted the cultural construction of sustainability, drawn attention to a variety of ethical positions, explored the nature of decision making and design advice, and discussed the complex system involved, but how do all these come together when we as architect are faced with making day-to-day designs? To illustrate the complexity of the problem we as architects face in terms of the social, scientific and professional positions[6]. Therefore, minimizing energy consumption and promoting human health should be the organizing principles of sustainable design.

6-4. Strategies for approaching ecological design and planning

As it was pointed earlier, in the current university education structure, most specializations related to design and construction on the surrounding environment are offered and taught separately under a given distinct specialization title and grouped in departments based on the science branch they belong to. Architectural students get acquainted in their classes with these study subjects and other related topics. They can experience the application of newly known concepts in their design assignments; but majoring in different fields such as architecture, construction and facilities, urban development, planning, landscape design and internal decoration, students rarely work together to learn from each other as a group. This is while in the principles considered to achieve sustainability, communication and group working is given special attention as one of the main themes to sustainable design.

In educational approach, in order to transfer the sustainability perspective to the students, instead of defining the problem in the context of limited perspective "design", need decided to let students experience the architectural design in a wider range. In this view, the role of architect in creating built environment shall not be limited to design, but in performing the role, architect shall directly get involved in providing sustainable peripheral so that all dimensions of the proposed problem may be seen, designed and resolved in the context of a project with sustainability in the architect's mind. Application or employment of an intermediate place (between university area and professional medium) is another new empirical approach based on which, professional identify for architect is developed and followed and also fundamental and structural changes in architectural trainings is sought. In this substituting method, in pursuit to provide empirical education to architectural students and establish bi-directional relationship between architecture sector and education department, an intermediate place is prepared in which, students in cooperation with one another and with a group of professional architects and architectural professors discuss and learn the real experience of sustainability. The intermediate space is handled as a laboratory office, much like educational hospitals. In fact, a professional educational office is established that holds coexistence business and dynamic interaction simultaneously with university sector and free market.

6-5. Methods for achieving sustainable design

The ultimate goal and challenge of sustainable design is to find win-win solutions that provide quantitative, qualitative, physical, and psychological benefits to building users. There are many possibilities for achieving this seemingly difficult goal. The three principles of sustainable design — economy of resources, life cycle design, and humane design — provide a broad awareness of the environment issues associated with architecture. The strategies within each principle focus on more specific topics[1]. Integrate and apply the relevant knowledge in areas related to building surveying practice such as design, material selection and detailing of building construction development, application of building regulations survey and maintenance of buildings, assimilation of building services knowledge in the design of buildings, contract administration, management of property and building projects etc. Understand the fundamental technical, economic and legal aspects of a project in the construction industry; and develop skills in building communication in the form of drawings, technical reports, specification, charts, diagrams and illustration. This method as a design process can help to achieve sustainable design.

6-6. Shortage of teaching material for environmental education

The survey indicated a significant shortage of teaching materials for environmental education in architecture. In preparing resources and valid documents, it is required that serious efforts are taken so as to be able to respond to necessary needs of the near subject. One of the new solutions to prepare local resources may be the establishment of sustainability programs proposed in this paper [4].

7. Current statues of education on sustainable architecture in Shiraz University

According to the curriculum of architecture education, which is defined to Iranian Universities non-continuous architectural Master degree program curriculum, in regard of extensive dimensions and also ever increasing needs of the architectural field including environmental design and development, counts on science and specialization power as a necessary means to provide proper ground for the growth of specialized tendencies and consequent enhancement of efficiency. This curriculum for establishment program on architectural engineering was termed as securing public efficiently. Therefore, it was later proved the proper place for introduction of sustainability. In this extent in order to achieve objectives and ideals of sustainable development, the architectural department of the faculty of Art’s and Architecture of Shiraz University has been offered a two-hour arbitrary course on sustainable design to get students (of this field) familiarized with sustainability notion in construction design.

The course on principles and foundations of sustainable architecture-based design is offered in two parts. The first part of the class is to familiarize students with principles and fundamentals of sustainable architecture-based design including man-built environment, health issues, safety, welfare and economics. This part is composed of seven sessions. In this sessions all student presented in the class internal and foreign resources (books and internet) about sustainable architecture. In the second part of the program, which lasts another seven sessions, students tried to review the methods, which is used to apply sustainable factors in finished projects. In this program teachers tried enhance students' sensitivity to environmental issues and to scientific fundamentals to achieve sustainable design and knowledge.

7-1. Suggested method for continuing sustainable architecture education

As it was mentioned earlier, the objective in sustainable architecture programs is to embolden students' sensitivity to environmental issues, scientific fundamentals and their capabilities in the framework of ongoing educational courses and towards responsive design of environment. However, attention and emphasis of the majority of curricula in graduate programs is put on environmental design, gaining special and specific skills in the domain of the problem under consideration. Application of guidelines, methods and special technologies in the design domain keeps students so busy that they do not have much time to dig into the roots, reasons and necessities of the problem, with such compact study programs. Graduate programs on sustainable structure emphasize mainly on this aspect of the problem that graduate students of architecture must try to direct themselves towards more research work and innovative idea development. To achieve this, curriculum authorities have made efforts to develop solid sustainability thinking foundation in students’ minds. In this program, instead of training architects who merely use the existing prevailed set of proposed methodologies, graduates must be more self-relying on carrying out research and come up with new sustainability ideas.

On this basis, the second proposal with respect to training a new generation of architectural specialists is to use professional work and educational experiences, which requires establishment of bi-directional relationship between professionals and education sectors in order to provide and intermediate office- like space (which runs much like educational hospitals), common to all architectural students willing to take part in sustainable architecture issues. In the space, students, professionals and professors work together to make a bridge between construction industry and educational center to maintain sustainable development and environment.

7-1-1. The first proposed method for sustainable architecture training: Familiarization of students with principles and fundamentals of sustainable architecture – base design
This sustainable development training method is started from 2007 in this faculty. In this method, while presenting sustainability issues to the students, professors try to persuade them to do research works and present the results in the class (two-man group classmates). All students in the class are practically introduced to various sustainability parameters (even reviewing real projects already finished). This training method provides large volume of information to the students during the term so that they would be able to apply experiences to carry out sustainable architecture oriented design. Accordingly, after acquaintance, of students with principles and fundamentals of sustainable architecture, the sustainability group of this faculty intends to offer sustainable architecture plan project (a separate project design) in the next term. Considering the rate of acquaintance of students with principles and fundamentals of sustainable architecture, it seems that students may be able to do their plan applying the above principles.

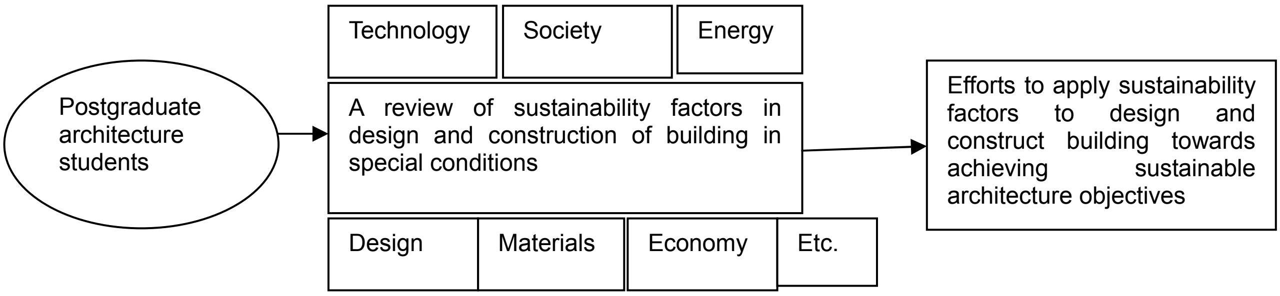


Figure 2 Diagram of processes of the first method for sustainable architecture education

Figure 3 Photos form sustainable architecture class in faculty of Art's and Architecture,Shiraz University

7-1-2. The second method in sustainable architecture education system:
Sustainability education with cooperation and collaboration of experts related to construction industry, where architectural specialists are the main pillar who has responsibility and authority to guide education toward sustainability. In the second method also, efforts are toward defining and posing the sustainability topic in classes and persuading students to do research works (in two sessions) in their own fields of specialization (even reviewing real sustainability projects) toward achieving sustainability. This part will almost last up to mid-term. In the second part of the exercise, while defining a design project in a real construction site, design process is carried out commonly, trying to reach sustainability. In this type of project, putting emphasis on resolving a problem instead of merely designing a project may be an effective help in sustainable education. At this level, group members concentrate on various aspects of the problem according to their line of interest, but they all work for an optimum output in the conceptual framework of the group. Considering the formation

trend of the program, it may be said that intra- field training approach is mostly the backbone and common problem and that would be resolving a problem instead of simply designing. In order to persuade communication among major–fields, it may be required that parts of the work is carried out on actual human settlements in need of various specializations. Using this method it would be possible (in the long run) to review the subjects more deeply (by the above experts) and define various educational programs with various tendencies. Even by using these methods it is possible to define PhD programs for architecture students.

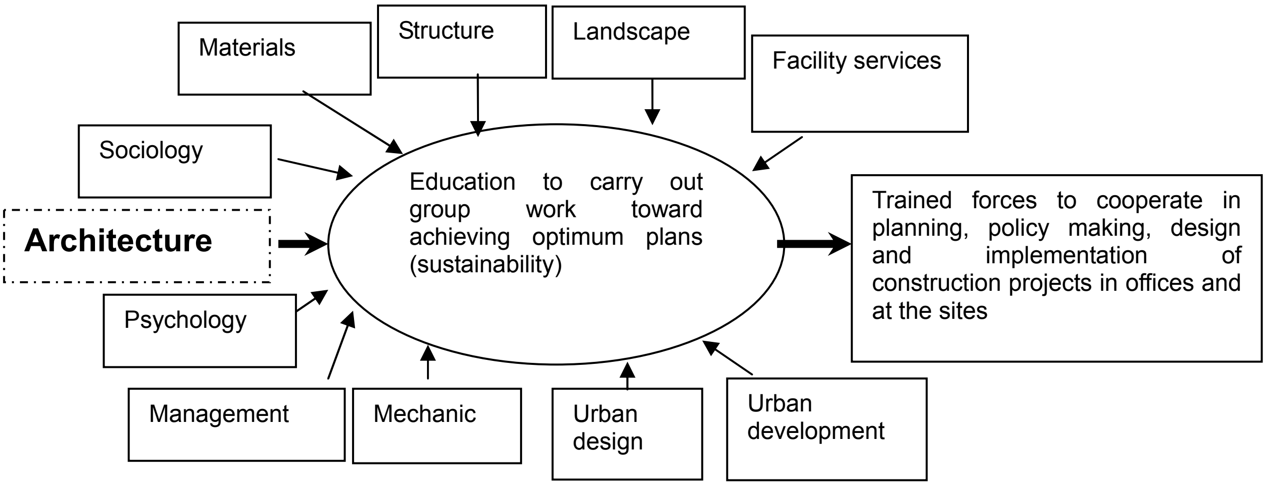

Figure 4 Diagram proposed for second method for sustainability in building industry

8. Conclusion

Studies revealed that caring for environmental issues are one of the necessities of today is societies. In view of formation and momentum of the environmental issues being posed nowadays, it seems to be necessary to institutionalize and publicize this line of through universities and colleges. Educational schemes on their way to achieve sustainability objectives will need to apply special educational methods. This requires full use of existing capacities to make the methods operational. Construction sector is one of the influential factors to alter the environment this subject has recently caught attention of experts. To achieve environmental sustainability in the building sector, it is crucial to educate architecture students in environmental issues, which is called Sustainable Architecture. For successful application it must be understood by all whose work touches on building owners, architects, engineers, contractors, material suppliers and operators. Most cannot be expected to have either depth or breadth in the knowledge available. It is clear, therefore, that participants in the building industry require assistance in matching available technology with the specific problems encountered in their day-to-day activities. It is expected that professional and academic bodies will be attracted to develop collaborative education system. Because studies show the result of this collaboration benefit not only current students but also practicing building professionals who need continuing professional education. In the long run, the field of building technology can be advanced and the object of sustainable development can be promoted. Accordingly, two methods for teaching sustainable architecture in the faculty of art's and Architecture in the Shiraz University are being followed up to train students toward conducting construction projects with sustainability in mind. If educational objectives are met, more control over construction industry activates natural resources and especially environmental potation, which in the disastrous of all factors may be in reach.

Summary

Laws are made by people and for the people. If the majority of the people do believe something must be done or something should not be done legislation is there to arrange activities in society. This also goes for the building sector. In this research various government policies and advice are analysed in order to obtain sustainable buildings. Many laws are clear and useful. In this research some specific cases with very clear sustainable impact and some cases with questionable impact are analysed. The majority of people as individuals consider sustainable issues as very important, but as soon as serious investment or a reduction of personal comfort is involved, often the sustainability possibilities will be neglected. Sustainability aspects at little cost, bringing a clear and guaranteed profit to the owner in the long run can be successful. This research shows that sustainability aspects are to be communicated as simply as possible, and will be most successful when future savings in operating cost can be proven for the future home owner. Surprisingly sustainability items can be very successful under a logical and profitable financing scheme in one country and a total failure with a different financing scheme in the country next door.

Introduction

The aim of housing laws and related legislation is to ensure safe, useable, healthy and energy efficient buildings. Due to general public environmental awareness, political pressure and personal involvement, many local authorities show strong intentions emphasizing sustainability aspects to be included for new homes in order to improve the sustainability level of the local building stock.
In order to achieve this goal a wide array of mandatory items, preferred solutions, advice and recommendations are given to the public both in building and operating a home. The subjects vary from the obligation to use a specific building material, the minimum thickness or performance of thermal insulation material, types of windows and energy related issues like heating and cooling equipment and generating hot water. Also lots of advice on how to operate a home is given.
In this research the effectiveness of some of this advice has been analysed. This study also focuses on possible new options that could be added in order to achieve more sustainable housing, profitable for the occupant, the community and the environment.

1. What is sustainable building?

Sustainable building can be seen as building in such a way that environmental load is reduced to a minimum both during the construction and operation of the building. The building itself must be safe, useable and comfortable to people with a minimum use of fossil energy or preferably no fossil energy use at all. Quite contradictory requirements, as the building is there to create an attractive and desired climate for people that is different to the outside climate. In order to realize this difference a separating structure is needed and energy is needed to maintain the difference. As a consequence sustainable building can be approached focussing on two items: the building design process choice of materials and systems and the operation of the building.

2. Building a house, the basic materials.

For building a house, materials and labour are needed. Materials are produced from natural resources this process involves energy and labour. Once the material is produced it needs to be transported to the building site, involving energy and labour next the material needs to be mounted and connected to other material and waste needs to be disposed of, again involving energy and labour.
The embodied energy of all these accumulated actions can be assessed, the energy needed to realize that specific material in that specific quantity on that specific spot. It is obvious, that such a calculation of embodied energy can only bring a rough estimate as the exact amount of energy of every aspect cannot be precisely established. Common sense will help.

As an example in a specific recommendation sea sand is advised. Sea sand is plentiful so depletion of sea sand is no issue, but desalination and transporting the sand over a long distance will involve great amounts of energy. It is obvious that locally excavated sand in terms of embodied energy is preferred.

For building walls many materials are available such as wood, brick, concrete even straw bale. Every material has some advantages and some disadvantages.

Wood can be locally produced from well operated and maintained forest. The Swedish Forest Council claims that in Sweden in spite of the very large production and export of timber, the actual surface of forest is increasing due to a very active policy on planting new trees. Planting trees is an easy process, and can be done highly efficiently. Trees will grow almost without any cost or effort, harvesting is easy and processing can be done highly mechanized again at low cost. Working with wood has been done for ages and craftsmanship and tools and equipment are available almost everywhere. In terms of embodied energy wood seems to be the ideal material as the carbon is stored for life of the wood. Yet wood also has its disadvantages. It can burn needs maintenance and can be deteriorated by biological means. So wood in some cases is not the ideal material at all. Medieval European cities often were entirely built out of wood, as in the middle ages no electric light was available, often an open fire was used for heat, cooking and lighting. As sometimes things go wrong, one house might catch fire, and with it the entire city. Today we are surprised that many cities suffered this situation more than once, and only after many years when building in stone or brick became mandatory by law, the image of the city completely changed.

This could suggest brick to be the ideal material. Brick is a very durable material - brick walls aging over 500 years can be seen all over Europe. It needs almost no maintenance, but building a brick wall is very labour-intensive and manufacturing brick uses a lot of energy.

Another excellent example of a material with advantages and disadvantages is straw bale. A material that in some places is an agricultural left over, almost free. Very limited embodied energy, available forever, with excellent thermal insulation and when covered with some 20 mm plaster offers a very high fire resistance. But special craftsmanship is needed and the long-term behaviour is questionable.

In modern building in The Netherlands pre-cast concrete is used. Due to the small distances in The Netherlands transportation is never a limiting factor. It is known that concrete consists of cement, sand, gravel and water. Sand and gravel are to be excavated from the environment, so it is logical to consider for sustainability reasons replacing a certain amount of gravel with waste concrete granulate from a demolition. In a government guide line it is stated that for sustainability reasons without any further consideration 20% of the gravel can be replaced by granulate from waste concrete. Questioning the manufacturer of the pre-cast concrete elements about the possibility of this 20% replacement the answer was that this was never done for two reasons. Adding granulated material from a demolition means adding material from an unknown source, so the quality of the end product could not be guaranteed. Also the process of making pre-cast concrete is mechanized in such a manner that granulate would disturb the process and so generate higher cost.

Surprisingly the same answer was heard in the float glass factory producing window panes 24 hours a day, 365 days a year for seven years. This process was considered to be so precise and sensitive that no one would even think of risking a disruption by adding unknown material.

2.1. Building a house, the life time consequences of choices

Once materials and products are chosen a specific design should be made related to the chosen materials and products. The importance of this statement can best be illustrated by using an example of a façade consisting of sandwich panels, with doors and a window. (figure 1) It looks like this façade is made without knowing anything about the materials and products involved. In figure 2a the black surfaces give the dimensions of the wasted parts of the original sandwich panels, as sandwich panels are produced in a linear process. Panels have been cut to make doors and window fit and brand new material is turned into useless waste. In figure 2b the alternative design is given: no on site cutting of panels, no waste generated. Less material is needed, less waste is created and most important, less money is spent with only a little extra design effort. It is obvious that legislation cannot prevent waste to be generated, however a tax penalty on building site generated waste could well be considered, or high cost for waste disposal.

Figure 1 Sandwich panels, Doors and windows in the existing situation.

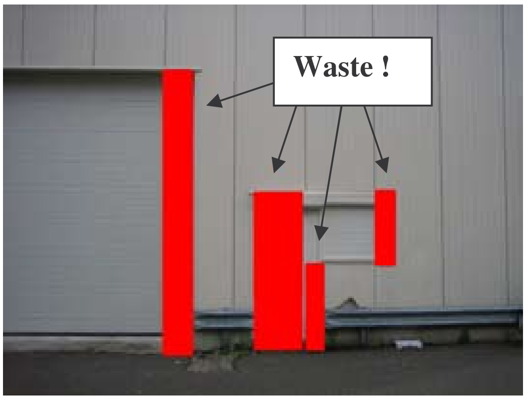

Figure 2a Wasted surface of sandwich panels

Figure 2b With a little extra design no waste

When designing a house it makes sense to think about a covered outside area suitable for laundry drying. Modern tumble dryers consume some 400-500 kWh of electricity a year, and this energy consumption can be avoided with a proper place for drying laundry. At an average overall electricity use of some 3500-4500 kWh per year, a simple design decision can save more than 10% of the yearly electricity bill. In the purposely-designed Swedish low energy example a balcony has been designed for this purpose.

The balcony also acts as an overhang preventing summer sun entering the house and heating it up. In this case the overhang will also prevent rain water reaching the wall and window frame, resulting in a reduced maintenance need. (Figure 3)

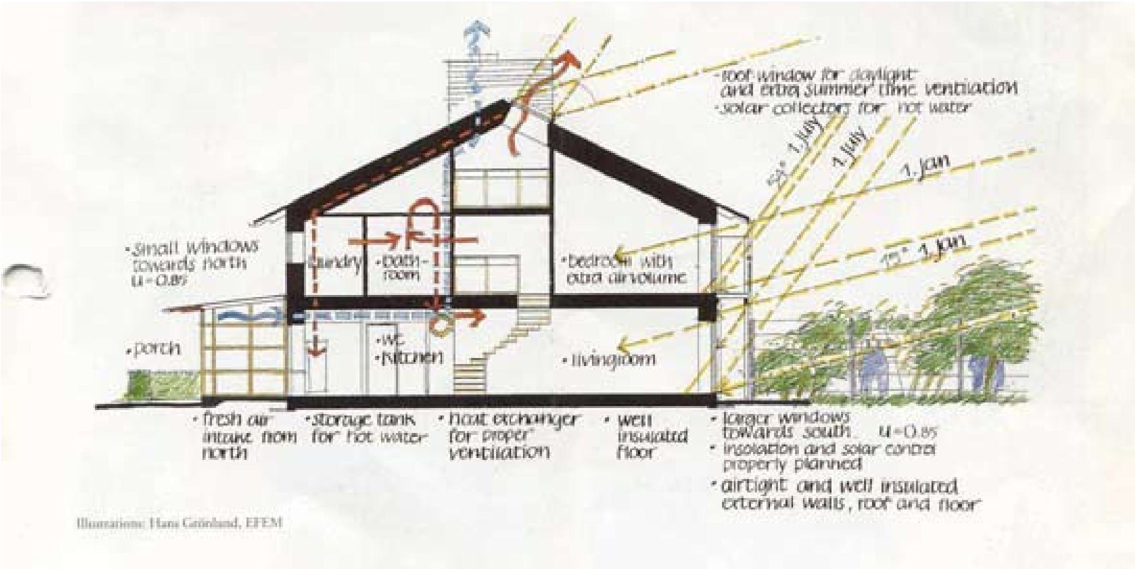

Figure 3 The Swedish Low energy housing concept with balcony and overhanging roof.

3. Operating a house, Energy consumption

Another important life-time issue is the energy performance of the house. On average some 8000 kWh of energy is needed for heating alone in modern Dutch housing. This energy usually is realized by burning natural gas. Energy consumption for other than heating purposes (light, household equipment, pumps etc) usually amounts to some 3500-4500 kWh per year. In Germany the passive house standard developed in 1992. A house is considered “passive” when yearly heating demand is less than 15 kWh/m2. For an average 100 m2 house this means a total yearly heating demand of 1500 kWh. A passive house can be characterized by 400 mm thermal insulation, high performance windows, an air tight structure and a heat recovery ventilation system, obviously all expensive items to realize. Yet no financial support at all is given to people in the process of realizing such a project, not even support or priority in obtaining building permits.

3.1. Operating a house, electricity

Another important aspect for the generation of sustainable energy is the use of Photo Voltaic panels. If a house is situated with a South facing roof, even in Northern Europe (52 degrees North) it is quite feasible to install Photo-Voltaic panels, or PV panels. PV panels and the related installation are expensive, some 400 Euros per m2. The yearly sustainable electricity yield in useable electricity amounts to some 100 kWh /m2. At present 1 kWh of electricity will cost some 20 eurocents, so the yield in money consists of 20 Euros per year. Period for return on investment is over 20 years making PV a very bad investment. In spite of many subsidies for buying PV systems in the Netherlands PV never reached any significant contribution in the sustainable energy supply.

Surprisingly in the country next door to The Netherlands, in Germany, PV are very popular and many companies exist in the field of supplying and installing home PV systems. Under German law the payback for the sustainable PV kWh is 50 eurocents, and this contract has a fixed price for 20 years. A rough calculation shows the pay back time is reduced to 8 years. Also in specific cases individuals can have an income tax reduction when investing in sustainable energy. Of course the 50 eurocents for

the sustainable PV kWh output must be paid. This is realized with a slight increase of electricity prices or electricity tax, so the person investing in sustainable energy makes a profit, to be paid by the person not investing in sustainable energy.
It is most surprising that this system has worked well in Germany since 1997, but has only recently been discovered by other governments.

In this respect it is also surprising that calculators running on batteries are still being sold. Calculators powered by solar cells or PV have existed for years offering the same quality at the same cost but without batteries that run out sooner or later and are reduced to chemical waste. With a double or triple VAT for such polluting products with available sustainable alternatives the problem of generating toxic waste caused by the disposed batteries could be solved easily?

3.2. Operating a house, domestic hot water use

For modern housing in the Netherlands roughly 25% the energy is for heating, 25% for hot water and 50% other. So quite a significant amount of energy is needed for generating hot water. The worst advice found in reducing energy use was to set the water heater to 120 ºF (48 ºC) Unfortunately this temperature is ideal for the Legionella bacteria to develop, especially in non chlorinated drinking water. A Legionella bacteria outbreak once happened in The Netherlands on a fair back in 1999 with 133 confirmed cases and 28 deaths. It is clear that saving energy must be done with safety first. This is illustrated by the American Society of Professional Engineers (ASPE) recommending temperatures for water heaters to be at least 140 ºF (60 ºC).

A far easier method for saving energy on domestic hot water is using heat recovery of shower wastewater. A simple device is placed around the drained shower water. Wasted shower water has a temperature of some 28 ºC, this will heat up the cold water supply from 10 ºC to 27 ºC so less warm water is needed. The device once installed will run for ever, no electricity, no controls needed, it will only work when showering and stop when you stop showering. No possibility for Legionella to develop. The principle is given in figure 4

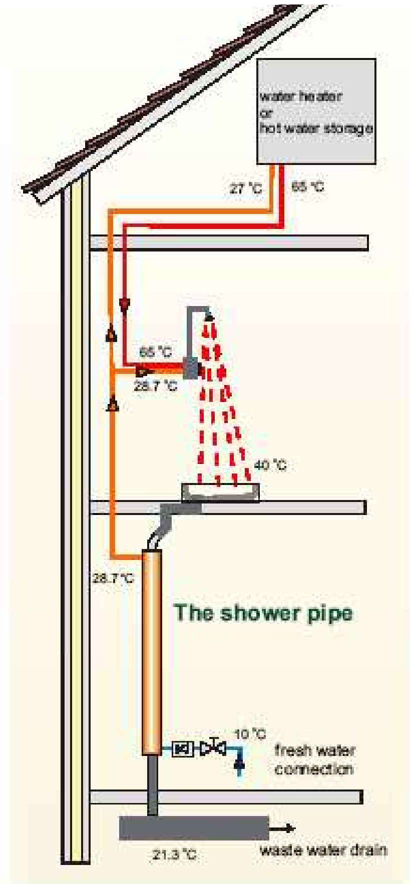

Figure 3 The heat recovery Shower waste water equipment

The recent water shortage in Brisbane, Australia shows that active promotion and giving information really helps. In order to save water the price of water saving devices was halved and installing was free. Also people were provided with a 3 minute sandglass, for timing showers so they could contribute personally to solving the problem of limited water supply.

4. Conclusion

Sustainable building and operating a house is an important issue. Many, very many technological and technical options exist to contribute to sustainable building, however when applying these options one must be fully aware of the consequences. Any reduction of safety is unacceptable. An investment in sustainable issues must be paid back in a reasonable period, else the initiative will be a failure. Successful, profitable items are to be communicated as clear as possible.

THE OPTIMIZATION OF THE OVERALL PERFORMANCE OF BUILDINGS

Keywords: overall comfort, indoor air quality, acoustic behaviour, thermal behaviour, daylighting, sustainability

Summary

Building plan and shape are the result of a complex process. Functional, technical and aesthetic considerations all contribute to the building design. Wind, solar availability, shelter, exposure, air quality and noise conditions will affect the relationship between the building and its external environment and influence the shape and the design of the envelope. Materials selection, heating, cooling, daylighting, indoor air quality (IAQ), acoustic behaviour and energy strategies should be meshed at an early stage with the other requirements to ensure the buildings sustainability and overall comfort conditions.

To accomplish this goal it is necessary to predict the thermal, acoustic, lighting and IAQ behaviour of the buildings, on the design phase, in order to be able to do the right choices, regarding, for instance the geometry, fenestration strategies, construction solutions and materials, to improve the occupants overall comfort and, simultaneously, to reduce the energy costs and increasing the sustainability of the buildings.

So it is necessary to have an integrated approach to ensure the best overall behaviour taking into account all of the, sometimes incompatible, comfort and sustainability requirements.

The aim of this study is to select a range of optimized solutions (envelope construction solutions, materials, fenestration and ventilation strategies, etc.), in order to improve the overall performance of buildings (comfort and sustainability).

1. Introduction

As the building sector in the EU is responsible for 40% of the final energy demand (30% in Portugal) and of 1/3 of the greenhouse gases emissions, it is mandatory to control the energy consumption in the building sector, while maintaining or even improving the indoor comfort conditions and reducing the environmental impact.

Having this challenge in mind and considering that a healthy and comfortable indoor environment is a basic premise in all buildings, it is during the design phase that the sustainable building concepts should be applied, through the implementation of a combined strategic action that allows improving the comfort and the energy performance, while reducing the environmental impact, by a judicious selection of materials, technologies and construction methods to be used.

To achieve this goal it is necessary the use of environmental friendly products (to minimize the Volatile Organic Compounds - VOC - and other emissions), methods and techniques for buildings, re-use of components or use of recycled materials, minimize the use of materials or components that rely on scarce materials resources, select materials that balance durability and low embodied energy and design and plan the building for demolition and re-use and also to minimize the operation cost, namely the energy need for heating, cooling and domestic hot water.

To guarantee an adequate thermal, acoustic and daylight behaviour and the internal air quality (IAQ) of the buildings it is necessary to consider thermal storage (thermal inertia) using the building structure, selecting exterior walls systems and insulation according to the climatic zone, implement passive heating and cooling solar systems (using solar and photovoltaic panels).

It is also necessary to select the correct fenestration for each orientation, according to the latitude, lighting and natural ventilation, considering also the solar gains, the outdoor obstructions and choosing the shading devices to optimize the energy and comfort needs to ensure the acoustic and thermal exigencies, the indoor visual comfort related to the visual task to be performed.

It is necessary to optimize the building envelope, by improving insulation, glazing, optimizing natural ventilation and daylighting techniques through appropriate design in order to reduce the thermal losses of the building.

The solutions adopted in buildings, usually, only optimize no more than one of the necessary comfort requirements. In many cases, the best solutions to accomplish different comfort requirements are not compatible, especially in what concerns natural ventilation and lighting strategies and the acoustic and thermal performance. For instance, the type of window used can have a strong and opposite influence on the thermal and acoustic performance of the building, just not to mention its interference on the indoor air quality (IAQ).

The solutions adopted on the conventional buildings are only compatible with one or two of the necessary requirements, and don't fulfil the others (for example the windows' frame air tightness is good for the thermal and acoustic performance, but not to natural ventilation and doesn't interfere with the natural lightning). Therefore, it is necessary an integrated analysis to ensure the best overall behaviour (for instance, the definition of the area, shape, shading device, way of opening, type of glazing of a window, considering its orientation, the external environment, etc.).

Therefore, and as the buildings are complex systems, where all aspects are interconnected and influence each other, it is necessary to have an integrated approach to the building, that should enhance indoor health and comfort besides the energy savings and environmental sustainability, to ensure the best overall behaviour taking into account all of the, sometimes incompatible, comfort requirements.

The aim of this study is, then, to select a range of optimized solutions (envelope construction solutions, materials used, fenestration and ventilation strategies, etc.), in order to improve the overall performance of buildings accomplishing all the comfort requirements, because a well designed building has the potential to reduce energy costs and also to improve the occupants' comfort.

This study will consist on the optimization of the overall comfort conditions throughout the analysis and control of four major parameters related to the thermal insulation level, the acoustic insulation level, the illuminance levels (taking into account the indoor daylight requirements) and the number of air changes per hour (related to the indoor air quality), considering the factors that have influence on the buildings behaviour.

To achieve this goal a three bedroom dwelling, representative of the conventional Portuguese buildings, will be studied, estimating the heating and cooling needs necessary to maintain the indoor temperatures between 20 and 25ºC (comfort zone) according to the Portuguese thermal regulation (RCCTE, 2006), the acoustic behaviour of the envelope elements, estimating the weighted normalized airborne sound insulation index and the weighted normalized impact sound pressure level index, the indoor daylighting conditions, and the Indoor Air Quality (IAQ), for several construction solutions for its envelope and partition elements.

2. Methodology

To improve the overall performance of buildings it is necessary to select the right solutions (envelope construction solutions, materials, fenestration and ventilation strategies, etc.), considering the building characteristics, such as shape and orientation.

To evaluate the range of solutions, a three-bedroom dwelling, representing typical Portuguese buildings was selected in order to ascertain the potentialities of each one of the construction solutions and materials, in order to identify the ones that can improve the occupants overall comfort.

As, in general, in Portugal residential buildings are only acclimatized during occupied periods, the HVAC system was defined to maintain the indoor temperatures above 20ºC in winter and under 25ºC, in summer, according to the Portuguese legislation (RCCTE, 2006), only during this period.

The occupied period considered was between 7pm till 8 am and the non-occupied period between 8 am and 7 pm.

2.1 Simulation Tools

The Prediction of the building thermal behaviour will be done using computer modelling, with EnergyPlus, estimating the heating and cooling needs to maintain the indoor temperatures between 20 and 25ºC during the occupied period, for different construction solutions for the envelope and for the partition elements. The IAQ will be assessed by the number of air changes per hour (ach) ensured by the air inlets on the windows frame and by the mechanical ventilation of the WCs. In summer, during night periods the building is ventilated to use the cooler outside air to reduce the temperature inside the building. The number of hours where the occupants were uncomfortable in the zone was determined by EnergyPlus based on ASHRAE 55 - 2004 graph (Section 5.2.1.1) (ASHRAE 55, 2004).

The acoustic behaviour will be considered estimating the weighted normalized airborne sound insulation indexes and the weighted normalized impact sound pressure level index ($D_{n,w}$, $D_{2m,\,n,\,W}$ and $L'_{n,w}$), using the Acoubat Sound Program.

The lighting behaviour will be verified using the Desktop Radiance Tool, for the 21st of December and for the 21st of July, calculating the illuminance levels and the daylight factor which is the International Commission on Illumination (CIE from its French title) recommended method to determine the performance of a daylighting system, and is independent on the window design and location, outdoor obstructions, optical characteristics of inner surfaces and windows. It is useful for estimating the amount of glazing needed to illuminate a space.

2.2 Building Charateristics

The building under analysis, with 129.3 m^2, has three south oriented bedrooms. The kitchen and the dining and living room are north oriented (Figure 1).

The WCs are mechanically ventilated and the windows have adjustable air inlets in the frame to guarantee the ventilation of the dwelling.

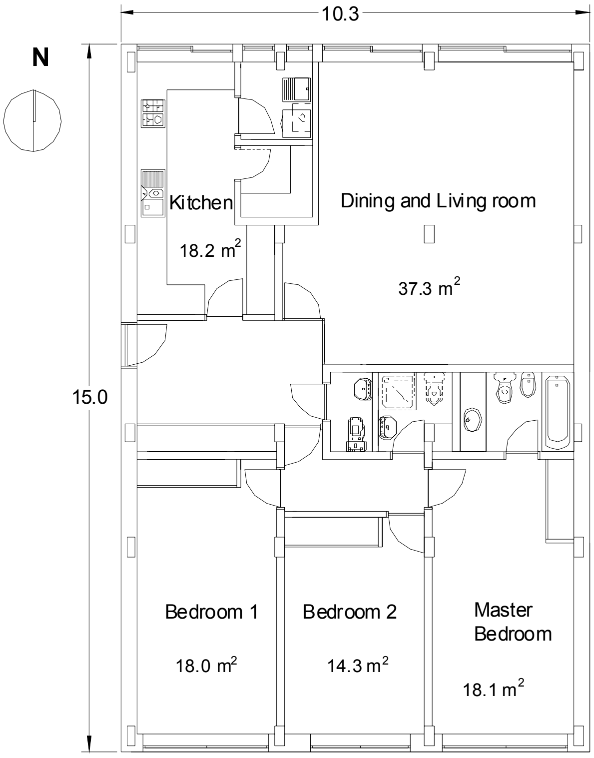

Figure 1 Schematic plan of the studied building

On an initial stage, the windows, with 1 m high, had a glazing area corresponding to 15% of the floor area (30% of the wall area), to maximize the use of the solar gains in winter and the daylight use (3.36 m^2 on the kitchen, 5.15 m^2 on the dining and living room, 2.75 m^2, 2.20 m^2 and 2.75 m^2 for the bedrooms). On a second stage, the glazing area was doubled to 30% of the floor area (window doors with 2 m high) to evaluate the influence of the window area on the energy needs, acoustic and daylight behaviour.

2.3 Construction Characteristics

The factors studied are the ones that need to be considered when designing the building envelope including amongst others: the area of windows, their orientation and type shading device used; the insulation levels used in the building; the air tightness of the building construction; the colour of the building and its surface properties; the potential for natural ventilation; and the amount of exposed internal thermal mass.

The construction solutions analyzed are shown in Figure 2 and listed on Table 1, for the different types of elements of the building envelope. The constructive solutions selected, single and double pane walls (hollow concrete blocks, brick, hollow brick and plasterboard), concrete, hollow core concrete and beam and pot slabs and materials (concrete, brick, plaster), cover a wide range of situations.

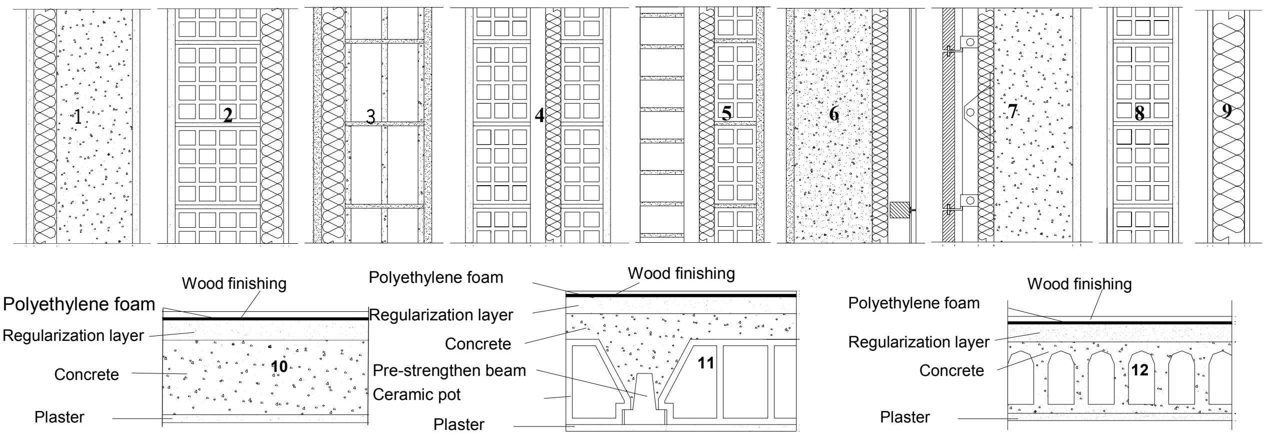

Figure 2 Vertical cross-section of some of the construction solutions of the buildings walls and floors (external and partition elements)

The study was done for two insulation materials (expanded extruded polystyrene, XPS, and mineral wool, MW), with several thickness (0, 2, 4, 6, 8 or 10cm). The insulation could be placed: in the exterior or in the interior of the single pane walls; or in air cavity or in the interior of the double pane walls (Figure 2).

The windows have an adjustable shading system (venetian blinds) on the outside to maximize the solar gains during winter and minimize the unwanted solar gains during summer and at the same time allowing the control of the daylight, thus, avoiding the use of artificial lighting.

Table 1 Construction solutions characteristics

Element	Construction Solutions (see Figure 2)	
Façade (with several insulation material thickness, finished with plaster on both sides)	Single pane concrete wall with 15cm (1)	
	Single pane hollow brick wall with 22cm (2)	
	Single pane hollow concrete wall with 20cm (3)	
	Double pane wall, hollow brick with 15cm and hollow brick with 11cm (4)	
	Double pane wall, brick with 11cm and hollow brick with 11cm (5)	
	Double pane wall, concrete wall with 20cm and plasterboard wall with 1.3cm (6)	
	Double pane wall, stone with 5cm and concrete wall with 15cm (7)	
Walls separating dwellings and common circulation zones	Double pane hollow brick wall (11cm + 11cm), with 4 cm of mineral wool in plates placed in the air cavity and finished with plaster on both sides	
Partition walls	Single pane hollow brick wall with 11cm, finished with plaster on both sides (8)	
	Double pane plasterboard wall with 1.3cm and with 10cm mineral wool (9)	
Floors and ceilings	Concrete with 20cm, 4cm regularization layer, 0.5cm of polyethylene foam and 0.8cm of wood as top surface finishing and plaster as inferior surface finishing (10)	
	Pre-stressed concrete “T” beams and 26cm hollow pots, 4cm regularization layer, 0.5cm of polyethylene foam and 0.8cm of wood as top surface finishing and plaster as inferior surface finishing (11)	
	Hollow core concrete slab with 20 cm, 4cm regularization layer, 0.5cm of polyethylene foam, 0.8cm of wood as top surface finishing and plaster as inferior surface finishing (12)	
Windows	Metallic window frames with adjustable air inlets, venetian blinds on the outside and overhangs on south windows	Double pane clear glazing (8+10+6) mm
		Double pane Low-E glazing (6+10+4) mm

3 Results

3.1 Thermal behaviour

The typical Portuguese dwelling usually doesn’t have HVAC systems and has double pane hollow brick walls (15cm + 11cm) with 4cm of expanded extruded polystyrene placed in the air cavity (solution 4 in Figure 2) and windows with metallic frame and double glazing. In this situation the inside temperatures are under 20ºC and above 25ºC, for long periods, as Figure 3 shows for the coolest and hottest day.

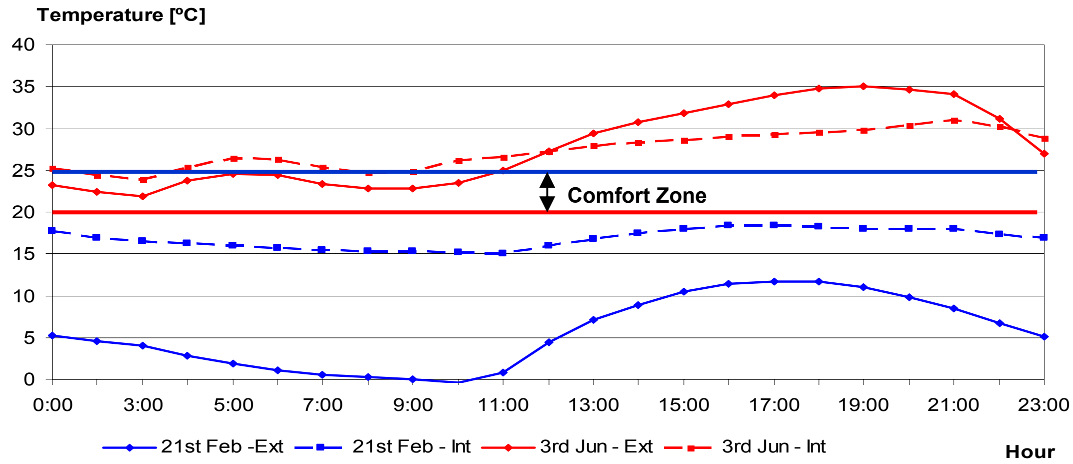

Figure 3 External and internal temperatures for the coolest and the hottest day – without HVAC.

So, it is necessary a mechanical system to maintain the indoor temperature above 20ºC in winter and under 25ºC in summer, during occupied period, which will mean a 3016.6kW/year consume (75% of which in winter).

On Table 2 are listed the heating and cooling needs and the comfortable period during occupied hours, for two different constructive solutions for single walls (a 15cm thick concrete wall, with plaster on the inside, and a 22cm thick hollow brick wall, finished with plaster on both sides), with several thickness of expanded extruded polystyrene on the outside and windows with 15% of the floor area (corresponding to 30% of the area of the wall).

Table 2 Thermal behaviour of the dwelling with single external walls and windows with 1m high

Constructive solution	Heating needs [kW/year]	Cooling needs [kW/year]	Heating + Cooling needs [kW/year]	Comfortable period [%]
Concrete wall with 15cm thickness, with several thickness of expanded extruded polystyrene placed on the outside				
Without insulation	3258.0	849.1	4107.2	36
2cm XPS	2546.4	748.4	3294.8	43
4cm XPS	2287.6	732.0	3019.6	48
6cm XPS	2161.1	726.8	2887.9	50
8cm XPS	2086.5	724.1	2810.6	52
10cm XPS	2037.2	722.5	2759.7	54
Brick wall with 22cm thickness, with several thickness of expanded extruded polystyrene placed on the outside				
Without insulation	3101.0	848.5	3949.5	38
2cm XPS	2481.7	745.2	3226.9	44
4cm XPS	2260.0	732.3	2992.3	48
6cm XPS	2146.6	728.2	2874.8	51
8cm XPS	2078.0	726.1	2804.1	52
10cm XPS	2032.0	724.5	2756.5	53

As Table 2 shows, a concrete wall has a worse thermal behaviour in winter than a single pane hollow brick wall with 22cm due to its higher conductivity, but during summer it has a better performance due to its higher thermal mass.

As can also be seen on Table 2, if the external walls don't have insulation, according to ASHRAE 55, only in 36% (concrete wall) or 38% (brick wall) of the occupied period the occupants were comfortable because not only of the low temperatures verified inside but also due to the radiation asymmetry between indoor walls surfaces and low surface temperatures. Increasing the insulation level, the number of comfortable hours is increased in 10%.

The same occurs when the windows are replaced for equivalent window doors (windows with 2m high which correspond to 30% of the pavement area and to 60% of the area of the wall)), duplicating the winter solar gains. In this case, both walls have a similar thermal behaviour, better during heating season than the one with windows with 1m high (15% of the pavement area, corresponding to 30% of the area of the wall), but worse during summer due to higher solar gains. For example for a single pane brick wall with 4cm of extruded expanded polystyrene, the heating needs are reduced in almost 30%, but the cooling needs are increased by 43%, resulting only in 3% reduction on the global needs.

The same kind of study was done considering the placement of the insulation material (on the outside or in the inside of single walls) and it was verified that the heating and cooling needs are similar and are more significant for higher mass and insulation levels and in the cooling period (5%), due to the effect on the thermal inertia.

The same type of analysis, but with windows doors with 2m high and Low-E glazing, was carried out. In this situation the solar gains were increased and the heat losses were reduced. In this case a concrete wall with 15cm and 6cm of expanded extruded polystyrene on the external face has a better thermal behaviour than a single pane hollow brick wall with 22cm and 10cm of expanded extruded polystyrene, and uses less space.

The reduction on the heating needs is of 24% and an increase of 37% on the cooling needs meaning a reduction of 4% in the global needs each year. The increase on the cooling needs due to the higher glazing area could be minimized with a better shading device or with the use of reflective glazing which will reduce also the solar gains during winter.

This study shows that it is necessary to pay attention to the glazing area and to the shading devices, because even with a good glazing and shading systems it is required to control the solar gains during summer.

The same kind of analysis was done for double pane walls. In this case it was verified that there are no significant differences (2%) in the thermal behaviour due to the type of insulation material (extruded expanded polystyrene or mineral wool). The differences on the energy needs, due to the different types of constructive solution (double pane walls with hollow concrete bocks, brick or hollow brick) are of about 3%, being smaller for the higher insulation thickness.

The increase on the insulation thickness can reduce the energy needs in more than 33%, for example when comparing a concrete wall without insulation and with 10cm of polystyrene expanded extruded, and a minimum of 4.6% when replacing 4cm by 6cm of the same insulation material.

Reducing the number of air changes per hour (from 1.0 to 0.6 ach, minimum value according to the Portuguese Thermal Regulation) will decrease the energy needs to almost 1/4, considering an optimized solution with 10cm of insulation and Low-E glazing. In this case there is no need to heat the space during winter (Figure 4).

In this situation the occupants will be comfortable in more than 80% of the time. In the other 20% of the time, the mean radiant temperature is under the desirable values.

Another possible approach is to reduce the north façade windows' area (kitchen and dining and living room), that have few heat gains, avoiding unnecessary heat losses.

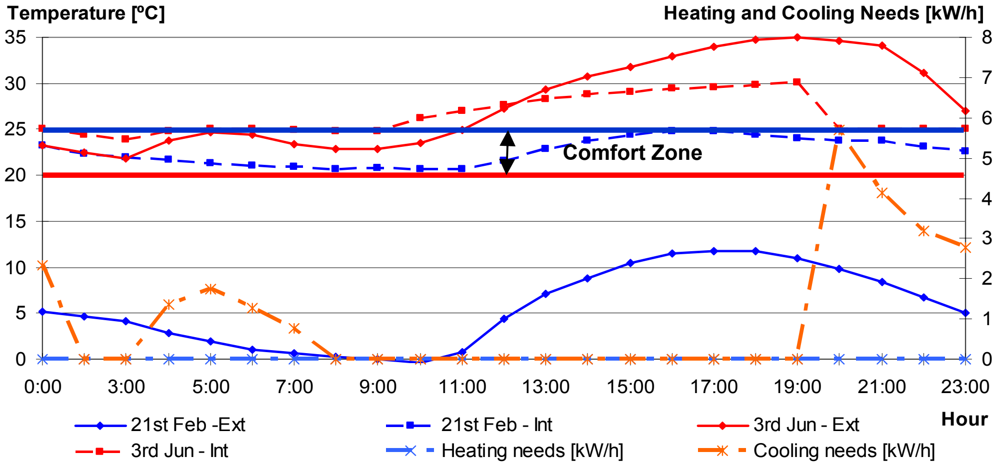

Figure 4 External and internal temperatures for the coolest and the hottest day – without HVAC

3.2 Acoustic behaviour

The acoustic requirements according to the Portuguese Building Acoustics Legislation (Decree-Law nº 129/2002) for residential buildings are the ones presented on Table 3.

Table 3 Acoustic requirements according to the Portuguese Building Acoustics Legislation (Decree-Law nº 129/2002)

Partitions	Weighted normalized airborne sound insulation index ($D_{n,w}$)	Impact sound insulation index ($L'_{n,w}$)
Between dwellings	≥ 50 dB	≤ 60 dB
Between dwellings and garages	≥ 50 dB	-
Separating dwellings from commercial areas	≥ 58 dB	≤ 50 dB
Between bed or living rooms and common circulation zones of the building	≥ 48 dB	≤ 60 dB
Between bedrooms or living rooms and vertical circulation paths (stairs), when the building has elevators	≥ 40 dB	-
Weighted normalized airborne sound insulation index of façades, measured at 2 m from them ($D_{2m,n,w}$)		
Sensitive zones (as defined on the Decree-Law nº 9/2007)	Exposed to $L_{den} \leq 55$ dB(A) and $L_{night} \leq 45$ dB(A)	≥ 28 dB
Mixed zones (as defined on the Decree-Law nº 9/2007)	Exposed to $L_{den} \leq 65$ dB(A) and $L_{night} \leq 55$ dB(A)	≥ 33 dB

On Table 4 are shown the estimated values for the weighted normalized airborne sound insulation index ($D_{n,w}$) and the weighted normalized impact sound pressure level index ($L'_{n,w}$) of the three studied floors.

The beam and pot slab studied don't fulfil the minimum requirements of the Portuguese Building Acoustics Legislation (Decree-Law nº 129/2002).

The concrete slab and the hollow core concrete slab fulfil the airborne, but not the impact insulation requirements.

Table 4 Acoustic behaviour ($D_{2m,n,W}$) of the dwelling floor

Element	$D_{n,W}$	$L'_{n,w}$
Concrete with 20cm, 4cm regularization layer, 0.5cm of polyethylene foam and 0.8cm of wood as top surface finishing and plaster as inferior surface finishing	52dB	67dB
Pre-stressed concrete "T" beams and 26cm hollow pots, 4cm regularization layer, 0.5cm of polyethylene foam and 0.8cm of wood as top surface finishing and plaster as inferior surface finishing	49dB	72dB
Hollow core concrete slab with 20 cm, 4cm regularization layer, 0.5cm of polyethylene foam, 0.8cm of wood as top surface finishing and plaster as inferior surface finishing	51dB	70dB

The acoustic behaviour of the floors, especially in what concerns the impact sound insulation, must be improved, using better resilient elements and floating pavements. A possible solution is the use of a resilient layer of expanded extruded polystyrene, which will improve the acoustic and also the thermal behaviour of the floor. This solution will fulfill the airborne and the impact insulation requirements ($D_{n,w}$ = 51dB and $L'_{n,w}$ = 57 dB). The wall separating dwellings and common circulation zones (double pane wall, hollow brick with 11cm and hollow brick with 11cm, with 4 cm of mineral wool in plates placed in the air cavity and finished with plaster on both sides) has a weighted normalized airborne sound insulation index, $D_{n,w}$, of 50 dB, fulfilling the exigencies of the Portuguese acoustic regulation. In the partition wall (single pane hollow brick wall with 11cm) the $D_{n,w}$ is of 38 dB.

On Table 5 are shown the estimated values for the weighted normalized airborne sound insulation index of the façade ($D_{2m,\,n,\,W}$). For the situation under analysis, almost all the cases fulfil the Portuguese acoustic regulation. The exceptions are the kitchen and the dining and living room with 2m high windows. As Table 5 shows, for external walls with 4cm of expanded extruded polystyrene and for the two types of windows (1 m and 2 m high, corresponding to 15% or 30% of the area of the wall, respectively)), there are no significant differences considering the different constructive solutions, as they are all heavy. However, comparing the performance of the situation with 1m and with 2m high windows, there are differences of 2 dB. So, to improve the quality of the façade walls it is essential to balance the window area and the acoustic quality of the glazing.

The reduction on the north windows area, as previously suggested, will also have a favourable effect on the acoustic behaviour.

Table 5 Acoustic behaviour ($D_{2m,n,W}$) of the dwelling external walls

Constructive solution	Single pane walls with 4cm of polystyrene expanded extruded on the outside		Double pane walls with 4cm of polystyrene expanded extruded on the air cavity	
	Concrete 15cm	Hollow brick 22cm	Hollow brick and hollow brick (15+11)cm	Massive and hollow brick (11+11)cm
Double glazed windows (6+10+8) mm with 1m high (15% of the pavement area and 30% of the area of the wall)				
Kitchen	34	34	34	34
Dining and living room	33	33	33	33
Bedroom 1	34	34	34	34
Bedroom 2	35	35	35	35
Double glazed windows (6+10+8) mm with 2m high (30% of the pavement area and 60% of the area of the wall)				
Kitchen	32	32	32	32
Dining and living room	31	31	31	31
Bedroom 1	33	33	33	33
Bedroom 2	33	33	33	33

Traditionally Portuguese buildings are heavy ones, and the study performed shows that in general the façade fulfil the requirements, for the case where the glazing has 1m high (area is of about 15% of the pavement area, corresponding to 30% of the area of the wall), if the windows area is doubled the requirements are not verified. So, in this case it is necessary to increase the quality of the windows.

3.3 Daylighting behaviour

The illuminance levels and the daylight factor for an overcast sky, recommended by CIE, are shown on Table 6 (CIE, 1975). Figure 5 shows the illuminance levels and the daylight factor for the 21st of December and for the 21st of July, for the bedroom 2, for windows with 1 m high (15% of the pavement area, corresponding to 30% of the area of the wall).

Table 6 Illuminance and Daylight factor for an overcast sky (CIE, 1975)

Illuminance Levels (Lux)		Daylight Factor (%)	
Dining room	100	Bedroom	0.5% at 3/4 of room depth
Living room, kitchen	200	kitchen	2% at 3/4 of room depth
Study	300 - 500	Living room	1% at 3/4 of room depth

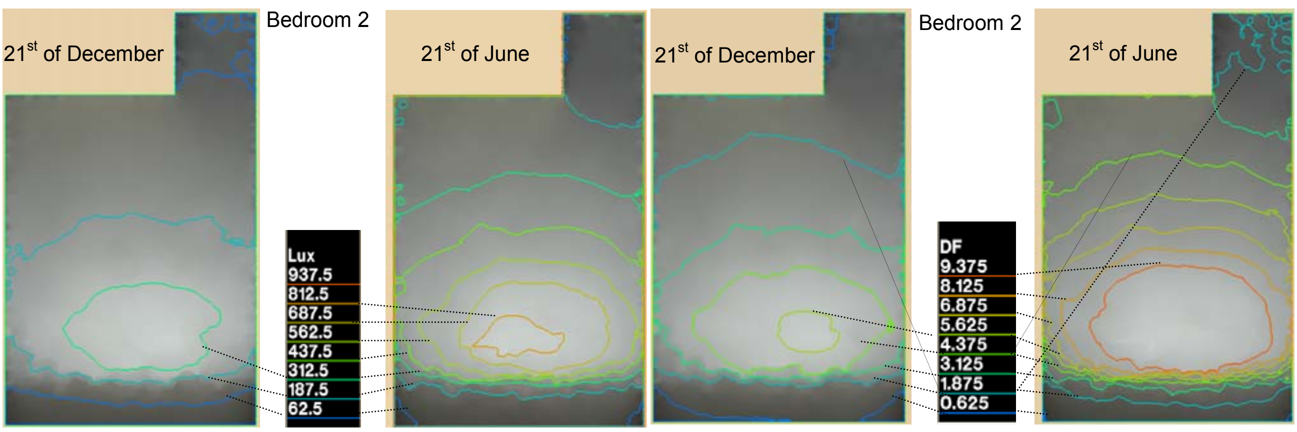

Figure 5 Illuminance Level and Daylight Factor for the bedroom 2, for an overcast sky

The recommended illuminance levels for the studied zones in winter are respected only on the area near the window, and in almost space during summer, but, for the Portuguese luminous climate, the recommended external minimum illuminance considered for an overcast sky is exceeded in more than 90% of the time during the year (Silva, 2002). According to the CIE recommendations, a daylight factor of 2% - 5% is usually the optimum rage of daylighting for overall energy use, and considering the recommended daylight factors for bedrooms these values are fulfilled during winter, but are largely overcome in summer or even in winter when the windows have 2 m high (30% of the pavement area, corresponding to 60% of the area of the wall) (CIE, 1975). The reduction on the north windows area will also have a favourable effect on the daylight behaviour, minimizing the glare, as, even in winter, in the zones nearest to the windows, the daylight factor and the illuminance levels will be high.

3.4 Global behaviour

Analyzing the results of the study it was possible to verify that, even with conventional solutions used in Portugal, it is possible to achieve a good global behaviour, considering the buildings' thermal, acoustic and daylight behaviour, but it is necessary to increase the insulation level of the external walls, and the acoustic quality of the glazing. It is also necessary to improve the acoustic behaviour of the pavements, increasing the quality of the resilient layer and using floating pavements.

5 Conclusions

From the analysis performed it was possible to conclude that there are a great number of constructive solutions, that when adequately used will fulfil the comfort exigencies.

In Portugal it is necessary to improve the thermal insulation levels of the façades and the acoustic quality of the glazing parts of the façade. It is also necessary to use windows with improved frames, with low permeability, to guarantee that the number of air changes per hour is of 0.6.

The selection of the shading devices must also be done carefully to reduce the heat losses during the heating season and the heat gains during the cooling season, and at the same time allowing the penetration of natural light and not reducing the acoustic behaviour of the façade.

The improvement of the night cooling of the buildings with high thermal inertia, during summer, and with the control of the radiation that penetrates into the building will also improve the thermal behaviour of the building.

The shading devices must be movable allowing the control of the radiation but, at the same time admit the entrance of the daylight, control the glare and adjust for variations on daylight availability.

The acoustic behaviour of the conventional floors and of the windows must be improved.

It is necessary to select the correct fenestration for each orientation, according to the latitude, lighting and natural ventilation, considering the solar gains, the outdoor obstructions and choosing the shading devices to optimize the energy and comfort needs to ensure the acoustic and thermal exigencies, the internal air quality and the indoor visual comfort.

But through the integrated approach to the building performance it was possible to conclude that the overall comfort exigencies are not restrictive, because there are a large number of constructive solutions that will assure all the requirements being only necessary to integrate the exigencies of the different requirements.

The windows area and the quality of the frame, the glazing and the shading device are the most important factors to take into account to fulfil the overall comfort requirements. The solution adopted for the fenestration must be selected carefully and may be different for each orientation.

The optimization of the building envelope, by improving insulation, glazing, and optimizing natural ventilation and daylighting techniques through appropriate design in order to improve the overall comfort does not limit the creative process of the designer.

Keywords: solar heat high reflectance paint, temperature abatement, urban heat island, radiation, roof

Summary

Solar heat high reflectance paint is highly reflective in the sunlight radiation range while highly radiative in the black body radiation range is expected to counteract temperature increase in the painted object.

The effect of solar heat high reflectance paint roofs on the yielded temperature abatement as follow:

a) During the summer, in the roof surface, average reduction of temperature of about 16.9°C as maximum and of about 4.1°C as minimum temperature; and in the underside surface, average reduction of temperature of about 10.5°C as maximum and of about 4.5°C as minimum temperature.

b) During the winter, the temperature abatement due to the solar heat high reflectance paint corresponded to average reduction of temperature of about 11.4°C as maximum and of about 4.1°C as minimum temperature in the roof surface as well as of about 6.6°C as maximum and of about 3.5°C as minimum temperature in the underside surface.

1. Designing of solar heat high reflectance paint

Figure 1 shows the radiation energy distribution of sunlight and a black body. As can be seen from this figure, the sunlight is recorded an energy peak of about 0.5µm, while a black body at 50°C is recorded a peak at of about 9µm. Paint that is highly reflective in the sunlight radiation range while highly radiative in the black body radiation range is expected to counteract an increase in temperature in the painted object and to reduce the thermal load of the object.

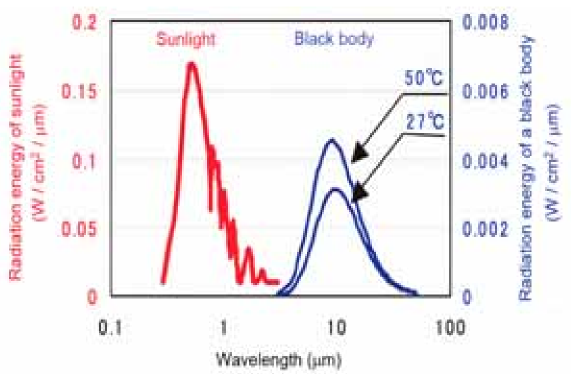

Figure 1 Radiation energy

2. Temperature abatement verification test at a roof of building in Tokyo

2.1 Outlines of experiment

Temperatures of the roof surface and underside surface were measured for two buildings of the same construction in Tokyo. The roof surface of one of them was painted by solar heat high reflectance paint and the other was not. Simultaneous with the temperature measurement at each spot, atmospheric temperature and amount of global solar radiation were measured and recorded.

2.2 Experimental results

Table 1 shows the average temperature and maximum amount of global solar radiation based on all data collected throughout the test period. The results indicate that the temperatures abatement of the roof surface and underside surface of the painted roof are lower than the non-painted roof. Comparison between the effect of painted roof and non-painted roof on the yielded temperature abatement as follow:

a) During the summer, in the roof surface, average reduction of temperature of about 16.9°C as maximum and of about 4.1°C as minimum; and in the underside surface, the average reduction of temperature of about 10.5°C as maximum and of about 4.5°C as minimum temperature.

b) During the winter, the abatement of temperature due to the high reflection paint corresponded to the average reduction of temperature of about 11.4°C as maximum in the roof surface and of about 4.1°C as minimum temperature as well as of about 6.6°C as maximum and of about 3.5°C as minimum temperature in the underside surface.

Table 1 Average temperatures and global solar radiation

Roof	Average temperature	Summer		Winter	
		Roof surface	Roof underside surface	Roof surface	Roof underside surface
Painted roof	Max. temp.	32.4°C	29.8°C	10.1°C	8.3°C
	Min. temp.	23.3°C	25.4°C	1.5°C	5.0°C
Non-painted roof	Max. temp.	49.3°C	40.3°C	21.5°C	14.9°C
	Min. temp.	27.4°C	29.9°C	5.6°C	8.5°C
Atmospheric temperature	Max. temp.	33.0°C		16.8°C	
	Min. temp.	25.2°C		1.9°C	
Max. amount of global solar radiation		858 W/m^2		479 W/m^2

Keywords: occupant behaviour, energy performance, indoor comfort, health, dwellings

Summary

Building activity, through the life span of a dwelling leads to environmental burden through material and energy consumption. Related research aims at accelerating energy performance focusing on building envelope and mechanical systems. However, strong indicators reveal that the precautions do not lead to the expected energy saving levels. Reasons for this could be problems about the building itself and occupant behaviour. This paper summarises the previous research about the relationship between occupant behaviour and energy performance, considering indoor comfort/health. First, actual behaviour of the occupant is briefly explained, then how actual behaviour relates to energy performance and indoor comfort/health is studied. Reviewed literature is categorised according to the factors related with occupant behaviour as; occupant characteristics [social, educational, economical] in household and individual levels and dwelling characteristics [site- climate, architectural layout, building envelope, mechanical systems and lighting & appliances]. Main findings of this study are: [1] most of the research about occupant characteristics and especially on education and economy aspects do not validate the proposed indicators with achieved saving levels, [2] and also in some of these studies periods of collecting data and validation about occupant characteristics are not well defined, [3] systematic studies are missing covering both occupant and dwelling related aspects, [4] previous research generally focus on energy consumption or indoor comfort/health. It should be emphasized that long term measurement covering both winter and summer behaviour in relation to energy performance and comfort, and its validation is needed.

1. Introduction

Human being shapes the physical environment around itself and in response; the physical environment that he deformed begins to change him. Currently, this mutual interaction has been leading to environmental depletion and energy resource decay in broad term and without hesitation the measures proposed for reducing energy consumption have to meet the demands for optimum liveable environment for the inhabitant. Nevertheless, in most cases, these two goals can not be achieved at the same time, this is either because of the defects in the building systems and components or resulting from the unexpected behaviour of the occupant. Aim of the paper is to develop an understanding of the relation between occupant behaviour, indoor comfort and energy performance in dwellings. Previous research conducted about the subject matter is analyzed in order to derive out the actual behaviour of an occupant, how it occurs, the consequences in terms of comfort, health and energy performance and to produce a framework for evaluation of the relationship.

Considered literature focuses on the relationship between occupant behaviour and energy performance or occupant behaviour and comfort/ health. Few studies make assessments of actual occupant behaviour from both energy performance and comfort/ health respects. This kind of research is mainly within the context of a specific dwelling type [single family dwellings-multifamily dwellings/apartments], condition of the dwelling [renovation/new built or old/new], the energy conservation approach ['energy efficient'/conventional] or from a project framework. Besides, when the occupant behaviour is considered, it is either a typical activity domain [heating, cooling, ventilation…] or an activity scenario [studying, eating, cooking….]. Reviewed literature is classified according to the parameters related to the occupant behaviour [Figure 1]. This selected literature is mostly preferred because of being conclusive parts of research projects, which could be important in terms of validation of data and they take homogenous measurement samples in terms of occupant size. Besides, more attention is drawn to the studies that analyse especially occupant behaviour both from energy performance and indoor comfort/health aspects.

In the literature reviewed, common method used is post occupancy evaluation. Data about actual behaviour of occupants are collected mainly through interviews, questionnaires and diaries; and in some of the cases through measurements like photography, micro switches and observation. Data about indoor air quality, thermal comfort and energy performance is collected also through field measurements and evaluated with simulation and/or statistical analysis.

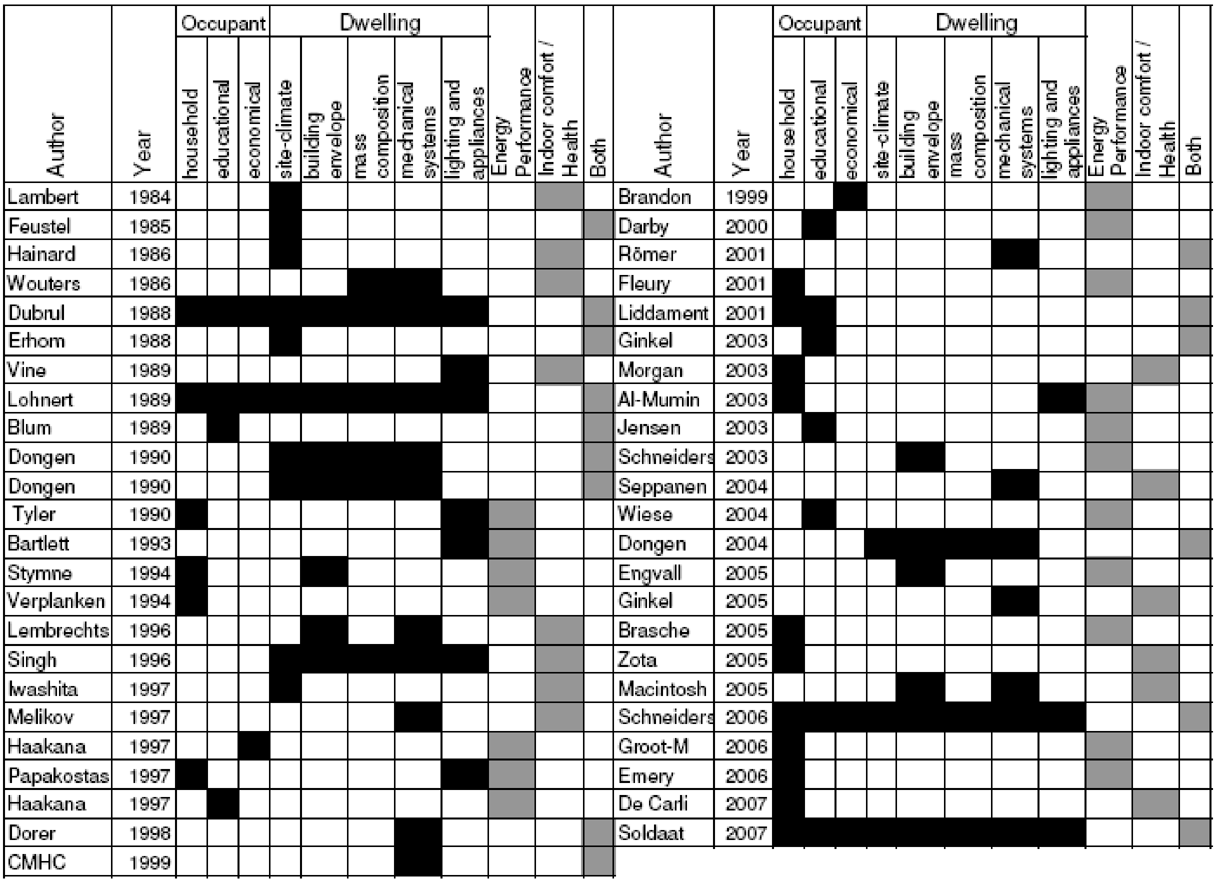

Figure 1 Overview of the studies according to the author, year and context.

2. Actual Behaviour of the Occupant

Planned behaviour is a consequence of behavioural intentions. These intentions result from attitudes, norms, and control perception. Underneath behaviour lie beliefs of behaviour, norm and control. Perception also influences behaviour but in separate twofold pathway [Armitage et al. 2003]. In Giddens's structuration theory, the analysis of environmental behaviour focuses principally on the behavioural or social practices in which human agents participate. Discursive and practical consciousness affects behaviour through lifestyle, rules and resources affect behaviour through provision systems [Spaarragaren et al. 2000].

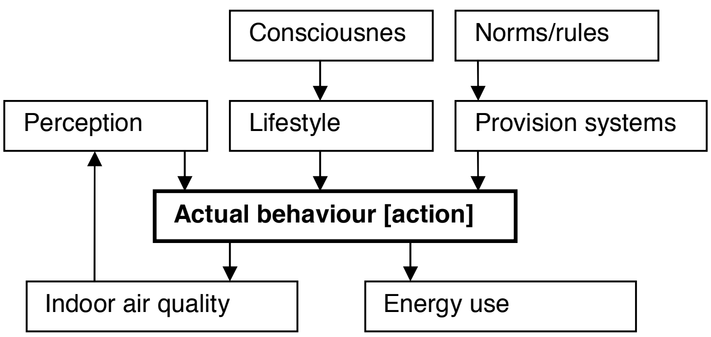

Figure 2 Frame of the actual occupant behaviour.

As actual behaviour influences indoor air quality and energy consumption in dwellings, existing or resulting indoor air quality influence behaviour through perception [Figure 2]. For example ventilation behaviour [Engvall et al. 2004] is strongly correlated with indoor air quality through perception. The occupant reacts depending on how he perceives fresh/ stuffy air, dry/humid air, cooking odours and other strong odours. At this point it should be emphasized that adaptation is involved in perception. Occupants adapt to the changing indoor air quality levels in every 15 minutes. Besides, adaptation raises the acceptability to indoor pollutants when the pollutant source is human behaviour like smoking, whereas building originated pollutants are less acceptable. Also cross adaptation is observed when among many sources of pollution, acceptability changes according to the concentration change of the main pollutant that the occupant is exposed [Gunnarsen et al. 1992].

3. Relation between Occupant Behaviour – Energy Performance and Comfort

Analyzing energy performance of a dwelling has building related and occupant behaviour related aspects. Occupant influences energy performance through its daily activities like studying, watching TV, washing up etc, through internal heat gain generated from metabolic rate [Tanimoto et al. 2008] and through reactions to the changes in the indoor environment. Since indoor air quality and indoor comfort level have health consequences, health could also be an indicator to evaluate indoor air quality and energy performance, consequently. The total energy consumption cannot be predicted closer than ±15-20% if the inhabitant's influence is unknown [Pettersen, 1994]. In literature, occupant behaviour in dwellings is analysed by specific daily activities, most of which are interrelated in terms of the output patterns such as heating and electricity use, cooling and ventilation etc. Relation between occupant behaviour, energy performance and comfort is bilateral: Either the occupant behaviour affects them and/or they affect occupant behaviour. This relation makes it obvious that the actual behaviour of the occupant must be analyzed, through how it occurs.

3.1 Occupant Characteristics

3.1.1 Household Characteristics [Social]

Size and composition of a household has an influence on occupant behaviour [Fleury et al. 2001; Liddament, 2001], and especially in terms of electricity consumption by household appliances and lighting [Papakostas et al. 1997; Al-Mumin et al. 2003; Tyler et al. 1990]. Occupation density together with poor ventilation, volume of the house and heating system has a significant impact on NO_2 concentration. Increase in NO_2 concentration may lead to health problems like asthma and allergen illnesses [Zota et al. 2005]. Considering occupant lifestyle, there are conflicting results in literature, some studies claim that it has strong effects in energy consumption and should be changed through education for energy conservation [Groot-Marcus et al. 2006], whereas some others show that differences in lifestyle do not have much effect on space heating energy behaviour [such as Emery et al. 2006]. Occupant age affects the time spent at home; the elder and the children are less outside [Brasche et al. 2005]. Habits are also major elements of behaviour, the stronger the habits are the weaker the influence of knowledge and attitude on behaviour [Verplanken et al. 1994]. For example, clothing habit is a means for the occupants of the dwelling to maintain their own energy balance with indoor climatic conditions, and the extent to which they rely on physiologic responses to maintain that energy balance determines the magnitude of their thermal discomfort and attendant dissatisfaction. Indoor thermal conditions influence body heat balance which leads to thermal discomfort feeling through physiological strain and this process results in behavioural thermoregulation [clothing] [Morgan et al. 2003]. In naturally ventilated buildings, clothing behaviour of the occupants is more related with outdoor temperature than in mechanically ventilated buildings [De Carli et al. 2007].

3.1.2 Educational Characteristics

Educational profile of the occupants has two perspectives, one is the education level of the occupant which may result in awareness about energy consumption and environment, second is motivation leading to awareness. Motivation could be through information and economic measures. In a study in Finland, first economic reasons provided the motivation for households to save energy: the occupants were eager to save energy by changing their lighting appliances, sealing windows, lowering room temperature and reducing hot water consumption. Households wished to get advice on use of electricity, space heating, ventilation and use of water. Half of the users began to turn down lights in the rooms not occupied, 29% reduced water use, 27% change clothing habits [Haakana et al. 1997]. In Denmark, eco accounts are used to provide information [Jensen, 2003] for tenants, after one year, heating energy reduced by 9% and electricity consumption by 22%. Product information about energy conservation also affects behaviour but relies on the actual willingness of the user to initiate or change specific behaviour patterns [Wiese et al. 2004]. Provided feedback and general information to the occupants about energy consumption, have strong influence on occupant behaviour. For example, when occupants do not know that ventilation demands are only met at the highest speed level of the exhaust fan, either the indoor air quality level or energy consumption level is not achieved due to the misuse of the system [Ginkel et al. 2003, Liddament, 2001]. Feedback should not be handled alone; factors such as the conditions of housing, personal contact with a trustworthy advisor when needed, and support from utilities and government which can provide the technical, training and social infrastructure are important to make learning and change possible [Darby, 2000]. Satisfaction of the occupant and their education about using the energy efficient features, good performance of a passive house, and about cleaning and maintenance requirements are important behavioural aspects. Lastly, occupant involvement in design stage is mostly crucial for achieving aimed energy performance levels [Blum et al. 1989].

3.1.3 Economical Characteristics

Economics treat attitudes, beliefs, values and the like as mere preferences and tastes are exogenous to economic models. Economic psychology provides psychological and financial influences in combined and contrasting means [Brandon et al. 1999]. Psychological influence would be observed in owner occupied houses where energy consumption level is less [Schneiders et al. 2006]. Financial influence is to supply energy consumption feedback to users [Haakana et al. 1997]. Design Context Booklet, the report of Task VIII conducted in IEA-SHC program, states the economical determinants of user behaviour as individual; ownership, income level, savings, employment situation or general; subsidy and advancement, tax reduction, energy, building and appliances costs [Lohnert et al. 1989].

3.2 Building Characteristics

In this study, the components of a dwelling that have impact on occupant behaviour directly or indirectly, are categorized as site & climate, architectural layout, building envelope, mechanical system and lighting and appliances.

3.2.1 Site and Climate

Outdoor air temperature, horizontal global irradiance, wind velocity and wind direction have an impact on user behaviour in terms window opening [Erhorn, 1988; Feustel et al. 1985]. The weather plays a main role in opening or closing the window. Users tend to open windows less depending at day/night and temperature below 12 ℃ and when the wind velocity is greater t han 3 m/s whereas horizontal global irradiance has a minor impact on user behaviour in correlation with outdoor temperature. The use of windows is linearly correlated with the outside temperature for temperatures between -10 ℃ and 25 ℃ and inversely correl ated with wind velocities. When it is raining or snowing, windows are less often used [Hainard et al. 1986]. In mild climates, residents' behaviour during the summer season and whether the residents opened windows/doors or operated air conditioners is very different [Iwashita et al. 1997]. Next to the weather characteristics, the quality of the outdoor environment; air pollution [odour] and noise [Van Dongen et al. 1990] are important factors. People shut the windows when the outside noise level is between 60 and 65 dB[A] and take more serious precautions like sound insulation, changing spatial organization, when it is more noisy than 65 dB[A] [Lambert et al. 1984].

3.2.2 Architectural Layout

Occupants use natural ventilation less when volumes of rooms are smaller; windows are less oriented to sun and more oriented to the prevailing wind direction [Van Dongen, 1990]. Windows that are fixed on the bottom of the frame and that open inwards are more often open than other types of windows [Wouters et al. 1986]. Upper wings of windows are open twice more often than the lower ones that are opening outwards. If the window in open stand can not be fixed at several positions through a grip, it is possible that the window will never be used [Van Dongen, 2004]. On the corridor side of the apartments the windows or vent-lights were opened maximal half an hour on average and on the balcony side maximal 1.4 hour when nobody was at home. Fear for burglary and for escaping of pets also plays a role here [Van Dongen, 1990].

3.2.3 Building Envelope

Basic natural ventilation is through the cracks in building envelope [Van Dongen, 1990]. Air tightness of the wall and material choice for fill, insulation and cladding are also influencing. Thus, construction quality and maintenance are crucial. Reducing the air tightness of the envelope may cause an impaired air quality perception and may lead to health related consequences [Stymne et al. 1994; Singh, 1996; Engvall et al. 2005]. This is a proof of the necessity for further studies to figure out occupant reaction to the change in indoor air quality conditions. However, a profound review about airborne particles in the indoor environment reveals that existing scientific evidence does not necessarily prove that indoor air quality has direct health consequences [Schneiders et al. 2003].

3.2.4 Mechanical Systems

The type of heating system plays a role. In dwellings with central heating windows are less often open than in other dwellings [Wouters et al. 1986]. Closely related with heating system, ventilation system is important both in terms of occupant use and indoor air quality effects. Ventilation rate should be as low as possible for energy conservation, on the other hand to sustain indoor air quality, it should be at a certain level which may conflict with energy conservation aim and this relation is strongly open to the occupant behaviour impact [Dubrul, 1988; Soldaat et al., 2007]. Behaviour is related with ventilation system type: Natural and/or Mechanical ventilation use differ together with household size, house's age, and its being single or multifamily [Stymne et al. 1994]. When household includes elderly and children, mechanical ventilation is less used. Grills are preferred more than windows for natural ventilation [Van Dongen, 1990]. However, mentioning that air temperature fluctuations may cause feeling of draught in rooms, largest temperature fluctuations appear in mechanical exhaust ventilation system and the minor changes are measured with balanced ventilation systems [Melikov et al., 1997].

Thermal comfort and health aspects are means for ventilation behaviour: Higher ventilation reduces the prevalence of air borne infectious diseases. Ventilation rates below 10 Ls^{-1} per person are associated with a significantly higher prevalence of one or more health or perceived air quality outcomes. Increases in ventilation rates above 10 Ls^{-1} per person, up to approximately 20 Ls^{-1} per person, are associated with a significant decrease in the prevalence of Sick Building Syndrome [SBS] symptoms or with improvements in perceived air quality [Wouters et al. 1986]. Poor ventilation in longer periods would lead to fungi growth in bathrooms, but there is no clear relationship stated between ventilation and dust mite allergies [Ginkel et al. 2003]. They further state that number showers, together with age of the ventilation system have a direct relationship with the mould growth in bathrooms [Ginkel et al. 2005]. Besides, Seppanen puts forward respiratory allergies and asthma as health consequences of poor ventilation system use. On average, the prevalence of SBS symptoms is higher in mechanically ventilated buildings than in naturally ventilated buildings. Better hygiene, commissioning, operation and maintenance of air handling systems may be particularly important for reducing the negative effects of Heating Ventilation and Air conditioning [HVAC] systems [Seppanen et al. 2004]. Römer indicates that together with the introduction of balanced ventilation to houses, as energy consumption decreased around 15-20%, health risk is elevated mainly due to the change in tap water temperature, relative humidity, dust and air exchange rate [Römer, 2001]. Lembrechts et al. [1996] point out that seldom use of the mechanical ventilation system in full capacity, result in radon increase in Dutch dwellings, together with the decrease in air tightness levels and building material use change. Dirty filters/heat recovery cores/ Heat Recovery Ventilation [HRV] cabinets, substandard ventilation and unbalanced supply and exhaust air flows create health problems in dwellings [CMHC, 1999].

Satisfaction and comfort level with respect to heating and ventilation system performance: If the air inlets do not fit with the esthetical preferences of occupants they may remove them. Noise from ventilation system plays a main role here [Van Dongen, 2004]. In a field study about HRV use, it is found out that; cooking, noise from outside, smoking, shower and cooling are mentioned behaviours not to use HRV so additional exhaust ventilation is required. Occupants have complaints about perceived air quality and dust around filters, nevertheless feel control over the HRV system [Macintosh et al. 2005] and satisfied. Most failures leading to discomfort and dissatisfaction are observed owing to bad manufacturing of components, improper selection and installations of components, bad system flow balancing, and inadequate commissioning, too high sound emission at supply and extract terminals and sound transmission, excessive window airing by occupants and general poor acceptability [Dorer et al. 1998].

3.2.5 Lighting and Appliances

Lighting behaviour in a dwelling depends on the type and characteristics of the dwelling, the type and duration of activities performed there, and the lighting habits of the members. Variations and behavioural factors about lighting and appliances among households can also be explained, in part, by the demographic composition of an area or country and its institutional setting [Bartlett, 1993]. Several studies are conducted to measure how different household appliances are used [Papakostas et al. 1997; Al-Mumin et al. 2003; Tyler et al. 1990] and it could be stated that use of household appliances is also directly and mostly related with culture and habits. Appliance control behaviour is clearly different according to occupant characteristics and thermal comfort level [Vine et al. 1989].

4. Discussion

Occupant behaviour is influenced by [1] occupant's educational and economical background and household properties, [2] dwelling's outdoor environment and climate characteristics, its architectural layout and envelope, mechanical systems installed, and lighting and appliances used in the house. Behaviour is either a reflection of the occupant's inherited and developed personal characteristics or a reaction to the perception of the indoor comfort conditions created. Dwelling's architectural characteristics, service systems and outdoor environment affect occupant behaviour in terms of their contribution to the indoor comfort conditions. Therefore in order to understand the occupant behaviour with respect to indoor comfort and energy performance of the house, these relations must be analysed in correlation [Figure 3]. However, in the literature revised, research that covers these aspects in correlation is lacking but they rather approach from one aspect. Besides, since perception is part of the behaviour and adaptation to indoor air quality has a considerable impact on perception; it should be studied to what extend adaptation affects perception.

Secondly, most of the research covering occupant characteristics aspects, and especially focusing on education and economy do not validate the proposed indicators with achieved saving levels and periods of collecting data and validation about occupant characteristics are not well defined. This reduces the reliability of these research results.

In literature, systematic studies are missing covering both occupant and dwelling related aspects, research generally focus on energy consumption or indoor comfort/health. It should be emphasized that long term measurement covering both winter and summer behaviour in relation to energy performance and comfort, and its validation is needed. Occupant and building characteristics that are covered in literature are categorised in Table 1. Further research should cover the interrelation of actual behaviour - energy performance and indoor comfort through the framework [Figure 3] and characteristics list [Table 1] proposed in this study. Moreover, it is important to realize if behaviour should be modified or the technology should be adapted to achieve reduced energy consumption levels and how.

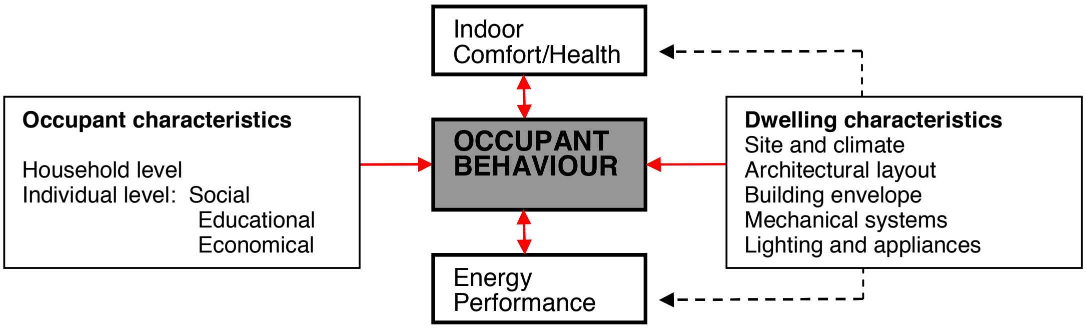

Figure 3 Occupant Behaviour Evaluation Framework.

Table 3 Characteristics affecting occupant behaviour [related with indoor comfort/health - energy performance]

Occupant Characteristics				Building Characteristics				
House-hold level	Individual Level			Site-Climate	Architectural Layout	Building Envelope	Mechanical systems	Lighting & appliances
	Social	Educational	Economical					
o Size o Compositon o Age o Presence	o Culture o Lifestyle o Hobbies o Habits	o Awareness o Knowledge o Realization o Attitude o Motivation o Sensitivity	o Ownership o Energy use pattern o Income level	o Weather: global irradiance wind direction, wind speed o Site: noise, odour	o Floor heights [volume] o Special design elements	o Air tightness o Material use o Insulation level o Window design	o Space heating system o Water heating system o Ventilation system o Appliances	o Lighting o Household appliances

Lastly practical information should be produced for actors in building process about design of systems and equipments to better adapt the systems to user behaviour. In addition to this practical guidance, more information for legislation especially about air tightness and ventilation rate standards is needed.

Keywords: energy performance, lighting, automation system, visual comfort

Summary

In this paper, we present the final results of a comparison of lighting energy performance in two groups of spaces, namely lecture rooms in an academic building (Faculty of Engineering, University of Trento). The study was carried out at the "CUnEdI: Centro Universitario Edifici Intelligenti" of the University of Trento. The first group of three lecture rooms is operated in a conventional manner: luminaries are switched on and off manually by the users. In the second group (spatially similar lecture rooms in the same floor/building and with the same orientation) different automated control regimes were implemented and monitored over a whole academic year. In all 6 lecture rooms (with both conventional and automated operation regimes) occupancy sensors and power consumption meters were installed to monitor these parameters separately for each lecture room.

In the referred research a new design methodology has been developed and verified, that relates energy saving and visual comfort. The analysis of the energy saving potential of automated lighting scenarios, carried out using specific standardization techniques, have been monitored in real use conditions and not in controlled laboratory environment, in order to prove the automation systems efficiency in operating time.

1. Introduction

Climate changes are one of the main challenges that our society will face in the incoming years. In this context the built environment plays an important role: the residential and commercial sectors account for more than 40% of end energy consumption in the European Community and are thus responsible for an important part of carbon dioxide emissions systems [UNEP, 2007]. Lighting has a substantial impact on the environment [ECCP, 2001]: the commercial sector account more than 25% of energy consumption in EU for the lighting sector.

Considerable savings could be achieved even by application of intelligent control technologies in existing buildings, with acceptable economical parameters [Zalesak M., 2006]. New European Regulations refer specifically to the use of occupancy and light sensors to control the artificial light and to improve the systems efficiency [prEN 15193, 2006].

Design software tools are intended to help designers with the qualitative and quantitative elements of daylighting design through features that commonly include: visualization of the luminous environment of a given daylighting design, prediction of daylight factors in a space lit by diffuse daylight, control of the penetration of the sun's rays and visualization of the dynamic behavior of sunlight [IEA, 2000].

In the last years, multiple studies have been carried out internationally to collect data on building users' interactions with building control systems and devices, in order to develop a stochastic model for predicting lighting energy consumption [Reinhart, 2004]. ADELINE has been used for the physically based computer simulation/visualization techniques developed for the specific case study analyzed in this research.

The analysis of the state of the art synthetically reported in this paragraph, about sustainability and voluntary protocols, innovation in field of energy saving, lighting automation systems and visual comfort, underlines the importance of lighting system effectiveness.

Based on the literature overview, it is becoming increasingly important to establish a realistic baseline of the actual lighting energy consumption in buildings for the different scenarios nowadays used (both manually and automatically operated), which incorporates occupant behavior. The features of lighting simulation tools currently available emphasize the importance of defining suitable reference cases for benchmarking the performance of automated lighting control.

At the same time, there is indeed need for a comprehensive understanding of the occupants' needs and preferences in daylit spaces that relates level and characteristics of the light and users' performance, even because recent developments in automated control systems and novel materials and technologies require new investigative directions [Brennan, 2007].

2. Method

In the research referred in this paper innovative design tools for lighting systems have been elaborated, specifically:

- the methodological approach for the energy efficiency evaluation (design methodology, software tool outputs evaluation methodology, data analysis method);
- the application for technological system choice of multiple criteria decision analysis;
- the development of specific model sheets to monitor and analyze visual comfort conditions.

These design tools have been implemented in a specific case study during the academic year 2006/2007: the Faculty of Engineering of Trento. The cross layout of this building is characterized by two parallel wings, both with the same south exposure. The referred lecture halls (manually and automatically operated) are symmetrical and have the same shape (Fig.1). This configuration allows their simultaneous comparison.

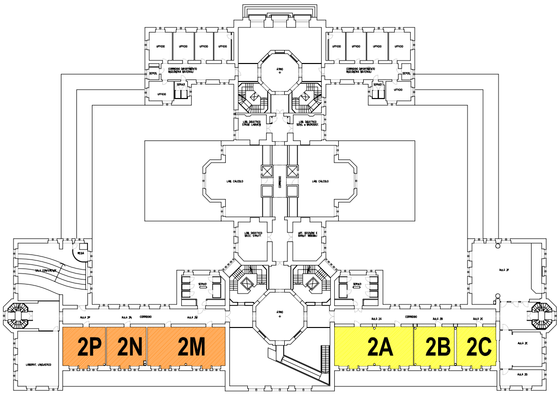

Figure 1 Building layout (east wing: traditional classrooms; west wing: automated classrooms)

The goals of the complete data analysis, concerning a whole year of data monitoring, are:

- to calculate the different percentage of the energy saving potential for various applications (Scenarios) of building automation systems for lighting control;

- to understand the users behavior in lecture halls with the traditional lighting system and to quantify the amount of energy loss for an improper use of the artificial light;

- to deeply analyze how the automated systems work, in order to improve the scenarios efficiency.

The comparison objects in this research are the performances, in terms of energy efficiency and visual comfort maintained, of lighting system operating manually and lighting system operating by automation system described by Scenarios.

The manual light system is assumed in this research as operated by switching on/off; the Scenarios are defined as follow:

Scenario 1 (2P): occupancy detection and minimum illuminance level control, as primary condition to switch on the lighting system (if $E_m > E_{threshold}$ then switch off);

Scenario 2 (2N): occupancy detection and minimum illuminance level control as primary condition to switch on the lighting system (if $E_m > E_{threshold}$ then switch off); dimming regulation of the artificial light as function of the natural light level detected in discrete points, as second automation level;

Scenario 3 (2M): occupancy detection by zones (the space has to be divided into discrete parts, each one detected by a presence sensor) and minimum illuminance level control as primary condition to switch on the lighting system (if $E_m > E_{threshold}$ then switch off); dimming regulation of the artificial light in more rows of dimming channels in order to approximate an ideal continuous dimming in the space, as second automation level; use of different and more efficient lighting sources.

Scenario 1in summer calculation (2P): scenario 1 and dimming regulation of the artificial light in 3 rows of dimming channels. That means that the light system is regulated and dimmed through 3 light detectors and 3 dimming channel in order to have a minimum illuminance.

2.1 Methodological approach development and application

The method of the case study evaluation has been divided in four phases [Frattari A., Albatici R., Chiogna M., 2007]:

- Analytical phase: monitoring and analysis of existing situation
- Programmatic phase: definition of project objectives and system requirements
- Propositional phase: system solution
- Evaluation phase: evaluation and verification

The developed methodology focuses on the following issues:

1. simulation, calculation and discussion of the ADELINE software tool outputs and comparison with the monitored data, developed in collaboration with the Fraunhofer Insitute of Stuttgard;

2. elaboration and statistical analysis of the users behaviour, calculated with the Technical University of Wien, in order to introduce improvements in the modelling process;

3. evaluation of the visual comfort maintained and perceived by the users, in relation with the illumination levels, in order to verify if the proposed model allows the visual comfort users requirements, in collaboration with the Ophthalmology ward of S. Chiara hospital in Trento.

2.2 Multiple criteria decision analysis: application for technological system choice

Many different criteria should be considered, in order to design a lighting automation system in compliance with environmental sustainability principles (efficient use of electrical light and control of the user's visual comfort) and at the same time with feasibility principles (use simplicity, economic convenience in installation and maintenance phase, esthetical characteristics, ect.).

For this purpose a specific design tool has been developed, based on multiple criteria decision analysis. The decision maker (DM) for the developed case study is the lighting designer/system integrator.

The specific approach developed in this research can be described as MADM, because it includes a unique object: the definition of the best automation devices for the implementation of an energy saving oriented lighting system and for the development of the system functionality measurement, monitoring and analysis. The system components have been defined in relation to a finite number of alternative solutions.

The definition of formal value structure has been developed, formally in form of criteria-tree.

The meta-criteria of the analyzed decision problem are reported in Fig.2 and, in order to specify and qualify each meta-criterion, the correspondent criteria have been definite and ordered in an importance growing scale.

Using the ordinal ranking weighting system, an evaluation scores has been defined. Moreover a graphical sheet has been developed, that can be filled simply by the system integrator and that calculates directly the score in tenth of the device tested. The calculation output includes an evaluation table as well, that is not only useful to get an overview of the problem but is also used to recover how the data are measured.

2.3 A model sheet to monitor and analyze visual comfort

The goals of the visual comfort subjective test experimented are:
- to check, if present, the uncorrected refractive errors of the students, for different contrast conditions;
- to define the critical detail for the student in a typical lesson condition, for defined boundary conditions;
- to compare the veiling luminance level perceived and the literature discomfort value;
- to evaluate the visual discomfort indexes of the students;
- to analyze the visibility, as calculated and perceived value, for defined boundary conditions.

The sheet is divided into the following 5 sections.

2.3.1 Boundary condition definition
The boundary conditions of the evaluated situation have been checked and monitored, as primary factors affecting the visual test results. For this aim, it was necessary to use a luxmeter to measure the inside illumination level, a weather station to evaluate the outside illuminance conditions, and a questionnaire to describe the individual visual deficit.

2.3.2 Critical detail definition
It was necessary to define the critical detail in the classrooms monitored, considering the two room sites: the 2M is 12 m long; the 2N and 2P are 6 m long. For this reason, two different optometric boards have been prepared: one with the standard dimension to detect the visual acuity from a distance of 5m, one with a double dimension to detect the visual acuity from a distance of 10m.
These two measures represent the critical distance, from the last work desk of the classrooms to the black board. Two different contrast conditions have been examined: positive and negative contrast.

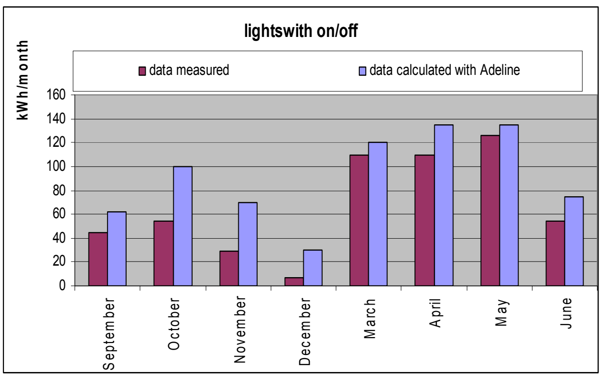
2.3.3 Visual discomfort evaluation
For different illuminance conditions the veiling luminance has been calculated [IEA, 2000]. The illuminance level has been measured in different significant points of the classrooms, describing the mean student's condition and as well the more critical position.
A model of the room has been adapted thanks to this data to the measured conditions and the contribution of each single glare source for different position has been calculated.
In the experimental test the glare perception has been evaluated. In particular the environmental conditions and the consequent glare feeling changing the shatter and blend position has been considered.

2.3.4 Visibility evaluation
Visual acuity and threshold contrast are two different aspects to define the visibility of a target. Visual acuity sets the minimum size for a target to be seen and threshold contrast sets the minimum luminance contrast that is required for a target of a given size to be seen. The contrast sensitivity function combines these two measures by showing the minimum contrast required for a target of different size to be seen. The visibility levels for different illuminance conditions have been calculated by the Adrian Model [Adrian, 1989 and 1993].

3. Results and discussion

3.1 Software tools outputs comparison

The Fig.3 shows the energy consumption comparison between data recorded for Scenario 1 (lightswitch on/off) and Scenario 2 (dimming) versus simulation outputs results. The Scenario 1 has been run only in winter semester. By the data analysis the energy saving for this scenario has been calculated the 40% of the respective energy consumption in traditional classrooms. On the basis of this result the summer semester energy consumption has been calculated.



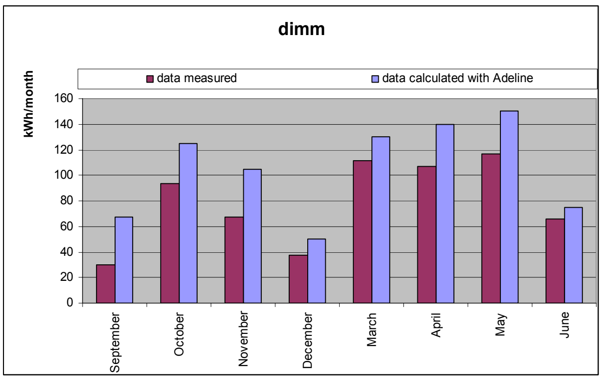


Figure 3 Energy saving calculated by Adeline and recorded for Scenario1 and 2.

These results can be improved setting the shading system variables. Indeed the ADELINE parameter file can be set as follow: none shading system fixed shading system, daylight-optimized shading system.

If it is supposed a shading coefficient equal to 0.7 for fixed shadow, the percentage difference between simulation results and real data follow sensibly as reported in Fig.4 The mean difference percentage changes:
- from 20% to 13% for the *Lightswitch On/Off Scenario*;
- from 22% to 15% for the from , *Continuous Dimming for Reference Point Scenario.*

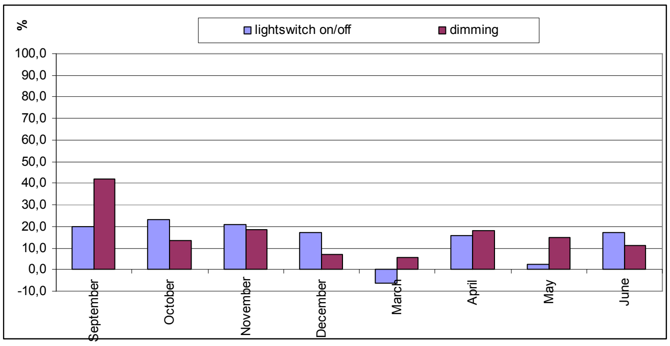

Figure 4 Energy saving percentage difference for Continuous Dimming for Reference Point and Lightswitch Adeline calculation: results for 0.7shading factor setting

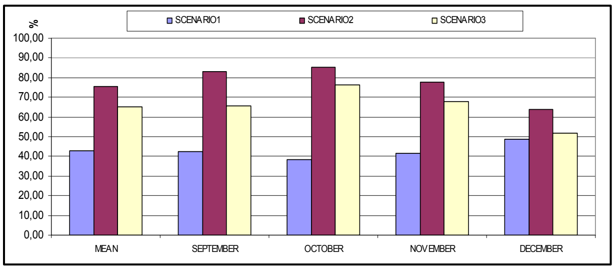
Manual On/Off Probability, in ADELINE implemented equations, is defined by Hunt and predicts the probability for use of artificial lighting in a manually operated on/off-switching control system. The method is based upon patterns of switching behaviour observed in field studies in England. Hunt found out that the probability of someone switching on the artificial lights in a space is correlated with the minimum daylight illuminance on the working plane. From the data set of the field study, an empirical algorithm was defined [Hunt, 1979].
Running Adeline for the saved electrical energy calculation, the results obtained do not describe correctly the real situation for the traditional classrooms. Indeed a difference between the 80% and the 160% in winter semester and between 30% and 50% in summer semester has been evaluated.
The inside illuminance simulated by Adeline is underestimated, because of the user's behaviour positioning the curtains. The difference could be explained by the different use of the room considered: the first one is an office, where a person works alone; the second one is a classroom where more persons should attend a lesson. It has been verified that during the lessons the windows can be partially covered (because they could have been forgotten close by the previous lesson, because the lesson could include partially projections, sometimes for any specific reason) so that it would be necessary to select a shading factor = 0,7 to simulate better the real situation [Frattari A., Chiogna M., De Boer J., 2007].

3.2 Data recording evaluation

Using standardisation techniques that consider differences in occupancy duration, as well as indoor and outdoor illuminance levels, it was possible isolate the quantitative difference between energy performance of conventional and automated control scenarios [Frattari A., Chiogna M., Mandavi A., 2007]. The monthly energy saving results, obtained using the named normalization factor, are reported in the Fig. 5.



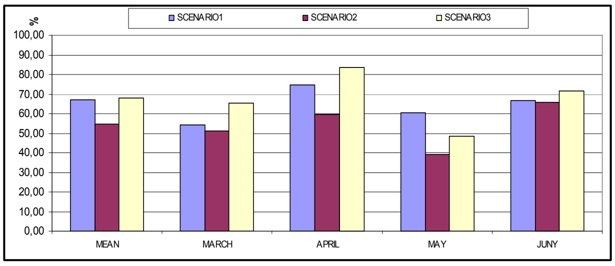


Figure 5 Energy saving of the three scenarios in the summer semester

Considering the whole observation period the energy consumption percentage is:
• 40%, if all three rows of luminaries are switched on when occupancy is detected and the room illuminance level (measured in the middle of the room) is below a predefined minimum level (Scenario 1- winter semester)
• 65%, if three rows of luminaries are switched on when occupancy is detected and dimmed (in two separately controlled circuits) so as to provide predefined minimum illuminance levels, measured at two points in the room, each corresponding to a circuit (Scenario 2). This lighting system has a better performance in winter than in the summer

• 65%, if the three rows of luminaries are switched on when occupancy is detected and dimmed (in three separately controlled circuits) so as to provide predefined minimum illuminance levels (measured in three points in the room, each corresponding to a circuit).
There are any significant different results if the lecture room is controlled in terms of two separate spatial zones (front and back) with dedicated occupancy sensors.
From October to December the energy saving percentage decreases, indeed it increases from March to April, in accordance with the outside illumination level. The disability and discomfort glare influence this trend, because an improper use of the shadow system often causes the unnecessary use of artificial light.
The minimum illuminance level value maintained in the traditional classrooms is low, especially in winter semester in the early morning and late in the afternoon.

Comparing winter and summer trends, the mean energy saving for Scenario 3 is above the 70% for the whole year. Checking the difference between Scenario 2 and 3 in summer semester, there is not any significant improvement of the system efficiency. This means that any effectiveness is detected in the lecture room controlled in terms of two separate spatial zones (front and back) with dedicated occupancy sensors.
The mean difference between winter and summer semester performance is mainly significant for the Scenario 2: indeed the energy saving percentage for this scenario deceases from the 75% in winter semester to the 55% in summer semester.

3.3 Visual comfort evaluation test

The detail definition in different illuminance levels has been defined for the fixed conditions expressed above, concerning the population age, the critical detail dimension and the background/target reflection factors. In particular 3 different illuminance settings have been evaluated:

a) inside illuminace between 200 lx and 300 lx, in order to describe the inside illuminance conditions in the traditional class room, when the artificial light is turned off in low outside illuminance conditions;

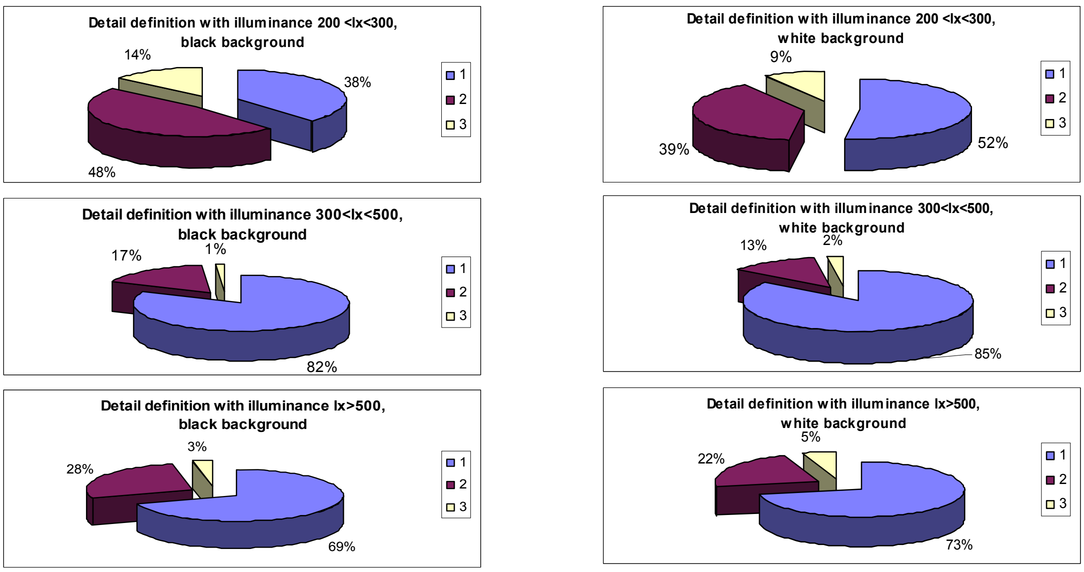
b) inside illuminance between 300 and 500 lx, in order to describe the inside illuminance level in compliance with the regulation UNI 10840 and UNI 12464-1;

c) inside illuminance >500 lx, in order to describe the inside illuminance level for possible glare conditions.

For the illuminance level (a) the percentage of the students that perceived a good detail definition is 38%, with black background, 52% with white background (Fig.6). That means that the percentage difference of the satisfied is 14%. Similar conditions have been measured for instance at 8.30, only with the natural light and the shatter completely open for the work places close to the inner wall. On the inside half part of work positions there is an illuminance level inferior to 200 lx.

For the illuminance level (b) the percentage of the students that perceived a good detail definition is 82%, with black background, 85% with white background (Fig.6). Similar conditions have been measured at 8.30, with artificial light operating and the shatter completely open or at 10.30, with only natural light and the shatter completely open. On the inside work positions there is an illuminance levels superior that 300lx.

For the illuminance level (c) the percentage of the students that perceived a good detail definition is 69%, with black background, 73% with white background. Similar conditions have been measured at 10.30, with artificial light operating and the shatter completely open.



1= it is possible to read easily | 2= it is possible to read with difficulty | 3= it is not possible to read

Figure 6 Detail definition for black and white background

Considering each different illuminance level described above and the correlated test results, it is possible to conclude that:
• black task on white background is the preferred contrast condition (negative contrast), especially for low illuminance level, often verified in the classrooms during the first and last classes;
• there is a lower difference in the detail definition between the inside illuminance condition of 300 lx instead of 500 lx than between positive and negative contrast;
• the main visual discomfort causes is the disability glare in the classrooms, perceived especially in the places closed to the windows. For this reason the shadow system is often not properly closed, so that the illuminance level could result lower than what expected.

So it is possible to define the following design guidelines for classrooms: to introduce a proper shadow system, in order to control the disability and veiling glare and at the same time in order to use the natural light contribution and to replace the old blackboard with the white, that permits a higher visibility level in different illuminance condition.

5. Conclusion

The research outputs have the following main implications.

1. Practical/technical implication: the definition of new automation lighting scenarios and their potentialities for the specific case study analyzed.
The research results demonstrate that the use of automated systems for the artificial light control can yield considerable energy savings, roughly between 40% and 60% depending on the complexity of the implemented system and of the parameters controlled, in the observed classrooms during the academic year 2005/2006.
The automated control system of the experiment could be further improved by incorporating shading control functionality. In fact, the improper use of the shading system can negatively influence the automation system efficiency and the daylight utilization.

2. Theoretic/cognitive implication: the new functions that it is possible to implement control-oriented user behavior software tools, in order to calculate energy consumption estimations more realistic.
Several studies have been and still are developed internationally to collect data on building users' interactions with building control systems and devices. Such data can bring about a better understanding of control-oriented user behavior in buildings and thus support the development of corresponding behavioral models for integration in building performance simulation applications.
The monitored data analysis has pointed out that the manual on/off probability used by Adeline doesn't correspond to the real condition in the observed lecture halls: specifically with an inside illuminance level higher than 500 lux it is still possible to have the light turn on (probability equal to 40%).
The obtained information would support the assessment of energy saving potential due to consideration of occupancy and behavioral patterns specifically in university buildings.

3. Comfort and efficiency evaluation: the relation between visual comfort perceived and the lighting system operational standard required.
Improving the energy-efficiency of lighting systems should include better use of daylight, but it will require the development of control systems that result in luminous conditions and that are suitable to occupants. Such the section 1.5 shows, what control system features would be most acceptable is not yet know, nor what range of luminous conditions the system should permit. Moreover the evaluation of visual comfort and visual ergonomic has been related mainly with the office/working places especially in reference to the use of VDT.
The analysis carried out in this research would include another application field for these concepts: the educational building, specifically the lecture halls of university building.
By the literature analysis, it is important to evaluate the correlation between productivity and satisfaction of the users on one hand and the efficiency of the lighting system on the other.

The monitoring data results could support the effective and proactive operation of building service systems for indoor environmental control. During the operation period of the automated systems, the following considerations have been pointed to a useful operation mode:
- the luminaries efficiency could be wiped up by the improper use of the blind system
- the occupancy detection in different spatial zones could bring any contribution for the energy saving, if the student are spread in classrooms even if they are a scan number in comparison with the available workplaces
- the use of the dimming regulation in classroom, where power point show has been used, could improve the students performance; it is indeed possible to maintain a balanced illuminance level that could allow simultaneously the slides vision and the writing action

In conclusion, the use of automation system guarantees a more efficient use of the artificial light and a higher visual comfort level: in fact it has been recorded that the minimum illuminance level value maintained in the traditional classrooms is low, especially in winter semester in the early morning and late in the afternoon, while on the contrary it is always guarantee in the automated classrooms.
Moreover the energy saving percentage is mainly related with the outside illuminance level; even if the disability and discomfort glare influence this trend (an improper use of the shadow system often causes the unnecessary use of artificial light).

The referred research evidences some significant results in order to better understand the effectiveness application of automated lighting systems.

Moreover, during the case study development, the following weak points have been pointed out:
- the lack of blind position data, because specific sensors were not installed in the rooms monitored
- the lack of weather data format file required by the simulation software and moreover the absence of complete weather databank for a significant monitoring period for the case study location
- the influence of the orography location (presence and dimension of the mountains) is not correctly modeled by the software simulation
- the improper use of the automation system by the users, during the first operating period, because they don't have enough familiarity with the new lighting system operation mode.

Finally, the following future steps could be developed, also in order to improve the limitations indicated above:
- the general patterns definition of user control behavior as a function of environmental parameters (indoor and outdoor), in order to develop proved models than can implement the reliability of computational building performance simulation application;
- the application of the new design tools in different building typologies: the methodological approach and the scientific rigor defined in this research could be a general praxis to be used in other case studies.

RESTORATIVE SUSTAINABILITY, LEAN CITIES & LOW CARB MATERIALS

David Baggs B. Arch, FRAIA, ABSA, Green Star AP, MRoySocAS

Chartered Architect, Technical Director, ecospecifier.org, Brisbane, Queensland, Australia, david.baggs@ecospecifier.org

Keywords: Greenhouse impacts, 'net positive' initiatives, cradle-to-cradle, restorative sustainability, green roofs, eco-balanced cities.

Summary

The current focus on energy supply sources in relation to the greenhouse impacts of current cities is only the tip of the iceberg in mitigating the societal impacts of climate change and resource utilisation. Just as we count carbohydrates to lose weight, our over-bloated cities and individual lifestyles need to go on a different kind of 'low carb' diet. Instead of counting carbohydrates, we need to count carbon outputs.

While this might smack of a single focus on energy once more, we need to realise that consumption *per se* is a major factor in itself. Just as we talk about the need for balanced lifestyles, we need to re-double and quadruple our focus on creating and utilising ecobalanced products, materials and technologies. This involves not just energy and resource use but the whole process of how we create and re-create the built environment.

This paper looks at what it will take to make ecobalanced cities and ecobalanced products that are engineered with multiple life-cycles considered before sale and how they can be re-use enabled by information flow into design, construction and higher levels of activity in physical re-sculpting at end of use. The Concept of Restorative Sustainability is presented and case study solutions provided.

1. Introduction

As 'Developed' nations', our cities, lifestyles and attitudes are the drivers of the biggest challenge humankind has ever faced and it is entirely of our own doing. There is now a real need to look beyond the superficial sound bites and the politically driven mantra that climate change is largely due to the obvious energy consumption of electricity and transport. The recent publication 'Climate Code Red' puts a very strong case for a 'climate emergency' response similar to the 'war footing response of economies' in times of war. Our response to climate change focussing on operational energy consumption has to date been superficial and slow footed.

Digging deeper we see that while the energy consumption of electricity and transport in homes and businesses is obviously a major issue there is significant carbon other resources embodied in the actual buildings, infrastructure and lifestyles as well. There are also more fundamental drivers underlying this energy consumption that are not being addressed. The 'great unsaid' in the debate to date is consumption in general and our growth economic models that recognise all economic activity as 'positive' (even if it is rebuilding from natural disasters or cleaning up after toxic spills that have devastating environmental consequences) and still more fundamentally, population growth itself.

"The economy is a wholly owned subsidiary of the environment, not the reverse."

Herman Daly, The ex Chief Economist for the World Bank, Quoted in 'The Age' May 4 2007

While it takes massive amounts of energy to run cities, it also takes vast amounts of energy to build cities, resource, feed, clean, maintain, demolish and renew them. Our commitment to buying the 'latest and greatest', means there is a need for us to change our behaviour about what we design, construct or buy, how we use, maintain and even dispose of all personal and societal 'acquisitions'.

To date, when considering how we might reduce impacts, we have, importantly tended to focus on reducing future impacts by the now common ‘3Rs’ catch phrase of actions, ‘Reduce, Re-use, Recycle’ and a range of variants promoted by such pertinent books as Lovins’ et al in ‘Factor Four – Doing More with Less’, William McDonough and Michael Braungart’s ‘Cradle-to-Cradle’, Paul Hawkins’ Natural Capitalism’ and Janine Benyus’ ‘Biomimicry’. Focussing on how we reduce past impacts has to an extent been left in the margins and to nature. It has been assumed that ‘if we reduce our impacts, nature can look after herself and will recover in time’. While the ‘Reductive Sustainability’ most discussed in the above works have a critically important role in promoting sustainability up to a point, how can we create a net positive impact to redress the past if we only ever reduce a future negative impact?

Along with all the necessary strategies dealt with in the above works, there is a need for an additional ‘enhancing nature’ focus. A focus on how we can begin to pro-actively support nature where possible, to create initiatives that have a ‘net positive’ impact that ‘put back’ more than they ‘take out’ of our ‘Natural Capital’. These are initiatives that can be described as ‘Restorative Sustainability’. This paper looks at the role of cities in our un-sustainability and explores the full spectrum of strategies and solutions as to how cities might become a pathway towards a ‘Low Carb’ future and how, using carbon as a proxy, we can move towards a more sustainable future with cities as part of a ‘5Rs’ solution.

2. The Inconvenient Truth

This paper will firstly analyse the major issues and actions within cities generating impacts that are accelerating our unsustainable demands on our Natural Capital, then look at the important ‘Reductive Sustainability’ actions that can be implemented to reduce future impacts. It will then investigate a definition of what makes something ‘restorative’ then present some examples of ‘Restorative Sustainability’ initiative and how cities can be used as part of the solution.

2.1 The Issues

When we consider the impacts of cities and the societies that live in them, it is useful to understand where the impacts are being generated and more importantly, where the potential savings are. Most studies, such as the Vatenfall study cited below when reviewing these impacts, only review recurrent operational impacts:

> *The buildings sector generates 8.2 GtCO_2 or 21% of total global CO_{2e} emission; 8% through emissions from primary fuel types (coal, gas, oil), 13% generated from power production to meet electricity demand from residential and commercial buildings.. (Vattenfall 2007)*

Furthermore, seen from figure 1 below, the growth in this sector has been astronomical over the last 50 or so years.

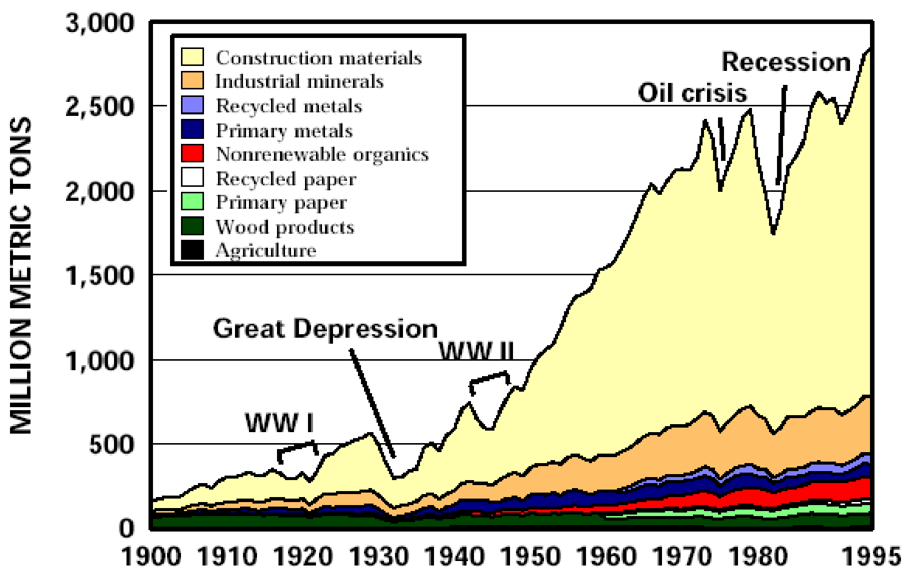

Figure 1 The growth in US materials consumption by sector 1900-1995 (Matos & Wagner, 1998)

A significant amount of embodied energy is being overlooked in the macro studies of potential CO_{2e} savings given that building and construction accounts for 40 percent of global use annually. (Roodman & Lenssen 1995)

When we look at the relevant proportions of operational vs. embodied energy in the residential sector, as exemplified by the analysis of a typical household (Treloar et al, 2000), and a 40 year analysis of 40,000m2 office building (Treloar et al, 1999), the majority of energy is consumed in operational energy. However, we also see a significant proportion of overall energy resulting from embodied energy, not just of the buildings themselves but of also of recurring consumption as part of the overall 'lifestyles' (over 50%) of occupants and commercial fitout churn.

2.3 Heat Islands: The Urban Negative Feedback Loop

A major negative global warming 'feedback loop' has emerged in the way that our cities have now been shown to heat up and retain heat compared to surrounding less densely settled surrounding areas. This 'urban heat island' effect has been identified around the world and most recently in Melbourne Australia. Melbourne has been shown to be on average 3.5-4.5 ^{o}C hotter during summer evenings and up to 10.0^{o}C hotter on still summer evenings. (Morris 2000)

3. How we can 'ecobalance' our cities

In beginning to look at how we can ecobalance or cities much has already been done to analyse what benefits can easily be found. Of the identified potential annual savings of 26.7 Gigatonnes of carbon emissions costing under €40/tonne, nearly 14% are in building alone and the influence of the buildings, materials, infrastructure and consumption can be seen throughout the rest (McKinsey 2007). A total of 3.7 $GtCO_2e$ of low-cost abatement options have been identified- 3.0 $GtCO_2e$ in the residential sector and 1.3 $GtCO_2e$ in the commercial sector which would hold emissions growth to 26% for the Construction sector by 2030. Heating and ventilation including building envelope improvements, water heating and air conditioning provide the largest potential beneifts for both residential and commercial buildings, contributing a total of 2.3 GtCO2e (62%). Lighting is potential contributor mainly in residential building, potentially leading to 0.3 GtCO2e emission reduction. Improving other appliances and reducing standby losses yields another 1.1 GtCO2of abatement (Vattenfall 2007).

3.1 The Role of Materials & Design: 'Reductive Sustainability' as Part of the Solution

If we are to reduce CO2 by 60% by 2050 to stop global warming rising beyond 1oC to the 2-2.5oC that current emissions rates would generate, (Raupach 2007) further economical CO2 savings need to identified. The role of materials has been highlighted in the above data and provides ready evidence that materials have a key role to play. The key next question is now – how can cities and their materials's potential as part of the solution be realised given they can provide benefits with little, or often no cost, sometimes even with cost savings. These focus on reducing impacts by design, cleaner production strategies, materials selection and evaluation strategies. They can all be categorised as falling within the concept described by this author as 'Reductive Sustainability' as the following strategies illustrate:

3.1.1 Materials choice
There is much to be gained from identifying the 'best of class' within any materials categories. A review of comparative embodied energy data of different residential building assesmblages by Walker Morison et al (2007) has shown there can be up to nearly a 1900% difference between the best and worst performers in some categories.

3.1.2 Industrial Ecology & 'Cradle to Cradle'
Since the early nineties, various authors including Frosch (1992), Allenby (1992) and Ayres (1994) have introduced the concept of industrial ecology where technical cycles are designed to mimic natural organic cycles in nature where there is no waste at all. McDonough and Baungart (2002) coined the term 'Cradle to Cradle' to describe how materials, products and technologies (and cities) need to be re-designed to ensure that all elements or sub-components of any product on deconstruction, to fit within one (or both) of these cyclic production/consumption/remanufacture/consumption systems. To ensure this approach works products need to be designed for disassembly.

3.1.3 Design For Disassembly (DfD)
Manufacturers and all sectors of the built environment need to design, manufacturer and incorporate materials, products and technology in cities (and the built environment generally) in ways that facilitate DfD, or

at the very least do not hinder it. The key criteria for designers relating to DfD, according to Walker Morison (2007) is to 'Start by designing with the end of life in mind'.

3.1.4 Design For Climate (DfC)
Also known as 'passive solar' design, DfC means designing buildings and incorporating materials in such as way as to maximise the use of environmental heat sinks and sources in the heating and cooling of the internal spaces for thermal comfort and daylighting. DfC is the most powerful design strategy we have to minimise the carbon footpint of operational energy consumption in buildings. We are yet to see zero-carbon footprint buildings mandated, although the UK is planning to yet they are technically feasible in most climates.

3.1.5 Buy Recycled
One of the most important initiatives to ensure that the carbon footprint of materials are minimised is the make sure that products being purchased and specified already contain recycled content. While being recyclable is important, first priority should be give to those products that already contain high levels of preferably, post consumer content and have constituent componentry clearing identified to facilitate the next recycling cycle.

3.1.6 Design for Durability
The single most important issue in life-cycle impacts of buildings and materials is durability, providing the carbon payback period is more or less, short term. It is an unfortunate reality than many (not all) highly durable materials are high in embodied energy. For this 'carbon investment' an 'avoided energy' return needs to be calculated, i.e. are the savings that accrue as a result of a material or product's durability due to avoided maintenance or unnecessary replacement,

3.1.7 Biomimicry
By using nature as a model we are finding amazing ways to reduce the impacts of how products are made and recycled. Janine Benyus in her 1997 book looks at case studies of how products are being designed using natural criteria and processes. Key lessons that can be drawn from this approach relate to how we evaluate products, how we choose beween alternatives and how we integrate industrial ecology cycles, ensuring that the materials and technology with the lowest carbon and toxics life-cycles and biodiversity impacts prevail.

3.1.8 Dematerialisation & Factor Four$^+$
Dematerialisation is about increasing the efficiency of materials e.g. the Weisacker and Lovins' Factor Four: Doubling wealth, Halving Resourse Use' is about 'doing twice as much with half as much' i.e., increased resource efficiency sometimes also known as eco-efficiency. Dematerialisation is also an issue in building design where efficient use of resources can be influenced by structural design efficiencies, detailing practices and the level of finish.

3.1.9 Renewable Inputs
Subject to where and how products are manufactured, transported and used and hence the extent of the importance of durability, the use of renewably sourced products can have a major impact on reducing overall environmental and carbon impacts..

3.1.10 Identify Carbon Sinks
Some products that bind large amounts of carbon in the materials themselves during use are called carbon 'sinks'. Provided the materials are long lived, there are significant benefits in starting to increase the use of products that are high density carbon sinks, e.g. claimed carbon sink benefits of a natural rubber based flooring over other natural and synthetic floor coverings. (Dalsouple International).

3.1.11 Embodied Water
Another emerging issue due to both lack of the resource as a result of global warming and the negative global warming impacts of the embodied energy of water is the embodied water content of products. Crawford and Treloar (2005) showed that the embodied energy content of a 11,200m2 office building ranges from 6.3 kL/m^2 using process analysis, to 54.1 kL/m^2.

3.1.12 Durability vs Greenhouse
Another key concept that has gained strong acceptance within the marketplace is that 'durability is good sustainability'. This is not always the case. In light of the case put forward by 'Climate Code Red' and recent work by the author, it is apparent that we need to study the carbon intensity of products and assess the life-cycle benefits of products and materials against much shorter timeframes than many materials and contexts will allow. The life cycle carbon intensity of external non-structural steel and aluminium components are so significantly higher than timber that the durability benefits of these metals just cannot payback within the lifetime of the products (even allowing for full recycling) in many instances.

3.2 Materials & Design: 'Restorative Sustainability' completing the solution

Along with 'Reductive Sustainability' strategies however, there is a dire need for an additional 'enhancing nature' focus. This focus on pro-actively supporting nature requires us to where possible, create initiatives that have a 'net positive' impact that 'put back' more than they 'take out' of our natural capital by integrating initiatives that 'Repair and Restore', such initiatives are described by this author as 'Restorative Sustainability', however, we first need to identify what actually constitutes sustainability from a scientific viewpoint.

3.3 Defining Sustainability'

While there are numerous literary definitions of sustainability *per se*, such as the Brundtland Commission's and Australia's National ESD Policy, that focus on mitigating impacts, maintaining intergenerational equity and working with the 'Precautionary Principle', these are very broad overarching Principles that do not really help us actually identify and implement actual strategies. In fact, we do not really have a clear idea what a truly sustainable city actually looks like or how it can operate given the extent of existing development infrastructure and systems. There is no doubt that a truly sustainable city will of necessity be radically different to what we are doing now- not just from a physical standpoint, but from a systems (transport, services, energy etc) and societal standpoint as well. According to the Australian CSIRO, the 3 'Sustainability Wedge' strategies required to deliver sustainability are, as seen in Figure 2:

1. A values based decline in consumerism
2. A dematerialisation of Product and services; and
3. Closing the Loop in Industrial Ecology.

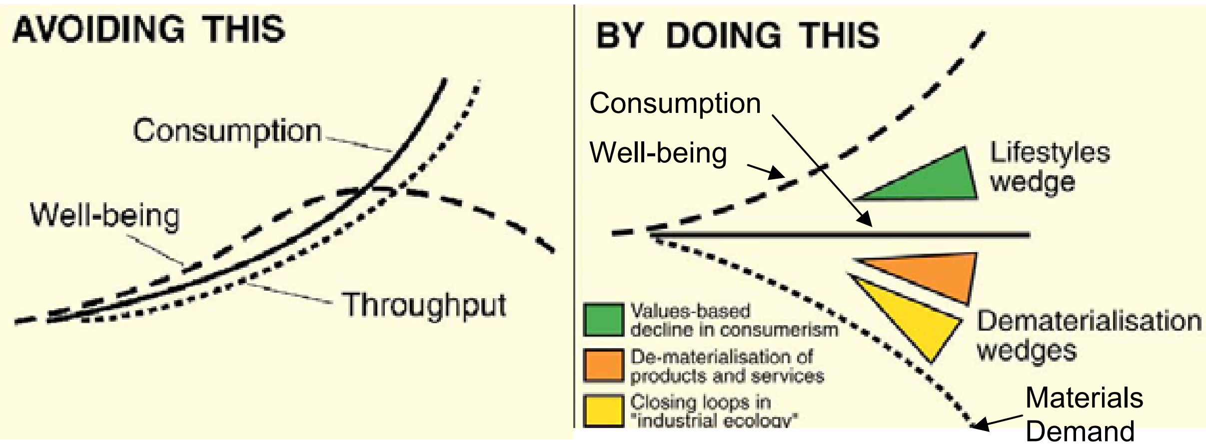

Figure 2 CSIRO vision of unsustainability and its impacts (left) and 3 proposed interventions necessary to deliver sustainability.

While there are numerous literary definitions of sustainability *per se*, The Natural Step Institute has developed 4 System Conditions for Sustainability define sustainability from a scientific standpoint and can be used as a 'compass' for setting policy in city reformation:

1. Substances from the lithosphere (within the earth) must not systematically increase in the ecosphere;
2. Substances produced by society must not systematically increase in the ecosphere;
3. The physical basis for the productivity and diversity of nature must not be systematically deteriorated;
4. The fair and efficient use of resources with respect to meeting human needs.

3.4 Defining 'Restorative Sustainability'

If we are to solve the looming global warming crisis, we need all the tools in our armoury to be fully primed and must be ready to actively implement them. The interventions needed to current consumption patterns include not only the first three Sustainability wedges shown in Fig 3 below (as adapted by Heij (2002) from Raskin (2002)) a fourth needs to be added:

1. A values based decline in consumerism
2. A dematerialisation of Product and services;
3. Closing the Loop in Industrial Ecology; and
4. Identifying and incorporating 'Restorative Sustainability';

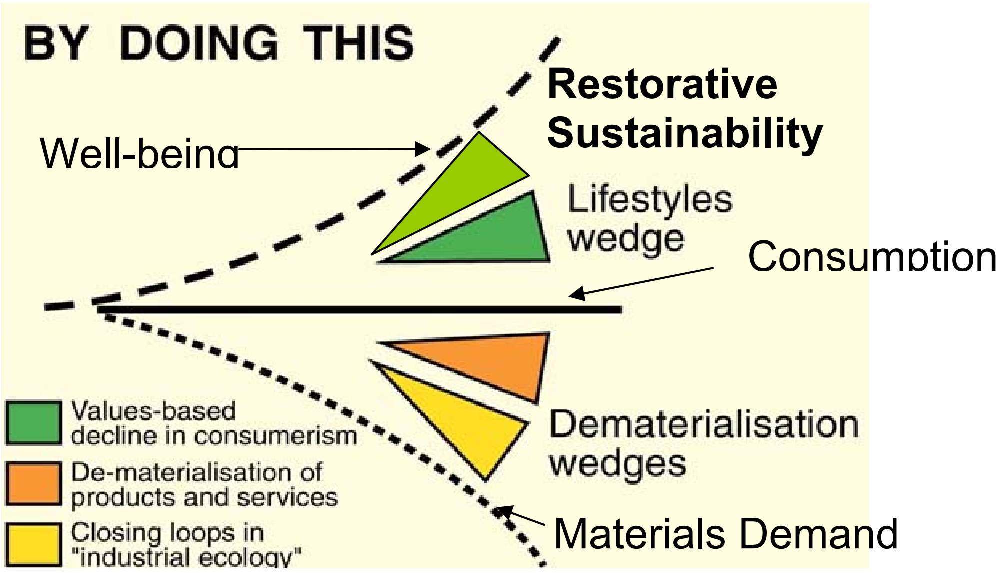

Figure 3 The full complement of 'Sustainability Wedge' Initiatives required to deliver sustainable, lean, ecobalanced cities (adapted from Heij 2002)

So what is 'Restorative Sustainability' and what constitutes a restorative solution? To be restorative a strategy, process or product would;

- meet all TNS System Conditions for Sustainability;
- be long lived perpetual or self perpetuating;
- be non maintenance or low maintenance
- likely be biological or biomimicking or ?

So far as outcomes are concerned, they create:

- net positive environmental and health outcomes
- multiple ecological benefits
- long lasting effects

3.5 'Restorative Sustainability' Solutions in Practice

A range of initiatives that have been identified as currently available and meeting the above criteria are presented below. There may well be others not yet identified and this author would welcome suggestions as to others or comments on the above proposed criteria.

3.5 1 ClimatePositive:
An Australian carbon offset organisation that focuses on tree-planting offsets. For every tonne of CO2 subscribers produce, 1.3 tonnes is offset - 1 tonne with verified emission reduction projects, and an additional 0.3 tonne over time through ecologically diverse forest restoration projects. All or part of an individual, family or company's annual CO2 emissions including travel, food, buildings and lifestyle can be offset. (ClimatePositive)

3.5.2 Green Roofs
Green roofs and earth covered buildings provide a diverse set of benefits including potential: energy savings; air pollution and CO_2 sinks; nutrient & pollutant sinks; stormwater volume reduction; biodiversity restoration; reduced urban heat island impacts; higher levels of visual amenity; Lower maintenance and longer life of roof surfaces; Dual landuse including recreation and productive urban garden potential. (Baggs et al 2007)

3.5.3 Green Walls
Plantscaping in general provides numerous benefits similar to green roofs,but to a slightly lesser extend depending on the volume of soil present: energy savings; air pollution and CO_2 sinks; nutrient & pollutant sinks; stormwater volume reduction; biodiversity restoration; reduced urban heat island impacts; higher levels of visual amenity; Lower maintenance and longer life of wall surfaces; Dual use including privacy (e.g. CH2 Building, Melbourne City Council) and productive urban garden potential (Baggs et al 2007)

3.5.4 Plantscaped Interiors
Have been shown by research to reduce air pollution and provide CO_2 absorption. They absorb and bind indoor volatile organic compounds (VOCs) and airborne pollutants including CO_2 into biological matter. This ability results from the interaction between soil, micro organisms. Plants also provide additional psychological benefits resulting in a contribution to increased worker satisfaction and potentially productivity.

3.5.5 Beneficial Microorganism Water Treatments
Are non-toxic, biodegradable, and self perpetuating, probiotic treatments which digest solid waste, transforming effluent ponds into usable water, removing any organic waste or odour control and sanitation in industrial, commercial and residential applications with the effect of multiplying the efficiency of the plants significantly – up to several times, potentially saving some large industrial or municipal waste water treatment plants 10s or even 100s of millions of dollars in avoided upgrade requirements or delayed expenditure. Whatsmore, the microorganisms continue to assist even out into the broader environment maintaining their beneficial conversion of nutrients and reduction of pathogens provided aerobic conditions exist (ecospecifier.org).

3.5.6 Microorganism-based Waterless Urinal Conversion
Waterless urinal conversion systems such as Desert ™ Cubes also contain naturally occurring microbes to turn existing trough or bowl facilities into touch-free waterless urinals. The embedded microorganisms naturally breakdown the organic matter inside the drain and interfere with the bacterial digestion that produces unpleasant odours. Reduces drain clogs and stains and reduces pathogens. Installed in any existing urinal or after construction, as above, the microorganisms continue down the pipe provided aerobic conditions exist. (ecospecifier.org)

3.5.7 Net Positive Renewable Energy
Renewable Energy sources are greenhouse emission free except for their embodied energy. Different types of systems have differing rates of embodied energy payback from 2-4 years (Baggs & Haines 2006). While ever the size of a PV or other renewable energy system is designed to replace only the emissions of a particular load, it is a 'reductive sustainability' solution. However, as soon as the embodied energy is paid back and the energy generated exceeds the annual load of the site and provides net positive energy into the grid it can be said to be a 'restorative solution'.

3.5.8 Restitution of Indigenous Plant Associations and Ecological Quality
While not relevant to every site, some sites and roofs tops may be suitable for the re-establishing of areas of plantings using locally indigenous plants and soil profiles. When grown on roofs, the benefits of green roofs (see above) would also apply.

3.5.9 Offsite Tree Planting
This strategy is being used widely as an emissions offset tool already. The benefits that accrue will actually depend on a variety of issues such as the area being planted, the planting style (monoculture or diverse), adjoining ecosystem integrity (better if diverse communities planted adjoing high quality forest with similar locally derive seedstock to allow more holistic re-colonisation of the ecosystem over time) and forestry practices (use of baits, genetically modifed seedstock or not etc).

4. Ecospecifier: a Key Tool for Implementation

One of the factors limiting the implementation of sustainability is the difficulty design and construction professionals find in locating products with *bona fide* preferential environmental and health features.

Ecospecifier.org publishes several online knowledgebase and databases in Australia, New Zealand and Middle East, incorporating verified, life-cycle based information over 5000 ecologically and health preferred products, materials and technologies that provides built environment professionals with detail needed by each market to understand how each product relates to the relevant scheme/s in each country.

The information provided is both quantitative and qualitative; life-cycle assessment based and focuses on all aspects of restorative sustainability including closed loop product cycles. Products have to meet specific entry criteria and all claims are verified by experienced professionals with enhanced listings product manufacturers required to submit third party test data to back all key environmental and health claims. Ecospecifier also reviews products against credits relating to major international Green Building Rating tools such as Green Star™, LEED® and in the near future BREEAM into product verification and search processes.

5. Conclusions

Policymakers, designers, engineers and constructors responsible for urban outcomes need to refocus their policy, design and built outcome towards ecobalanced, lean, low carb cities materials and strategies. The past 'Reductive Sustainability' mantra of the '3Rs' ('Reduce, Re-use, Recycle) needs to be expanded to include concepts of industrial ecology and 'Restorative Sustainability' and replaced by the '5Rs' 'Reduce, Re-use, Recycle, Repair + Restore' and these outcome need to actually be delivered by every new project.

Keywords: glass, energy efficience, window, sustainable, building.

Summary

The study evaluates the influence of the specification of the glass of window in the energy consumption of the constructions. It uses software RESFEN 5,0, developed for Lawrence Berkeley National Laboratory of California for calculation of thermal load and costs of conditioning of a construction related to the properties of the window. It was simulated a typical construction whit one floor of 100 m² in the city of Belo Horizonte and São Paulo. The evaluated glasses had been: Float 4 mm clear (reference), Float 3 mm clear, Float 6 mm clear, Float 4 mm green, Float 4 mm grey, Laminated 8,4mm clear, double glass (4 mm + 6 mm of air + 4 mm) clear. The calculations had been made for the orientation west, of bigger incidence of solar energy. They had been simulated also, the orientation north, east and south for the window with the reference glass. The variation of the thickness of the glass showed resulted modest in the energy efficiency of the window, similar in the two cities. The color of the glass produced resulted significant in the improvement of the energy efficiency of the window, also similar in both the cities. The glass systems (laminated and double glass) had produced a medium results in the energy efficiency of the window, being that, in São Paulo, the double glass had better performance of what in Belo Horizonte. The orientation of the windows showed great influence in the building energy consumption related to the window. However, the orientation east presented different results in the two cities, with small reduction in Belo Horizonte and great reduction in São Paulo.

1. Introduction

Great part of the energy consumed in the constructions is used for thermal conditioning and illumination. The solar radiation is the main agent to determine the characteristic of thermal and illumination performance of the building. It is energy that brings beyond energy in the form of visible light, energy in the form of heat for the building; therefore she must be used carefully. Design, the architectural details and the materials used in the building, have direct influence in how the building relates, appropriates and controls the solar radiation.

2. Simulation tool - RESFEN 5.0

Program RESFEN is software, developed for Lawrence Berkeley National Laboratory of California (LBNL), United States, as a tool to assist in the choice of the window whit better energy efficiency and better cost for determined residential application (figure 01). It calculates the used energy for conditioning, heating and refrigeration and associates the cost and peaks of consumption, of a determined window. The RESFEN uses DOE 2.1E (LBL 1980, Winkelmann et al. 1993) as tool of energetic balance calculation.

The RESFEN uses a custom version of the DOE-2.1E configured in dynamic link libraries (DLL) for operation in PC platforms. The DOE-2 is a term-energy program of simulation of constructions, also developed for the LBNL, known and widely used. As the DOE-2 reproduces the typical constructions characteristics of its native country, the simulation process must have a critical analysis in relation a variable adopted automatically by program. The DOE-2 did not have its basic algorithms modified. The results calculated for identical situations, are equal in the RESFEN and in DOE-2.1E.

In version 5.0, the RESFEN allows that if it defines a type of residence (one or two floor, frame or masonry), geographic localization (BIN archives), details of the core and shell of the construction (walls, floor and ceilings), type of HVAC systems (gas, electric, heat pump), cost of electricity and gas, orientation and thermal properties of the window in study. The thermal data of the window required are the U-value, SHGC and air leakage. It can be defined the solar gain reduction. The possibility of use a climatic BIN archives, together with the definition of the properties of the core, shell and windows, allows the study to use the RESFEN in other countries. Version 5.0 have library for China and Chile, beyond U.S.A. and Canada

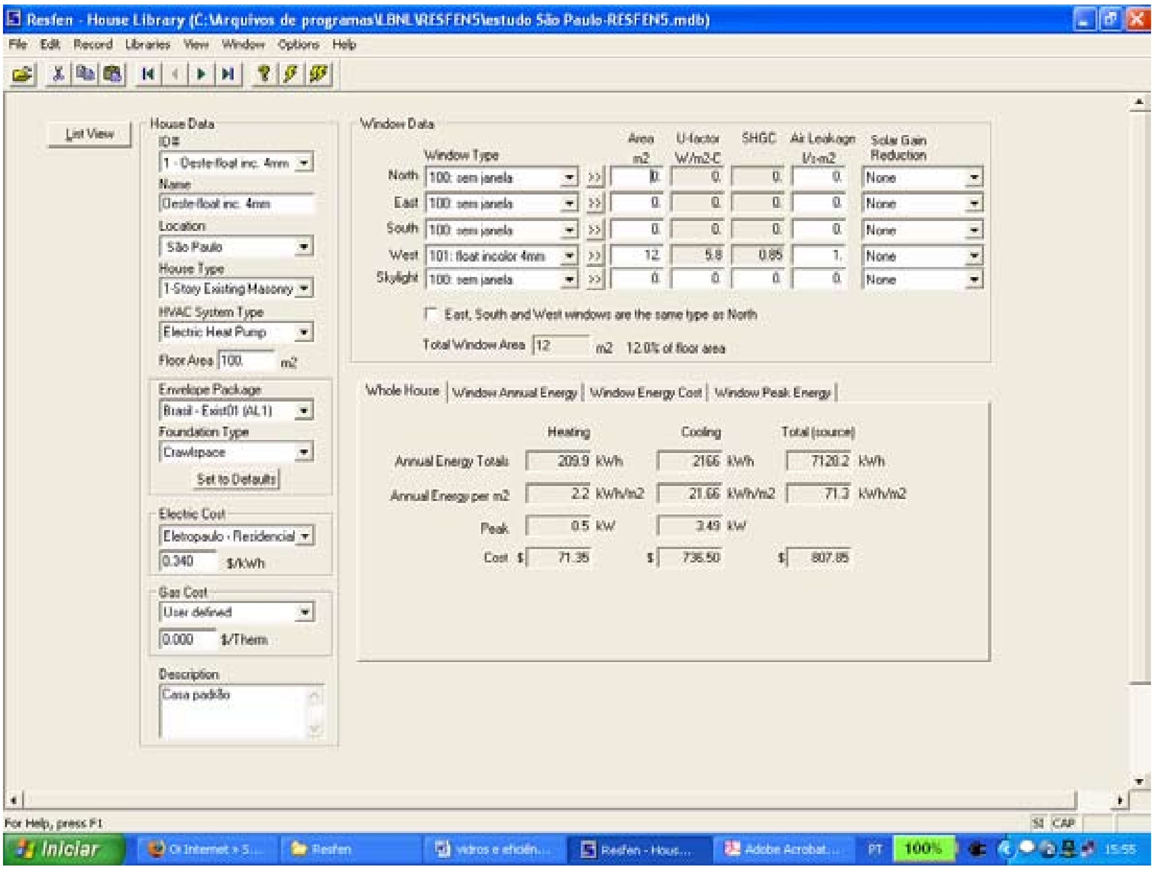

Figure 01 – RESFEN main screen.

Based in the supplied data, RESFEN generates a BDL archive (Building Description Language) for DOE-2, and then, processes the archive as an entrance module (DOEBDL). After that the module is simulated, using the defined climatic archive. The simulation generated an archive with the consumption and annual cost of the construction for heating and refrigeration, the peak demands, and how much of this consumed energy can be attributed for the window. Figure 02 presents an organization chart of the calculation method.

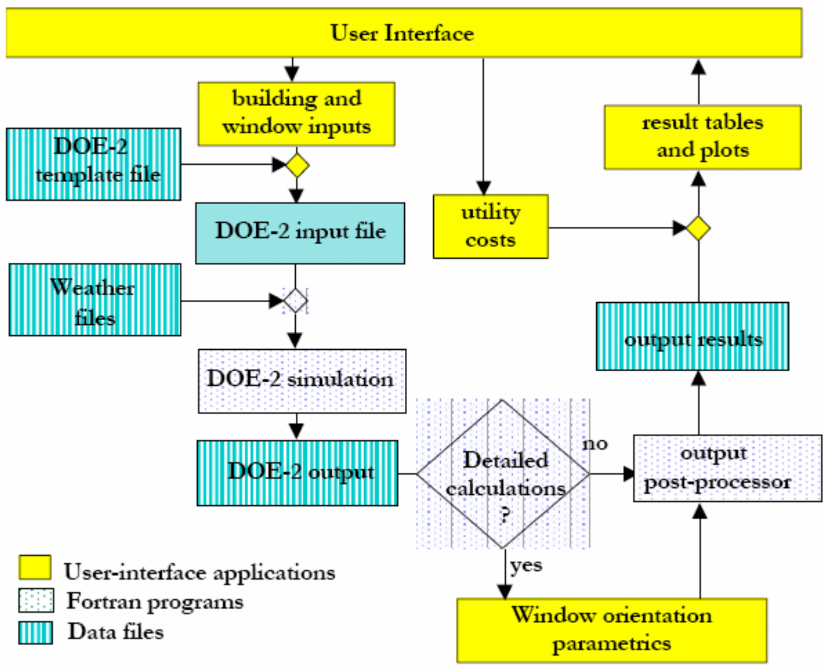

Figure 02 - Organization chart of the calculation method.

3. Data and parameters

The RESFEN was configured for the locality of Belo Horizonte and São Paulo. The entrance data in program are presented in table 01.

Table 01 – Used parameters in the RESFEN.

Parameters	Belo Horizonte	São Paulo

Weather data	Bhrea95.BIN (LabEEE)	SaoPauloTRY1954_06.BIN (LabEEE)

The window was defined with simple aluminium frame, with dimension 1,0 x 1,2 meters each, and total area of twelve meters ². The program allows only 12% of area of window in relation to the floor area. Diverse windows had been criate, varying the glass through the determination of U-value and SHGC. Glasses with diverse thicknesses, diverse colors, lamination systems and double glass had been studied.

The U-value and SHGC of each glass had been gotten in the program Pilkington Spectrum V01.03.07 (figure 03), that it calculates the thermal and optics properties of glasses and its combinations, manufactured by Pilkington.

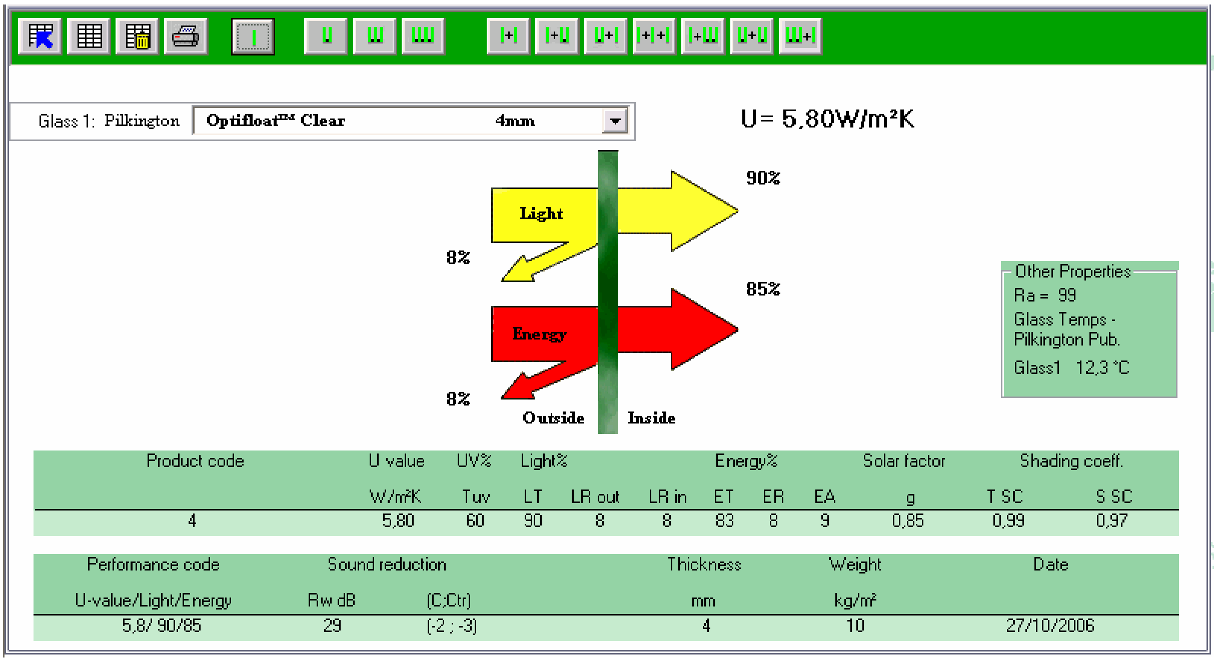

Figure 03 –Pilkington Spectrum Interface (V01.03.07.).

The properties are calculated by European Norm EN673 of U-value calculation and EN410 of solar and ótic performance of glasses. The bands of wave length considered are:

- UV Transmission - 280-380 nm.
- Visible Transmission - 380-780 nm.
- Solar Energy Transmission - 300-2500 nm.

The values of glass properties considered in Pilkington Spectrum calculation are:

- Thermal Resistivity - R = 1.0 mK/W.
- Corrected emissivity for uncoated float glass - e = 0.837.
- Temperature difference inside/outside - dT = 15oK.
- Exterior heat transfer coefficient - he = 23.0 Wm²K
- Interior heat transfer coefficient - he = 8.0 W/m²K

The U-value is calculated in glass centre. The frame effect was not incluse in the calculation. The Pilkington Spectrum program was used because its have glass data equal of glasses that was manufactured in Brazil by Pilkington. The reference window uses float glass clear 4 mm.

The electricity cost in Belo Horizonte was defined R$ 0,664 kWh, having as reference the value of 100kW residential count, inclued taxes. The electricity cost in São Paulo was defined R$ 0,340 kWh, having as reference the value of 100kW residential count, inclued taxes.

To study the thickness influence, the colour influence and the glass system influence, in the energy consumption of building, each window was simulated with orientation west, that have a bigger thermal profit for the solar radiation.

The reference window was shaped in the north, east and south orientation, to evaluate the orientation influence in the energy consumption of building.

The studied glasses and the summary of its technician data, gotten in the Pilkington Glazing Calculator program, are shown in table 02.

Table 02 – Glass technician data.

VIDRO	U-value (W/m²K)	SHGC
Float Clear 4 mm.	5,8	0.85
Float Clear 3 mm.	5,83	0.86
Float Clear 6 mm.	5,73	0.82
Float Green 4 mm.	5,8	0.66
Float Grey 4 mm.	5,8	0.67
Laminated glass clear 8,4mm.	5,7	0.77
Doble glass 4 mm + 6 mm air + 4 mm – clear.	3,3	0.76

4. Results

The summary of the results gotten for Belo Horizonte is shown in table 03.

Table 03 – Belo Horizonte results.

GLASS	ANNUAL COST DUE TO THE WINDOW (R$)	TOTAL ANNUAL COST (R$)
Float clear 4 mm - West.	1725,23	2941,77
Float clear 3 mm - West.	1745,79	2962,58
Float clear 6 mm – West.	1649,99	2866,76
Float green 4 mm – West.	1253,99	2470,33
Float grey 4 mm – West.	1276,08	2492,45
Laminated clear 8,4mm – West.	1525,74	2741,81
Doble 4+6+4 mm clear – West.	1569,48	2786,45
Float clear 4 mm – North.	1175,91	2422,09
Float clear 4 mm – East.	1640,58	2906,59
Float clear 4 mm - South.	736,36	2087,88

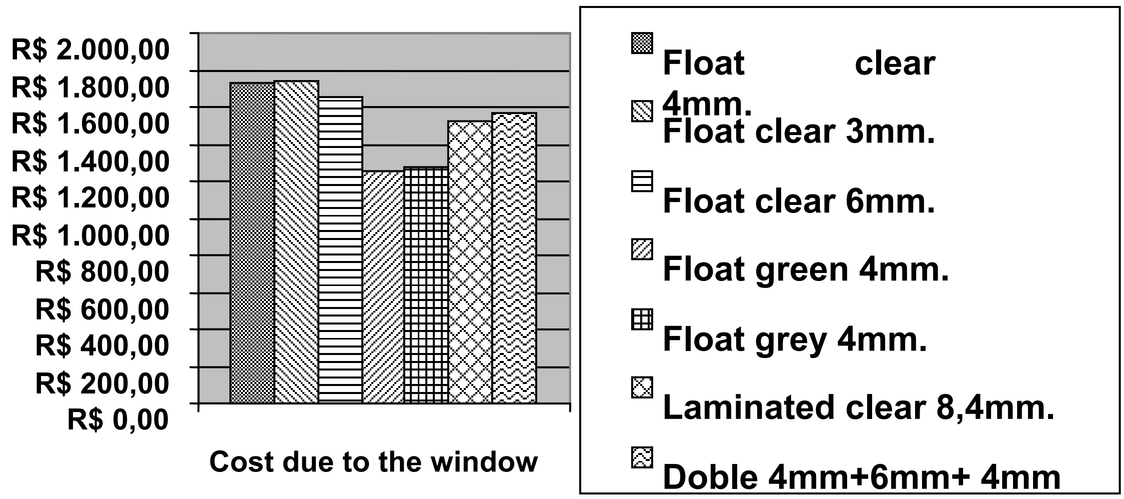
The summary of the results gotten for São Paulo is shown in table 04.

Table 04 – São Paulo results.

GLASS	ANNUAL COST DUE TO THE WINDOW (R$)	TOTAL ANNUAL COST (R$)
Float clear 4 mm - West.	551,16	807,85
Float clear 3 mm - West.	559,17	815,83
Float clear 6 mm – West.	524,28	781,19
Float green 4 mm – West.	402,69	660,16
Float grey 4 mm – West.	409,20	666,53
Laminated clear 8,4mm – West.	483,03	739,99
Doble 4+6+4 mm clear – West.	480,45	736,55
Float clear 4 mm – North.	420,20	670,24
Float clear 4 mm – East.	393,82	638,21
Float clear 4 mm - South.	228,30	484,03

5. Analysis of the Results

The Belo Horizonte annual cost of conditioning due to the window, varying the glass, is showed in graph 01.



Graph 01 – Belo Horizonte, glass variation.

Thickness:

Clear glass 3 mm showed a annual cost of conditioning due to the window, R$ 20,56 or 1,19% greater than the reference glass 4 mm.

Clear glass 6 mm showed annual cost of conditioning due to the window, R$ 75,24 or 4.36% lower than the reference glass 4 mm.

Color of the glass:

Green glass 4 mm showed annual cost of conditioning due to the window, R$ 471,24 or 27,31% lower than the reference glass 4 mm.

Grey glass 4 mm showed annual cost of conditioning due to the window, R$ 449,15 or 26,03% lower than the reference glass 4 mm

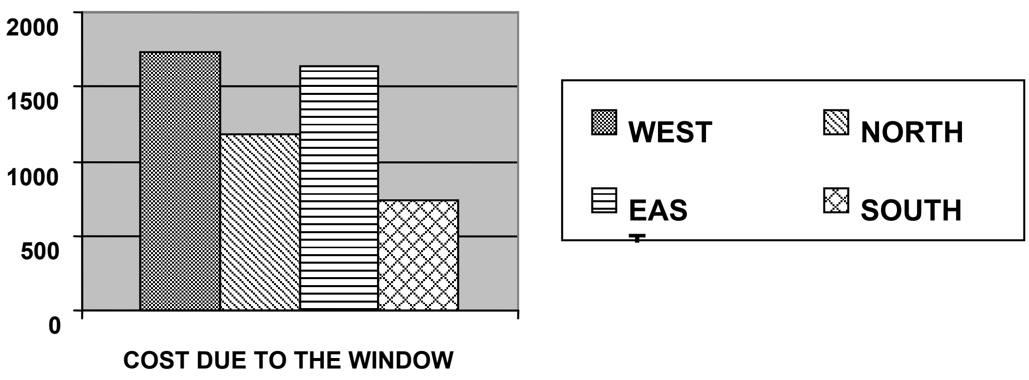
Glass systems:

The laminated glass 8,4mm showed annual cost of conditioning due to the window, R$ 199,49 or 11,56% lower than the reference glass 4 mm.

Doble glass 4 mm + 6 mm + 4 mm showed cost of conditioning due to thr window, R$ 155,75 or 9,03% lower than the reference glass 4 mm.

Window orientation:

The Belo Horizonte annual cost of conditioning by the window, varying the orientation, is showed in graph 02.



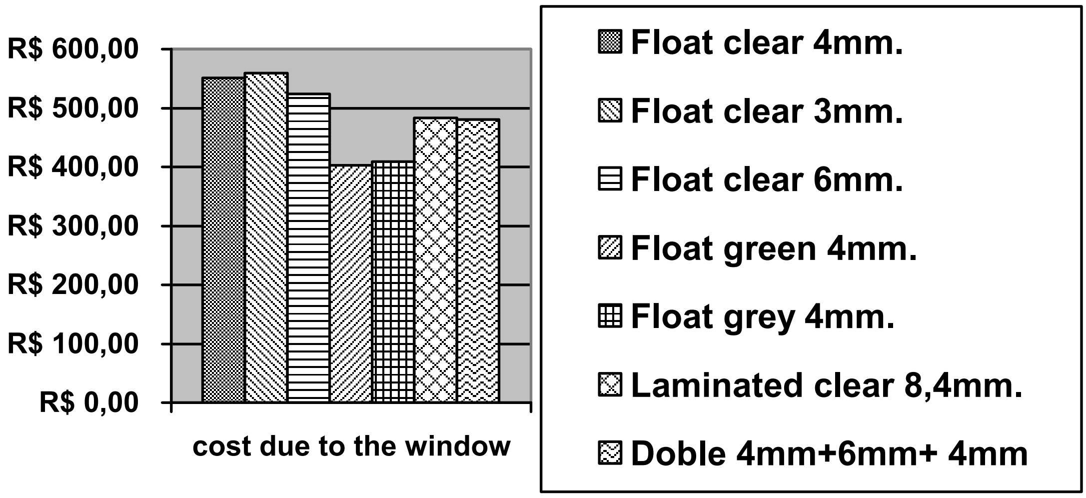
Graph 02 – Belo Horizonte, window orientation.

The orientation north presented annual cost of conditioning due to the window, R$ 549,32 or 31,84% lower than the reference glass 4 mm.

The orientation east presented annual cost of conditioning due to the window, R$ 84,65 or 4,91% lower than the reference glass 4 mm.

The orientation south presented annual cost of conditioning due to the window, R$ 549,32 or 31,84% lower than the reference glass 4 mm.

The São Paulo annual cost of conditioning by the window, varying the glass, is showed in graph 03.



Graph 03 – São Paulo, glass variation.

Thickness:

Clear glass 3 mm showed a annual cost of conditioning due to the window, R$ 8,01 or 1,45% greater than the reference glass 4 mm.

Clear glass 6 mm showed annual cost of conditioning due to the window, R$ 26,88 or 4.87% lower than the reference glass 4 mm.

Color of the glass:

Green glass 4 mm showed annual cost of conditioning due to the window, R$ 148,47 or 26,93% lower than the reference glass 4 mm.

Grey glass 4 mm showed annual cost of conditioning due to the window, R$ 141,96 or 25,75% lower than the reference glass 4 mm

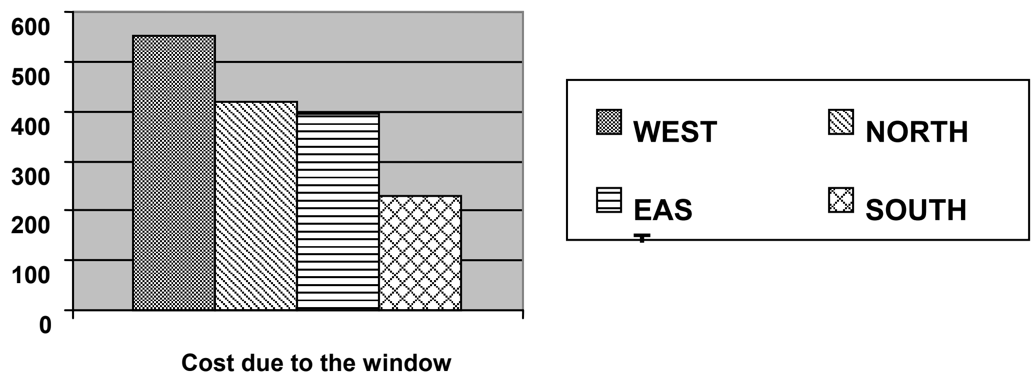
Glass systems:

The laminated glass 8,4mm showed annual cost of conditioning due to the window, R$ 68,1 or 12,36% lower than the reference glass 4 mm.

Doble glass 4 mm + 6 mm + 4 mm showed cost of conditioning due to the window, R$ 70,71 or 12,83% lower than the reference glass 4 mm.

Window orientation:

The São Paulo annual cost of conditioning by the window, varying the orientation, is showed in graph 04.



Graph 04 – São Paulo, window orientation.

The orientation north presented annual cost of conditioning due to the window, R$ 130,96 or 23,76% lower than the reference glass 4 mm.

The orientation east presented annual cost of conditioning due to the window, R$ 157,34 or 28,54% lower than the reference glass 4 mm.

The orientation south presented annual cost of conditioning due to the window, R$ 322,86 or 58,58% lower than the reference glass 4 mm.

6. CONCLUSIONS

The thickness variation maded a modest resulted in the energy efficiency of the window, in Belo Horizonte and São Paulo. An increase of 50% in glass thickness did 4,5% reduce cost of conditioning by the window.

The alteration of the glass color maded a significant results in the energy efficiency of the window, in Belo Horizonte and São Paulo. A Reduction of 27% for the green glass was gotten. However the influence of the opacity in the natural illumination must be analyzed and eventual increases of energy consumption for natural illumination.

The glass systems maded a medium results in the energy efficiency of the window, in Belo Horizonte and São Paulo. In Belo Horizonte, the laminated glass, with presence of another material (PVB-polymer) in the interior of the glass maded a reduction of 11,56%, superior than the doble glass (9,03% reduction), that it possesss air layer with 6 mm in the interior. In São Paulo, city of more cold climate, the doble glass had better performance, with reduction of 12,83%, superior than the laminate reduction (12,36%). The most cold climate, and the influence of the glass isolation, can explains the result.

The windows orientation maded a great influence in the energy consumption by the window. The south orientation showed reduction of 57,32% in the cost by the window for building conditioning in

Belo Horizonte. In São Paulo, reduction of 58,58% for south orientation was observed. The results had shown that the orientation east of the window cost different costs in Belo Horizonte and São Paulo. In Belo Horizonte, the orientation east had reduction of 4,91% and in São Paulo of 28,54%. The climate hottest and bigger solar heat, can explains the result. The orientation north also presented considerable difference, reduction of 31,84% for Belo Horizonte and 23,76% for São Paulo. Probably, it´s because the climate difference.

We can conclude that the glasses of the windows are significant for energy efficiency of the building. For a bigger energy efficiency, we must considered the place climate and the solar incidence in the construction, especially in the windows. The strong influence of the solar orientation of the window is shown by the results.

RESFEN showed adequate for the proposal situation, a fast calculation of model building thermal performance. With development of customizações for Brazil, this can be used for comparative degrees of energy efficiency of windows. A possibility is the development of Brazilian windows library, using software WINDOW 5 (LBNL), where the thermal properties of a shaped window are calculated, including glasses and frame, to be used in the RESFEN

Summary

Sustainable building is a very important topic in Europe at the moment. This is especially true in Belgium where a large number of initiatives are being carried out by the federal, regional and local authorities to raise the awareness of builders about the importance of designing a sustainable built environment with high technical quality.

To support those who develop sustainable construction projects, the authorities have targeted their approach on two areas. Firstly, public buildings are designed in accordance with a sustainable construction strategy. This first approach comes within the framework of the "Green Public Procurement" activity encouraged by the European Commission. Secondly, they are creating support centres to advise architects, works supervisors and building technicians.

To be credible, it is imperative that the buildings supporting this approach are perfect examples of sustainable construction. Therefore various projects are being developed to illustrate the approach implemented by the authorities.

The projects have as their common aim the promotion of the use of bricks as a sustainability vector.

1. Belgian is a country of bricks

Belgium is a country of bricks… It is also said that "Belgians are born with a brick in their stomach"... a general expression which bears testimony to the interest this country shows in construction, and more specifically the residential sector. If the brick material is at the heart of this expression it's because of its significance. We have in fact seen generations of builders shape our developed landscape by creating striking buildings made of bricks. Thanks to the material's longevity, these buildings are still, today, inescapable elements of our architectural heritage.

For generations, our country has been characterised by the great concern we attach to the architectural quality of our homes. For some years we have noticed that the interest shown by the population, construction professionals and the authorities is no longer centred solely on the aesthetic criteria but is broadening to include sustainable construction.

2. Sustainable construction and construction traditions

A considerable amount of information abounds today and we can become disorientated. In terms of sustainable construction, the emphasis is mainly on energy efficiency and the use of natural materials, renewable where possible.

These aspects are sometimes very technical and the "soul" of the building seems all too often to be forgotten. The only thing that seems to matter is the building's performance in terms of energy efficiency, waste and waste water management, adaptability, etc. These are, without a doubt, essential factors in sustainable construction, but the cultural aspect all too often becomes the poor relation in the sustainable construction debate.
This aspect forms the basis of this presentation; more particularly the exemplary role the authorities can play in terms of sustainable construction. The projects described are brick constructions which have been designed with the sustainable construction criteria in mind and which also have a strong link with their surroundings and Belgian construction traditions.
These creations go beyond the "simple" technical aspects linked to sustainable construction, offering a style of architecture which is both contemporary and in keeping with Belgian construction traditions!

3. Brick : cultural value and sustainable construction

It is first necessary to put sustainable construction in the international context of sustainable development, defined as the management of human, economic and environmental resources which meets the needs of today's society without endangering the needs of future generations.
One must therefore keep in mind this socio-economic-environmental triple dimension when talking about sustainable construction. Among the social factors, maintaining a link with construction traditions and our built heritage is an essential element. However, we notice a growing tendency to exclude anything that approaches us from the past, as though only high-tech construction solutions could support sustainable construction. Nevertheless, traditional materials have an essential role to play!

Whilst sustainable construction has become a real issue in society, brick remains the quintessential material which contributes to a sound, sustainable constructed environment which also performs on an interior comfort level! It is not by chance that brick has been shaping Europe’s constructed environment for centuries. Made from the natural raw material clay, brick is one of the highest performing construction materials, meeting all thermal and acoustic comfort, security, sustainability and building flexibility requirements.

4. The authorities : an exemplary role

Sustainable construction is a very fashionable topic in Europe. This is especially the case in Belgium where federal, regional and local authorities operate policies with the aim of making potential builders aware of the importance of creating a sustainable constructed environment of a high technological quality.

To support those who develop sustainable construction projects, the authorities have targeted their approach on two areas. Firstly, public buildings are designed in accordance with a sustainable construction strategy. This first approach comes within the framework of the “Green Public Procurement” activity encouraged by the European Commission. Secondly, they are creating support centres to advise architects, works supervisors and building technicians.

5. Buildings

To be credible, it is imperative that the buildings supporting this approach are perfect examples of sustainable construction. Therefore various projects are being developed to illustrate the approach implemented by the authorities.
These creations have the common purpose of advancing the use of terracotta materials as a means of sustainability.

5.1 Centrum Duurzaam Bouwen (CEDUBO) : "House of sustainable construction"

CeDuBo is a European Union-supported projected. Located on the former Heusden-Zolder mining site, CeDuBo is a sustainable construction information and coordination centre.

The “house of sustainable construction” was set up in 2002 in a renovated brick building as a witness to sustainable construction. The architects in charge of the renovation of the building were chosen for their significant vision of the sustainable renovation of such a historical site.

5.2 Vlaamse Milieumaatschappij (VMM)

It is not by chance that this group of offices for the "Vlaamse Milieumaatschappij"(VMM) won the Belgian Building Awards 2005. Indeed, thanks to the intervention of the De Smet Vermeulen architects, this creation is more than a group of offices; it is a unifying element between the inhabitants of the area, the various public institutions which have their offices there and the town of Aalst itself.

In order to create a feeling of acceptance of the building among all the stakeholders, the architects established a frank dialogue and an active collaboration with the management and employees of VMM, the town and the population from the outset. It was possible to take the needs and concerns of all parties into account.

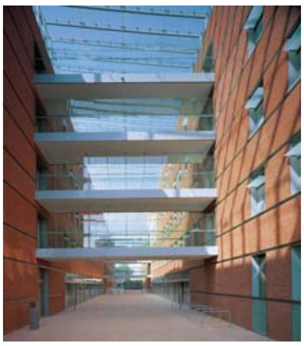
It was important, for the VMM, to integrate the environmental scale into this creation so as to reflect its commitment to the promotion of an ecological and sustainable approach. In order to meet these environmental objectives the architects used two elements: sustainability and flexibility. On the one hand, sustainable materials were used. On the other hand, the architects designed a low-energy building where every factor is managed electronically – lighting, ventilation, heating, etc. The sometimes untimely intervention of staff is no longer required and the interior climate is thus always well regulated.
The flexibility of the space inside is reflected in the common areas – reception, auditorium, and cafeteria – and the offices, which are reduced in size but functional and flexible.

This creation enriches the inhabitants' living environment. Since two areas, one public, the other semi-public, were created, they accepted the nuisance caused during the construction stage. The communication paid off as the inhabitants have taken the site into their hearts and are now its best guarantors against vandalism...

When the VMM called on the architects, their offices were already located on this site, in a former cloister with no particular architectural or historical interest and which, on the contrary, was causing the disintegration of the whole area. The proximity of Aalst station was a key element in the VMM's decision to stay on this site. The architects were immediately persuaded that demolishing the old cloister would allow them to bring the site's potentialities up to date. They then convinced the local authorities to keep only the old vicarage, which is now joined to the brick building via a glass walkway.

The architects also very soon began making every effort to work around the symbolism of the hundred-year-old tree located on the site. This was left in place to be

5.3 Vlaams Administratief Centrum (VAC)



In each of the Flemish provinces the regional council constructs an administrative centre with the aim of centralising provincial services. The "Vlaams Administratief Centrum" in Hasselt thus unites the public services of Limbourg.
This creation, as a symbol for the province, had to have an impact and set an example in terms of quality architecture incorporating the principles of sustainable construction. In order to ensure that it had a certain aura this ensemble had to be made accessible, authentifiable and open to the population.

The VAC's privileged position makes it easily accessible to the public and to the civil servants who work there. The location of the project at the entrance to the town, near to both the station and the motorway, was therefore an essential factor in its smooth running.

The VAC's quality architecture and the concept it embodies makes it without a doubt a key part of the town. Two long wings of red-orange bricks house the facilities open to the public (library, restaurant, auditorium, meeting room, etc.) on the ground floor and the offices on the upper floors. These two main buildings are linked by a glass-covered internal walkway. It is intended to be a "pathway" expressing the local government's wish to open itself up to the public. In this sense, the administrative centre completely lays itself open, lending a certain "transparency" to the activities and the working of the public services when seen from the outside.

The flooring of the internal walkway is also made of red-orange bricks and thus helps create a sense of unity.

Particular attention has been paid to user comfort. Furthermore, the architects have ensured that this public building is an example of sustainable construction. For this reason, the ventilation, lighting and heating technology used have been designed with sustainable and ecological construction in mind where each user is free to play a part in their working environment.

Through its scope, its simple volume boosted by a horizontal rhythm created by means of metal sections and the use of a brightly coloured brick, this creation gives some character back to this area surrounding the station.

5.4 Sint-Katelijne-Waver Town Hall

A town hall which would set the tone in terms of sustainable construction… such was the Sint-Katelijne-Waver local authorities' objective. This new creation had to be representative of the actions carried out by the municipality in terms of sustainable construction and, in this particular case, in terms of using sustainable materials, flexibility of space and the use of interior climate technical installations.

It is through suggesting such a striking and prestigious creation that the two architects won the competition organised by the municipality. From the beginnings of the project, facing bricks were used for their aesthetic qualities, whilst perforated bricks were then used for the interior walls for technical reasons.

The town hall consists of two buildings. The intersection of the two forms a sharp angle and the architects decided to make this the reception and public information area. One of the buildings is designed to house ticket booths for the public, the burgomaster and deputy burgomaster's offices and the boardroom. The other building houses the public services offices. The open-plan offices have a very flexible layout.

The main entrance is located at the exterior corner of the building but direct access from the car park is also planned. A second phase is expected to landscape the surroundings and the space between the two wings.

The bold architecture of this creation plays on asymmetry, on the one hand, and the internal/external contrast on the other.
A three-level building located opposite the neighbouring constructions forms the part in which the main entrance is located, whilst the height of the other building decreases gradually as it "disappears" into the ground!

The internal/external contrast consists of playing the dark, monolithic aspect of the facing off against the brightness of the inside of the building. The facing has been created using thin joint masonry. The remarkable accomplishment and the attention to detail, especially in relation to the sharp angle at the entrance to the building, should be pointed out. On the inside, the town hall welcomes visitors into a three-level area where the colour white is omnipresent.

Different elements, including the use of bricks, make this creation a success in terms of sustainable construction.

6. Cultural value and sustainable architecture

If there's one thing desperately missing from today's societies it's our roots. Without foundations, society can grow and evolve but there's a risk to lose our values.
The same goes for sustainable construction. Of course, a lot of technical equipment must be used and building physics principles applied in order for buildings to reach high performance levels whilst respecting our needs and those of future generations… But it is misleading to think that these buildings will be viable in the long run if they are not strongly linked to cultural values and local construction traditions. Without that there is nothing to relate them to society!

Using bricks in sustainable construction is in itself sustainable architecture! Far from being backward-looking, it is a question of progressive architecture… a progress rich in cultural value!

TITLE: RESEARCH ON THE DETERIORATION DEGREE EVALUATION OF NATIONAL GOVERNMENT BUILDINGS

Takanori KOSAKA, Senior Deputy Director [1]
Yasushi AKIMOTO, Deputy Director of Facility Management Planning Office[1]
Hiroo INOUE, Chief of section[1]

[1] Facility Management Planning Office, Planning Division, Government Buildings Department, Ministry of Land, Infrastructure, Transport and Tourism (MPS/PD/GBD/MLIT)

Keywords: repair, renovation, deterioration degree evaluation, building component

Summary

National government buildings in Japan, if they are observed from the point of asset, are enormous and aging. And those aging government buildings need to be repaired and renovated systematically to extend their service life under the tight budget circumstances. As building- related carbon dioxide gas emission is one third of the total carbon dioxide gas emission in Japan, the technologies to expand the service-life and to make effective use of existing buildings are considered very significant to the sustainability and the global environment. In this research started in 2004, GBD/MLIT has developed, 'a method for prioritizing repair and renovation' that consists of 'a deterioration degree evaluation stage' and 'a prioritizing stage', a systematic method to prioritize deteriorated building components in deferent buildings in consideration of building earthquake-resistance capacity, risk priority in disaster, security, functional continuity etc. After the development, GBD/MLIT has conducted a series of trial surveys on national government buildings to examine the effectiveness of 'the method' and reviewed and finalized it.

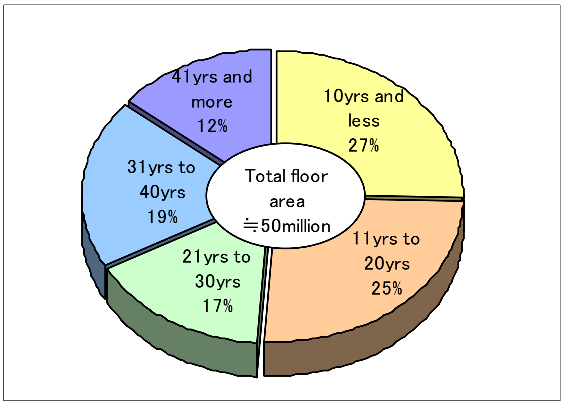
1. Introduction

1.1 What is required for national government buildings

National government buildings consist of joint-use offices, single-use offices, cultural-use buildings, educational-use buildings etc. These buildings are required to have high safety and continuous functional performance for their public use as well as to have long-term use of existing buildings for mitigating environmental impact.

1.2 Status-quo of national government buildings

Based on the data of 'national asset information system' developed by the Ministry of Finance, total floor area of national government buildings, enormous asset, is approximately 50 million m^2 and the number of buildings is approximately 19,000. Classified distribution of floor area and the number of national government buildings by their ages are illustrated in Figure 1. Buildings over 30 year after the completion are approximately 30% by floor area and 40% by the number of buildings.



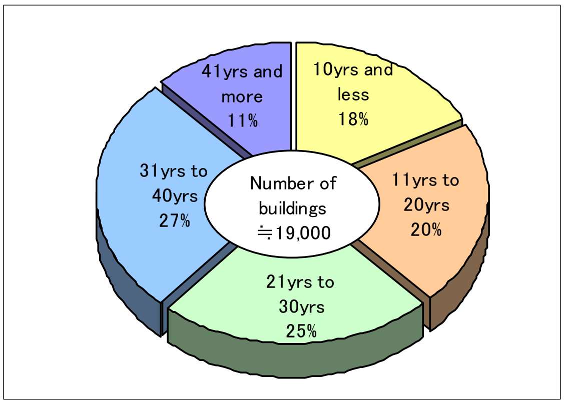


Figure 1 Classified distribution of floor area and the number of national government buildings by ages

1.3 Items needed for long-term building use

GBD/MLIT has been conducting 'periodical building condition survey' on national government buildings every 5 years to grasp the actual condition of buildings including the deterioration. But major objectives of the survey are to collect the information on judging the timing of reconstruction and to grasp rough condition of the deterioration. Therefore in order to execute the appropriate repair and renovation based on the deterioration condition, it is necessary to develop detailed survey for every component of a building.

2. Objectives

In this research, we have conducted detailed and systematic survey, analysis and evaluation on the deterioration condition of every component of government buildings and its related facilities, hereinafter referred to as buildings etc.. And with this result, we have developed 'a method for prioritizing repair and renovation' aiming at;

a) supporting to conduct appropriate guidance of maintenance

b) supporting to determine appropriate timing of repair and renovation

c) supporting budget planning and repair and renovation project

3. Development, trial survey and review of 'a method for prioritizing repair and renovation'

'A method for prioritizing repair and renovation' consists of two stages; deterioration degree evaluation stage and prioritizing stage. We have developed 'deterioration degree evaluation stage' and 'prioritizing stage' in 2004 and have conducted trial survey in 2005 to review both stages.

3.1 Identifying target components for survey

Building components for prioritizing repair and renovation, which are identical with the target components for survey, are the minimum size of the portions for budget planning. We have determined 11 major building components for 'deterioration degree evaluation stage' and for trial survey; those components are 3 for architecture and structure, 4 for electrical and 4 for mechanical.

3.2 The structure of 'a method for prioritizing repair and renovation'

To prioritize easily the surveyed building components, we have introduced a digital comparison method which is made of evaluation items, judging criteria and deterioration degree evaluation sheets for 11 building components.

3.3 Development of 'deterioration degree evaluation stage'

Evaluation system in 'deterioration degree evaluation stage' is made after 'a guideline for judging criteria of repair and renovation' developed in 1988; which is a systematized and efficient method to judge small repair and large-scale renovation by evaluating deterioration degree at the first step survey and the second step survey and if judged as small repair, detailed repair method shall be investigated in each project.In the 'deterioration degree evaluation stage', the same evaluation concept is taken from 'a guideline for judging criteria repair and renovation'.

Also, the flowchart of 'deterioration degree evaluation stage' is developed after 'a guideline for judging criteria of repair and renovation'; it means that the second step survey will be conducted by the result of the first step survey. Consequently the deterioration degree for evaluation is the score of the final step survey that is applied.

3.4 Deterioration survey method

Deterioration survey consists of the first step and the second step if necessary and the fundamental contents of survey in each step are as follows;

a) The first step survey

It is conducted by an engineer who has common knowledge on architecture, electrical and mechanical. It is conducted without scaffold and is conducted by optical observation,palpation and conventional tools.

b) The second step survey

It is conducted by a professional engineer and is conducted mainly by optical observation and palpation. It is conducted with professional investigation instrument and/or destructive investigation, if necessary.

3.5 Deterioration degree evaluation sheets and judging criteria

To conduct the deterioration survey of the first step and the second step, deterioration degree evaluation sheets with evaluation items and judging criteria are developed. A sample of deterioration degree evaluation sheets, for reinforced concrete and steel reinforced concrete structure at the first step, is illustrated in Figure 2.

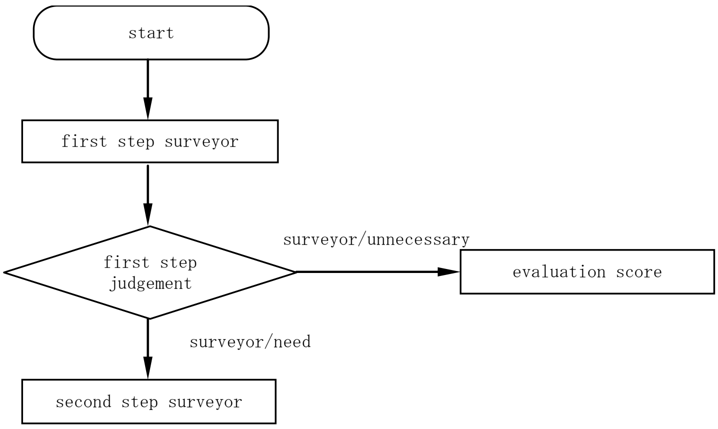

Figure 2 Flow chart

3.6 Development of 'prioritizing stage'

Based on the score of the deterioration degree evaluation sheet in the deterioration survey, 'prioritizing stage' has been developed. The priority of repair and renovation is determined not only the deterioration degree evaluation of a target component but considering items listed below to take account of high safety and continuous functional performance;

a) evaluation by the earthquake-resistance capability, including the grade for disaster

b) evaluation by the maintenance condition survey

c) evaluation by the building grade for daily use

d) evaluation by the fundamental building capability

Thus the evaluation score for prioritizing repair and renovation will be calculated by the following formula;

$$P_m=a(c_1\times Q_1+c_2\times Q_2+c_3\times Q_3+c_4\times Q_4)+b'\times \alpha_m\times L_m$$

P_m: repair and renovation priority score

Q_1: building criteria score for earthquake-resistance capability

Q_2: building criteria score for maintenance condition survey

Q_3: building criteria score for building grade for daily use

Q_4: building criteria score for fundamental building capability

a , b' , c_1-c_4 , α_m: weight coefficient

L_m : deterioration degree evaluation score

3.7 Conducting trial survey

A series of trial surveys were conducted nationwide at the regional bureau in 2005 and following issues were identified and reviewed.

a) The number of target components for deterioration degree evaluation sheets are not enough and they should be increased.

b) The number of evaluation items in evaluation sheet was so many that the average duration for survey was too long.

c) Deterioration degree evaluation sheet is so complicated that it caused many mistakes.

d) Evaluation items for different building components are not identical that it is questionable whether the evaluation sheet can maintain appropriate evaluation.

e) The second step survey took long time and high cost.

f) A formula for the evaluation score of prioritizing repair and renovation is so complicated that it is difficult to understand.

g) Prioritizing repair and renovation stage gives technical evaluation and maintenance condition survey is considered unnecessary.

Based on the issues mentioned-above, deterioration degree evaluation sheets, 'deterioration degree evaluation stage' and 'prioritizing stage' were reviewed and revised.

4. A revised method for prioritizing repair and renovation after a series of trial surveys

4.1 Increased target building components

Though at the start of the research, target building components for survey are determined 11, they should be increased to 82 as is illustrated in Table 1 to include most of the typical building components

Table 1 target building components for survey (excerpt)

construction	electric equipment	Heating, Air-conditioning and Sanitary
steel-frame reinforced concrete structure	electric light equipment(luminaire・wiring device)	direct fired absorption water heater chiller
reinforced concrete structure	clock system(time indicator)	refrigerating machine 又は chiller
steel structure	public address system	boiler
reinforced concrete block structure,other(structure)	lightning system(lightning protection system)	air-conditioner
roofing(bituminous membrane waterproofing)	telephone exchange system(private branch exchange)	cooling tower
roofing(exposed bituminous membrane waterproofing)	substation(circuit breaker)	air-conditioning duct
roofing(liquid-applied membrane waterproofing)	substation(disconnecting switch)	air-conditioning pipe
roofing(synthetic polymer roofing sheet waterproofing)	substation(transformer)	air-conditioning pump
roofing(other ( ))	substation(capacitor・reactor)	exhaust air duct
exterior wall(multi-layer finishing material)	substation(high voltage electromagnetic contactor・high voltage	fan
exterior wall(mosaic tile)	substation(cabinet)	smoke control fan
exterior wall(double sized tiles,mosaic tiles)	substation(DC power supply:rectifier)	smoke control duct

4.2 Revised survey method and 'revised deterioration degree evaluation stage'

Evaluation items in deterioration degree evaluation sheets were simplified and unified to give appropriate and equivalent evaluation as they were too complicated. And to maximize the role of the first step survey, periodical inspection record, legal inspection record, renovation and alteration record, accident and ill-condition information were added to review items for deterioration degree evaluation sheets.

With these revisions, most of the deterioration surveys on building components were completed at the first step survey. Then the first step survey and the second step survey became 'revised first step survey' and 'revised second step survey' respectively.

4.3 'Revised prioritizing stage'

Evaluation score formula for 'prioritizing repair and renovation' developed and reviewed in a series of trial surveys was revised, in consideration of issued identified in 3.7, to include building criteria, risk priority of each building components and deterioration degree evaluation score. The revised formula is;

$$P=Q+R+(a\times K)$$

P: repair and renovation priority score

Q: building criteria score for earthquake-resistance capability(35-75)

R: risk priority score of each building component in consideration of safety, disaster prevention, function and security (22-90)

a: weight coefficient (6)

K: deterioration degree evaluation score (0-45)

Varying weight coefficient (a) to investigate the appropriate relation among building criteria score, risk priority score and deterioration degree evaluation score, weight coefficient(a) was determined as 6 to present the proportional relation with repair and renovation priority score and deterioration degree evaluation score as is illustrated in Figure 3.

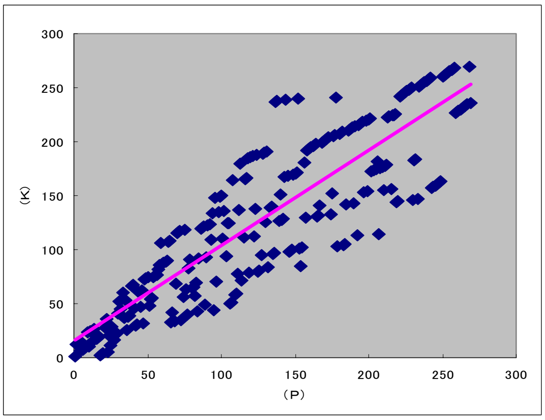

Figure 3 the relation with repair and renovation priority score and deterioration degree evaluation score

4.4 Long list

In a higher order of the scores of all the surveyed buildings and building components calculated by the evaluation score formula for ‘prioritizing repair and renovation’ evaluation, long list shall be prepared. In case repair and renovation priority scores (P) are identical, their priority shall be determined as follows;

a) in the order of higher deterioration degree evaluation score (K)

b) in the order of higher risk priority score (R)

c) in the order of higher building criteria score importance(Q)

d) in the order of larger total floor area

Table 2 example of long list

ranking	name of building	rigion	(P)	(Q)	(R)	weight coefficient	(K)
1	○○custom	exhaust air duct	333	35	40	6	43
2	○○local meteorological	electric light equipme nt	326	60	56	6	35
3	○○national government building	exterior wall(mosaic tile)	321	60	75	6	31
4	○○tax office	reinforced concrete structure	293	60	89	6	24

5. Revised second step survey(Professional survey)

Revised second step survey shall be applied to the specific building components that cannot be detected their potential defect or deterioration by the revised first step survey. Those building components are exterior walls, water supply pipes and drain pipes, and the survey methods applied are the technologies that are developed in private companies and are verified their technical credibility.

5.1 Exterior wall survey

In exterior wall survey, the revised first step survey is applicable to the portion where optical observation and palpation is applicable and the revised second step survey shall be applied to the remaining portion. Optical observation and hammer test with mobile elevating work platform is applicable to small buildings and infrared thermography method with infra-red camera is applicable to large buildings as is illustrated in Photo1 and 2.

Photo 1 hammer test

Photo 2 infrared thermography method

5.2 Water supply pipes and drain pipes survey

Though the exterior deterioration of water supply pipes and drain pipes can be detected by optical observation in the revised first step survey, the interior of them cannot be detected. As the detailed survey by cutting pipes will suspend water supply and hinder the occupants' life, X-ray photo method is applied to avoid cutting pipes.

Photo 3 X-ray generator

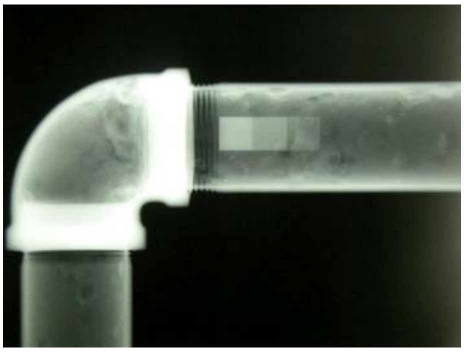

Photo 4 X-ray photo

6. Conclusion

6.1 Achieved result

The research on the deterioration degree evaluation of national government buildings has been advanced so far and the achieved result is;

a) The revised first step survey with deterioration degree evaluation sheet and optical observation, deterioration degree evaluation can be conducted by engineering staff of regional bureau of MLIT.

b) A systematic method of 'prioritizing repair and renovation method' in consideration of building grade, risk priority and deterioration degree evaluation has been developed and reviewed and confirmed to be effective.

c) As for the infrared thermography method, items listed below have been confirmed.

- Though the accuracy of the method is slightly lower than hammer test method, it can be applied for large buildings in shorter project period. As this method can be conducted without scaffold, mobile elevating work platform or hammering exterior walls, it can save the preparation period for occupant approval.
- This method cannot be applicable for the building portion where sun light is not uniform by reflection or shadow. Consequently, preliminary survey will be necessary to check obstacles and influencing buildings etc..
- This method is more applicable to voids finished with tiles or motor and cracks with water invasion than dry, fine cracks. For those deteriorations, optical observation and hammer test shall be accompanied.

d) As for X-ray photo detective method for pipes, items listed below have been confirmed.

- This method is applicable without cutting pipes or removing insulating material. As all the process of this method including developing is conducted in-situ, photos can be checked instantly and can be taken again if necessary.
- Stucks, bumps by corrosion as well as remaining thickness of pipes can be detected to forecast remaining service-life.

6.2 Issues to be discussed

MLIT is planning to conduct the first step and the second step surveys to review issues listed below.

a) Verifying the significance of deterioration degree evaluation score

As the relation of the score of deferent building components has not been discussed, following items shall be verified.

- How many score is the threshold for repair and renovation in deterioration degree evaluation score?
- Is the threshold for repair and renovation in deferent building components assumed to be identical ?

b) Additional second step survey

- For large-scale renovation, structural survey is important. Consequently, concrete compression tests and neutralization trial tests shall be conducted to review the problems and effectiveness of deterioration evaluation.

c) Feedback the second step survey to first step survey

- If the second step survey can feedback to the first step survey, it can save survey cost. Then the relation of the deterioration degree evaluation scores in the first step and the second step shall be reviewed.

DURABILITY OF BUILDING MATERIALS: MODELLING OF FREEZE/THAW PHENOMENA IN FIRED CLAY PRODUCTS

Marie Anne BRUNEAUX [1]
Georges WARDEH [2]
Bernard PERRIN [2]
Thierry VOLAND [1]

[1] Centre Technique de Matériaux Naturels de Construction, Clamart, France, ma.bruneaux@ctmnc.fr
[2] Laboratoire Matériaux et Durabilité des Constructions, INSA Génie Civil, Toulouse, France

Keywords: durability, fired clay, roofing tiles, freeze/thaw resistance, modeling, pore pressure, crystallization pressure

Summary

Fired clay products are formed by a porous media that is sensitive to frost action. During winter, products undergo several freeze-thaw cycles, sometimes associated with high water absorption. These lead to fatigue stress and progressive damage of the porous media. According to the nature of the clay and the processing method, the frost damages can take several forms, from chip to severe loss of mechanical strength. To optimize the parameters of fired clay processing and improve the frost resistance of fired clay products, a thermo-hydro-mechanics numerical code was implemented.

First, the strains in two roofing tiles were measured during freeze/thaw cycles. From the results, the pressure building up in the pores is calculated and the pressure of crystallization is identified. This step allows the pressure of the liquid phase to be deduced. For saturated products, it is concluded that the absorbed water is subjected to an overpressure during the freeze/thaw test.

By coupling the various mechanisms at the origin of the internal pressures developed in the roofing tiles, the the influence of the different products parameters (pore size distribution, permeability, modulus of elasticity and boundary conditions) is analyzed.

1. Introduction

Like all porous construction products, clay roofing tiles are sensitive to frost action and products exposed to cold climates can present progressive damage. When associated with high water absorption levels, freeze/thaw cycles provoke several forms of surface and structural damages, according to the nature of the clay and the shaping method, e.g. chips, scaling, flaking, delamination, cracking. The two latter damages traduce a severe loss of mechanical strength.

By experimentating with conditions of water absorption and temperature close to those generally found in situ, it is possible to reproduce the defaults that appear when tiles are frost sensitive. The saturation procedure, the kinetics and number of the freeze/thaw cycles are defined in a European standardized accelerated freeze/thaw test (method E from EN 539-2). In this test, a wet linen cloth is placed on the back side of the tile to create a temperature difference between the two sides of the product.

The motivation of this research is to identify and optimize the parameters of fired clay processing that are relevant for the improvement of the tiles frost resistance

The main parameters influencing the durability of fired-clay based materials submitted to freeze/thaw cycles are the characteristics of the clay body (Hansen 1988 and Maage 1984), such as porosity, modulus of elasticity, water permeability, as well as the boundary conditions imposed. The motivation of this research is, with the help of a numerical code being implemented, to determine the influence of these different parameters on the clay roofing tile ability to resist freeze/thaw cycles. In the future, optimization of the parameters will be conceivable and longer lasting fired clay roofing tiles will participate in building more sustainable houses. Moreover, minimizing energy consumption in the factory units without any loss in frost resistance will be possible.

In this work experimental results concerning the behavior of two models of fired clay roofing tiles are presented. In particular, the part of the total strains of the materials which is due to internal stresses generated by mechanical interaction between the solid skeleton and ice during its formation is determined. From it, the internal pressure generated by water and ice during freezing can be deduced.

2. Experimental study of freeze/thaw strains developed in roofing tiles

2.1 Materials

Two models of clay roofing tiles were selected on the basis of their different frost resistance and tested. They are referenced as CH3 and 2P2 (Wardeh 2004). CH3 is known for its excellent frost resistance whereas 2P2 is particularly frost sensitive.

The principal physical characteristics of the two materials were determined: they are presented in table 1.

Table 1 Physical characteristics of the tested roofing tiles

	CH3	2P2
Porosity: mercury intrusion test (%)	29.45	22.85
Mean diameters of pores (µm)	0.77	0.14
Specific area (m²/g)	0.8	3.1
Density	1.87	2.04
Modulus of elasticity (MPa)	8000	4000
Thermal conductivity (W/m.K)	0.46	0.56
Thermal expansion coefficient (K^{-1})	$6.6x10^{-6}$	$6.9x10^{-6}$
Permeability (m²)	5 to $6x10^{-15}$	2 to $2.5x10^{-16}$

The main differences between the materials are: their porosity, their chemical composition, their modulus of elasticity and their intrinsic air permeability. The porosity has been measured with a mercury intrusion porosimeter. CH3 is characterized by its greater porosity constituted of larger pores, resulting in a higher permeability. However, 2P2 has a broader distribution of relatively small pores resulting in a lower permeability.

2.2 Freeze/thaw resistance tests results

Each material was submitted to several freeze/thaw cycles according to the method E of the European standard EN 539-2 (Wardeh 2004). Two series of tests were conducted: tiles covered on the back side by a linen cloth (AT), or not (ST).

First, the roofing tiles are progressively saturated in water and covered by the cloth when needed. Then, they are placed in a freeze/thaw device where they are submitted to the freeze/thaw cycles. During each cycle, temperature of the material is first stabilized at around 15°C, dropping down to a temperature of -16°C, at a rate of approximately 7°C per hour. During the last step of the cycle, thawing is carried out by immersion in water, up to 15°C. Figure 1 represents the temperature evolution inside the CH3 tile, along with the temperature of the surrounding air, during the cycle.

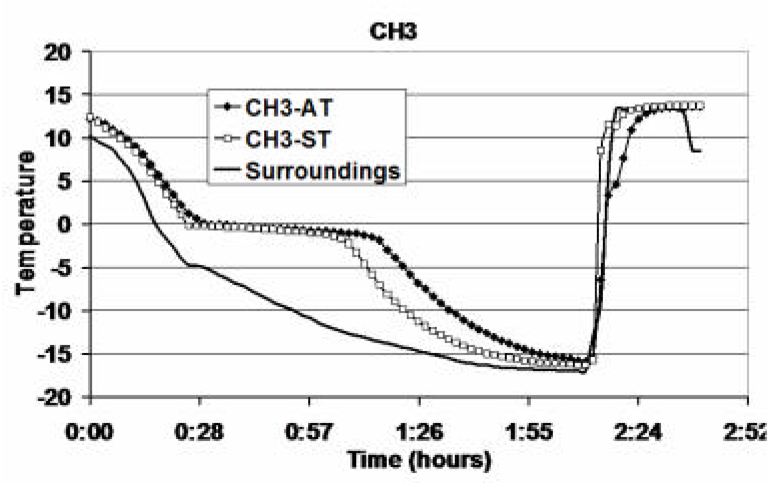

Figure 1 Temperature evolution in the CH3 tile, with (CH3-AT) and without linen cloth (CH3-ST) on its back side, along with the temperature evolution in the surrounding air (surroundings).

CH3 has a better frost resistance than 2P2: 2P2 displays more damages than CH3 after the same number of cycles. The presence of the cloth results in more cracks. The degradations occur mainly in the form of exfoliation and/or delamination. Whatever the position of the cloth on the tile, damages are always located at the same place. This observation certainly shows that the degradations show where the initial stresses concentrations are important. This factor seems to be more important than the dissymmetry induced by the presence of the cloth.

2.3 Experimental strains measured during the freeze/thaw cycles

The tiles were instrumented with strain gauges and temperature sensors in order to record the strains in all directions. During the test, the strain perpendicular to the thickness of the tiles was the more representative of the delamination of the clay body. The strains are presented in figure 2.

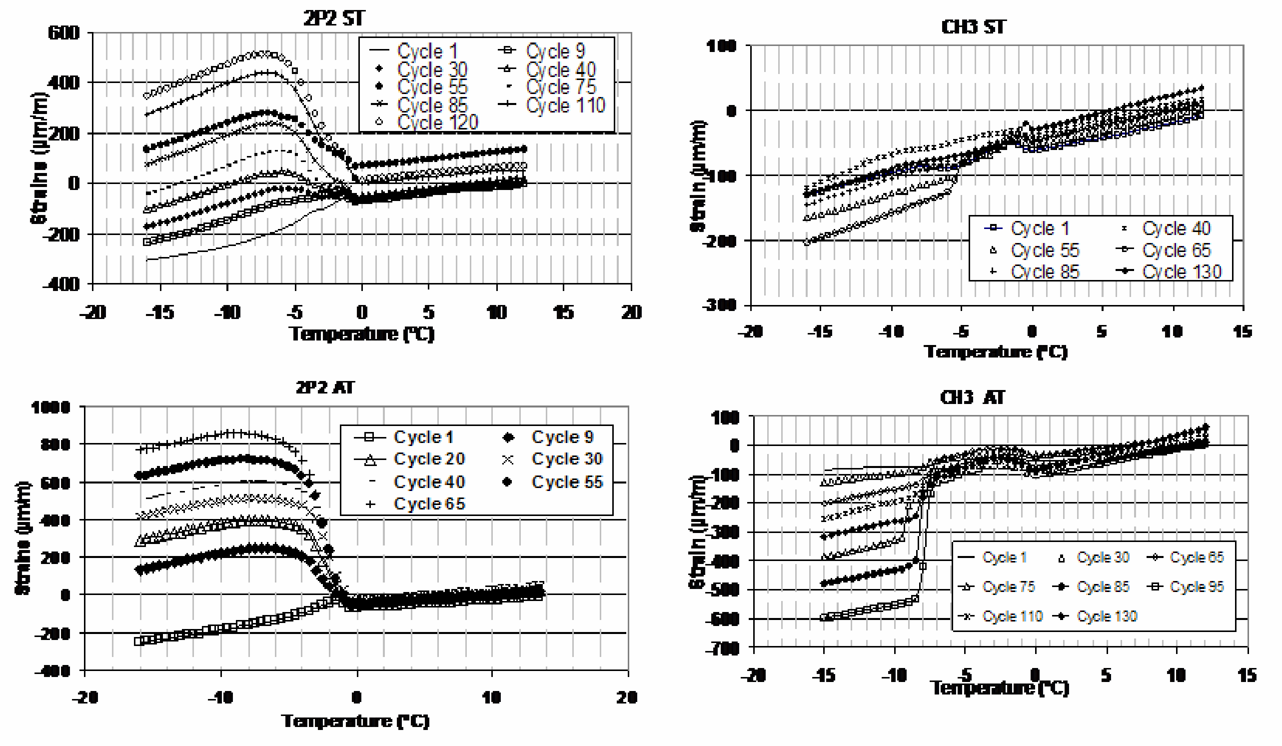

Figure 2 Strains measured in the thickness of the CH3 and 2P2 tiles, with (CH3-AT) and without linen cloth (CH3-ST) on their back sides.

The two models of tiles present very different behaviors: CH3 contracts more and more with the growing number of cycles, whereas 2P2 presents more and more expansion between the clay layers. When the back sides of the tiles are covered by the cloth, the strains are increased.

Furthermore, observation of the curves reveals the existence of three periods, corresponding to three temperature intervals.

Period 1: from 12°C to -0.5°C. Thermal contraction of the saturated material.

Period 2: from -0.5°C to -9°C. Progressive freezing of the water contained in the porous material. Large differences can be observed between the behavior with and without the cloth for both materials. At the beginning of freezing, CH3 stretches slightly from -0.5°C to approximately -2°C. After that, the strains are more or less stable according to the presence or absence of the cloth. Then there is a large contraction in the case of the material covered by the cloth, the contraction increasing with cycle number. As soon as the freezing process starts in 2P2, the gauge measures a large extension, which gradually decreases as the cycle progresses. This extension increases with the cycle number.

Period 3: from -9°C to -16°C. Linear strains due to thermal contraction of the fired clay in which all the pores are filled with ice.

3. Modeling of ice formation in fired clay materials

The model developed by Zuber (2000, 2002, 2004) was used to find the macroscopic strains starting from the knowledge of the pore size distribution. Modeling the behavior of materials during freezing implies a multi-scale approach as the occurring phenomena have to be described at both pore scale and macroscopic scale. At the pore scale, equilibrium between the phases of the interstitial solution was considered within the concepts of traditional thermodynamics. The material was then regarded as a continuous, completely saturated, porous medium. Finally, the relation between the transport mechanisms and the mechanical behavior was taken into account within the framework of the mechanics of continuous porous media.

The whole implementation scheme of the thermo-hydro-mechanics model can be found in Wardeh (2008). The physical basis of the hydro-mechanical model is the mass conservation equations of the solid matrix, water and ice. The constitutive laws of these three phases, combined with Biot's model and Darcy's law for porous media, allow the strains of the medium and the various phase pressures to be coupled. The mechanical equilibrium equation leads to the final system of equations, the resolution of which gives the space and time variations of the stresses and strains. The interest of the physical formulation is to provide an expression for the hydrostatic pressure related to the presence of the phases in the porous volume, in the form of a liquid pressure and an additional term corresponding to the presence of ice in the frozen pores which can be deduced from the pore size distribution.

3.1. Ice propagation within the pores

It is supposed that water and the ice coexist in the pores. When water freezes, the interface liquid/ice is propagating towards the not yet frozen zones. The conditions of this propagation are described by thermodynamic equilibrium between the phases liquid water 'and ice. The equilibrium conditions between the three phases present in the porosity are influenced by their interface curvatures, by the presence or the absence of species in the solution and by the pressure applied to the phases. The Gibbs–Duhem relation allows the description of the phenomenon, assuming that the medium is saturated with a non-pure solution.

It has been shown that the influence of pressure on the stability temperature as well as the degree of water purity can be neglected.

3.2. Interaction between ice and pore walls: expression of the crystallization pressure

A crystal at equilibrium, located in a large pore connected to another pore of smaller radius, neither tends to grow nor to melt. If the temperature is lowered, the crystal grows until it fills the pore volume. Consequently, it is assumed that the pressure in the crystal is controlled by the solid–liquid interface and the Laplace relation is applicable. In order to maintain mechanical equilibrium at the adsorbed layer–crystal interface, the walls of the pore have to exert a pressure on the crystal. This pressure can be expressed in the porous media by assuming that the ice–liquid interface at the entrance of the pore is spherical and that the pores have a cylindrical. The maximum pressure exerted by the fluid on the walls of a frozen pore is reached in large pores.

If a large pore is connected to several pores of different sizes, the maximum pressure will be determined by the radius of the smallest pore, because the liquid continues to flow through this channel until the crystallization starts in this small pore and blocks the flow. Therefore, the pressure in the pores is not uniform on a microscopic scale. It depends on whether the pores are frozen or not and the size of the neighboring pores.

However, at the scale of the continuous porous medium, in an elementary representative volume, this pressure intervenes only through a single value corresponding to an average value of the microscopic pressures in the elementary representative volume, called the mean pore pressure. This mean pore pressure in the elementary representative volume is obtained by weighting each pressure by the volumetric fraction of each given radius existing in the elementary representative volume.

3.3. Mechanical behavior of a saturated porous medium

The classical poroelasticity equations for an isotropic porous medium fully saturated by water were developed according to Biot. It is assumed that, at every point, the medium is occupied by both the solid and the liquid phases. Consequently, the total stress of the saturated material is divided into an effective stress carried by the solid matrix, and the stress carried by water, considered as a negative hydrostatic pressure.

The response of the medium to the applied stress is strains in the porous skeleton and the fluid. The linear elastic behavior of the drained medium (porous skeleton) is described by the traditional Hooke's law. The constitutive relation of the total strain combined with the equation of static equilibrium for a continuum gives a relation between the strains (or the displacements) in the porous skeleton, the volumetric forces, the temperature and the pore pressure.

3.4. Mass balance – constitutive relations and constitutive laws of the various phases

The former mechanical equilibrium equation contains two additional unknowns, the temperature and the pore pressure. These unknowns can be expressed by the balance equations for mass and energy. If the temperature is known, the only the average pore pressure must be determined. The resolution of the relation requires an additional scalar equation. This equation is provided by the conditions of mass conservation of the various phases present in the system under study.

The mass conservation equations are written for each phase (solid, liquid and ice). As far as the solid phase is concerned, it is considered that no solid mass creation is possible. The mass conservation equation can be simplified to the variation of porosity with time. For the liquid solution, the mass source term in the mass conservation equation is due to transformation of a part of the solution into ice during freezing. The mass rate of ice formation has to be defined, which can be done using Darcy's law. Finally, the mass conservation equation of ice is deduced assuming the medium is saturated. In this case, the mass source term is opposed to the one appearing in the liquid mass conservation equation. Moreover, it is assumed that the ice does not run out and its velocity is that of the skeleton.

Using the constitutive laws of the different phases, the state of each phase is described by a function of the temperature and pressure applied to it. This function is deduced through the expressions of the density variations of the different phases. Later, the density can be linked with the effective stress and the pore pressure.

3.5. Mathematical description of the porous media

Since the system is supposed to be saturated at all times, the general expression of the system equation can be written in the following simplified form:

$$\beta \frac{dP_l}{dt} = div\left(\frac{K_{rl}K}{\mu}\nabla P_l\right) + S - b\frac{d(tr\varepsilon)}{dt} \quad (1)$$

Where:

$$\beta = \frac{nS_l}{K_l} + \frac{nS_s}{K_s} + \frac{b-n}{K_m} \quad (2)$$

$$S = \left(\frac{1}{\rho_s} - \frac{1}{\rho_l}\right)\dot{w}_{l\to s} + \overline{\alpha}\frac{dT}{dt} - \frac{b-n}{K_m}\frac{dX}{dt} - \frac{nS_s}{K_s}\frac{dk_s}{dt} \quad (3)$$

$$\overline{\alpha} = nS_l\alpha_l + nS_s\alpha_s + (b-n)\alpha_0 \quad (4)$$

$$b = 1 - \frac{K_p}{K_m} \quad (5)$$

$\dot{w}_{l\to s}$ is the mass rate of ice formation,
a_0 is the volumetric coefficient of thermal expansion of the drained material,
K is the intrinsic permeability,
K_{rl} is the relative permeability,
μ is the dynamic viscosity of liquid,
ε is the strain,
K_p is the bulk modulus of the drained material (porous material),
K_m is the bulk modulus of the solid matrix,
b is Biot's coefficient,
n is the porosity of the porous media,
S_i is the degree of saturation of the phase i (s = solid, l = liquid),
ρ_i is the density of the phase i,
K_i is the isothermal modulus of compressibility of the phase i,
a_i is the isobaric coefficient of volumetric thermal dilation of the phase i,
k_s is the curvature of the solid–liquid interface,
X is the additional pressure due to the presence of ice,
P_l is the liquid pressure.

The major term in this relation is the term S, defined as the term responsible for the liquid pressure generation. This term integrates a number of physical phenomena such as: the difference of density between the liquid water and the ice crystal, the thermal contraction effects on the drained medium and the other components, the disjunction pressure representing the interaction between ice crystal and pore walls, and the pressure of the ice crystal.

The problem to be solved is to check that the system of equations below holds for all points and all times:

$$\begin{cases} \nabla\sigma = 0 & (6) \\ \beta\frac{dP_l}{dt} - \nabla\left(\frac{K}{\mu}\nabla P_l\right) - S + b\nabla\frac{du}{dt} = 0 & (7) \end{cases}$$

The unknowns of this problem, which can be solved by the finite element method, are the displacements and the liquid pressure at each point.

The final step is to define the boundary conditions. It is assumed that the ice is formed on the external surface of the sample and that its pressure thus remains equal to the atmospheric pressure. The liquid pressure consequently undergoes a depression given by the following relation:

$$P_l = -\frac{2\gamma_{ls}}{R_{eq}} \quad (8)$$

Where γ_{ls} is the surface tension of the ice–liquid interface and R_{eq} is the radius of the interface at equilibrium.

The physical characteristics of the materials studied as well as of water and ice, are necessary in order to solve this system.

4. Numerical simulations, results and discussion

The objective of this study was, on the one hand, to study the influence of the physical parameters such as porosity, permeability and modulus of elasticity for a standard material and, on the other hand, to test the aptitude of this numerical model to describe the behavior of fired clay materials.

4.1. Influence of the different parameters of the porous media

4.1.1. Pore size distribution

Five different pore size distributions giving the same total porosity were tried. The modulus of elasticity, the permeability, and the coefficient of thermal expansion were taken to be the same for the five distributions and fixed at representative values of the physical characteristics of fired clay materials.

It can be seen that, as the pore diameter decreases, the temperature of ice formation decreases while the medium undergoes an increasingly significant relative dilation and the magnitude of variation of the average liquid pressure increases. Everything else remains unchanged.

For a given distribution, the liquid pressure reaches its minimum at the same time as ice begins to form. As the liquid pressure increases with temperature, a cryo-suction phenomenon can be induced. It appears as if the temperature is not uniform. Water then moves from high pressure (and high temperature) towards low pressure (and low temperature), where it transforms to ice first. During the progressive development of ice, the pressure in the liquid in contact with the ice crystals increases, and an opposite water movement must then occurs. The ice volume increase controls the water movements thereafter.

4.1.2. Permeability

When the permeability is low, the average pressures become significant after ice formation. The apparition of hydraulic pressure involves a water flow opposed to the water pressure gradient. If the low permeability impedes the water movement, the resulting strains and liquid pressure will be significant.

4.1.3. Porosity

The S term responsible for the liquid pressure generation is strongly influenced by the value of the porosity. The higher the porosity, the more significant the S term. This phenomenon is simply explained by the fact that, as the porosity increases, the quantity of water increases, and the quantity of ice formed during freezing is also increased.

Concerning the X term, that is to say the additional pressure due to the presence of ice, it shows no variation since it is directly related to the radius of the pores and not to the porosity.

The strains and the average pressures become higher as the porosity increases.

4.1.4. Boundary conditions

The influence of the boundary conditions was evaluated by varying the magnitude of the liquid pressure imposed on the surface of the porous media. The tested values correspond either to water or to ice at atmospheric pressure. An intermediate situation was also evaluated.

The results of the numerical simulations show that the behavior is strongly related to the pressure imposed at the surface. The change of state of the liquid at the boundaries of the porous media implies a change of behavior of the medium, with accentuated strains.

4.2. Application to clay roofing tiles

As far as the two tested models of tiles CH3 and 2P2 are concerned, the pore size distribution, the porosity, the kinetics of ice formation and the strains developing during the freeze/thaw test were experimentally characterized and recorded (figures 2, 3 and 4). It can be observed that the pressure exerted on the pore walls of the 2P2 is higher than the one exerted in the case of the CH3 since the pores of the 2P2 are smaller.

The mechanical and hydraulic characteristics and the pore distribution being identified, it remained to impose the boundary conditions during ice formation. As the numerical code does not consider all the phenomena involved at the boundaries (e.g mass exchanges between the environment and the tiles such as water absorption), it cannot provide a realistic resulting liquid phase pressure. Therefore, it was chosen to impose on the external border of the tile the liquid pressure deduced from the experiment. The results are presented in figures 5 and 6.

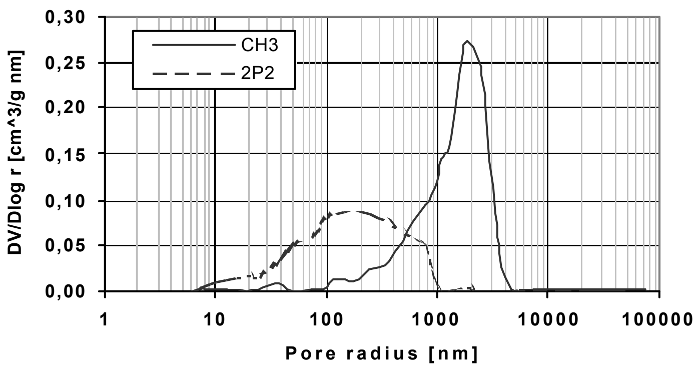

Figure 3 Pore size distributions of the two tested tiles: 2P2 and CH3.

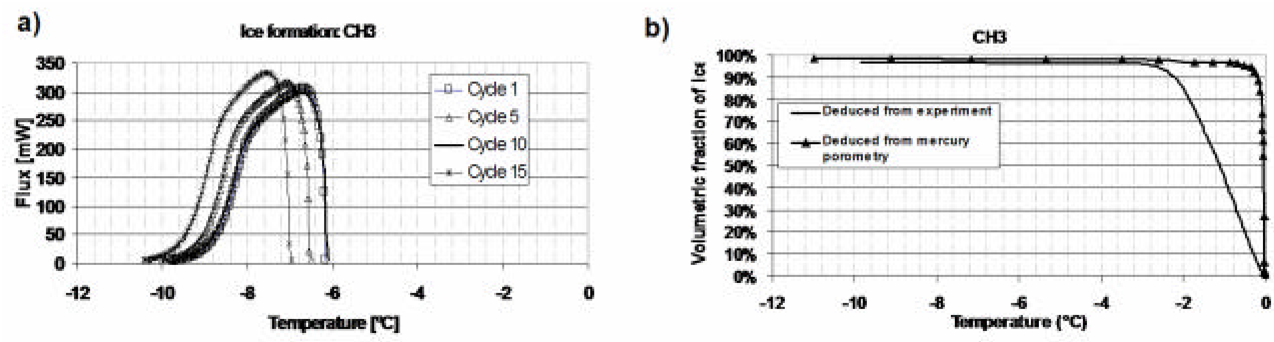

Figure 4 Ice formation: a) in CH3 tiles for different freeze/thaw cycles as obtained by DSC – b) Volume fraction of ice as a function of temperature, deduced from experiments and mercury porometry.

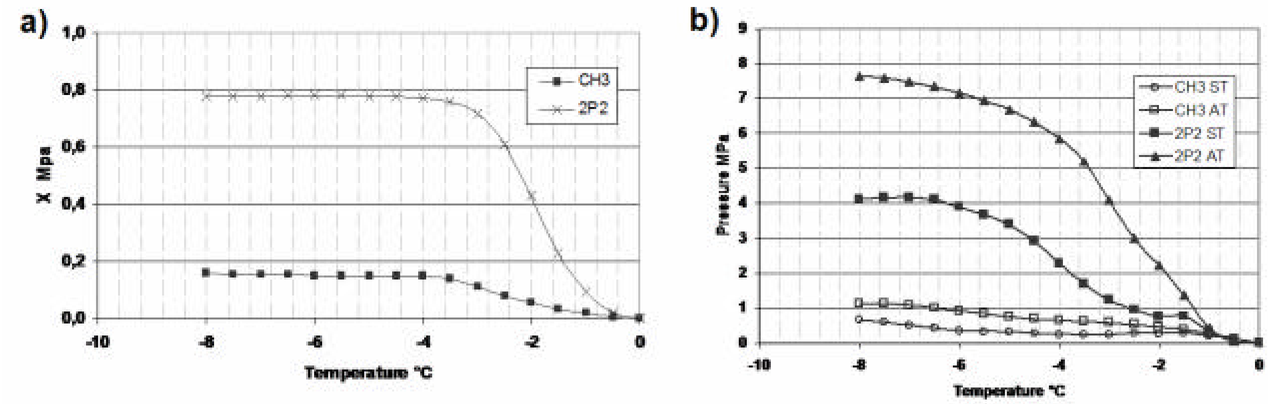

Figure 5 Numerical results obtained by the system for the two tested tiles: a) Additional pressure due to ice formation (e.g. X term) – b) Liquid phase pressure (e.g. corresponding to the S term).

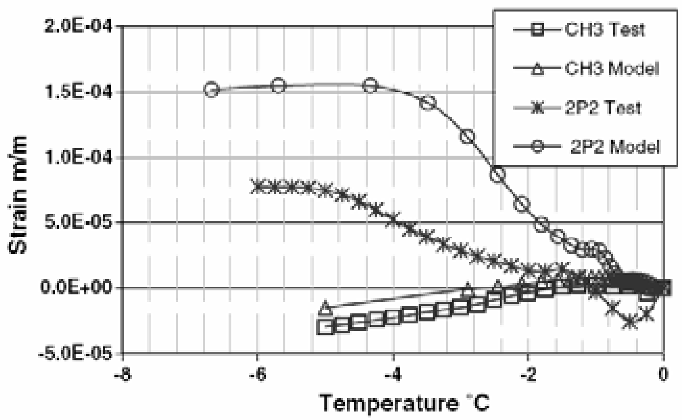

Figure 6 Numerical strains obtained by the system for the two tested tiles by imposing on the boundaries of the liquid the pressure deduced from the experiment.

The numerical model shows difficulty in reproducing exactly the experimental behavior. However, it is a very interesting qualitative tool for studying the behavior of porous media such as fired clay subjected to freeze/thaw cycles. Threfore, the study of the influence of the most significant parameters (e.g. pore size distribution, modulus of elasticity, and liquid permeability) becomes possible.

5. Conclusions

The implemented numerical code constitutes a very interesting qualitative tool for studying the behavior of media subjected to freeze/thaw cycles. Therefore, it was possible to study the influence of the most relevant parameters, such as pore size distribution, modulus of elasticity, and liquid permeability on a material with fictitious porosity but displaying mechanical characteristics close to those of the tiles. Its implementation for the tested 2P2 and CH3 tiles does not yet correctly reproduce their experimental behavior during freeze/thaw cycles. Although the physical model on which the code is based is one of most complete currently in existence, it still has some limitations related to the simplifications it contains. Indeed, in the case of saturated media, the code does not take into account all the exchanges at the boundaries of the material. Finally a comparison between calculations and experiment highlighted the importance of the boundary conditions, as well as the liquid permeability of the medium. Complementary experiments are currently being done at the CTMNC to improve the code and compare the results of the numerical simulations with experimental data from fired clay tiles displaying a wide range of characteristics. The objective is to obtain a quantitative tool to predict the freeze/thaw behavior of fired clay roofing tiles.

Once the code has been validated, it will be possible to estimate the freeze/thaw resistance of fired clay products and to optimize their characteristics in order to produce longer lasting roofing tiles, to build constructions with longer lifespan. Moreover, by adjusting the physical properties of the fired clay to respond to their intended use, minimization of the energy consumption in the processing unit will become conceivable.

REPORT ON STUDIES CONDUCTED TO IMPROVE THE QUALITY OF AIR TIGHTNESS IN MASONRY BUILDINGS FOR SUSTAINABLE BUILDINGS

Olivier DUPONT arch.DPLG[1]
Daniel PALENZUELA Ph.D[1]

[1]Centre Technique des Matériaux Naturels de Construction, 17 rue Letellier, 75015 Paris, France, o.dupont@ctmnc.fr

Key words: Sustainable, building, masonry, clay, block, monomur, air tightness

Summary

1. Research objectives

Construction choices and interfaces between components that make up the outer walls of a building have a major influence on its global thermal performance, especially in the case of masonry structures (ADEME *Agency for the Environment and Energy Management* study "test campaign of housing air tightness 1999-2000").

A further study conducted by the CTMNC (TECHNICAL CENTRE FOR NATURAL BUILDING MATERIALS) consisting in numerous measurements of air tightness in individual houses built all over France since 2000, aims to make a strong contribution to the design and creation of energy and resource efficient habitats with low environmental impacts. Wall construction systems consist in either clay Monomur blocks (Clay monolithic block without added insulation) with no additional insulation or masonry walls lined with a clay backing wall covered on the inside with plaster.

Test campaigns have enabled the definition of recommendations concerning the choice of masonry finishes, treatment of window junctions, weatherproofing of rolling blinds, the wall/roof junction and all other openings in the walls. These measures allow us to achieve today a permeability of less than 0. 65$m^3/h/m^2$ under 4Pa.

This quality approach to air tightness of buildings has translated today into a demand for certification of compliance with new French thermal regulations (decree of 24th May 2006, appendix VII) supported by technical specifications that enable us to achieve a level of permeability inferior to 0.65$m^3/h.m^2$ under 4Pa.

2. Permeability test campaigns

From June 2000 to December 2007 the CTMNC conducted, with joint research teams from the CETE of Lyon -Laboratory of Autun (specialised in technical tests of equipment), 8 test campaigns concerning air

permeability of individual house envelopes using a significant sample of more than 40 housing units located all over France.
The tests concerned air permeability of the overall building envelope based on measurements obtained using a "blower door" system. Tests were carried out using a test protocol in compliance with European and French standard NF EN 13829. The principle consisted in artificially depressurising premises and then measuring leakage. The "blower door" is set up in place of an outside opening (front door…). It is installed in such a way as to ensure the air tightness of the opening. Test preparation is completed by blocking all voluntary openings in the envelope of the different houses. Permeability of a house's envelope can be measured once the "blower door" is completely installed with a ventilator as well as a control unit and data acquisition system.

Example of report	**Intervention site and ID N°**	**Intervention date**	**Type of construction**
Case N°12671	**CUGAND (85) France B2000-5**	**27th June 2000**	**Monomur**

Individual single-story house located at Le hameau des Giraudelles, 85610 Cugand FRANCE
Private construction client: Mme XXXX
This house is not totally finished.

Heated volume in m³ (1)	**Heat loss areas in m² (2)**	**Area of openings in m² (3)**	**(1) (2)**	**(3) (1)**	**(3) (2)**	**Permeability under 4 Pa[1] m³/(h.m²)**	**ACH (10)[2]**	**Equivalent leakage area (in cm²)**
211	196.72	11	1.07	0.052	0.056	0.14	0.25	52

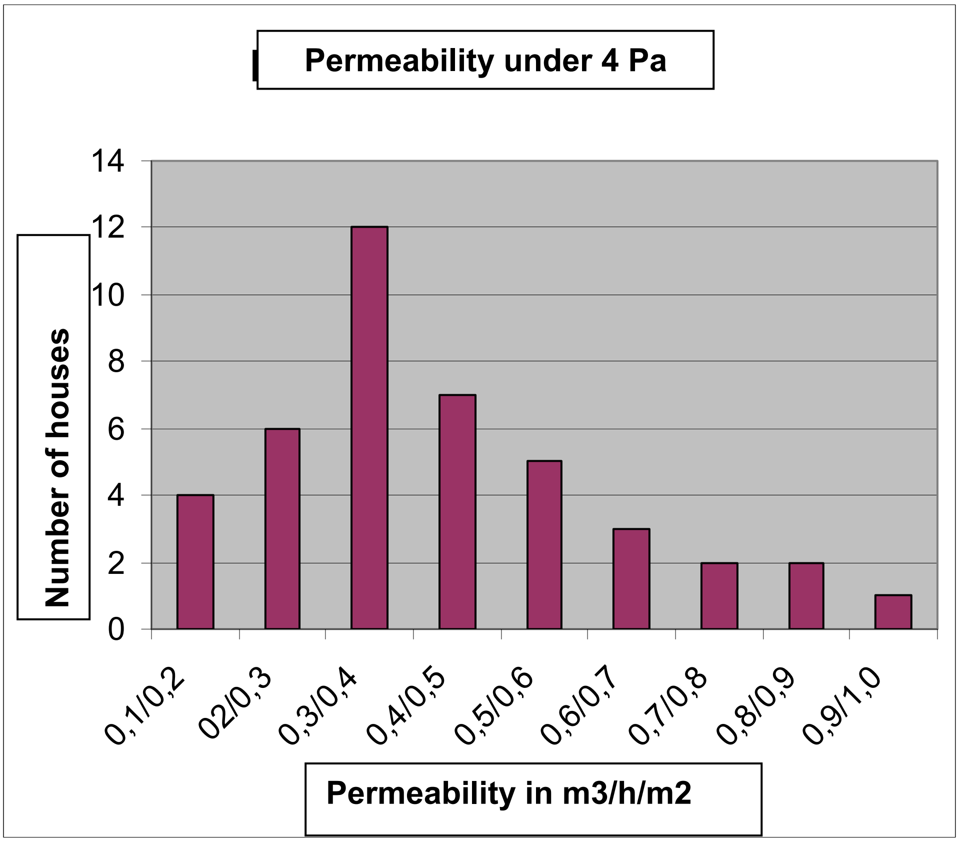
P≤0.2	0.2<P≤0.4	0.4<P≤0.7	0.7<P≤0.9	0.9<P≤1.3	P>1.3
Excellent	**Very good**	**Good**	**Average**	**Poor**	**Unsatisfactory**

Excellent permeability under 4 Pa =0.14 m³/(h.m²)	**Regulatory threshold = 0.8 m³/(h.m²)**
Location of outside air penetration points	**Type of leakage[3]**
-Living room: wall-mounted lighting fixture	!
-Water pipe in living room (30 cm x 5 cm hole), wall/floor junction The hole was filled during the tests; this defect will be repaired	!!!
-Kitchen electrical outlet	!

[1] According to article 15, decree of 29/11/2000.
[2] Air renewal rate under 10 Pa
[3] Intensity of leakage: ! Low !! Medium !!!Strong !!!Very strong

Important remark: the measurements of the air tightness value used in calculating regulatory compliance were made in houses that had no special treatment except that the walls had been plastered on the inside (either Monomur or with clay backing). Measurements were carried out in several regions and houses were only selected according to "availability" during the CETE test campaigns. They are therefore representative of typical French constructions.

Test campaign synthesis;
Values obtained by the CETE (*Centre d'Etudes Techniques de l'Equipement*). These values were also obtained using ALDES equipment.



The mean of these 42 values is 0.43m3/h.m2
The fractile 85 is 0.65m3/h.m2

3. Establishing quality standards for air tightness of buildings

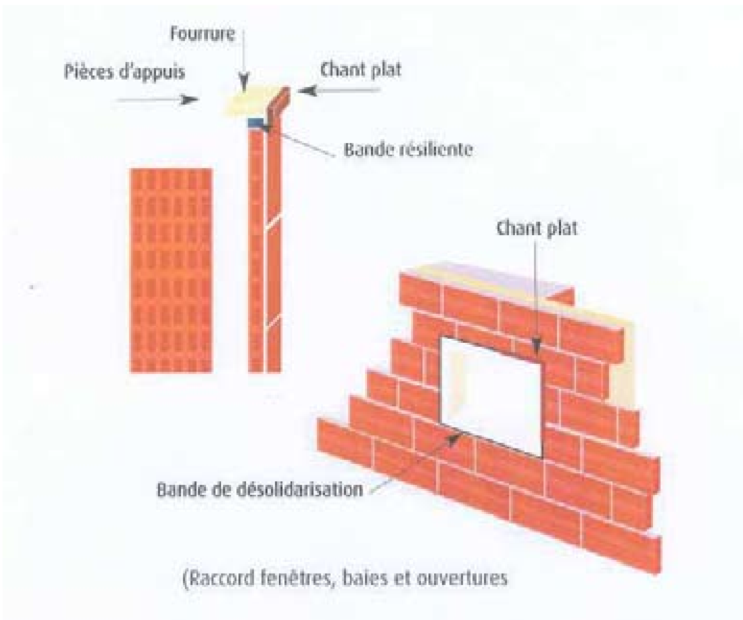
The standards proposed by the CTMNC and the FFTB (French Federation for Roofing Tiles and Bricks) aim to deal with the most common forms of leakage encountered in the construction of individual homes all over France. Wall construction systems consist either in Monomur brick walls or masonry walls lined with clay backing.

For the construction of an individual house, the customer or builder specifies at the start of construction that the building will be carefully monitored for air tightness. He agrees to provide craftsmen with the complete list of standards even if they are only concerned by part of these measures. Indeed, we believe it is important that all parties involved in the construction project are aware of their roles as well as the roles of others so as not to hinder each other's work. The customer, or his representative, will check these measures himself.

The following measures will be applied:

- Monomur clay blocks or clay backing walls will be plastered on the inside in order to prevent air leaks at structural junction points.

- Windows will be classified A*E*V* level A*2 minimum with improved permeability (French AEV classification in compliance with standard FD P 20-201 indicated the air tightness of the window (A), water tightness (E) and wind resistance (V) on a scale from 1 to 3, 3 being the highest level of efficiency).
- For installation of flush or recessed window casings, the inside or reveal must be levelled if the evenness does not comply with standard DTU 20.1. The weatherstripping joint must always be placed at the junction of the window frame and the carcass.
- Housings for rolling blinds: weatherstripping is placed at the junctions of the housing and the carcass and the window/door frame.
- Wall/roof junction
  There are two possible cases:
  The ceiling is also plastered: no special measures required
  The ceiling is in plasterboard: taping between the board and masonry before applying plaster.
- All openings in walls providing access to the outside or an unheated room will be finished with weatherstripping.



These measures enable us to obtain a value of 0.65m3/h.m2 without testing at the end of construction.

BUILDING CERTIFICATION SYSTEM ACCORDING TO SUSTAINABLE BUILDING TOOL: ITALIAN EXPERIENCE

Giuseppe PICCOLI Dr.Eng.[1]

[1] iiSBE Italy, Turin, Italy, giuseppe.piccoli@iisbeitalia.org

Keywords: Sustainable Building Certification System, Accreditation System, Green Building Challenge, ITACA Protocol, Italian Regions, SBTool, Standardization

Summary

The assessment systems which are available, can define the level of the sustainability of the buildings but do not guarantee the private and public stakeholders with a defined responsibility for the certificate.

It is necessary to develop a certification system which identifies the process, the roles and responsibility in order to assess and certify, and define the certification procedures to obtain the certificate.

In Italy many certificates are issued both in the private and public sectors in accordance with the SB Method and the certification system which is available.

ITACA is a Federal Organization of the Italian Regions, which approved an assessment tool named "ITACA Protocol" in accordance with the SB Method that is used in assessment and certification systems by many Regions. The performance levels of sustainability in buildings are used to promote and finance public and private building.

This Tool should assess sustainability of residential buildings at 3 levels of complexity. The "ITACA Protocol" identifies criteria divided into two important areas, resources consumption and environmental impact, in accordance with European and Italian regulations and norms.

The structure of the Certification Scheme identifies the process and the roles of ITACA, the Italian Regions and iiSBE Italy.

ITACA should define strategic guidelines, supervise certification systems and guarantee the upgrade of the assessment tools.

Italian Regions should define their own procedures of certification and accreditation systems and identify the responsibility to issue the certificates.

iiSBE Italy established a written agreement with ITACA in order to support the Italian Regions to define and apply the assessment and certification system.

1. From the Assessment to the Certification

The Assessment Systems which are available, can define the level of the sustainability of the buildings but do not guarantee the private and public stakeholders with a defined responsibility of the certificate.

It is necessary to develop a Certification System which identifies the process, the roles and responsibility in order to assess and certify, and to define the certification procedures to obtain the certificate.

The Accreditation Scheme promotes the adoption of a process approach when developing, implementing and improving the effectiveness of a certification system.

The Accreditation Scheme guarantees that the Certification Process and the Evaluating Team's competences meet the requirements defined to assess and certify the Sustainability of the Built Environment.

In Italy many certificates are issued both in the private and public sectors in accordance with the SB Method and the available certification system.

ITACA is a Federal Organization of the Italian Regions, which approved an assessment tool named "ITACA Protocol" in accordance with the SB Method that is used in assessment and certification systems by many Regions. The performance levels of building sustainability are used to promote and finance public and private residential building.

ITACA has established an agreement with iiSBE Italy to support the Regions to develop and maintain the public certification system.

1.1 Sustainable Building Assessment System

The Sustainable Building Assessment System is performed through Assessment Methods to define the potential environmental impacts of the building.

The Guidelines to define a Sustainable Building Assessment System identify two important instruments:

- Assessment Tool
- Assessment Process

The design and implementation of an Assessment Tool is influenced by several needs: the particular destination of the building, the building phase, the local context and the size and structure of the building.

The application cases can be:

- design of a new building,
- refurbishment of an existing building,
- improvement of operations,
- operating building
- planning for modernization
- planning for demolition and waste management.

The Assessment Process includes the review of the documentation, the definition of the tool requirements data, the application of the assessment procedures and an analysis and report.

The Assessment Process, that uses the Assessment Tool, shall be organized in an Assessment System which can be improved in order to verify the results of the application experiences.

The stakeholders of the Assessment System can be investors, owners, developers, designers, builders, suppliers of building materials, users, occupants, facility managers, operators, sponsors, insurance companies, real estate brokers and governmental agencies.

The application of an Assessment Process to measure the building sustainability should be a strategic decision made by customers or interested parties.

The results of the Assessment Process provide a reference as a common basis for owners, design teams, contractors and suppliers who can define effective performance strategies.

The design process can be assisted by the Assessment Process to define the key environmental considerations and support the team to a results.

Another important issue is to be able to communicate and promote the built environmental quality, which is useful to design the certification system as activities and procedures to get a certificate.

1.2 Qualification Process of the evaluating team

The Evaluating Team should be a group of individuals who seek to have all relevant knowledge and skills available to the Assessment Process.

The competences of the evaluating team should allow to be able to use the Assessment Tool and apply the Assessment Process.

The training process of the evaluation team should be designed in order to develop and maintain the theoretical competences and practical applications.

The periodic re-qualification process of the team guarantees the assessment process quality results over time.

In order to qualify the trainers, the training process should be specified and designed according to the contents and methodologies to manage the Assessment System.

The courses for the evaluation team, followed by a final exam, shall be organized and held by the local chapters.

The accreditation system manages the qualified evaluators register and identifies the process of the supervision of the evaluators' re-qualification process.

1.3 Certification System

The Certification System is an structured ensemble of methods, tools, procedures, roles and responsibilities to give performance measures, to apply the assessment system, to get a certificate and to communicate the results.

The diffusion of sustainable building and the recognition of the best works for performance and cost reduction are two such good practices.

Gathering and organising information on good works can be used to lower operating, financing and insurances costs and can increase marketability.

The administration of public housing can check and evaluate building performances to finance public housing programs aimed at the socially and economically weaker segments of the population.

The availability of a certification system shall permit the estate market to tweak the market demand towards high performance buildings that can guarantee a higher return on investment and lower management costs.

In order to design and develop the certification system many important characteristics to meet requirements shall be identified.

The assessment method shall be based on scientific elements, depending on the climatic, social, economic and cultural context of the nation and region where the building is located.

The correlation to an internationally recognized system aims to bridge the gap between national and regional methods and provide a common framework for their expression.

The best practices concerning the assessment and certification system which exist in a regional context can be taken into consideration to improve the national system.

The certification system must be designed and developed in order to ensure that all of the scientific and technical characteristics, the methodology and procedures, the organizing system and the process should achieve very high levels of performance.

The indicators for the assessment process may be either qualitative or quantitative information and the quality of entry data must be checked because it will influence the results.

The certification system should be economically, financially, technically, environmentally, and socially sustainable.

The success of a certification system depends on its own capability to involve common stakeholders in the process and lead all parties to the results. The procedures must be easily applicable and available and the management control must be effective.

The cost of the system must be correlated to the activities and the resources needed. Continuous improvement activities must be planned to reduce the costs and improve the efficiency of the system.

The certification system must be able to maintain and improve its characteristics over time. The process of monitoring the performance and of the evaluation of the effectiveness of the system must be available.

For this document, a Certification Body is a qualified organization accredited by an Accreditation Scheme to perform the assessment process of sustainable built environment evaluation and to register the audited buildings.

Certification Bodies should meet the requirements of accreditation guidelines. The most important roles of the Certification Body are to design and maintain the certification process, provide technical support in the adaptation of the assessment tool to the local context and support the upgrading of the tool.

The roles of the Certification Body are to manage the contract whit the customer, identify the evaluation team, do assessment activities, validate the certificate through an accrediting body and update the certificate register.

The contribution of the Certification Bodies should focus on the continuous improvement of overall performance and efficiency, as well as the effectiveness of the system.

2. Accreditation Scheme Guidelines

For this document, an Accreditation Body is an organization with authority to accredit Certification Bodies to issue sustainable built environment certificates.

The roles of the accreditation body shall be to define the following strategic guidelines, develop certification and accreditation procedures and apply the process to qualify and re-qualify evaluation teams and procedures to monitor and evaluate the effectiveness of the certification system in meeting customer requirements.

The Accreditation Body shall update the Register of accredited bodies and oversee the certification bodies' activities.

The Accreditation Scheme promotes the adoption of a process approach when developing, implementing and improving the effectiveness of a Certification System.

The Accreditation Scheme concerns 4 main steps defined in a structured process which include roles and responsibilities of the accreditation and certification bodies:

Step 1 – Define Assessment Process

Step 2 - Define qualification process of the Evaluating Team

Step 3 – Identify Certification Body roles

Step 4 – Identify Accreditation Body roles

2.1 Step 1 - Define Assessment Process

The activities to define Assessment process are:
define the Strategic Guidelines. Identify assessment tool and procedures of the Sustainable Built Environment Assessment Process. Upgrade the assessment tool. Oversee the application of the Tool and procedures.

2.2 Step 2 - Define qualification process of the Evaluating Team

The activities to define qualification and re-qualification process of the evaluating team are:
define the competences of the Evaluating Team. Specify training process of the Evaluating Team. Qualify the trainers. Design the training process (Contents and Methodology). Hold the courses followed by final exam. Oversee the Qualified Evaluators Register. Supervise Evaluator's Requalification Process.

2.3 Step 3 - Identify Certification Body roles

The activities to identify the certification body roles are:
define minimum requirements of the Certification Body. Define process and procedures to obtain the Certificate. Identify Roles and Responsibilities in order to Assess and Certify. Define the Guidelines for Certification System. Guarantee that the Guidelines are followed.

2.4 Step 4 - Identify Accreditation Body roles

The activities to identify the accreditation body roles are:
define Accreditation Process to accredit Certification Bodies. Define Roles and Responsibility for the accreditation Process. Define the Procedures of Accreditation Scheme. Upgrade Register of Accredited Bodies. Monitor the Certification Bodies' activities. Define the Guidelines for Accreditation Scheme. Guarantee that the Guidelines are followed. Monitor and Evaluate the Accreditation Scheme.

3. Italian Certification System

At the present in Italy we have issued many important certificates for sustainable built environment.

These certifications have been of two types :

1. SB Method Certification System for Private Buildings
2. "ITACA Protocol" Certification System for Public and Private Buildings

3.1 iiSBE Certification System

The Scheme of the Certification System based on SB Method covers the iiSBE certification process applied in Italy to private buildings.

The model of a process-based certification system shows connections between the customer and iiSBE Italy.

The Customer characterizes the building on the basis of its construction and dimension data, function and life state and provides requested documents and data.

The document review determines if the documentation of the building meets all requirements of the assessment tool defined for each particular application with regard to the data input required. If the data are not satisfactory, the customer makes the necessary revisions.

The assessment process determines the degree and effectiveness of the performances of the building. In this phase it is necessary to establish the evaluation team's competences, organize the team, plan the activities and conduct the assessment. If the assessment is not satisfactory, the evaluation team repeats any necessary activities. After analysis and report reviews of the assessment procedures, the accreditation body shall confirm the process. The validation procedures are a confirmation by examination and provision of the evidence that the performance requirements of the building have been fulfilled.

Fig. 1 shows the certificate issued to one of most important commercial organizations located in Italy. This organization, named Coop, manages locations all over Italy and planned the certification process of its Sesto Fiorentino plant, near Florence. The building had been in use for two years. The GBC tool defined 6 areas of assessment and identified many criteria according to the Italian regulations and norms. iiSBE Italy was supported by two scientific partners: ITC-CNR, Italian Research Council and Environment Park of Turin, to define the context and apply the assessment tool.

The certificate issued identified the performance level of the building and established the date of issue and the date of expiry (5 years from issuing). To keep the certificate valid over time, it is necessary to repeat the assessment before this expiration date.

iiSBE Italia is collaborating with the most important stakeholders from the private sector performing building assessment on office buildings, hypermarkets, schools, etc...

At this moment it is in charge of the certification of the two major new skyscrapers that will be constructed in Italy (Turin) in the next 5 years. The first tower will be the Regional Government Headquarters, and the second one will be the Intesa-San Paolo banking Group Headquarters. The certification process will be performed on design, construction and operation phase.

The application of SB Method and ITACA Protocol is generating a demand of training and education from professionals, from technicians of the private and public sectors. iiBSE Italia, in cooperation whit several architectural and engineering institutes and with educational institutes is carrying out training courses on Green Building and ITACA Protocol application in several Italian Cities.

An Information Center on Green Building for public and private organizations is available to provide technical support for the Sustainable Building Certification process. A web-site provides the collection of all data of Italian and international information related to sustainable building.

Conferences, seminars and workshops on Green Building are organized by iiSBE Italy in cooperation with other public and private organizations to spread and promote Sustainable Building in Italy.

iiSBE ITC ENVIRONMENT PARK

Il presente certificato è soggetto al rispetto del regolamento per la certificazione del livello di sostenibilità ambientale definito da iiSBE

3.2 ITACA Protocol Certification Scheme

ITACA is a Federal Organization of the Italian Regions which is competent for Sustainable Building. In 2004 ITACA approved an Assessment Tool named "ITACA Protocol" in accordance with the GBC and SB Method. This Tool should assess sustainability of residential buildings at the different levels of complexity.

For the Italian Constitution, energy and environment fall in to the competence of the Regions and a regional law on energy and environment has priority on national ones.

That means that the ITACA Protocol is a national labeling system recognized from all the Italian Regions as appraisal system both for public and private context.

The Ministry of Environment and the Ministry of Productive Activities are including the ITACA Protocol as a reference labeling in the national guidelines for the Energy Certification System.

The ITACA Protocol is used in Assessment and Certification Systems by many Italian Regions to define the performance levels of sustainability and to promote and finance public housing.

In the public context, the ITACA Protocol is used to define policies and to promote sustainable building through financial incentives, building codes, urban plan and guidelines.

The Protocol has been used by Italian Regions in different applications:

- Piedmont: funding program for social housing for several million Euros
- Lombardy: guidelines and urban plan
- Tuscany, Veneto, Friuli Venezia Giulia, Liguria, Lazio, Basilicata, Calabria: guidelines and social housing program
- Marche: its own Certification System and the founding program for social housing
- Apulia: reference labelling system, regulations and Certification System

In the private context the ITACA Protocol is used to promote financial products aimed to award green building, such as "Aedifica bioedilizia" by Intesa - San Paolo Banking Group, and insurance products by RAS (Alliance Group). iiSBE Italy acts as scientific support to promote and spread these initiatives in the Italian Market.

Through the ITACA Protocol rating system a major impact on the building sector in Italy is underway, with the beginning of a market transformation.

The well known ITACA Protocol for residential buildings identifies 12 criteria divided into two important areas, resources consumption and environmental impacts, in accordance with Italian regulations and norms (Synthetic ITACA Protocol for Residential Building, Edition 2, approved in 2007). Assessment tools are available as criteria set, appraisal scheme, application manual and software.

The structure of the Certification Scheme for Italian Regions, shown in Fig. 2, illustrates the process and the roles of ITACA, of the Italian Regions and of iiSBE Italy.

ITACA should define strategic guidelines of the Certification Scheme and guarantee that the certification system is based on scientific elements, correlated to an internationally recognized system, solid and sustainable, user friendly and easily applicable, suitable, cost efficient and reliable.

ITACA should establish the Assessment System and provide the upgrade of the Assessment Tool in order to follow the evolution of national regulation requirements.

ITACA should oversee and supervise certification systems and guarantee the quality of the results.

Italian Regions should define their own certification and accreditation systems and establish the rules to issue the certificates. They choose which type of the protocol to use, and define certification and accreditation procedures. They monitor and evaluate the certification and accreditation systems.

iiSBE Italy is the National Control Body of the ITACA Protocol, provides technical support to ITACA, supplies the evaluation team, carries out the assessment and updates the certificate register.

In several regional founding programs, iiSBE Italy has the important role of Certification Body in the Certification Scheme.

The role of iiSBE Italy is to establish and maintain the relationship with the international Sustainable Building Challenge process.

Keywords: Reuse of members, Steel structure, Rigid connection, Non-welding, Ring-panel, structural behavior, Loading test, Disassembling test

Summary

To realize the environmentally sustainable society, the development of building construction methods for reuse of structural members is required these days. The Ring-panel connections, newly developed in this paper, makes the steel members more possible to be easily disassembled and consequently to be reused.

The Ring-panel consists of a steel pipe with outer diaphragms and beam brackets, and with a little larger size than connected steel columns. The steel columns are inserted into the Ring-panel, with "disassembling steel plates" inserted into the gap. Mortar is filled into the gap, and then the rigid connection is formed.

The authors verified the structural performance of the Ring-panel connections by experiments, and derived the evaluation method for the strength of the Ring-panel connection. On the other hands, the authors tested the disassembling procedure using full-scale specimens, and could disassemble easily the all members without any damage.

1. Introduction

A sustainable social system has been one of the urgent themes for global environment in the 21st century. In construction fields, the energy saving measures has been discussed much more especially from the viewpoint of building machinery engineering. However, it is also important to approach the global environment issues from structural engineering.

One of the approaches from structural engineering is to reuse the steel structural members and decrease the CO_2 emissions in the member production stage. The authors have proposed a sustainable building system called "adaptable building" as shown in Photo 1. This system allows easy assembling and disassembling, and helps reuse the building members. The authors realized the adaptable building by applying the "Ring-panel connection method". The Ring-panel connection can be realized by non-welding connection method, maintaining high construction performance and disassembling performance of the steel members. This paper reports outlines of the Ring-panel connection and the experimental studies on the structural behaviors of the Ring-panel connection.

Photo 1 Adaptable building

2. Outlines of Ring-panel Connection

An outline of the conventional Ring-panel connection is shown in Fig.1 (a). The Ring-panel consists of a steel pipe with outer diaphragms and beam brackets, and with a little larger size than connected steel columns. The steel columns are inserted into the Ring-panel. Mortar is filled into the gap between the columns and the Ring-panel. The stress transfer mechanism in the connection is shown in Fig.2. The connection resists against the shear force and moment from columns with the leverage reaction force and compressive strut. The compressive strut occurs between the flat bars attached to both ends of the Ring-panel and the columns. This mechanism consequently forms the rigid connection.

An outline of the reuse type of Ring-panel connection is shown in Fig.1 (b), which can disassemble all members without any damage. The reuse type of Ring-panel connection has disassembling plates inserted into the gap, which are placed in advance to where the mortar is supposed to be filled. When the structure is disassembled, the plates are removed to make voids in the mortar, leading to easy disassembling. In the conventional Ring-panel connection, the flat bars at end of the Ring-panel would obstruct disassembling. Therefore, in the reuse type the flat bars are removed, and instead the Ring-panel is made longer in a vertical direction to increase the friction resistance and leverage reaction force. If the flat bars are fixed with bolts, the Ring-panel height can be made lower.

3. Structural Test

3.1 Outline of Test

In order to verify the structural behaviors of the Ring-panel connections, loading tests were carried out using 2/3 scale specimens. The specimen configurations are showed in Fig.3 and Fig.4, and the test parameters are showed in Table 1.The specimen J1 is designed as the conventional Ring-panel method and its Ring-panel height “h” is 600mm. The specimen S1 is designed as the reuse type Ring-panel that has flat bars fixed with bolts, and the Ring-panel height “h” is identical to that of the conventional type. For the specimen S2, the Ring-panel height “h” is taken as 800mm; 1.3 times of the conventional type because of no flat bars. These specimens are designed to ensure the beam yielding prior to any other parts. The mechanical characteristics of steels and mortar used in the specimens are shown in Tables 2 and 3.

A shear force of inverse symmetry is applied to each end of the beam. The top and bottom ends of the column are simply supported. A cyclical loading is conducted with the story drift angle once for 1/120, twice for 1/60 and 1/30, and once for 1/20. After the cyclic loading, specimens are loaded up to 1/15 of story drift angle in one-way direction.

S2	32	78.1

3.2 Result of Test

The relationship between the shear force of columns and the story drift angle is shown in Fig.5. The failure example of the specimens at final loading stage is shown in Photo 2. The local buckling was found at each beam end in all specimens, and then the maximum load was reached. The reuse type specimens S1 and S2 showed a slight slippage in the shear force vs. drift angle curves, however no significant difference was shown compared to the conventional specimen J1.In the specimen J1, cracks occurred on the surface of the mortar, but there was no crush in the mortar inside the connection. In the specimens S1 and S2, the slippage out of the disassembling plate and the crush on the surface of the mortar occurred at the loading cycle of 1/30, but there was no crush in the mortar inside the connection as in the specimen J1. In all specimens the columns, Ring-panels, and diaphragms all remained elastic.

A comparison of skeleton curves based on the shear force vs.drift angle curves for all specimens are shown in Fig.6. As shown in Fig.6, the reuse type Ring-panel connections have almost the similar structural performance to the conventional Ring-panel connections.

The potential strengths when each part of the specimens would yield are shown in Table 4. For calculation of the strength of mortar crushing, the stress distribution in the Ring-panel as shown in Fig.7 is assumed. The calculation values based on the yield strength and the ultimate for all specimens met a good agreement with the test results.

4. Disassembling Test

In order to confirm the disassembling performance of the reuse type Ring-panel connections, disassembling tests were carried out using full-scale specimens. The specimens consisted of a column (Pipe-609.6x22mm), a Ring-Panel (Pipe-711.2x22mm), 20 disassembling plates (Length: 450mm), and mortar (compressive strength: 48N/mm^2).

Each disassembling plate was pulled out from the mortar. The pull-out force was about 10kN at maximum for each plate. And the time required for disassembling was about a minute for each plate. After all plates pulled out, since the consequent voids made the column and the Ring-panel separated, the column was easily removed from the Ring-panel. The total time for disassembling was about 30 minutes, and it was confirmed to disassemble all the members without any damage.

5. Conclusion

The authors proposed the Ring-panel connection method for the reuse of steel members. According to this method, the steel members can be easily disassembled without any damage. The structural performance of the Ring-panel connections was verified through the loading tests. And the disassembling performance was verified through the disassembling tests using full-scale specimens.

Keywords: EHP, GHP, air conditioning, cooling, heating, heat pump, performance, COP, part load

Summary

Split-type air conditioning systems or heat pump systems with multiple indoor and outdoor units are becoming very popular for air conditioning and room heating of small or middle-sized non-residential buildings in Japan. However, their running performance is yet to become known due to the difficulty of measuring actual amount of heat transferred by the system. Mixed irregular flow of vapor and liquid refrigerant has prevented building engineers from obtaining accurate amount heat flow between indoor and outdoor units.

This study introduces alternative methods to calculate heat transferred by the system from air volume and enthalpy measured with simple sensors attached to the indoor units as well as measuring amount of heat exchanged by outdoor units. Results at a national university building in suburban Tokyo and an office building in central Tokyo showed unexpectedly low COP values mainly due to the capacity of the systems far exceeding actual heat demand and imbalance between summer and winter heat demand both resulting in the prevailing low part load factors especially in winter which is under 20% of the system capacity.

1. Introduction

Recent rise in environmental consciousness and deteriorating state of the earth combined with approaching deadline for public commitments to reduce CO2 emissions and increasing energy consumption at private sectors have intensified importance of developing and promoting methods for conservation and efficient use of energy.

Somewhat irrelevant to these situations, multiple-unit electric and gas heat pump (EHP/GHP) systems have been rapidly spreading from the aspect of cost saving and convenience and installed even in the buildings with several tens of thousand square meters of floor area in major Japanese cities. From the aspect of energy efficiency, however, it is suspected that their high rated COPs based on the Japanese Industrial standard do not necessarily represent actual values in use. It is also suggested that EHP/GHP may constitute a primary source of heat island, because unlike centralized air conditioning systems equipped with cooling towers which primary discharge latent heat, EHP/GHP exclusively discharge sensible heat into the urban canyon directly rising its air temperature. Their efficiency therefore is also a primary interest from the aspect of urban environment. In order to obtain state of the art knowledge to these pending questions, series of researches have been conducted in cooperation with three universities and Tokyo Gas, a major GHP distributor, to measure energy efficiency of a typical EHP and GHP system under actual operating environment. The results will help us in designing and installing them in a better way.

2. Indoor Measurement at an University Campus Building in Suburban Tokyo

A multiple type EHP system consisting of 7 indoor and 4 outdoor units installed on a national university campus in west suburb of Tokyo was the site of the first measurement. For this system, multiple points indoor measuring method was applied to examine its system efficiency (i.e. COP: Coefficient of Performance) in daily operation. Summer measurement was conducted from August 26 through September 5, 2005 with the indoor setting temperature of 27deg. and winter measurement from February 14 through 22, 2006 with the setting temperature of 24deg. (February 14 through 16), 22deg. (17 through 19) and 20deg. (February 20 through 22). Climate during summer measurement was normal ranging between 21.9 and 33.1 degrees and warmer during winter between 2.2 and 18.5 degrees. Throughout measurement, airflow of the indoor units was set at strong mode while airflow direction was set no swing with middle low angle blowout position.

2.1 Measurement Specification

2.1.1 Specification of Measured Units

Measured units are specified in Table 1 and 2. The total cooling (i.e. air conditioning without humidity control) capacity of indoor units is 50.9kW (at 50Hz, same hereinafter) while heating capacity is 57.0 kW, 11% exceeding cooling capacity. Outdoor units consume 21.18kWh of electricity to remove 56kWh of heat for cooling and consume 18.3 kWh of electricity to provide 53kWh of heat for heating. Including small power consumption by indoor units, rated COP for the system is 56/(21.18+0.63) = 2.57 for cooling and 53/(18.3+0.63) = 2.80 for heating. Electricity consumption of all 7 indoor units, 4 outdoor units and their control systems were measured every minute by attaching clamp watt meters to the grid power line.

Table 1 Specification of indoor units (50Hz/60Hz)

	Heating	59.3/65.1A

2.1.2 Thermal Flow through Indoor Units

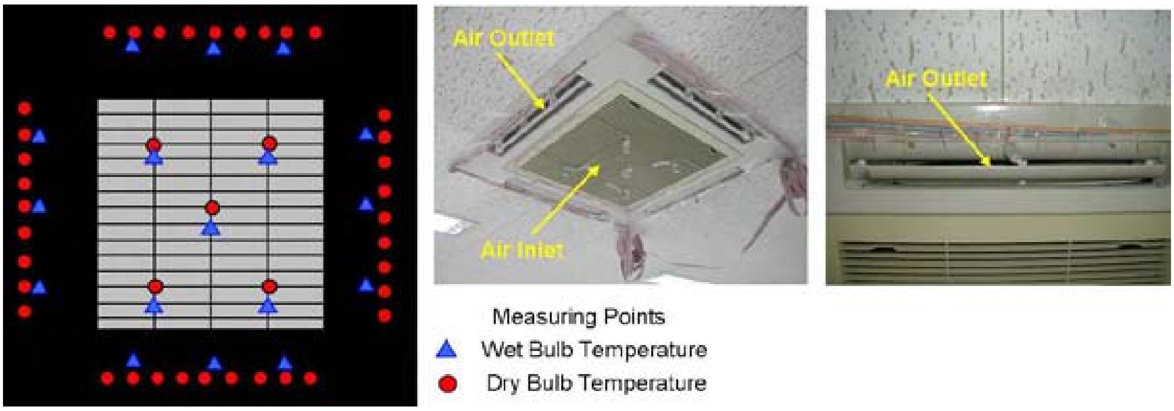

Figure 1 Temperature and humidity summer measurement points of a indoor unit

For all indoor units, 9 dry and 3 wet bulb temperatures were measured at each air inlet while 5 dry and wet bulb temperatures were measured at outlet with thermocouples and a data logger as shown in Figure 1. Airflow velocity at air inlets and outlets were pre-measured with a traverse unit reproducing the same airflow as during the measurement. Heat exchange quantity was calculated by multiplying inlet and outlet enthalpy difference and airflow volume calculated by the airflow velocity distribution described later. Measured items on indoor units are specified on Table 3.

Table 3 Measurement specification of indoor units

Position	Item	Sensor	Specification	Points (Summer)	Points (Winter)
Air outlet	Temperature	Thermocouple 0.32T-G		9 x 4=36	9 x 4=36
	Humidity	Thermocouple 0.32T-G	Wet-bulb temperature measurement with moisture gauze	3 x 4=12	1 x 4=4
Air inlet	Temperature	Thermocouple 0.32T-G		5	5
	Humidity	Thermocouple 0.32T-G	Wet-bulb temperature measurement with moisture gauze	5	1

2.1.3 Indoor and Outdoor Thermal Environment

In order to measure indoor temperature distribution, 15 representing points were designated each with three vertical measurements making up 45 altogether as shown in Figure 2. In addition, outdoor temperature, humidity, solar radiation, airflow direction, airflow velocity, atmospheric pressure and precipitation were measured with a portable weather station.

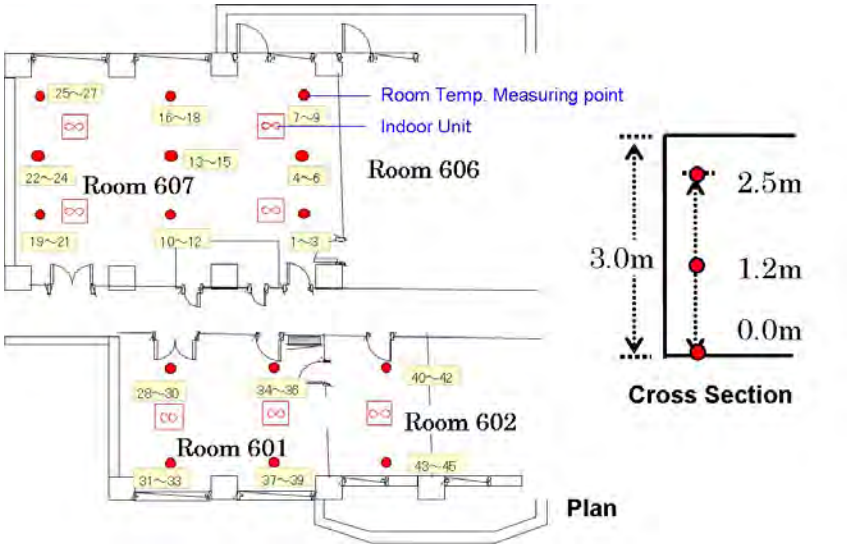

Figure 2 Horizontal and vertical location of thermo-hygrometers set around indoor units

2.2 Airflow Volume Calculation

Airflow velocities in and from an indoor unit were measured with a traverse unit" designed by Professor Shigeki Kametani for the study (Figure 3). A scalar and a vector anemometer traverse across an indoor unit by a tenth of an inch precisely measuring three dimensional airflow velocities in and from it creating accurate airflow velocity distribution curve (line graphs of Figure 4). Airflow

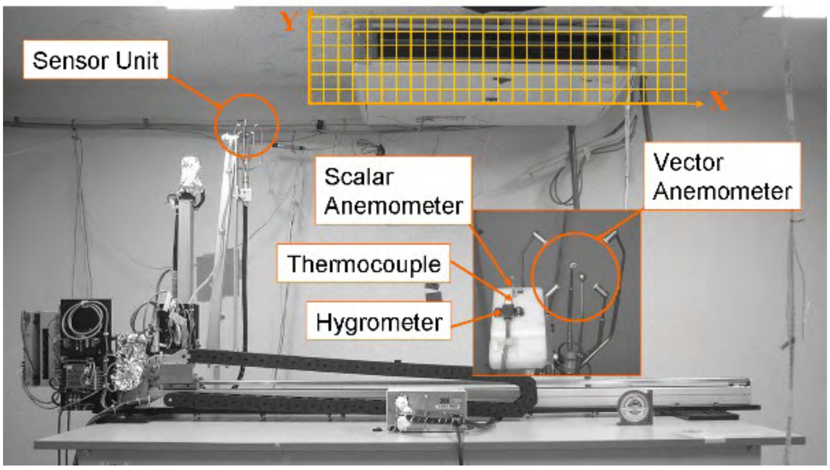

Figure 3 Kametani Traverse Unit

velocity at each measuring point was calculated by modeling these charts (bar graphs of Figure 4)

Airflow volume at each measuring point of an air outlet was calculated from modeled airflow velocities. Inlet airflow volume was calculated according to the representing area of each measured point (Figure 5). A sum of calculated airflow volume was adjusted to match the rated airflow volume for strong airflow mode and distributed to each measuring point.

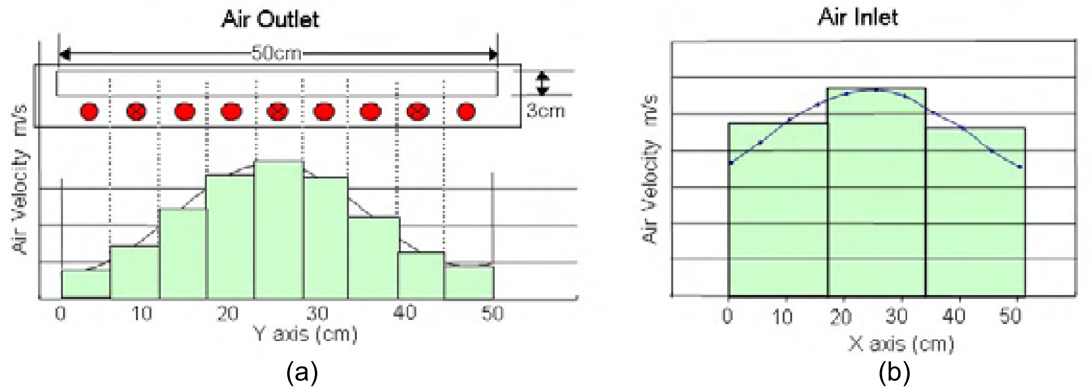

Figure 4 Airflow velocities distribution of air outlet (a) and inlet (b) with approximation at each measuring point

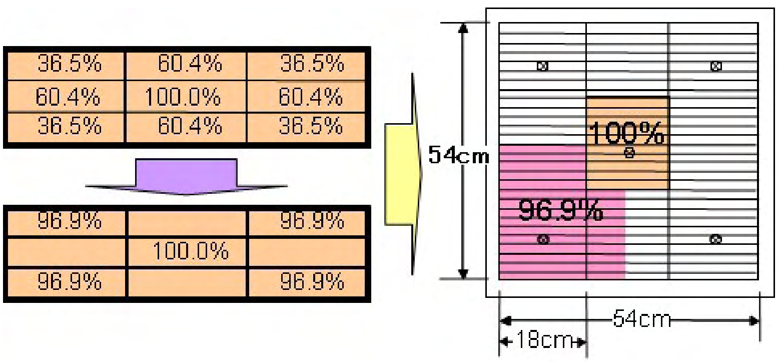

Figure 5 Air inlet volume distribution at each measuring point

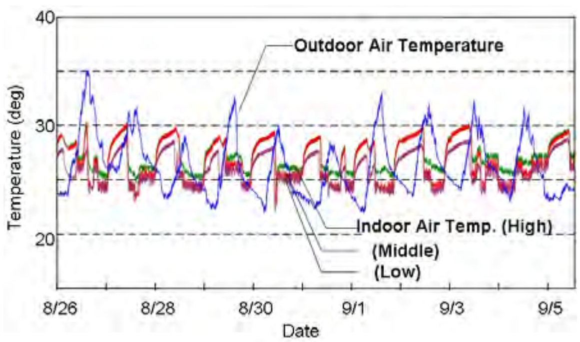
2.3 Results

2.3.1 Summer Measurement

Outdoor air temperature and room temperatures at three vertical measuring points are shown in Figure 6. During most of the operating time (10am-9pm), room temperatures stayed well at the preset temperature or a little below identifying cooling were properly functioned.



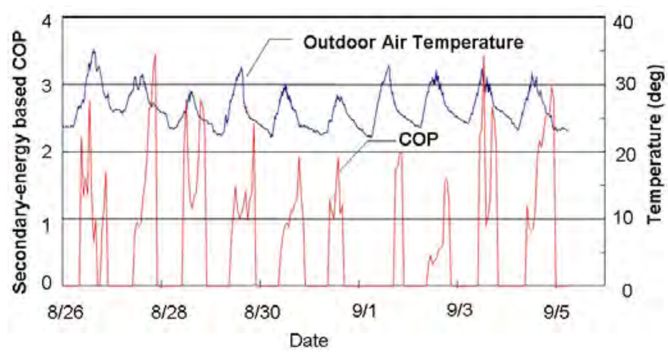


Figure 6 Outside air and room temperature (Summer measurement)

Figure 7 Change of COP (Summer measurement)

The change of COP during operating time in summer measurement is shown in Figure 7. Average COP calculated by formula (1) was considerably lower than the rated COP of 2.57. Figure 8 and 9 show distribution of load factor. Most of the load is concentrated under 30% of the capacity. It is assumed that the system has excess capacity.

$$COP = \frac{\text{Quantity of heat exchanged by the indoor units}}{\text{Electric power consumption by indoor and outdoor units}} \quad (1)$$

= 715.806 [kWh] / 411.382 [kWh] = 1.74 (10am-9pm, August 26-September 5, 2005)

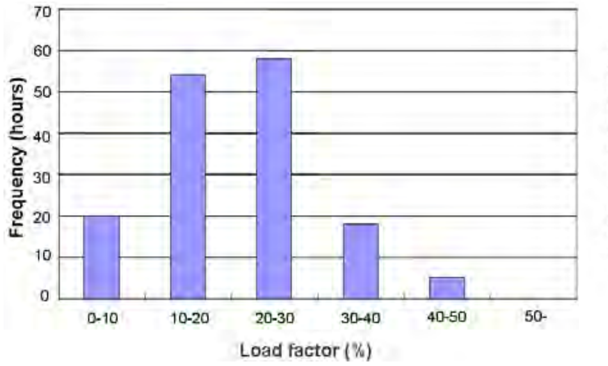

Figure 8 Frequency distribution of load factor (summer measurement)

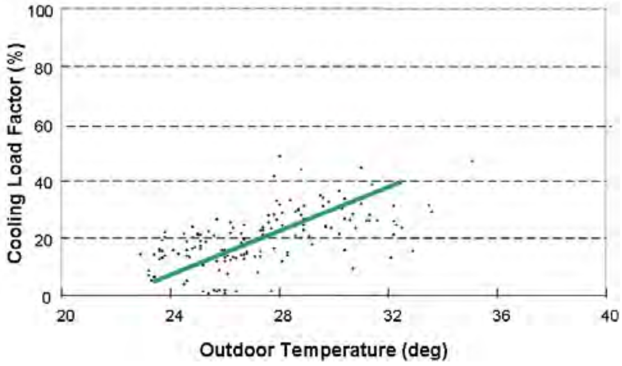

Figure 9 Relation between outside air temperature and load factor (summer measurement)

2.3.2 Winter Measurement

Outdoor air temperature and room temperatures at three vertical measuring points are shown in Figure 10. During operating time (10am-9pm), room temperature stayed well around the preset temperature identifying heating was properly functioned.

The change of COP during operating time in winter measurement is shown in Figure 11. Measured COP calculated by formula (1) was much lower than the rated COP of 2.80. One of the reasons for such low COP in winter is the use of oil heaters adding to the stand-by power consumption.

COP= 92.700 [kWh] / 153.898 [kWh] = 0.60 (10am-9pm, February 14 - 22, 2006)

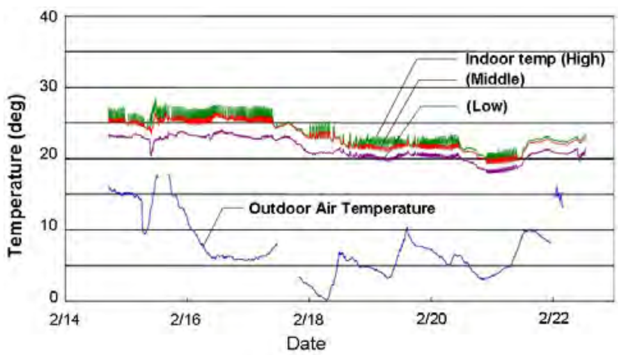

Figure 10 Outdoor air and room temperature (winter measurement)

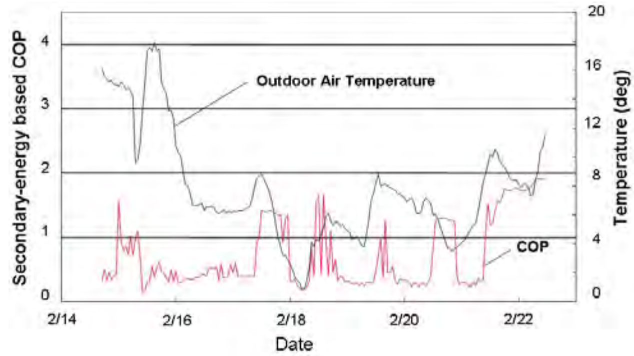

Figure 11 Change of COP (winter measurement) (winter measurement)

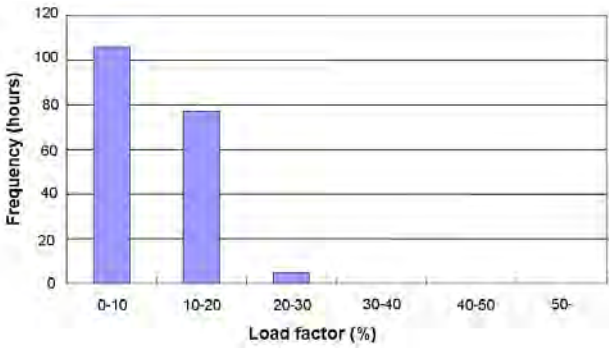

Figure 12 Frequency distribution of load factor (winter measurement)

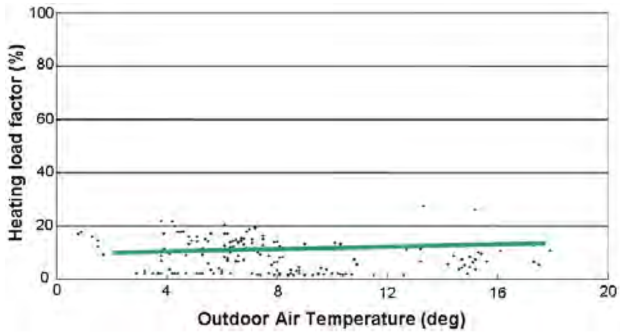

Figure 13 Relation between outside air temperature and load factor (winter measurement)

Load factor distribution during winter measurement is shown in Figure 12 and 13. Most of the load is concentrated under 20% of EHP's capacity. Load Factor was lower in winter than in summer because relatively high outdoor air temperature prevailed during the measurement had worsened imbalance of summer and winter heat demand in addition to its excess capacity. It is observed from the measurement that for a building with more daytime and less night time use, load factor can stay very low for the most of winter except for a few snowy cold days because in Tokyo metropolitan area heating demand maximizes at night and early morning hours when outdoor temperature falls and hit the bottom.

3. Outdoor Measurement at an Office Building in Tokyo

A multiple type packaged gas heat pump (GHP) unit installed in an office building in central Tokyo was the alternative outdoor unit measurement site. The measured system consists of an outdoor unit driven by a 30HP gas engine fueled by city gas and 11 indoor units each with 7.1kW of cooling and 8.0 kW of heating capacity. Rated COP of this unit is 1.25 for cooling and 1.37 for heating at primary energy basis. Referring to an EHP, its secondary-energy based COP is 3.39 for cooling and 3.71 for heating. Probing sensors insertion method exclusively developed for this measurement was applied for the first time to measure the amount of heat exchanged through heat exchange chambers of outdoor units in daily operation. The measured system installed on rooftop of three stories building provides primary heat source of cooling and heating of 384 m^2 of office floor. Measurement was conducted from July 11, 2007 through February 13, 2008 without interruption. Neither indoor measurement was conducted nor measurement informed to workers on the object floor.

3.1 Measurement Specification

Figure 14 shows how probing sensors as well as airflow velocity sensors were fitted on the outdoor unit. Each probing sensor consists of two T type thermocouples, one of which is put on the exterior of heat exchange fins and the other penetrates through fins into exhaust air chambers so that temperature of before and after heat exchange could be measured at one time. Figure 15 shows the works of sensors fitting through heat exchange fins (a), a penetrated sensor appeared in an exhaust chamber (c), CPU fans for PCs are placed over the exhaust air fans to measure velocity of exhaust air (b). To make good representation of total heat exchanged by the system, total of 27 probing sensors were fitted on three sides of the outdoor unit (shown in round dots in Figure 14). Velocity of exhaust airflow was measured on each fan unit (shown in oval dots in Figure 14) so that volume of air through heat exchange fins can be calculated with the performance curve supplied by the manufacturer. Assuming all the heat was exchanged only as sensible heat, amount of exchanged heat was simply

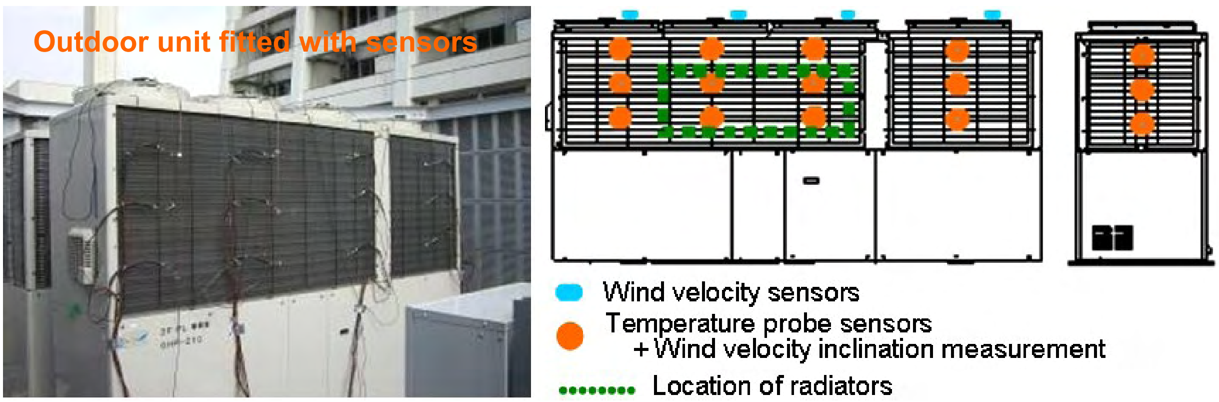

Figure 14 Location of sensors set on the outdoor unit

Figure 15 Sensors fit into (a) and penetrate through (c) heat exchange fins and placed on exhaust air fans (b)

calculated by multiplying temperature difference between exterior and interior sensors and volume of air came through heat exchanging fins.

Electricity consumption of both outdoor and indoor units was measured with cramp power meters not disturbing daily operation. To measure gas consumption, however, an additional gas meter had to be installed halting the operation for half a day. Measurement was conducted at 10 minutes interval throughout the term. All the measured data were automatically sent wireless by cellular phone radio wave to a data center and accumulated for later analysis. Weather condition throughout the measurement was observed by a portable weather station.

Table 4 Measured contents

Measured Item		Sensor or sensor method
Exchanged heat through outdoor unit		Probing sensor insertion method
Power consumption	Indoor units	Cramp power meter
	Outdoor units	Cramp power meter
Gas consumption		Gas meter, Pressure gauge
Exhaust gas heat value		T type thermocouple
Outdoor climate		Weather Station

3.2 Results

3.2.1 Heat Exchange and Primary Energy Consumption

Upper part of Figure 16 shows amount of heat exchanged daily both for cooling (left half) and heating (right half). It is easy to recognize that there is big difference between cooling and heating demand presumably due to Tokyo's worsening heat island and to the global warming. It is also easy to understand that if we decide the capacity of the system by cooling demand, then in winter we must operate it under lower part load because all heat pumps have structurally more than 10 % larger heating capacity than cooling capacity as was the case on measured GHP: 7.1kW for cooling and 8.0 kW for heating per indoor unit. Lower part of Figure 16 shows primary energy use, which is a sum of

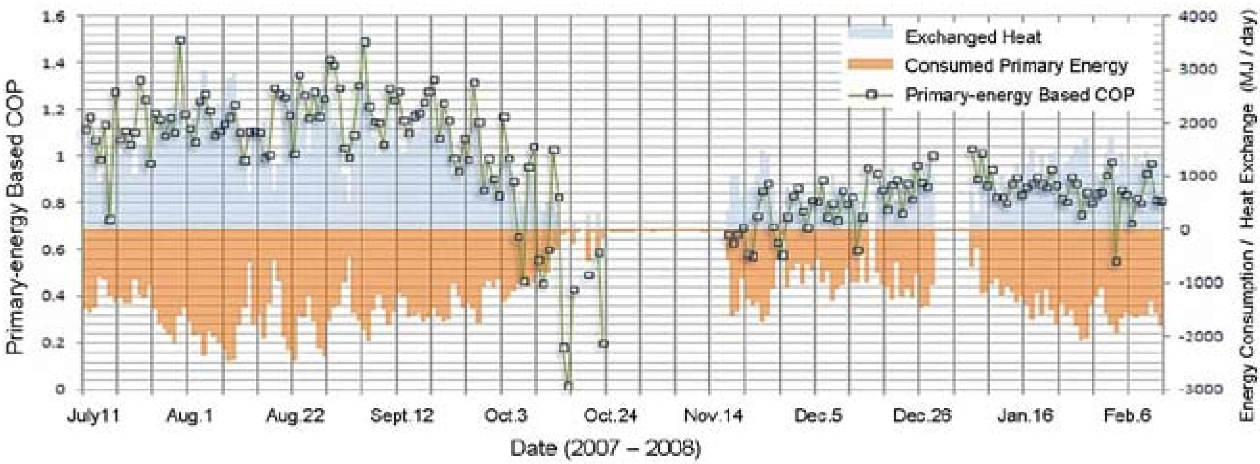

Figure 16 Daily heat exchange, primary energy consumption and COP

gas and electricity consumption. By simply dividing amount of heat exchanged by total amount of primary energy consumed, COP of the GHP unit was calculated and shown in line graphs. It is clear that COP for heating is much lower than the rated value staying between 0.6 and 1.0. These values were a little higher in comparison with indoor unit measurement, but it is likely that low part load was preventing the unit from running at expected efficiency not only at a university campus but also at an office building.

3.2.2 COP Classified by Outdoor Temperature

It has been observed that efficiency of heat pumps varies much with the change in outdoor temperature. Thanks to continuous measurement over seasons, relation between climate and COP has been clearly disclosed in this measurement. Bar graphs of Figure 17 show accumulated time length of operation classified by outdoor temperature, the left bars show total heating and the right bars show total cooling hours. Line graphs with colored background show part load factors for corresponding temperature. Line graphs with dots and numbers are the average primary-energy based COP at corresponding outdoor temperature. It has become clear from figure 17 that during cooling operation, COP rapidly drops as outdoor temperature rises beyond 30 degrees because the unit has an excess capacity and never runs over 50% of the capacity even on summer peak days. It has to be investigated how far COP can rise if a system with proper capacity and better part load is installed. For heating season, fall of COP by outdoor temperature is moderate for GHP because it can choose operation between heat pump cycle and direct heating by burning gas. EHP without such alternative operation should demonstrate worse performance.

From this measurement it has become clear that EHP/GHP is sensitive not only to the part load but to the outdoor climate and their performance varies with the inlet air temperature much grater than our recognition. Therefore more attention must be paid to its capacity and climate of the site before the installation of an EHP/GHP.

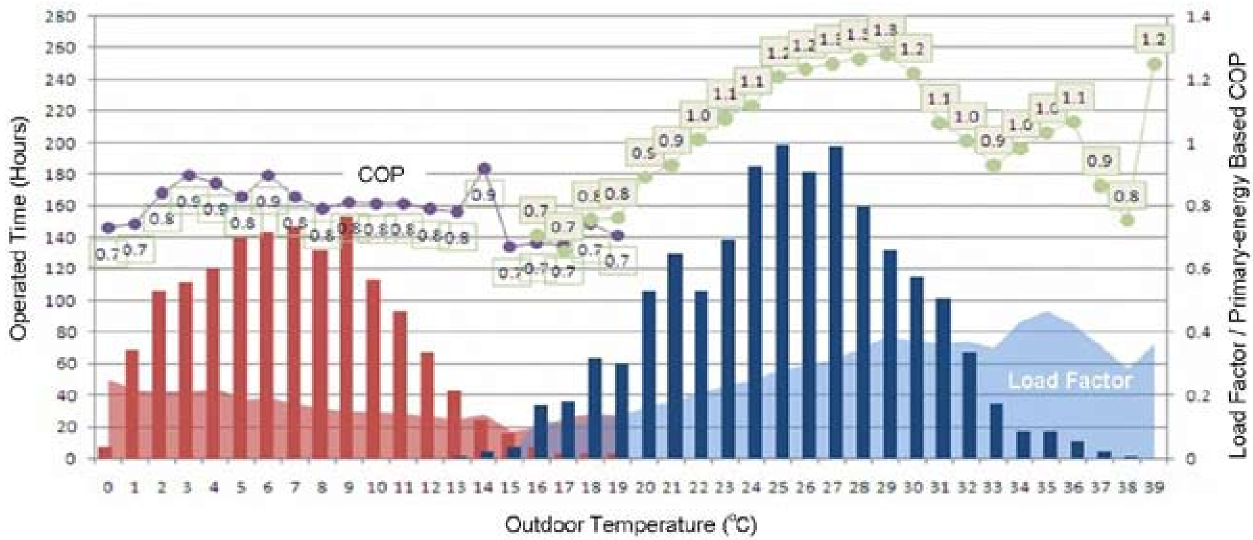

Figure 17 Change of primary-energy based COP classified by outdoor temperature

4. Conclusion and Discussion

Running performance of split-type electric and gas-engine multiple-unit heat pump systems were measured under actual operating environment at a university campus building and at an office building in metropolitan Tokyo. For the measurements, classic indoor measuring method and probing sensors insertion method for outdoor units originally developed for the study were applied respectively. Both results showed considerably low COP compared to the rated values of the systems because cooling and heating capacities were far exceeding actual load resulting in operation under low part load throughout measured period. Fall of COP values were also explained by the difference of air temperature from that of peak COP. Therefore more attention should be taken to the operating climate all year around especially to the cooling at 30 degrees centigrade or above and 25 degrees or below. COP was lower for heating than for cooling because imbalance of summer and winter heat demand is increasing probably due to urban heat island and global warming. To solve these problems, more accurate load calculation and proper designing with reliable data and software must be conducted. And also, a technological breakthrough to integrate heat load into fewer outdoor units to operate them at higher part load is expected.

Keywords: sustainability, energy conservation, public electric facilities, high-rise residential buildings

Summary

This study analyzed the electrical consumption of the public building services at residential buildings with 15 floors or more for the possibilities of saving energy. The review of literature, the on-site measurement, and the summarization and spreadsheet of the energy-saving technology are employed to understand the features of electrical consumption of public utilities and the possibility of saving energy. The cases are the buildings in Tainan and Kaohsiung cities in Taiwan. There are three main results (1) The average electrical consumption is 27.3% for elevators, 28.8% for power plants, 33% for the lighting, 4.1% for the air-condition, and 6.8% for the other items. (2) To save energy for the residential buildings, the rationalization of the contract capacity, the increase in the power factor, the adoption of efficient running water pumps and lighting, and the adjustment in the operation time of exhaust fans are helpful. The ratio of energy saving is 17.9% and the PBY is five months to 5.3 year.

1. Introduction

1.1 Research Motive

Since the government actively promoted the energy saving measures to the industries with high energy consumption and the commercial buildings in recent years, the benefits of those measures have gradually appeared. Residential buildings consumes 20% of the national electrical consumption in Taiwan, but the benefits of the energy saving measures at these buildings type are not to be noticeable. In another way, the less electricity is consumed, the less CO2 (carbon dioxide) is emitted. So decreasing the electrical consumption of the residential buildings is very important. Then, there are two main purposes of this research:

（1）We will analyze the composition and characteristic of electric consumption of the public building services at the residential buildings.

- To collect and analysis the public electrical consumption features from the past electrical receipts.
- To measure and analyze the public electrical consumption features including operating and standby mode of building services.

（2）We will evaluate the electricity saving benefit in the public building services that assume to adopt the energy saving products.

1.2 Research Range

The research focuses on the electrical consumption of the public building services at the buildings of at least 15 floors or those of at least 50 meters high. The public building services exclude those consuming other kinds of energy like natural gas and heavy oil. The building services includes water supply and drainage system, air-condition, elevators, ventilation system, and fire escape equipment. The investigated areas are Tainan and Kaohsiung (Cities and Counties included).

1.3 Research Method

The study chooses 50 residential buildings of at least 15 floors in Tainan and Kaohsiung as the investigating samples, whose records of electrical consumption and relative information (the floor, household numbers, the total floor area, the building age, and the occupancy rate) for the previous year are collected.

The research conducts the on-site measurement of electrical consumption for the elevators, power, air-condition, and lighting individually at 10 of the 50 samples in order to calculate the KWH. The records of electrical consumption from the 50 samples do not indicate large variation in the monthly consumption. Consequently, the measurement for this study lasts only one week for the understanding of the consumption features and for the prevention of interference from the measurement devices installed too long for the residents' daily life.

2. Composition of Public Electrical Consumption

The public electrical consumption is influenced by the level of the residential building in construction and the use frequency & behavior of the public building services in daily life. This research divides the 50 cases into three categories, which are luxurious, normal, and economical residential buildings. In Table 1, the public electrical fee of luxurious buildings per household each year can be up to NT$ 10,701, while the fee of economical buildings is only NT$ 887. The difference among different categories is up to 4.9 times.

When the households is fewer (or the floors is higher or the more luxurious or comfort), it results in the higher public electrical consumption. The electrical consumption of public building services is a stable load which does not fluctuate significantly according to season. Only in few of the cases, the increase in electrical consumption is found in the summer, due to the increase in the electrical consumption of air-condition.

62% of the cases made the very high contract capacity of power supply, leading to the increase in the public demand charge. Taiwan Power Company imposed penalties on 6% of the cases with the very low contract capacity. The company imposed penalties on 44% of the cases with the power factor lower than 80%.

Table 1. Classifying Public Electrical Consumption according to building level

Category	Public facilities	Number	KWH per Household	Fees per Household
Luxurious	1) High hall 2) Movie theater 3) Conference room 4) Classroom of rhythmic gymnastics 5) Gymnasium 6) Movie theater 7) Banquet hall & Audio-visual room 8) Play room 9) Reading room 10) (Warm) swimming pool 11) SPA & Saunas 12) Scene lighting 13) Atrium scenery building 14) Parking space on B3F 15)Fountain 16) Computer game room 17) Air-condition in all indoor public space	9	4,345 (KWH/year)	10,701 (892NTD/month)
Normal	1) Normal entrance hall 2) Caretaker room 3) Movie theater & conference room 4) Gymnasium 5) Reading room 6) Simple atrium facilities 7) Parking space of two floors underground	24	1,540 (KWH/year)	3,731 (311 NTD/month)
Economical	1) Simple entrance hall 2) Parking space of one floor underground 3) Lighting for staircases and elevators	17	887 (KWH/year)	2,467 (206 NTD/month)

Luxurious: for luxurious, magnificent, and comfortable demands
Normal: for elementary demands of daily life and recreation
Economical: for elementary demands of daily life

3. Workable Measures to Save Energy

This study expects the energy saving technology for the public building services. The technology shall be (1) fully developed to provide enduring products (2) economically efficient to save the daily electrical consumption and to reduce the high price for maintenance (3) able to overcome the on-site problems.

3.1 Improving the Building Services Efficiency

3.1.1 Running water pumps and control devices

So far, the standing, lying, and sinking running water pumps are highly efficient. Generally speaking, brands such as Ebara, Tsurumi, EMU, and Groundfos (with efficiency up to 75%) are more efficient than Taiwanese brands (with about 40%). What's more, the durability of brands like Ebara usually is better and the rate of breakdown is low. When we select highly efficient equipments, both of the operation electricity consumption and the contract capacity of the public electricity will reduce.

3.1.2 Air-condition

The investigation results demonstrates that the ratio of electrical consumption of the air-condition is only 3.93% (compare with the electricity consumption for public building services). The common air-conditioners are window-type or split-type, without large installed capacity or high use frequency. All the window-type and split-type air-conditioners have met the EER (energy efficiency ratio) standards required by the Bureau of Energy as the conditioners were produced in that time. As a result, the old air-conditioners shall be replaced with the efficient products carrying energy labels to save the energy.

3.1.3 Lighting, Evacuation Lamps, & Floodlight

Traditional Fluorescent lamps that consist of T9 fluorescent tubes and traditional ballasts is popular. If they are replaced with T5 fluorescent tubes and electronic ballasts, the electrical consumption can be reduced by 25% for ballasts and 30% for tubes. With the high rendering average (Ra≧84, T9'Ra is 61%), T5 tubes contain less mercury for environmental protection and last longer. As spiral lamp holders of the original lamps are replaced by energy saving bulbs, the electrical consumption of incandescent lamps can be reduced by 60%. 10W fluorescent lamps, used by most pilot lamps for emergency exits and for evacuation routes and turned on for 24 hours a day, should be replaced by LED's ones to save energy. Most floodlights are charged with constant currents, but floodlights charged with constant voltage consume less electricity.

3.1.4 Fans at Underground Parking Space

Most of the fans are controlled by timers. The first energy saving measure is to prevent the simultaneous operating time in different floor of fans. Because different exhausting zone should take turns their fans, the contract capacity will be reduced. The second measure is to replace the domestic fans (used in most cases and with less than 50% efficiency) with foreign fans (with up to 70% efficiency) like Nicotra, Kruger, ABB. The third measure is to replace the duct system (the fan and duct system) with the fan and inducer fan system. The inducer fans averagely arranged in space can induce out the air surrounding the outlets in order that the bad quality of air common for the duct system should be improved. Besides, the removal of old ducts can improve the clear height and offer a better view of the whole underground parking space.

3.1.5 Fire Fighting Transformer

Transformers ranging from 37.5 to 50 KVA are installed in all the cases to provide electricity for the fire fighting sockets. The transformers, only to be driven at fire, do not have to be in standby mode, which wastes electricity for the iron losses and the consumption of the power lines despite the no-load power connection. Given the capacity of transformers at 50 KVA, the annual standby electrical consumption can be reduced by 2155 KWH. Therefore, the automatic and manual switches should be installed on one side of the transformers and connected with the switch of the automatic fire alarm system.

3.1.6 Elevators

The elevators driven by the variable-frequency & transforming motors and by the spiral gear windlasses, consume at least 15% of energy less than traditional elevators. In addition, floor buttons should be able to change the pressed buttons, the fans should be turned off automatically 30 seconds after the stop, and the lighting should be turned off automatically 10 minutes after the stop. These measures can save energy.

3.2 Improvement of Building Services Management

3.2.1 Management of Contract Capacity & Power Factor

60% of the studied cases do not manage the contract capacity or the power factor well and thus order the most suitable contract capacity. As the Governing Rules for User Premise Power Line Placement of Taiwan Power Company require, the power factor must be higher than 80%. The 0.3% more of electric fees as penalty for 1% less of the power factor and the 0.15% discount for 1% more of the power factor are ideal and economical improvements.

3.2.2 Lighting Control

Besides the manual lighting switch, the two-wire lighting control system, the infrared ray sensors, the timers, and the daylight sensors are automatic control measures.

3.3 Evaluating Efficiency of Energy Saving for Cases

This study evaluates the energy saving efficiency before and after the improvement in six cases. The evaluation includes the annual electrical consumption, the reduced electrical consumption, the saved electrical fees, the electricity saving efficiency, and the PBY of investment. The annual electrical consumption is evaluated to be 615,800 KWH/year. The energy saving measures are(1) the rationalization of the contract capacity, (2) the increase in the power factor, (3) the adoption of efficient running water pumps, (4) the adoption of efficient lighting fixtures and lighting control systems, and(5) the adjustment in the operation time of exhaust fans.

This evaluation shows that the average electricity saving efficiency can be up to 17.9%, and that the PBY ranges from five months to 5.3 years. Therefore, the energy saving measures of this research are beneficial enough to recommend to the management committee. The energy saving measures and efficiencies of the studied cases are listed in Table 2.

Table 2. Evaluating Efficiency of Energy Saving for Cases

Case No.	Floor	Household No.	Energy saving measures	Annual electrical consumption (KWH/year)	Reduced electrical consumption (KWH/year)	Saved electrical fees NTD/year	Electricity saving efficiency (%)	PBY of investment (Year)
1	B2F~16F	235	1、2、3、4	442,920	65,248	370,998	14.7	3.8
2	B3F~17F	578	1、3、4	784,720	129,552	365,094	16.5	5.3
3	B7F~41F	143	1、2、4、5、6	869,040	180,102	487,327	20.7	5 month
4	B2F~21F	246	3、4	283,360	62,280	194,305	22.0	5.2
5	B2F~21F	180	1、3、4、7	267,280	62,365	204,193	23.3	4.4
6	B3F~24F	521	1、4	1,047,480	161,160	476,249	15.4	3.9
Average				615,800	110,118	349,814	17.9	--

1. energy-saving measure
（1）Rationalization of contract capacity（2）Increase in power factor（3）Adoption of efficient running water pumps
（4）Adoption of efficient lighting fixtures（5）Efficient lighting control systems
（6）Adjustment in operation time of exhaust fans（7）Improvement of emergency lighting fixtures
2. Electricity saving efficiency ＝ （Reduced electrical consumption / Annual electrical consumption）× 100%

The reasons why some energy saving measures are not adopted during the evaluation are as follows:

1） Some cases already have some of the energy saving measures. For example, the infrared ray sensors have shortened the use of the lighting. When the lighting adopts electronic ballasts, the electrical fees can be reduced but the energy saving efficiency is not high.

2） PBY of some cases is longer than five years: The PBY of investment in Taiwan ranges from five to seven years, which can motivate the committees of management to improve their public utilities. New pilot lamps for emergency exits at emergency doors and for evacuation routes can reduce the electrical fees. Nevertheless, it is not recommended to replace old pilot lamps since the cost cannot be paid back within five years. In the future, the lighting fixtures should be gradually phased out and replaced with electricity saving lighting fixtures. Furthermore, the energy saving elevators and the fans at the underground parking space have the PBY of longer than five years.

4. Conclusion

This study, analyzing the features of the electrical consumption and the efficiency of the energy saving measures in the high residential buildings in southern Taiwan as the cases, comes to the following conclusion:

1） The main public building services that consume electricity are elevators, power plants, and lighting. The average electrical consumption is 27.3% for elevators, 28.8% for power plants, 33% for the lighting, 4.1% for the air-condition, and 6.8% for the other items

2） The main factors for the electrical consumption of the public building services are the building scale, the building layout, the natural daylighting, the building services efficiency, and the users' demands.

3） High efficient lighting and running water pumps , rationalization of the contract capacity, the increase in the power factor and the adjustment in the operation time of exhaust fans are the most economical measures to save public electric consumption.

4） The average ratio of energy saving is 17.9% and the PBY is five months to 5.3 year.

Abstract

Since 2005, the Electrical & Mechanical Services Department (EMSD) Headquarters Building has been used as a showcase venue to demonstrate to the public the application of sustainable building technologies. The building is an eight-storey high building with offices, vehicle workshops and data centres. Installed on the roof is a 350 kW solar photovoltaic panel system, which is the largest of this kind in Hong Kong. Ten sun pipes utilizing natural lighting for illumination are also installed on the roof. These renewable energy technologies can be seen by visitors in a glass-made viewing gallery fitted with integrated photovoltaic glass panels. Moreover, various energy efficient technologies and green features have been incorporated in the building design. Motion and daylight sensors automatically turn off or dim down lights when artificial lighting is not required. Water-cooled ammonia chillers, with zero global warming potential, are used to minimize electricity use. Other sustainable features include sunshade screens installed outside the building facade, green roof gardens, grey water recycling system and thermal storage utilizing "slurry ice" etc. The building has been a persuading case of utilizing sustainable building technologies. It will continue to be used for demonstrating the successful application of advanced energy efficient and renewable energy technologies under local conditions.

1. Introduction

The EMSD Headquarters building is situated at Kowloon Bay and in the old Kai Tak Airport site. The building was formerly a cargo terminal building. It has been designed to make full use of the concrete structure of the former cargo terminal building as far as possible without demolition of the old building structure, resulting in a saving of HK$600-$700 million. By retaining most of the concrete and steel structure of the old building, the conversion has greatly reduced the use of energy and construction material as well as construction waste created in the process. The volume of construction waste saved can fill a four-storey building of the size of a football pitch.

The building is an eight-storey building. The lower floors are vehicle workshops, electronics workshops and car parks. The top two floors are offices of nearly 20,000 square metres. Also, a fully equipped computer data centre and staff canteen is located on the first floor.

Various renewable energy technologies, energy efficient technologies and green features have been incorporated in the building design as described in details in the following paragraphs.

Figure 1 The EMSD Headquarters Building

2. Application of Renewable Energy

This building has utilized various kinds of renewable energy resources including solar and wind for contributing electricity and hot water for use in the building.

2.1 Grid Connected Photovoltaic Panels

Rows of photovoltaic panels nearly cover the entire roof space of the building. With an installed peak capacity of 350 kW, the photovoltaic panels system is one of the largest of its kind in Hong Kong. The installation consists of more than 2,300 photovoltaic panels and has a total surface area of about 3,100m^2. The panels are grid connected to the electricity distribution network, contributing around 350,000 kWh of electricity per year from solar energy which helps to avoid annual emission of about 250 tonnes of CO_2, 860 kg of SO_2 and 430 kg of NO_x into the atmosphere.

Figure 2 Photovoltaic Panels installed at the roof of the building

2.2 Micro-wind Turbines

To demonstrate the applicability of wind technologies on top of a building located in an urban area, two types of micro-wind turbines including a 1-kW horizontal axis wind turbine and a 1.5-kW vertical axis wind turbine are installed on the roof of the building. The two wind turbines are also grid connected to electricity network and contributing over 1,000 kWh of electricity for the building annually.

Horizontal-axis wind turbine

Vertical-axis wind turbine

Figure 3 Micro-wind Turbines installed at the roof of the building

2.3 Solar Water Heating System

The solar water heating system installed on the roof of the vehicle reception office building is of high efficiency evacuated tube type solar collectors. It is used to pre-heat incoming water for hot water supply for canteen and the showering facilities in the workshop. The system can provide hot water for shower of around 40 persons. It is estimated that the annual solar energy absorbed by the system and converted into useful heat energy is 25,000kWh, equivalent to avoiding emission of about 18 tonnes of carbon dioxide from the power plant.

Figure 4 Evacuated tube types solar collectors installed on the roof of vehicle reception office building

2.4 Sun Pipes

Utilisation of natural light can minimize the artificial lighting demand in a building. In the building, ten sun pipes are installed on the roof to use daylight to provide illumination to part of the lobby at 7/F.

Sunlight is captured through dome shaped collector at the roof top of each sun pipe. It then travels down the sun pipe's highly reflective tube to illuminate the corridor. The ray bender inside the dome helps capture and reflect light that is not directly above the tube. The light captured is then channeled through a highly reflective shaft and diffused indoor.

On a sunny day, the brightness of each sun pipe is equivalent to the brightness of about 4 nos. of 11W compact fluorescent lamps.

Daylight collector

Sun pipes illuminating the lobby

Figure 5 Sun pipes

3. Intelligent Lighting System

3.1 Description and Working Principle

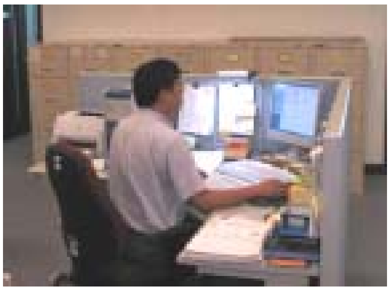
The lighting system installed in the Building is an Intelligent Lighting Control System consists of a Lighting Control Server which interfaces with the building Central Control Monitoring System (CCMS).

The control system saves energy by automatic light switching. It switches off the lighting automatically when the occupancy sensor detects no people in the space for a preset time period. The delay time for switching off the lighting fittings is 7.5 minutes in office areas and 2.5 minutes in circulation areas. It can be adjusted to suit the activity pattern of the occupants. On the other hand, the occupancy sensors in the open space offices will switch on the light fittings automatically once people are detected and keep the illumination at adequate illumination level. It will be topped up by task light for intensive reading and other specific activities.

Integrated light and motion sensors are also installed in cellular offices. The light sensors will monitor the resultant illumination on desk top of the cellular offices and adjust the light output of the dimmable lighting fittings so that daylight enters into the rooms can be fully utilized to minimize the energy requirement for artificial lighting.

To evaluate the actual energy saved by using this system, the power consumption of the light fittings on an office floor recorded by the CCMS was compared with the calculated total rated power and gear loss of conventional lighting system. In a weekly power consumption analysis, the energy consumption recorded by the CCMS is 6,380 kWh. The calculated power consumption of the same number of lighting fittings using conventional lighting switches is 8,130 kWh. It is found that the energy saving by the Intelligent lighting System at an office floor per week is 1,750 kWh or about 20% of the conventional lighting system.

Occupancy sensor



Task light

Figure 6 Occupancy sensors and energy efficient task lamp

3.2 Installation of Sensors and Automatic On/Off Controls for Lighting in Toilets

In order to conserve more electrical energy, occupancy sensors will be installed in toilets as well. At present, there are 56 nos. of toilets in the building, in which, the light fittings are operated by manual switches. The proposed control strategy is that half of the lighting fittings in the toilet would be switched off automatically if the sensors detect no movement in a preset time (say 30 minutes). The remaining light fittings would be switched off automatically if the sensors further detect no movement in another 30 minutes. As such, around 43,000 kWh of electricity would be saved annually.

4. Air-conditioning and Ventilation System

Four nos. of 1,055 kW ammonia chillers are installed at the building to cater for a cooling load of 3,500KW in summer. An ice-maker of rated cooling capacity of 700kW is installed in the chiller plant room to produce iced glycol solution at night and the iced solution were stored in 5 nos. 110m^3 thermal insulated bulk tanks with total storage capacity of 19,000 kWh to supplement the cooling capacity of the air-conditioning central chilled water system at day time. A heat rejection system which consists of 4 nos. of freshwater evaporative condensers is employed for the chiller plant. The air-conditioned spaces are served by VAV/AHU with under-floor air delivery system.

4.1 Ammonia Chillers with Evaporative Condensers

Ammonia is an environmentally friendly refrigerant as its ODP is zero and it has no green house effect. Its chemical components are nitrogen and hydrogen which are gases naturally exist in the environment. To minimise the disturbances to the building, the plant room for ammonia chillers is located outside the building area and a water scrubber system for emergency exhaust of ammonia refrigerant is provided.

4.2 Thermal Storage Using Slurry Ice

The coefficient of performance of the entire ice-storage system, from the chiller to the heat exchanger output, is about 3.5. At daytime, the iced glycol solution "slurry ice" in the ice storage system absorbs heat from the central chilled water system via heat exchanger and therefore reduces the maximum cooling load of the central chiller plant.

As the ice-maker is operated at nighttime, the peak load demand can be reduced. The ice-maker can produce a daily cooling capacity 8,300 kWh. This is about the full load capacity of an ammonia chiller. The peak load demand is reduced by about 250kVA.

Figure 7 Ice storage tank at the entrance of the building

4.3 AHU Equipped with Free Air Cooling Facility

Free air cooling (FAC) utilises cool outdoor air to provide space cooling in lieu of mechanical cooling thus saving energy. An air handling unit (AHU) fitted with FAC has 3 operation modes: (1) normal operation with full mechanical cooling, (2) fully free air cooling, and (3) partially free air cooling supplemented with mechanical cooling. A controller will continuously compare the temperature, relative humidity and enthalpy of outdoor air and indoor air with their design values. It will then determine the fresh air, return air and exhaust air quantities required to achieve the designed indoor conditions, and adjust the dampers accordingly.

One of the air handling units serving the office floors of the building has been modified to be equipped with FAC facility. The supply air quantity of this selected AHU is 5m^3/s and the outdoor air intake, before FAC modification, was 1m^3/s. To make provisions for FAC operation, alterations and additional works including additional outdoor/exhaust air ducts, exhaust air fan completed with variable speed drive, sensors and control devices, and modification of existing CCMS programme have been carried out.

The real time operating data of the modified AHU and another AHU without FAC control with the same cooling load profile and operating hours have been measured. It was found that the energy saving for each FAC hour could be as high as some 60%.

5. Other Sustainable Features

5.1 Grey Water Recycling System

The Grey water Recycling System installed in the building is for treating the wastewater discharged from showers and wash hand basins in the kitchen and toilets. The treated grey water is used as toilet flushing water for the entire Building.

The water treatment process comprises three stages:

(i) Biological treatment - Micro organisms consume nutrients and transform suspended and dissolved organic matter in the water into acceptable end products. The surplus activated sludge will then be stored and removed regularly.

(ii) Micro filtration - After biological treatment, the water is pumped through submerged microfiltration membrane sheets that filter out particles including bacteria.

(iii) Disinfection and adjustment - After filtration, chemicals are added to disinfect the water, adjust the pH value (acidity) and to maintain residual chlorine in the treated water.

The average daily designed flow of the grey water recycling system is 26,000 litres per day, which is capable of serving a maximum of 2,500 persons in the building.

5.2 Double-layer Curtain Wall

The office uses double-glazing serves as heat insulation and noise insulation. The void between the two glasses minimizes the radiant heat transmission from outside and therefore reduces the amount of energy consumed by the air-conditioning system

5.3 Sunshade Screen

Sunshades screens are installed at the south-east and south-west portion of the building facade which minimize direct sunlight penetrating into the building in the summer and thus reduce the energy required for providing air conditioning.

Figure 8 Sunshade screen

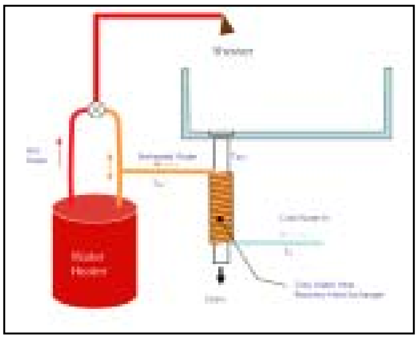
5.4 Solar Control Window Films

Solar control window films can reduce solar heat gain through fenestrations and result in energy saving in air conditioning. The windows at the corridor of the roof garden where there is large area of fenestration exposed to direct sunlight have been fixed with window film. The window film reduces about half of the solar heat gain through fenestration and lowers the average space temperature by 1-2 °C.

Fig. 9 Corridor with large fenestration area exposed to direct sunlight are fixed with window film.

5.5 Grey Water Heat Recovery System

Grey water heat recovery system has been installed as a pilot installation in the building. The system recovers thermal energy from the drains of 12 shower cubicles to preheat cold water supply to one of the bath rooms in the building. The system recovered about 2,300 MJ of thermal energy from the drain in a year.



Operating principle

Heat recovery pipes

Fig. 10 Operating principle of grey water heat recovery system

5.6 Green Roof Garden

Forming part of the sustainable building design, a green roof has been built into this building. The green roof not only provides a simple landscaped rest area for the staff, it can also keep down the roof surface temperature in summer.

Figure 11 Green roof garden

6. Education Path

An Education Path has also been built in the building to offer on-site public education tours for students and the public on sustainable building design. It comprises 2 exhibition galleries and a rooftop viewing gallery.

At the roof viewing gallery, the visitors can see the renewable energy features including the photovoltaic panels, wind turbines and sun pipes.

There are 17 sets of interactive exhibits in the exhibition gallery on ground floor. The exhibits provide comprehensive information on energy issues, renewable and clean energy technologies, energy efficiency schemes, energy efficient building services features, energy data, etc. The exhibition area on 7/F contains 4 nos. exhibits to introduce the safety of electrical, amusement rides, gas and lifts and escalators installations.

Figure 13 Interactive exhibits at the ground floor exhibition gallery

Figure 14 Exhibits introducing electrical and mechanical safety

7. Summary and Conclusions

Intelligent lighting control system, energy efficient chillers, cooling towers and variable air volume control air-conditioning system are effective energy efficient technologies applicable for buildings in Hong Kong. The EMSD Headquarters building is on the leading edge to use these energy efficient technologies as well as others including energy saving lamps, solar window film, thermal storage system and heat recovery systems. The building has put forth much emphasis towards incorporation of renewable energy technologies including photovoltaic panels, wind turbines, solar water heating system and sun pipes. Together with the incorporation of other green features including green roof garden, sunshade screen and grey water recycling system, the EMSD Headquarters building has won the Grand Award of the Green Building Award 2006 organised by the Professional Green Building Council, Hong Kong.

The Education Path provides an on-site public education tours for students and the public on sustainable building design. It promotes awareness and provides education on energy efficiency and renewable energy through the use of interactive exhibits and physically shows the innovative energy efficiency and renewable energy features of the building to the public.

The building has been a persuading case of utilizing sustainable building technologies. It will continue to be used for demonstrating the successful application of energy efficient and renewable energy technologies under local conditions.

Keywords: sustainable, building, construction, tools, method, assessment, criteria, weighting, environment impacts

Summary

Four different tools used to assess construction sustainability are reviewed and compared, namely LEED, GBTool-SBTool-es, the Regional Guide edited by the Basque Country (Spanish acronym GCAPV) and CALENER. The effect of the Technical Building Code recently implemented in Spain on sustainable construction is likewise analyzed.

Housing construction in the Autonomous Community of Madrid is of major importance to the region's economic and social development, accounting for nearly 10% of regional GDP and employing around 15% of the workforce. The industry's growth indicators have remained strong for over ten years. While this bonanza has indisputably contributed to regional economic development, it has also generated a series of adverse effects: a substantial rise in the volume of construction and demolition waste, urban sprawl, need for a larger water supply and, of course, intensified energy demands, which have grown seven-fold in the last forty years. The paper submitted forms a part of a research project whose primary aim is an in-depth analysis of HOUSING CONSTRUCTION SUSTAINABILITY in the region of Madrid.

1. Introduction

According to UNEP and OECD data on global environmental impact (UNEP SBCI, 2006), buildings account for 25 to 40% of total energy demands, 30 to 40% of solid waste and 30 to 40% of GHG emissions.

The need to quantify, classify and clarify this domain of sustainability has led to the development of a series of models and tools of varying scope.

The present article analyzes several tools for evaluating building sustainability, taking account of the various factors involved in the respective assessment methods such as Annex 31 of the IEA (2004), Green's EGBF File (2001), or the Final report of the EU Working group Sustainable Construction Methods and Techniques (2004): social, economic and environmental dimensions, the scale of the impact (global, regional or local), the agents and processes involved, the environmental loads considered and their effects (in a given timeframe), the requirement evaluated and the existing legislation.

2. Methodology

2.1 Tools selected

Three evaluation tools were selected on the grounds of availability, variety of structures and scope: Guía CAPV (EVE, 2006), LEED NC (USGBC, 2006), SBTool-es (IIsbe, 2007), y Calener VyP (Ministerio de Vivienda, 2007), the tool most representative of Spanish legislation on energy efficiency and certification, was evaluated but not actually used in the comparison.

The Guía CAPV, *Guía de edificación sostenible para la vivienda en la Comunidad Autónoma del País Vasco* (Guide to building sustainable housing in the Basque Country, Spain), contains nearly eighty measures or good practice recommendations that can be applied throughout the life of a building.

LEED (US Green Building Council) evaluates a series of technical requirements for building and facility construction; a building's overall rating is computed as the sum of the credits awarded for compliance with these requirements. In addition, certain minimum pre-requisites must be met to opt for certification. While it has been applied primarily in the United States, this scheme has been used to certify buildings in other countries, making it one of the most commonly used tools of its kind in the world.

In SBTool (iiSBE, Green Building Challenge) buildings are compared to two references, one representing normal practice and the legislation in force and the other the best possible practice given the technology available. While an international tool, SBTool-07 is presently in place, a version here called SBTool-es, that incorporates methodological adaptations and regional parameters is being developed specifically for Spain. This tool assesses buildings on the grounds of the impact reduction achieved with best practice.

Calener VyP is the benchmark tool for energy certification in Spain. It addresses the existing requirements (Technical Building Code – March 2006) on the limitation of energy demands and includes emissions data for different types of equipment for comparison with the standard building used as a reference.

2.2 Framework for comparison

In most cases, the analytical and methodological approach adopted in the various tools is unclear or unknown. The models used for internal calculations, specific system limits, scope of the life cycle analysis, technological scenario assumed and, most importantly, the analytical method and environmental model used for the assessment, are issues addressed below in the discussion of the entry data required and results or output.

In light of the variety of methodologies and parameters used, the indicators or criteria proposed by the different tools were taken as the starting point and organized in accordance with the categories defined in SBTool.

The comparison focuses on the design stage, the most strategically complete phase and the one that foresees many of the actions implemented during building construction and end of life. Only the criteria applicable to residential building in Spain were analyzed.

The areas and categories were weighted on the grounds of the weights applied in the tools themselves, which often differ depending on the country or region involved. Since as a rule this type of evaluation is conducted in response to political or commercial tendencies or even to the difficulty involved in estimating certain data, the parameters studied may vary widely. Climate change, for instance, or high CO2 emissions have become a priority in recent years both nation- and world-wide, and yet waning biodiversity, fertility and the depletion of the ozone layer, very topical issues only five years ago, are now accorded only secondary importance.

2.3 Organization of criteria and assignment of values

The procedure used to break down the maximum possible values allocated by each tool and distribute the different criteria by categories is described below.

The area distribution proposed by was used (see Table 1). The categories within each area defined by the international tool were included and the different criteria were grouped as a supplement to this study.

Area H (Other) was added to consider questions difficult to assign to any other area.

When several criteria were assigned to a given indicator, their weights were added. Where, on the contrary, a single criterion was assigned to several indicators, its weight was divided equally among them.

Guía CAPV. In this tool, the indicators for the pre-building stages were chosen, namely special subdivisional plan, development plan, preliminary design, design brief and full construction design.

Each item was weighted as specified in the Guide. Criteria appearing in several stages were counted in only one.

LEED. All the criteria described in LEED NC were considered. The requirements applicable during construction and use are established in the design stage.

Since this tool scores each criterion, the values were simply converted into percentages. The prerequisites (PR) specified for the various areas are shown but were not weighted.

SBTool-es. The criteria proposed in were included directly in the respective category. The phase for selecting criteria was the design stage. This included pre-building decision-making.

Although in this tool the raw scores are based on a scale of 0 to 5, it specifies the weight given to each area and criterion in percentage. For this reason, only the percentages were used to determine the maximum possible value.

Calener VyP. This tool, which assesses efficiency on a scale of A to E, was not used in the comparison because it only covers energy efficiency-related issues. In the energy and atmosphere category, however, it was taken as a proxy for Spanish legislation. Since most of the tools are based on existing legislation and grant a premium for strategies that improve on standard sustainability criteria, a score of “E” (minimum) was adopted as the reference for possible design improvements in this case.

2.4 Standardization of allocated values

In a first approximation, all the categories and criteria and their relative weights were used in the weighting exercise. This provided an overview of how areas and categories are weighted in the various tools. Subsequently, the areas containing criteria not shared with any other tool were set aside and their weights distributed proportionally among the rest of the areas. Broadly speaking, the areas set aside were G (economic and social factors), H (Other) and some of the categories in area F (Service quality). The results are given in Table 1.

Table 1. Summary of values by category and areas (%) and mean.

		G-CAPV		LEED NC			SBTool-es		Mean
		*	**	*	**		*	**	**
A	**Site selection, p. planning and development**	**17,9**	**17,9**	**20,3**	**21,9**		**33,4**	**36,7**	**25,5**

* Relative weightings including all cathegories and areas
** Relative weightings not including special cathegories and areas

3. Comparative analysis

3.1 Areas

Areas G and H are associated exclusively with the SBTool-es and LEED tools, respectively. Despite their higher relative weight (8.8% and 7.2%, respectively) than found for other areas such as *potable water*, this singularity disqualified them for the comparison.

Area G – economic and social factors – places the same weight on social factors such as accessibility, construction site accidents and privacy, as on economic factors such as building costs and selling or rental prices. This area does not cover criteria related to perceived or local cultural values, some of which are included under other areas in SBTool-es.

Area H – Other – encompasses innovation criteria proposed by LEED, which take into consideration both exceptional performance in any of the other criteria and innovative performance in categories not specifically addressed by the tool.

As Figure 1 shows, *energy and atmosphere* is the area most heavily weighted, followed very closely by choice of site. Between them, they account for around 50% of the total. *Potable water*, at 10%, is the area assigned the lowest weight. The rest of the areas accounted for abut 14% each.

This area classification is not directly related to type of impact. While *energy and atmosphere* are directly associated with greenhouse gas emissions, the relationship is more ambiguous in other areas. Moreover, many of the criteria included in other areas are also directly associated with this same type of impact: transport or materials, for instance. This is the logical outcome of regarding energy to be a key parameter in the environmental impact generated by buildings.

As a rule, these assessment tools evaluate the environmental load on water, air, soil, landscape and plant and animal life in terms of the resources used and the waste generated (in the broadest sense of both). Building habitability, however, covers other types of parameters such as the items included under the heading *indoor environmental quality* that affect health, hygiene and comfort. This approach deals with factors relating to people's quality of life.

Figure 1 shows the weights by cathegorys of each of the tools and the mean after the redistribution following the removal of areas G and H and some of the service quality categories.

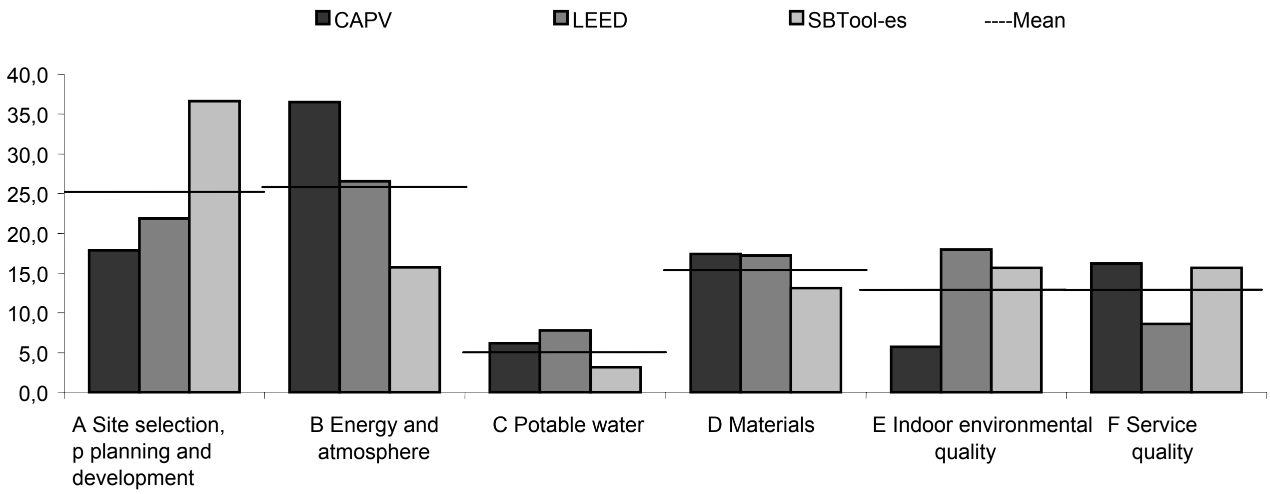

Figure 1 Weights by area

In the draft Green Paper on the Environment for urban Spain (Libro verde de Medio Ambiente Urbano para España – Ministerio de Medio Ambiente 2007) were identified as the main causes of non-sustainability in the building: the unbridled growth, inefficiency in the use of resources, and the rigidity of housing supply. All are linked directly to the medium in which they are engaged.

3.2 Categories

In the following discussion, the areas and categories are broken down into the respective criteria for a more detailed comparison.

3.2.1. A- Site selection, planning and development (mean weight, 25.5%)

The area is subdivided into three categories:

- A1 Site selection. Intended for the agent choosing the building site. It includes the criteria determined by the site and type of existing planning, such as development density and community connectivity.
- A2 Planning. Associated with the specific circumstances of the site to be chosen, such as its orientation or value as prime farmland.
- A3. Urban design and area development. Including design strategies applicable to the site chosen, such as the reduction of light pollution or fitting the building with a waste separation or water recycling facility.

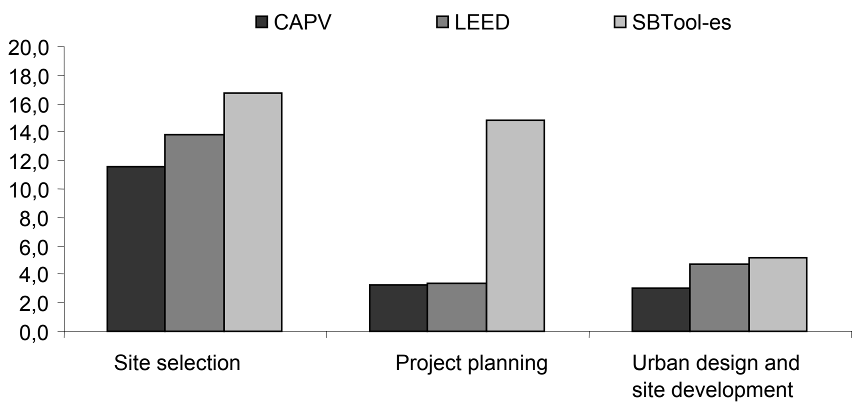

Figure 2 Category weighting in area A – Site selection

This area stresses the interdependence between the building and its urban surroundings. The difficulty lies in precisely defining and delimiting the surroundings.

The criteria used by the various tools are approximately similar in this regard, the most prominent of which are the inclusion of provisions in the design for mixed use or to avoid the possible shading of adjacent lots.

The relationship between the design and the existing landscape, compatibility with local cultural values or property value are features specific to SBTool-es.

Some of the criteria included in this area are also considered in others, such as trees with shade potential or site orientation, which have a direct effect on energy efficiency.

Differences can be identified between the requirements of the various tools, however. In LEED, for instance, the maximum allowable distances to public transportation are 800 m (for underground or similar) and 400 m (at least two bus lines), while the Guía establishes a maximum distance of 500 m to some form of public transportation providing service at 20-minute intervals or less.

As a rule, many of the criteria are directly related to their impact on climate change which, as noted above, is the chief priority.

This area contains only sparing recommendations with respect to the legislation in force, although account must also be taken of the type of urban design or planning processes and proceedings presently in place.

SBTool-es is the application that attaches most importance to this area, which at 37% nearly doubles the weight allocated by the other two tools (LEED, 22% and the Guía, 18%).

After the redistribution exercise, category weighting in SBTool-es is: 15% for planning, another 15% for choice of site and only 5.1% for urban design.

The agricultural and ecological value of the undeveloped area and the impact on surface and underground water are assigned very little weight in general. Acording to Naredo (1997), the urban sprawl of the last twenty years, has used more land than the land used two thousend years before.

3.2.2. B- Energy and atmosphere (mean weight 26.3%)

The area is subdivided into two categories:

- B1. Renewable energy and GHG emissions. This includes the type of energy source used and greenhouse gas emissions.
- B2. Other emissions. Emissions with other types of environmental effects.

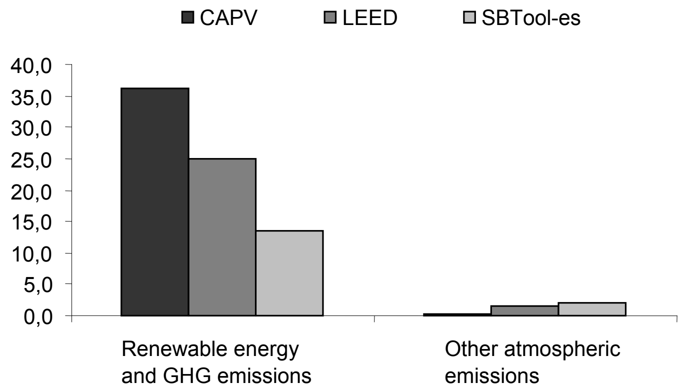

Figure 3. Category weighting in area B – Energy and atmosphere

This is the area where tool criteria and Spanish legislation on energy efficiency and renewable energy are most closely correlated. Essentially, the difference consists in the type of requirements. Improvements on minimum standards are rewarded and possible strategies are recommended, such as the design of passive systems.

The main enhancements with respect to the existing legislation are found in the provisions on the use of local products to avoid having to ship materials and on the amount of energy needed to produce them. This is directly related to area D (Materials), where reuse or recycling entails the reduction of waste as well as of the demand for resources.

Here it is the Guía CAPV (which, it will be recalled, was developed at the same time as the new legislation) rather than SBTool-es that weights the area most heavily. Improvements in the envelope and heating and air conditioning systems are the most relevant factors for the former tool.

The reduction of the amount of equivalent CO2 emitted by HVAC systems is the basic consideration, even though such emissions are addressed in the present legislation, specifically in the Technical Building Code and energy certification standards. Initially, the differences lie in the improvements over the standard requirements: many of the criteria set out in the Guía are included in the legislation, while in LEED the reference standard is ASHRAE and SBTool-es takes account of improvements over Spanish legal requirements.

The graph by areas also shows the importance attached to greenhouse gases over other types of emissions. The distribution of consumption (heating, cooling, hot water, ilumination, and others), and the type of energy suply in residential buildings, variate depending on the region and climate area studied, and consecuently, the potential impact reduction (UNEP 2007).

3.2.3. C- Potable water (mean weight 10%)

The area is subdivided into two categories:

- C1. Potable water. Focused on reducing consumption.
- C2. Rain-, storm- and wastewater. This category considers the use of these types of water as a source of supply.

The criteria applied to water, similar in all the tools, consist basically in lowering consumption through reduced use (highest score) and the deployment of alternative sources where potable water is not needed. Criteria such as water quality or the water content in materials are not addressed.

Spanish legislation contains a number of recommendations in this regard, but no specific measures for minimizing the associated impact.

SBTool-es associates these criteria with the loss of aquatic life and the depletion of resources.

3.2.4. D- Materials (mean weight 15.9%)

The area is subdivided into two categories. As the two are closely related, the subdivision clarifies little in this case:

- D1. Materials. Reused, reusable, recycled, recyclable. Composition and origin are other factors considered here.
- D2. Solid waste. Generated essentially during construction or demolition, but also during the building's service life.

This area focuses essentially on products containing harmful substances and their possible active re-entry into the environment through recycling and reuse. Production criteria for certain materials such as certified wood are also covered.

The Guía is the only tool that takes account of waste generated during construction and demolition, although these items could be included in the databases used by the other tools or in the type of strategies proposed for construction and demolition in the site development stage.

Both LEED (14.1%) and SBTool-es (13.1%) score reuse or recovery as a basic strategy higher than recycling and propose the use of existing elements and precast/prefabricated or industrialized elements.

3.2.5. E- Indoor environmental quality (mean weight 13.1%)

The area is subdivided into five categories:

- E1. Indoor air quality
- E2. Ventilation
- E3. Temperature and relative humidity
- E4. Daylight and lighting
- E5. Noise and acoustics

The legislation is more closely patterned to the requirements laid down in this case. Ventilation, temperature, humidity, light and noise are directly reflected.

However, differences are again encountered in the stringency of the requirement. In this case, as well as in service quality as discussed below, monitoring and controllability play an important role.

The air quality criterion contains no reference to outdoor air quality, that in some areas exceeds the levels of pollution limits for the protection of human health (OSE 2007).

The Guía is the tool that attaches least importance to this area, while focusing on the quality of indoor air and ventilation. LEED also takes this approach, but places less weight on temperature, humidity and lighting. SBTool-es distributes the values more or less evenly across the various areas, with greater weight going to noise and acoustics than in the other tools. In light of the new legal requirements respecting noise, this emphasis proves to be excessive.

3.2.6. F- Service quality (mean weight 13.5%)

The area is subdivided into five categories. The first two (F1- *Safe usage* and F2- *Functionality and efficiency*) were eliminated from the comparison because they are addressed in the legislation and do not score in any of the tools:

- F3 Controllability

- F4. Flexibility and adaptability
- F5. Commisioning and manteinance of facility system.

SBTool-es assigns similar values to system controllability, flexibility and maintenance, while LEED attributes no value to flexibility and the Guía attaches greater importance to system delegation and maintenance.

Since *controllability* and *building delegation and maintenance after completion* are closely related, the inter-tool differences are not significant.

3.2.7. G- Economic and social aspects (relative weight excluded)

The cost per square meter-hour of building use is an indication of the long-term efficiency of solutions.

The cost of land is not considered.

3.2.8. H- Other (relative weight excluded)

Area H – Other – encompasses innovation criteria proposed by LEED, which take into consideration both exceptional performance in any of the other areas and innovative performance in categories not specifically addressed in the tool.

4. Discussion, conclusions and proposals

4.1. Output or results

In the Guía and SBTool-es, the results are displayed on fact sheets showing the relevance of the impact generated. In LEED, by contrast, the result is the rating level obtained. The fact sheet display, which shows partial and total results, affords a more complete overview of the multidimensional assessment. The final score is an addition of different partial issues, like health, CO2, security or NOx, and it leads to mistake the score weight for its relevance, so clarity in fact sheet layout and differentiation depending on the degree of detail desired are other important features.

In the Guía, project scores are given in percentage and shown on a graph. The weighting factors and breakdown by categories are also visible, providing a broader view of the domain affected by the load (materials, soil, potable water…). The inclusion of the partial results obtained on every one of the pages as the form is filled in is extremely useful.

In SBTool-es, scoring is based on impact prevention and each of the criteria within the categories refers to the type of impact involved. This method is similar to the procedure followed in the Guía, although the scores reflect the effects caused by specific loads and an attempt has been made to use these loads as the unit of measure.

Energy certification is clear and revealing, but is not intended as a design aid.

Generally speaking, the rationale for criterion weighting is difficult to understand. While the value assigned to the volume of harmful gases is conceptually comprehensible, for instance, there is no notion of the scale of their significance. Much the same can be said of materials and waste. The quantities by content in material recycling or the degree of recycling possible are often hazy or ill-defined.

A more complete view of local, regional and global impact, reflecting the beneficial and adverse effects of the process studied, would be highly useful. Moreover, the inclusion of the real impact associated with the various requirements would lead to more responsible decision-making.

In housing construction, it would be helpful to have results in terms of the number of persons or users for which a building is intended. Broken down by areas, such results would indicate, for instance, the number of kg of material used or the amount of land deteriorated and/or reclaimed *per capita*.

4.2. Design process

The tools analyzed are geared to design decision-making. As such, they set out a series of guidelines referred to present construction practice. One final outcome provides an indication of the degree of compliance with requirements, which is useful where the objective is merely to obtain a certificate or a high score. As reference tools for selecting specific strategies, or as educational tools, however, they clarify very little.

For the design process it will be helpful and efficient, to synchronize the assessment with other modelling tools and building databases, in order to simplify the management of the building cycle, exchanging and integrating construction information, legislation or documentation and involve the various actors. This may improve the evaluation of sustainable options and quality of solutions.

4.3. Regionalization

When tools are regionalized, they are adapted to a greater or lesser degree, fortifying non-regulated sustainability criteria or criteria of greater regional or local relevance. Some of the criteria excluded from the comparison, therefore, are not being taken into account because they are included in the existing legislation. Regional adaptation is one of the features that distinguishes and adds value to these tools.

4.4. Legislation

Both the Guía and SBTool-es are based on energy certification under Spanish legislation, directly adopting this (or some similar) assessment as a criterion.

Spanish legislation should promote or include the points where the tools clearly and decidedly concur.

4.5. Type of criteria and organization

The areas, categories and criteria of the tools analyzed are imprecise and their limits blurry. The structure could mirror the sustainability model used for the assessment.

Where social and economic factors are – exceptionally – considered, the treatment is cross-sectoral. This is odd, when users' lifestyles and habits are so closely related to buildings and have such a long-term impact, and when a new order is being proposed for the production system on which construction is based.

The cost-sustainability ratio should be reviewed. The e*nvironmental profitability* conceit, i.e., the savings in the cost of water and energy throughout the service life of a building, could be extended to other categories. Sustainable buildings are more costly than buildings erected using standard practices and procedures. And yet cost increases in this type of practices are widespread.

In light of land development and occupancy in Spain, the need to develop tools for rehabilitation would appear to be inescapable. Criteria might also be included on the necessity of construction: second homes as opposed to housing for disadvantaged communities, for instance.

The inclusion of regional data on outdoor air quality, urban complexity, noise or the location of recycling sites and the orderly reference to systems recommended for their sustainability would facilitate decision-making.

The surroundings where buildings are sited and the way they contribute to the formation and use of cities are directly related to construction *per se*. A review of the indicators used in urban systems reveals analogies and differences with the tools analyzed here. Generally speaking, they have much in common, but there are fields where the tools could go into deeper detail, such as participation, reduction of inequalities and social inclusion, furtherance of local employment or facilitation of integrated design, defining the areas that correspond to the various actors involved and specifically addressing issues as closely related to building as quality of life, public space, diversity and complexity.

Summary

As a result of structural change, new inner-city conversion areas are increasingly emerging in European cities (due to the relocation or closure of facilities and properties used for industrial or military purposes). Using the tool of prospective project development and integral planning, taking account of demographic development and different lifestyles, the goal of sustainable district development can be achieved.

The task and goal that we set ourselves was to use best practice models, in other words projects we have implemented, to set an international example of the sustainable, energy-efficient renovation of listed buildings, backed up by scientific measurements.

We will be reporting on fully or partially completed property renovation projects carried out by a network that we set up. The future residents, who are at the centre of the action, receive comprehensive advice and support from us.
We involve the residents in planning right from the redesign phase. They receive competent advice from experienced architects and economists, alongside a financing option tailored to suit the concept at hand. This option, which encompasses grants for sustainable renovation and cooperation contracts, enables communal areas and multi-purpose areas to be established, thus enabling individuals with a lower level of income to also own their own property within these units.

1. Rediscovering the city – sophisticated living

The charm and appeal of inner-city districts in European cities comes from the historical structures that have evolved over time.
This is what sets European cities apart from many of their American or Asian counterparts and defines their identity.
People are now rediscovering inner cities as places to live. City centres are becoming increasingly attractive to single people, young couples, families and older people who no longer wish to live “away from the action”, and who consider the city with its unique supply structure the best place to live.
As a result of structural change, new inner-city conversion areas are increasingly emerging in European cities (due to the relocation or closure of facilities and properties used for industrial or military purposes). These areas and buildings that have lost their original function now offer space for individual, sustainable living concepts.
The German government introduced guidelines for sustainable construction back in 2001. However, what is missing in Germany is a clear label that makes the recording and assessment of economical, ecological and socio-cultural factors transparent and traceable. The “Future Construction“ research initiative from the German Federal Ministry of Transport, Building and Urban Affairs is set to present a label of this type in 2008.

1.1. Re - thinking the city

This was one of the contributions from the European Commission conference in October 2007 entitled "Towards a post-carbon society – European Research on economic incentives and social behaviour".
Taking account of climate change, the EU's aim of achieving a "post-carbon society" by 2020 as well as the need to not only save energy in buildings but also provide energy, it is evident that intelligent, decentralised solutions are required. Innovations should result in legal obligations with high benchmarks so they can be implemented across Europe in the mid-term.

In decades to come, societies will be faced with two main challenges:
– Economic and social adaptation to climate change, which has already begun
– Economic and social development alongside ever-increasing prices for energy resources.
The economical and social costs in this area are immense. In cash terms, these costs are estimated at more than one hundred billion euros per year. This, of course, has a detrimental impact on the well-being of society as a whole and on quality of life.

The aim of the European Union is to incorporate research on social adaptation into climate research in order to bring about the consciousness required for a "post-carbon society". Jean-Michel Bear, Director of the European Commission DG for Research, Science, Economy and Society has explained that humanists and social scientists urgently need to get involved in the debate and define new forms of responsible leadership in the business world or in cities.
The necessary social contact in city districts brings together people who do not live in the form of the "classic" family. City living also offers a lot more freedom to those with children.

1.2. National urban development policy

In climate protection, particular attention is also paid to urban development policies.
In Germany, three quarters of inhabitable buildings are deemed in need of renovation. However, due to insufficient attention paid to energy efficiency, etc., the aim of sustainable construction has not yet been reached for existing buildings. In addition, 40% of energy used is needed for running buildings. In the last 10 years, building heating costs have risen by around 90%. On one hand, all parties involved need to change their way of looking at things. On the other hand, sustainability must be made measurable and comprehensible to everyone so that it becomes a new competition factor in the housing industry.
One of people's primary needs is healthy and safe living or working in an enclosed space. Positive changes in behaviour regarding health protection, ecological protection and conservation of resources are becoming apparent through living or working in "sustainable" buildings.
The advantages of city living are obvious. These advantages, including a short journey to work, cultural entertainment, educational facilities, medical care and other benefits, are in high demand.
Are consumers responsible for paving the way towards a "post-carbon society"?
Will new social values lead to rapid and lasting changes in behaviour (similar to the way in which smoking has negative connotations in today's society, for instance)?
Could *Passivhäuser* (ultra-low energy buildings) or low-energy houses accelerate the change process, and lead to changes in the way consumers think?
The answer to these questions is a resounding YES. As economist Franz-Josef Radermacher states in his book *Welt mit Zukunft* (World with a future), a balanced world can only be achieved by all people making a change in their immediate surroundings.

Figure 1 aerial view of Ludwigshafen Hemshof 2003, building Rohrlachstr. 79 front and courtyard view.

Regional diversity and identity give rise to major urban development and profiling potential in terms of the Leipzig Charter. Including listed buildings in the 2020 outlook is of great importance in achieving the aim of energy-independent, energy-efficient houses and districts without a loss of their identity.
Adapting existing properties to contemporary user requirements and demographic change, while taking sustainability into account and using existing architecture as a resource, requires changes be made more rapidly to existing properties.

2. Project implementation

Using the tool of prospective project development and integral planning, taking account of demographic development and different lifestyles, the goal of sustainable district development can be achieved.
The task and goal that we set ourselves was to use best practice models, in other words projects we have implemented, to set an international example of the sustainable, energy-efficient renovation of listed buildings, backed up by scientific measurements.

The aim of the projects run by Osika GmbH is to achieve sustainable district development – meaning development that is socially open, that spans generations, that is committed to cultural heritage, that is functionally differentiated, that is ecological, that is ambitious in construction terms, that networks various urban areas and that opens up public spaces. This aim is proven by examples of the company's projects in Ludwigshafen-Hemshof, Mannheim-Schwetzingerstadt and the "Quartier Normand" in Speyer.

These examples demonstrate how to go about carefully protecting existing buildings that are worth preserving, while adapting them to suit future development challenges in districts.
In Ludwigshafen-Hemshof, the old town, which is around 50 hectares in size, has been given a new lease of life through involving both public and private individuals and property owners.

2.1. Sample project Quartier Normand, Speyer

In Speyer, an area of land that has been isolated by military use for 120 years is being reincorporated into the city as an inspirational "city building block".

Figure 2 historical picture 1900, Quartier in 2003, district development in 2004

The individual measures that have been taken or will be taken are as follows:

- Interdisciplinary development of a district strategy
- Reaching a consensus in committees and public authorities
- Selective deconstruction
- Static reinforcement
- Renovation of listed properties
- Energy-saving modernisation of constructional and technical structures:
    - Interior insulation of building fronts
    - Controlled ventilation with heat recovery
    - Incorporation of elements of passive houses
    - CO_2-neutral heating system with a heating network based on biomass and solar power

Figure 3 innovative interior insulation, CO_2- neutral heat supply,ventilation with heat recovery

- more than 80% reduction in the primary energy requirement
- Buildings with a heat requirement of fewer than 60 kilowatt hours per square metre per year
- Division into manageable owner communities (house-in-house principle)
- Addition of individual free areas for each unit of use
- Various housing offers for different user groups
- Development of individual planning designs from a 1-room apartment to a loft apartment
- Combined commercial and residential use
- Sophisticated grounds as an integral part of the project

In this way, these new, “old” parts of the city are not only being sustainably renovated and developed for their own benefit, but are additionally setting an example that is being followed in neighbouring districts.

Starting with integrated planning and incorporating networks of all those involved, such as project developers, utilities, councils, specialist planners, investors and users, and using best-practice procedures supported by the German energy agency DENA and the national urban development policy, higher-level sustainability targets can be reached in many areas within a short space of time.
In the case of individual historic buildings, for instance, these targets are being met by renovating the building to make it energy efficient, mainly by using passive-housing components. In the case of districts, these targets are being met by decentralised, autonomous provision of renewable energy.

Figure 4 Visualisation 2005 of the historical building in Speyer, Quartier-Normand

2.2. Sample project Transformation at Luther Square, Ludwigshafen

The aforementioned goals are being pursued as part of a project in Ludwigshafen to transform Luther Square.
The project, “Living at Luther Square”, can be viewed as a pilot project for the planned city redevelopment measures in Ludwigshafen.

Future inhabitants are looking for:

- Sophisticated living and a return to the city
- A tranquil living environment
- Adaptable concepts
- *Bauhaus* architecture
- Life in a place with historical flair
- Life in energy-efficient buildings
- Accommodation suitable for families

- Independence in old age
- Proximity to work/amenities and a good infrastructure
- Cultural diversity
- A mix of generations
- Houseshares
- The young and the elderly helping each other
- Childcare for small children
- Care for the elderly or the ill, if required
- Increased quality of life though a sense of community
- People of a similar mindset, regardless of their income

The following terms can be used to describe the concept strategy:

- Establishing desirable places to live
- Unique selling propositions
- Diversity of usage
- Developing a neighbourhood
- Expanding and renovating existing structures
- Promoting community, civil participation and social communication
- Dealing with empty properties and wasteland
- Prioritising internal development over external development
- Improving the habitability of inner cities
- Modernising existing housing, adapting it to suit current needs
- Establishing new forms of housing
- Increasing the living quality of properties, creating green areas, creating open spaces between housing blocks
- Stabilising the social structure
- Increasing the amount of condominiums
- Making the city a more attractive place to live
- Developing a positive image

Good project management enables all types of homeowners and homeowners' associations with different financial arrangements to participate positively in finding a solution to meet everyone's needs.

Figure 5 Visualisation 2008 Building Berlinerstraße/ Lutherstraße

Revitalisation of areas in terms of sustainability, energy efficiency, inspiration and flexibility to suit the lifestyle of people of all ages is expressed by the transformation at Luther Square in Ludwigshafen as follows:
The imposing former council house can be split into numerous small properties that are grouped into various owner communities in line with the house-in-house principle.
Each owner community has its own entry door to the main building, some have lifts and are accessible to the disabled. Each community has balconies overlooking the courtyard. It is possible to change the living arrangements and communal spaces if required.
33 residential units and units for offices and cultural use ranging in size from 40 square metres through to 200 square metres of effective useable floor space can be created in this building.

This means that the building, which lends identity to its area, is an attractive example of the overall concept of inner-city renovation.

Figure 6 Cancellation of the inner block area, planed inner courtyard situation

3. Data and evaluation

Our own annual empirical data dating from 1994 onwards has been analysed in terms of energy efficiency and energy-saving potential. This data concerns a total of 160 residential and office units with a total of 17.200 square metres effective useable floor space in the Rhine-Neckar Metropolitan Region, including larger cities such as Ludwigshafen, Mannheim, Heidelberg and Speyer. This data shows how on the one hand primary energy needs and the energy required for living change over time, and on the other hand how the people residing in these units behave regarding the environment and climate protection in their immediate setting.
The project in Speyer for the revitalisation of a former barracks compound was used as the basis of a lifecycle analysis, and analysed using the LEGEP tool in connection with the other two contributions from Germany to the World Sustainable Building Conference 2008.

The following data analysis are predicated on the evaluation of the project Quartier – Normand Speyer with the LCA,LCC tool LEGEP:

The graphic shows the Final Energy consumption before (left) and after (right) the renovation of the building.
The heating energy consumption with only 21.629 kWh/m^2/a after the refurbishment shows the reduction of 94% of the heating energy.

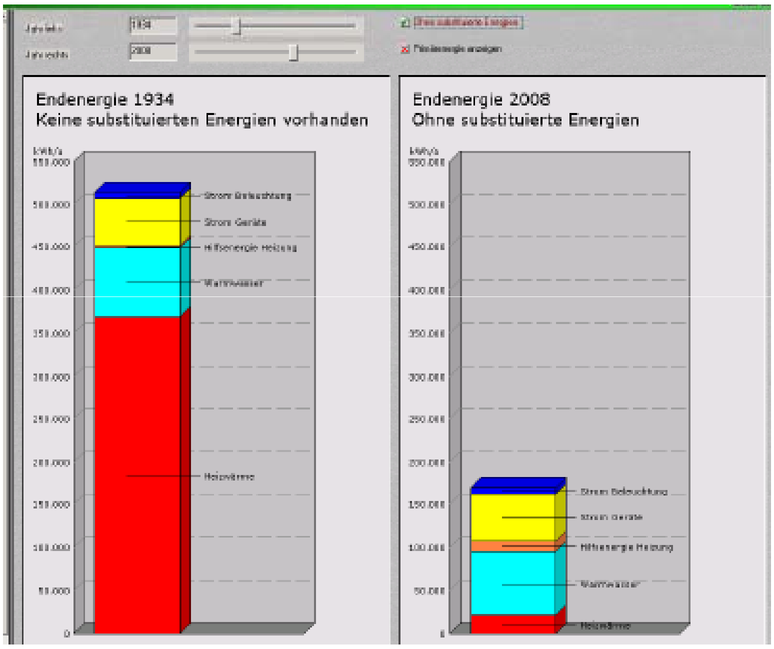

Figure 7 Final Energy consumption

The changes of the enviromental impact, (kg CO_2 – equivalent) shows that the amortisation occurs after 3 years in 2011.

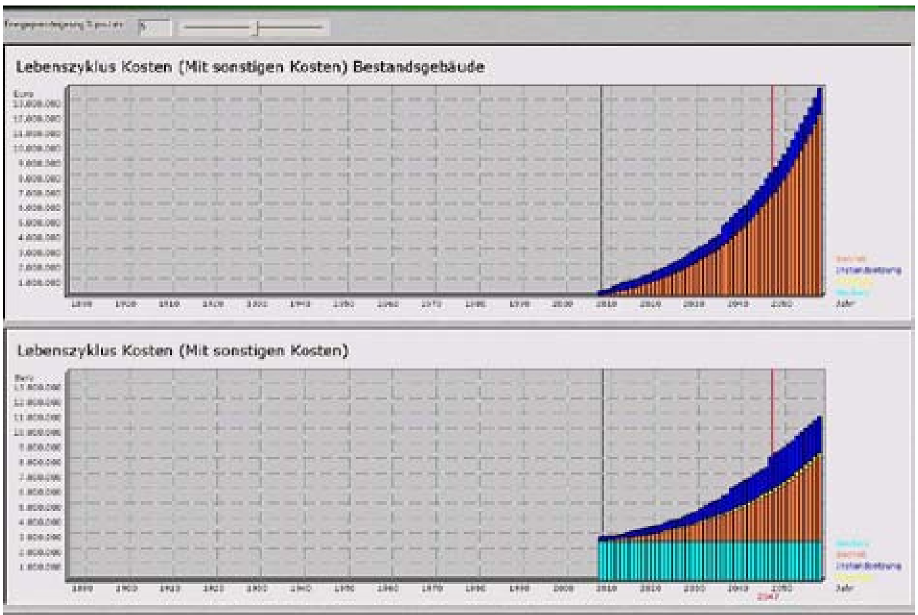
after renovation

Figure 8 -kg CO_2 - greenhouse gas emmissions

This graphic shows the values of Life Cycle Costs if the energy prices increases about 6%/a over a period of 50 years



before renovation

after renovation

Figure 9 LCC with energy price increase of 6%/a during 50 years

4. “Homes for living” initiative

The floor plans of the individual residential units can be adapted to suit the needs of the residents. Here, the owner communities also form small mutual support communities, so that a family with 3–4 children, for instance, can also afford a large home, as the part of the purchase price that exceeds the family’s budget is financed by the other residents through a cooperative model. Competent specialist advisors who can think innovatively in terms of both legal and economical issues are required to support and run this process. That’s why in 2007, we launched the “Homes for Living” initiative – sustainable buildings for more quality of life.

Figure 10 Impressions entrance and indoor Quartier Normand, Speyer

5. Successful and sustainable networking – connected, viable, liveable

The Rhine-Neckar Metropolitan Region, with an area of 5,637 square kilometres and 2.4 million inhabitants, is the seventh largest urban agglomeration in Germany. Networked structures in business, science, politics and administration allow successful collaboration at all levels with a view to taking increased regional responsibility in these areas.
Following acceptance in the group of European metropolitan regions on 28 April 2005, the Minister-Presidents of the Federal States of Baden-Württemberg, Hessen und Rhineland-Palatinate clearly expanded the leeway of the region and its players with a new state treaty on 26 July 2005.

More than 100,000 companies operate in this region. Key issues and areas of action for the various players are sustainability but, in particular, energy efficiency, and sociocultral values.
Faced with global competition, the regions that will be successful will be those that consolidate their strengths and communicate a clear profile both within and outside the region.

Alongside this large network, there are numerous smaller networks, which are held in high regard in terms of their impact and acceptance.
Examples here include EnergieEffizienzAgentur Rhein Neckar gGmbH, the Stiftung für Ökologie und Demokratie e.V. foundation and the Energieagentur Speyer Neustadt Südpfalz energy agency, which even makes a key contribution in conjunction with German national urban development policy.

Keywords: Environmental Building Assessment, High Rise Building, Sustainable Building, efficiency, Office Buildings

Summary

The French Ecology and Sustainable Development and Planning Ministry contracted with CSTB in order to get aware of and to take benefit from the existing examples of "sustainable" high rise offices towers all over the world

The study has been a two step process:

- A description and a comparison of the main existing sustainability/environmental assessment methods of offices buildings, has been developed as a follow-up of a previous study, with a specific focus on the low energy performances.

- An international survey of. high rise "sustainable" office buildings has been carried out. An overall analysis methodology was proposed in order to collect and take the most of relevant data, firstly based on bibliography and internet sources, and secondly on direct contacts with the concerned people.

This paper focuses on the survey. It first explains the analysis methodology, and reports on the results at the different steps. At the final stage, five towers selected from the initial inventory have been deeply investigated, with a special attention towards the climate, energy and ventilation concepts and the real performances in use. Main objectives were to elaborate a state of the art of the "sustainable" technologies used, and to collect performances in use and feed back from the owners and users, in order to make choices based on actual experience.

At the end, we try to provide a partial answer to the following question: Can a high rise office building be "sustainable"? The debate has to be initiated at the early stage of the process, with only the programme in hand.

1- Introduction

Among all the office towers which have been erected recently, or which are planned in different cities in the world, some projects have been designed with the concern of sustainability. The aim of the study ordered by the French Ministry for Ecology and Sustainable Development and Planning was to get an overall view of the best examples, together with a good knowledge of the tools enabling the assessment of the sustainability of the works.

The study has been performed in two steps:

- A description and a comparison of the main existing sustainability/environmental assessment methods of offices buildings, has been developed as a follow-up of a previous study, with a specific focus on the low energy performances.

- An international survey of. high rise "sustainable" office buildings has been carried out. An overall analysis methodology was proposed in order to collect and take the most of relevant data, firstly based on bibliography and internet sources, and secondly on direct contacts with the concerned people.

The following development focuses on the second part, the survey. We first describe the methodology, then present the results. The second part of the paper is dedicated to the lessons learned, with a more developed section on the energy consumption aspects. The study was conducted in close contact with an advisory committee composed of technical experts together with national authorities' representatives, who commented our results in terms of transposition feasibility.

2- International survey on high rise sustainable office buildings

2-1 Methodology

Objective of the study was firstly to inventory some remarkable high rise office buildings in term of sustainability.

The survey has been performed in two steps:

- a bibliography enquiry has been made by CSTB, using mainly internet sources, which procured plenty of information
- a mobilization of the international CSTB network in order to collect complementary and real information.

To collect data and analyze information, CSTB made different types of questionnaire and analysis and evaluation documents which were discussed and validated with the ministry. The questionnaires were sent to out international contacts with a document describing our study in order to get one or two references in each country.

A simplified questionnaire was focused on project characteristics, actors of the project (owner, architects…), state of the work, operation description, site characteristics (surfaces, high of the work, usage), economic data, principal objectives of the work in term of sustainability and environmental quality, thermal performances expected and in use, space organization and some others aspects of sustainability matter.

In order to analyze deeply five towers of this preliminary inventory, a detailed questionnaire was made which focused more precisely on the sustainable and environmental quality issues, on the space organization, on the comfort in use of the building, on the innovating solutions and systems in order to get the performances of the building, and on the real performances in use.

We have been confronted to difficulties to get completed questionnaires returned from our contacts. The difficulties came from the short delay to respond to our enquiry, and from the fact that real performances in use of "sustainable towers" are not always known by the owner, and not always communicated. The expected performances are set up by the architect and engineers teams of the project, but not often evaluated when the building is in used, and if known, not communicated. This study pointed that expected performances of a high rise building are not often matched when the building is in used, a special point about the usage of the tower which does not correspond with the expected use during its design.

2-2 Results

This non exhaustive inventory showed that there is a lot of high rise office buildings around the world, lot of them with "supposed" sustainable characteristics. Our analysis focused on 25 towers, most of them in Europe and USA, and few in Asia, in order to get more confident and transposable information. In a second part of the study, five selected projects were deeply investigated and analyzed.

This inventory showed that environmental preoccupations are not a design priority for older towers. Nevertheless, the sustainable principles are more and more taken into account, and become inescapable in the design and construction of new towers.

The five deeply investigate projects have been chosen with the ministry for:

- the sustainability preoccupations, and especially environmental and energetic concept and performances,
- the climatic, cultural and social criteria, in order to get usable and transposable information for the ministry,
- towers in used in order to get experiences returns and real performances in used.

The five selected towers are:

- Commerzbank Tower (Germany)
- Conde Nast Building (USA)
- Post Tower Bonn (Germany)
- St Mary Axe (or "Swiss Re" in GB)
- Highlight Business Tower (Germany)

Commerzbank Tower is located in Frankfort and has been made by Foster and Partners for Commerzbank AG. This triangular building has been delivered in 1997 and is 259 meters high (300 m with antenna). It has been considered by many as the first "green" high rise office building in Europe. Four storey gardens spiral up the tower and are linked to a 200m central and triangular atrium.This building has been designed in order to optimize daylight penetration utilize natural ventilation for a large proportion of the operating cycle, using mechanically assisted air conditioning only under extreme conditions.

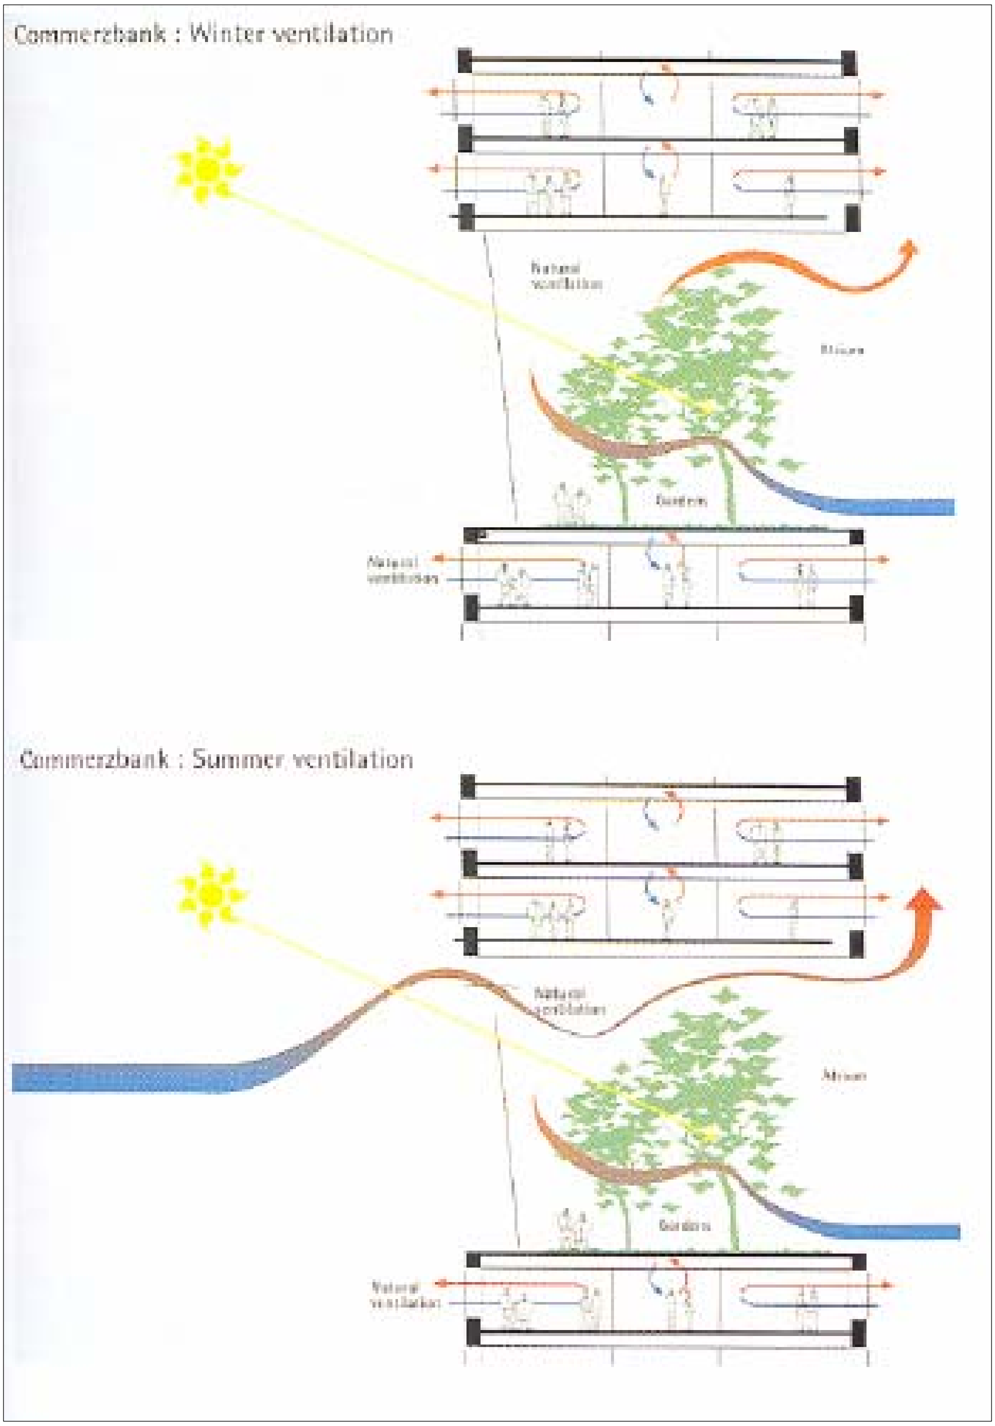

Figure 1 Commerzbank : functioning scheme in summer and winter (Michael Wigginton and Jude Harris, 2002 Intelligent skins)

Conde Nast Building is located in New York and has been made by Fox and Fowle architects for the Durst Organization. It has been delivered in 1999 and is 247 meters high (264 m with antenna). It was the first “green” high rise building in New York with high consideration in terms of energetic performances of the building and renewable energy

. Post Tower Bonn is located in Bonn in Germany and was conceived by Helmut Jahn for Deutsche Post and was delivery in 2002. This 161 meters high building is composed by two twin towers connected by glass bridges at each floor. This building develops a double skin façade in glass. At the design stage, energy demand of Post tower Bonn was evaluated at 117 kWh/m²/year, compared to 390 kWh/m²/year of a standard office building. Measures done in 2003 showed a real energy demand of 166 kWH/m²/year (source TRANSSOLAR), 66% higher of the estimated figures

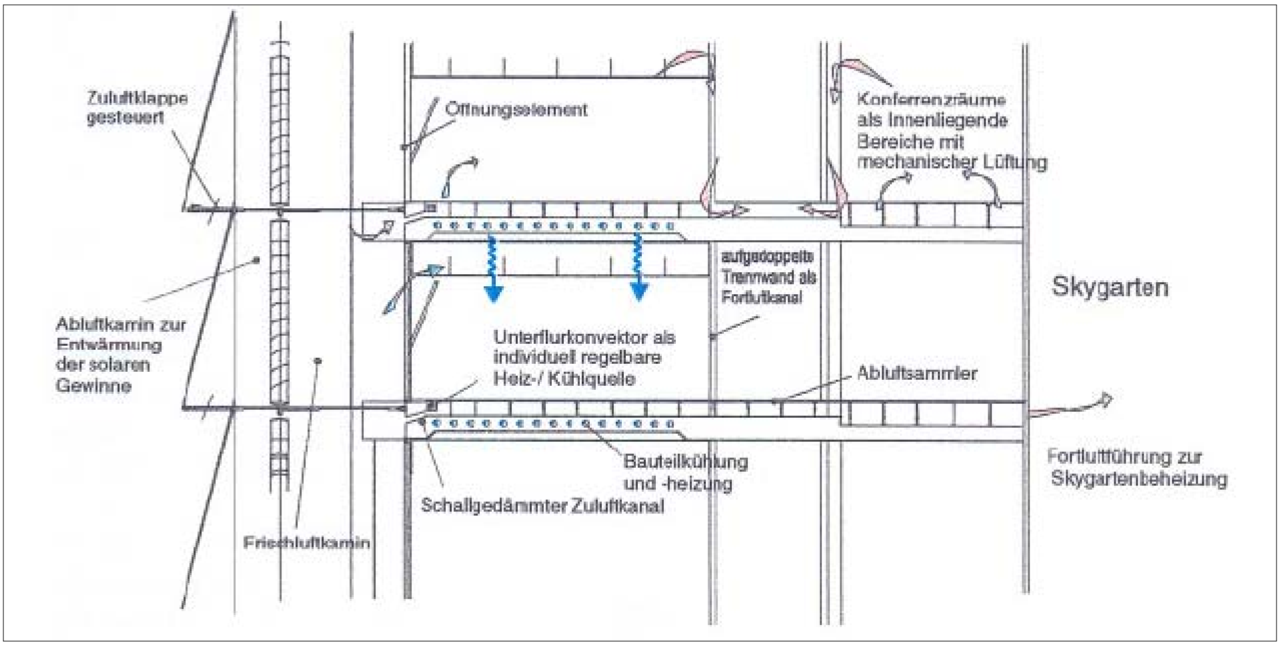

Figure 2 *Post Tower Bonn: Conditioning and ventilation scheme (TRANSSOLAR Energietechnik GmbH)*

St Mary Axe is located in London in UK and was conceived by Foster and Partners architects for Swiss Re. This 180 meter high tower is helical shape and has a double skin ventilated façade in glass. This building was conceived in order to reduce energetic consumption and to optimize natural daylight inside. It was supposed to work with hybrid ventilation, but this concept is not used in the fact. The consumption target was 150 kWh/m²/year but the real figure (not communicated) is supposed to be about 400 kWh/m²/year in reality.

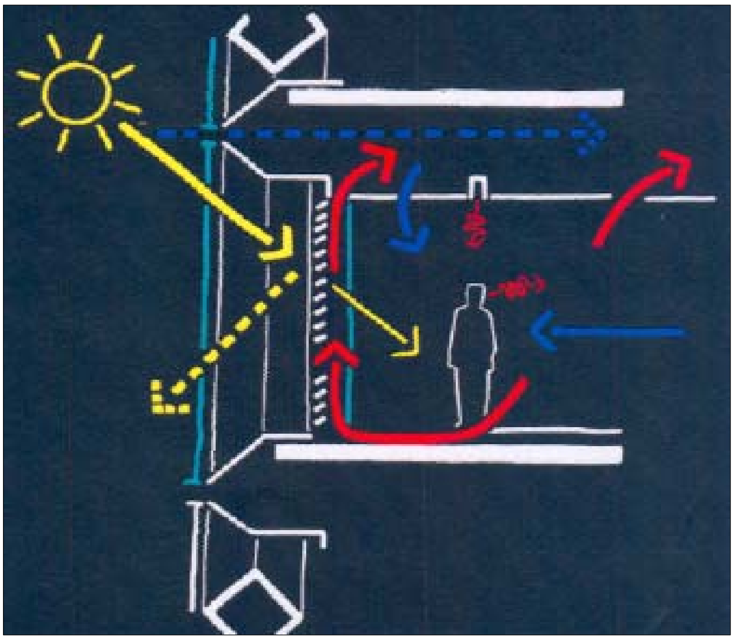

Figure 3 *St Mary Axe: Façade scheme (document Swiss Re)*

Highlight Business tower is located in Munich in Germany and was conceived by Helmut Jahn for Kan Am International GmbH. This building is composed by two twin and thin entirely glassed towers, which are connected by glass bridges at the 9th, 10th and 20th floor. It was build with the objectives to be the most transparent, and to reduce energy consumption and cost constructions. The façade is in triple layer glass. This building optimizes daylight penetration.

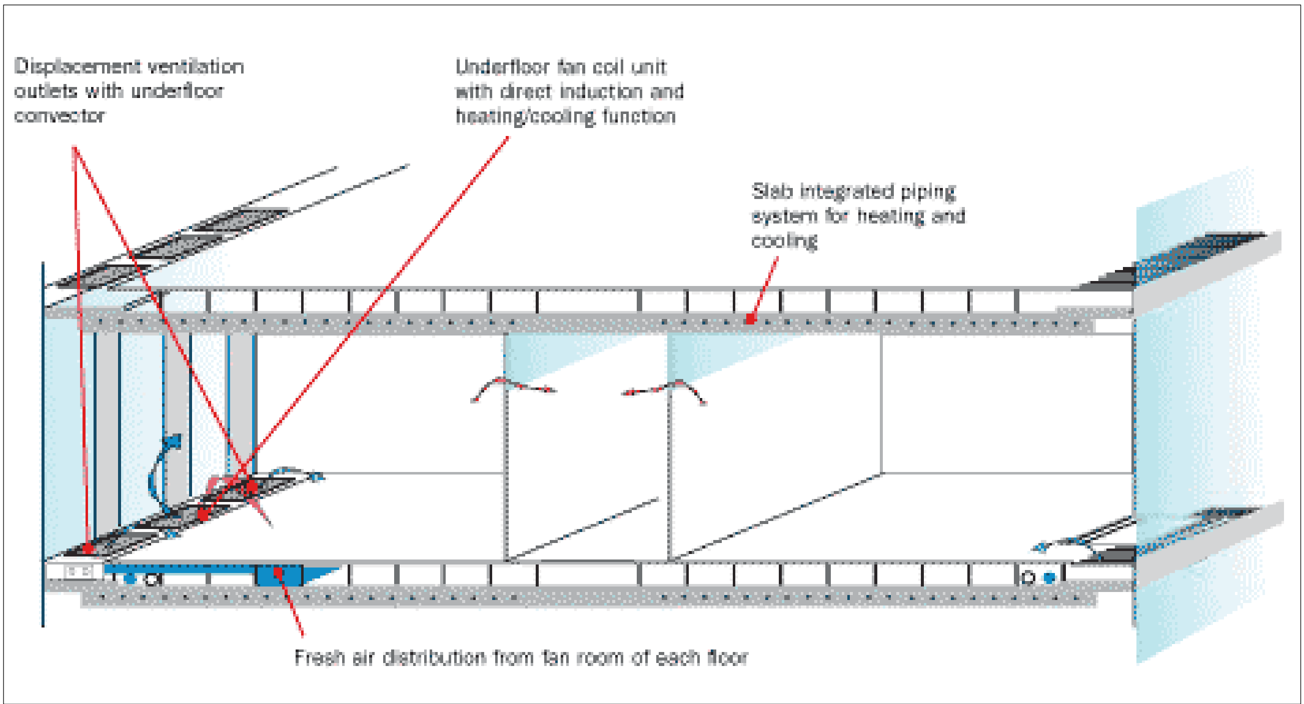

Figure 4 Highlight Business Tower : Heating/ventilation system diagram

3. Main points and lessons learned from the study

3.1 Why towers?

Nowadays, the problematic of the towers can't be considered without the sustainability concern, and even the sustainable urban development approach. Towers are seen to be the building with the largest energy consumption. One of the major stake is to reduce it. It is nevertheless a solution to the densification of the city, territories are not inexhaustible. A joined reflection has to be done on the transport on site, in order to reduce transport of the user, and favor the use of public transportation. Four issues have te be together considered: the high rise performances, transportation ways, optimal use of the land, and biodiversity.

The tower configuration can be an answer to some sustainable problematic (densification, use of public transportation) but a special attention has to be carried out on the environmental characteristics and energetic performances which are more difficult to obtain

3.2 Spaces

3.2.1 Public spaces

Most of new office towers are looking toward offering large and quality public ground spaces in a very constraint environment. The possibility for the public to circulate in the ground floor is a necessity to not cut towers from public space and external world. The immediate surrounding is also very important in the implantation of new towers.

In regards to very constraint sites for the implantation of new tower, interrogation on the choice of the site and relation of the tower towards surrounding environment with creation of public space at ground have to be taken into account as soon as possible, at the beginning of the project.

3.2.2 Space organization

Most of new office buildings are looking to offer more flexible and progressive floor plans of variable surface in order to answer the needs of all users.

Flexibility, modularity and adaptability of building in long term have to be considered at the design stage. Partition of office space has to be adaptable to different organization and technical systems have to be modifiable and adaptable. Cores and circulation have to be though in order to obtain this flexibility. Quality meeting and relaxing places are also a necessity for users.

3.2.3 Thermal and visual comfort

Guarantee thermal and visual comfort, in summer and winter, in office high rise buildings is a primordial stake. Users want more and more a real comfort in their office space.

In order to obtain thermal an visual comfort in office high rise buildings, a special attention has to be taken to the following points:

- The façade performance, with a maximum glazed part of 50%, providing external pleasant views
- A good solar gain and dazzle control and management with automated and effective solar blinds
- A good artificial lighting control and management with repartition of the intensity of lighting, presence sensors, and natural daylight sensors in order to control the artificial light need.

A special attention has to be taken on real use of the building and its interior fitting up has to be thought in order to best adjust the different systems to the real needs. The individual management by the user of his working environment has to be thought and limited in order to prevent drifts due to the use of the building.

Users of the building have to be associated at the design stage in order to explain its functioning, and allow some user behavior change and explain why limiting user management of its working environment.

3.2.4 Vertical displacement

One of the stakes in tower is to allow user to move up and down in a limited time, with a high speed and a limited number of lifts. Elevators are also a high consumption energetic post. Innovations in elevators are the double deck lift, sky lobbies, and intelligent management of elevators call. Some buildings now have lifts which deserve only one floor on three.

3.3 Energetic performances and innovations

3.3.1 Office buildings in use

Studies done in 2001/2002 in Frankfort showed that primary energy demand for office buildings can vary between 200 and 1000 kWh/m²/year, with a mean value of 500 kWh/m²/year.

Since 1990, the construction of energy efficient office building, towers in particular, became a very important stake. Energy efficiency is more and more important, design methods changed with innovative technologies.

In efficient high rise office buildings, heating demand is limited, especially due to high internal load with densification of working area, and lighting demand. However, other posts are more energetic consumer. In relation to a low rise office building, specificities of a tower rise its energy demand. As a matter of fact, a large building increases energy consumption for some posts:

- Ventilation: large building rise ventilation systems losses and their energy consumption. The setting up of hybrid ventilation with natural ventilation becomes more complex.
- Cooling needs: cooling via natural ventilation becomes complex for large buildings. Internal loads are higher, due to working post densification and office equipment, and artificial lighting
- Lighting: artificial lighting demand is higher due to large floor surfaces.

3.3.2 Integral design

Most effective way to reduce energetic consumption in office buildings is “integral design”.

The different parts and systems of the office building were typically separately conceived, by different design teams.

Integral design allow to conceive simultaneously different parts of office building, as the façade, heating, cooling, ventilation and lighting systems, office equipments and energy provider system in allow to optimize the dimensioning of all this posts.

Integral design method allows investment and functioning cost reductions, as environmental impacts (limitation of carbon dioxide emissions, air quality…)

Studies showed that energy demand can be reduced by 30 to 50% with integral design.

3.3.3 Double skin façades

Double skin façade means a system composed by two glass skins separated by a significant air space. Those two skins can act as a thermal insulator. The buffer space between the two skins can also allow ventilation, permitting a good air circulation between the two skins. The double skin façade allows better thermal and acoustic performances, a space for blinds protections, and allow natural ventilation with openings of windows of the double skin. However, many different types of those façades exist and there is only few knowledge and experience returns on the real functioning of this type of façade.

3.3.4 Hybrid ventilation

Some towers were and are conceived with natural ventilation for a part of the year, with the possibility for the user to open the window when the climatic conditions allow it. When the windows are opened, heating, ventilation and cooling systems are automatically shut, reducing the electricity use. In the fact, most of the existing high rise buildings don't use natural ventilation mode, because the final office floors fitting up with partition don't allow it..

Mixed mode ventilation can reduce energetic consumption of a building. However, such a solution has to be considered with the final fitting up of the office floors, taking into account the partition spaces in the system dimensioning.

3.3.5 Reduction of internal loads

In high rise office buildings, increasing of internal loads due to office equipments and lighting induce higher cooling needs of the building.

Within the perspective of a building that should be build in few years, consumption of office equipments in this perspective of time.should be taken into account

The need of cooling is high in regards to those internal loads, and the just dimensioning of the cooling system has to be considered with limited lighting installed power and evolution of office equipment.

Electricity consumption of building can be reduced a lot by the setting up of advanced office equipments, and by limited installed lighting power. This consequently will also reduce cooling demand.

3.3.5 Renewable energy use

Before renewable energy integration, the building has to be low energy conceived. The use of renewable energy became necessary to compensate for energetic consumption in building. Local production of energy is dependant of site potential. However, local production of photovoltaic electricity can only cover a few part of electricity demand, due to tower configuration which only offers a low surface of façade and roof in regards to floor area. Pertinence and efficiency of wind electricity has not been proved until now.

The energetic performance of a high rise office building can't be achieved without the reduction of its energy consumption. Local production of renewable energy can then represent a higher part of its energy consumption.

3.3.6 Cogeneration

Some experiments in Frankfort showed that new office buildings should have cogeneration or tri-generation systems, which reduce by 30% primary energy consumption and dioxide carbon emission.

4- Conclusion

Most of the teaching is focused on energetic performances of offices towers, with the objective of "low consumption building" (BBC label) . One can notice that for high rise office buildings, energetic transportation consumption could be introduce in the global energetic assessment of the building. However, energetic performances oh high rise office buildings can't be compared and reach energetic consumption of low rise office buildings, due in particular to their higher need of ventilation, conditioning, lighting, and the necessity to have efficient lifts.

Optimization can be get with integral design of the building, efficient façades, joined with efficient heating, ventilation and cooling systems, and hybrid ventilation if possible. A special attention has to be taken on office equipments and a limited lighting power.

A refection at the design stage has to be initiated with the management and maintenance actors and the final users of the building, in order to explain the building functioning and allow some behavior change in order to optimize building performances.

The consideration of other environmental characteristics as products choice, energy contained in products, health preoccupations and water management are never considered as a priority in building design, but are nevertheless present in the design of new office towers.

Others aspects of sustainable development as social and economic matter are until now never really considered.

SUSTAINABILITY@HOME: DRIVING CHANGE BEYOND COMPANY WALLS

Matthew CLIFFORD[1]
Shauna COFFEY[2]

[1] Sustainability Projects Coordinator, Mirvac, Sydney, matthew_clifford@mirvac.com.au
[2] Group Sustainability Manager, Mirvac, Sydney, shauna_coffey@mirvac.com.au

Keywords: sustainability, sustainable living, employee, customer, education, engagement, website

Summary

At a time when corporate sustainability programs have become almost ubiquitous, one often marvels at how quickly change can occur. In a matter of years, corporate sustainability has brought issues such as climate change, water scarcity, and resource consumption to the forefront of the public and corporate psyche, particularly in the building sector.

Considering the outstanding capacity to achieve sustainable outcomes within the corporate world, one must ask, what role can corporations play in driving sustainability beyond company walls? How can the lessons learnt in our board rooms be translated into connected, viable and liveable communities? This paper examines the Mirvac Sustainability@Home Program, as an example of an extended corporate sustainability program, which reaches beyond the normal scope of operations, and promotes meaningful changes in the broader community.

The Mirvac Sustainability@Home Program provides staff and their families with useful information, practical knowledge and meaningful support, to promote a culture of change and a lasting shift towards more sustainable living. The hub of the program is the Sustainability@Home website; providing tools, and information on sustainable living, while doubling as a sustainability forum, spreading ideas and knowledge among Mirvac communities.

By partnering with various eco-product and service providers, Mirvac staff and their families have access to energy efficient appliances, low volatile organic compound carpets and paints, recycled office supplies, biodegradable cleaning products and more at preferential rates. This way, previously unattainable tools for promoting sustainable living and creating viable communities have become a real possibility for many homes.

1. Mirvac's Sustainability Strategy

Since mid 2007 Mirvac has worked hard to develop and consolidate its sustainability strategy, the cornerstone of which includes clear performance objectives, targets and measures that provide the necessary structure for the Group's forward planning and expansion.

Important milestones in this journey to date include a detailed review of current business activities to clarify sustainability related impacts and opportunities; defining Mirvac's sustainability values – how will Mirvac judge its long-term sustainability performance; identifying sustainability priority areas considered 'most significant' to Mirvac and its stakeholders; structuring objectives for sustainability performance against each of these priority areas; and, establishing performance targets for all areas of activity.

Guiding principles have been established in-line with Group values which set the vision for sustainability performance.

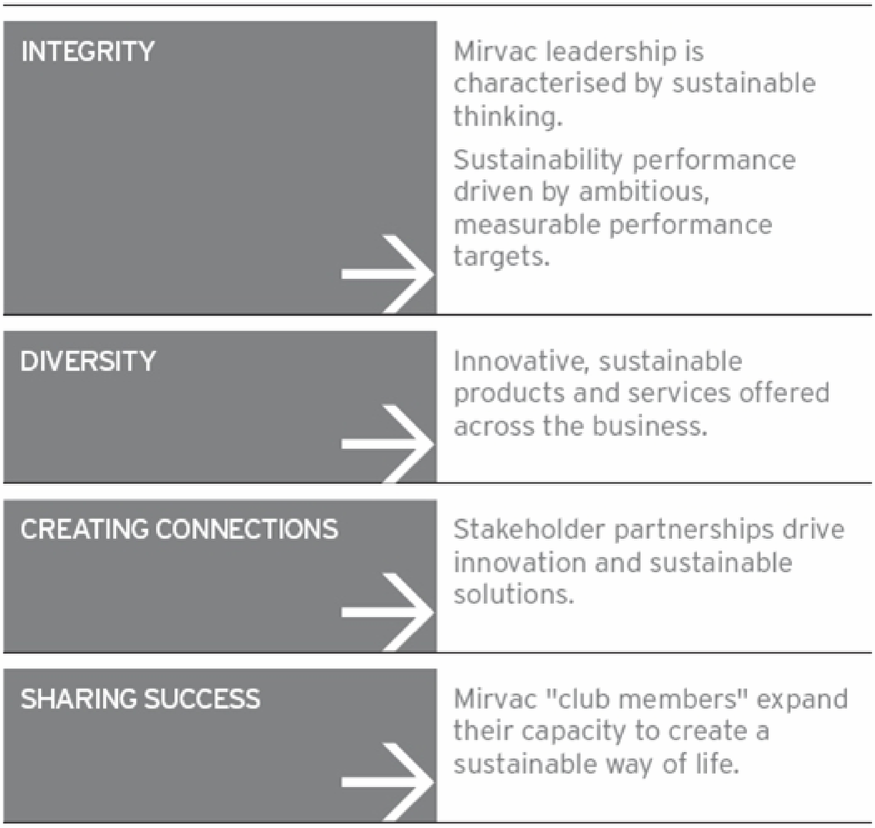

Figure 1 Mirvac's Sustainability Guiding Principles

Six sustainability priority areas are identified as 'most significant' to Mirvac and its stakeholders. Against each of these priority areas, objectives have been developed and performance targets established for all areas of activity. They are under constant review and may change as Mirvac, and the world in which it operates changes.

Priority Area	What does this include?	Objective
BUSINESS CONDUCT	Management of Sustainability	To effectively manage sustainability performance across the Group.
	Corporate Governance	To maintain a high standard of honest, ethical and legal business behaviour in accordance with Mirvac policies at all times.
	Industry Advancement	To contribute to advancing the sustainability of the Real Estate Investment Trust sector.
MIRVAC PEOPLE	Health and Safety	To minimise risk and prevent harm to people or the environment.
	Corporate Culture	To foster a high performance culture committed to sustainability
STAKEHOLDERS	Customers	To provide Mirvac customers with an experience that delivers excellence, meets or exceeds expectations of sustainable performance and engenders loyalty.
	Investors	To provide Mirvac investors with an experience that delivers excellence, meets or exceeds expectations of

Priority Area	What does this include?	Objective
		sustainable performance and engenders loyalty.
	Community	To enhance the communities in which Mirvac operate through active engagement, innovative design and giving programs.
SUPPLY CHAIN		To include companies in Mirvac's supply chain who have a commitment to sustainability in line with our own.
ENVIRONMENTAL IMPACT	Management	To ensure appropriate systems to minimise environmental impacts of all Mirvac activities.
	Energy	To optimise the productivity of all energy employed in Mirvac activities.
	Water	To reduce the consumption of water and impacts on water quality of all Mirvac activities.
	Waste	To reduce waste produced and maximise recycling and resource recovery from all Mirvac activities.
	Ecosystems	To minimise the impact of all Mirvac activities on local ecosystems.
	Transport	To minimise environmentally detrimental transport dependency of Mirvac operations and products.
	Materials	To minimise the environmental impact of materials used by Mirvac.
	Indoor Environmental Quality	To provide for healthy indoor environment quality.
CLIMATE CHANGE ACTION		To position Mirvac for optimum performance in a changing climate and carbon constrained economy.

Figure 2 Mirvac's Sustainability Priority Areas

Full details of Mirvac's commitments and targets can be found at www.mirvac.com.au.

1.1 Mirvac People – Part of the Commitment to Sustainability

Mirvac's commitment to fostering a high performance culture committed to sustainability extends beyond the company walls, and into the homes and communities of our employees. By promoting the message of sustainability not only at work, but also more broadly, we aim to make a meaningful impact in the lives of our employees.

Central to this aim, is the Mirvac Sustainability@Home Program, providing our staff with information and resources to drive change in their own lives.

2. Mirvac Sustainability@Home Program

The Mirvac Sustainability@Home Program aims to provide staff and their families with useful information, practical knowledge and meaningful support, to promote a culture of change and a lasting shift towards more sustainable living. The hub of the program is the Sustainability@Home website; providing tools, and information on sustainable living, while doubling as a sustainability forum, spreading ideas and knowledge among Mirvac communities.

The interactive website is based around a Mirvac designed home layout, allowing users to navigate to each room, and the outdoor areas. The information on the site is layered, to provide varying degrees of detail and complexity depending on user interest and need. Each room has a number of 'clickable' items, such as stoves, waste bins or taps, which when selected provide simple and straightforward tips and ideas including cooking efficiently, reducing waste and saving water.

Figure 3 The Mirvac Sustainability@Home website homepage

Figure 4 The Mirvac Sustainability@Home website – room view

To learn more, users can follow links at the bottom of each pop-up, or the top of the page, which directs them to detailed fact sheets on more complex topics, such as choosing efficient appliances, comparing electric, gas and solar hot water systems, improving home insulation, and reducing toxins in the home.

Figure 5 The Mirvac Sustainability@Home website – fact sheet listing screen shot

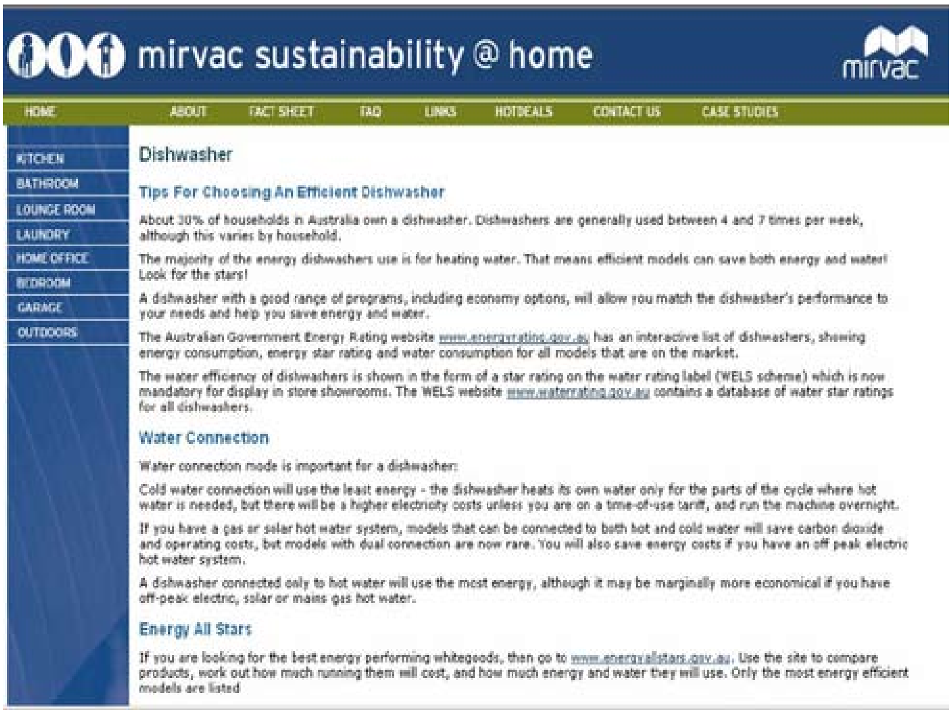

Figure 6 The Mirvac Sustainability@Home website – dishwasher fact sheet screen shot

2.1 Research – Sources and Challenges

In many cases, information on sustainable living already exists in the public domain. One of the key challenges in delivering this program is collating credible and accurate information, and providing it in a format accessible to beginners and technical specialists alike.

The information included on the website has been gathered through extensive and careful research, primarily from Government Departments or research institutions. Often, these sources provide highly technical information, which required extensive editing to be suitable for the lay reader.

In some cases, information was sourced from non-Government organisations, industry groups and businesses. Here the challenge was ensuring that information and claims were robust and transparent, with enough detail to suit the technically-minded reader. Links and references are provided throughout for users to learn more.

With much research yet to be done in the field of sustainability, this process is certainly imperfect. As interest in sustainability grows, and online and other resources abound, it is important that constant review is undertaken to maintain the accuracy of information listed on the site.

2.2 Sustainable Living Case Studies

In late 2007, Mirvac ran the first initiative of the Sustainability@Home program – a competition challenging staff to provide an interesting and compelling case study of how they have incorporated sustainability into their own life. The focus was not on the most expensive, nor the most extensive initiatives, but rather those that inspire and educate, and show that simple steps can make a meaningful difference.

The prize for 9 lucky winners, were tickets to see former US Vice President, and renowned environmentalist Al Gore speak on the future of energy, thinking green, and how climate change will affect corporate economic strategy for the 21st Century.

A high standard of entries were received, with staff presenting both simple and complex steps that they had taken to incorporate sustainability into their lives. The winning entries ran full spectrum, with initiatives including car pooling, shopping with green bags, buying local, water efficient gardening and home renovations.

These case studies are now hosted on the Sustainability@Home website, to showcase to Mirvac staff how simple steps can lead to big changes.

Mirvac received such a positive response to this contest that it intends to run similar events annually.

2.3 Supplier Agreements

Mirvac also uses the Sustainability@Home website as a means of promoting a number of key supply chain agreements, offering staff preferential rates on a range of products and services which assist in moving towards sustainable living.

Mirvac has a large number of preferred supplier agreements, covering a wide variety of products and services across our Group, including our development, hotels and corporate services activities. These agreements often extend to Mirvac staff, giving them access to products and services at discounted or wholesale rates. In many cases, these agreements cover categories with clear linkages to sustainable living, such as appliances, carpets, paints, rainwater tanks and more. This way, many tools for promoting sustainable living and creating viable communities have become a real possibility for many homes.

By educating our staff about the benefits of water and energy efficient appliances, low volatile organic compound (VOC) paints and carpets, saving water and so on, and providing access to discounts on these specific products, Mirvac hopes to positively influence the purchasing decisions of our people, to turn ideas into positive action promoting sustainable living.

3. The Next Steps

Mirvac plans to continue developing and expanding the Sustainability@Home website over time, including new ideas, technologies and knowledge as the property industry, and the broader community continue to learn about sustainable living.

Logically, Mirvac will move to include the knowledge and lessons learned from our projects and developments in this website, linking specialist sustainability practitioners within the organisation, to the broader Mirvac community.

Similarly, as additional supplier agreements are negotiated, they too will be added, broadening the scope of products available to Mirvac communities.

The most significant next step for the Sustainability@Home program is rolling it out to Mirvac customers, as a home operators guide.

3.1 Home Operators Guide

In the residential development field, marketing materials tend to focus on traditional areas, such as location, lifestyle, and design. Certainly these are key inclusions; who would buy a home without these prerequisites?

However, as we design and deliver increasingly complex 'green' homes, complete with water and energy savings features, passive cooling, on-site energy generation, water-efficient landscaping and so on, we transfer greater responsibility to the home buyer and occupier to make sure these design features are utilised to their full potential. Without adequate explanation and training, these outstanding design features are at risk of being misused or under-utilised.

To counter this, Mirvac is working to include the Sustainability@Home website as a companion to the existing information in the Mirvac Home Buyers packs. By educating our customers on the design, and operation of their homes, and providing them with sensible and readily understandable tips on reducing their ongoing impact, we aim to ensure that our designs function appropriately, and that our positive influence does not end when we hand over the keys to the door.

Conclusion

A key consideration in any corporate social responsibility initiative is to understand and take full advantage of your strengths. Mirvac has aimed to do just that, by leveraging the existing knowledge and experience from within our company, and combining it with external research, to deliver a simple, yet comprehensive program to educate our people and promote sustainable living. By creating linkages between the Sustainability@Home Program and standard corporate operations, sustainability moves farther away from the periphery, and towards the core of Mirvac business activities.

While still in its early days, Mirvac hopes to grow the Sustainability@Home Program to broaden our role as educators, and add value to our people, our customers and the community.

ENERGY MANAGEMENT IN EXISTING BUILDINGS-ONE SIZE DOES NOT FIT ALL!

Lidia Rozman, Associate
Connell Wagner

INTRODUCTION

Ecologically Sustainable Design (ESD) does not only apply to new buildings. Existing buildings can be improved to have a more sustainable ecological footprint. The status quo has been challenged for occupational health and safety reasons. **Now** is the time to challenge the way things have been done for sustainability reasons.

Water reduction, energy efficiency, indoor environment quality, maintenance, materials, waste management, and the outdoor environment are just some of the issues to be addressed.

One size Does NOT fit all!

Each building is unique and requires a solution that is tailored to the needs of the building and its occupants. This applies equally to new and existing buildings.

Effective sustainable design concept development must be based on a sound understanding of engineering detail **and** operational building imperatives. Pragmatic solutions that respect future operations and facilities management objectives are required.

Environmentally sustainable principles need to be adopted, in line with the objectives of the building owner/ occupants, in a cost effective manner and which **enhance** both staff use of the facility and improves the health of the building.

NEW BUILDINGS

There is a strong emphasis on good passive design right from the start of the design process. We all understand that to get best value from every dollar spent, ESD needs to be embedded in the construction in an integrated manner. This can only be achieved by all of the team members working closely together to achieve multiple benefits from single pieces of construction. By optimising orientation and the use of thermal mass; savings in mechanical and electrical capital and operating costs can be achieved.

It is important that appropriate energy benchmarks are set at the start of any project and are monitored using energy models at each project stage.

Indoor air quality and the indoor environment is becoming even more important to owners because we spend so much of our time indoors, that issues such as, the amount of outside air, avoidance of off gasing materials, good air filtration etc. are carefully considered as well as maximising opportunities for views to outside. These all impact on client well being.

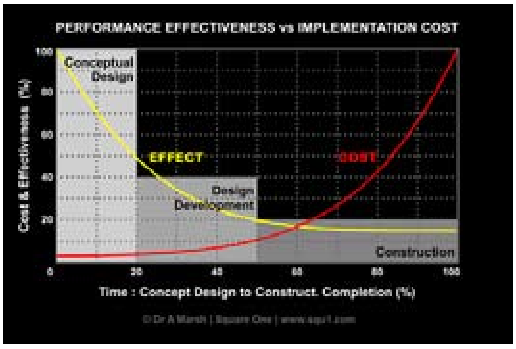

Fig 1 Performance effectiveness vs Implementation cost at various project stages

From the Proceedings of the World Conference SB08 - ISBN 978-0-646-50372-1
www.sb08.org

PRACTICAL APPLICATIONS OF ESD INCLUDE:

The following elements are essential components of a sustainable project:

- Energy Conservation
- Minimising Greenhouse Gas Emissions
- Water Conservation and Reuse
- Material selection
- Design for disassembly and reuse
- Recycling materials
- Minimising waste, reduction in emissions
- Whole of life cycle assessment

Fig 2 Margaret Tobin Mental Health facility at FMC

CASE STUDY 1- MARGARET TOBIN MENTAL HEALTH WARD AT FMC

This example is of a site where it was not possible to reorientate the building as the site was a long narrow site that faced south west. It has fantastic views from the site to the beach. The lower floor is a laboratory floor, while the upper floor is mental health inpatient accommodation.

By working together with the Architect at the very early stage of the project, we came up with the concept of the angled walls, which effectively have north facing glass, which was easy to shade. Due to the geometry it actually became fully shaded glass, yet the views to the sea were retained.

But best of all, the cost savings in the mechanical plant were almost enough to pay for the angled walls, and they will of course enjoy significantly less running costs for the life of the plant.

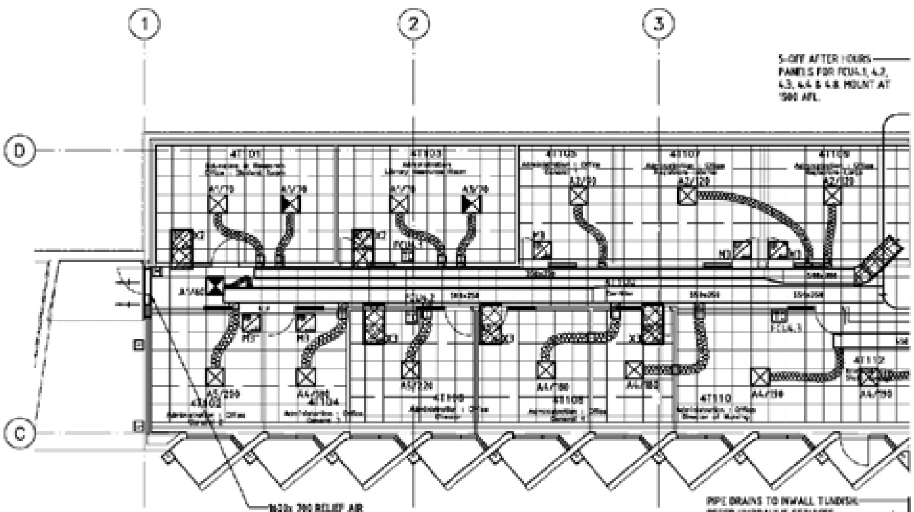

Fig 3 Plan view of Margaret Tobin Mental Health facility at FMC showing the angled window shading

EXISTING BUILDINGS

Many people are concentrating on new buildings, but what about the existing building stock? Have they kept up with the energy revolution or are they still in the last century chewing up energy as if it was cheap?

Energy efficiency is not only about new designs, it is equally important to be looking at existing installations and evaluating opportunities to save energy, running costs and the environment, as well as improving the amenity for the building occupants.

There are great opportunities to save energy in existing buildings. Many companies are able to save up to 20% on their energy bills by putting an energy management program into practice.

Energy management starts with an understanding of where your building is currently benchmarked by calculating an energy use base line and understanding which tenants or systems are the high energy density users.

Systems can then be evaluated to determine where changes can be implemented most effectively to reduce energy consumption without affecting the operation of the building's functional requirements.

Substantially improved performance and energy savings have been demonstrated by some buildings for a comparatively small investment by fine tuning the building systems and getting the systems working as designed.

SO HOW DO I GREEN MY EXISTING BUILDING?

Buildings should be evaluated based on their projected energy requirements and emission of refrigerants. Heating, Ventilation, Air Conditioning and Refrigeration (HVAC&R) systems contribute to greenhouse gas releases indirectly through energy-related effects and directly through the effect of refrigerant losses.

Energy-related impacts (contribution to CO_2 releases) are addressed by reducing the energy consumption of equipment, systems, and buildings and by modifying user behaviour. HVAC&R technologies provide the tools for the design and application of comprehensive energy-savings techniques in buildings and for the selection and proper use of energy efficient equipment and system integration.

ENERGY AUDITS

The first step is to take stock of where the building is performing. This can best be achieved through an energy audit. This draws the line in the sand so to speak.

An energy audit generally includes:

- Audit of historical data
- Walk-through audit
- Detailed investigation and analysis.

Audit of historical data requires the auditor to identify and quantify each of the energy forms as well as establish a general trend or pattern in energy use over a number of years.

The walk through audit is used to identify any immediate opportunities to reduce energy costs. This step will also establish the feasibility for potential cost savings in each area of energy consumption and the priority for allocating resources.

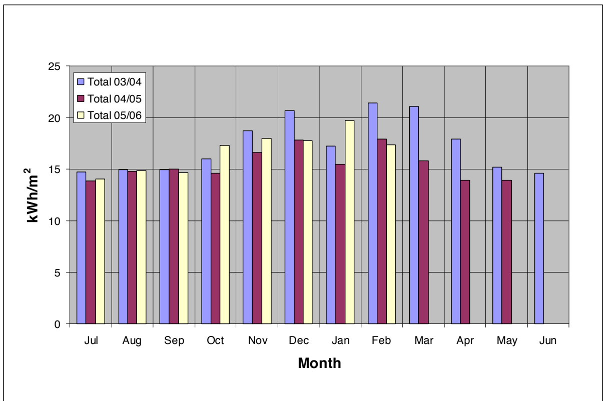

Fig 4 Typical energy audit data output

A simple survey including a walk around the work place will identify areas where there seems to be excessive energy usage. Spot checking soon find areas where equipment or lights are left on when not required. There is generally an opportunity to save energy, particularly in older installations.

The major step in an energy audit is the detailed investigation and analysis, based on the areas that were identified in the walk through audit as requiring further investigation.

Australian Standard AS 3596 Energy management programs - Guidelines for definition and analysis of energy and cost savings would be the basis of the investigations. With results from this step and those obtained in the walk through survey a detailed energy management program for the business can be developed, or an existing program reviewed.

Once a program or policy has been put in place it needs to be reviewed on a regular basis to make sure that it is achieving the objectives that were set in the energy management plan.

A level 2 energy audit is a good start, this will then identify which areas should be further investigated with a level 3 energy audit. There is no point in wasting resources in conducting intensive level 3 energy audits of everything, this will just frustrate everyone.

It is important to have a good consultant that can identify the energy wasting practices that occur in the buildings. From this you will be able to identify the areas that can be improved through opportunities for energy reduction. Some of these will be easy to implement, others will be more expensive or more difficult.

It is good practice to outsource this investigation because you get a fresh set of eyes looking at the systems and the problems. This can often challenge the “way we've always done things”.

Once the audit is complete then you can then set the targets for energy reduction.

The building owner will also understand whether the building has potential to be upgraded.

EXISTING PROBLEMS

So what are the likely problems that your buildings could experience?

MECHANICAL SYSTEMS

- **Noisy plant**, vibration is often passed through the building structure and causes disruption to tenants. It is often an indicator that there are significant losses and inefficiencies occurring within the plant or equipment.
- **Infiltration** through old window seals or poorly sealed facades. This is a problem as infiltration allows unconditioned unfiltered air to enter the air-conditioned space; adding significant load to the plant and discomfort for occupants.
- Old plant is generally **inefficient.** Technology has improved efficiencies of modern plant to the point that significant energy and cost savings can be made if the old plant is replaced.

Fig 5 Typical old chillers are inefficient and often contain ozone depleting substances

- Old plant is generally more **costly to maintain.** As plant ages spare parts are more difficult to source and the breakdown costs become more frequent.
- Old plant, such as chillers and refrigeration units often contain **Ozone depleting substances.**
- **Pneumatic controls = poor controls**. The range of control strategies available with pneumatic controls is very limited. Unless well calibrated and maintained, the controls may not actually be doing what they were designed to.
- **Old BMS systems = glorified time clocks**. Many older style BMS systems only report status points and turn plant on/off at pre-determined times. There are no "smarts" in the controls.
- **Calibration of sensors** and controls? If these are out of calibration- well what are you controlling?
- **Averaging temperature sensors**- that is a sure way of ensuring that everyone is unhappy!
- **Insufficient air movement**- stuffy stale environment are often complaints in older buildings where air quantities were often too low to provide comfort.
- Old cooling towers- do they comply with AS 3666? Are they a **Legionella Risk!** How much water do they waste?
- Outside air quantity may not comply with AS 1668 and can lead to **sick building syndrome**

Fig 7 old cooling towers pose potential health problems and are high in maintenance costs

Fig 6 Dust and mould growth accumulate inside ducts

- **Dirty ducts and mould?** These are a particular problem in tropical environments where moisture encourages mould growth. Moulds are often toxic and can cause significant irritation to the building occupants.
- Is there **economy cycle?** Many older buildings did not have economy cycles (free cooling) or if they did, then often include seized dampers and can not operate.
- **After hours use** of plant- does the entire building need to run to keep one tenant cool after hours?
- **Rogue zones** eat energy- these are spaces that are not compatible with the rest of the building load, and always require cooling when no other areas do, therefore driving systems needlessly into cooling modes.
- **Reheat strategy?** Many old buildings had one perimeter cooling coil and then reheated each zone to meet the load requirements for that zone. In one such building where the cooling valve was 60% open, and the four reheat coils heating valves ranged from 40% to 80% on a mild 18C ambient day.
- **Hot and cold decks**- these are so inefficient the BCA has now outlawed them.

ELECTRICAL SYSTEMS

- **Over lighting-** many old buildings have light levels much greater than necessary. This is to cover the poor efficiencies of the older style lamps.
- **Inefficient lighting-** magnetic ballasts and losses through these are significant.
- **Poor lighting control-** does anyone know where the light switches are? Do they turn on/off the entire floor on one switch? Why are the lights on when no one is in the room or the sun is coming in through the windows.?
- **Lack of energy monitoring-** No one has any idea how much energy is being used and where.
- **Spaghetti in the ceiling space?** Changes over time can result in a mess such as this one where live wires were found even after the switchboard was isolated.

HYDRAULICS

- **Inefficient fixtures and fittings**- these can waste lots of water- particularly through flushometers or full size WC cisterns.
- **Inefficient irrigation**- what are you really watering?
- **Water heating systems** are there more losses in your hot water system than the energy used to heat the water actually used?

- **Water leaking from existing pipes and fixtures**- how do you know there are no leaks?
- **Old storage tanks at top of buildings?** When did you have these checked out- are they at risk of failure?

OTHER

- **Asbestos?** This should be removed wherever possible if there is any way that it can be dislodged into the airstream.
- **Inefficient façade treatment-** many old facades are very inefficient. The aluminium frames often had no thermal breaks. Have you tried putting your hand on the window frame when the sun is shining on them? You can burn yourself! That is all heat that the air conditioning system has to remove.
- **Imperial ceiling tile grid-** it is difficult to source new light fittings and fixtures that suit the old grids?
- **Outdated fitout, base building toilets, foyers-** there may be nothing wrong with them, but they are not going to attract the high level tenants.
- **Leaking facades-** allow both moisture and air to enter the conditioned space. This is particularly serious in tropical areas where mould growth and condensation are a problem.
- **Inefficient lifts-** some lifts are very inefficient, use significant amounts of energy, yet are also inefficient at serving the building occupants with long waiting times, bumpy rides and jerks.
- **Non compliance with disability act requirements-** any building upgrade required the installation of access toilets, accessible lift buttons and equitable access to the buildings entry.
- **BCA compliance issues-** Do the fire and life safety elements of your building still comply with the BCA? Often not and a major upgrade will require a BCA compliance check.
- **Have you been on those vacant floors lately?** Just look at the picture- could this be your building?

Fig8 A pile of bird excrement- it obviously liked to roost on the door

POSSIBLE SOLUTIONS

MECHANICAL

- Replace major plant with energy efficient state of the art equipment
- Non ozone depleting refrigerants

- Service and overhaul all remaining plant
- Clean all ductwork
- Install Outside Air Economy Cycle
- Recommission and recalibrate all systems
- Maintain Control Systems
- Install heat recovery systems
- Install variable speed drives and floor isolation dampers
- Install monitoring equipment to monitor energy and water consumption
- Remove rogue zones such as meeting rooms onto a separate system and control with occupancy sensors
- Review flaws of existing air conditioning systems and resolve
- Install state of the art BMS system and replace all pneumatic controls
- Check integrity of insulation on systems

Does your building contain a diesel generator that never gets used apart from testing time?

Evaluate the savings that can be made through peak electrical demand lopping by running it on peak days

Convert it to a green fuel; bio-diesel or gas on diesel. This will save the environment and your energy bills.

Fig 9 Cogeneration can save on greenhouse gas emissions

Cogeneration- provides standby power capacity independent of the grid. Natural gas has much lower rate of greenhouse gas emissions than electricity, so CO_2 savings can be made. Also utilise waste heat recovery through

- absorption chillers
- Heating system
- Saves energy and greenhouse gas emissions

CONTROL SYSTEM MAINTENANCE

- Control systems need to be maintained over time
- Re-calibration of sensors
- Complete commissioning of plant and controls
- Optimisation of systems
- Valves that do not shut off tightly by-pass fluid
- Leaking dampers can introduce excess outside air
- Check for temperature sensor locations that do not represent conditions etc
- Significant energy savings achieved by properly setting up and maintaining control systems.
- Consider some PV

FULL OUTSIDE AIR ECONOMY CYCLE

Provides a building's cooling requirements via full outside air when ambient conditions permit. (30% or more of plant operating hours). This works better in dry places like Adelaide, Melbourne etc.

If your building does not include outside air cycle, consider how this can be installed. It also enables other energy saving strategies such as night purge, where the building is flushed out at night (summer time) with cooler night time air, leaving the building fresh and removing the heat from the thermal mass of the building.

VARIABLE SPEED DRIVES ON FANS

Air flow can be optimised to match the required duty or reduced during periods of low load eg at night, significant energy savings can be achieved. Install dampers on floor by floor basis to enable floors to be isolated if unoccupied.

HEAT RECOVERY

- Used where air recirculation is not possible to recover heat and 'coolth'

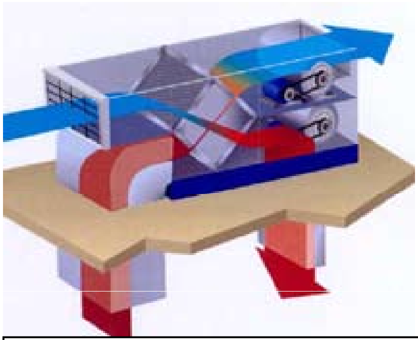

Fig10 A typical air to air heat recovery system

- Run around coils used where enthalpy wheels and Plate heat exchangers do not fit
- Good energy savings but cost and space can be barriers

VARIABLE SPEED DRIVES ON PUMPS

Oversized pumps are usually installed in practice, these can be up to 10% excess water flow, resulting in a higher than necessary energy requirement all the time!

Excess water flow is removed by closing balancing valves, leading to unnecessary pressure drops and high pump power requirements.

Variable Speed drives on Pumps should be incorporated in new and refurbished systems.

Rebalancing and amended controls strategies are necessary for efficient pump operation.

WATER SAVING FEATURES

WATER IS OUR MOST PRECIOUS RESOURCE

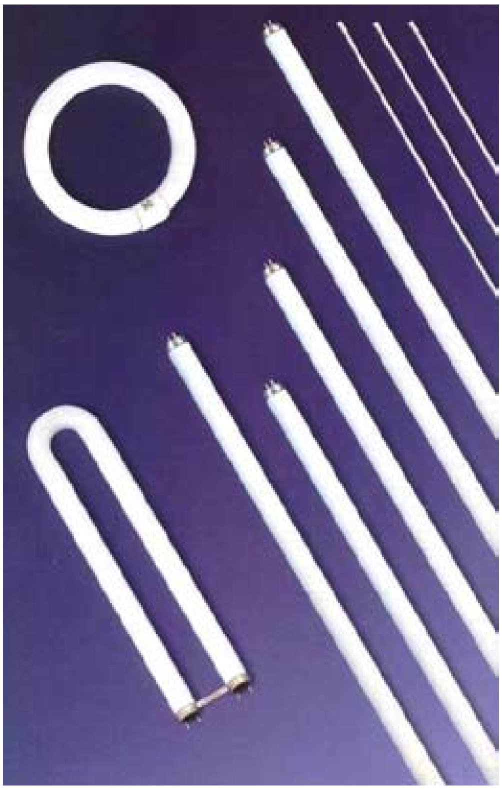
- Install Low Flow tap ware. Low flow tap ware using aerators can provide the required flow with equivalent comfort and/ or performance.
- Replace existing tap ware and fixtures with 4 star WELS. Current water efficient tapware (labelled as AAA-rated) uses up to 50% less water than older products.
- Do not use flick mixer taps, these use hot water when you do not want to (lever set in middle)
- Capture rainwater for reuse in toilet flushing and irrigation
- External gardens and water features create cooler micro climates.

Domestic hot water (DHW) is used in many areas of buildings, including showers, wash basins, kitchens and laundries.
Reductions in total water usage has benefits including reductions in:

- Water Usage
- Hot water (and other) energy consumption
- water supply
- Sewer disposal costs
- Investigate long DHW piping runs these also create losses
- DHW Storage and generation
- Install Solar Hot Water generation
- Check insulation on pipe work and tanks to minimise losses.

LIGHTING

- Lighting uses approx 30% of total electricity in a building.
- Install occupancy sensors particularly for intermittently used rooms like meeting rooms.
- Modify switching to have smaller switching groups to enable lights to be switched off when not required.
- Provide electronic control gear.
- Replace lighting with low glare T5 fittings.
- Add an indirect lighting component
- Provide automatic lighting controls
- Sensors within the various areas measure the amount of natural light and dim the high efficiency internal lights to save energy.



POWER FACTOR CORRECTION

- Power factor is a measure of effective use of energy supplied by utility.
- There are a number of options for improving power factor including:
    - Selection of equipment on demand side
    - Installation of power factor correction
- Although the energy utility sees the majority of financial benefits, the environmental benefits are universal and paybacks for 3 to 7 years are achievable.
- The supply arrangement will affect the ease of implementation, but retrofits can be successful.
- Day to day operations won't be affected, however the life of plant is increased, and the capacity of the electrical infrastructure is increased.

HIGH EFFICIENCY MOTORS

- Many electric motors are used throughout a building for pumps, fans, lifts and escalators.
- High efficiency motors attract a small cost premium, but savings will be rapidly achieved. Particularly where systems operate many hours per day.
- Government MEPS now require the use of high efficiency motors.
- Typical paybacks of 1-3 Years are achievable, where failed motors are replaced with HEMS.
- Longer paybacks (14 Years) for replacement of existing operating motors within High efficiency motors.
- Don't take the small capital cost saving by not putting them in!

STAFF AWARENESS

- Instigate an education program which make staff aware of energy saving opportunities and encourages and empowers them to participate in Energy saving.
- The paybacks are immediate.
- Options range from simple 'posters and e-mail campaigns' to formal staff training.
- Added benefits include increased staff morale, and support for the engineering team.
- Updates are essential for longevity.
- Older buildings have more 'manual' controls and would benefit greatly from staff awareness. New buildings would also benefit, as they would 'run properly from the beginning'

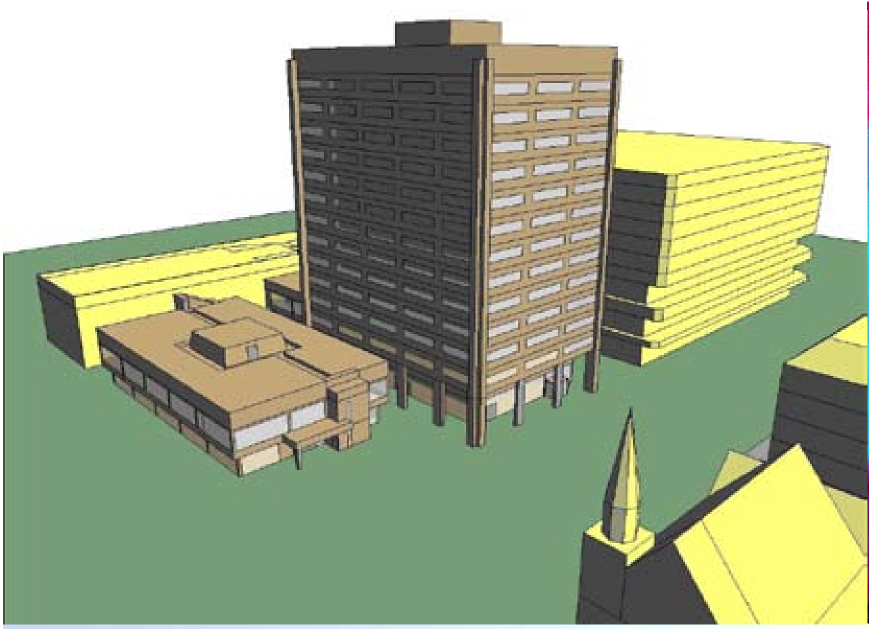
CASE STUDY 2 -40 ALBERT RD, MELBOURNE

6 star GreenStar- office design world leadership. Building refurbished to include

- 1200 m^2 over 4 levels faces E-W
- New glazing, atrium natural ventilation, daylighting
- Greenhouse gas neutral
- Gas engine driven air conditioning
- 1kW fuel cell
- Solar power and water heating
- Central vacuum system
- Low VOC materials throughout
- Lighting control system

CASE STUDY 3- EXISTING CBD BUILDING

- Existing Adelaide CBD 14 storey building, built in the 1970s
- Investigate different options for glass types
- Include veil ventilated façade



Above left: IES model of the existing building

Above: Photograph of the existing building

Left: IES model of the building with full height windows and veil

The existing building incorporates double glazed punch windows with reflective bronze glass and integral internal blinds sandwiched between the panes. The window frames are dark aluminium with no thermal breaks. When the sun shines on them, you can almost burn your hand on the internal faces of the frame. This significantly increases the cooling load required for the building. Additionally there is a 100mm thick uninsulated concrete spandrel below the windows which has a very poor U value and does not comply with the current BCA requirements.

The architect was keen to explore "opening up" the building to create a visual connection between the internal and external environments. We were asked to evaluate a number of scenarios including the addition of a glass veil incorporating additional shading structure at each level that would enable the cleaning of the glass as well as providing additional shade to the façade.

We evaluated the following glass types using IES computer modelling software.

Table 1 – Glazing Properties Comparisons

Glass Type	U Value (W/m^2K)	SHGC	SC	VT (%)
Single Glazing	5.8	0.81	0.94	87
Clear Low E Single Glazing	3.7	0.7	0.76	82
Existing Glazing (without Venetians)*	3.42	0.46	0.53	-
Existing Glazing (with Venetians)*	3.42	0.36	0.41	-
Low E Double Glazing (inner clear)	1.9	0.66	0.76	73
Clear Low E Single Glaze + Low E Veil	1.9	-	0.58	-

Properties estimated

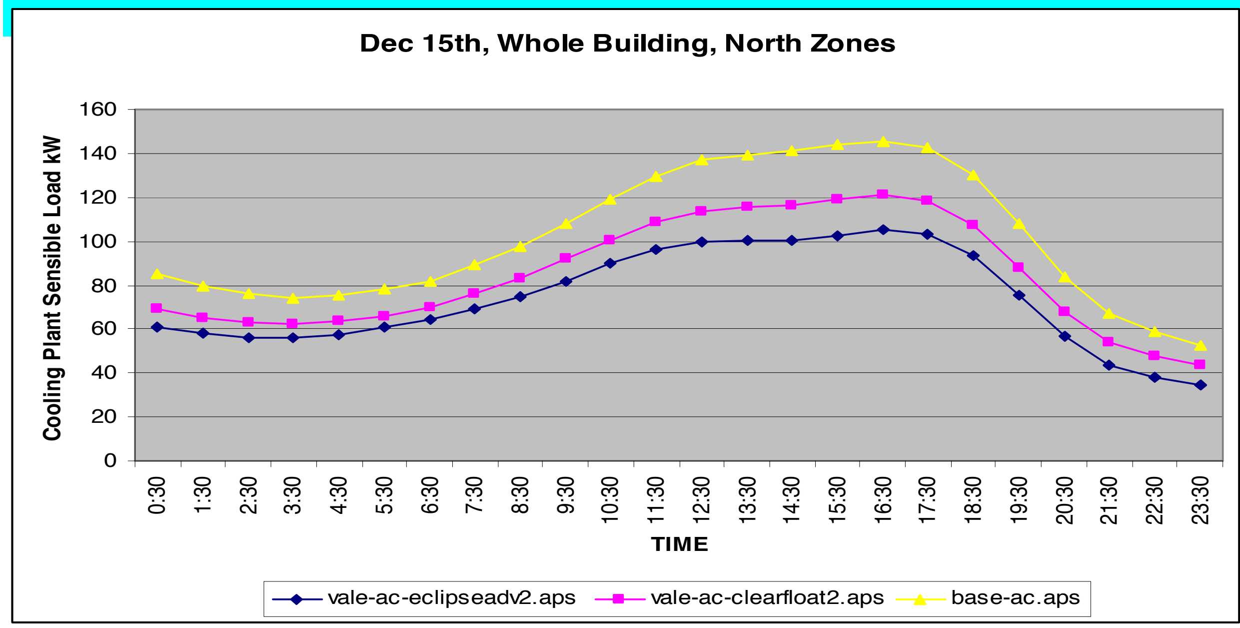


Fig 11 Results for the peak day on the entire North Zone of the building –punch windows

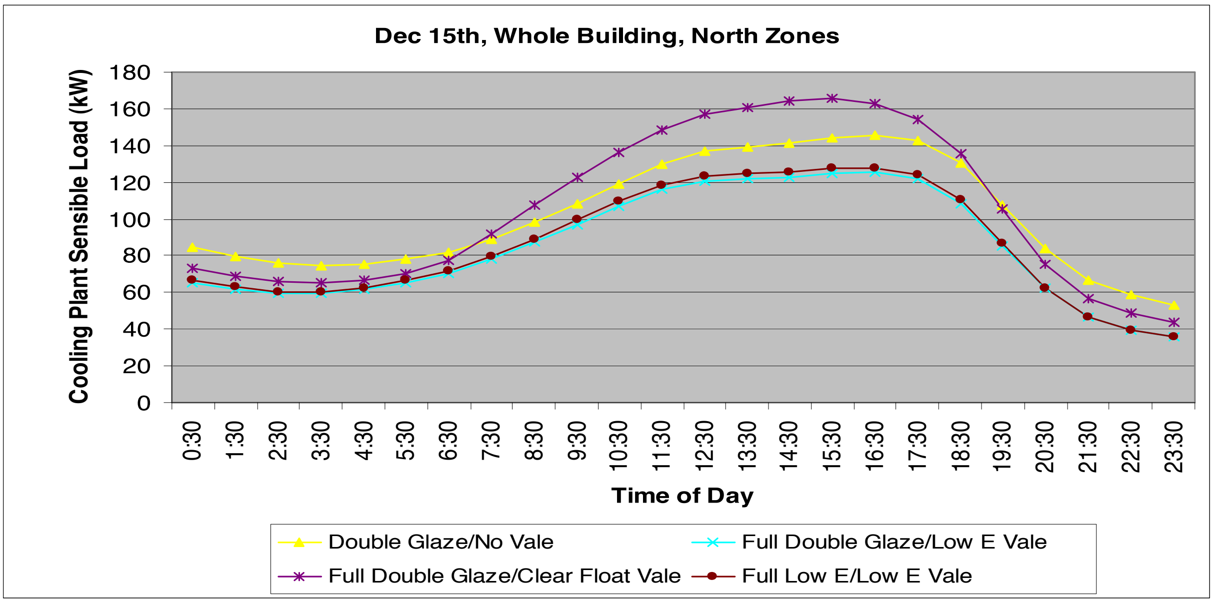
Fig 12 Results for the peak day on the entire North Zone of the building –full height windows



As expected, the addition of a clear float veil reduces the peak cooling load, changing this to a low-E glass veil reduces the cooling load even further. A total of 40kW energy reduction can be achieved in the size of the plant at the peak day.

Increasing the windows to full height double glazing with a clear veil increases the cooling load required during the day time, when compared with the existing façade. Utilising a low-E glass in the veil makes a significant difference to the cooling load, much more than the addition of a double glazed vs single glazed low-E glass.

The graphs indicate that the worst performing facade is a full height infill double glazed window with a clear float veil. The best performing facade is the existing double glazed windows with a low-E Veil. All other options have a lower maximum cooling load than the base case (yellow line).

It is obvious however that the veil needs to be low –E glass, particularly if the infill glass option is considered.

Unfortunately the budget did not stretch to replacing the façade, however it is interesting to note that much larger clear looking (i.e. Low E) windows could be installed in the building and actually reduce the energy demand of the plant.

CONCLUSION

ONE SIZE DOES NOT FIT ALL!

FOR NEW BUILDINGS

ESD considerations must be included early in design development.
The right solution will depend on the building and its occupants

FOR EXISTING BUILDINGS

The first step is understanding what you've got by conducting a base line audit.

What you do and how far you go will again depend on the building, the existing systems and your budget.

BRINGING THE INDUSTRY UP TO SPEED – MASTER BUILDER GREEN LIVING, AN EDUCATION PROGRAM FOR DOMESTIC BUILDERS.

Philip Alviano Ph.D[1]

[1] Master Builders Victoria, Melbourne, Australia, palviano@mbav.com.au

Keywords: building, sustainable, accreditation, training, industry, engagement, education

Summary

When contemplating the construction of new houses or renovations, many consumers only contact with the building industry is through a builder. The Master Builder Green Living program is designed to provide builders involved in the residential sector with a suite of improved management and business skills to enable builders to pursue energy innovations in their constructions. They will be issued with the necessary tools and information to identify the design features of energy efficient structures that not only meet minimum standards but set a new benchmark in the housing sector for energy innovation. This will result in a positive for the builder by improving their customer service ability by providing informative advice to clients about sustainable solutions in the design and construction of their dwelling.

By identifying builders that view sustainability issues as an important part of their business, consumers interested in addressing sustainability issues during the construction or renovation of their homes have the ability to seek out these builders. By bringing together like minded individuals the chances of improved sustainability outcomes for everyone are increased.

1. Introduction

Often the first point of contact for people contemplating the construction of new houses or renovations is through a builder. Domestic builders have experienced an increase in questions from their clients about sustainability issues, helping to raise the awareness amongst builders of the importance of incorporating sustainability into their operations. This has subsequently driven the demand for increased information from Master Builders which led to the development of the program.

The question then becomes one of presenting the required information in a format that is accepted by participants that usually do not have a strong academic background. While there is a large amount of information available on improved sustainability outcomes in the construction sector the challenge is to be able to translate this information from the academic to a series of goals, strategies and techniques understandable to and accepted by builders.

The Master Builder Green Living program is designed to provide builders involved in the residential sector with improved management and business skills to enable them to pursue energy innovations in their constructions. These include the necessary tools and information to identify design features of energy efficient structures that not only meet minimum standards but set a new benchmark in the housing sector for energy innovation. The builder is also able to improve their customer service by providing informative advice to clients about sustainable solutions in the design and construction of their dwelling.

This innovative program focuses on sustainability issues relevant at all stages of the construction process from important design considerations through materials selection and site management to interior fit out and health considerations. The information is easy to digest and focuses on common sense, practical solutions that are not necessarily expensive.

The other benefit for the builder is the linking of the program and work practices with a unit of attainment from the national training system which encourages further training for a nationally recognised qualification.

The program was developed by the Institute of Sustainable Futures for Master Builders through an Australian Greenhouse Office grant in 2005. Since then the program has been further developed by Master Builders Victoria. Over the last 2 years, Master Builders Victoria has seen over 150 builders complete the 2 day training program and sign a written commitment to incorporate sustainability objectives into their day to day operations. The program has also been presented by other Master Builders in Western Australia, Tasmania, New South Wales and the Australian Capital Territory.

By identifying builders that view sustainability issues as an important part of their business, consumers interested in addressing sustainability issues during the construction or renovation of their homes have the ability to seek out these builders. By bringing together like minded individuals the chances of improved sustainability outcomes for everyone are increased.

2. The Program

The Master Builder Green Living Program consists of a 2 day course, an accreditation system and the provision of a number of resources. It focuses on the often used, reduce, reuse and recycle message and considers the need to reduce impacts, energy and water use in the first place. It then explores a group of ideas that have a big impact on minimising the environmental impact of the house, without necessarily imposing an increased cost by using what we call deadest winners.

2.1 The training course

The training course is structured in a manner that follows the building cycle. It commences with a look a number of environmental issues such as greenhouse gas production and biodiversity loss and the impact of construction on these issues.

It then looks at the importance of project planning by emphasising the importance of thinking about sustainability features right from the beginning of the project. This is where features can be easily incorporated into the building project at minimal additional cost as they are integrated at the design phase.

The importance of design is then introduced, in particular passive solar design ideas. Once again the focus is on providing ideas that will reduce operational energy use and environmental impact without necessarily introducing additional costs.

The next few topics cover the environmental issues to be considered during the construction phase such as on site management, waste management and erosion and sediment control. Materials selection used in the framing and structure and the building envelope becomes important when we consider, where these materials come from, their recycled content and embodied energy. Concepts such as sustainably sourced and grown timber resources are also introduced.

Methods to reduce water and energy use are then explored by focusing on the big users and easy methods to reduce consumption. The importance of design considerations are not forgotten as a series of activities allow the participants to apply the ideas to real plans. These practical activities deliver a number of other outcomes such as group work and the sharing of ideas

Once the construction of the building is completed the issues to be considered during interior fitout are explored. As well as again looking at the importance of materials selection and embodied energy, indoor air quality is introduced as a topic that an increasing number of people are concerned about when they think about the emissions given off by solvents, glues, carpets and paints used in their homes.

The final topic covers business strategy and discusses methods to incorporate what they have just learnt into their day to day operations to make the whole process as easy as possible. In order to sell their increased knowledge of sustainable construction the accreditation process is discussed and a number of ideas of how to best to use the brand to differentiate their business from others in the market are introduced.

2.2 Resources

The goal of the program is to increase the chances of builders incorporating sustainability considerations into their developments. A number of resources are issued to participants during the course in order to make this process as easy as possible.

As well as a set of training notes a checklist is distributed as part of the Green Living domestic builder course. It is designed for the builder to use with their client to determine the range of environmentally friendly options to be incorporated into their development. This not only helps to remind the builder of the options available but also helps to clarify the client's requirements. The checklist follows the construction process and considers outcomes concerned with passive solar design, materials selection (environmental impact and embodied energy), water and energy conservation, recycling and indoor air quality.

All participants are also issued with a list of useful resources which is continually updated on the Master Builder Victoria Green Living webpage (www.mbav.com.au/training/greenliving.html). This list of useful suppliers and resources is once again designed to make the process of finding environmentally preferable materials as simple as possible. If the sourcing of a product or service becomes too difficult it is likely to be dismissed by the builder.

They are also given a copy of the "Your Home" manual (Australian Greenhouse Office 2005) a technical guide to environmentally sustainable homes. The guide provides them with additional information that they can read at their leisure or use as a future reference.

Once builders complete the program they continue to be supported through e-newsletters and an annual workshop. The newsletter, which is sent out tri-monthly, is able to keep Master Builder Green Living builders updated on regulatory changes, events that may be of interest and useful new products and resources. A one day workshop is also held annually which includes guest speakers from government who are able to provide insight into proposed regulatory changes, industry speakers and useful product suppliers. There is an opportunity for the builders seek clarity by having their questions answered. Each year a number of builders are also asked to speak about their own developments. This is often well received by the attendees as they are able to hear from a real builder about some exciting projects, how they overcame various problems and what they found useful along the way.

Accreditation

Only Master Builders members who complete the 2 day training program and sign a written commitment are able to refer to themselves as Master Builders Green Living Builders and to use the associated branding. The signing of a written commitment significantly increases the chances of the person putting a verbal commitment into action (McKenzie-Mohr and Smith 1999). The commitment includes:

- submission of an annual report to Master Builders that includes information and details on the total number of residential projects and Master Builder Green Living projects (including checklists) completed,
- an estimate of the amount of material recycled or diverted from landfill
- an assurance that sand, soil, screenings, concrete and chemicals were confined to the building site (completion of annual report declaration).

The annual report is required from the builder in order to continue to maintain their accreditation and is considered to be evidence of sustainable strategies being put in place. On provision of this evidence participating builders can continue their accreditation and also be eligible to receive a nationally recognized statement of attainment for the unit of competency demonstrated - BCGBC4020A Build thermally efficient and sustainable structures (domestic).

3. Achievements and Results

As of March 2008 152 builders have completed the Master Builders Green Living program in Victoria. Importantly 88% of those who complete the course have signed a written commitment to incorporate sustainability objectives into their day to day operations. Results compiled from reports submitted by the builders as part of the accreditation process indicate that;

- on average each of these builders are working on 8 projects per year covering 1072 building sites.
- 73% of these sites are recycling 47% of their waste.
- all these sites are controlling discharges to the storm water system.

4. Conclusion

Feedback from course participants has been excellent indicating that the information is presented in a format that they respond positively to. In evaluations completed at the end of each course 99% of participants rate the course as very good or excellent. There are also numerous comments on how useful they found the discussions and ideas shared with other like minded builders.

Providing training in a practical easy to follow format that is complemented by a variety of tools, ensures that builders feel more confident when discussing environmentally friendly practices with their clients. Providing improved training for builders in a format they are comfortable with and identifying builders, who have an interest in providing more sustainable housing, increases the chances that consumers who want these outcomes make contact with the appropriate person.

This approach results in an improved level of cooperation between client and builder which in turn increases the range and likelihood of these practices being incorporated into new developments. A builder who is not confident in dealing with sustainability issues is likely to be dismissive of questions asked by their clients.

SUSTAINABLE CONSTRUCTION - COMMERCIAL. A PROGRAM DESIGNED TO IMPROVE THE KNOWLEDGE OF SMALLER COMPANIES AND WORKERS INVOLVED IN COMMERCIAL CONSTRUCTION.

Philip Alviano Ph.D[1]

[1] Master Builders Victoria, Melbourne, Australia, palviano@mbav.com.au

Keywords: building, sustainable, commercial, training, industry, engagement, education

Summary

There has been an increased importance in the incorporation of sustainability practices into commercial building construction due to the increased inclusion of sustainability requirements in tender documents. This has resulted in the need for companies tendering for projects and their subcontractors to be more aware of sustainability issues and the methods of addressing them during the construction process.

Master Builders Victoria through its membership has identified a need for improving the knowledge base of commercial builders, site managers and other employees. It has addressed this by developing a practical program and an associated DVD which clarifies sustainability issues and methods to address them as simply as possible. An improved understanding of developer and tender requirements will enable site managers and contractors to improve compliance with environmental requirements on site.

1. Introduction

Master Builders' members are increasingly recognising the importance of sustainability in construction due to the popularity of "Green Buildings" and the Greenstar rating system, and the inclusion of sustainability criteria in government tender documents in the commercial property market. This demand is being driven by major companies wanting to be seen as good corporate citizens by housing themselves in "Green" buildings; because of the realisation that there are staff retention and productivity benefits associated with the improved working conditions due to better natural lighting and indoor air quality; minimum ABGR and Greenstar requirements from Government for leased office space and a realisation from developers that "Green" buildings are better investments (Green Building Council of Australia 2006).

This has resulted in the need for builders to respond to an increasing number of tenders that have a range of sustainability requirements in them. Builders have had to start thinking about the types of materials included in their buildings and the importance of incorporating sustainability into their operations. This has subsequently driven the demand for increased information from Master Builders on environmental policies, environmental management plans and materials suppliers, which led to the development of the program.

The Master Builder Sustainable Construction - Commercial program is designed to provide builders involved in the commercial sector with improved management and business skills to enable builders to better respond to sustainability requirements in tender documents, source information on appropriate materials and to incorporate these requirements into their day to day operations.

This innovative program focuses on sustainability issues relevant at all stages of the construction process from important design considerations through materials selection and site management to interior fit out and health considerations. The information is easy to digest and focuses on common sense, practical solutions.

The other benefit for the builder is the linking of the program and work practices with a unit of attainment from the national training system which encourages further training for a nationally recognised qualification.

The program was developed by Master Builders Victoria with the aid of funding provided by Sustainability Victoria and the first course was run in May 2007. The program was further enhanced by the production and incorporation of a DVD, developed in conjunction with Kestrel Media with the aid of funding provided by Incolink (a building industry redundancy payment fund). The DVD clarifies a number of sustainability issues and methods to address them via on site management practices as simply as possible.

An improved understanding of developer and tender requirements will enable site managers and contractors to improve compliance with environmental requirements on site.

2. The Program

The Sustainable Construction - Commercial course consists of a 2 day course, some audio visual resources and a range of activities that leave the participants with a simple environmental policy and management plan that they can then adapt for their own requirements. It focuses on the often used, reduce, reuse and recycle message and considers the need to reduce impacts, energy and water use in the first place. It then explores a group of ideas that have a big impact on minimising the environmental impact of construction, without necessarily imposing an increased cost.

2.1 The training course

The training course commences with a look at the concept of sustainability, a term that builders often hear about, but may not necessarily be aware of its exact meaning. This abstract term is given a concrete meaning by using the Ecological Footprint concept (Environment Protection Authority Victoria 2006). The concept attempts to determine just how much land is required to meet the resource requirements of a population in relation to their lifestyle. The concept is reinforced by using information from the group on their travel habits, food and lifestyles to determine just how many earths would be required to meet this need if everyone on the earth lived as they did. It then explores a number of environmental issues such as greenhouse gas production and biodiversity loss and the impact of construction on these issues.

The reasons for the increasing popularity of Green Buildings and the increasing requirements for builders to respond to sustainability requirements in tenders are then explored. Market drivers for sustainable buildings are then discussed. These drivers include;

- major companies wanting to be seen as good corporate citizens by housing themselves in "Green" buildings;
- the realisation that there are staff retention and productivity benefits associated with the improved working conditions due to better natural lighting and indoor air quality;
- a move to minimum ABGR, Greenstar and sustainable development requirements from Local, State and Federal Government for office space and
- a realisation from developers that "Green" buildings offer better investment returns (Green Building Council of Australia 2006).

This is followed by a familiarisation exercise looking at the various sustainability scorecards such as GreenStar and the Sustainable Development Scorecard used by a number of Victorian councils. The goal is to introduce participants to the manner in which they operate and the methods by which developments are scored according to the methods used to reduce the environmental impact of the building.

It then looks at the importance of project planning by emphasising the importance of thinking about sustainability features right from the beginning of the project. This is where features can be easily incorporated into the building project at minimal additional cost as they are integrated at the design phase.

The importance of design is then introduced, in particular passive solar design ideas. Once again the focus is on providing ideas that will reduce operational energy use and environmental impact without necessarily introducing additional costs.

The next few topics cover the environmental issues and legal requirements to be considered during the construction phase such as on site management, waste management and erosion and sediment control. The DVD is used to clarify a number of sustainability issues and provides practical examples of on site management practices filmed on building sites to address the issues as simply as possible. The participants are then issued with a series of site plans and asked to complete an environmental management plan for that site.

Materials selection used in the framing and structure and the building envelope becomes important when we consider, where these materials come from, their recycled content and embodied energy. Concepts such as sustainably sourced and grown timber resources and certification systems are also introduced.

Methods to reduce water and energy use are then explored by focusing on the big users and easy methods to reduce consumption. This material is backed by a number of case studies where real examples are used to show exactly how much energy and water use can be reduced. The importance of design considerations are not forgotten as a series of activities allow the participants to apply the ideas to real plans.

Once the construction of the building is completed the issues to be considered during interior fit out are explored. As well as again looking at the importance of materials selection and embodied energy, indoor air quality is introduced as a topic that an increasing number of people are concerned about when they think about the emissions given off by solvents, glues, carpets and paints used in their workplaces. The benefits to workplace productivity, staff retention and decreased absenteeism are also discussed.

The final topic covers business strategy and discusses methods to incorporate what they have just learnt into their day to day operations to make the whole process as easy as possible. In order to sell their increased knowledge of sustainable construction, methods to highlight this knowledge in tender documents are also outlined.

2.2 Resources

The goal of the program is to reduce the mystery around sustainability and to increase the chances of builders incorporating sustainability considerations into their developments. A number of resources are used by participants during the course in order to make this process as easy as possible.

The Sustainable Construction – Commercial DVD, is used to provide real examples filmed on building sites of methods to reduce the environmental impact during construction. A series of activities completed during the course ensure that participants leave with their own example of an environmental policy and an environmental management plan which they can adapt to fit their own requirements.

All participants are also issued with a list of useful resources which is continually updated on the Master Builder Victoria Green Living webpage (www.mbav.com.au/training/greenliving.html). This list of useful suppliers and resources is once again designed to make the process of finding environmentally preferable materials as simple as possible. If the sourcing of a product or service becomes too difficult it is likely to be dismissed by the builder.

Link to National Training Scheme

As a Registered Training Organisation, Master Builders Victoria is able to provide participants who complete the 2 days training and submit their environmental management plan for assessment with a nationally recognized statement of attainment for the unit of competency demonstrated;

- BCGBC5011A Manage building or construction, environmental management practices and processes (commercial)

This links the program and work practices directly in with the national training system and encourages further training for a nationally recognised qualification such as a Diploma of Occupational Health and Safety.

3. Conclusion

The Sustainable Construction – Commercial program was first delivered in March 2007. As of March 2008, 39 building industry professionals have completed the program.

Providing training in a practical easy to follow format that is complemented by a variety of tools, ensures that builders feel more confident when responding to sustainability issues and tenders. Providing improved training for builders in a format they are comfortable with increases the chances of an improved level of cooperation between developers, designers, builders and sub-contractors.

REDUCING THE ENVIRONMENTAL FOOTPRINT: MORNINGTON PENINSULA SHIRE COUNCIL CASE STUDY

Usha IYER-RANIGA PhD, MASA, B.Arch[1]

Trivess MOORE BSc Env (Hons) [2]

[1] Centre for Design, Royal Melbourne Institute of Technology, Melbourne, Australia, usha.iyer-raniga@rmit.edu.au

[2] Centre for Design, Royal Melbourne Institute of Technology, Melbourne, Australia, trivess.moore@rmit.edu.au

Keywords: environmental footprint, local council, sustainability checklist, Mornington Peninsula

Summary

The Mornington Peninsula Shire Council, located just outside the City of Melbourne in Australia, has taken significant steps in implementing a range of initiatives to become a sustainable shire. The Shire appreciates that a number of benefits exist for reducing their impact on the environment including the potential for cost savings. They have demonstrated leadership by example, by managing their own assets.

To ensure that sustainable practices are adopted by contractors responsible for maintenance and refurbishment of council owned properties, a checklist of items including whitegoods, heating and cooling units and some building materials was developed. The intention of this checklist was to incorporate sustainability criteria wherever possible when existing items needed to be replaced or new items ordered as part of renovations/refurbishment of Shire assets. Criteria in the development of the checklist included considerations such as energy and water impacts, materials choice and indoor environmental quality. Due consideration was also given to practical issues such as place of manufacture, availability/servicing capability within the Shire and costs.

1. Introduction

The built environment has a significant impact on the natural environment, both in Australia and globally. The OECD (2002) reported that buildings are estimated to consume 30 - 50% of available raw materials and account for 25 - 40% of final energy consumption. They generate about 40% of waste to landfill in OECD countries (OECD 2003). There is therefore an untapped opportunity for the built environment to help reduce environmental impacts through their design and use.

Buildings in Australia have a turn over rate of about 2% per year (Horne R 2007), meaning that it will be 50 years or more before current building stock will be replaced and sustainability features of new buildings rolled out across all buildings. It is therefore important to focus on implementing sustainability into current buildings through refurbishments and renovations so that we can make an impact on reducing the built environments impacts on the natural environment.

The UNEP (2007) found that internationally, operational energy of buildings tends to be around 85% of the total energy of the life of a building. As reported by McKinsey & Company (Bressand et al 2007, p. 13) large opportunities for improving energy efficiency exist across the different sectors. The potential demand reduction in 2020 through enhanced energy productivity can create 10% opportunities in commercial sector, and 30% in industrial sectors. It is noteworthy that most council assets would fall within these sectors.

Also reported by McKinsey & Company is that the commercial sector offers more opportunities for boosting energy productivity (Farrell et al 2008).There is an opportunity of 20 to 30 percent in the commercial sector in the US (Bressand et al 2007). The commercial sector is generally dominated by lighting and other electricity powered appliances, followed by space heating (Bressand et al 2007, p. 109). It is expected that the figures in Australia would be very similar. Efficiencies in heating and cooling offer large energy productivity opportunities, leading to attendant greenhouse gas abatement. Therefore, it is strategic to focus on opportunities where energy efficiency policies and programs can be developed and implemented.

The checklist developed for the Mornington Peninsula Shire Council (MPSC) offers another way of reducing our impact on the built environment. By preparing a prescriptive checklist for council contractors and designers, the Shire is making some in-roads into dropping its use on operational energy, and attendant greenhouse gas emissions. This paper outlines the process undertaken in the preparation of the checklist and presents findings. It also presents feedback from the council contractors in the use of the checklist and offers recommendations in the development and implementation of such types of checklists.

2. Mornington Peninsula Shire Council

As organisations around the world and in Australia are starting to realise the benefits of 'going green' they are starting to look for every opportunity where they can make reductions to their overall environmental footprint. In Australia, many local councils are taking a leadership role and leading by example in their efforts to be sustainable.

The Mornington Peninsula Shire, located south just over an hour's drive from Melbourne, is the most popular informal recreational area in Victoria. The Mornington Peninsula is a boot-shaped promontory separating two contrasting bays: Port Philip and Western Port and has over 190kms of coastline.

3. Aim of the project

To ensure that sustainable practices are adopted by their contractors responsible for maintenance and refurbishment of council owned properties, the Mornington Peninsula Shire Council (MPSC) decided to use a checklist of items including whitegoods, heating and cooling units and wherever possible, provide opportunities for reducing environmental impact through choice of building materials and products. Due consideration was given to practical issues such as place of manufacture, availability/servicing capability within the Shire and costs.

The checklist was deliberately aimed to be prescriptive rather than a decision making tool. An underlying reason for this was to make it easy for contractors and other players in the refurbishment process to adopt sustainability practices. It was recognised, that as a result of this, the checklist will have a rather short shelf life.

4. Scope of the project

MPSC wanted to create a checklist of sustainably preferable products and materials across a range of costs and performances and they also required a contractor compliance sheet. The specific deliverables were:

- Developing a ESD Building Refurbishment Checklist
- Tailoring the existing Contractor Compliance Sheet for ease of use and appropriate information provision.

The Checklist needed to:

- Be a simple and easy to use document
- Provide a list of objectives and targets for each of the subheadings
- Provide additional product options within the range described
- Identify purchase price and local availability within the Mornington Peninsula
- Calculate payback time for major appliances (this was later refined further for application)
- Provide an indication of the percentage increase to the maintenance budget associated with using product alternatives. This was to be achieved by identifying the cost difference between typical existing products and their eco-preferred option identified on the checklist. The price difference was to allow for a calculated percentage variation to the budget.
- Provide a checklist induction session with the Shire

The Contractor Compliance sheet was designed to be used by the contractors when replacing, upgrading or installing new appliances or selected materials. It is to be used as a check to make sure that appliances are replaced only when necessary and replaced with one of the recommended options to maximise water and energy savings.

The Contractor Compliance Sheet needed to:

- Be a simple and easy to use document
- Indicate relevant information: for example - existing conditions (site, building element and existing in-situ product/s) and replacement activity (identify checklist product/s, price, changed conditions etc.). The scope of compliance sheet requirements outside these parameters was to be evaluated in discussion with relevant council members and contractors if possible.

The checklist and contractor compliance sheets were to be used for renovations and refurbishments of projects within MPSC.

5. Research Design

The checklist was developed in two parts. The summary sheets at the front end of the checklist with detailed information following, and the raw data sheets. The summary sheet, as the name implies, provided a summary of the information contained in the detailed sheets. The summary sheet consisted of the recommended product in each of the different product and material areas and each of the different size requirements. Each of these products and materials contained the following information: cost, warranty, dimensions, energy/water ratings and consumption rates.

The detailed information contained the following information: cost, warranty, dimensions, product description, energy/water ratings, energy/water consumption rates, energy/water ratings and consumption rates for average (not-specially energy/water efficient) products and a weblink to further product information.

The raw data sheets contained the same information as the detailed information but also contained payback periods for the different products. The payback period was worked out by using the cost difference (if any) of the more energy/water efficient appliances compared to an ‘average’ product and working out the payback period based upon the costs of those utilities.

Desk research provided most of the information. Two main areas of information were used to populate the spreadsheets: products and materials. Products were those that were usually replaced during renovations or refurbishments. They contained:

- Products – Air conditioning, bathroom appliances, dishwashers, dryer, hot water system, lighting, ovens and stoves, refrigeration and freezers and washing machines.
- Materials – Cement, insulation and paint

Two different approaches for used for each of the above. Products were grouped under different categories such as air conditioning, bathroom appliances, dishwasher etc, (see Development of Checklist section below). Within these categories, information included the physical dimensions of the product, the prices, and web links for information. Wherever possible, product descriptions included water savings and consumption information. Likewise, they also contained energy savings and consumption information. Each category required 4-6 products (where possible) which covered a range in environmental performances as well as durability and costs.

Materials information contained descriptions regarding recycled content, Volatile Organic Compounds (VOC) information and recycability information.

Durability and costs were included for both products and materials.

After an initial list of products was put together, further research into each product was carried out. Local suppliers were contacted and asked about the availability of these products and if there were any others they would recommend. Information such as costs, dimensions and warranty was also gathered and the spreadsheet populated. Information about an ‘average’ product was also gathered for comparison to the more environmentally friendly products.

Material information was gathered by calling different suppliers and requesting information about their materials as well as using sources such as Ecospecifier (2008). Sustainability information such as recycled content, low Volatile Organic Compound (VOC’s) and recycability was then recorded about their products.

Lists such as WELS (2008) and Energy Rating (2008) were researched for appliances which were in the highest water and energy star rating categories. The energy star rating categories included products from the very highest star ratings to those with the lowest star ratings. Other sources such as Choice Magazine were also researched for recommended and non-recommended products.

6. Development of checklist

It was agreed at the outset between the MPSC and the Centre for Design that there may be elements of the checklist that would be iterative. As a starting position, it was agreed that the checklist include the following subheadings for products:

- Product name
- Brief product description
- Dimensions, where applicable
- Water saving rating and consumption rates
- Energy star rating and consumption rates
- Price
- Weblink for further product information
- General cost and energy and water consumption for an ‘average’ product (for a comparison)

And not included on the final checklist itself but calculated and provided with the raw data sheet:

- Pay back periods for the more sustainable products compared to the ‘average’ product
- Water and energy savings compared to the ‘average’ product

The product categories and subheadings were set up in a spreadsheet so it could easily be populated with the required information. Once the spreadsheet was set up, desk research was undertaken to populate the checklist.

Once all this information was collected, each product and material category was narrowed down to 4-6 products which covered the size requirements and desired performance. The best couple of environmentally performing products and materials in each category were kept along with the products and materials with the lowest price (regardless of environmental ratings) and some that were recommended by other credible sources such as Choice Magazine or Ecospecifer.

Pay back periods were calculated for each of the products for their energy and water saving features compared to the extra cost over an ‘average’ product of similar size and requirements. This payback information was used to show how long it would take for the more environmentally friendly products to come out ahead of an ‘average’ product based upon capital and operational costs.

From these lists, one product or material was recommended for each of the categories and subcategories based upon the following:

- Preference was given to the best environmentally performing product or material;
- Where the top environmentally performing product or material was significantly more expensive than the second place product or material, then consideration was given to the cheaper option as long as its environmental performance was not significantly less
- Consideration was also given to warranty length and type, as well as payback periods and any other relevant information.
- Where there was too great a range to narrow down to one product such as for lights or tap fittings (as these will differ depending on requirements and style), a general guiding principle was given and targets to aim for (for example taps – aim for 6 stars rating, 1.5L/min to 6L/min).

These chosen products and materials were then compiled into two A4 pages as a summary for contractors to quickly check (refer Figure 1). All relevant information such as product, product description, capacity size, dimensions, warranty, price and energy and water ratings and consumption rates was provided. Payback periods and other attendant information was not provided with this overview as this was considered part of the detailed information. The contractors were encouraged use this list when purchasing products or materials. If the product or material was not available for whatever reason, then a product of equal environmental performance was recommended to be purchased.

	Size	Product	Product Description	Dimensions (w,d,h) m	Warranty	Price	Energy star rating and consumption	Water rating and consumption
Airconditioning	Single split system up to 5kWh	Fujitsu (ASTB12LDC)	3.5kW cooling capacity	0.79x0.23x0.28	5 years	$1,650	Cooling: 6 star, 0.91kWh Heating: 6 star, 1.22kWh	NA
	Single split system above 5kWh	Fujitsu (ASTA 30LCC)	8kW cooling capacity	1.30x0.23x0.32	5 years	$2,300	Cooling: 4 star, 2.55kWh Heating: 4.5 star, 2.64kWh	NA
Dishwasher	12 place setting	Fisher and Paykel DW60CGX1	12 place setting dishwasher	0.50 x 0.60 x 0.85	2 years	$625	NA	3 star, 257kWh/365 washes
Dryer	Small load (up to 4.9kg)	Simpson 39P400M	4kg capacity	0.50 x 0.46 x 0.79	1 year	$349	1.5 star, 159kWh/52 uses	NA
	Medium load (5-6.9kgs)	Kleenmaid KED600	6.5kg capacity	0.50 x 0.64 x 0.84	5 years	$1,499	3 star, 247kWh/52 uses	NA
	Large load (7kgs plus)	Fisher & Paykel DEIX1	8.0kg capacity	0.59 x 0.71 x 1.06	2 years	$1,499	2 star, 339kWh/52 uses	NA
Hot water system	Solar gas boosted (1 to 2 person)	Rheem Solar Premier Hiline - 52H180-G	180 L	1.50 x 2.80 for panels	1 to 5 years	$4,276	NA	NA
	Solar gas boosted (2 to 5 person)	Rheem Solar Premier Hiline - 52H300-G	300 L	2.20 x 2.80 for panels	1 to 5 years	$5,391	NA	NA
	Solar electric boost (1 to 2 person)	Rheem Solar Premier Hiline - 52H180	180 L	1.50 x 2.80 for panels	1 to 5 years	$2,737	NA	NA
	Solar electric boost (2 to 5 person)	Rheem Solar Premier Hiline - 52H300	300 L	2.20 x 2.80 for panels	1 to 5 years	$3,881	NA	NA
	Gas immersion DHWS (1 to 3 person)	Rinnai Infinity V series INF16	16-26L/min	0.35 x 0.20 x 0.53	3 to 10 years	$880	5.5 star, 15MJ/h	NA
	Gas immersion DHWS (3 to 6 person)	Dux Endurance Plus Gas Continuous Flow	26L/min	NA	3 to 10 years	$1,120	5.5 star, 17MJ/h to 199MJ/h	NA
	Electric immersion DHWS (1 to 3 person)	Rheem Optima - 411250	250 L	0.55 x 0.71 x 1.39	1 to 10 years	$1,350	4.8kW	NA
	Electric immersion DHWS (3 to 6 person)	Rheem Optima - 411400	400 L	0.67 x 0.71 x 1.88	1 to 10 years	$1,746	4.8kW	NA
Oven/stove units	Gas oven/stove unit	Kleenmaid FEG605X		0.60 x 0.60 x 0.90	5 years	$3,499	29.5MJ/h	NA
	Electric oven/stove unit	Westinghouse PPN776S	80L oven capacity	0.60 x 0.57 0.60	2 years	$1,379	NA	NA
Refridgerator	Bar fridge	Fisher and Paykel P120 EZKlean	115 L Fridge	0.53 x 0.57 x 0.82	2 years	$307	2.5 star, 291kWh/yr	NA
	Small 150-300L	Fisher & Paykel E249T	248L (191 L fridge, 57 L Freezer)	0.38 x 0.61 x 1.63	2 years	$809	4 star, 387kWh/yr	NA
	Medium 301 - 450 L	Fisher & Paykel Active Smart Elegance E440T	447L (342L Fridge, 105L Freezer)	0.79 x 0.73 x 1.72	2 years	$1,649	4 star, 476kWh/yr	NA
	Lage 450L +	Simpson 520L STM5200WA	250L Fridge&Freezer	0.80 x 0.73 x 1.72		$1,199	4.5 stars, 510kWh/yr	NA
Washing machines	Small load (up to 5.5kg)	Simpson 45S556E	5.5kg capacity	0.60 x 0.59 x 0.85	2 years	$600	2.5 star 368kWh/365 wash	4 star, 56L/wash
	Medium load (5-7kg)	LG WD-8015C	7kg capacity, front loading	0.60 x 0.55 x 0.85	2 years	$906	4 star, 235kWh/365 wash	4 star, 69.5L/wash
	Large load(7.5kg plus)	LG WD-1238C	7.5kg capacity, front loading	0.60 x 0.55 x 0.84	2 years	$1,249	4.5 star, 205kWh/365 wash	4 star, 70L/wash

Figure 1: A screen shot of a summary page of the best value products for each category. Products were rated on environmental performance as most important with cost and durability also considered as secondary importance.

A more comprehensive list of all the products and materials including all information was compiled into a booklet for MPSC to use as a reference (Figure 2). The booklet provided details on where contractors could find further information if they required it. It also provides a comparison between all the products and materials in terms of environmental impacts and cost so it can be seen why the preferred product or material on the summary sheet was chosen.

7. Feedback on the checklist

Almost a year after the checklist was developed, the authors sought feedback from MPSC on the use of the checklist. The checklist was distributed to consultants for the building refurbishment program ($2 million pa). It was also distributed to a number of other councils, however whilst some of these councils found it useful, others found its use very limited.

The general feedback was that the checklist was helpful for selecting some appliances and is one of a number of tools the Council were using to improve the sustainable design of their buildings. It must be noted that the champion in the organisation whose idea it was to develop the checklist in the first place no longer worked for the organisation, therefore, the uptake of the checklist was expected to be quite modest. It was also reported that the document had been useful for the selection of some appliances and products for the refurbishment program.

A designer appointed by the Shire to work on refurbishments found the checklist very useful. Feedback from the designer indicated that the checklist assisted in specification of refurbishment works for the Shire.

The main criticism, however, was that the appliances in the checklist was suitable more for domestic rather than commercial use. This was not surprising as this was flagged while preparing the checklist, and the needs for commercial use is often "tailor made" rather than being generic – contrary to the approach taken in the development of the checklist.

Specific comments included that while selecting air conditioning brands, the checklist was useful. While the information for instantaneous gas hot water units was useful, the checklist did not address adequately larger units. The information covered in the checklist for bathroom, insulation and paint was very useful. The information for ovens and stoves was helpful, but more information was needed for commercial fridges.

It was suggested that the checklist, while limited in its application worked quite well with other tools available within the local government sustainable buildings program such as the Sustainable Design Scorecard (SDS) developed by Moreland and Port Phillip councils in Victoria.

DISHWASHER

Figure 2: A screen shot of a complete category listing. It shows all the products which were researched across the spectrum of cost, size and durability as well as environmental performance.

8. Conclusion and recommendations

The development of the checklist, while a time consuming exercise, offers yet another resource to key players in the building industry. An underlying reason for developing the checklist was to ensure that the players involved in the Shire's refurbishment process would not have to "think about it". They would simply pick out the appropriate appliance/product from an existing document, making it as simple and easy as possible.

The checklist's reasonable short shelf life was recognised. Resources would need to be directed at appropriate intervals to ensure that the information contained in the checklist was current. The checklist alone was not enough, it needed to be part of a range of resources available to the Shire and their building industry stakeholders.

A decision making checklist would add value to this document. A decision making checklist would provide an educational value and enable contractors, designers and other building industry players to base their product/material choices on broader considerations such as: energy and water efficiency and conservation both in its manufacture and use, reuse/recyclability, toxicity, supply chain stewardship and other similar environmental considerations.

A potential next step for this project would be to expand the existing checklist, and prepare a decision making one suitable for all Councils in Victoria, containing a greater range of products and materials. This could then be updated at appropriate intervals to keep abreast of changes to products and new products entering the marketplace. A web based system may also provide a quick, easy to use reference document for not just councils, but also other professionals in the building industry.

Summary

This report describes a probe insertion method for on-site evaluation of variable refrigerant volume (VRV) systems and evaluation results for VRV systems using a gas heat pump (GHP). This method allows calculation of production calories for outdoor units based on the energy balance and measurement of exchange heat. The former is to determine input energy and output energy of the VRV system. The latter measures air temperature before and after the outdoor unit heat exchanger to determine the amount of heat exchange. A sheath-type thermocouple is inserted from the outside of the heat exchanger, and air temperature after heat exchange is measured. This method is able to evaluate four types of VRV system operations [cooling while using an electric heat pump (EHP), heating while using an EHP, cooling while using a GHP, and heating while using a GHP]. Result of an on-site evaluation for a VRV system using a GHP clarified characteristics of energy consumption. This evaluation was conducted from July 2007 to February 2008. The results showed that the VRV system was operating under an extremely low load.

1. Introduction

In Japan, the use of VRV systems in small and medium-sized office buildings is widespread. This situation also is becoming common worldwide. These VRV systems are considered to provide good performance. However, the characteristics that affect performance of the equipment during actual operation are not well understood, and how energy is used is uncertain. This is a disadvantage for facility designers and users. This report describes how energy is consumed by an actual system using a probe insertion method.

In addition, a simultaneous test using a method generally done in an examination room without disturbances exist was conducted to verify the accuracy of this method. This result showed that the system coefficient of performance (COP) error margin of this method was +19% in cooling with EHP use, and, +6% in cooling with GHP use.

Practical operation conditions of a VRV system installed in building K were investigated using the probe insertion method during a 30-week investigation period over summer and winter. A GHP outdoor unit with specifications of 30 HP was installed. This system managed temperature control for a 384 square meter office.

Results of on-site evaluation of a VRV system can help predict the success or failure of a facility design, and demand of the indoor unit.

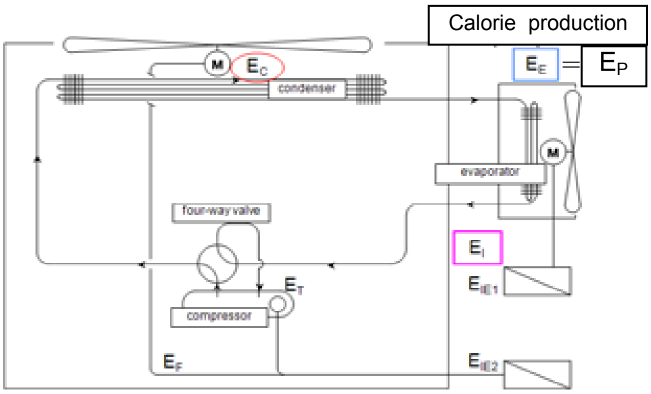
2. Probe insertion method

2.1 Calculation of calorie production on an outdoor unit

The energy balance in each system is shown in Figures 1-4. The outdoor unit was considered as heat source equipment for this research, with the evaluation based on calorie production of the outdoor unit. The following energy balance is assumed to have calorie production on the outdoor unit (E_P) correspond to calorie use of the indoor unit. This method disregards the influence of heat loss in the refrigerant pipes.

For EHP cooling and heating, calculation of calorie production can be done on the outdoor unit. Figure 1 (cooling) and Figure 2 (heating) show the energy balance. Energy to the compressor of total input energy on outdoor unit is shown by equation (1). Moreover, energy balance in the refrigeration cycle is shown by equation (2), and calorie production of the outdoor unit during cooling is described by equation (3), derived from equations (1) and (2). Calorie production of the outdoor unit during heating is described by equation (5). Therefore, COP of the whole system is described by equations (4) and (6).

Figure 3 (cooling) and Figure 4 (heating) show energy balance at cooling and heating with a GHP. Each energy balance during cooling operation is described by equations (7) and (8). Energy balance during heating operation is described by equations (11) and (12). Energy to the compressor and total input energy of the outdoor unit are described by equations (7) and (11). Moreover, energy balance during the refrigeration cycle is shown by equation (8), and heat production of the outdoor unit during cooling is described by equation (9), derived from equations (7) and (8). Heat production of the outdoor unit during heating and is described by equation (13), which is derived from equations (11) and (12). Therefore, system COP is shown by equations (10) and (14).



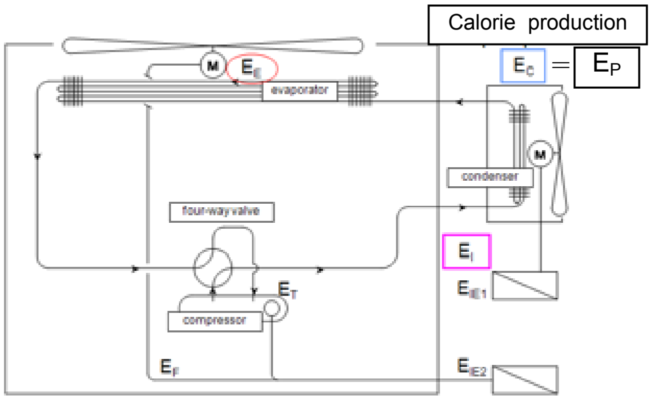
$$E_T = E_{IE2} - E_F \quad (1)$$

$$E_E = E_C - E_T \quad (2)$$

$$\therefore E_E = E_P = E_C - E_{IE2} + E_F \quad (3)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_C - E_{IE2} + E_F)}{(E_{IE1} + E_{IE2})} \quad (4)$$

Figure 1. Energy balance during cooling with EHP



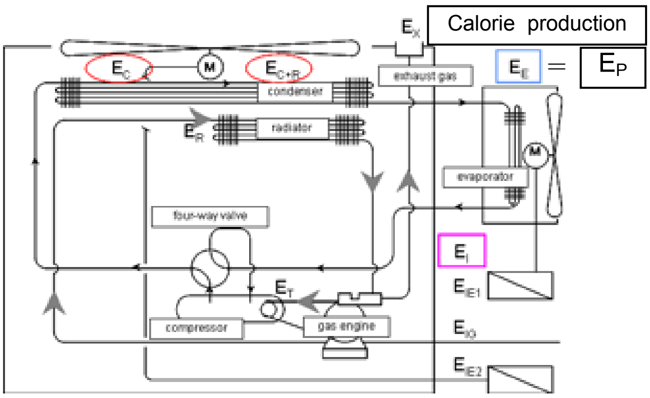
$$E_T = E_{IE2} - E_F$$

$$E_C = E_E + E_T$$

$$\therefore E_C = E_P = E_E + E_{IE2} - E_F \quad (5)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_E + E_{IE2} - E_F)}{(E_{IE1} + E_{IE2})} \quad (6)$$

Figure 2. Energy balance during heating with EHP



$$E_{IG} = E_T + E_X + E_R$$

$$\therefore E_T = E_{IG} - E_X - E_R \quad (7)$$

$$E_E = E_C - E_T$$

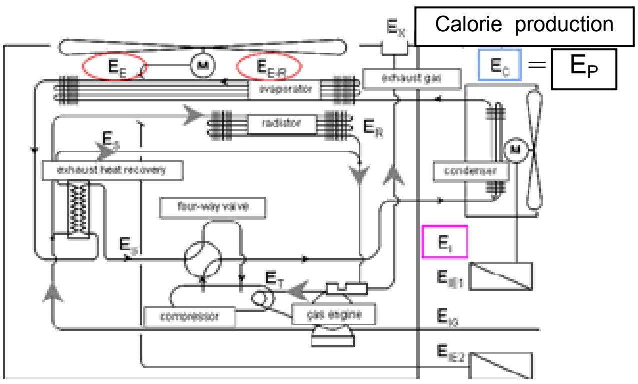
$$\therefore E_T = E_C - E_E \quad (8)$$

$$\therefore E_{IG} - E_X - E_R = E_C - E_E$$

$$E_E = E_P = E_C + E_R + E_X - E_{IG} \quad (9)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_C + E_R + E_X - E_{IG})}{(E_{IE1} + E_{IE2} + E_{IG})} \quad (10)$$

Figure 3. Energy balance during cooling with GHP



$$E_{IG} = E_T + E_X + E_R + E_S$$

$$\therefore E_T = E_{IG} - E_X - E_R - E_S \quad (11)$$

$$E_C = E_E + E_T + E_S$$

$$\therefore E_T = E_C - E_E - E_S \quad (12)$$

$$\therefore E_{IG} - E_X - E_R - E_S = E_C - E_E - E_S$$

$$E_C = E_P = E_E - E_R - E_X + E_{IG} \quad (13)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_E - E_R - E_X + E_{IG})}{(E_{IE1} + E_{IE2} + E_{IG})} \quad (14)$$

Figure 4. Energy balance during heating with GHP

E_T : compressor energy
E_E : evaporation calorie
E_C : condensation calorie
E_P : production calorie
COP_S : systemCOP
E_I : total input energy
E_{IG} : input gas energy
E_{IE1} : electric power indoor
E_{IE2} : electric power outdoor
E_R : radiation calorie
E_X : exhaust calorie
E_S : exhaust heat recovery calorie

2.2 Measurement of exchange heat on the outdoor unit

Figure 5 shows a schematic of the probe insertion method. To calculate calorie production of the outdoor unit based on equations (3), (5), (9), and (13), it is necessary to measure exchange heat of the outdoor unit. For example, in equation (3), the calories correspond to E_C. In addition, other items can be measured. For GHP [equations (9) and (13)], measurement of E_R is difficult. Generally, a radiator is set up in parallel with the heat exchanger. Therefore, the amount of heat exchange of the radiator and heat exchanger is added based on equations (9) and (13).

Air that flows into the heat exchanger passes through a fan for heat exchange promotion. Therefore, the amount of heat exchange of the outdoor unit is calculated by measuring the change in temperature of the air.

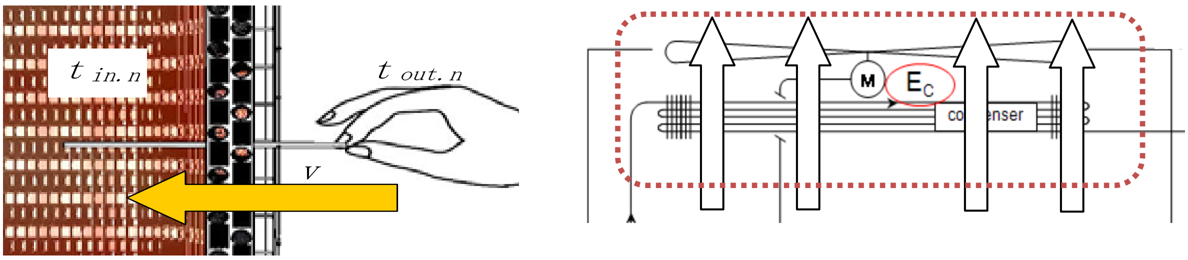


Figure 5. Probe insertion method idea

Equation (15) describes the basics of this system. It calculates the state of air under fixed pressure conditions. To calculate the amount of heat exchange, air temperature before and after the outdoor unit heat exchanger is measured. A sheath-type thermocouple is inserted from the outside of the heat exchanger, and air temperature after heat exchange is measured.

$$Q = v \times s \times \rho \times C_p \times (t_{before} - t_{after}) \qquad (15)$$

In addition, the amount of air that passed through the heat exchanger also is measured. Here, equation (16) excludes serious disturbance. Exhaust air speed from the fan (V_{FAN}) and air speed past the heat exchanger (v_n) are proportional. Then, v_n is a target variable, and V_{FAN} is assumed to be an explaining variable. Thus, *α* is derived from equation (17) and calculated from measurements.

$$\frac{v_{n.2}}{v_{n.1}} = \frac{V_{Fan.2}}{V_{Fan.1}} \qquad (16)$$

$$v_{n.2} = \alpha \times V_{Fan.2} \qquad \alpha = \frac{v_{n.1}}{V_{Fan.1}} \qquad (17)$$

Figure 6 shows the measurement points of the probe insertion method. Exchange heat is measured by all points simultaneously while considering distribution of air speed currents. More measurement points are preferable. Actually, the representative area is allocated and totaled, with the assumption of exchange heat on the outdoor unit [equation (18)].

outdoor unit heat exchange

$$q_{all} = \sum_{n=1}^{n} \alpha_n \times V_{FAN.t} \times s_n \times \rho \times C_p \times (t_{after.n} - t_{before.n}) \quad (18)$$

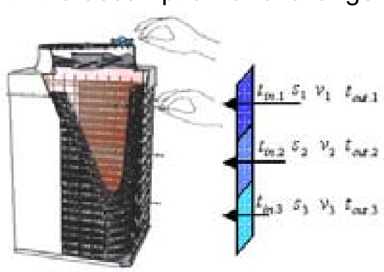

Figure 6. Measurement points of probe insertion method

$V_{FAN.t}$: Exhaust air speed $[m/s]$
s_n : Representative area n [m2]
ρ : Specific weight [kg/m3]
C_p : specific heat [kJ/kg K]
$t_{after.n}$: Air temperature after heat exchanger n $[^0C]$
$t_{before.n}$: Air temperature before heat exchanger n $[^0C]$

3. Measurement example in VRV system by probe insertion method

3.1 Outline of building K and object system

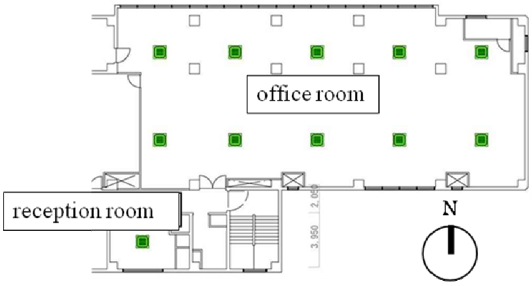

Figure 7. Building K 2F plan

Table 1. Outline of building K and object system

Position	Tokyo in Japan	
Object floor	second floor	
Use	office room	reception room
Space	360m^2	24m^2
Indoor unit	7.1[kW]/8.0[kW]×10	7.1[kW]/8.0[kW]×1
Outdoor unit	GHP	
Refrigerant	R410A	
Controller	indoor	
systemCOP	1.25/1.38	

※cooling/heating

Measurements were taken using the probe insertion method from July 13, 2007 to February 11, 2008.

Rooms include a reception area and office with a large north-facing window (Figure 7). Table 1 shows characteristics of the VRV system using a GHP. Specifications included 203 square meters [W/m^2] in cooling mode and 229 [W/m^2] in heating mode. In addition, room temperature could be set with an indoor controller. This is a generalized facility design common in Japan.

3.2 Measurement point

Figure 8. Appearances of object

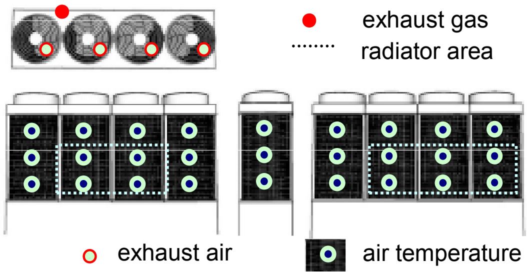

Figure 9. Measurement points

Air temperature before and after the heat exchanger was measured at 27 points, while exhaust air speed was measured at 4 points and the temperature of exhaust gas was measured at 1 point, as shown in Figure 9.

Object system energy consumption was measured. The power consumption and consumption of gas of the outdoor unit system were measured. Additionally, indoor unit power consumption was measured from the second floor distribution panel.

3.3. Results and discussion

3.3.1 Outside air temperature and humidity during the experimental period

Figure 10 shows daily average outside temperature and humidity. The maximum daily average temperature was 33.0°C, recorded on August 16, 2007; the minimum daily average temperature was 1.7°C, recorded on February 3, 2008.

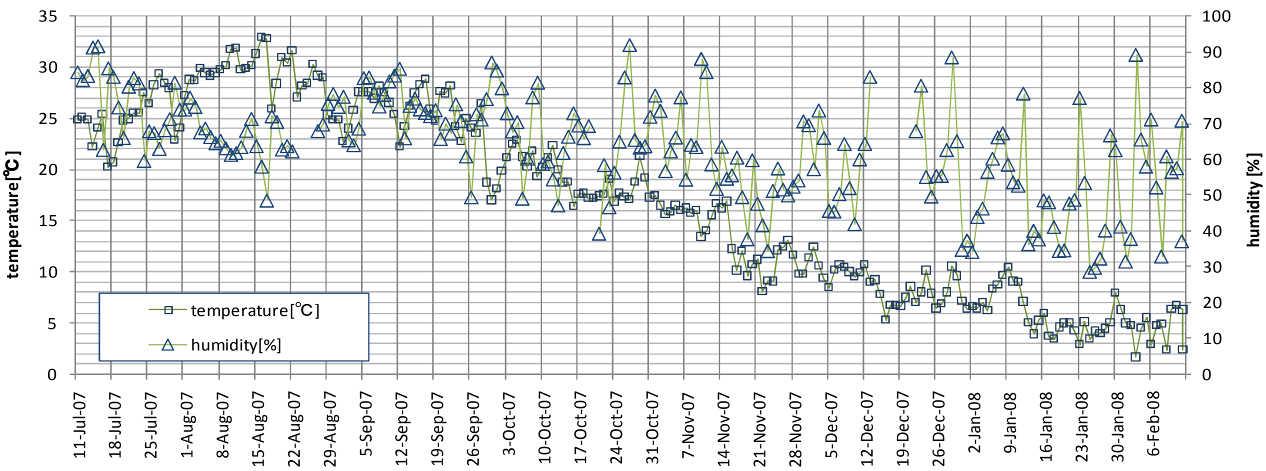

Figure 10. Daily average outside temperature and humidity

3.3.2 Multiple energy consumption by day, calorie production per day, and system COP per day

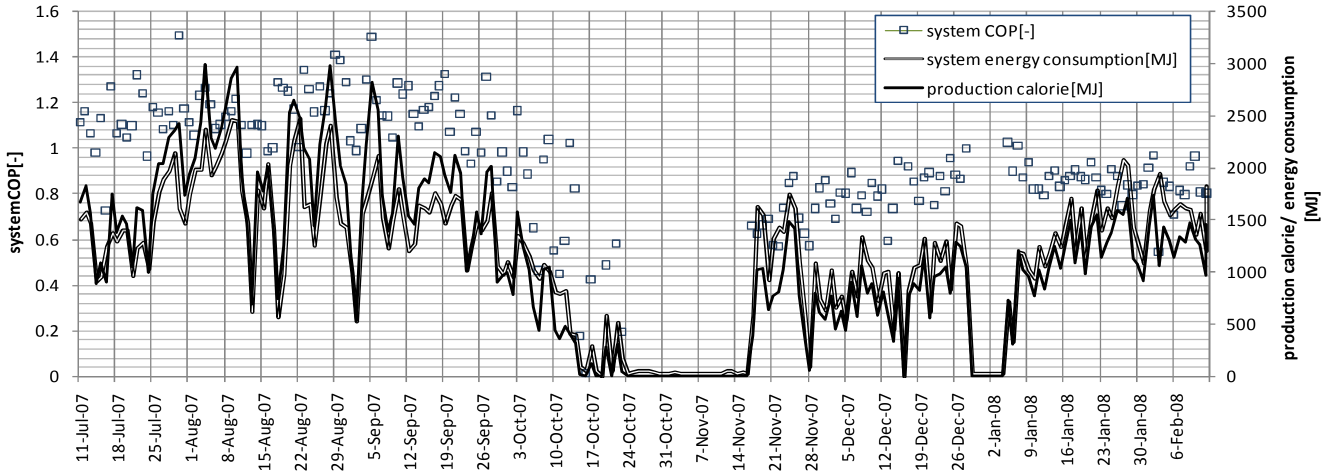

Figure 11. Multiple energy consumption per day and system COP per day

Figure 11 shows multiple energy consumption by day and system COP by day. The time from July 13, 2007 to October 24, 2007 was a cooling period, while the time from November 17, 2007 to February 11, 2008 was a heating period. The daily maximum energy consumption while cooling was 2851 [MJ/day] recorded on August 9, 2007; the maximum recorded during heating was 2066 [MJ/day] recorded on January 27, 2008. Average energy consumption while cooling was 1389 [MJ/day]; average while heating was 1223 [MJ/day]. Thus, more energy was used during the cooling period than during the heating period. Indoor heat generation rate from any equipment is assumed to be related. Average system COP during cooling was 1.05, while that during heating was 0.82. Generally, when the outside air temperature is low, system COP improves at the same load during a cooling period. However, Figure 11 does not show this trend, because the load of the object system was changing.

3.3.3 Object system characteristic

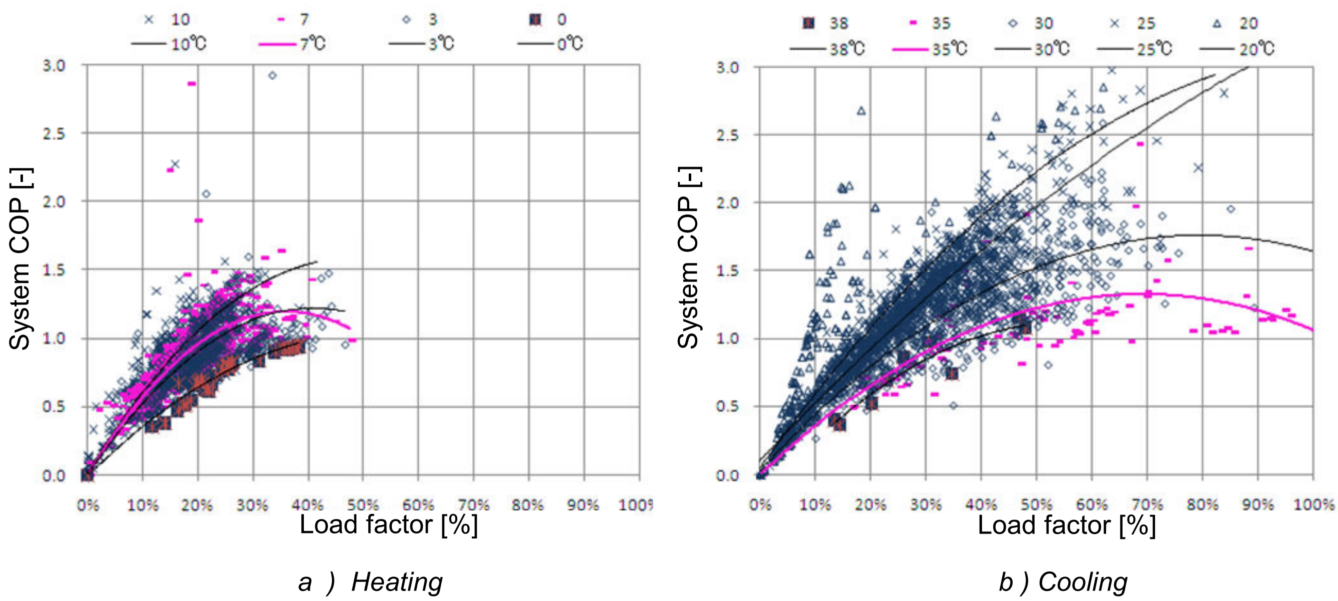

Figure 12. Object system characteristics during: a) Heating b) Cooling

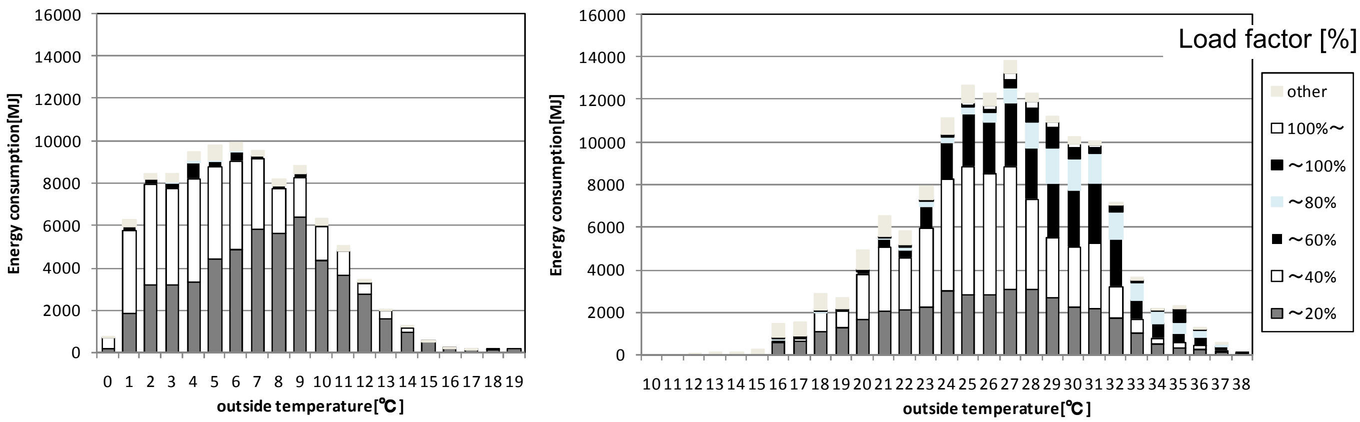
Figure 12 shows object system characteristics. System COP and load factor are plotted every ten minutes for each typical outside temperature. Load factor is a value for which calorie production is divided by specified ability. In Japan, specified ability in cooling is determined at an outdoor temperature of 35°C and indoor temperature of 27°C. And, specified ability in heating is determined at an outdoor temperature of 7°C and indoor temperature of 20°C. At the same load factor, system COP improves with a low outside temperature during a cooling period. Similarly, system COP improves with a high outside temperature during a heating period. Additionally, system COP is high too, when load factor is high at any outside temperature. However, during the cooling period, the load factor of 25% or less increased to 44%. And during the heating period, the load factor of 15% or less increased to 43%. At these low load factors, system COP also is low.

3.3.4 Energy consumption according to outside temperature



a) Heating *b) Cooling*

Figure 13. Energy consumption according to outside temperature a) Heating b) Cooling

Figure 13 shows the amount of multiple system energy consumption at each outside temperature. The bars are classified by load factor and were divided group into categories of 20%, 40%, 60%, 80%, and 100%. Ventilation mode of indoor unit and standby power are classified as "other." The energy consumed reached a maximum of 13850 MJ at an outside temperature of 27°C during cooling, and a maximum of 9946 MJ at an outside temperature of 6°C during heating. Additionally, during cooling, most of the system energy consumption was at a load factor of 40% or less. As mentioned earlier, during heating, indoor heat generation rate from any equipment may ease object system load. Generally, energy is used for driving that load factor and system efficiency is not high. Moreover, energy use at low load factor is not lost to outside temperature.

4. Conclusions

This study describes a probe insertion method for on-site evaluation of VRV systems and demonstrates the usefulness of actual measurement. The object VRV system operation does not interfere with the probe insertion method, which is highly advantageous. In addition, this method is easy to apply and perform.

The measurement example clarifies the actual operation of the VRV system. First, the evaluation period included 30 weeks covering both summer and winter, with system COP demonstrating actual performance. The performance was not maintained by a relative increase in low load factor. Second, the object system characteristics show the possibility of high-performance VRV system operation. However, most actual operation was at a low load factor and low system COP. Third, energy is used at a low load factor, and low load factor exits at each outside temperature. These data suggest a lack of stability in VRV system operation, possibly due to facility design and the demand of the indoor unit.

This study demonstrates that it is very difficult to achieve a high-performance VRV system (according to the catalog) over the long term.

Summary

This report describes a probe insertion method for on-site evaluation of variable refrigerant volume (VRV) systems and evaluation results for VRV systems using a gas heat pump (GHP). This method allows calculation of production calories for outdoor units based on the energy balance and measurement of exchange heat. The former is to determine input energy and output energy of the VRV system. The latter measures air temperature before and after the outdoor unit heat exchanger to determine the amount of heat exchange. A sheath-type thermocouple is inserted from the outside of the heat exchanger, and air temperature after heat exchange is measured. This method is able to evaluate four types of VRV system operations [cooling while using an electric heat pump (EHP), heating while using an EHP, cooling while using a GHP, and heating while using a GHP]. Result of an on-site evaluation for a VRV system using a GHP clarified characteristics of energy consumption. This evaluation was conducted from July 2007 to February 2008. The results showed that the VRV system was operating under an extremely low load.

1. Introduction

In Japan, the use of VRV systems in small and medium-sized office buildings is widespread. This situation also is becoming common worldwide. These VRV systems are considered to provide good performance. However, the characteristics that affect performance of the equipment during actual operation are not well understood, and how energy is used is uncertain. This is a disadvantage for facility designers and users. This report describes how energy is consumed by an actual system using a probe insertion method.

In addition, a simultaneous test using a method generally done in an examination room without disturbances exist was conducted to verify the accuracy of this method. This result showed that the system coefficient of performance (COP) error margin of this method was +19% in cooling with EHP use, and, +6% in cooling with GHP use.

Practical operation conditions of a VRV system installed in building K were investigated using the probe insertion method during a 30-week investigation period over summer and winter. A GHP outdoor unit with specifications of 30 HP was installed. This system managed temperature control for a 384 square meter office.

Results of on-site evaluation of a VRV system can help predict the success or failure of a facility design, and demand of the indoor unit.

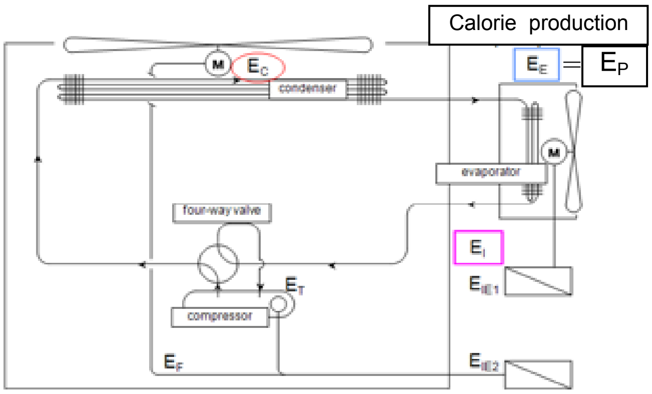
2. Probe insertion method

2.1 Calculation of calorie production on an outdoor unit

The energy balance in each system is shown in Figures 1-4. The outdoor unit was considered as heat source equipment for this research, with the evaluation based on calorie production of the outdoor unit. The following energy balance is assumed to have calorie production on the outdoor unit (E_P) correspond to calorie use of the indoor unit. This method disregards the influence of heat loss in the refrigerant pipes.

For EHP cooling and heating, calculation of calorie production can be done on the outdoor unit. Figure 1 (cooling) and Figure 2 (heating) show the energy balance. Energy to the compressor of total input energy on outdoor unit is shown by equation (1). Moreover, energy balance in the refrigeration cycle is shown by equation (2), and calorie production of the outdoor unit during cooling is described by equation (3), derived from equations (1) and (2). Calorie production of the outdoor unit during heating is described by equation (5). Therefore, COP of the whole system is described by equations (4) and (6).

Figure 3 (cooling) and Figure 4 (heating) show energy balance at cooling and heating with a GHP. Each energy balance during cooling operation is described by equations (7) and (8). Energy balance during heating operation is described by equations (11) and (12). Energy to the compressor and total input energy of the outdoor unit are described by equations (7) and (11). Moreover, energy balance during the refrigeration cycle is shown by equation (8), and heat production of the outdoor unit during cooling is described by equation (9), derived from equations (7) and (8). Heat production of the outdoor unit during heating and is described by equation (13), which is derived from equations (11) and (12). Therefore, system COP is shown by equations (10) and (14).



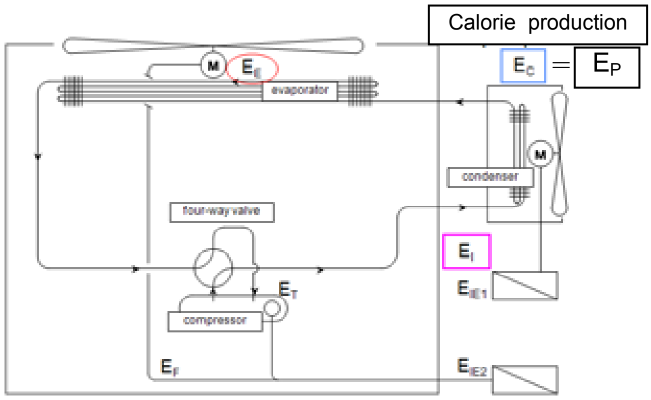
$$E_T = E_{IE2} - E_F \quad (1)$$

$$E_E = E_C - E_T \quad (2)$$

$$\therefore E_E = E_P = E_C - E_{IE2} + E_F \quad (3)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_C - E_{IE2} + E_F)}{(E_{IE1} + E_{IE2})} \quad (4)$$

Figure 1. Energy balance during cooling with EHP



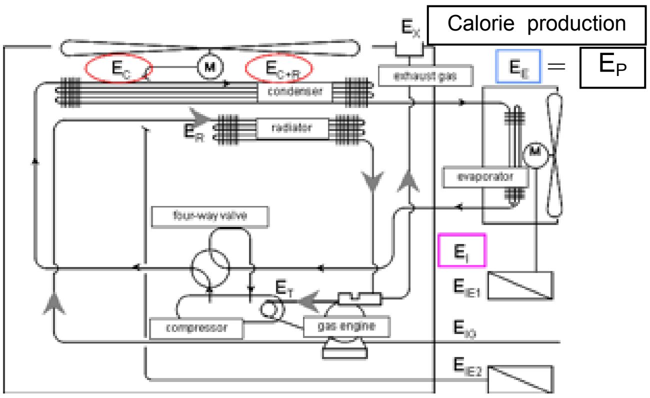
$$E_T = E_{IE2} - E_F$$

$$E_C = E_E + E_T$$

$$\therefore E_C = E_P = E_E + E_{IE2} - E_F \quad (5)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_E + E_{IE2} - E_F)}{(E_{IE1} + E_{IE2})} \quad (6)$$

Figure 2. Energy balance during heating with EHP



$$E_{IG} = E_T + E_X + E_R$$

$$\therefore E_T = E_{IG} - E_X - E_R \quad (7)$$

$$E_E = E_C - E_T$$

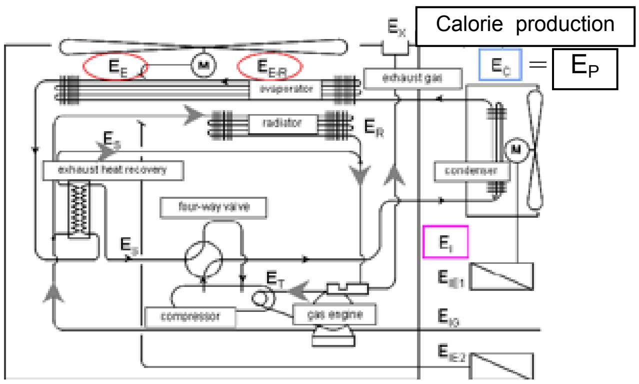
$$\therefore E_T = E_C - E_E \quad (8)$$

$$\therefore E_{IG} - E_X - E_R = E_C - E_E$$

$$E_E = E_P = E_C + E_R + E_X - E_{IG} \quad (9)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_C + E_R + E_X - E_{IG})}{(E_{IE1} + E_{IE2} + E_{IG})} \quad (10)$$

Figure 3. Energy balance during cooling with GHP



$$E_{IG} = E_T + E_X + E_R + E_S$$

$$\therefore E_T = E_{IG} - E_X - E_R - E_S \quad (11)$$

$$E_C = E_E + E_T + E_S$$

$$\therefore E_T = E_C - E_E - E_S \quad (12)$$

$$\therefore E_{IG} - E_X - E_R - E_S = E_C - E_E - E_S$$

$$E_C = E_P = E_E - E_R - E_X + E_{IG} \quad (13)$$

$$COP_S = \frac{E_P}{E_{IE}} = \frac{(E_E - E_R - E_X + E_{IG})}{(E_{IE1} + E_{IE2} + E_{IG})} \quad (14)$$

Figure 4. Energy balance during heating with GHP

E_T : compressor energy | E_I : total input energy | E_R : radiation calorie

2.2 Measurement of exchange heat on the outdoor unit

Figure 5 shows a schematic of the probe insertion method. To calculate calorie production of the outdoor unit based on equations (3), (5), (9), and (13), it is necessary to measure exchange heat of the outdoor unit. For example, in equation (3), the calories correspond to E_C. In addition, other items can be measured. For GHP [equations (9) and (13)], measurement of E_R is difficult. Generally, a radiator is set up in parallel with the heat exchanger. Therefore, the amount of heat exchange of the radiator and heat exchanger is added based on equations (9) and (13).

Air that flows into the heat exchanger passes through a fan for heat exchange promotion. Therefore, the amount of heat exchange of the outdoor unit is calculated by measuring the change in temperature of the air.

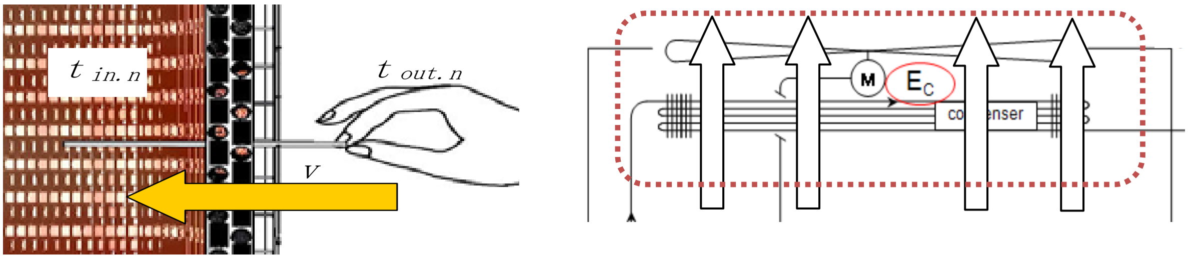

Figure 5. Probe insertion method idea

Equation (15) describes the basics of this system. It calculates the state of air under fixed pressure conditions. To calculate the amount of heat exchange, air temperature before and after the outdoor unit heat exchanger is measured. A sheath-type thermocouple is inserted from the outside of the heat exchanger, and air temperature after heat exchange is measured.

$$Q = v \times s \times \rho \times C_p \times (t_{before} - t_{after}) \qquad (15)$$

In addition, the amount of air that passed through the heat exchanger also is measured. Here, equation (16) excludes serious disturbance. Exhaust air speed from the fan (V_{FAN}) and air speed past the heat exchanger (v_n) are proportional. Then, v_n is a target variable, and V_{FAN} is assumed to be an explaining variable. Thus, α is derived from equation (17) and calculated from measurements.

$$\frac{v_{n.2}}{v_{n.1}} = \frac{V_{Fan.2}}{V_{Fan.1}} \qquad (16)$$

$$v_{n.2} = \alpha \times V_{Fan.2} \qquad \alpha = \frac{v_{n.1}}{V_{Fan.1}} \qquad (17)$$

Figure 6 shows the measurement points of the probe insertion method. Exchange heat is measured by all points simultaneously while considering distribution of air speed currents. More measurement points are preferable. Actually, the representative area is allocated and totaled, with the assumption of exchange heat on the outdoor unit [equation (18)].

outdoor unit heat exchange

$$q_{all} = \sum_{n=1}^{n} \alpha_n \times V_{FAN.t} \times s_n \times \rho \times C_p \times (t_{after.n} - t_{before.n}) \qquad (18)$$

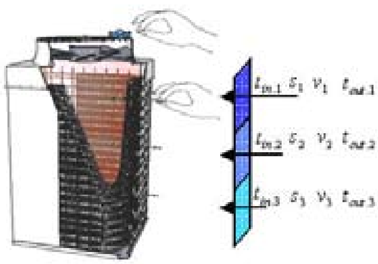

Figure 6. Measurement points of probe insertion method

$V_{FAN.t}$: Exhaust air speed $[m/s]$
s_n : Representative area n [m2]
ρ : Specific weight [kg/m3]
C_p : specific heat [kJ/kg K]
$t_{after.n}$: Air temperature after heat exchanger n [^{0}C]
$t_{before.n}$: Air temperature before heat exchanger n [^{0}C]

3. Measurement example in VRV system by probe insertion method

3.1 Outline of building K and object system

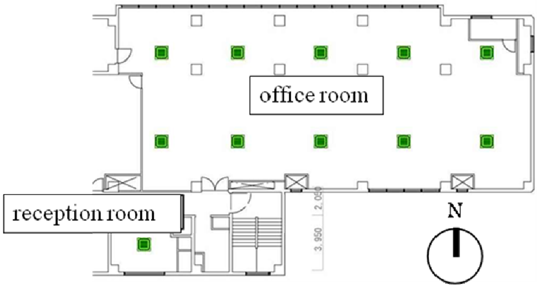

Figure 7. Building K 2F plan

Table 1. Outline of building K and object system

Position	Tokyo in Japan	
Object floor	second floor	
Use	office room	reception room
Space	360㎡	24㎡
Indoor unit	7.1[kW]/8.0[kW]×10	7.1[kW]/8.0[kW]×1
Outdoor unit	GHP	
Refrigerant	R410A	
Controller	indoor	
systemCOP	1.25/1.38	

※cooling/heating

Measurements were taken using the probe insertion method from July 13, 2007 to February 11, 2008.

Rooms include a reception area and office with a large north-facing window (Figure 7). Table 1 shows characteristics of the VRV system using a GHP. Specifications included 203 square meters [W/m^2] in cooling mode and 229 [W/m^2] in heating mode. In addition, room temperature could be set with an indoor controller. This is a generalized facility design common in Japan.

3.2 Measurement point

Figure 8. Appearances of object

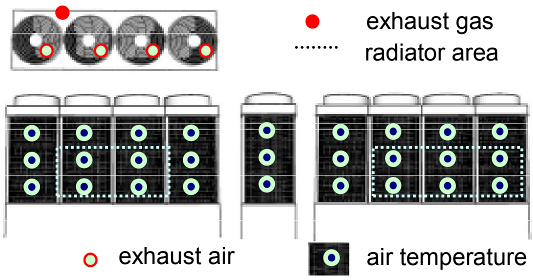

Figure 9. Measurement points

Air temperature before and after the heat exchanger was measured at 27 points, while exhaust air speed was measured at 4 points and the temperature of exhaust gas was measured at 1 point, as shown in Figure 9.

Object system energy consumption was measured. The power consumption and consumption of gas of the outdoor unit system were measured. Additionally, indoor unit power consumption was measured from the second floor distribution panel.

3.3. Results and discussion

3.3.1 Outside air temperature and humidity during the experimental period

Figure 10 shows daily average outside temperature and humidity. The maximum daily average temperature was 33.0°C, recorded on August 16, 2007; the minimum daily average temperature was 1.7°C, recorded on February 3, 2008.

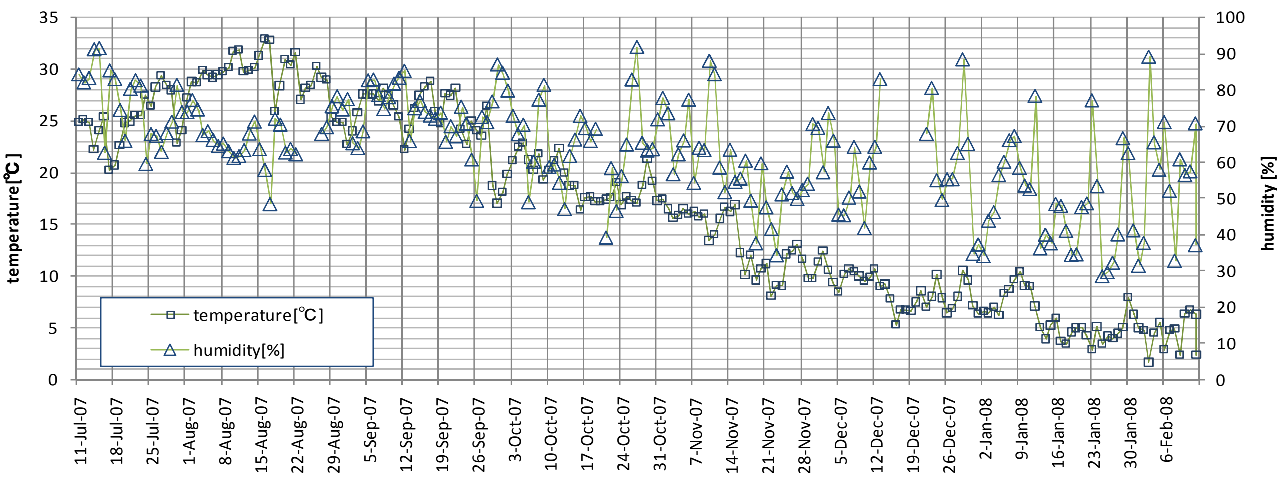

Figure 10. Daily average outside temperature and humidity

3.3.2 Multiple energy consumption by day, calorie production per day, and system COP per day

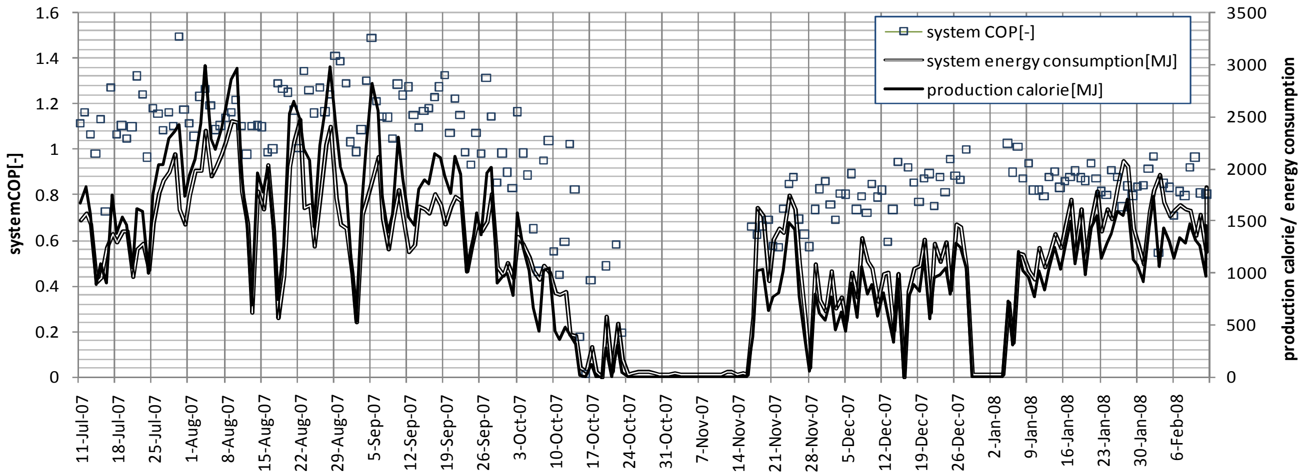

Figure 11. Multiple energy consumption per day and system COP per day

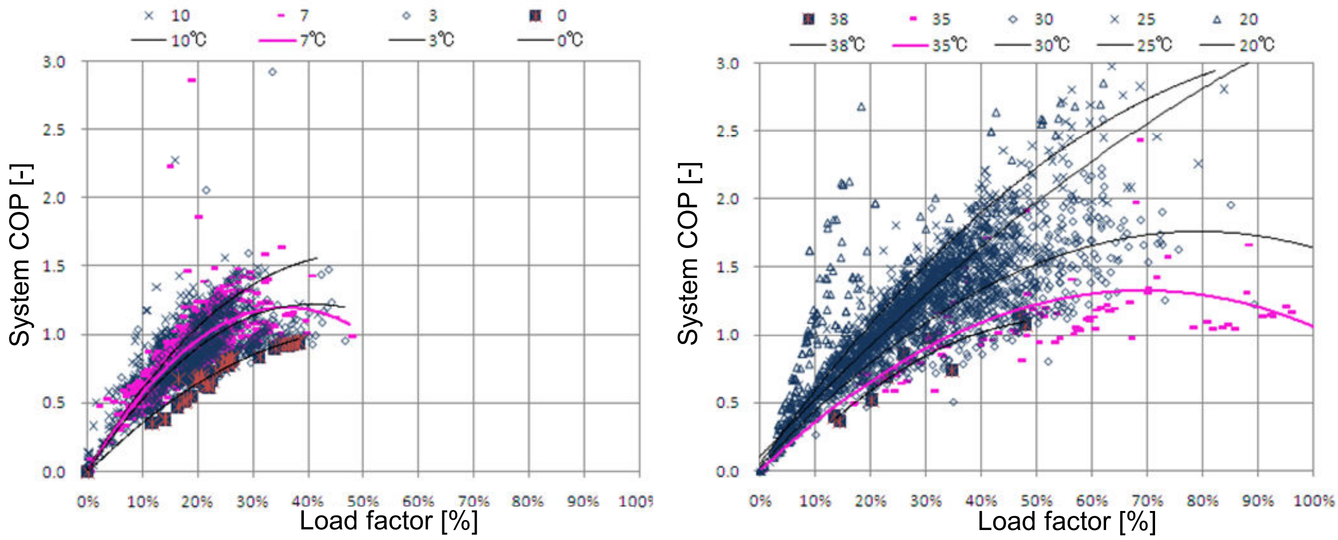
Figure 11 shows multiple energy consumption by day and system COP by day. The time from July 13, 2007 to October 24, 2007 was a cooling period, while the time from November 17, 2007 to February 11, 2008 was a heating period. The daily maximum energy consumption while cooling was 2851 [MJ/day] recorded on August 9, 2007; the maximum recorded during heating was 2066 [MJ/day] recorded on January 27, 2008. Average energy consumption while cooling was 1389 [MJ/day]; average while heating was 1223 [MJ/day]. Thus, more energy was used during the cooling period than during the heating period. Indoor heat generation rate from any equipment is assumed to be related. Average system COP during cooling was 1.05, while that during heating was 0.82. Generally, when the outside air temperature is low, system COP improves at the same load during a cooling period. However, Figure 11 does not show this trend, because the load of the object system was changing.

3.3.3 Object system characteristic

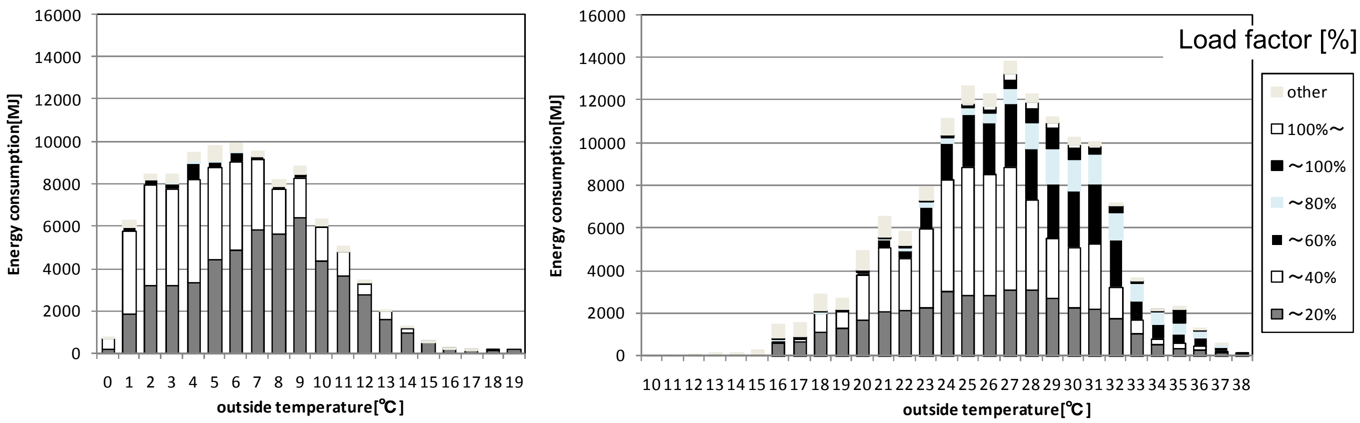


a) Heating *b) Cooling*

Figure 12. Object system characteristics during: a) Heating b) Cooling

Figure 12 shows object system characteristics. System COP and load factor are plotted every ten minutes for each typical outside temperature. Load factor is a value for which calorie production is divided by specified ability. In Japan, specified ability in cooling is determined at an outdoor temperature of 35°C and indoor temperature of 27°C. And, specified ability in heating is determined at an outdoor temperature of 7°C and indoor temperature of 20°C. At the same load factor, system COP improves with a low outside temperature during a cooling period. Similarly, system COP improves with a high outside temperature during a heating period. Additionally, system COP is high too, when load factor is high at any outside temperature. However, during the cooling period, the load factor of 25% or less increased to 44%. And during the heating period, the load factor of 15% or less increased to 43%. At these low load factors, system COP also is low.

3.3.4 Energy consumption according to outside temperature



a) Heating *b) Cooling*

Figure 13. Energy consumption according to outside temperature a) Heating b) Cooling

Figure 13 shows the amount of multiple system energy consumption at each outside temperature. The bars are classified by load factor and were divided group into categories of 20%, 40%, 60%, 80%, and 100%. Ventilation mode of indoor unit and standby power are classified as "other." The energy consumed reached a maximum of 13850 MJ at an outside temperature of 27°C during cooling, and a maximum of 9946 MJ at an outside temperature of 6°C during heating. Additionally, during cooling, most of the system energy consumption was at a load factor of 40% or less. As mentioned earlier, during heating, indoor heat generation rate from any equipment may ease object system load. Generally, energy is used for driving that load factor and system efficiency is not high. Moreover, energy use at low load factor is not lost to outside temperature.

4. Conclusions

This study describes a probe insertion method for on-site evaluation of VRV systems and demonstrates the usefulness of actual measurement. The object VRV system operation does not interfere with the probe insertion method, which is highly advantageous. In addition, this method is easy to apply and perform.

The measurement example clarifies the actual operation of the VRV system. First, the evaluation period included 30 weeks covering both summer and winter, with system COP demonstrating actual performance. The performance was not maintained by a relative increase in low load factor. Second, the object system characteristics show the possibility of high-performance VRV system operation. However, most actual operation was at a low load factor and low system COP. Third, energy is used at a low load factor, and low load factor exits at each outside temperature. These data suggest a lack of stability in VRV system operation, possibly due to facility design and the demand of the indoor unit.

This study demonstrates that it is very difficult to achieve a high-performance VRV system (according to the catalog) over the long term.

Keywords: Ryodoraku, physiological and psychological evaluation, sound environment

Summary

The reduction of energy consumption on air conditioning in sustainable buildings of subtropical areas is a critical issue. However, noises can be transmitted easily in semi-open living space due to the necessity to utilize natural ventilation in buildings. In order to avoid the noise and promote the privacy of Inhabitants in a semi-open living space, a specific type of Background Music(BGM)+Soundscape system was applied into this experimental sustainable building (Symbiosphere1Center). Furthermore, the physiological and psychological evaluation of Background Sound+Lighting(BGS+L) system for symbiotic living environment were carried out. The project was carried out by four participants who live in the urbanization area, but they were situated in Symbiosphere 1 Center for experiment. The evaluation of experiment was measured for 3 days after their arrival. In order to compare the difference, the other two long-term residents were as the contrast group. The evaluation of experiment was measured in the length of 60 min. per test at immobile time for 3 days. The psychological evaluations were obtained by the 6 semantics analyze that are included comfortable, relaxed, etc. Moreover, the physiological reaction is measured by using a Ryodoraku detector of Traditional Chinese Medicine. The results show a positive effect of psychological reactions in BGM environment. The participants' reactions become more comfortable, stable, relaxed, and joyful of the psychological assessment. However, the Ryodoraku reactions are affected after 30 min exposed but not in the long-term exposed. The evaluations of Ryodoraku values of four short-term exposed participants were obtained and exceeded the health range at the first day, but their Ryodoraku values of meridians were obviously improved and recuperated to the health status in Symbiosphere 1 Center at the second and third day. However, the Ryodoraku values of two long-term exposed participants whose Ryodoraku values of meridians are within the health range. The results show Symbiosphere 1 Center provides the possibility for living in health in comparison with the situation of living in the urbanization area.

1. Introduction

Taiwan is located in subtropical zone as sustainable building that the natural ventilation is typically designed for a semi-open living space(Chiang,2002). Under such condition, the sound is very freely to emit. Therefore, the conversation of residents will be the interference to each other in the living space. On the other hand, there is no privacy and perplexed for the sound disseminating(Lin,2005).

This research carries out the establishment and operation evaluation of Background sound (BGS) system (consist of Soundscape and BGM), and carry out an psychological evaluation to identify the usefulness of BGS system. Life and environment sound (Soundscape) system contains four sets of microphone in order to collect the sound sources from life and the environment in Symbiosphere 1 center. The sound sources were mixed adequately by microphone mixer and broadcast to the public area in order to receive the message from the life, environment and the weather immediately. BGM system broadcast Background Music (BGM) by central DVD player and speakers in individual rooms, residents can adjust volume or turn off the music in individual rooms. Effect of mixed-sound can increase the abundance of the life sound environment, mask the noise and promote the privacy of residents.

2. Evaluation of BGS System

After operation for two months, an psychological evaluation of BGS system was carried out. The evaluation scale was divided into 7 with a mean of 4. The analysis of the questionnaire for Soundscape system appears that it is satisfied highly with the users (the average evaluation is 5.6 points). The analysis of the questionnaire for BGM system appears that it is satisfied highly with the residents (the average evaluation is 5.8 points). The style of the broadcasted music of the BGM system was piano music. Most of the users were satisfied with this kind of BGM. The results of the questionnaire analysis for BGS system appears that The residents were satisfied with the BGS system (including the Soundscape and BGM) , the average point is

5.6. It appears that this system can be accepted by the residents (as shown in Table 1). Furthermore, the physiological and psychological influence evaluation of BGS+L system for symbiotic living environment were carried out.

Table 1 The integral satisfaction evaluation of BGS system

evaluation of system	average point of satisfaction
Soundscape system (life and environment sound)	5.6
BGM system (background music)	5.8
BGS system (consist of Soundscape and BGM)	5.6

3. Physiological and Psychological Evaluation of Sound and Lighting environment

3.1 Laboratory environment

The testing location is one of the living units in Symbiosphere 1 Center (*Figure 1*). During the testing, the indoor temperature 19• ; relative humidity 75%, the indoor table lamp and headlight were open at the average 408Lux. The indoor background noise was measured around 43 dB(A), and 56 dB(A) with BGM broadcast.

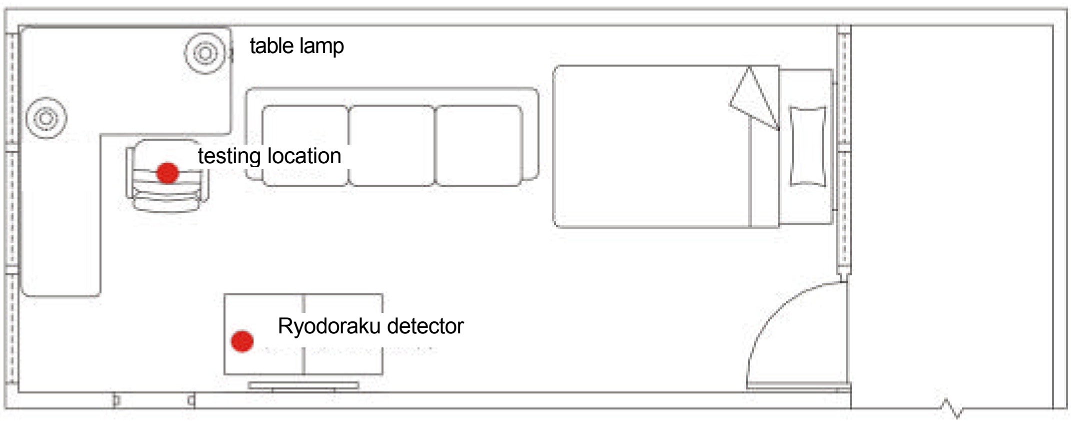

Figure 1 The plan of laboratory and test arrangement.

3.2 The Evaluation Methods

The psychological evaluations were obtained by the 6 semantics analyze that are included comfortable, relaxed, stable, awake, and weary of the psychology assessment criterion. Moreover, the physiological reaction is measured by using a Ryodoraku detector of Traditional Chinese Medicine. The value of Ryodoraku reaction is depended on the electric resistant of the object. The Ryodoraku is increased with the resistant decreasing.

The physiological reaction is measured by using a Ryodoraku detector of Traditional Chinese Medicine(Kobayashi,1986).The project was carried out by four participants who live in the urbanization area, but they were situated in Symbiosphere 1 Center for experiment. The evaluation of experiment was measured for 3 days after their arrival. In order to compare the difference, the other two long-term residents are as the contrast group. Piano music (56dB(A)) was used as BGM sound source. The evaluation of experiment was measured in the length of 60 min. per test at immobile time for 3 days.

4. Results and Discussions

4.1 The Influence of BGM on the psychology and physiology of human

4.1.1 Reaction of the percipience of human psychology

The influence of BGM broadcast (after playing, 15 min and 30min) was investigated (*Figure 2*). The results show a positive effect of psychology sensation. The tester's sensations become more comfortable, stable, relaxed, and joyful of the psychology assessment in BGM with a piano music.

4.1.2 The Ryodoraku reaction

The Ryodoraku is measured in the varieties BGM broadcast conditions results were shown in *Figure 3~4*. There are significant effects on the meridian and channel reaction (such as Pericardium Meridian, Heart Meridian, Sanjiao Meridian, Large Intestine Meridian, and Bladder Meridian) in the both 15 min. before and simultaneous BGM broadcast. However, the human body adapts the BGM condition and the Ryodoraku reaction recuperates to the original status after 30 min. BGM broadcast.

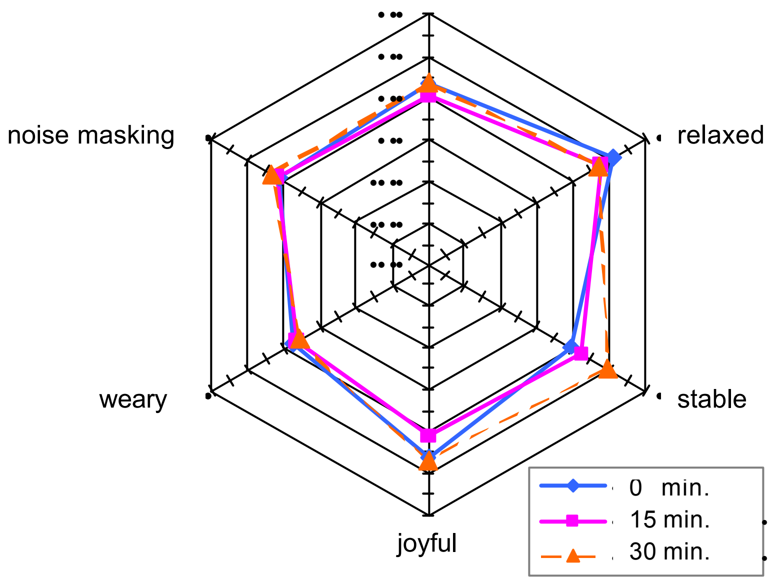

Figure 2 Overall evaluation of influence of BGM

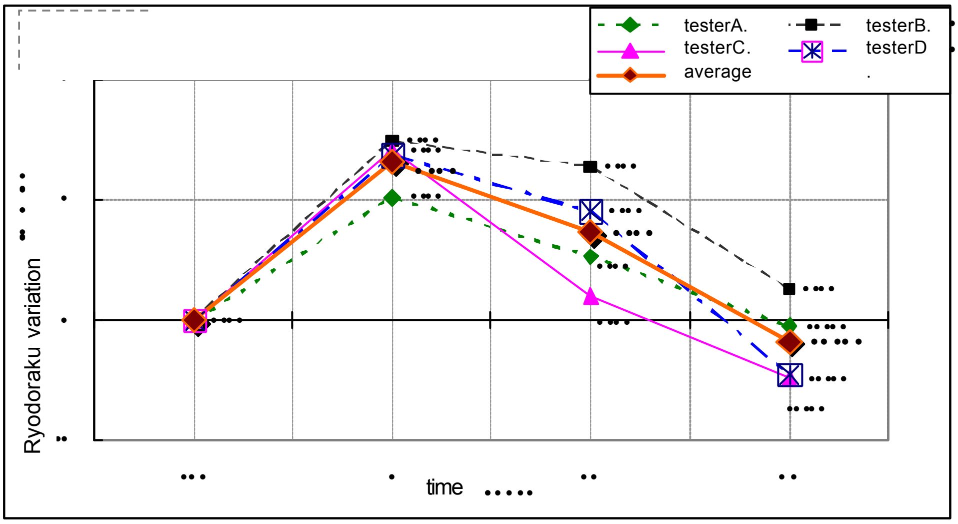

Figure 3 The time average of Ryodoraku reactions were measured at varieties BGM broadcast conditions

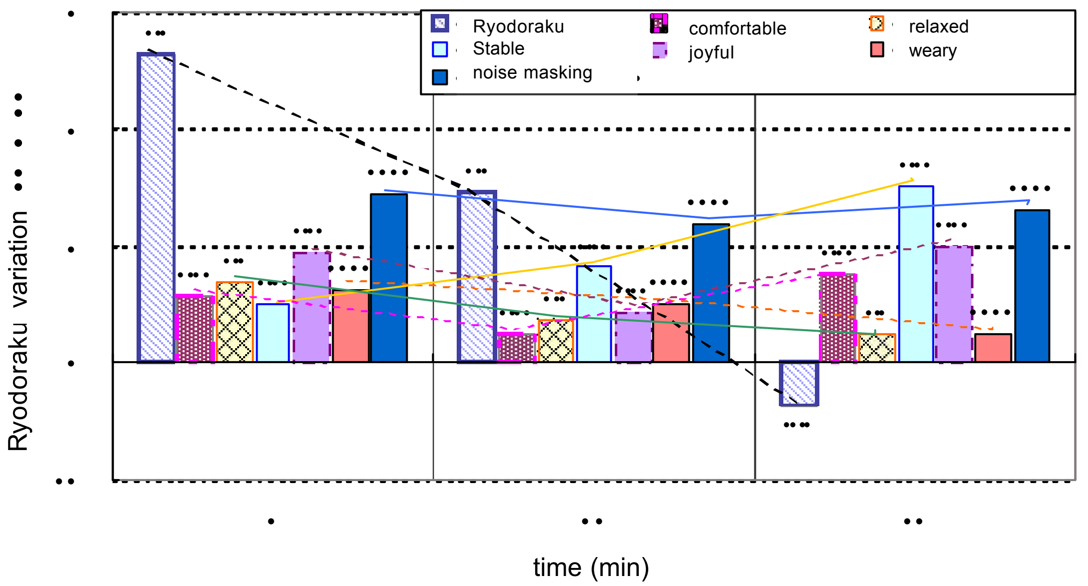

Figure 4 The time average of Ryodoraku reactions and the psychology were obtained at varieties BGM broadcast conditions

4.2 The trend of Ryodoraku of the short-term residence

The average Ryodoraku values for four testers in 3 days period of the measurements were shown in *Figure 5~8*. For Tester A ,the Ryodoraku values (Sanjiao Meridian, Left-side Liver Meridian, and Right-side Gallbladder Meridian) are exceeded the health range•• ••• • • in 1st day. Furthermore, all Ryodoraku values recuperate to the health status in 2nd and the third day.

For Tester B ,the Ryodoraku values (Sanjiao Meridian) are exceeded the health range in 1st day. However, the Ryodoraku values of Pericardium Meridian, Heart Meridian, Liver Meridian, Kidney Meridian and Bladder Meridian are at upper limitation. The Ryodoraku values of Pericardium, Heart, Liver, Kidney, and Bladder Meridian are recuperated to the original status in the third day. Furthermore, the Ryodoraku value (Sanjiao Meridian) is drew back to the health status.

For Tester C, the The Ryodoraku values (Sanjiao, Bladder, and Stomach Meridian) are significant exceeded the health range in 1st day. However, the Ryodoraku values of Pericardium Meridian, Heart Meridian, Liver Meridian, Kidney Meridian and Bladder Meridian are at upper limitation. The Ryodoraku values of Sanjiao, Large Intestine, and Stomach Meridian are significant improved and recuperated to the health status in the third day. Furthermore, others Meridian Ryodoraku values are drew back to the original status.

For Tester D, the The Ryodoraku values (Lung, Pericardium, Liver, and Stomach Meridian) are exceeded the health range in 1st day. However, The Ryodoraku values of Lung, Pericardium, and Liver Meridian are significant improved and recuperated to the health status in the third day.

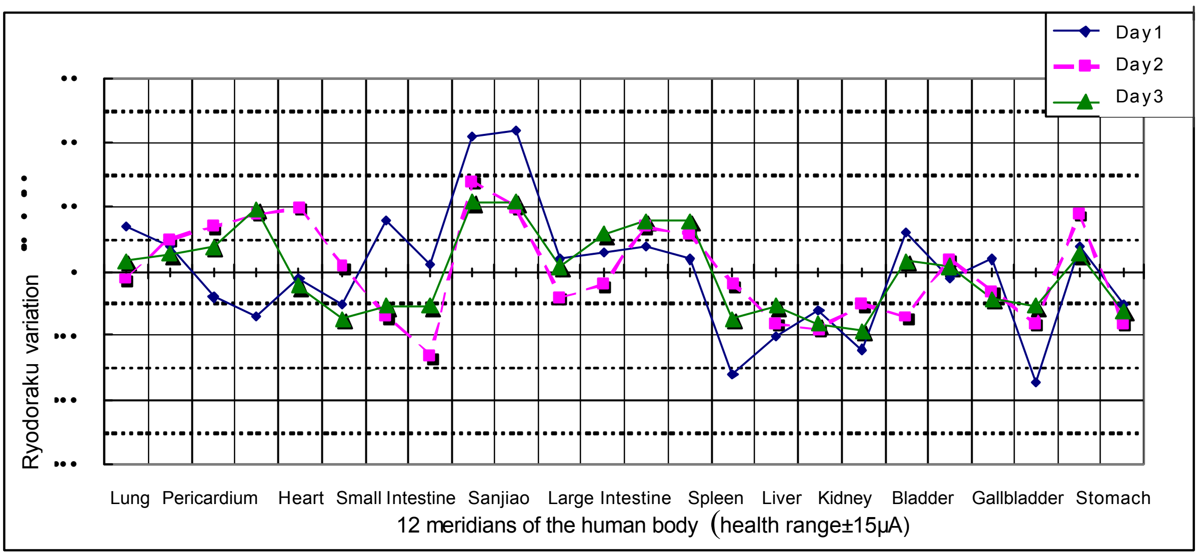

Figure 5 The Ryodoraku reactions of Tester A who lived in Symbiosphere 1 Center for 3 days

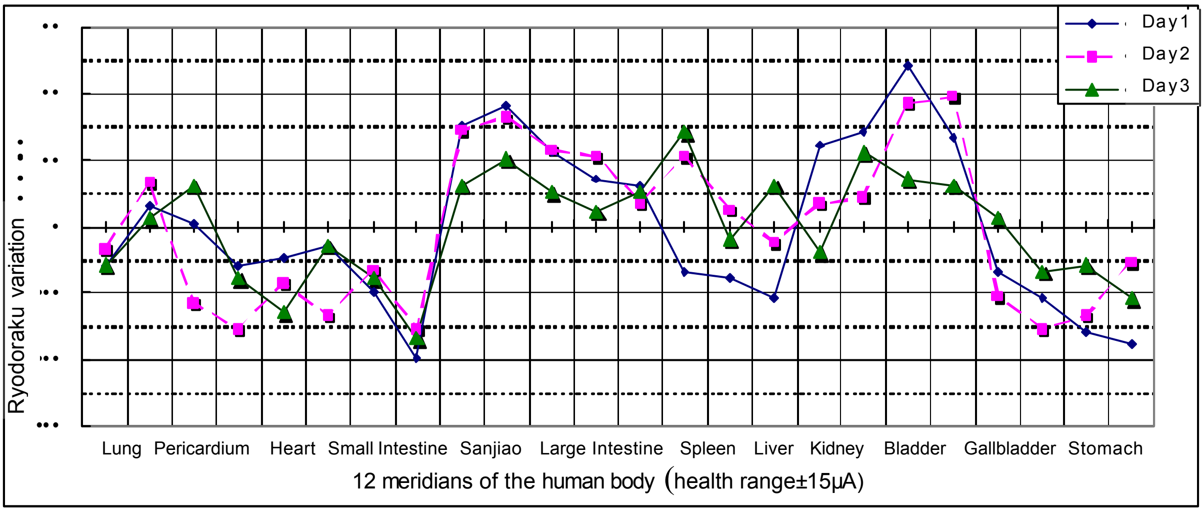

Figure 7 The Ryodoraku reactions of Tester C who lived in Symbiosphere1 Center for 3 days

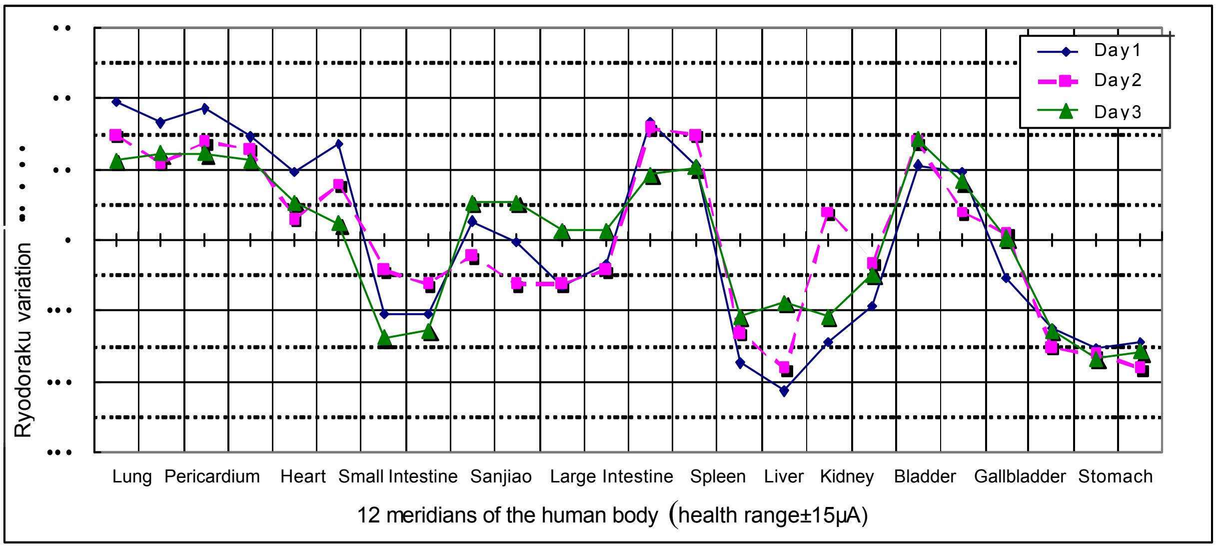

Figure 8 The Ryodoraku reactions of Tester D who lived in Symbiosphere1 Center for 3 days

4.3 The trend of Ryodoraku of the long-term residence

The average Ryodoraku values for two long-term living participants were shown in Figure 9. The Ryodoraku values of two long-term exposed participants whose meridians are under the health status. Symbiosphere 1 Center environment provides the better health in long-term living participants than comparison with the situation of short-time living participants.

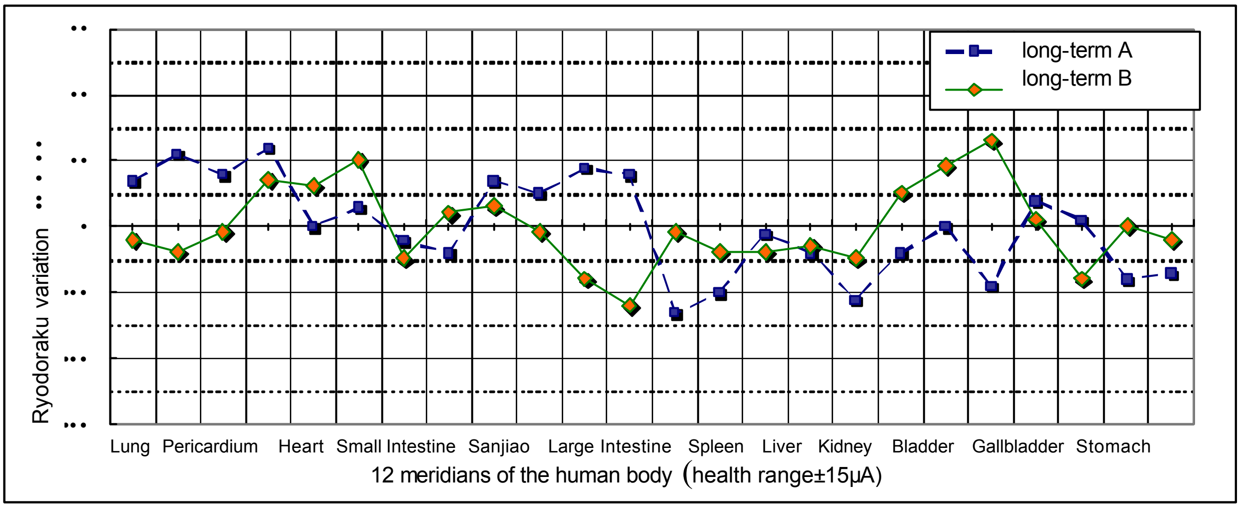

Figure 9 The Ryodoraku reactions of participants who lived in Symbiosphere 1 Center for long-term exposed

Conclusion

The results show a positive effect of psychological reactions in BGM environment. The participants' reactions become more comfortable, stable, relaxed, and joyful of the psychological assessment. However, the Ryodoraku reactions are affected after 30 min exposed but not in the long-term exposed. The evaluations of Ryodoraku values of four short-term exposed participants were obtained and exceeded the health range at the first day, but their Ryodoraku values of meridians were obviously improved and recuperated to the health status in Symbiosphere 1 Center at the second and third day. However, the Ryodoraku values of two long-term exposed participants whose Ryodoraku values of meridians are within the health range. The results show Symbiosphere 1 Center provides the possibility for living in health in comparison with the situation of living in the urbanization area.

MODULAR STRAW BALE BUILDINGS PREFABRICATED IN A "VIRTUAL FACTORY"

Robert Wimmer, Dr
Rudolf, Bintinger, Mag. (FH)[1]
Hannes, Hohensinner, DI[1]

[1] GrAT - Centre for Appropriate Technology, Vienna University of Technology, Vienna, Austria, rw@grat.at, rb@grat.at, hh@grat.at

Keywords: virtual factory, renewable resources, sustainable building, industrialized series production, mass customization

Summary

As a result of research and development in straw bale building technology, the need for a modular, prefabricated straw bale building system has been recognized.

The production itself is organized in a so called "Virtual Factory", which makes the best use of already existing small-scale local players like carpentries and farmers (for raw material), while marketing and logistics are organized centrally. The main benefit of this structure is its flexibility caused by the network of local actors. Furthermore the application of prefabricated systems produces higher profitability resulting from less construction failures. Design can be also customized. The system is anticipated to be competitive over big players based on the strength of professional central planning and logistics.

1. Background: Growth of Sustainable Building Solutions

In many countries, especially in Western Europe, sustainable building solutions have been widely introduced in the market (e.g. a thousand passive houses in Austria). Through research and development programmes supported by governmental institutions, a wide range of new construction materials and building components as well as efficient engineering methods have been developed especially in consideration of sustainability.

The "S-HOUSE (www.s-house.at)" is an extraordinary example of a passive house. Profound basic research on the materials and the reflective design and construction which consider economic and environmental consequences were done by the Centre for Appropriate Technology (GrAT). The whole project was funded by the government of Lower Austria, the Austrian Federal Ministry for Transport, Innovation and Technology (BMVIT) through the "Building for Tomorrow" programme and the EU-LIFE Environmental programme. The paramount achievement of the S-HOUSE is the integration of all relevant aspects of sustainable building methods, from selection of materials to disposal. As a result, the building is below the high standard of energy consumption for passive houses with approximately 6 kWh/m²year. Material and energy consumption were minimized during the construction of the S-HOUSE by a Factor of 10, compared to conventional constructions applying state-of-the-art technology (tested in cooperation with IBO, the Austrian Institute for Healthy and Ecological Building). The building demonstrates appropriate use of building materials derived from renewable raw materials. In addition, a large number of suitable solutions have been developed that enable problem-free reuse of all building materials after completion of their lifespan. During the entire development of the project, close cooperation between experts in different fields resulted in achieving innovative technical solutions, such as a particular screw for straw bale mounting and biomass stoves. Specific building engineering techniques led to significantly reduced energy consumption.

Other excellent practices supported by the "Building for Tomorrow" program demonstrate how resources can be saved, and how innovations can be realized. Renewable building materials like straw, reed and clay show reliable physical properties, highly effective heat insulating ability and safety levels (e.g. fire resistance). They ensure simple rebuilding and optimum reusability after application in constructions. Furthermore in terms of social benefit these materials can contribute to the enhancement of the regional economic growth.

Today, there is a wide range of high quality products made from renewable raw materials available. Growing numbers of clients are interested in sustainable and environmentally sound solutions. As an indicator, the number of energy efficient buildings in Austria rose from 154 in 2002 to 950 buildings in the year 2005. However, the limitation of these sustainable building solutions was recognised developing the S-HOUSE project. As mentioned earlier, this building is remarkable as it combines the whole spectrum of sustainable building solutions. Extensive studies were required to search for and figure out right materials among the great variety. Also, harmonious amalgamation of those alternatives was another important task of all partners involved. Therefore, as a follow-up scheme of the S-HOUSE project, the series production of those construction materials, engineering knowledge and dissemination strategies was suggested.

2. Limit of sustainable building solutions in the market

In spite of the increasing market awareness and acceptance of sustainable building alternatives, related players (i.e. architects, research centers, companies) still remain in the non-mainstream group. If one builds a house without making particular efforts, it will be provided by the majority of housing enterprises with materials and methods that do not sufficiently consider the economic and environmental performances. Why are the companies specialized in sustainable building solutions not competitive enough in the market? There are a number of obstacles to market expansion, and they are linked one way or another. The following points explain those factors:

- Cost

For many years there has been a continuous increase of building costs in the industrialized countries in Europe. Most of material products such as food, cars and many other artifacts are mass-processed or mass-produced. Through the economy of scale effect, these outputs can be sold at a lower price. However in Europe houses are rather individually designed and constructed. Therefore design and building costs are still at a high level. In these circumstances, a single house remains a prototype.

- Quality consistence

Currently, prefabricated systems are scarcely used. The main parts of the building are erected at site which results in time losses caused by a lot of manual work combined with unpredictable weather risks. When the shell is finished, wiring and plumbing risks to destroy the airtight construction. Production today is characterized through 'one by one' prototyping, spontaneous finishing on site, inconstant quality problems, and informal dissemination of construction techniques. Partly or completely prefabricated systems are more efficient as they are standardized and not manufactured at site. Also, the prefabrication level results in lower costs, lower weather risks and lower probability of critical failures.

- Limited research efforts

Building companies often lack research with which they can improve building and construction qualities, in terms of materials, energy efficiency, air tightness, heating systems and so forth. The disconnection between the upfront technologies and actual application delays progress of the industry. One of the major reasons is that training for workers is too expensive. On the other hand, the new skills of workers are generally not noticed, relevant information is handed down orally and only among workers. Systematic evaluation of the state-of-the-art in technological development and training of workers will accelerate business growth and improve quality.

- Lack of cooperation among stakeholders

Numerous companies are related to building and construction business. However, their cooperation is extremely limited. For example, producers of building parts can not control the application of the products. Workers on site do not pay enough attention to the product application in order to achieve optimal performance. This may lead to significant loss in utilization of specific product features. Being concerned with cost increase, builders often hesitate to involve new expertise. For best outcome, however, engagement of relevant stakeholders seems highly required. Customers/building users are important players. Their specific needs and wants need to be taken into account in planning, designing and constructing as much as possible. Lack of sufficient communication between actual users and builders may bring additional work as well as degradation of customer satisfaction.

- Absence of institutional framework

Environmentally friendly building materials are sometimes not certified, therefore not generally accepted in the marketplace. For example, straw bales are hardly obtainable as a building material despite their large amount available in the field as a by-product of cultivation. There is no official quality control standard of straw bales to be used in buildings and there are few reliable suppliers. This is a burden for the customer who wants to build a straw bale house, especially if he also has to convince skeptical building companies, who have no experiences in building with straw. The material is 'new', not standardised, and varies in its dimensions.

To summarise, an industrial evolution is urgently needed in the sustainable building area. Currently, many of ecological building materials and techniques are far from series production and standardization, in spite of their excellent ecological performance (Wimmer et al. 2001). The proliferation is strongly dependent on motivated and idealistic owners and architects. As mentioned earlier, the hindering factors above are fairly related to each other. With a small number of solutions most of the problems can be solved.

3. Market analysis: prefabricated production and construction

In the building sector in general the following three production methods are commonly used:

1) Fully industrialized mass manufacturing. Buildings are prefabricated in factories in large quantities. High quality is guaranteed by standardization and prefabrication of the construction elements. Professional marketing, extensive official achievements or additional equipment distinguish the suppliers.
2) Highly individualized manufacturing. Small companies, for example carpentries or master builders, carry out the whole planning and production processes. The building is mainly constructed on the building site.
3) The partial prefabrication of components, like a wall segment. These standard components are mounted at the building site.

It is clear that prefabricated construction can reduce building costs, as companies can manufacture at a cost-effective volume of production and increase the quality level.

There is an emerging trend of prefabrication for building materials and parts in the global scale. In terms of the total number of prefabricated buildings, Japan is the leading country in the world. Considering their strong prefabrication technologies in the car industry it is not surprising that they expanded the application of prefabrication into housing. The number of prefabricated houses in Japan in 2005 was 156.254, and the market share (rate of occupying in all residences) is 12.6% (Prefab Club 2005). Among the 1.230.000 residential houses newly built, about 1 in 8 houses is a prefabricated house. One of the market leaders in Japan, the company Sekisui Chemical Co. Ltd. started its unit-housing business in 1970 with more than 80% of its houses being manufactured under quality control on assembly lines in the plants. The total number of Sekisui unit houses in Japan today is more than 400,000 and on average each house comprises 15 units, so there are about 6,000,000 structural units (Iwahara, Suzuki 2005).

The growing ratio of prefabricated houses is seen in European countries as well. For example in Austria, the market demand for pre-manufactured houses has constantly increased for many years (Kreutzer, Fischer & Partner 2007). An international comparison shows that the highest share of prefabricated (single family and semidetached houses) houses can be found in Sweden followed by Austria with 33 %, Great Britain with 15%, Switzerland with 12% and Hungary with 3.9 %. In Austria, the number of prefabricated houses has increased from 400 in 1970 to 5,350 in 1998. Approximately 31% were sold in Lower Austria. Prefabrication for parts has been growing but is mainly used for office buildings or hotels.

Nonetheless, there is a clear difference between prefabricated housing companies in Japan and Europe. Japanese housing companies are mostly large enough to produce the whole prefabricated houses including the interior decoration at the factory. They can standardize dimensions of parts, and therefore, relatively easily integrate them under one roof system. A remarkable point is that some of them (e.g. Sekisui Chemical) are highly devoted to environmental performances of their business and they try to provide such products and services.

In contrast to this, housing companies in Europe are dominated by small- and medium- sized enterprises (SME). Especially, those who are environmentally conscious are often very small. Contrastingly, large housing entities do not pay enough attention to sustainable issues. When considering this specific situation in Europe, a different approach is required to make prefabricated sustainable housing system possible.

4. Industrialised Serial Production

Industrialized serial production using the "Virtual Factory" is the solution GrAT suggests. This new concept for production and logistics for sustainable building components and technologies can make the sector more competitive in the market. The key strategies are as follows.

4.1. Virtual Factory: Centralized Planning and Localized Production

The title "Virtual Factory" describes the characteristics of the partnership. SME in a certain regional boundary form a membership-based association to provide customers with a range of sustainable building solutions. The Virtual Factory consists of two parts by large. At the centre is a group of organisations in charge of strategic planning, basic element design (e.g. modularization), quality control, logistics, R&D, and marketing. Production, delivery, and construction of components itself is processed by registered members individually or collectively. The members are mostly already existing small-scale players like carpentries and farmers (for raw materials supply). They are linked via the virtual network and share the strategic functions from the umbrella organization. Similar business models have been already successfully implemented in other branches such as furniture, fashion and other design related industries. Within building industries, however, the system will lead to a shift of paradigms. The following picture illustrates the envisaged transition processes in the Virtual Factory.

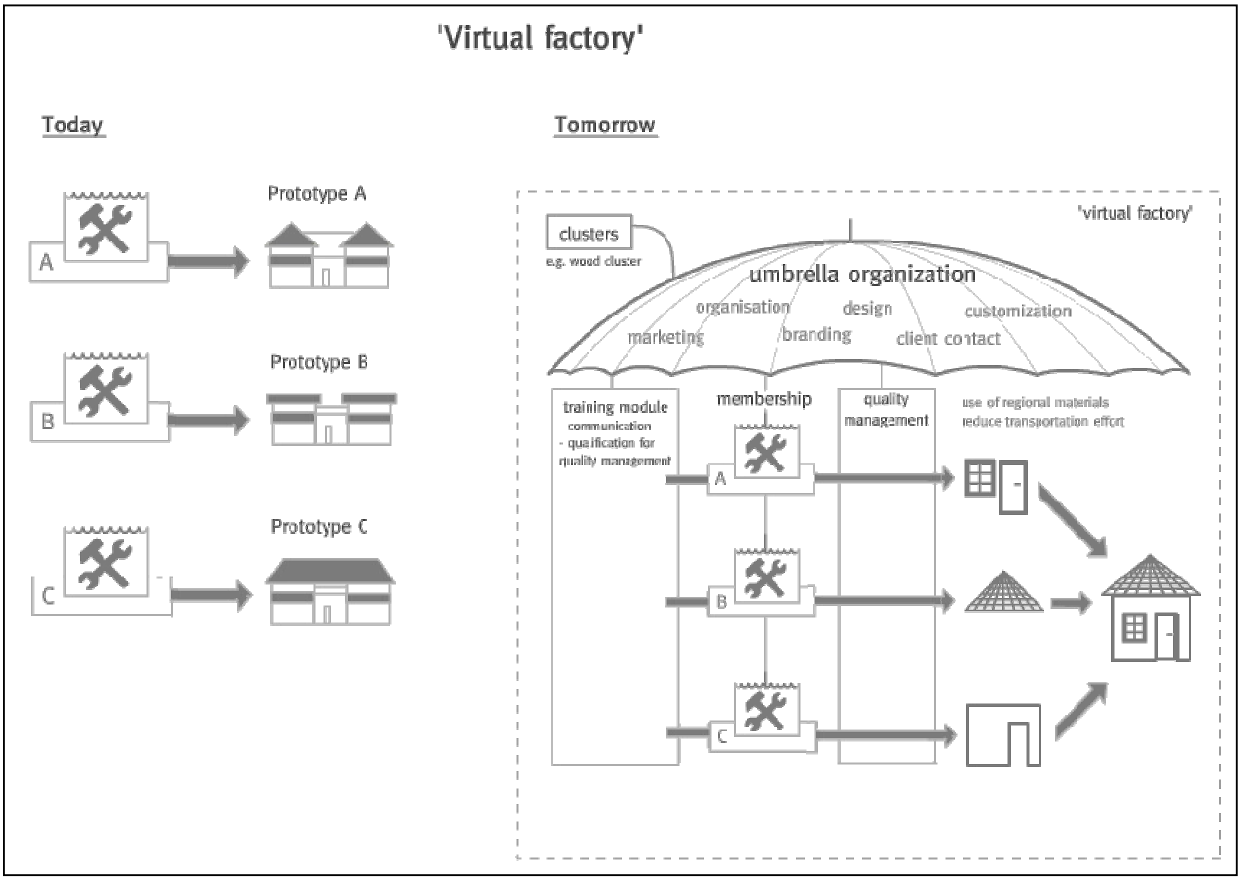

Figure 1 Industrialized production and construction through "Virtual Factory"

Today, if customers want to build sustainable houses, they need to organize each building element from different producers and combine them into one house by workers who are not specialized in sustainable building techniques. This approach demands a lot of time, energy, and money. Moreover, the result could be unsatisfying due to incompatibility of components and poor quality control. In the Virtual Factory system, they can order high quality houses with lower costs and within a short time.

4.2. Units and functions

The system of the Virtual Factory is characterized by the intensive segmentation of business functions and the strong quality control.

- Umbrella organization

The umbrella organization includes all the companies which participate in the planning, designing, construction, and marketing processes. As local companies produce and assemble prefabricated systems according to the order from this organisation, their role in the virtual network is highly important. They need to establish an intelligent modular system which allows flexible assembly of various components produced by different producers. The communication between the umbrella organization and the producers should be systematized precisely and efficiently. In a sense, this umbrella organization can be understood as an enhanced unit of coordination, marketing and Single Point of Contact for the customer.

- Quality management and training

Quality control and training modules are vital as many of small building companies are yet lacking awareness and knowledge of renewable building materials. Sometimes these materials (e.g. straw bales) require specific treatment and sophisticated application. The quality of the building has to be strictly examined (e.g. thermo-graphical analysis, blower door tests, etc.) to guarantee the energy efficient performance, not only during the production processes but also during construction. Advanced training on the basis on the state-of-the-art technologies and skills will improve the overall quality level of the outcomes.

- Logistics

The key to the success of the system lies above all in a centrally steered efficient logistics. Managing logistics is necessary to enable companies to work together and to avoid long transport distances. The chance arises to minimize the distance of transport as a result of the dispersion of the production plants. This is especially relevant in terms of the large quantity and rising transportation at the building industry.

- Purchasing association

To raise the market share a competitive price and customer acceptance is important. Therefore the umbrella organization functions as a buying syndicate to achieve lower prices for passive housing components. Buying syndicates are common in the sports or electrical goods branch. Such an association enables lower wholesale prices by means of its higher purchase power. Thus small shops, especially those in rural areas, can compete with large franchise shops. It seems that this kind of syndicate could be a feasible way for them to achieve higher profitability whilst sustaining their original scale.

4.3. Benefits

The benefits of this structure are manifold:

- Low capital investment for establishment

Creating a virtual network among existing units costs far less than establishing a large firm. With relatively small amount of initial capital, internal infrastructure (e.g. communication media, shareware, etc.) can be set up. On the other hand, individual companies also have benefit in terms of initial investment. They do not need abundant expense for planning, customer contact, and marketing for new businesses. For example, a farmer can become a member of the Virtual Factory, and provide other straw bale producers with straw. From his point of view, straw is a by-product from his major business, i.e. farming, yet he can contribute to the sustainable building industry with some profit.

- Increased market competitiveness

Finally, such small players are able to compete with large companies with the strength of central planning, quality control, and viable costs. It is considerable that the local small enterprises will keep their traditional forms, yet evolve towards industrialised processes through the virtual partnership. Such cooperation will guarantee higher profitability and a higher market share of sustainable building solutions. Also, this concept is economically beneficial as a certain level of a feasible scale (i.e. number of production unit) can be achieved. Available production capacities can be used more efficiently. In terms of public advertisement, a common brand representing the partnership can be known in a far easier way. The great number of members can be already such a powerful marketing instrument.

- Independence of local members

The small companies who are members of the Virtual Factory can continue their current local business. They can get involved in the network, in order to provide their special knowledge and skills. In return, they gain not only financial payment, but also competitiveness by getting to know the latest research and technology information.

4.4. Design

The design of the construction plays a vital role regarding environmental and economic performances. The following principles need to be taken into account.

- Avoidance of mixture of building elements concerning durability and material composition

Currently, most of building materials are extensively mixed with renewable resources (e.g. wood, straw), mineral building products (e.g. clay, stone, glass), and synthetics (e.g. plastic, chemical substances). In sustainable building, it is important to separate these materials as far as possible to optimise reuse and recycling after the lifespan of the building.

- Customized design

Mass customization[1], the business model well-established in the car production, is one of the principles the Virtual Factory is based on. It enables the companies to sell customized products and at the same time using efficient production methods. Customers can choose their preferred options within a given range.

The customization centre discusses the type of construction as well as the price, planning and design with clients. There are several construction types and materials available. The selection is up to the customer and s/he can also to some degree modify structures. This individually customized planning is based on prefabricated components. By using computer applications, customers can already design their own buildings. They can choose desired size, exterior and interior design, and the location of doors and windows. During this process, prices for each application are already shown. Moreover, within the given structure and materials, the amount of energy and resource savings can be calculated.

Local prefabrication systems, for example, can produce kitchen units, staircases, heating facilities, electricity, ventilation, and plumping systems which satisfy the customers' preference. As far as they follow specific dimensions for modular assembly, they can provide diverse alternatives. A modular design enables high flexibility in architectural design.

- Modularised and standardized components

To make the sequential production and assembly feasible, the building components need to be modularised and standardised. Establishing module standards deserves a long-term investigation, development, monitoring and improvement.

- Detachable joining techniques

Detachable connections, especially of resource intensive building parts (e.g. concrete cellar) can dramatically reduce waste generation as well as construction time on the building site. Furthermore they can be refurbished and used for new buildings after its life time. The expansion and downsizing of buildings to address the changing customer needs (e.g. number of family members, various ambient) should also be taken into account.

- Accessibility of the installed equipment

Appropriate and timely maintenance and modernisation of parts can considerably expand the useful life time of buildings. For example, some facilities like heating, ventilation, and lighting can be upgraded. Therefore easy access to such units is desired.

The following table shows many advantages arise through the design principles along the life cycle of a building respectively.

Table 1 Advantages of modular, detachable constructions

Stage	**Advantages**
Planning	Clients can design various parameters within limited options according to their prioritised preferences and given budget. The basic construction stays the same.
Prefabrication	Standardized building components allow quick and seamless assembly on the spot, though multiple companies were involved in the production of different components.
Construction	Detachable joints allow short construction of the building shell and wiring.
Use of the building	The building can be easily expanded or downsized according to the needs of the owners.
Deconstruction and disposal	The detachable joints allow a non-destructive disassembly, and therefore facilitate further reuse of whole or partial components. Parts which are of no use can be sold, or environmentally disposed, owing to the clear separation of material types to be controlled in the early phase of fabrication.

[1] Mass customization refers to a customer co-design process of products and services which meet the needs of each individual customer with regard to certain product features. All operations are performed within a fixed solution space, characterized by stable but still flexible and responsive processes. As a result, the costs associated with customization allow for a price level that does not imply a switch in an upper market segment. (Piller 1998)

5. Discussion

The initiative of the Austrian Federal Ministry for Transport, Innovation and Technology (BMVIT) and rising prices for fuel boosted the development of energy efficient buildings in Austria. To reach low level of energy consumption a combination of air tightness, insulation, orientation of the building and ventilation technology is needed. The most material intensive part is the higher level of insulation to reduce heat loss. When designing sustainable building solutions, the materials used should be considered to minimize the amount of carbon dioxide emitted and the waste after the life span of the construction. In this context straw bales seem to be an ideal product because of their low thermal conductivity and their low impact on the environment.

In spite of the increasing awareness and acceptance, the main hindering factors to use straw bales are low availability, irregular dimensions and no professional marketing strategies to advertise the advantages of straw bales as building material. These problems are topics of other research projects addressed by GrAT.

Another hindering factor is the low prefabrication and standardization rate of sustainable buildings. They are mainly prototypes and therefore cannot compete with prefabricated houses.

In this context the Virtual Factory seems to be the most promising solution for the Austrian situation above all because it enables small companies to act as one network, share resources and gain more market power.

Geissler and co-authors (2005) highlighted the importance of large scale post-industrial production and trans-national marketing for the residential construction in the future. However, in the Austrian building industry which is characterised with small companies, it is not simply feasible. In this dilemma the Virtual Factory can be an intelligent compromise.

This concept addresses the business profile of building industry in Austria and many European countries: Instead of setting up a new large company, creating a virtual production sequence over a number of small companies can be a clever strategy in such SME dominant areas.

As a follow-up task of the successful demonstration of the S-HOUSE, an industrial series production concept has been elaborated. Materials and technologies taken in passive housing, including straw bales, will be further standardized and marketed by the Virtual Factory system. Because of the larger scale of production and centralized management power, higher economic and environmental efficiency will be achieved. Customization can be achieved within a number of options based on a modular configuration.

To prove and improve the concept of the Virtual Factory the first step will be to enhance the system of the Virtual factory whilst building a Zero Carbon Village (ZCV) with 30 to 40 units in Austria. The Virtual Factory will be put into practice, using mainly locally available resources derived from renewable resources, regarding logistics (reduction of transport), quality control, reducing transport, and achieving a high level of living quality. Additionally the ZCV will be energy autonomous due to reducing drastically the amount of especially electric and thermal energy through innovative ways of energy supply by renewable resources.

Keywords: facade design, double skin, natural energy, thermal performance, cost performance

Summary

A multifunctional double skin system called NEXAT has been developed to minimize the thermal skin load of buildings while maintaining the perimeter area as comfortable as possible. NEXAT consists of a double glazing window unit equipped with Venetian blinds and an air flow control system comprising ducts, dumpers and fans. It can be installed in all building floors. It has five mode patterns depending on flow channel change and its relationship to the air-conditioning system. It improves energy saving because it has functions in addition to those of the conventional Japanese double skin system. Constant thermal performance was achieved for every mode in laboratory model tests, and confirmed by full size field tests from annual measured data. NEXAT was applied on a large scale on the west side facade (about 1,500 m^2) of an office building completed on January 31st, 2007. This paper describes the thermal characteristics of NEXAT and its effect on energy conservation in buildings.

1. System figure and feature

1.1 Schematic diagram

Figure 1 shows an example of an air-conditioning system incorporating NEXAT.

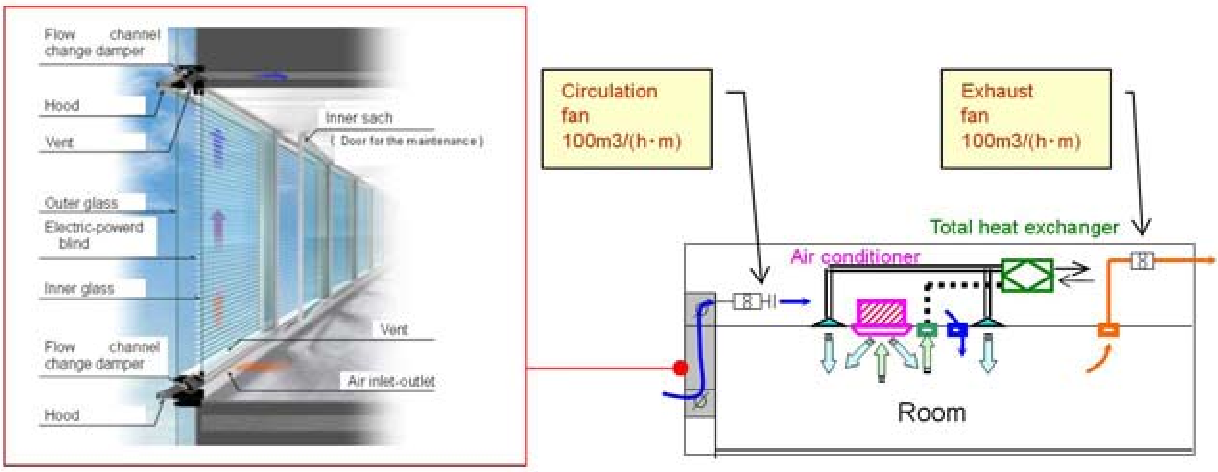

Figure 1 Schematic diagram of NEXAT

1.2 System feature

NEXAT provides an opening in the top and bottom of a double skin sash separated at each floor and has the mechanism of opening and shutting using a flow channel change damper. It adjusts the slat angle of the electric blind installed in the double glazed window so that it can introduce as much indirect natural light as possible while interrupting a direct solar radiation. It thus achieves air-conditioner energy saving while maintaining a comfortable thermal environment in the perimeter area throughout the year by self-adjusting the air flow according to the outdoor climate and the indoor thermal environment. It thus improves cost performance by reducing running costs (annual air-conditioner energy consumption) compared with that of the conventional double skin system. It reduces annual air-conditioner energy consumption by about 14%, and the initial cost by about 2.5%. As a result, NEXAT achieves a simple payback period of about 9 years. In addition, it is compact (20 cm deep) and can be used to retrofit existing buildings.

Figure 2 shows a mode pattern by flow channel change. In summer, the space within the double-glazed window is ventilated by letting outside air enter from the bottom and exit from the top by natural ventilation, which reduces the effect of solar radiation. In winter, the space is completely closed or ventilated by room air to reduce the window's thermal transmittance. When the solar radiation intensity is strong, this system can recover solar energy. In spring and autumn, outside air can be taken from the openings at the top or bottom of the window system, which results in ventilation cooling or night purging. This system provides three additional modes other than the summer sun shading mode and the winter insulation mode not provided by the conventional double skin system. These have the advantage of energy saving. Figure 2 also shows the restraint value of the energy saving effect. The annual energy reduction percentage becomes 34% that of the single skin sash system that uses a float glass due to the model building restraint.

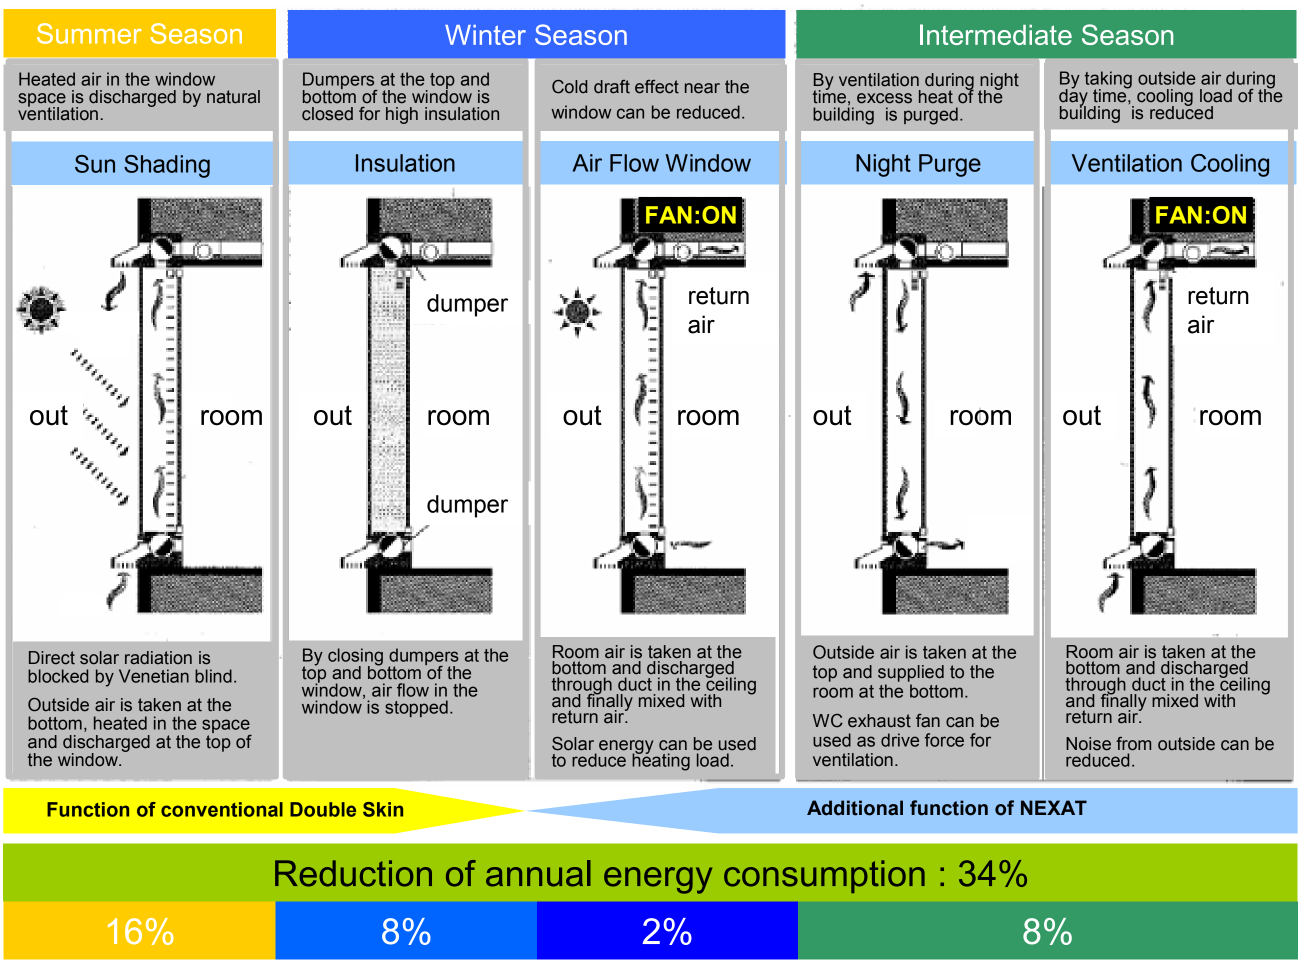

Figure 2 Example of effect of NEXAT on reduction of annual energy consumption of a building in Japan

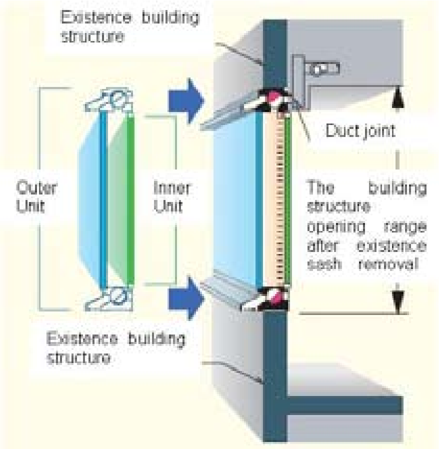
Figure 3 shows two retrofitting methods for existing buildings. The field test discussed later is based on case 1.

Case 1



↑ (Case 1)

Remove existing sash and attach new inner and outer units.

Apply when there is no distance between the building's outer wall and the site boundary.

→ (Case 2)

Leave existing sash and attach only outside unit.

Case 2

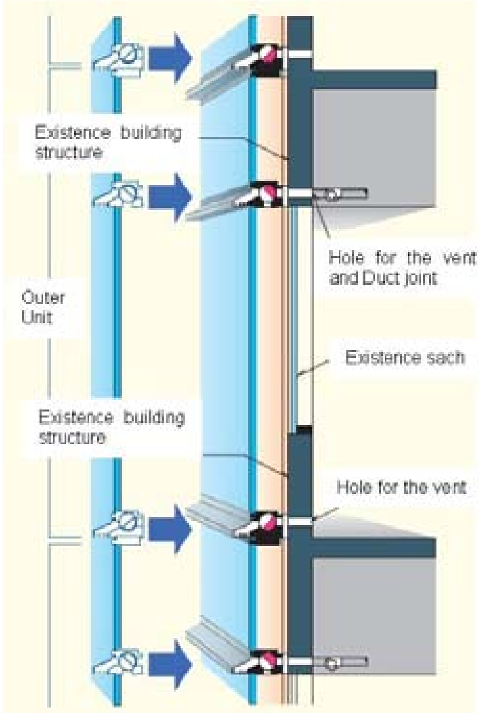


Figure 3 Concept of application to retrofitting of existing buildings

1.2.1 Thermal characteristics

Laboratory testing of thermal performance (Figure 4) confirmed that the sampler achieved the performance goal (solar shade factor 0.2) as shown in Table 1.

[Test apparatus]

Across the middle division wall installed in the sampler, the outdoor side comprises a low-temperature room and the indoor side comprises a constant-temperature constant-humidity room.

Sunlight is irradiated by the sunlight equipment from outside the room. (The irradiation is adjusted by changing the distance between the sunlight equipment and the irradiation surface.)

Temperature and wind speed are measured by a thermocouple and an anemometer installed in the sampler.

The sunlight equipment uses sunlight lamps (metal-halide lamp 150W×48) near the relative spectral energy distribution of the sunlight. The maximum irradiation becomes 600W/m^2 at 360 mm.

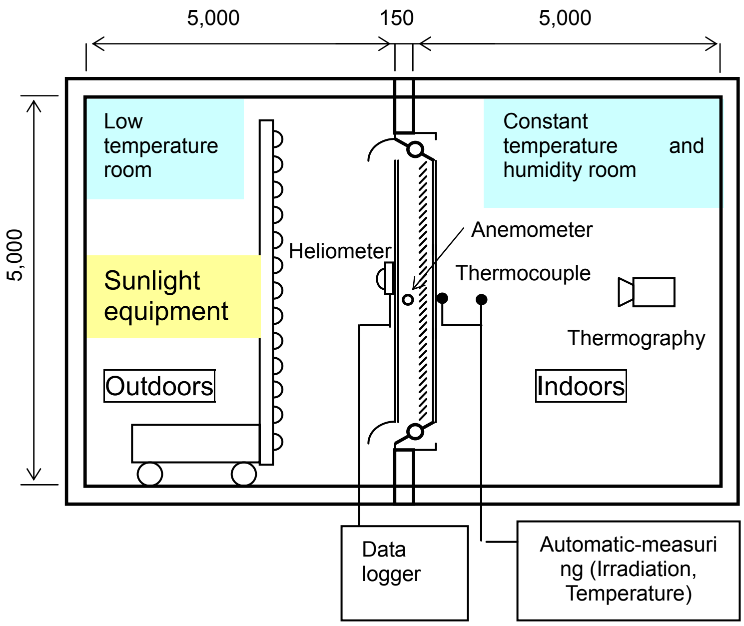

Figure 4 Thermal facility to performance test

Table 1 Thermal characteristics

Test item	Testing condition	Test outcome
Coefficient of heat removal	Mode：Sun Shading Outside air temperature：35℃ Room temperature：26℃ Irradiation：600w/m^2 （Equivalent to afternoon sun in summer）	Air flow rate(natural ventilation)：111m3 / (h/m) Heat extraction：704.0W Coefficient of heat removal：26.4%
Overall coefficient of heat transfer	Mode： Ventilation Cooling Outside air temperature： 35℃ Room temperature： 26℃ Air flow rate： 105.0m^3/(h･m)	Heat flow rate： 18.78W/m^2 Overall coefficient of heat transfer： 2.15 W/（m^2･k）
	Mode： Air Flow Window Outside temperature： 0℃ Room temperature： 22℃ Air flow rate： 105.0m^3/(h･m)	Heat flow rate： 23.9W/ m^2 The value of the appearance(Overall coefficient of heat transfer)： 1.07 W/（m^2･k）
	Mode： Insulation Outside air temperature： 0℃ Room temperature： 22℃ Air flow rate： 0m^3/(h･m)	Heat flow rate： 38.2W/m^2 Overall coefficient of heat transfer： 1.81W/（m^2･k）
Solar shading coefficient	Mode： Sun Shading Outside air temperature： 35℃ Room temperature： 26℃ Irradiation： 600w/m^2	Solar shade factor： 0.19 To calculate a value above, it assumed that the radiant heat transfer coefficient is 4.7W/(m^2･k) and that the convective heat transfer coefficient is 7.79W/(m^2･k).
Ventilation resistance,	Mode： Air Flow Window Air flow rate： 105.0m^3/(h･m) Mode： Ventilation Cooling Air flow rate： 108.4m^3/(h･m)	The delta-pressure between the air inlet is provided for the indoor side at the bottom and the duct joint part at the top： 9.5Pa The delta-pressure between the hood is provided for the outdoor side at the bottom and the duct joint part at the top：22.5Pa

2. Field test

2.1 Overview

We began a field test in the building in October, 2005 to confirm thermal performance, durability and maintenance requirements. The sampler under test was installed for case in the outer wall (1 span) on the 3rd floor southeastern surface of the institute building (gross floor area 1, 291m^2) in Kiyose City, Tokyo. Figure -5 shows the outward appearance and the introspection of the building. We varied the operating controls of window A and window B.

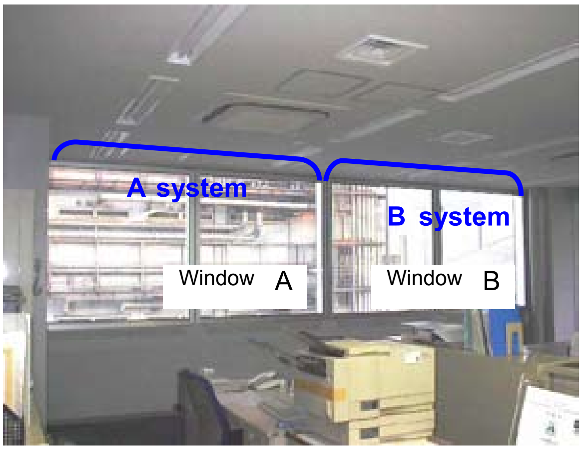

Figure 5 Exterior (the left figure) /interior view (the right figure) of the building

2.2 Measurement results

Figure 6 shows the solar shade factor estimated from data of experiments carried out from August to September 2006, comparing the performances of the single skin and the double skin. This factor was calculated by the standard for 10mm heat absorbing glass comprising the outside glass. It was estimated to be 0.26 from linear regression. This performance was approximately the same as that achieved in the laboratory test because the solar shade factor of 0.2 in the laboratory test is calculated by the standard for 10mm float glass. Figure 7 shows the assessed value with the overall coefficient of heat transfer in winter. The overall coefficient of heat transfer in the midnight hours in February was 1.43 W/m^{2}K. This was equivalent to about 1/4 of the value with the overall coefficient of heat transfer of the 10 mm float glass and the high insulation performance of the multifunction double skin of the development article.

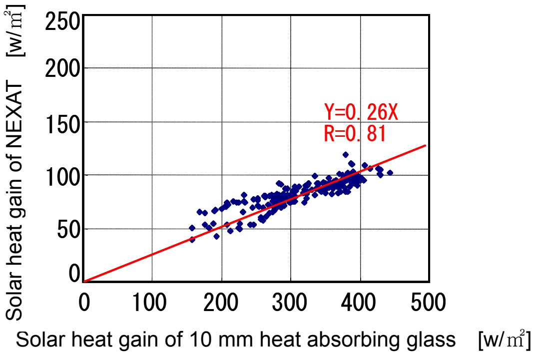

Figure 6 Solar shade factor (August- September, 2006)

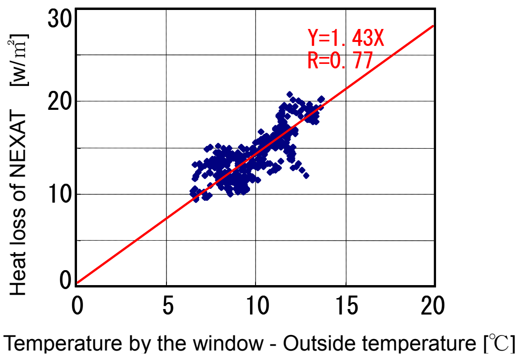

Figure 7 Overall coefficient of heat transfer (February, 2007)

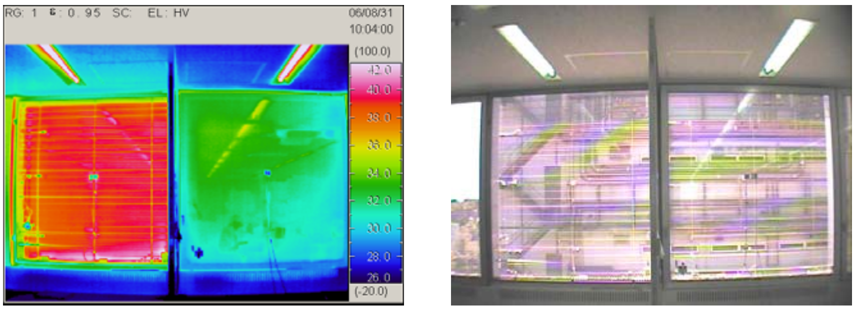
2.3 Comparative test

There is a great effect of spaciousness and comfort when the slats level compared with the case where the blinds are closed. Figure 8 shows the heat image and the visible image when the direct solar radiation becomes a maximum on a fine day in summer. The window on the left side forms a single skin when the inner glass is opened. When the slats are level, as for the single skin, the window inside surface temperature reaches 39°C.
However, the multifunction double skin of the development article (the window on the right side) falls to 32°C. Thus, the thermal environment is aggravated.



(blind slat is level)

Figure 8 Thermal image and visible image of single skin (left window) and double skin (right window) in case of the summer fine weather (10:00 August 31st,2006)

3. Implementation application

3.1 Overview

An overview at the building equipped with NEXAT on the facade on the western surface on a large scale, and annual operating data in March, 2007, are described. The left of Figure 9 shows the building's outward appearance of its northwestern surface. The right shows the status of the installation of the opening hood of NEXAT installed in the building. A mutual short circuit is avoided by arranging an approaching opening among the floors with a staggered layout. Table 2 shows the building overview. Table 3 shows the specification of double skin sash.

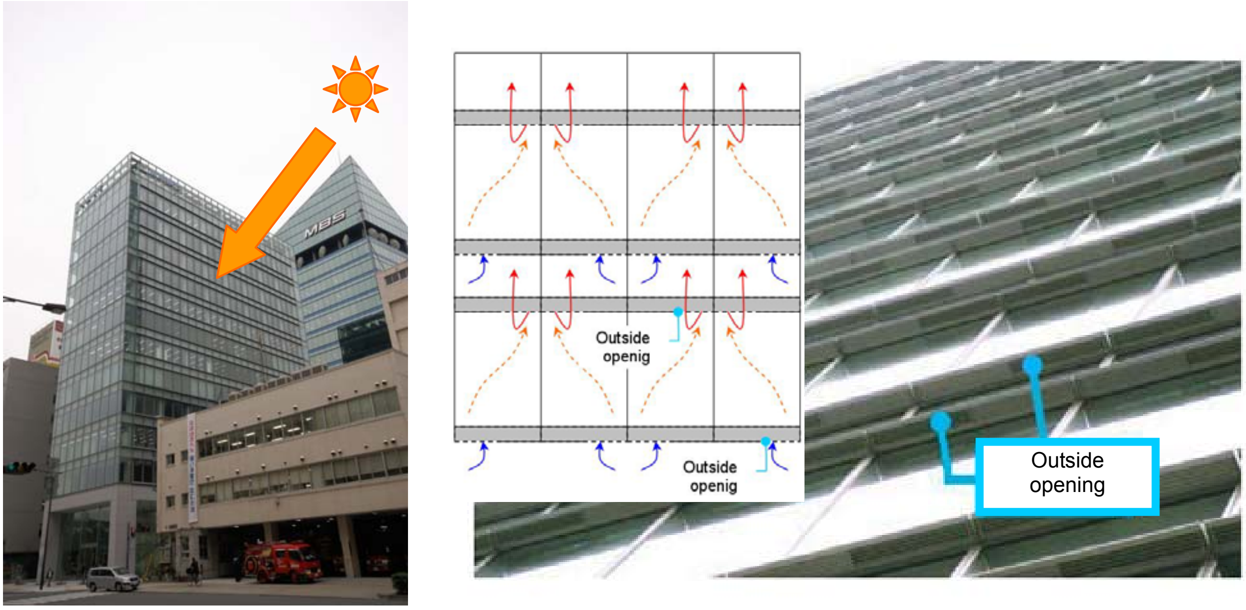


Figure 9 Exterior of building

Table 2 Building overview

Building name	Oosaka-Umeda Ikeda Bank Building
Building structure	Skeleton-construction, Reinforced-concrete-construction (the part),
Building scale	The 13rd floor the ground, the 1st floor the basement, the 1st floor penthouses
Site area	1,248.91 ㎡
Building area	686.25 ㎡
Total floor area	8,781.67 ㎡
The roof height	56.5 m
Construction period	The middle in July, 2005-the last day in January, 2007

Table 3 Specification of double skin

Size	Width：1,500mm Height：4,180mm
Glass	Tempered glass 12 mm (The outer side)
	Float glass 10 mm (The inner side)
Operator	The drive according to the top and the bottom

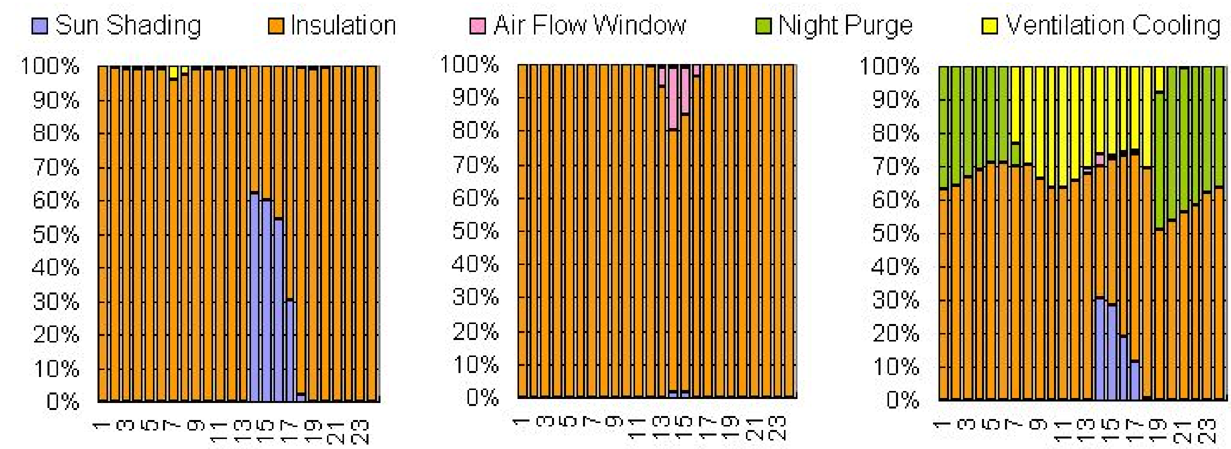
According to the logic shown in Table 4, the mode that realizes energy saving while ensuring comfort is chosen from the sensor information in each place. The adjustment of the slat angle is controlled to ensure as much sight as possible while it interrupts direct solar radiation based on the sunlight incidence angle which was calculated every month and time in the annual schedule.

3.2 Actual result data

The left of Figure 10 shows the results of the operation mode from July to September, 2007. When under the influence of afternoon sun, NEXAT switches over to Sun Shading mode, and at other times it is set to the insulation mode and improves energy saving. Also, in night, because the outside temperature is high throughout this period, without the Night Purge mode, it is sets to the Insulation mode. Incidentally, when comparing it with the air flow rate of natural ventilation measured in the Sun shading mode and the result of the experimental data, it is confirmed that NEXAT achieves fixed sun shading performance approximately.
The center of Figure 10 shows the results of the operation mode from December, 2007 to February, 2008. It is operated mainly in Insulation mode through this period.
Also, it performs heat recoveries by Air Flow Window mode. The right of Figure 10 shows the results of the operation mode from March to June and from October to November, 2007. Using cool fresh air, Ventilation cooling mode in the daytime and Night Purge mode in night are actively operated. Also, because the outside temperature is high from the afternoon, under the influence of the afternoon sun, when the ventilation cooling with outside air is invalid, it is controlled by the Sun Shading mode.

Table 4 Logic for mode change

Weather		Noon-night	Afternoon sun	Amount of insolation	Condition of temperature, enthalpy and so on	Mode	Circulation fan	Exhaust fan
Bad weather	In case of the cloudburst (Above fall 10mm/h) or In case of strong wind (The equal to or more than 15m/s wind speed)	Noon 7:00-19:00	—	—	Set value (5℃)< Outside temperature < Set value (15℃) and Air temperature at the top of the space in the double glazing window > Room temperature	Air Flow Window	Operation	Stop
					When missing from the above	Insulation	Stop	Stop
		Night	—	—	—	Insulation	Stop	Stop
Good weather	When missing from the above	Noon 7:00-19:00	existence 14:00 ～ 18:00	—	Set value (15℃)< Outside air temperature < Set value (25℃) and Outside air dew point < Set value (18℃) and Air enthalpy at the top of the space in the double glazing window < Room air enthalpy	Ventilation Cooling	Operation	Operation
				> Set value (100W/㎡)	Outside air temperature > Set value (15℃)	Sun Shading	Stop	Stop
				—	Set value (5℃)< Outside air temperature < Set value (15℃) and Air temperature at the top of the space in the double glazing window > Room temperature	Air Flow Window	Operation	Stop
				—	When missing from the above all	Insulation	Stop	Stop
			non-existence	—	Set value (15℃)< Outside air temperature < Set value (25℃) and Outside air dew point < Set value (18℃) and Air enthalpy at the top of the space in the double glazing window < Room air enthalpy	Ventilation Cooling	Operation	Operation
				—	Set value (5℃)< Outside air temperature < Set value (15℃) and Air temperature at the top of the space in the double glazing window > Room temperature	Air Flow Window	Operation	Stop
				—	When missing from the above all	Insulation	Stop	Stop
		Night	—	—	Set value (15℃)< Outside air temperature < Room temperature and Outside air dew point < Set value (16℃)	Night Purge	Stop	Operation
			—	—	When missing from the above	Insulation	Stop	Stop



Summertime in July - September, 2007

Winter in December, 2007 - February, 2008

March - June, 2007 and October - November, 2007

Figure 10 Operation mode rate of each season

3.3 Restraint of the effect

We estimated the annual energy saving effect of Ventilation Cooling and Night Purge. In case of restraint, the air-conditioned energy amount reduced by these was calculated, assuming that the coefficient of performance of the air conditioner is 4.0～5.0. Figure 11 shows the annual air conditioner power consumption and energy saving quantity by Ventilation cooling and Night Purge at the 7th standard floor office. The energy saving quantity of Ventilation Cooling and Night Purge is 11%, 11% of the annual power consumption (the one to have added the assumed power consumption when not performing Ventilation Cooling and Night Purge) respectively and is 22%. We found that this exceeded the 8% of the restraint example of Figure -2 and that the NEXAT application of this building contributed to the energy saving effect.

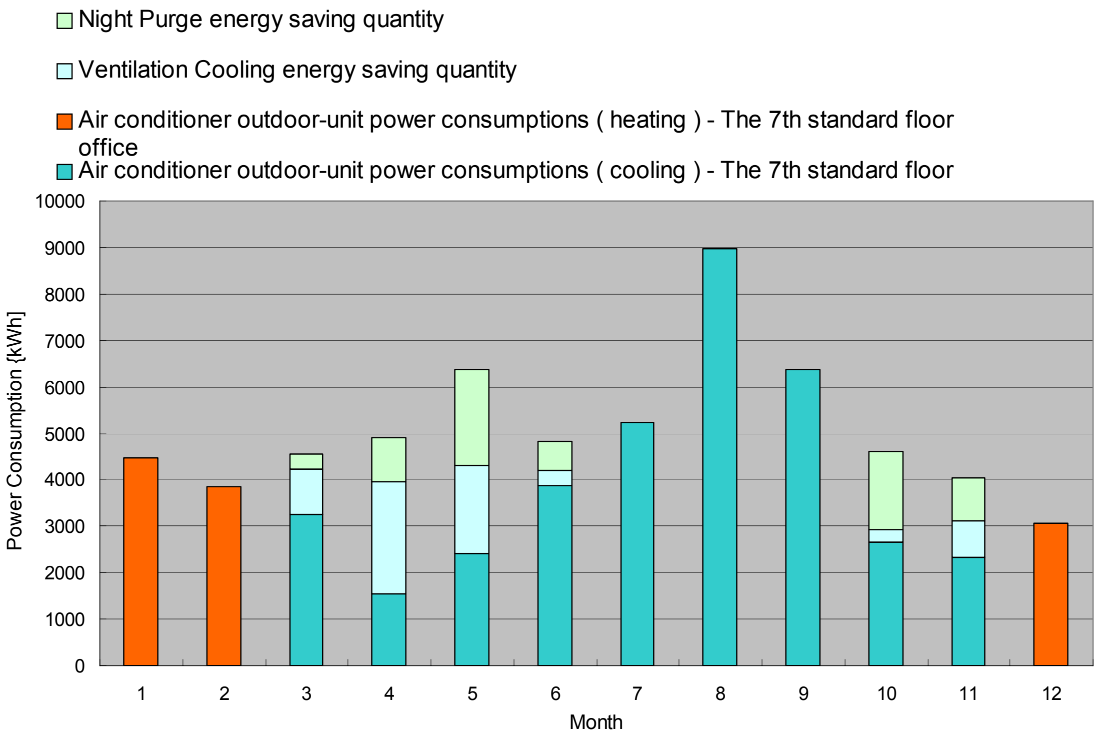


Figure 11 Energy saving effect about Ventilation Cooling and Night Purge

4. Conclusion

This study and development was implemented from 2003 to 2005 to realize a multifunction double skin system with higher energy saving performance than the conventional Japanese double skin system. As a result, the unitization could verify improvement of applicability to a building. Moreover, while considering the balance of performance and cost reduction, we made a product. Thus, while reducing annual air-conditioner energy consumption by about 14% by the model building restraint, the initial cost could be suppressed by about 2.5% compared to that of the conventional double skin system. Then, NEXAT achieves a simple payback-period of about 9 years. To confirm its performance, we carried out performance testing of a sampler in the laboratory. We confirmed that the performance was achieved by collecting annual data from field testing. Moreover, the field test confirmed that the control (the mode change) of the air flow according to the conditions of the weather outside functioned in the validity of energy saving and comfort, in addition to confirming the thermal performance achieved in the laboratory. By applying it to a large scale test on the west side façade of the office building, we verified that reliability was improved.

YOUR DEVELOPMENT: CREATING SUSTAINABLE NEIGHBOURHOODS

Michael AMBROSE[1]

Keywords: sustainable development, urban planning, web portal

Summary

To assist the development sector produce more sustainable infill and greenfield developments, the Department of Environment, Water, Heritage and the Arts (DEWHA) in partnership with CSIRO's Division of Sustainable Ecosystems is undertaking a project called Your Development. This project will provide a national 'one-stop-shop' technical Web resource that is based on the latest research and real-life case studies, with the potential to demonstrate the business case for sustainable subdivisions through the consolidation of available knowledge.

Your Development will provide an information base to assist urban development practitioners incorporate sustainable solutions into their planning, design and construction of new residential developments. The resource will cover a range of topic areas including estate design, site ecology, materials and recycling and sustainable energy services and provide national and international best practice examples. The central information resource for creating sustainable suburbs will have such spins-offs as strengthening the industry and research relationship while importantly building industry's capacity in sustainable knowledge transfer and implementation.

Your Development complements existing DEWHA projects including Your Home and Your Building that focus on environmentally sustainable housing and commercial buildings respectively. Your Development bridges the gap between these two resources by considering predominantly residential, low-rise developments.

The final Your Development resource will initially be a set of integrated web-based materials packaged for use by specific groups of practitioners, including urban planners and developers, designers, industry associations, financiers, utility providers and government. The material will be updated on a regular basis to meet demand and will cover the impact on the environment, society and costs of decisions at all stages of new residential developments including concept, design, implementation and operation.

1. Introduction

People have been living in cities and neighbourhoods for many millennia. Indeed, formal city planning is attributed to the Greeks and in particular Hippodamus who designed cities such as Miletus around 450BC. This early city designer was fully aware of how the natural environment should interact with the urban environment and Hippodamus designed Miletus so that the winds from the mountains and the sea could flow through the city and provide cooling during the hot summer. The city also uses a grid plan, with public buildings located in the centre and neighbourhood zones located around this centre, allowing for easy access by all residents to the city's heart. The grid plan was also intentionally laid out with a north/south axis to allow houses to have good solar access during the winter and shading from the sun in summer, a building practice that had been occurring in Greece since 400BC (Lahanas 2008).

This early understanding of a sustainable neighbourhood unfortunately did not last and subsequent civilisations and societies allowed cities to be developed in highly unsustainable ways. As populations grew so did the cities. The industrial revolution saw unprecedented levels of growth in cities as rural people flocked to the booming city economies. For most industrial cities their existing infrastructure was not capable of supporting such large populations and consequently disease and overcrowding was common. These overcrowded and polluted cities created the catalyst for a change in how cities were planned and saw the start of recreating healthier and more sustainable neighbourhoods.

The Garden City Movement was started by British planner Ebenezer Howard who published a book in 1898 entitled *Tomorrow: A Peaceful Path to Real Reform*, which was then republished in 1902 as *Garden Cities of Tomorrow*. Howard proposed a move away from industrialised cities to communities that combined the social and public conveniences of towns with the healthy aspects of rural living (Friedman 2007). Industry was located at the town centre and surrounded by a ring of parkland. Around the park were shopping areas and the next layer out were the houses with attached gardens. At the periphery were rail lines and larger farms. This segregation of land use would later be seen as the contemporary model for town planning.

Howard's ideas were not necessarily new and indeed he had Australian inspiration from Colonel William Light, who designed Adelaide's layout in the 1830's (Figure 1). Howard include a sketch of the Adelaide plan in his book and Light's design for splitting the city into smaller sections surrounded by parklands was a major influence on the idea of the green belt (National Library of Australia 1995). Howard's garden city idea inspired the development of Letchworth, located in Hertfordshire just out of London, in 1903. This was Britain's first planned garden city and its designers, Raymond Unwin and Barry Parker, also planned Hampstead Garden Suburb in London in 1907.

Figure 1 Adelaide's city layout with gardens ringing the two city sections

The post World War 2 era saw suburbs expand rapidly, mainly due to the rise in use of private cars. Planning of these new areas was also driven by earlier desires to separate out dwelling, industrial, commercial and retail areas from each other, but the desire from residents to have large lots, the typical quarter acre block, created large sprawling suburbs that no longer had the density to support much of the infrastructure and services required for a sustainable suburb. Consequently the infrastructure and services now need to draw their user base from a much larger land area, diminishing the ability for residents to access them by walking and thus the need for the private car has become mandatory in these suburbs. The need for the car has itself only exacerbated the problem, requiring more land for wider roads that have to deal with peak loadings, larger homes that need to house increasing number of cars and larger carparks to carter for the increasing number of single person trips.

Like with the industrial cities, many residents in our modern cities are now seeking change and realising that the way we are living is not sustainable. Developers and regulators are also grappling with the problems of the ever increasing sprawl and are starting to reinvent our modern suburbs to become less car dependant, more self reliant, better linked to the natural environment and generally lower the overall impact that our suburbs have on the environment.

2. Sustainable neighbourhoods

Outline the new trends towards creating green suburbs – following on from the green building movement. List some examples like Currumbin, etc.

The move to creating the modern sustainable neighbourhood probably first begun with creating a more sustainable house. Energy and water efficient homes, using low embodied energy materials and employing the principles of passive design, have been built for many years. Like the idea of the garden city, the principles of sustainable building design have been in existence for decades and have remained virtually unchanged. Indeed, many of the principles are taken from traditional building practices that can date back centuries. Before the advent of mechanical climate control systems and artificial lighting, dwellings had to be designed to deal naturally with the environment in which they were located. For example, Eskimos in Alaska for centuries built semi earth covered homes that used the soil as a highly effective insulating barrier against the extreme cold of an Alaskan winter. Early European settlers reported that these traditional homes remained between 15 to 20 degree Celsius using only two or three seal oil lamps and that the homes employed a natural ventilation system that ensured that fresh air was always circulating through the dwelling (Seifert 2007).

In Australia, the idea of building structures designed for the climate is also not new. Early 19th century settlers quickly saw the need for wide verandahs to provide shade and elevated light weight homes, such as the 'Queenslander', have been present for over a century in the warmer climates. In the cooler southern states too, the use of thermal mass has long been well understood and homes using mud brick and *pise de terre* type construction were introduced into Australia in the early 1930's by Justus Jorgensen who founded the Montsalvat artists' colony at Eltham in Victoria and whose work would later influence designers like Alistair Knox.

Moving from the individual sustainable house level to the sustainable suburb level has been slower to evolve, which is hardly surprising given that many more stakeholders are involved. Within Australia some early attempts were made, usually tackling a specific aspect of sustainable development. For example, the Kingsley With The Sun development in Wannaroo, Western Australia, was developed in 1986 and was the first subdivision in Australia which sought to protect solar access (Issac 1989). The establishment in 1994 of the Global Eco-Village Network (GEN) was probably the first modern organised movement for developing sustainable neighbourhoods. Foundered by Ross and Hildur Jackson, who were also founders of the Gaia Trust, GEN has the aim to "support the development of sustainable human settlements". The inaugural meeting saw representatives from eight communities from around the globe, including Crystal Waters Permaculture Village which is located in Queensland (Garden 2006).

Although the eco-village movement has seen many villages established around the GEN principles, there has also been criticism of the apparent elitism of the GEN movement. Garden (2006) argues that the GEN movement implies that ecological living is not possible in mainstream society and that it does little to directly address ecological or environmental crises. More recent eco-villages have taken a more proactive stance, engaging with a range of stakeholders and addressing the challenge of creating sustainable developments for mainstream society. The Ecovillage at Currumbin, located in Queensland's Gold Coast hinterland, is an excellent example of the new breed of eco villages that are developer driven but which prioritise community and social ecology along with economic and environmental sustainability on an equal basis with standard development practice. This development has received numerous awards, including the 2007 Urban Developers Institute of Australia national award for best environmental development. This recognition by the mainstream development industry demonstrates how the modern eco village can not only exist within the mainstream development industry, but also influence and demonstrate how modern neighbourhoods can be developed sustainably.

Figure 2 Newly completed house within the Ecovillage at Currumbin

3. Your Development

The rise in awareness of sustainability issues within the built environment has also lead to the need for knowledge on how this is best achieved. Numerous books, magazines and web sites have been devoted to a range of sustainability issues related to buildings. One of the best known is the acclaimed Your Home web site (www.greenhouse.gov.au/yourhome/), developed by the Australian Greenhouse Office in consultation with the building industry, it has established itself as the primary source for sustainable residential building information within Australia. The success of Your Home owes much to how it was organised and authored. A series of over 60 fact sheets authored by many of the leading experts within Australia on a range of sustainability topics including water, energy and material use and site related impacts. These fact sheets are then supported by an extensive range of real world case studies to demonstrate how the principles discussed are put into practice. Your Home has a wide ranging user base from the building professional through to the home purchaser and has allowed many in the industry as well as the home owner to understand the basic principles of sustainable housing.

The success of Your Home has lead to the development of two sister projects, Your Building, which focuses on sustainability issues related to commercial buildings, and Your Development, which focuses on sustainability issues of residential land development. The Your Development project has been a partnership project between the CSIRO's Division of Sustainable Ecosystems and the federal government's Department of Environment, Water, Heritage and the Arts and is complimentary to the Your Home web site in that it addresses the missing information set in the sustainable residential building world. Your Development realises the importance that the land developer has in ensuring that not only houses, but entire neighbourhoods are built sustainably.

3.1 Industry's role

When land is developed for residential housing, there is usually a once only opportunity to instil sustainability principles within that development. The way the natural topography is addressed in the development, how waterways are incorporated into the design, the positioning of roads, paths and building lots will usually be locked into that development forever once construction has been completed. If these aspects are done poorly, then it is virtually impossible for many to be undone. Unlike houses, it is very difficult to retrofit a subdivision. The layout of roads and building lots once completed are unlikely to be significantly altered in the future and if they were it would involve enormous costs. Consequently, those involved in the land development industry, including developers, planners and the various levels of government have an obligation to ensure that these developments are done in a way that will minimise their impact on the environment and encourage sustainable development.

Many of the large land development companies are now well aware of the sustainability opportunities that are available to them and many have incorporated these opportunities into their developments. Newington, the former Sydney Olympic village, Koolamara Waters, Wallarah Peninsula and Aurora are just some of the developments created by large development companies that have won national and state based environmental awards. However, small to medium sized developers often do not have the resources or knowledge that these large firms have available and consequently are often unaware or lack sufficient information to employ sustainability features within their developments. The same is often true of local government councils, who ultimately often have the final say on whether a development will proceed. Innovative developers putting forward concepts that local regulators only have limited knowledge of will often result in councils taking the conservative "business as usual' approach and rejecting any schemes that may contain a perceived higher degree of risk.

The perceived risk of some sustainable development strategies is often just that, perceived! In reality, there is often the same level of risk as the normal approach and in some cases it may even be a lower risk. The whole area of risk, who ultimately carries that risk and risk mitigation is a complex area and one that cannot be covered here, but often risk is used as an excuse for lack of knowledge. Addressing that knowledge gap is the main aim of the Your Development project. Additional aims of the Your Development project include:

- to create a one-stop-shop resource that explains the 'why' and 'how' of sustainable urban development and influence changes in market behaviours
- to bring together industry and research expertise, skills and knowledge to develop best practice and innovative content
- to build the capacity of the industry to respond to sustainable knowledge transfer and implementation
- to demonstrate the benefits of sustainable developments in terms of the triple bottom line, that is, environmental, economic and social benefits.

3.2 Structure

Your Development is structured as an online web based information portal. Like Your Home and Your Building, the content of the site is arranged as a series of fact sheets written by experts from research and academic organisations and backed up by industry knowledge and experience. The topics that the fact sheets cover and how they are organised was initially addressed in a scoping study that was carried out in 2005 by the Institute for Sustainable Futures (McGee & Partridge 2005). This scoping study identified a range of stakeholders involved in the development process and then carried out a series of surveys and workshops with these stakeholders to identify the topic areas that would be required. This preliminary list was then reviewed and refined into the following nine topic areas:

- **Site Ecology** – site issues, landscaping, biodiversity, soil and water management, ecological footprint.
- **Place Making and Social Sustainability** – housing stock, affordability, community issues and facilities, connection to facilities, heritage and safety, community education, community health and wellbeing.
- **Estate Design** – street and lot layout, urban density, mix use, open space provisions and infrastructure provisions.
- **Access and Transport** – public transport and bicycle infrastructure, pedestrian environments, innovative transport modes, transport integration and linkages.
- **Materials and Recycling** – life cycle assessment of materials, waste minimisation, waste management and recycling and healthy materials.
- **Integrated Urban Water Management** – water sensitive urban design, water sources, water efficiency and water quality.
- **Energy Management** – energy supply, distributed energy and energy efficiency.
- **Climate Change Adaptation and Mitigation** - greenhouse abatement and adapting to climate change.
- **Sustainability Management** – whole of life costing, financial models, partnerships, post occupancy evaluation, governance, industry education and sustainability assessment.

Under each topic area there is a series of fact sheets that cover different aspects of the topic theme. The fact sheets themselves are structured in a consistent style across all topic areas which allows a matrix style approach to finding relevant information. For example, each fact sheet covers a series of key issues that were identified as essential elements that developers would want to consider before implementing any sustainability initiative. These key issues are:

- Benefits – why should I do this? Environmental, marketability, economic and social benefits.
- Costs – what is the cost? Includes financial, time and other "costs".
- Savings – are there potential savings? Also covers financial and time related savings
- Risks –what risks might be involved? May be political, marketability and financial risks
- Barriers – what barriers might exist? Includes regulatory, government and public perception barriers.
- Benchmarks – what should I aim for? What are the national and international benchmarks that exist and what is "best practice" for a particular sustainability initiative.

In addition to these key issues, the fact sheets also aim to address how and, importantly, when in the development process sustainability initiatives should be implemented. Opportunities to implement certain features will only be possible through careful planning and scheduling during the whole development process. As work progresses, these opportunities may become more difficult, if not impossible, to implement. Consequently, the fact sheets break the development process into six phases:

- Feasibility – the initial project scoping stages;
- Planning – preliminary planning, legislative requirements, initial community consultation, etc;
- Design – formal design stages, master plan creation, layout, permits, etc;
- Construction - major construction phases, road and infrastructure placement, earthworks, community facilities, parkland development, etc;
- Lot Creation – construction of dwellings and ongoing lot release and development; and

Each fact sheet covers what actions are required at the various phases allowing developers to plan how best to implement their sustainability initiatives.

3.3 Case studies

Backing up all the fact sheets is a series of case studies demonstrating how a particular sustainability initiative has been implemented in the real world. Case studies are an essential part of the Your Development portal and provide all users with practical examples of how others have succeeded in their sustainability aims. Each fact sheet has a series of case study "snap shots" that highlight that specific feature. These "snap shots" are then linked backed to a comprehensive case study database that contains hundreds of case study examples from Australia and around the world. The powerful search engine included with Your Development allows users to search for a case studies in certain locations, that focus on particular sustainability aspects and then obtain the case study details and further contact information.

It is envisaged that over time, this database will grow to become the primary reference point for Australian residential land developers. The Your Development portal is designed to allow easy updating and addition of new developments providing all in the development industry the opportunity to showcase their development's sustainability achievements.

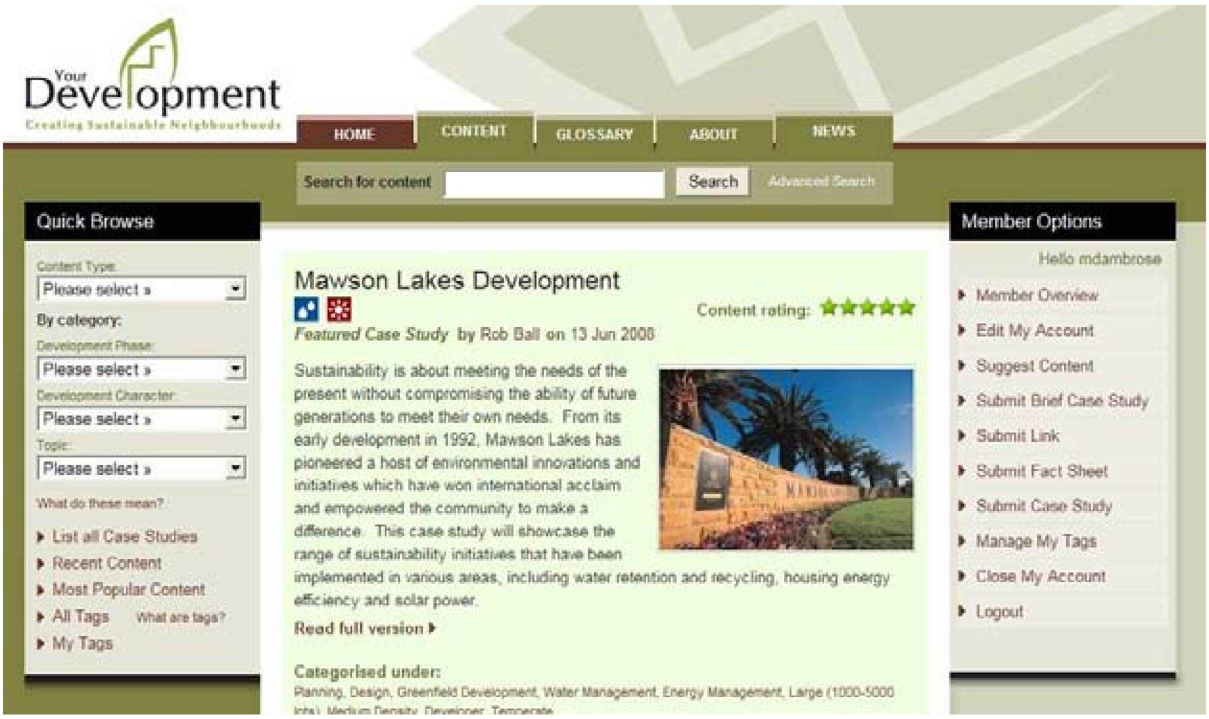

Figure 3 Screen shot from the new Your Development web portal

3.4 Web portal

The actual web portal has been designed to take advantage of the latest web based opportunities. Figure 3 shows how Your Development employs a "wiki" style interface as pioneered by Ward Cunningham on his WikiWikiWeb site in 1994 (Wikipedia 2008). Wikipedia, the online encyclopaedia is probably the best known example of a wiki based website. Wiki websites are collaborative websites allowing users to add new information and edit existing information. There are both advantages and disadvantages of this approach, but it is generally believed that the advantages far outweigh the disadvantages. The main advantages of the wiki approach are that information is continually updated and added to and errors in the information can be easily corrected by any user. It also allows new fact sheets to be easily added to the system allowing the whole site to become a dynamic repository of sustainable development information. Of course, allowing any user to edit content does mean that fact sheets run the risk of being vandalised and manipulated to push a certain user's personal opinions and/or bias. The original content authors for Your Development were instructed to write fact sheets that did not contain personal opinions and to avoid being prescriptive. The aim has always been to create fact sheets that are relevant, factual, unbiased and informative.

Initially, it is expected that editing rights to existing fact sheets will be restricted to the authors themselves and trusted others. New fact sheets will be encouraged by registered users and initially trialling of the editing process will help determine the speed that wider editing rights are enabled. Experience from other web sites that utilise this approach, including Wikipedia, suggest that new content needs to be independently reviewed and assessed before making it publically available on the main web site. Your Development will develop this group of reviewers that will vet content and ensure that information that is presented meets the objectives of the Your Development portal.

4 Future of sustainable neighbourhoods

The Australian Federal Government has made a commitment to reduce Australia's greenhouse gas emissions by 60% on 2000 levels by 2050 (Department of Climate Change 2008). As part of a package of initiatives are financial incentives, strengthened energy efficiency regulations and targeted information at households to use less energy and water while saving money. The government has indicated that it is planning to not only strengthen existing energy efficiency regulations, but move to a more holistic sustainability focus by creating standard nationwide requirements. Such a move would require significant industry education and access to the latest knowledge and methodologies for achieving new sustainability goals. Our new and existing neighbourhoods will become key parts of achieving a more sustainable country, which is becoming more urbanised every year. Indeed, a recent United Nations report predicts that by 2050 93.8% of Australians will live in urban areas, up from 88.2% in 2005 (Edwards 2008). Ensuring that our new urban developments cater for this increase sustainably will be a significant challenge.

The Your Development web portal and its companion portals Your Home and Your Building, are valuable resources for an industry that is being increasingly challenged to provide developments, buildings and related infrastructure more efficiently and sustainably while still retaining high quality and affordability to the general public. Your Development's collaborative based structure means that users from all stakeholder groups have the opportunity to share their knowledge and ensure that information provided is both relevant and accurate. Access to a broad range of case studies helps both developers and regulatory agencies understand how sustainability initiatives have been implemented in the real world and helps ease the reluctance and trepidation that often accompanies the take up of innovative solutions.

Sustainability through Prefabricated Construction in Hong Kong Public Housing Projects

Joseph YW Mak

Hong Kong Housing Department, HKSAR Government, HKSAR

ABSTRACT: Prefabrication offers cleaner, more efficient and safer construction and makes a significant contribution to sustainability in housing development. The key benefits from these methods are the conservation of construction materials, savings in overall resources and energy, minimizing construction waste, providing a clean and healthy working environment and shortening the overall construction time. Upon completion, there are also life cycle cost benefits when compared with the hitherto more traditional approaches to design and construction.

The Hong Kong Housing Authority (HA) has been a pioneer in developing prefabrication in the territory. In the early 1980's, the HA initiated a programme to encourage prefabrication and mechanized construction technology through well known international contractors. In the late 80's, leading local contractors were encouraged to develop their own pre-casting systems to suit the Hong Kong context. The follow-up contractual, procurement and quality assurance measures were then developed and implemented in building contracts. In parallel, new technological initiatives have been introduced one by one and a very comprehensive prefabrication system for high rise residential buildings has evolved.

This paper will share the experience in the evolution and development of prefabrication initiatives in the public housing programme, for the benefits to be appreciated by the industry as a whole and for the advancement of the sustainability in the construction industry.

1. INTRODUCTION

In the mid 1960's, due to the influx of immigrants from Mainland China to Hong Kong, the majority of these immigrants lived in squatters or very old buildings. A large number of flats had to be built speedily to meet the massive demand for housing. At the same time, rapid industrial development meant people had begun to receive stable incomes, and hence higher expectations in the supply of better housing.

On the other hand, the construction industry in Hong Kong in those years was still relatively primitive, low skills and labour intensive. The public housing blocks then developed could only serve the functional requirements, but not on durability and sustainability.

2. SUSTAINABILITY OF EARLIER HOUSING STOCK

Starting in the early 1970's, because of the growing population in HK, medium rise reinforced concrete buildings were the normal mode of accommodation for the citizens at large, in particular those living in public housing. Concrete material was adopted basically due to the abundance of granite rock from the excavation of local quarries and from Mainland China, instead of importing structural steel from abroad which was more expensive. Concrete was deemed to be more durable under the subtropical humid climate in Hong Kong.

Resettlement Blocks in mid 1970's

However, at the technological level in the 1970's to 1980's, there were some critical shortcomings in the quality of construction workmanship at that time:-

a) The method of construction was by traditional in-situ construction, using timber formwork. The finished profile and in particular the concrete cover protecting the reinforcement from corrosion were very much subject to the carpentry skills of the workers.

b) The other aspects of workmanship such as steel fixing, compaction of concrete, finishing of concreting works, all operated in a very labour intensive and congested working site and generally with unskilled labour. This had worsened the corrosion protection to the concrete elements.

c) The secondary infringement by water seepage at joints (e.g. at windows), water ponding in slabs (e.g. roof, cantilever corridor), water leakage at pipe connections (e.g. exterior of kitchen and bathroom), also led to the deterioration of the building structural frame and fabric.

Traditional Method of Construction of Housing Blocks during 1970's

In Hong Kong, there were over 250 nos. of public housing blocks constructed in this way during the period of 1970's to 1980's, ranging from 7 stories to 20 stories buildings. These blocks have been under an extensive maintenance programme over the years in tackling concrete spalling, recasting of concrete elements and even substantial strengthening works. The table below shows the repair cost trend of the housing blocks constructed in different periods in the past.

Table 1: Cost Trend of Concrete Repair

Age of Blocks (years)	Handover Year	No. of Blocks Completed	Cost of Repair per flat per year (HK$)
31 -- 35	1972 ~ 1976	60	301
26 -- 30	1977 ~ 1981	194	158
20 -- 25	1982 ~ 1987	219	15

The life cycle of the earlier domestic blocks have been typically in the range of 40 to 50 years when the maintenance cost is continually increasing. Because of the need to go for more high rise redevelopment due to the scarcity of land and the upgrading of living standard through enlarged flat sizes, the majority of these earlier blocks have been progressively demolished under the Housing Authoriity's Comprehensive Redevelopment Programme. From the sustainability point of view, compared with other structures like bridges which have the life of over 100 years, this is a significant cost tag to the society and should be improved.

In Table 1 above, it is clear that maintenance expenditure on the older buildings is greater. It can also be seen that the repair cost drops significantly in the 1980's which was the time when mechanization and prefabrication was introduced.

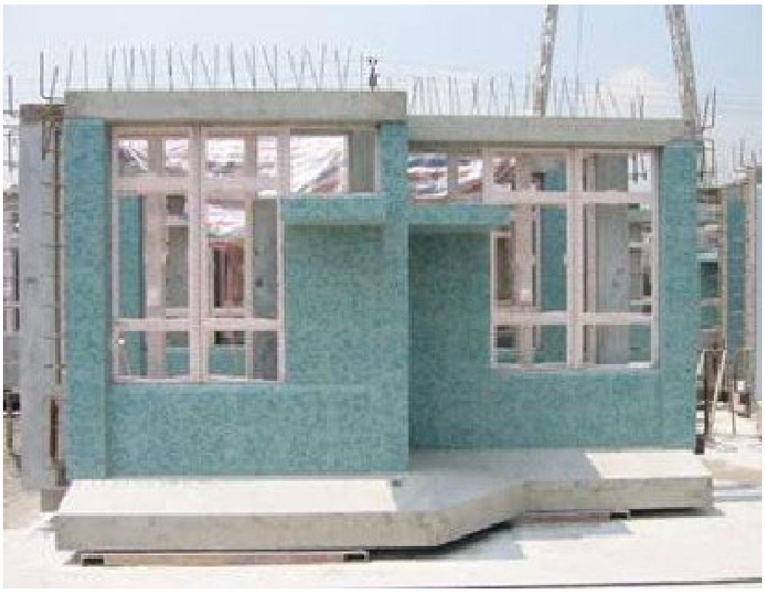
3. ENHANCEMENT OF QUALITY AND WORKMANSHIP OF STRUCTURAL WORKS

With a strong strive to enhance the quality and workmanship of structural works, the Housing Department responsible for the construction of the public housing had mandatorily introduced the use of large panel steel formwork and associated mechanized construction in the mid 80's

Mechanized and Prefabricated Construction

This is not only a pioneer environmental initiative to reduce the use of timber, but also gives assurance to the accuracy in lines and profiles of the structural elements. The surface finish of off-form concrete is also much enhanced with no more uneven surfaces and/or left-in peeling off timber pieces in concrete.

In the early 1990's, another great step forward in the public housing construction was the mandatory use of precast facades. The main purpose of the move was to prefabricate the complicated concrete profile of the facades in a factory instead of casting them at the working floors and to cast-in the windows in the facades to avoid water leakage at the window/façade interfaces.



Precast Facades

From a sustainability point of view, the immediate benefits of precast concrete construction are:

a) Great reduction in use of timber for formwork.

b) Assurance of concrete cover to reinforcement as a front line defence to corrosion.

c) More robust and reusable steel formwork/steel mould which facilitate better compaction of concrete.

d) Better surface finishes to greatly minimize the touching up with repair materials which might detach in the longer term.

4. PROCUREMENT OF MECHANIZATION AND PREFABRICATION

During that period, the HA has also initiated a programme to encourage prefabrication and mechanized construction technology by inviting well known international contractors to participate. The outcome was promising. Stakeholders in the industry began to be exposed to these new technologies both in design offices and on site. However, in the later years, not many of these international contractors could sustain their business because of the higher overhead costs and their difficulty in managing local subcontractors. In the early 1990's, leading local contractors were encouraged to develop their own precasting systems to suit the Hong Kong context, drawing experience from the international contractors and from experience in Singapore which has a similar form of construction of medium rise buildings.

5. MORE PREFABRICATION IN DESIGN

Following the design of precast facades, more prefabrication had been developed. These precast components are reckoned to be "for a purpose" within their different locations and contexts, which are elaborated as follows:-

a) Semi-precast slabs, tie beams and staircases

To prefabricate these components in factory instead of constructing it at working floors. The latter would require relatively substantial formwork/falsework on site, which might be vulnerable to poor workmanship and have severe safety concerns.

Semi-precast Slab

Precast Tie Beam

Precast Staircase

b) Volumetric precast bathroom/kitchen

To precast a box-type structure to be installed to each flat unit. With this volumetric set up, it could embody numerous pipeducts, fittings, tiles, waterproofing membranes, etc. It could also incorporate cast-in pipe sleeves instead of box-outs which are vulnerable to leakage. A lot of wet trade could be transferred to the factory which is a better controlled working environment. From past experience, bathrooms and kitchen areas are locations which call for frequent maintenance throughout their life spans.

Precast Bathroom

c) Precast structural walls

A pilot project in Kwai Chung Flatted Factory has been launched successfully to extensively try out the use of precast structural walls. This innovative approach has opened up a new era for high rise precast construction which could further reduce the operations on site. Their applications are currently being reviewed for their effectiveness and opportunity cost.

Precast Structural Wall

d) Prefabrication along the building perimeter

Prefabrication not only enhances construction workmanship but also enhances safety construction at height. In normal mechanized construction, it is prudent for the contractor to make provisions for safe working platforms at open edges along the building perimeter. Metallic working platform with robust railings are required. Nonetheless, there is still a risk of workers falling out of the railings. By adopting precast facades and semi-precast walls (also called 'lostforms'), the perimeter could basically be surrounded by precast 'walls' and workers are not required to step outside into the working platforms. Hence, all activities are confined within the building enclosure. This approach is becoming popular in the private sector in Hong Kong and has also been tried out in our Kwai Chung Flatted Factory pilot project.

Semi-precast Wall (Lostform)

6. PREFABRICATION FOR HIGH RISE CONSTRUCTION

Prefabrication and modular construction have been widely used in European countries like France, UK, Sweden and many others. They are usually adopted, however, in low rise houses or medium rise blocks up to around twenty stories. These countries do not have the need to construct high rise residential blocks like those in Hong Kong. The precast technology in Hong Kong is therefore somewhat unique though reference have been made to similar usage in Singapore. In Singapore, not until recent years, their building heights has been up to 30 stories with column beam structures as their main stream. In Hong Kong our residential blocks are 40 stories or above, where the structural forms are essentially shear wall structures.

Prefabrication in high rise construction in Hong Kong demands special considerations for buildability: -

a) Symmetry of Block Layout

Blocks are designed with symmetry to allow for more repetitiveness in the components and to facilitate the rotary construction by tower cranes .

b) Modular Flat Unit

The flat units are designed to be in modular types, including one bedroom, two bedroom, three bedroom, etc. These have a lot of benefits in terms of unifying the flat unit components, including the building and structural components, and allow the repetitiveness in prefabricated production.

c) Weight of Precast Components

Weight of components is critical. Heavier items may require greater carnage of the tower crane, hence jacking up the construction cost. Similarly, volumetric precast components have to be carefully located in the layout to ensure that the tower crane has sufficient capacity to lift them during construction.

d) Monolithic Connections

Connections of precast elements with the insitu structure should be through monolithic construction. Post-fixing with brackets and grout/mortar infill are not desirable for tall buildings, mainly because of to the high cyclic wind load which may render the connections unstable and/or lead to cracking of infill grout, hence water leakage.

e) Dimensional Tolerance

In high rise construction in which precast components are interlocking with insitu structural components like shear walls or columns, dimensional accuracies are very important. Only very tight tolerances could be allowed for the components to be fitted into, otherwise the construction cycle would be disrupted.

7. QUALITY ASSURANCE OF PREFABRICATION

Prefabrication off-site was an activity rather new in our contract procurement. It has also triggered the establishment of another sector of suppliers to invest in setting up factories in region of South China next to the Hong Kong. This is because Hong Kong has a scarcity of land for accommodating large factories and the cost of labour is also high. With the introduction of extensive prefabrication, many of our main contractors have the incentive to set up factories and inject management staff to undertake the factory production.

One of our major concerns is the quality assurance in these remote factories. The HA has now established a series of QA measures as elaborated below:-

a) Independent consultants have been appointed to supervise the production of these factories, with full time staff stationed at the factories.

b) Each factory has to carry out internal audits at regular intervals. The independent consultant is required to conduct monthly external audits and the HA would also carry out regular audits to the performance of the consultants.

c) A Performance Assessment Scoring System (we called the PASS) is also imposed to these factories, with particular focus on the workmanship of the production. Scores obtained from the PASS would be related to the performance of the main contractor employing the precast supplier and affect the tendering eligibility of the main contractor.

d) At the initial set up of the factory, it has to be accredited to ISO standards. In addition, the supplier has to carry out a pilot production run to demonstrate its competence before it is approved for production.

8. CONCLUSION

Prefabrication offers cleaner, more efficient and safer construction and makes a significant contribution to sustainability in housing development. The key benefits from these methods are the conservation of construction materials, savings in overall resources, including energy, minimizing construction waste, providing a clean and healthy working environment and shortening the overall construction time. Upon completion, the result is an aesthetically pleasing, versatile and highly durable development. There are also life cycle cost benefits when compared with the hitherto more traditional approaches to design and construction.

The prefabrication experience gained by the HA is indeed very rewarding. Private sector in Hong Kong are following suit and are developing further in breadth and in depth because of their affordability to use more luxurious components. Compared with the earlier housing blocks in Hong Kong, this approach has brought about longer life buildings for our next generation to continue to live in.

POWERLINK QUEENSLAND EDISON BUILDING
A CONNECTED, VIABLE, AND LIVEABLE
SUSTAINABLE BUILT ENVIRONMENT

Keywords: sustainable building, environmental, refurbishment and recycling

Summary

In 1997 the Edison Building complex was completed. An asbestos cement clad steel framed industrial building, constructed for Queensland Rail in 1955 in an oil contaminated site, was recycled into a state-of-the-art office building for Powerlink Queensland.

In November 2008 the facility will be in continual operation for 11 years.

The Powerlink Queensland office building case study is a living example of best practice achieving excellent results in all the factors driving decision making in the built environment. It has stood the test of time.

Powerlink has experienced increased workplace productivity through innovative design and implementation, and uplifting cultural change and behaviour in the workplace as a direct result of the environment created in this building.

The visionary working environment brings people and plants together in a symbiotic relationship of calm offices and rainforest greenery. Central to the office is an 850 sq.m. landscaped atrium surrounded by 2 levels of open plan office space.

The award winning building complex utilises methodologies developed at the Johnson Space Centre by NASA[(1)] for the international space station now in orbit, where selected species of plants are used to clean the air and remove contaminates and generate positive ions into the built environment. The extensive water features and plants are an integral part of the air conditioning system, as all return air is directed via the rainforest for cleaning, and humidity control during its cycle.

(A) *(B)*

Main entrance facing northwest (A) in 1997 (B) in 2008.

Introduction

Powerlink Queensland is a Government Owned Corporation providing electricity transmission facilities for the State of Queensland. The Corporation was established under the GOC Act 1994 and commenced operation on 1 January 1995.

Prior to this, the Queensland Electricity Commission carried out the function of transmission. In this context, the QEC was a monopoly organisation managing the Generation and Transmission businesses as well as future generation and transmission planning for the State of Queensland. Staffing for that business was over 3000 people and the structure and operation were bureaucratic and control oriented.

The challenge for the Board of Powerlink Queensland from 1 January 1995 was to shed the management philosophies and overly bureaucratic trappings of the former QEC and build a streamlined commercially focused business comprising 500 employees.

In 1995 the Powerlink Board inherited a business that was operating from :

- A depot in Richlands on Brisbane's southside with high overheads;
- A large under-utilised and high cost workshop complex on Brisbane's northside;
- A Head Office located in the Brisbane City centre plagued by high rents and overheads.

The new workforce was drawn together from disparate groups with different goals and ambitions.

A key aspect of building the business was the creation of an identity that was not linked to the former role of the transmission business as part of the Queensland Electricity Commission.

In mid 1995, the Powerlink Board undertook to establish a headquarters that would be the focal point for the future. We were appointed to assist in identifying options for new headquarters, including:

- Leasing central business district offices;
- Leasing near city buildings;
- Building near the city (eg. Southbank);
- Utilising existing assets.

In November 1995, the Board decided that the best option was the consolidation of its business activities at its workshop site at Virginia. The plan included the relocation of all of Powerlink's business activities to a single location in Brisbane.

The option had many commercial benefits for the Corporation. It meant that the business was able to reduce its overheads by avoiding high CBD rents, obtain better utilisation of the workshops property at Virginia, and close down and sell a commercial property on the southside. It also meant that there was an opportunity to create a new employee culture to build a business that had to compete in a commercial arena without the benefits of the protection of the State.

The workshop complex at Virginia comprised two buildings. One was the major workshop building constructed in the mid 1950's and used for transformer repairs since the mid 1960's; the other was built in the early 1950's and used for administration, trade training and instrument workshops activities. The former building was still required as an integral part of the business, but the latter was under utilised, in a parlous state of repair, and its future use in the existing context was economically not viable.

The essential structure of the old railway shed was maintained when the building was recycled into a lush interior landscape surrounded by open-plan offices.

The decision taken was to refurbish the workshop building and redevelop it into the headquarters of Powerlink Queensland.

The fifty year old former Queensland Rail industrial building has been recycled into a modern office building set into a park-like landscaped setting, and named Edison Building.

The conversion of the harsh industrial site was seen by Powerlink Queensland as an important reinforcement of its corporate mission to practice responsible environmental actions and to be a good neighbour. The provision of a quality working environment for Powerlink Queensland's staff was also high on the development agenda.

The Edison Building

A detailed cost benefit analysis was prepared which analysed cost scenarios of several building options, including complete demolition and rebuild. Approximately 10% of the construction cost of a new facility was saved by re-use of the existing ground floor slabs and steelwork.

When the existing 13 bay saw-toothed shed was stripped of its asbestos cement cladding a well engineered and honest expression of steel industrial engineering was found. Features such as the 70m x 80m floor plan, large column spaces, and 7m height clearance lent themselves to recycling the shed into a two storey office building.

South facing clerestory windows in the saw-tooth roof allow ideal light for atrium plants – 1997.

In order to provide prime office space, i.e. – no one more than 9 metres from an outside window or a view, an 18m wide rectangular plan-form evolved. Wide overhangs were possible at the perimeters, and a landscaped atrium, integral with the office space, allowed the creation of a unique workplace environment. The existing structure, evident throughout the project, has been extended and embellished by the use of metallic forms and cables. Structural integrity is evident both internally and externally.

(A)

(B)

Wide verandahs (A) in 1997 (B) in 2008.

The project is a significant example of sustainable design, which has had an extraordinary impact upon Powerlink Queensland's organisation, and the neighbouring community. It has set a new benchmark for non-CBD office design in a healthy working and living environment.

The west elevation faces busy Toombul Road – 2008.

Because of the economy of structure and general economic sense to recycle rather than demolish and rebuild, the project has been able to afford some unique features such as extensive advanced landscaping, incredible staff amenities, and the spectacular cantilevered hydraulic lift – unique in its design.

We designed a cantilevered lift, which caters for a stretcher and also conveys disabled persons from ground to first floor with ease. Disabled persons have 100% accessibility to all staff areas at non-discriminatory locations.

Central landscaped Atrium – 2008.

The optimum human requirements of air quality, temperature and humidity in the office building were delivered in a unique way by exploiting the finding of new scientific evidence from NASA[(1)], that plant species can help mitigate indoor air pollution and improve greatly the aesthetic quality of spaces to be inhabited by human beings.

The central landscaped atrium and waterways is an integral part of the office environment. All return air is directed through the plants for pre-cleaning. The waterways add “white noise” to the office and help humidity levels to remain constant. South light has resulted in healthy plant growth and has given the office an unusual outdoor quality. Seating areas are provided in the garden where people can unwind to relaxation music, watch fish and frogs in the stream, or just enjoy the natural setting.

Co-ordination of the Facility Changes

This involved two aspects. Firstly the architectural changes to recycle the old building into a modern office complex, secondly the cultural changes to relocate a workforce in excess of 500 people, from cellular offices to an open plan environment.

There are no partitioned offices in the facility. Everyone, from office junior to the C.E.O. is in a workstation, and all workstations are the same size. Quiet rooms, with acoustic treated full height workstation screen walls are provided at a ratio of one per 10 people. All spaces such as these are available to all staff at all times.

There are over 450 workspaces and only 8 do not conform to the standard. These 8 workstations are different not because of status but because the people need special facilities to do their job. The way that facilities are provided will limit the future costs arising from the churn factor. Because everyone is in the same size workstation, when any changes are required, we move people not workstations. These are 'briefcase' moves.

All trappings of status in the workplace were removed to reinforce the new flattened management and team-based work ethic of the corporation.

In order to foster greater inter-departmental communication and socialisation, small cafes or refreshment nodes have been scattered throughout the facility where staff are encouraged to pause over a cup of coffee during the day.

We have also created numerous meeting places where staff experience unexpected encounters, for an enriched work experience.

Informal meeting areas are scattered around the office and atrium areas – 2008.

Conclusion

The opportunity to recycle Powerlink's redundant industrial building into a state-of-the-art modern building has delivered considerable cost savings to the Corporation. It has also delivered to its employees accommodation that provides cohesion in meeting the targets of the business, and placed in the hands of employees a creative, innovative and effective working environment.

As the landscaped atrium and waterways are an integral part of the buildings ecosystem, they have been regularly maintained and today have matured with the buildings systems, so that the Edison Building is as vibrant and energy efficient today as it was in 1997.

Innovative features used over 10 years ago such as solar collectors for hot water, air cooled AC condensers and heat exchange systems, P.E. cells controlling light circuits and rain water harvesting are now becoming common place in 'green' buildings.

The Powerlink Edison Building is a true pioneering sustainable building, that has stood the test of time, and which still has a considerable future ahead of it.

CREATING POSITIVE OUTCOMES FROM OUR BUILT ENVIRONMENT

Suzette JACKSON [1] B. Int. Design

[1] *Senior Associate Sustainable Futures Unit HASSELL, Melbourne VIC Australia sjackson@hassell.com.au*

Keywords: living buildings, positive building outcomes, sustainable, energy efficiency, reduced resource demand

Summary

Our generation is demanding more from our built environment. Not only do we want healthy buildings which are energy efficient; we no longer accept these as independent from the surrounding environment. In the global market we expect buildings and the organisations operating within them to interact with their community and share responsibility for supply and use of our resources. The more aware we are of our environment and the challenges we face, the greater expectation we place on building design and their outcomes. Globally we are challenging the design brief for the built environment in the move towards providing a better lifestyle for all; whilst facing global challenges of climate change, resource depletion and population growth.

Australia whilst only recently competing in 'world leadership' sustainable building design is producing some valuable additions to the built environment, yet is this enough?

Can our future built environment generate and renew the resources our communities require such as positive energy, water, material, food and social outcomes? We have the opportunity to create a new way of living in urban communities and new opportunities for large-scale renewable energy creation.

We explore future visions of how our built environment and sustainable communities could operate through changing values, reduction of resource requirements and our potential to create not just a self sufficient community but an abundant community model for all to share and adopt – the living building model.

Can we create a new breed of built environments that not only operate passively, generating and renewing resources onsite but in addition create enough renewable clean resources to supply themselves and their local community?

We review outcomes from current best practice built environments providing leading design solutions. What do our organisations and their buildings provide back to the community and what should we expect from them?

1.0 Living Built Environments

It would appear that in a frenzy of excess, consumerism and global neighbourhoods we have failed to appreciate the importance of taking responsibility for the resources and waste generated within our regions. Instead we have transported our polluted resources to other regions for disposal out of our sight. Whilst western society is attributed with the creation of much of today's consumer products we are also responsible for much of the earth's pollutions and waste. *How did we become so irresponsible in regards to our own needs and our planet?* The well referenced acronym 'NIMBY' - 'Not in My Back Yard' should perhaps be replaced by 'NIMP' - 'Not in My Planet'. Many older cultures / indigenous cultures value and respect the lands resources, believing they are one with the land, not through ownership but through spirituality and respect for our finite resources. We need to (re)create this respect in all who develop, design and manage our built environment; our community. We need a new understanding within our communities in respect to our environment and our resources.

For people in our community to change their behaviour, education and awareness is required, illustrating how much we waste our resources and pollute our communities through a cradle to grave approach to our resources and buildings. The alternative is to integrate a cradle to cradle approach whereby resources and waste are safe and reused within our community, self generating and creating abundance.

We need to question not only our communities' values but the values and benefits of our large organisations. How much benefit does a large organisation really provide to our community? Should we accept organisations providing a single product alongside many toxic outputs; thereby creating an additional health and resource burdens on our community? If they were a human cell they may be defined as cancerous and we would invest in research on how to rid society of them. As a community we need to demand organisations operate utilising clean inputs and outputs in the process of providing a product/commodity for the community? For too many years we have accepted building and manufacturing processes emitting toxic air, water and waste emissions as part of the necessary evil of modern day living. This has contributed to health problems globally that are related to toxic building materials and wastes; contributing to the enormous and increasing health costs for today's society.

We also have the critical challenge of significantly reducing our greenhouse emissions globally across a number of sectors but specifically from transport, manufacturing and buildings. This is globally understood, reported and supported by organisations such as the World Building Council of Sustainable Development (WBSCD), United Nations Environment Program (UNEP), World Health Organisation (WHO) and the International Program on Climate Change (IPCC).

Due to many current day health, environmental and climate change issues we now look to the design and management of our buildings to create a more holistic environment that will support our ongoing health and community needs. Responding to the needs of today's global community, a new model for the built environment is required, a further evolution from current best practice designs that look at significantly reducing energy and water demands; a new built environment model which not only reduces energy, water and materials demand but generates onsite clean and reusable resources to create building self sufficiency and positive outcomes for the local community.

1.1 The New Model

A new model is being suggested for the built environment which treats the building as a living organism with inputs and outputs operating within a larger ecosystem - our cities, continents and earth. The building itself can be viewed as a finely tuned environment within a delicately balanced ecosystem. Tipping towards an extreme overuse of energy, water and toxic outputs as we have already experienced in the 20th century causes chronic fatigue of the system, leading to more acute conditions globally such as excessive increase in greenhouse gas emissions, warming of the oceans, and melting of the arctic ice. We would do well to perceive the earth as human containing many living organisms. When diseased we need to find the causes and rebalance the system, just as we need to for buildings, cities and regions.

The living built environment model is based upon the concept of clean inputs, clean reusable outputs and mutually beneficial symbiotic relationships with the community. In a similar way to a 'cradle to cradle' approach to individual product design, a living built environment should adopt a cradle to cradle model. This will require living buildings accessing a responsible amount of clean inputs of air, water, energy and people resources, utilising these resources and providing these resources back in to the community to be reused in other ways. By all built environments responsibly utilising community resources and recharging them for use back into the community we can create balanced and abundant resources as demonstrated in Figure 1.

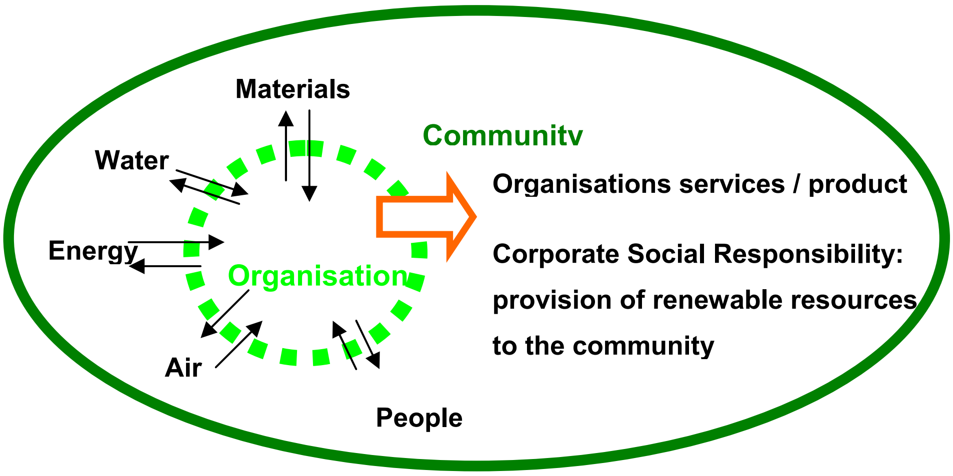

Figure 1 Model organisational operation within a community/planet.

This change to a new model requires business communities and organisations to change their approach from current practices of:

- Overuse of available resources thereby draining resources others require and upsetting the fine balance; and
- Creation of toxic outputs which can no longer be used within the community and only serve to disease the community.

It is the ongoing responsibility of our community to ensure that our buildings are not only designed as positive built environments utilising a cradle to cradle model but that they operate as positively within the community.

1.2 Greater Passive – Energy Building Design

A key objective of 'living buildings' is to minimise building energy use and provide onsite renewable energy generation through the design and operation of the built environment, thereby creating a low energy / self sufficient or energy positive built environment. The rebirth of energy efficient onsite renewable energy solutions such as trigeneration, wind, and solar becomes more viable for part or full onsite energy generation once we have a low energy built environment.

The following concepts consider how we may first minimise our building energy usage.

Passive and complimentary Active Systems: Our buildings need to be designed and operated for passive operations for the majority of occupation. New low energy building models propose annual building operation as 80% passive and as low as 20% active. The previous practice of operating buildings with 100% active systems running 24/7 for convenience is now seen as irresponsible and worst practice. If we are to significantly reduce our greenhouse gas emissions and maintain current rising world population levels we need to design and operate our buildings for general passive operation, with onsite energy generation.

Thermal Comfort / Ventilation Systems: There exists today the technology and expertise for buildings to be designed with both thermal insulation and significant ventilation as required to provide a thermal comfort level (subject to region/climate) for the majority of the year. The provision of separate heating and cooling systems to ventilation systems also allows further energy efficiencies when outdoor conditions are suitable for the internal comfort level. In this case natural ventilation methods or, if required, active ventilation methods may be utilised without activating the heating and cooling system. By creating a thermal building skin and compact building shape we may provide a more uniform indoor temperature allowing further efficiencies, and thereby decreasing the requirement for active heating/ cooling systems.

Whilst the heating load of an older building is approx. 200kWh/m2, more recent buildings designed with sustainable building principles can operate with a heating requirement of around 80kWh/m2. The use of solar passive and thermal design and an appropriate ventilation system with heat recovery can bring down the heating requirements to as little as 15kWh/m2. Buildings with such a low heating requirement are referenced as passive-energy buildings.

Natural /Artificial Lighting Systems: More recent buildings and workplaces are designed with sufficient daylight in the workplace or indoor environment to allow minimal or no artificial lighting during 'good' daylight hours. Artificial lighting needs and energy demand are therefore significantly reduced. This also occurs in modern housing where generally artificial lighting is not required in daylight hours.

In a number of commercial buildings low level artificial lighting and/or task lights are individually switched so end-users can operate lighting on demand when natural daylight is insufficient. Considering many of our built environments occupied by businesses/organisations are only occupied 8-10 hours per day (general daylight hours) and 5/7 days per week, the ability to significantly reduce lighting energy demand by naturally lighting indoor environments for the majority of occupied hours exists.

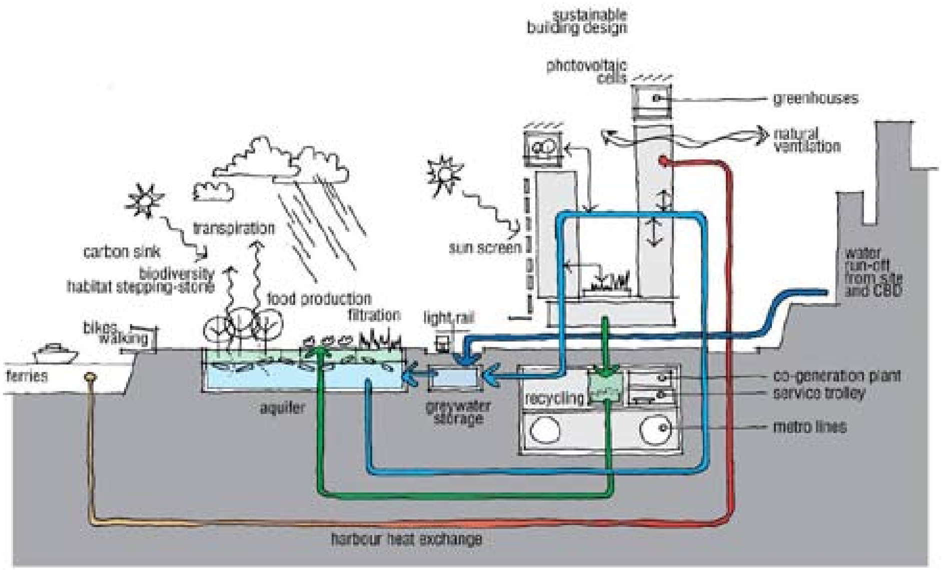
Vertical movement approach: The practice of providing compact low rise buildings with passive vertical movement (stairs) to reduce the need for energy driven movement (lifts) is commonly utilised world wide. Low-rise buildings provide benefits to organisations operating across a number of floors. The increased movement of people across and up floors provides exercise and enhanced communication interaction spaces. The more businesses/organisations encourage a sense of community with employees the greater the flow of natural communication and engagement within an organisation.

We need to choose to build zero energy / positive buildings that are low energy demand and will generate renewable energy for building operation and the community.

1.3 Creating Positive Outcomes – The Other Side Of Zero Demand

If we look at the commercial built environment as a biological process its purpose must be to contribute to the health and prosperity of the community it operates within: a cell (organisation/building) is only successful when the organism (community/planet) it operates within is successful. They have a mutually symbiotic relationship. To be successful the cell will provide a function within the community; it draws on resources to carry out its purpose, but it must also provide back to the community (reusable/non-toxic) resources as a bi-product of performing its role within the community.

Therefore the built environment and the organisations that occupy it must be required to provide the community with outcomes that assist with the success of the community through a balance of give and take of resources. The building/organisation should be required to provide back to the community clean resources from that which they utilised from the community. For example, CH2 Melbourne has been designed to draw black water from the passing street sewer, treat it onsite within the building, utilise treated water for the building operation and recirculate treated water to surrounding community/council gardens for watering purposes. In the 'Living Built Environment' sketch below we consider the inputs and outputs of our built environment in relation to the building operation and surrounding community operation. To achieve successful outcomes for the community the built environment must be fully integrated with the surrounding community and provide a balanced use of resource demand and re/generation.



Sketch 1 Living Built Environment - interrelationships with the environment and community. (HASSELL)

1.4 Future Indicators Of Success

So what do our built environments require to operate as a living built environment? There are a series of resources required as inputs and a series of outputs. To evaluate these we need to create key resource equations and indicators which will define the success of the living built environment. These must be used to continuously check against the design and management of the built environment to ensure a balance of resources is maintained and that the built environment performs a mutually symbiotic relationship with the regional and thereby global community.

Responsible use of local resources:

Each organisation / built environment must be required to demonstrate their positive contribution to society and equilibrium of clean input and output resource demand through a series of equations such as:

Energy Equation

Onsite renewable energy generation	+	Energy capture through building systems /reuse	=	Operational energy demand and renewable energy supply to community

Water Equation

Rain water collection	+	Grey water treatment system	+/or	Black water treatment system and sewer mining	+	Potable water resource from community	=	Operational Water demand and clean water supply to community

Air Equation

Clean indoor air quality with zero off gassing of toxins, pollutants or contaminants from equipment furniture or materials	+	Passive and active ventilation - air input from natural ventilation and active building systems, clean air outputs form building systems	=	Clean / healthy air provision for building occupants and local community

There must be clean and balanced inputs and outputs of energy, air and water resources of the built environment or organisations, as opposed to unbalanced and high resource demand of energy, air and water resources and toxic emissions. This is then extended and applied to all resource use and output. Organisations must ensure they generate clean bi-products throughout their operation. Products and services must begin to capture the cost of emitting clean bi-products / resources for the communities use.

The following criteria apply not just to the built environment operation but to an organisations operation within the built environment. These measures require an organisation to share community responsibility for the balanced use of community resources: ensuring clean inputs are balanced with clean outputs and that theirs is a self generating cycle of resources and materials within our built environments and each community.

Procurement of materials input: Procurement of simple products produced with clean/reusable emissions from recycled non toxic content and recyclable; cost of removing material to include disassembly ready for reuse in other products

Procurement of equipment input: Procurement of simple equipment and systems that are produced with no emissions/toxicity from recycled non toxic content and recyclable and produce no toxins in operation; Cost of removing equipment to include disassembly ready for reuse in other products

Recycling of materials and equipment: Procurement of equipment and materials to take into account long term usage, ability to be repaired/maintained/upgraded; and simplicity of systems to enhance long-term usage and maintenance

Food Input: Source local, seasonal and responsibly grown / produced fruit and vegetables, meats and legumes; source food produced without toxins, grown in suitable areas where toxic industry does not exist, and soil is non toxic.

Food Cycle: Ability to grow seasonal produce onsite or contribute to local production for local community consumption.

Food Output: Share / Compost food excess with business/ local community growers / community garden

Transport Input: Support and sponsor equitable public transport free from toxic emissions. Encourage and support pedestrian and bicycle transportation for employees and local community.

Transport Cycle: Support consumer availability of low cost/ no emission private transport options; Provision of cycling and pedestrian safe paths onsite and in community; provision of work within proximity to affordable sustainable housing communities**;** provision of onsite cycle storage and onsite charging of zero emission shared and private vehicles (such as electric/compressed air vehicles).

Transport Outputs: Investment into vehicles creating no emissions in operation and fully recyclable

Community / Social Output: Provide community services / support as appropriate for the region/ community size in physical environment or voluntary assistance through a range of community sectors (this already includes the provision of community facilities such as meeting spaces, shared fitness facilities, parklands, education and conferencing, community volunteering etc).

Corporate Social Responsibility (CSR) Community / Social Input: Source employees from region; incorporate/sponsor training and education within the region to ensure skills base; source experts and advisors from the region.

Due to the pressing need for cleaner energy and water resources organisations may focus social program opportunities on assisting the entire community to balance resource demand with resource availability. This requires business/organisations to ensure they minimise energy and water demand through reduced intake, provision of onsite generation and excess generation for community use.

2.0 ACHIEVEMENTS OF COMPLETED BUILT ENVIRONMENTS

2.1 Reductions, baselines and operational management

In the past 10 years Australian organisations and the building industry have made significant changes in the way we operate, manage and design our built environments. In response to a number of growing concerns, international standards and corporate best practices, we have increased our building efficiencies and moved toward a more environmental and sustainable building model.

Over this time a number of organisations have contributed significantly to our understanding and increasingly sustainable approach. The establishment of the NABERS Energy tool (previously ABGR – Australian Building Greenhouse Rating) by the NSW state government in the late 1990's provided benchmarking and baseline data on building and tenancy energy usage. This has been further developed to provide water, waster and indoor air quality benchmarking tools under the NABERS rating scheme. With the commencement of the Green Building Council of Australia in early 2000 and subsequent creation of the Green Star Rating system, Australian design and building professionals finally have a suite of rating tools to evaluate the built environment. This has inspired the Australian building industry and provided centralised resources, benchmarking and case studies for our built environment and industry professionals.

The establishment of Australian building environmental rating tools was further assisted by both State and Federal Government Green Star/ABGR mandatory benchmarking requirements. The referencing of these tools by the Property Council of Australia in the PCA commercial building rating has ensured further implementation by the Australian commercial built environment.

More recently we have seen the uptake of Environmental Management Systems (EMS) for many organisations as part of their environmental initiatives to operate with a more responsible use of resources and provide continual improvements. With impending Emissions Trading Schemes, Carbon Reporting is also implemented within organisations. This will enable an organisation to be well prepared to both monitor and reduce the greenhouse gas emissions. We envisage these operational and organisational indicators will become critical for building designers in the future.

Ongoing education, training and case study information from International and Australian rating tools and contributing organisations assists in the further evolvement of Australian sustainable and energy efficient buildings. Data and Case Studies from these two Australian rating tools have provided benchmarks and best case scenarios for much of what we design and build today.

2.2 Success against current indicators

Benchmarking sustainability initiatives and outcomes allows us to better understand areas of building design and operation requiring improvement. Australian buildings show a range of success against standard energy building measures where benchmarked against he NABERS tool. Measures utilised reference electricity density measured in MJ per m2 area and kWh usage. Current Best Practice for a building or tenancy currently sits between 5 and 5 + 40% ABGR (refer www.nabers.com.au).

The referenced buildings discussed in Section 3 reference current benchmarking measures provided by the Australian environmental building tools. Whilst only small samples of Australian buildings are referenced in this paper the results are indicative of what we find in the broader built environment in Australia.

Through the use of the ABGR/NABERS Energy tool many new buildings are achieving 30-60% savings in their energy rating as compared to a standard commercial building. Through the use of the Green Star rating scheme we have seen significant improvements in potable water reduction and air quality/ventilation rates.

Through the process of utilising these rating tools and the follow-up case studies industry benchmarks are created. Measuring environmental benchmarks thereby provide the feedback mechanism to the community for improvements to building design, informing and educating the community about what is being achieved and what more we can do. With these built environment tools and organisational Environmental Management System's (EMS) we as a community are seeing reduced energy demand from Australian buildings.

3.0 PREDICTED ACHIEVEMENTS OF CURRENT BUILDING DESIGNS

3.1 Reductions and New Initiatives

Current sustainable building design undertaken has lead to a greater understanding of sustainable building models suited to our region and changing climate. As our designs improve in respect to energy and more recently water resource use, we begin to introduce a new set of measures that are becoming more consistent and drive improvements in not only design but organisational commitments to the environment. The design, construction and operation of the following two buildings raise current best practice built building standards, providing alternative building system combinations, consistent benchmarks and case study references by further reducing energy and water demand and integrating new initiatives in building design.

CH2 Council House 2 Little Collins Street Melbourne

The CH2 building completed in 2007 by Melbourne City Council has been successful in lifting current best practice building standards in Australia. Through published research, building case studies and Productivity study outcomes, CH2 has contributed greatly to our building measures and perception of what is possible in our built environment.

The building is a 10 storey commercial office building with underground car and bicycle parking and ground floor retail space providing community engagement and activation. The building has a commercial office net lettable area of 9373m² and retail net lettable area of 500m².

The building systems utilised are non-conventional and challenge our notion of low energy technology.

The 'energy system' comprises: a cogeneration unit providing 60kVA of electricity which is estimated to supply 30% of buildings need; a Photovoltaic (solar) system supplying 3.5kW of electricity; solar hot water heater supplying 60% of hot water requirements; and wind turbines[1].

The 'water system' comprises: sewer mining and black water treatment of 100KL capacity per day to A grade quality; and a rainwater harvest capacity of 15KL. The estimated water usage reduction in comparison to existing building standards is 72%. The water system is designed to enable the council to utilise recycled water fro the building for use on local council parks and gardens, creating a positive benefit to the community.

The 'heating and cooling' system comprises: chilled ceiling panels within the office ceilings and radiant heating panels, along with shower towers to the southern façade to cool air used back into the building. Purge windows used in summer nights reduces cooling requirements by an estimated 20%.

The ventilation system allows for 100% fresh air intake.

The lighting system comprises: low level general lighting (150 lux supported by task lighting which is estimated to save 66% of lighting energy use.

The building is designed to maximise benefits from climatic conditions with individual façade design based on building orientation.

CH2 is a certified 6 star Green Star Office Design rating by the Green Building Council of Australia, and has achieved an ABGR (NABERS Energy) 5 star +20% reduction in carbon dioxide emissions. CH2 nominates on their website they are currently registered to achieve Green Star As-Built rating for the building also. The key success of this building would be the council's openness and transparency of the design process and building outcomes and the contributions to low energy building design research and case studies internationally which inspires our global community.

VS1 Victoria Square Adelaide

The VS1 building will house SA Water from November 2008 and has already generated much interest in the sustainability principles applied to the laboratory component and the building design overall. The building has already achieved a 6 star Green Star Office Design rating by the Green Building Council of Australia, and is registered for the Green Star As-Built rating and Green Star Office Interior rating. Through conference presentations and case study publications of the building design and predicted outcomes, VS1 has already contributed to the current understanding of building design and systems required for sustainable buildings. Productivity studies are underway which will add to current understanding of sustainability principles and productivity links.

The building is a 10 storey commercial office building with underground car and bicycle parking and ground floor information centre for SA Water providing community engagement and activation. The building has a commercial office net lettable area of 12000m^2 and laboratory net lettable area of 5000m^2.

The building has been designed with open stair ways and a central atrium to create greater internal daylighting, views and interaction between the commercial, laboratory and retail component of the building. The building systems utilised are conventional and non-conventional commercial building systems and together challenge our notion of low energy technology.

The 'energy system' comprises: a gas fired co-generation utilising a combined heat and power unit to generate power, heat hot water and run an absorption chiller; generates 25% of the base electricity load; and a photovoltaic (solar) system on the roof; and solar hot water. The 'energy system' for the laboratories includes: risk assessment approach to validate the use of ganged fume cupboard ductwork allowing significant reduction in fan energy; energy recovery from return air stream; demand reduction; and laboratory equipment efficiency. The building is estimated to achieve a reduction of approximately 50% in comparable greenhouse gas emissions and energy costs compared to a typical office building.

The 'water system' comprises: black water treatment to A grade quality; cooling tower water is recycled; fire test water collected and re-used; and rainwater harvested (from the roof of the building and the school roof next door). Due the significant focus placed on water reduction and recycling the office building is estimated to use a reduction of approximately 70% in potable mains water consumption compared to a conventional office building – a saving of 11 million litres per annum.

The 'heating and cooling' system comprises: high efficiency underfloor displacement ventilation system with individual control to occupants; and night purge of air removes heat and cools the building structure. The ventilation system uses 100% fresh outside air under most operating conditions.

The lighting system comprises: 75% of the office area lies within 8m of windows and the atrium; increased natural daylight and 18% less base building general fittings.

The building is designed to maximise benefits from climatic conditions with individual façade design based on building orientation. A fritted western veil in front of the building skin reduces the solar load on the western facade while still retaining views and daylight. High performance double glazing is utilised for the north, south and east facades.

VS1 has been developed as a commercially viable building that brings together many developed technologies to create a low energy building systems. The key success of this building would be the organisations commitment to leading low energy design and best indoor environment quality including improved air quality and design for the laboratories areas. The building and its operation will be monitored after completion with the outcomes providing further benchmarking indicators to ensure continual improvement in our building design and management.

3.2 Success Against Living Building Indicators

Obtaining consistent measurable indicators which can be used universally will allow us the greatest ability to move forward quickly and achieve our greenhouse gas emission and water reduction targets whilst achieving a built environment which achieves our community requirements.

The CH2 building design explores non-conventional building methods and systems to create a low energy, positive building which is successfully communicated to the community from the building construction process to occupation in 2007. Since then we have seen a greater uptake of commercial buildings demonstrating the viability of low-energy buildings in today's market demand. VS1 demonstrates the ability to use sustainable building design and conventional systems to create a commercially viable low-energy building only a year later than the completion of CH2. IN addition to this both organisations operating these buildings are progressive and demonstrate a commitment to improved environmental outcomes which includes an environmental policy, Environmental Management System and the creation of carbon reduction targets and carbon management.

What more can we expect from our leading buildings in the next couple of years? Benchmarking sustainability initiatives and outcomes from current and future building designs against the indicators of success for 'living buildings' will allow us to better understand our most recent improvements and move us closer to creating a low energy - positive living building model.

4.0 WHAT WILL IT TAKE TO CREATE THE LIVING BUILT ENVIRONMENT?

As in all areas, we cannot manage and improve upon that which we do not measure. Whilst we have the vision and technology to design living buildings which operate partially self sufficient of community infrastructures and provide recycling of resources and positive community outcomes, we are still developing consistent measures and benchmarking of built environments required to provide the understanding and improvements required at an international level.

What we must work towards now is the sharing and implementing of consistent benchmarking across all built environment key indicators. Whilst we understand holistically the principles required we all must take ownership of this issue and provide international measures.

So what will it take to create the model of living built environment? Technology is already available to create positive living as such. It will require education, expertise will power and cultural change to drive this. It also requires each individual, community, organisation, Government and Non Government Organisation to take responsibility for the resources they use and commit to sharing resources and the generation and reuse of clean outputs which supports mutual symbiosis within our entire community.

Our built environments, organisations and sustainable communities can and should operate to create not just a self sufficient community but an abundant community model for all to share and adopt – the living building model.

Footnote [1]The electricity generation from the CH2 rooftop wind turbines are unknown at time of publication. Information on CH2 has been obtained form published case study information available for the Melbourne City Council website. Refer www.melbourne.vic.gov.au

Summary

In Japan, approximately 500,000 detached houses are constructed per year. In order to improve the quality of houses, the “Comprehensive Assessment System for Building Environmental Efficiency (CASBEE) for Home (Detached House)” was introduced in 2007.

Since the CASBEE for Home is expected to be used by various stakeholders in the housing construction industry, such as clients, designers, contractors, and builders, it is designed to be easy to use. The structure of the CASBEE for Home" is similar to that of other CASBEE tools, and it can be used to evaluate both quality and environmental loads. The evaluation criteria are divided into 6 categories— Q1: comfortable, healthy, and safe indoor environment; Q2: sustainability to service life; Q3: regional contribution for view and ecology; LR1: energy and water conservation; LR2: resource conservation and reduction in construction waste generation; and LR3: contribution to improvement in regional and global environment. The assessment also includes 54 evaluation criteria that are based on the standards established in Japan. The comprehensive assessment considers not only the features of houses but also the features of their surroundings, the home appliances used by the occupants, the information provided to the occupants by the house owners, and the techniques used in the building material production and house construction.

The results for the case studies were obtained by using the CASBEE for Home. A total of 25 case studies were conducted at several construction sites from Hokkaido (northern part of Japan) to Kyusyu (southern part of Japan). For the case studies, 15 wooden (columns and beams) houses and 10 prefabricated houses comprising lightweight steel framework or wooden panels were selected. In addition, case studies of model houses that were built without taking the environment into consideration, taking the environment into consideration to some extent, and taking the environment into consideration in detail.

1. Introduction

The CASBEE evaluates the environmental load from various viewpoints. With the future of mankind being threatened by advancing global warming, it is necessary to build environment-friendly houses by reducing their environmental load. The use of CASBEE to evaluate houses is a very effective technique for reducing the environmental load. If the CASBEE is used extensively, environmental load of houses can be reduced to a large extent. The CASBEE also assesses the environmental quality of houses from various viewpoints, which aids in improving their quality. Builders are expected to construct comfortable houses, maintain them assuming them to social assets, and hand them over to their owners.

CASBEE tools for new buildings, old buildings, buildings in urban districts, etc. have already been developed. The CASBEE for Home was introduced in 2007. It evaluates the general environmental conditions on the basis of the two indices Q and L. Index Q is used to assess the improvement in the environmental quality within a hypothetical enclosure, and index L is used assess the negative impact on the external environment of the hypothetical enclosure. The BEE for a virtual enclosure is evaluated as shown in Figure 1. Each factor related to Q and Load Reduction (LR) shown in Tables 1 and 2 is evaluated. In this paper, we report the results of the case studies of the CASBEE for Home (Detached House). L indicates the environmental load and is evaluated on the basis of LR. The BEE chart is shown in Figure 2. Houses are given grades 1–5 on the basis of their BEE, and their grades are indicated by stars. Figures 2–4 present the results of the evaluation obtained using the CASBEE. The radar chart shows the equilibrium between the 6 criteria, Q1–Q3 and LR1–LR3. The warming effect chart shown in Figure 4 presents the $LCCO_2$ of a simple detached house and shows the reduction rate comparing to referenced general houses. The bar charts show the grades assigned to the houses on the basis of 21 additional criteria, which elucidates the equilibrium between the criteria. Using these criteria, detached houses can be evaluated precisely, and the results of the evaluation can be presented effectively through charts.

Table 1 Criteria for Q

Main Criteria	Additional Criteria
Q1 Comfortable, Healthy, and Safe Indoor Environment	1. Hotness and Coldness
	2. Health, Security, and Safety
	3. Brightness
	4. Peaceful Atmosphere
Q2 Sustainability to Service Life	1. Basic Life Performance
	2. Maintenance
	3. Functionality
Q3 Regional Contribution for View and Ecology	1. Consideration of Townscape and Scenery
	2. Creation of Biological Environment
	3. Safety and Security in Region
	4. Utilization of Regional Resources and Assimilation of Regional Culture

Table 2 Criteria for LR

Main Criteria	Additional Criteria
LR1 Energy and Water Conservation	1. Energy-saving Design of Buildings
	2. Energy Conservation by Use of High-efficiency Equipments
	3. Water Conservation
	4. Devices of Maintenance and Management
LR2 Resource Conservation and Reduction in Construction Waste Generation	1. Use of Materials that Aid in Resource Conservation and Reduction in Waste Generation
	2. Reduction in Waste Generation in Production and Construction Stages
	3. Promotion of Recycling
LR3 Contribution to Improvement in Regional and Global Environment	1. Consideration of Global Warming
	2. Consideration of Regional Environment
	3. Consideration of Immediate Environment

2. Range of Evaluation Criteria and Outline of Results

A total of 25 case studies were conducted on houses located in the region from Hokkaido to Kyusyu; these houses were constructed by using various methods and included both conventional wooden houses and modern houses. The list of case studies is provided in Table 3. In the case studies, 15 conventional wooden houses and 10 prefabricated houses comprising lightweight steel frameworks or wooden panels were considered. The case studies also included model houses that were built without taking the environment into consideration (Case 26), taking into consideration the environment to some extent (Case 27), and taking into consideration the environment in detail (Case 28). The specifications of the model houses are listed in Table 4.

The results of BEE are shown in Figure 4. Because we have chosen relatively good cases in which energy is conserved and/or the quality of environment is improved, we obtain relatively high grades. It can be observed from the results that the model houses have received high grades, which indicates that people are increasingly growing concerned about environment (Cases 26–28).

3. Results of Evaluation

The results of the evaluation are presented according to the evaluation criteria adopted in the case studies.

3.1 Q1: Comfortable, Healthy, and Safe Indoor Environment

The assessed houses in general got high ranks for insulation quality because approximately 90% of them satisfied the Next Generation Energy-Saving Standards established in Japan, and the air conditioners and heating systems were appropriately designed. However, a grade was low for the model house and for the case in which the air-conditioning units were not selected when evaluation. With respect to the building material, most of the houses got grade 5, which was the highest grade given in the evaluation, because they were made of ☆☆☆☆ building materials, which emit a low amount of VOCs. In the meantime, more than 50% of the houses got grade 3 with regards to prevention of house break-ins. In some cases such as Case 14 had laminated glass panes.

3.2 Q2: Sustainability to Service Life

The assessed houses in general got the highest grades for their earthquake-proof designs and natural-disaster-proof designs. The design of houses is the primary factor on which the strength of houses in Japan depends on. However, more than 50% of the houses got grade 3 with regard to the quality of outer wall and roof. With regards to barrier free, 50% of the houses got only grade 2 nevertheless there is a standard set in the law for promotion to secure the quality of house in Japan.

3.3 Q3: Regional Contribution for View and Ecology

Most of the houses got above grade 4 with regards to the arrangement of the building and the surroundings taking into consideration the landscape or safety. With regard to the use of local resources and the cultural heritage of houses, most of them got grade 3 because of the efficient use of the appropriate building materials or consciousness of use. However, the houses in Case 1, in which local building materials were extensively used, got grade 5.

3.4 LR1: Energy and Water Conservation

As mentioned previously, the assessed houses had high-quality insulation. However, most of them got grade 1 with regard to the efficient use of natural energy. With regards to the performance of air-conditioning units and hot-water supply systems, around 50% of them got grade 5 for air-conditioning units and around 80% of them got level 5 for hot-water-supply system. This was because most of the hot-water-supply systems is served together with house and easy to serve with explanation about effectiveness of the saving energy equipment. However, more than 50% of them got grades lower than grade 3 with respect to the insulation in bathrooms and piping. With respect to the effective use of energy, 2 cases had combined heat and power systems and 13 cases had photovoltaic power generation systems. They got high grades with respect to water conservation because most of them had water-saving-type equipments, but only 3 cases have rainwater tanks. Fifty percent of the houses served as model houses providing information on the ideal way of living and house maintenance and management.

3.5 LR2: Resource Conservation and Reduction in Construction Waste Generation

The houses generally got grade 3 with regards to the use of building materials taking into consideration resource conservation and reduction in the generation of construction waste. They got low grades because recycled building materials such as wood-based composite board or plasterboard for the finishing material were not used extensively although they use for back materials of both exterior and interior. On the other hand, most of the houses got grade 5 for their contribution to reduction in the waste generation during production of the building materials or construction. Thus, it is evident that environmental issues have been seriously taken into consideration by designers and builders.

3.6 LR3: Contribution to Improvement in Regional and Global Environment

Most of the house got high grades with regard to the contribution to the improvement in the surrounding thermal environment through appropriate building arrangement or tree plantation. With respect to the conservation of natural environment, more than 50% of them got grade 3.

4. Conclusions

The CASBEE (Comprehensive Assessment System for Building Environmental Efficiency) is an environmental labeling tool for buildings and is based on the assessment of the environmental parameters with respect to the building design. In Japan, approximately 500,000 detached houses are constructed per year. In order to improve the quality of houses, the “CASBEE for Home” was introduced in 2007.

The results for the case studies have been obtained by using the CASBEE for Home". A total of 25 case studies have been conducted at several construction sites from Hokkaido (northern part of Japan) to Kyusyu (southern part of Japan). It can be observed from the results that the model houses have received high grades, which indicates that people are increasingly growing concerned about environment. The results of the evaluation have been presented according to the evaluation criteria—Q1, Q2, Q3, LR1, LR2, and LR3—adopted in the case studies.

Summary

Building standards in Australia are controlled under an Inter-Government Agreement (IGA) between the Commonwealth Government and the governments of the states and territories. The IGA provides for an Australian Building Codes Board (ABCB) to create and manage the Building Code of Australia (BCA). Traditionally, building codes in Australia, and the BCA as first developed, have been concerned with minimum life-safety standards. The introduction of sustainability standards into the BCA has brought many challenges, not least of which are how to determine sustainability standards for energy and water use in buildings, and how to deliver them in a contentious political environment.

This paper outlines the introduction of energy-use standards for housing into the BCA, and then deals with the technical and political issues faced in Western Australia in going beyond the coverage of the BCA to introduce standards for greenhouse gas reductions in water heating and reductions in potable water use. It shows the rationale of the Western Australian Government for introducing these measures and gives an insight to the complex decision-making issues that surround public policy development in sustainability.

1 Introduction

Sustainability has been a key focus of the Western Australian State Government since 2003 when the introduction of the State Sustainability Strategy officially acknowledged its importance. The Strategy set out a range of actions under six major headings - governance, global sustainability, natural resource management, settlements, community and business. This was then supplemented by various other strategies that furthered sustainability in the State. These include the Greenhouse Strategy 2004, the State Water Strategy 2003, the State Water Plan 2007, the State Water Recycling Strategy 2008 and the Premier's Climate Change Action Statement 2007.

Sustainability has also been a key feature in the expansion of the scope of the BCA. Emerging environmental, social and economic trends have driven the momentum for increased sustainability measures in buildings. The Western Australian policy development experience in this area is unique in that two separate policy options were developed in parallel, a Western Australian version of the New South Wales' BASIX assessment tool and the BCA. This situation has led to the introduction of 5 Star Plus, which brings water efficiency measures into the BCA for the first time. This has preceded national policy development by the ABCB, which is just starting to research possible options for water efficiency and energy use in water heating.

2 Energy Standards in the Australian Building Regulations

In the late 1990s it became obvious to Australian governments that energy use in buildings was increasing significantly, and this was causing both greater greenhouse gas emissions from power stations and substantial infrastructure costs in delivering enhanced electricity and reticulated gas supplies. Of particular note was the rapid increase in use of reverse-cycle air conditioners during summer in Australia at a time when traditional "Californian bungalow" house designs were being superseded by Georgian and Tuscan styles with no eaves and exposed windows. These "M^{c}Mansions" were often poorly insulated, badly oriented and offered little scope for natural ventilation. By 2001 there was a growing belief that regulation through appropriate building standards was needed to ensure an adequate level of thermal performance in housing, as well as in commercial buildings.

In 2001 the ABCB was asked to prepare energy use standards for buildings. The first BCA energy provisions for detached houses were introduced in 2003, and steadily extended to cover all classes of buildings by 2006. These provisions addressed energy use in heating and cooling by requiring appropriate insulation, reduced heat gain and loss through windows and provision of adequate natural ventilation (ABCB, 2007a). In 2006 the standards for detached houses were increased to what is colloquially known as the "5 Star" standard. As is the case with all BCA standards, these provisions are set out as a performance requirement which can be met by using any scientifically valid building solution, or by adopting "deemed to satisfy" building solutions that are set out in the BCA (ABCB, 2007b)

In parallel to the development of these BCA standards, the New South Wales Government developed a sustainability tool known as BASIX. BASIX adopted energy provisions similar to the BCA to deal with thermal comfort, but added provisions to deal with water heating, appliance use and water use in houses and for landscaping. BASIX is applied through the planning system using an on-line certification process that allows a designer or owner to try different combinations of energy or water saving strategies to meet the required target reductions, before obtaining an online compliance certificate (New South Wales Government, 2007).

Increasing BCA energy provisions to the 5 Star standard, and in New South Wales the introduction of BASIX, proved politically contentious. A great deal of debate occurred about the true cost of introducing these sustainability provisions into houses, with suggestions ranging from no cost if a house is properly designed, to upwards of $20,000 for full compliance with all the energy and water saving requirements of BASIX. Because of industry lobbying, and because of their own concerns about housing affordability, some governments remained cautious about adopting the BCA 5 Star standards, while others were keen to go further and include provisions for water saving and water heating.

The IGA that governs the operations of the ABCB and the ABCB's commitment to best-practice regulation require each proposal for new regulation to be subjected to an appropriate Regulatory Impact Statement (RIS). This looks in detail at the costs of the proposed regulation, the benefits that flow to both consumers and the community, and whether non-regulatory approaches are a better alternative. Because of the differing views of possible cost, the 5 Star RIS was subjected to a high level of scrutiny and review. The final RIS demonstrated a small but positive benefit over cost.

At the November 2005 meeting of the ABCB board, the final decision was made to include the 5 Star provisions in the BCA for 2006. This decision was contentious. The ABCB noted that a number of governments were committed to proceeding with the 5 Star standards, whether they were included in the BCA or not. The Board believed that it was better to publish the standard as part of the BCA, with those governments not wishing to adopt it able to "vary it out" rather than not adopt it, and run the risk of some governments developing their own standards that were not compatible with the BCA proposals or similar proposals in other jurisdictions.

3. Water Use Requirements in Buildings

There are at present no sustainability provisions in the BCA dealing with water use, in the same way that energy provisions have been included. Studies are under way for the development of water use standards (ABCB, 2007c). Sustainable water use in housing relates to water used inside the house for cooking, washing and flushing of toilets and to water used outside the house for landscaping, swimming pools and the like. Normally BCA provisions would relate only to the fabric of the building and it is debatable whether BCA standards should regulate water use in landscaping where a building permit is not required.

Potable water is typically delivered through reticulated pipes by centralised water utilities. Conditions of drought in Australia, coupled with expanding urban areas and limited access to new water supplies or dam sites, have limited the amount of potable water available for household use. Most governments have responded to these conditions by imposing restrictions on how water can be used for landscaping, and some governments have gone further in trying to reduce water use within the house. Strategies for reducing water consumption are based on the use of reduced-flow fittings or appliances, or by substituting alternative water supplies for reticulated potable water. These strategies have not been uniformly applied across Australia, in Queensland, for example, the State Government has introduced building standards in addition to the BCA to deal with water use. In New South Wales, BASIX deals with both internal and external water use, as well as energy use.

4. The Western Australian Context

Western Australia is a large state with climatic and geographical conditions ranging from tropical monsoons in the north, through deserts in the centre to temperate woodlands in the south. Perth, the major city, is located on the south west coast and has a Mediterranean climate with high temperatures in summer and most rainfall concentrated in winter. Perth and the south western region of Western Australia have been subject to a step-change in rainfall since the mid-1970s as shown in Figure 1.

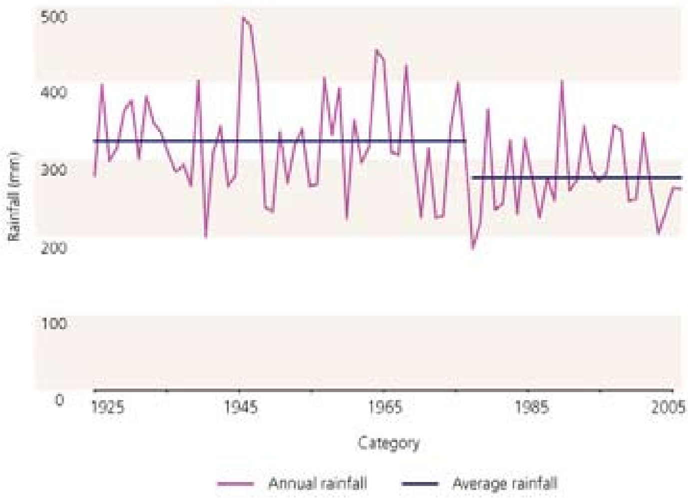

Figure 1: How our rainfall has changed – the South West (Indian Ocean Climate Initiative, 2005)

4.1 Western Australian Separation of Building and Planning

Political responsibility for building standards and applying the BCA falls to the Minister for Housing and Works while responsibility for the planning system falls to the Minister for Planning and Infrastructure. This is different from some other states that combine building standards and planning within the same ministerial portfolio.

Western Australia adopted the BCA 5 Star standard in 2006. A transitional provision in the State's building regulations allowed this to be phased in over a 12-month period with minimal adverse affect on house prices or industry capacity to deliver.

4.2 BASIX and the BCA

While the introduction of the BCA 5 Star Standard was under control of the Minister for Housing and Works, the Minister for Planning and Infrastructure became an enthusiastic supporter of the New South Wales BASIX system and commenced feasibility studies for the introduction of BASIX in Western Australia. The advantage of BASIX was that it goes further than the BCA and deals with energy use in water heating and appliances, and with water use for internal purposes as well as landscaping (Pracsys, 2006). Because BASIX requires an estimate of likely energy and water savings from a pre-determined benchmark it also provides a measure of potential energy and water savings that can be monitored and used for infrastructure planning (Pracsys, 2006). The disadvantage of BASIX was that it required considerable technical work to make the computer systems and website applicable to Western Australian requirements, required amendments to either planning or building legislation and introduced an additional step in the building approval process. Industry associations were wary of any regulation that would change the way houses and land were delivered in Western Australia At the same time many environmental groups and local governments agitated for early adoption of enhanced sustainability standards.

It was clear to all stakeholders that the energy provisions in the BCA did not go far enough and further regulation would be needed to deal with issues such as water use and water heating. In late 2006 the housing industry began to lobby government to make a clear statement on whether it was to use the BCA or BASIX as its sustainability tool for houses, and reiterated its opposition to increasing sustainability standards that only applied to new houses. In particular the industry emphasized its preference for "deemed to satisfy" standards rather than complex assessment tools such as BASIX. In early 2007 representatives of the housing industry approached the Government with a proposal to adopt a simple checklist of standards, coupled with rebates and educational campaigns focused at existing housing. Eventually the State Government adopted a position that it would quickly introduce additional "deemed to satisfy" provisions through the existing building regulation system. These were implemented by the Department of Housing and Works as "5 Star Plus". Further consideration of BASIX was deferred until a national working group had clearly delineated what sustainability measures should be managed through the planning or building regulatory processes, and what sustainability tools should be adopted for national use.

5. What is 5 Star Plus?

5 Star Plus was launched in May 2007 as part of the *'Premiers Climate Change Action Statement'*. It addresses the energy and water efficiency of the building stock in the State via two new codes: the *"Energy Use in Houses Code"* and the *"Water Use in Houses Code".* The Energy Use code applied from 1

September 2007. The Water Use code is split into two stages (Department of Housing and Works, 2007). The first stage was also applied from 1 September 2007 with the second stage to be introduced from 2008.

The *Energy Use in Houses Code* confirms the 5 Star energy rating provisions within the BCA, and requires low greenhouse hot water systems, which must be either a:

- Solar hot water system;
- 5 star gas system; or
- Heat pump system.

The *Water Use in Houses Code*, Stage 1 requires:

- Water efficient fixtures and fittings – 3 star WELS rated showerheads, 4 star WELS rated taps (except bath and garden taps) and 4 star WELS rated dual-flush toilet;
- Swimming pool and spa covers; and
- The pipe from a hot water system to the furthest hot water outlet cannot be more than 20 metres long, or 2 litres internal volume.

Stage 2 proposed:

- All new houses be arranged or pre-plumbed to allow an alternative internal water supply (rainwater tank, bore water, third pipe) to be fitted at a later stage without breaking into the fabric of the house;
- New houses on suitable lots be arranged or pre-plumbed allow a grey water diversion system to be fitted at a later stage without breaking into the fabric of the house;
- Those houses that are likely to use large amounts of scheme water internally to install an alternative internal water supply; and
- Those houses on lots of a size likely to use large amounts of scheme water on landscape watering to install an alternative internal or external water supply, or greywater system.

6. Developing 5 Star Plus

As outlined above, 5 Star Plus was required to be a "deemed to satisfy" set of building solutions that delivered useful sustainability outcomes within the current building approval process, and did not require variation from the BCA. The philosophy that underpinned the development of the standards was that energy (and particularly energy that involved emission of greenhouse gases) and water were scarce resources that should not be wasted, and that where possible, high quality energy (for example grid electricity) or potable water should not be used for low quality uses. A scan of existing or proposed regulations in other jurisdictions, including BASIX and the proposals from the housing industry, provided a menu of possible responses. These had to be confirmed with stakeholders before they could be adopted.

In principle 5 Star Plus was a compromise position between government, wishing to make early progress in dealing with greenhouse gases and water shortages, and industry seeking simple, easily implemented solutions that would not impact on housing prices and affordability. Because of the short time-frames available, consultation during the drafting of 5 Star Plus primarily occurred with industry peak bodies and core government agencies. Because of this limited consultation a number of more adventurous possibilities were not taken up, and the responses adopted are very much a minimum standard.

7. Drafting the Codes

A key factor in drafting the 5 Star Plus codes was to establish a framework that could be used at a later date by the ABCB to accommodate all state and territory additions to the BCA that covered water heating and water use. Also the codes had to read logically as a self-contained document. The key to writing the codes was to adopt the hierarchy and terminology of the BCA that works from an ***objective*** via a ***functional statement*** to a set of ***performance standards***. It is permissible to adopt any building solution that can be demonstrated to meet the performance standards, or the ***deemed-to-satisfy*** building solutions contained within the codes (ABCB, 2007b). In practice most builders will adopt the deemed-to-satisfy solutions, and it was these that required the most consultation and adaptation.

8. The Energy Use in Houses Code

The Energy Use in Houses Code has the objective to reduce greenhouse gas emissions. In order to reduce greenhouse gas emissions a building, including its services, is to be capable of efficiently using appropriate sources of energy. Two of the performance standards set out in the code repeat the BCA 5 Star provisions for energy efficiency of a building and its services. The third performance requirement is that a building's hot water systems, including any associated components, must have features that produce low levels of greenhouse gas when heating water.

8.1 Deemed-to-Satisfy Provisions —Hot Water Systems

For domestic hot water, the common aim was to replace electric hot water systems, ultimately dependent on fossil fuel-fired power stations, with solar hot water (preferred) or high-efficiency natural gas systems. Reticulated natural gas is widely available in Perth and the south-west region and gas hot water systems are standard fittings in most project homes. Bottled gas is popular in regional areas where gas is not reticulated. Although the capital cost is higher, the climate in Western Australia is highly favourable for solar hot water and there is good market penetration and supply by local manufacturers. Electrically driven heat pump water heaters are new on the market, but have been proven in remote areas where gas or solar have proven uneconomic. They provide an alternative that is perhaps more suitable for replacement of existing electrical storage hot water systems, and are particularly economical when used at off peak electricity rates. There was little debate in requiring new homes to have either a:

- Solar hot water system; or,
- “5 star” gas hot water system; or,
- Heat pump hot water system.

9. Water Use in Houses Code—Stage 1

The Water Use in Houses Code’s objective is to reduce water demand by efficiently using water, minimising the waste of water and facilitating the efficient use of alternative sources of water. To reduce potable water demand a building must enable the efficient use of potable water, prevent the excessive loss of potable water, have the capacity to connect to alternative sources of water supply and use alternative sources in situations of high water demand or restricted availability of potable water. Reducing demand and minimising waste were not controversial matters and there was a high level of support for provisions adopted to deal with these. As a result these were implemented as part of Stage 1. The problematical provisions for alternative water supplies were held over to Stage 2. The three Stage 1 performance requirements relate to water use efficiency, water loss prevention and hot water use efficiency.

9.1 Deemed-to-Satisfy Provisions—Water Use Efficiency

Useful water savings can be made by requiring low flow rate taps or shower fittings in appropriate areas. Such fittings are labelled in Australia under the Water Efficiency Labelling Scheme (WELS) and are normally installed as part of new construction. Dual flush toilets have been mandatory for new houses in Western Australia for many years. However continuous improvement in the design of toilet systems made it feasible to increase the efficiency rating as part of 5 Star Plus. There were, however, some constraints on reducing the water flow in toilets, and these are discussed below.

9.2 Deemed-to-Satisfy Provisions—Water Loss Prevention

Private swimming pools are very popular in Western Australia, where the Mediterranean climate supports an outdoor lifestyle during summer. Evaporation from swimming pools in Perth is estimated to equate to about 2.8 gigalitres per year (1 gigalitre equals a million kilolitres) (Premier’s Water Foundation, 2006). As a result, mandatory provision of pool blankets as part of the installation of new swimming pools was identified as a useful strategy for water saving.

9.3 Deemed-to-Satisfy Provisions—Hot Water Use Efficiency

During consultations, builders in Western Australia stated that a common issue raised by prospective purchasers of project homes was the time taken, and water wasted, for hot water to come to a tap from a distant hot water system, and were keen for this to be considered for inclusion in 5 Star Plus. Research suggested the maximum pipe length should be between 10 and 20 metres. Discussion with industry indicated that the longer length would be able to be introduced at minimal cost, whereas the shorter lengths might require the fitting of two hot water systems or the use of a recirculating pump at a cost of up to $1,000. In order to allow some flexibility, and to limit waste from larger diameter pipes, a volume limit of 2 litres was also adopted. This equates to about 20 metres of 13 mm copper piping.

10. Water Use in Houses Code—Stage 2

A key response to drought in many parts of Australia has been the introduction of restrictions on the use of scheme water for landscaping and other external purposes and the requirement to fit new houses with rainwater tanks to provide an alternative water supply. Most major cities are coastal and built on rock or clay soils so that any runoff in suburban areas runs quickly into the sea, and causes a stormwater disposal problem to authorities. Rainwater tanks plumbed directly into toilets reduce the draw on scheme water, with consequent savings in infrastructure costs, while also reducing the amount of runoff to be dealt with. In catchments where runoff is already below minimum needs, the water from a tank can be used on landscaping, thus preserving ecological flows.

Perth is in a different situation from the eastern states capitals, in that the majority of the metropolitan area is built on deep strata of saturated sands, and there is little or no effective rainfall over the summer (Environment Protection Authority, 2007). Rain falling in winter is not lost by running directly over the surface and into the rivers and the sea, but instead soaks into the aquifers (Environment Protection Authority, 2007). This groundwater is widely used, after treating, for scheme water, or directly on landscaping through domestic bores. State water policy had for many years encouraged householders to install bores for landscaping use (Department of Water, 2008). One of the difficulties in adapting BASIX to Western Australian use was its requirement for rainwater tanks, and the difficulty in adapting the water use aspects to include the use of bores as alternative water supplies.

Research commissioned by the Department showed that in Perth a modest sized rainwater tank could be used to flush toilets for nine months of the year, with useful savings in scheme water and infrastructure costs. Although the relatively low cost of water makes this hard to justify on purely cost grounds, pressures on the existing dams and groundwater sources were forcing water utilities into more expensive alternatives, such as desalination and it is foreseeable that the price of water will rise (Department of Water, 2008). The generally high quality of Perth groundwater suggested that there was no reason why water from domestic bores could not also be used for toilet flushing, and some new land developments in Perth are starting to provide a "third pipe" supply from a community bore, although Department of Health does not currently encourage this water to be used internally in the house.

There are therefore several options for an alternative water supply including rainwater tanks, bores and third pipes. A review of these options uncovered a number of issues, including the high cost of this water for householders compared to scheme water, Health Department concerns, and that the plumbing regulations do not require a licensed plumber to install an alternative water supply. Despite this there was strong support from the community and government for greater choice in the use of alternative water supplies for both internal and landscaping use.

The performance requirements of Stage 2 have two objectives – to 'future proof' all new houses to allow connection of an alternative water supply or grey water diversion system at a later date, thus allowing householders choice as to if or when they do so. It also requires houses that are likely to use large volumes of scheme water to connect to an alternative water supply or grey water diversion system for either internal or external use. To be suitable for adoption into the BCA these performance requirements cover all alternative water supply options available anywhere in Australia.

10.1 Deemed-to-Satisfy Provisions—Alternative Water Supply Use Capacity (Future Proofing)

Toilets and washing machines must be capable of being connected to an alternative water supply without breaking into the fabric of the house. This requires toilets and washing machines to be either located against an external wall, or to pre-install a second pipe in internal walls that runs either into the ceiling space or to an external wall.

10.2 Deemed-to-Satisfy Provisions—Grey Water Use Capacity (Future Proofing)

Bathrooms and laundries must be capable of being connected to a grey water diversion system without breaking into the fabric of the house. This requires the pipes from bathrooms and laundries to run directly outside the house to where they can be cut into, before the water is mixed with wastes from toilets, kitchens and the like (black water). The most effective grey water systems distribute the water through buried trickle irrigation pipes, and to avoid build up of contaminants in the soil the grey water must be diluted over a minimum area of suitable soil. This requirement therefore only applies to houses on a minimum lot size where sufficient dilution of grey water can take place.

10.3 Deemed-to-Satisfy Provisions—Alternative Internal Water Supply (Mandatory Supply)

New houses with more than two toilets or showers are required to connect an alternative water supply for toilet flushing. The requirement to install an alternative water supply to houses with more than two toilets or showers was a compromise that targetted potentially high users of water, where the savings would be greater, and avoided the lower end of the market aimed at first home buyers. The requirement was expressed as an alternative water supply, rather than a rainwater tank, so that third pipe and suitable bore water could also be used, subject to health regulations.

10.4 Deemed-to-Satisfy Provisions—Alternative External Water Supply (Mandatory Supply)

New houses on lot sizes on large lot sizes are required to connect an alternative water supply or grey water diversion system for landscaping purposes. The most common alternative water supply used for landscaping in Perth is a domestic bore. The requirement to install an alternative water supply to houses with large areas of landscaping was a compromise that targetted potentially high users of water and also avoided the lower end of the market used by first home buyers, who tend to buy on smaller lots. To provide more flexibility for builders and homeowners this requirement can also be met by providing an alternative internal water supply.

11. Implementing 5 Star Plus

The Water Code provides for two stages. Stage 1 consists of the least problematic measures that have been agreed upon by all stakeholders, and are low cost in nature, such as low-flow tapware. The more controversial items have been left for stage 2 to enable further consultation. In October 2007 a Technical Advisory Group (TAG) was convened to discuss various technical issues that became apparent through desktop research. The group provided recommendations which went on to inform a public consultation document. In addition a regulatory impact assessment was undertaken which provided an analysis focussing on economic issues and high-level discussions were held across government agencies. Meanwhile, there has been rapid evolution of State Government policy on water with the release of the Western Australian State Water Recycling Strategy. This has made parts of Stage 2 problematical, with an overlap in policy objectives creating possible perverse outcomes. An example of this is the large-scale greywater recycling project being proposed by the state water utility, which will treat and inject waste water into aquifers. The removal of greywater at the household level would reduce the quantity of waste water available for this purpose.

These developments highlight the dynamic nature of policy development and have led to a revised, pragmatic policy position that endeavours to increase the sustainability of new houses through the BCA, without impeding other government jurisdictions from meeting the same objectives as Stage 2 but at a lower cost to the individual and society. The policy position also takes into account the advice from the TAG that there may be impacts on infrastructure by reduced waste water flows into household and municipal sewer lines, which have been designed to function assuming a particular flow rate.

The revised policy position, therefore, is that 5 Star Plus, Stage 2 will proceed with the future proofing requirements of the alternative water supply and greywater use capacity detailed above, but will only require the mandatory supply provisions in Regional Water Plans, as they are developed. They will not be required in the Perth and Peel regions where sandy soils allow aquifers to be filled directly by rainfall and accessed by domestic bores or water utilities. This is in line with the majority of feedback from all the stakeholders consulted and the State Water Recycling Strategy.

The staged implementation has given the Western Australian Government time to progress various policy options and has provided time for extensive consultation. This has meant that 5 Star Plus is aligned with government strategies, will prove more effective and will have a reduced chance of creating perverse outcomes for industry and individuals.

11.1 Bringing 5 Star Plus into legislation

The simplest way of bringing the 5 Star Plus standards into effect would have been to publish them as a Western Australian addition to the BCA. Unfortunately the annual update cycle for the BCA meant it was too late to incorporate any standards in BCA 2007, and it was not acceptable to wait until BCA 2008 came into effect in May 2008. Building standards are set in Western Australia through the *Building Regulations 1989* that allow the adoption of a “code” either in whole or in part. The Regulations adopt the BCA as the primary building code. It was therefore decided to set out the 5 Star Plus standards as “codes” that could be adopted by the Building Regulations 1989 as an interim measure before being published in BCA 2008. The way the codes were set out and worded followed where possible the precedent of the BCA. In this way, the energy measures and Stage 1 of the water measures were applied in Western Australia as from 1 September 2007. From 1 May 2008, these requirements were transferred to the WA appendix of the BCA. The same approach can be adopted for Stage 2..

12 Evaluation of 5 Star Plus

A key aspect of good policy making is evaluation of policy to ensure that it is providing the outcomes that were intended. This will be part of the policy development of 5 Star Plus, and will help to inform and focus further sustainability policy. Data on water use and energy use will be available through various agencies and industry associations.

13 Conclusion

The policy development of 5 Star Plus is a case study in how to deliver better sustainability outcomes, whilst ensuring key stakeholder support. Without key stakeholder support it is politically very difficult to introduce new regulations or legislation. Lack of industry support was a key factor in the decision to not proceed with BASIX.

5 Star Plus has managed to get the support of environmentalists and sustainability practitioners as well as industry, without placing a significant burden on society, particularly on those least likely to be able to afford it (e.g. first homebuyers). It fits well within existing regulatory mechanisms and has pushed the overall agenda within the BCA, helping raise the minimum standards of housing throughout the State and Australia.

Summary

The K2 Apartments development is a public housing project in Melbourne. It departs from the norm in Melbourne public housing by incorporating a range of sustainable features including passive solar design, natural cross- ventilation, photovoltaics, solar thermal heating systems, rainwater and grey water recycling, and stormwater remediation using on site swales. It has been occupied from May 2007 and is undergoing a post-occupancy study. This paper reflects on the design process, evaluates how well the design has met its environmental and social objectives, and comments on how this might inform the design of future public housing in Melbourne.

1. Introduction

The K2 Apartments development is a 96 unit public housing project for the Victorian Office of Housing (OoH), located in Windsor, Melbourne. The project was initiated by an open competition, which challenged applicants to design a housing development which was at the forefront of sustainable design, including the following key aspirations:

- Produce net zero CO_2 emissions in use.
- Use no non-renewable energy for operations.
- Reduce mains water use by 50%, when compared to a similar conventional building.
- Have a design life span of up to 200 years.

Arup, in collaboration with DesignInc architects won the competition in 2001, and were engaged to carry out full engineering design services for the project, including structural, mechanical, electrical, hydraulics, vertical transportation, acoustics, fire safety, performance based fire engineering and civil engineering. Design commenced in 2001, construction in 2005 (by Hansen Yuncken) and practical completion was achieved in May 2007.

Public housing supports people who cannot access the private rental or ownership markets. It is funded, wholly or in part, by government and rented at lower than market rates to people who meet eligibility requirements.

Today, the needs of the Victorian community have changed and the OoH is refocussing its approach. More than 30 per cent of public housing is over 30 years old and was constructed to meet the needs of a community that has changed. When public housing was built 30 years ago, public tenants were commonly families who could not afford private housing. As such, a high percentage of existing public housing is two and three bedroom houses and apartments. However, over the last ten years, the proportion of tenants seeking pubic housing who are single, elderly or smaller families has significantly increased.

K2 was designed to meet the changing social mix of our communities whilst significantly improving environmental performance compared to past public housing.

This paper reflects on the engineering design process, evaluates how well the design has met its environmental and social objectives, and comments on how this might inform the design of future public housing in Melbourne.

2. Engineering Design Approach

The following design approach was adopted in order to structure the engineering design to meet the OoH objectives for the project.

2.1 Establish design criteria

It was important to identify design criteria by which to assess and appraise engineering solutions. With the OoH and the architect, the engineering design team identified the following assessment criteria for engineering solutions:

- low maintenance
- proven and robust
- suitable to the tenant profile – potentially of poor health, born outside of Australia, or elderly
- exemplar
- environmentally sustainable
- long lasting
- low risk
- replicable in future housing projects.

2.2 Define team structure

The team structure for this project was based around incorporating sustainable design responsibility into each discipline, rather than tasking sustainable design to one 'champion' or advisor. This ensured ownership of sustainable design principles rested in each discipline and that there was a smoother transition from aspiration to design and documentation.

As many of the sustainable principles were interrelated between disciplines, team communication and coordination were important. For example a decision to expose concrete walls for thermal mass affected acoustic design for noise isolation, structural design for concrete finishes, electrical and hydraulics design for services routes and mechanical design for heating and cooling system design. Regular communication was important to facilitate meeting objectives in all disciplines, which was assisted by having all engineering design completed under the one roof.

2.3 Services approach

Building services systems were designed on the basis of the following:

1. Attempt to remove the demand for servicing.
2. Minimise the demand for servicing.
3. Service the demand as efficiently as possible.

Following this approach, the thermal performance of the building was optimised to remove or reduce demand. Efficient appliances were specified and tenant education encouraged to further reduce demand. Finally efficient services were specified to ensure consumption of water and energy was minimised. Detail on how this was achieved is discussed further in the report.

3. Feasibility assessment

Prior to commencing design, studies were undertaken to determine the feasibility of achieving the four project aspirations identified above.

3.1 Renewable energy feasibility study

Using no non-renewable energy on site and having net zero CO_2 emissions were challenging targets, particularly when combined with other design criteria of low risk, low maintenance and proven solutions - characteristics not often associated with large scale urban renewable energy systems.

To assess feasibility, Arup initially carried out an estimate of building energy consumption under various scenarios. Energy estimates were based on the services approach outlined above. Electricity consumption for the tenants depended on the efficiency of tenant appliances and the extent of time that they were used. Potential electricity consumption was estimated to range from 680MWh/yr for inefficient appliances with uneducated usage to 80MWh/yr for efficient appliances with educated usage. This highlighted the difficulty in controlling energy consumption when the level of control over the tenant's behaviour was limited. It also highlighted the extent to which positive education programs could have a drastic impact on energy consumption.

Domestic hot water heat energy requirement was estimated to be 165MWh/yr, space heating heat energy requirement estimated to be 160MWh/yr and base building electrical energy consumption estimated to be 245MWh/yr.

Due to the concurrent demand for electricity and heat, a combined heat and power (CHP) system was identified as potentially the most suitable renewable energy technology for the development. A solar powered organic rankine cycle (ORC) CHP system was initially investigated. Such a system would require up to 2000m^2 of solar collector area and up to 200kL of hot water storage to provide electricity and hot water self sufficiency annually. At the time of the study a suitable supplier was not available in Australia, and this together with the large space requirement for solar collectors, and potentially high cost for the system, led the design team to rule out this option.

Following the design criteria of low risk, low maintenance, proven solutions, more conventional photovoltaic (PV) and solar thermal systems were investigated for suitability. This study determined that zero CO_2 emissions could potentially be achieved with a large PV array, but natural gas would be required for hot water and heating demands, meaning that fossil fuel energy would be used. The system also came at a high cost which exceeded the available budget for the project.

A pragmatic balance of 170m^2 of crystalline PV and 130m^2 of flat plate collector based solar thermal systems was agreed upon. This would provide at least 50% of the expected domestic hot water energy demand annually and approximately 10% of the base building electrical energy demand annually.

3.2 Water feasibility study

The average daily water consumption within an Australian dwelling was estimated to be 350 litres per person, although for a unit this would typically be much lower, at approximately 250 litres per person. The water feasibility study determined that with water conservation measures such as low flow showers and aerated taps, along with the education of residents, water consumption could be reduced by 27%. This would result in an average usage of 193 litres per person per day. Further reductions in mains water demand could be made through rainwater collection, treatment and use and wastewater collection, treatment and reuse. Treating wastewater on site was not a new concept, although for residential developments had rarely been put into practice and reusing the residency’s wastewater was basically unheard of. This presented challenges to the design team, however none that were insurmountable. The study therefore concluded that the 50% potable water reduction target could be met.

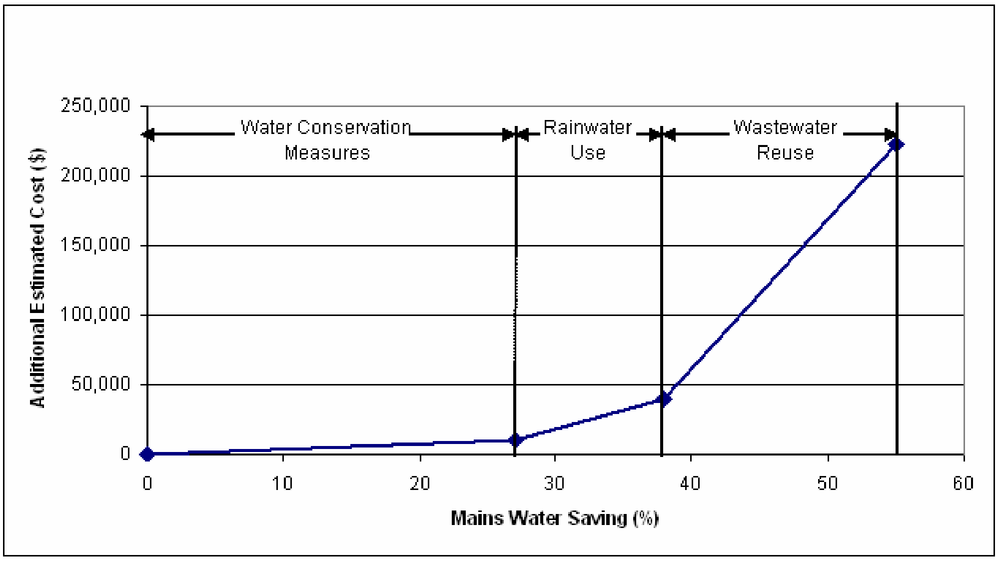

Figure 1 The additional cost of mains water saving initiatives at the Windsor development.

3.3 Design life feasibility study

Designing for a structural design life of greater than 50 years requires the determination of a specific loading regime, corrosion protection systems and durability requirements which are all more onerous than specified in the Australian Standards. It would lead to designing the buildings for higher loads and would increase member sizes, concrete cover, and the size of the foundations.

Assuming that at the time of refurbishment of the development in the future, an inspection of the structure is undertaken and any necessary remedial works completed, the structure integrity of the structure should be maintained well beyond 50 years.

In consultation with the OoH it was therefore decided that the structural elements of the buildings would be designed and detailed to the normal Australian code requirements, which assume a design life of 50 years.

4. Design Features

Specific design features implemented to achieve high levels of environmental sustainability are outlined below.

4.1 Energy

4.1.1 Passive thermal design

The engineering design team was involved very early on during the competition stage of the project to help inform building geometry, orientation, massing and solar access, and coordination with active engineering components. Passive thermal design was fundamental to reducing energy consumption and maximising design life. All design features were developed in such a way that the building would passively default to thermally comfortable conditions. This meant minimising the complexity of features and reducing the need for user control.

The development was designed with a 12 metre maximum depth to all four building blocks, which in conjunction with secure openings at the front and back facilitated effective wind induced cross ventilation of each unit for physiological cooling. This departs from the more common deep plan public housing tower design with units accessed off a common double loaded corridor.

The engineering team proposed insulation values for external fabric which were challenging at the time and far exceeded code requirements, whilst fitting within the allowable budget. Minimum U-values of 0.2W/m^{2}K and 0.4 W/m^{2}K were recommended for roof and wall constructions respectively.

All units were north facing, with windows to east and west minimised. Fixed external shades were provided to the north elevation, sized to minimise summer solar gain whilst allowing winter sun to enter the unit. Every unit was provided with a balcony and the design team assessed the benefit of enclosing the balcony in operable glass to create an indoor/outdoor winter garden space. This strategy was not adopted however given the potential for tenants to operate the glass incorrectly leading to overheating in summer and cooling in winter.

Figure 2 North elevation of rear building block showing solar shading and balconies (© Peter Hyatt)

Exposed thermal mass was provided in every unit to give thermal stability, reducing internal air temperature fluctuations. The diurnal range in Melbourne is often around 10-15^{o}C in summer, which makes night cooling an effective passive cooling strategy. To meet acoustic criteria only one side of each inter-tenancy wall was exposed, with the other lined with insulation and plaster, also providing a services distribution route. Approximately one third of the concrete soffit was also exposed - a balance between mass, servicing distribution routes and aesthetics.

Dynamic thermal modelling was carried out to assess and optimise the performance of all design features. This showed that comfortable conditions would be expected for most of the year without need for active heating or cooling. An average internal air temperature of approximately 20°C would be expected in winter, and peak summer internal air temperatures at least 4°C less than ambient temperatures, and rarely higher than 30°C. Summer modelling assumed the onerous scenario where windows would be left open during the day and night. In practice educated tenants would close their windows during the hot summer days, improving summer performance.

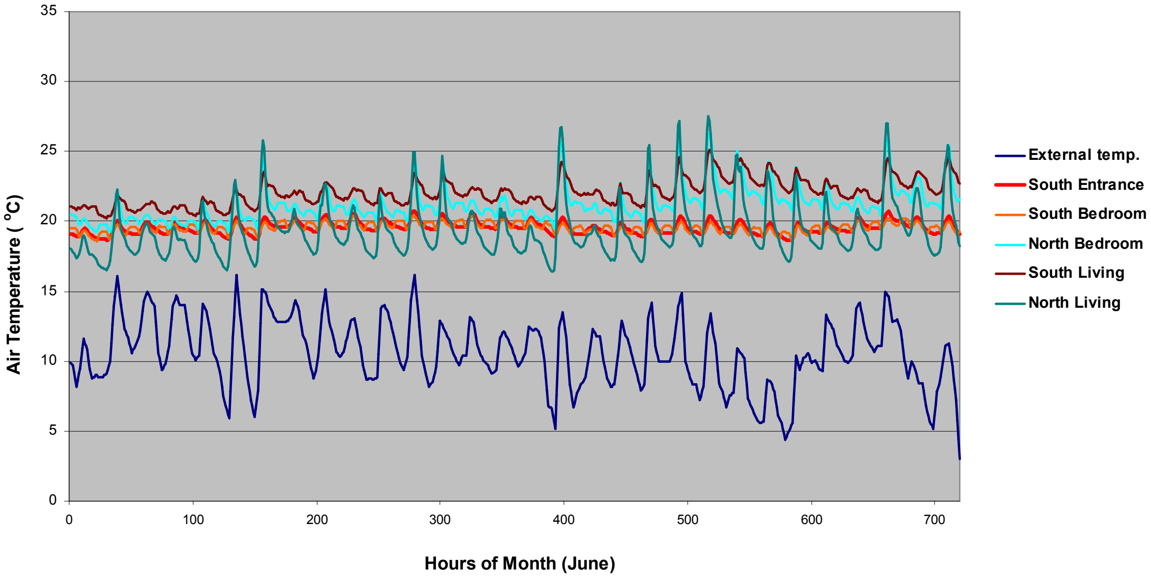

Figure 3 Internal air temperatures for a range of spaces within a typical unit during winter

As a result of the passive design measures, active cooling was not required to the units. For most tenants active heating would also not be required, however given that the tenant mix would include a significant number of elderly or physically disabled residents, the design team decided that mechanical top up heating should be provided.

4.1.2 Efficient systems and equipment

Lighting energy consumption was minimised through the use of T5 fluorescent luminaires for base building areas and efficient compact fluorescent luminaires for tenancies.

Toilet ventilation and kitchen exhaust systems were required in each unit to remove odours and control humidity. Individual tenant fans were provided so that fans only operated when required, not continuously. Fans discharged into risers which were ventilated by roof mounted wind ventilators rather than the more common roof mounted fan system, further reducing fan energy.

Top up heating was provided to units by a hydronic heating hot water system served by gas fired boilers. This was far more efficient than other common alternatives including electric radiators, heat pumps, electric fan convectors and portable oil heaters.

4.1.3 Solar hot water

A solar hot water system was recognised as good value for investment, and a focus was placed on providing sufficient roof space for solar thermal collectors over the less financially attractive PV system. Using flat plate solar collectors the solar hot water system was used to preheat make up water to the domestic hot water (DHW) system, providing an expected 50% energy savings for DHW annually.

4.1.4 Photovoltaics (PV)

Crystalline grid connected PV arrays were provided to the roof and façade of buildings 1, 2 and 4 to reduce reliance on mains electricity. The array comprised 134 off 160W panels, giving a peak power output of 21.4kW, and an expected annual energy yield of 25MWh/yr. The area of PV was dictated by available roof and façade space once solar hot water was optimised; and budget constraints.

Figure 4 Image showing photovoltaic panels (foreground), solar thermal collectors (background) and wind ventilators on exhaust risers. (© Peter Hyatt)

4.2 Water

4.2.1 Stormwater

The stormwater system on the site was designed to minimise pumping while capturing runoff from landscape elements through the site. The landscape design included elements such as bio-trenches along the entry and exit drives to treat run-off from hardstand areas while also detaining flows to restrict the peak outflow from the site and reduce any downstream impacts. Most impervious surfaces drain across vegetation strips before entering the stormwater system to allow for maximum opportunity for infiltration and vegetation uptake to reduce the total runoff volumes from the site.

A gross pollutant trap was incorporated at the discharge point to the council system to ensure all larger pollutants and any oil that enter the stormwater system were not allowed to enter the council system.

4.2.2 Grey water

A treated recycled water supply system was provided throughout the development, the first of its kind in Victoria. Black water recycling was not included as Authority approvals may not have been forthcoming and grey water recycling met the targets for recycled water established in the feasibility report. Separate grey water stack systems were provided in buildings 3 and 4 to supply grey water to a Membrane Bioreactor treatment plant for reuse as toilet flushing and irrigation supply.

Based on advice from the Victorian Department of Human Services the greywater system was treated to the same degree as blackwater would be for this type of development. This was due to the fact that controlling the quality of the greywater (laundry, shower and kitchen wastewater) within a multi-dwelling development such as the K2 Apartments would be difficult as residents cannot be made to take responsibility for what enters the system.

The grey water system was expected to reduce mains water consumption by 14%.

4.2.3 Rainwater harvesting

Rainwater is collected from the roofs of all four buildings and connected to tanks located in a central courtyard. The rainwater collection system was designed to capture 98.7% of average rainfall, with the remaining 1.3% overflow draining to stormwater. The capture of roofwater runoff equates to an estimated reduction of over 40% in the total runoff from the site to the council system. All rainwater is filtered and disinfected by a UV sterilisation unit and an automatic chlorine dosing unit, before being provided to the domestic hot water system as make-up water. The rainwater harvesting system was expected to reduce mains water consumption by 11%.

4.2.4 Water smart appliances

Water smart appliances such as low flow showers and aerated taps were recommended for the development, contributing to an expected reduction in mains water consumption of 27%.

4.3 Materials

4.3.1 Cement content substitution with fly-ash

Cement production is energy intensive, with one tonne of CO_2 produced per tonne of cement manufactured. To reduce the environmental impact of concrete, cement content was designed to be reduced by substituting it with fly-ash or slag. Fly-ash (FA) is finely divided ashes produced by burning pulverised coal in power stations. FA has been used in concrete since the 1930s. In the sustainability context, FA is beneficial in reducing the quantity of Portland cement (PC) in concrete with a consequent lowering of total CO_2 emission in production from the PC component. It also utilises a by-product that would otherwise have to be stored or disposed of.

The concrete specification identified primary objectives that were to be met and gave the contractor ESD objectives which they were challenged to maximise.

The range of percentages of fly-ash/slag given varied, as follows: Insitu beams and slabs: 10% to 40%, insitu columns and walls: 20% to 50%, precast walls: 10% to 30%, insitu retaining wall: 10% to 40%.

4.3.2 Recycled concrete aggregate (RCA)

Global demand for recycled construction products has increased substantially during the past decade. At the time of design in the state of Victoria, most of the demolition concrete waste generated was successfully recycled as fill material for road construction and related applications. As such, RCA was not a viable alternative for consideration to be used for structural applications, and was therefore not used.

4.3.3 Recycled steel reinforcement

Ninety five percent of steel reinforcement used within the structure was designed to be from recycled steel. A recycled quantity of 50% was specified for structural steel elements.

4.3.4 PVC minimisation

The use of PVC for hydraulic services elements was significantly reduced by specifying alternative products for sanitary drainage, cold water and rainwater systems such as HDPE and ABS plastics.

4.3.5 Embodied energy

Minimising embodied energy was not a key project goal and therefore did not form part of the engineering design criteria.

4.4 Education

4.4.1 Metering

As identified in the feasibility study, a potentially significant contributor to energy consumption was the extent of education of the tenants regarding resource use. In an effort to assist tenants to understand the impact their actions have on resource consumption, energy meters were provided to all units. The meters record heating energy and domestic hot water energy and store data at a central head end. Electrical check meters were also provided for each unit, allowing all energy data to be recorded and reported for each unit. The OoH can use this data for tenant education and as useful benchmark information for future housing developments.

4.4.2 Tenant briefing guides

Tenant briefing guides are provided to all tenants by the OoH, describing the environmental strategies designed into the development. This guide allows tenants to optimise thermal comfort and encourages tenants to consider appliance efficiency and sensible usage to reduce resource consumption.

4.5 Cost

The cost premium for sustainable design features, compared to a conventional public housing development of equal size, was estimated during design to be approximately $3m. Out of a $32.3m project cost, this equates to approximately 10%. This includes the following features: higher levels of insulation, exposed thermal mass, solar shading, double glazing, timber framed windows, building massing – four separate narrow plan buildings rather than one deep plan, solar hot water, photovoltaics, energy metering, efficient lighting, substitution of fly ash for cement, and grey water and rainwater treatment and reuse systems.

5. Building Performance

Since practical completion, the building has undergone monitoring of resource consumption to enable comparison to design targets, to assist with demand reduction via tenant education, and to inform future public housing design. As the building has not been occupied for a full year, complete building performance data is not available at this stage.

The following interim feedback provides an indication of the performance of the development.

5.1 Thermal performance

During summer, the OoH advised that internal air temperature in one unit was measured to be 30°C at occupied level on a 40°C day. This represents a 10°C temperature reduction from outside which is much improved from the 4°C temperature difference estimated during design. This was due to the tenant taking an active part in thermal control by closing windows during particularly hot weather and opening them overnight.

The OoH received only one complaint relating to the space heating system from a tenant during the winter period of 2007, which was much less than their experience on previous public housing developments.

5.2 Materials

5.2.1 Cement content substitution with fly-ash

During construction, the slower strength gain of concrete incorporating fly ash impacted on construction time. The concrete had to have sufficient strength the day after pouring to be able to fix masonry anchors into the top of the slab for the props to support the next level of precast walls. If there wasn't enough strength, then the placement of the walls would be delayed a day, which could have meant a delay of 4-5 weeks overall. To avoid this the amount of fly ash was adjusted according to the weather, so that in winter less fly ash was used, but as the weather got warmer, helping strength gain, the amount of fly ash was able to be increased. Overall 30% of cement was replaced with fly ash in insitu elements, which was in the middle of the design range.

The precaster was initially hesitant about including flyash for precast walls in the mix as they were concerned about early strength gains and achieving colour control and consistency. By the design team and contractor discussing this and working together, a mix with 20% flyash was achieved which was in the middle of the range specified.

5.2.2 Recycled steel content

The recycled content of reinforcement steel was 100%, in line with the design target. The recycled content of structural steel was reported by the builder to be 32%. This was due to the lack of availability of recycled steel at the time of construction. This percentage of recycled steel was considered to be acceptable, and a reasonable figure to have been able to achieve. This was not a project to force the industry to provide outside its current capacity, but more to work to achieve the highest level of recycling possible by the industry at the time.

6. Lessons Learnt

The K2 Apartments development was the first large scale multi-storey residential development in Victoria to incorporate sustainable features to such a great extent. As such there were some lessons to be learnt and aspects which would be designed differently on future projects.

A defined framework such as Green Star would have been very helpful for developing and assessing sustainable design elements. This was not available at the time, but is now available in pilot version for multistorey residential projects.

The metering strategy initially centred around education of tenants in their use of energy, and was not a whole building, end use defined metering strategy. To assist in reporting and assessing building performance, the OoH would like to interrogate all end uses. A more comprehensive metering framework would be established on future projects of this kind.

7. Future Public Housing

One important aspect of the K2 Apartments development was to provide an example for future public housing developments. All of the sustainable design principles applied to K2 Apartments could be reproduced in other developments, once tailored for site and end use conditions. Metering data will assist in understanding resource demands for future developments. The tenant feedback which is currently being sought by the OoH will also inform future designs.

The release of the K2 competition brief seven years ago had an immediate impact. TAS Housing and Homes West both requested to use it as a basis for their similar undertakings. Importantly, K2 has given the OoH the confidence to develop and proceed with other sustainable design and engineering pilots, targeting new and existing housing stock. The realisation of K2 has influenced the organisation to improve environmental performance in future redevelopment projects. The outcomes and learnings from this project are directly applicable to other medium and high rise residential buildings around Australia, not just public housing. This is a worthwhile precedent and offers lasting benefit for K2's residents and the wider community.

8. Conclusions

The K2 Apartments development demonstrates that it is possible to incorporate comprehensive sustainability features across all engineering disciplines within multistorey residential design. Indeed the particular demands of this type of development offer unique opportunities to apply sustainable design principles, such as water recycling, natural ventilation, passive thermal design and renewable energy systems. Such buildings demand close coordination, communication and commitment from all parties, and greater cost (approximately 10% in this case) but can result in very low environmental impact, affordable accommodation.

A STUDY ON THE MEASUREMENT OF THE VENTILATION PERFORMANCE OF THE NATURAL VENTILATION WINDOW SYSTEM WITH ATTACHABLE WINDOWS

Keywords: Natural ventilation window system, Blower door test, CFD simulation, Ventilation performance

Summary

In recent years apartments are becoming more insulated and airtight in an effort to save energy, and as the high airtightness makes the inflow of outside air difficult, the quality of indoor air was deteriorated with the conventional natural ventilation system due to the lack of fresh air and poor ventilation.

Accordingly, the Ministry of Construction and Transportation enacted the 'Indoor Air Quality Control in Public-use Facilities, Etc. Act' in January 2006, and selected apartments with more than 100 households for installation of ventilation systems. In February 2006 the Ministry amended the ‘Rules on the Facilities Standards of Buildings, etc.’ and determined the required ventilation of new or remodeled housing as 0.7 ACH, and made it mandatory to install a natural ventilation system or a mechanical ventilation system.

However, as the mechanical ventilation system increases energy consumption, and it cannot be replaced when it is inadequately managed or fails, it is highly likely to cause the building syndrome, fan noise and a mental disease like claustrophobia.

The purpose of this study is to develop open-module-type natural ventilation windows, install them in actual apartments, and evaluate the ventilation performance. They can be installed monolithically without deteriorating the view, insulation and airtightness of the windows, and can control ventilation 0.1~2 ACH by means of constant continuous ventilation. They can be used with any window and door types.

The ventilation performance was measured according to the 1) blow door system method, and 2) simulation analysis method.

1. Introduction

In recent years apartments are becoming highly insulated and airtight as part of the effort to save energy, and as the high airtightness makes the inflow of outside air difficult, the quality of indoor air has deteriorated with the conventional natural ventilation systems due to the lack of fresh air and poor ventilation. Especially the CO_2 from the respiratory system of residents, the Volatile Organic Compounds, and high concentrations of formaldehyde (HCHO) emitted indoors due to their content in construction materials and paints causes sick house syndrome which gives rise to respiratory symptoms and disharmony in the human body, and the main cause of this is known to be the lack of ventilation.

Accordingly, the Ministry of Construction and Transportation enacted the 'Indoor Air Quality Control in Public-use Facilities, Etc. Act' in January 2006, and selected apartments with more than 100 households for installation of ventilation systems. In February 2006 the Ministry amended the ‘Rules on the Facilities Standards of Buildings, etc.’ and set the required ventilation of new or remodeled housing at 0.7 ACH, and made it mandatory to install natural ventilation systems or mechanical ventilation systems.

However, as the mechanical ventilation system increases energy consumption, and it cannot be replaced when it malfunctions or is inadequately managed, it is highly likely to cause sick house syndrome, fan noise and mental illnesses like claustrophobia.

The purpose of this study is to develop open-module-type natural ventilation windows and doors applicable to all fittings, install them in actual apartments, and evaluate the ventilation performance. They can be installed monolithically without disrupting the view, insulation and airtightness of the windows, and can control ventilation to 0.1~2 ACH by means of constant continuous ventilation.

The ventilation performance measurements were taken using the 1) blower door test and 2) CFD simulation.

2. Outline of the Developed Natural Ventilation System with Attachable Windows

In developed countries natural ventilation systems are already being used in diverse forms for commercial and residential buildings. A representative case would be the system where the air is ventilated by preheating with the onset of outside air during the heating periods and blockage of the outside air during the cooling periods using the double structure of the windows. Also, window attachment type ventilation systems and wall penetration type ventilation systems which are both economical and highly applicable have already been incorporated in many buildings.

One of the ventilation systems noted recently in Korea for being economical and easily applicable is the natural ventilation system with attachable windows. Originally, along with the large scale supply of high apartments in the 80s, the natural ventilation system with attachable windows was used as a simple ventilation device installed on the lower part of the balcony window. However, the recently developed natural ventilation system with attachable windows enables precision ventilation control without opening or closing the window, and possesses the following features and properties, as well as having the advantage of securing maximum ventilation performance with the use of little equipment and energy. Moreover, the wind velocity, pressure, and the resulting noise of wind, sudden fluctuations of outside air infiltration etc. can be counteracted by detailed technology factors incorporating specific advanced technologies, and taking into account the domestic climate features, the probability of dew condensation occurrence was minimized.

The features of the natural ventilation system with attachable windows developed in this study are as follows.

- Addition of natural ventilation control capability to the fitting system (0.1 ~ 2ACH)
- Apart from natural ventilation, addition of minimal mechanical ventilation function when required (1 ~ 3ACH)
- Addition of regular ventilation function (small amount of continuous ventilation)
- Improved architectural appearance (system that suits the functions & appearance of the existing fittings)
- Open module type easy applicability (open module type that can be applied to any fitting)

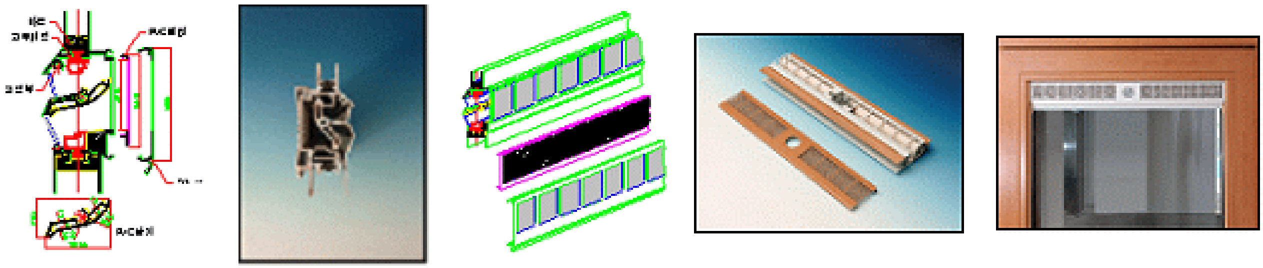

Figure 1 Developed Natural Ventilation System

2. Ventilation Performance Measurement Method

Building ventilation performance measurement methods include the Trace Gas method, Blower Door Test, and CFD simulation.

Firstly, the measurement method for the Tracer gas method is explained in KS F 2603 (indoor ventilation measurement method- carbon dioxide method) and ISO 12569 (Tracer gas dilution method). Depending on the particular injection & sampling methods there is the Concentration decay method, Constant concentration method and the Constant injection method. Of these, the Concentration decay method is the most simple and widely used, and in the beginning a standard amount of tracer gas is injected and after the inside air is mixed, the initial concentration is measured. After a certain time has passed, the natural ventilation amount is obtained by the index formula using the concentration decay value.

Secondly, the Blower Door Testis a pressure difference measurement method and is prescribed in the ASTM E779-87(Standard test method for determining air leaking rate by fan pressurization) and ISO 9972(Determination of building airtightness – fan pressurization method). As a method to measure the building ventilation performance, the decompression test is performed as a standard which exhausts the indoor air and maintains lower than the atmospheric pressure, and the pressure difference measurement points are taken from high pressure differential to low pressure differential points. The maximum pressure differential varies depending on the volume and form of the building, but usually 50Pa or above is seen as the measurement point. The pressure measurement method using the Blower door is not affected significantly by fluctuations in the outside air compared to the Tracer gas method, and is advantageous due to its easy & simple installation and measurement methods.

Thirdly, with the CFD simulation method, when analyzing temperature, air current speed & direction, concentration of pollutants etc. in relation to complex air currents in the building, the subject zones are divided into numerous control volumes and dynamic relationships between the very small volumes are calculated by which air movement is interpreted. Through a computer the CFD interprets the Navier-Stokes equation, a differential equation that governs fluid flow, and the indoor temperatures, air current & pressure distributions can be derived under steady and transient states. Strengthened by the recent development in computer interpretation technology, this method can obtain a more economical outcome compared to methods requiring much cost and time, so it enables estimation of effective results in a relatively short period of time, and many evaluations are being conducted using this method.

3. Ventilation Performance Test

3.1. Test Outline

As shown in Figure 2, the test was performed on the 84m² test apartment unit owned by Korea Institute of Construction Technology, and in order to determine the ventilation effects of the natural ventilation system with attachable windows 1) the aperture ratio of the natural ventilation system was set as the variable at 0, 12.5, 25, 50, 75, & 100%, and the 6 cases were measured 2) the length of opening was set as the variables and 3 cases were measured. This is summarized in Table 1. The Blower door system was used as the measuring equipment as it has simple onsite application.

Figure 2 Test Model

Figure 3. Ventilation Performance Test using the Blower Door System

Table 1 Test Conditions

Measurement case	Length of Opening [m]	Aperture Ration [%]	Pressure Conditions [Pa]
case 1	11.15	0%	10Pa 15Pa 20Pa 30Pa 40Pa 50Pa
case 2	11.15	12.5%	
case 3	11.15	25%	
case 4	11.15	50%	
case 5	11.15	75%	
case 6	11.15	100%	
case 7	5.60	100%	
case 8	4.10	100%	
case 9	3.50	100%	

3.2 Test Method

Under steady state, the indoor/outdoor pressure difference is approximately 1~4Pa, and in this condition ventilation performance measurement is extremely difficult. Thus, the indoor/outdoor pressure difference was raised from 10Pa to 50Pa in 5Pa and 10Pa intervals, and the wind volume was measured for each pressure difference. Based on the results, the ventilation under Pa steady state was indirectly estimated as shown in formula (1).

$$Q=C(\Delta P)n \qquad (1)$$

Here, C: air movement coefficient, ∆P : indoor/outdoor pressure difference, n : air movement index

The effective pressure difference measurement scope of this measurement device is 10Pa ~ 100P, and in the test measurements were taken for up to 50Pa. In accordance with the ASTM standards of America, the indoor/outdoor conditions on measurement were set with wind speed 0~2m/s and outside temperatures 5~35℃, and all air inflow areas were blocked except for the natural ventilation system.

3.3 Ventilation Performance Measurement Results in Accordance with Aperture Ratio

Table 2 shows the ventilation volume (㎥/h) measurements according to the indoor/outdoor pressure difference under the measurement conditions. The results revealed that wind volumes were proportional to the increase in aperture ratio and indoor/outdoor pressure differences rising in a linear fashion. Table 3 shows the conversion to air change rate by applying a K factor of 20 to the wind volume. The results suggest that in order to secure air change rate of 0.7ACH in a 84m² apartment unit, the natural ventilation system must be 50% or more opened.

3.4 Ventilation Performance Measurement Results in Accordance with the Length of Opening

Tables 4~5 and figures 5~6 show the air volume and ventilation performance in accordance with the lengths of openings in Cases 6~9. When the length of opening is 11.15m the air change rate is 1.43ACH, for 5.6m length it is 1.06ACH, for 4.1m length it is 0.83ACH, and for 3.5m length it is 0.84ACH.

In this study the data is insufficient and limited to determine the relationship between air volume and ventilation performance in accordance with the length of opening, so there is a need to obtain more data through following tests and simulations in order to establish the relationship between air volume and ventilation performance in accordance with the length of opening.

Also, the Blower Door test measures ventilation by forcibly creating indoor/outdoor pressure difference using a fan, and because it injects and extracts air through all openings, it has limitations in that there are differences to the natural conditions. Thus, comparison of ventilation performance must be conducted in natural conditions using the Tracer gas method, and to activate the supply of natural ventilation systems, there needs to be additional research on ventilation performance according to the length of the inflow and outflow sides.

4. Ventilation Performance by CFD Simulation

4.1Outline of simulation

The simulation model is identical to the test model in Figure 2, and the position was set at the medium floor. In terms of the boundary conditions, the natural ventilation system was set at 100% opening, outside velocity at 1m/s, wind direction south, outside temperature at -2℃, and floor heating was set for the interior with floor temperature at 29℃. Prior to the ventilation simulation on the apartment with natural ventilation system, item interpretation was conducted on the natural ventilation system and used the results as the boundary conditions for ventilation simulation on the apartment. The boundary conditions are as shown in Table 6, and the computational method is shown in Table 7.

Table 6 Boundary Conditions

Aperture Ration of the Natural Ventilation System	100%
Outside Velocity	1m/s
Outside Wind Direction	Southerly
Outside Temperature	-2℃
Interior Floor Temperature	29℃

Table 7 Computational method

Solver	STREAM
Convective term	Upwind(1nd order)

Turbulence model	MP k-ε model

4.2 Results of Simulation

When the CFD simulation was conducted in relation to ventilation on application of the natural ventilation system under the above boundary conditions, the ventilation performance was revealed to be 0.74ACH which satisfies the ventilation rate required for apartments in Korea.

Figures 7~8 show the item interpretation results of the natural ventilation system. When the outside velocity was 1m/s, the indoor/outdoor pressure difference was 51Pa, and centering on the PVC blades of the natural ventilation system, it was found that the positive pressure was relatively greater on the upper section than the lower section. Accordingly, it was also found that the speed of outside air inflow on the upper section was approximately 2m/s faster than the lower section.

Figures 9~10 show the outside pressure and air current distribution. According to the outside pressure distribution in Figure 9, positive pressure occurs in the position perpendicular to the wind direction, and to the rear of the positive pressure belt a low pressure belt is formed. Apart from the point of air current inflow, it was found that low pressure belts were formed in most sections.

Figures 11~12 show the air current distribution and stream line within the apartment unit. According to the stream line, the ventilation flow within the unit was smooth, so it can be assumed that no dead zones would have existed.

Figure 13 shows the inside temperature distribution within the apartment unit. Because the speed of the inflowing air current was fast, it was seen to move along the ceiling and drop towards the floor in the center section of the lounge room. Accordingly, there is the advantage of the occupants being able to breathe fresh air with low age of air, but as cold drafts can occur attention must be given to interior thermal comfort.

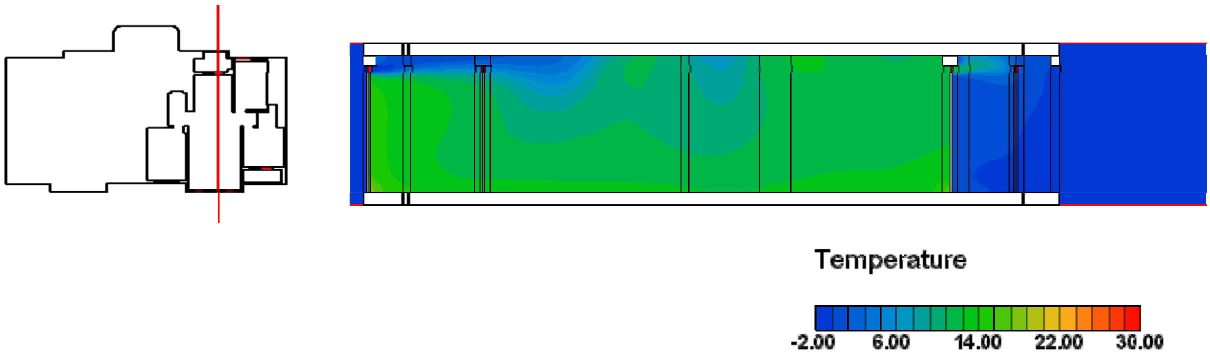

Figure 13 Unit Interior Temperature Distribution

5. Conclusion

In this study the ventilation performance of the natural ventilation system was measured using blower door test and CFD simulation.

The results of ventilation performance measured in an actual test apartment using the blower door test are as follows.

(1) With the increase in the aperture ratio of the natural ventilation system with attachable windows and the indoor/outdoor pressure difference, air volume also increases proportionately in a linear fashion. Moreover, the results suggest that in order to secure ventilation frequency of 0.7ACH in a 84m² apartment unit, the natural ventilation system must be 50% or more opened.

(2) With the natural ventilation system with attachable windows, when the length of opening is 11.15m the air change rate is 1.43ACH, for 5.6m length it is 1.06ACH, for 4.1m length it is 0.83ACH, and for 3.5m length it is 0.84ACH. However, in this study the data is insufficient and limited to determine the relationship between air volume and ventilation performance in accordance with the length of opening, so there is a need to obtain more data through following tests and simulations in order to establish the relationship with the air volume in accordance with the length of opening.

The results of the CFD simulation are as follows.

(1) When outside velocity was 1m/s, ventilation performance was 0.74ACH which satisfies the ventilation rate required for apartments in Korea.

(2) The ventilation flow within the apartment unit was smooth, so it can be assumed that no dead zones in air current would have existed.

(3) The air current flow within the unit was seen to move along the ceiling and drop towards the floor in the center section of the lounge room. Accordingly, there is the advantage of the occupants being able to

breathe fresh air with low age of air, but as cold drafts can occur attention must be given to interior thermal comfort.

In order to activate the future supply of this system, additional research must be conducted on ventilation performance of the natural ventilation system in accordance with size and shape of the apartment units, ventilation performance in accordance with the opening length of the air current inflow & outflow sections of the natural ventilation system, and ventilation volume calculation methods when there is simultaneous inflow & outflow through which data required for ventilation system design must be accumulated. Also, by conducting research on energy consumption with the incorporation of diverse outer systems, economic analysis must additionally be performed including comparisons with mechanical ventilation systems.

SUSTAINABLE WORKPLACES AND CULTURAL CHANGE

Suzette JACKSON B. Interior Design[1]

1 Senior Associate, Sustainable Futures Unit, HASSELL, Melbourne, Australia, sjackson@hassell.com.au

Keywords: sustainable workplace, productivity, cultural change, indoor environment quality, energy efficiency

Summary

The potential marketing and cost benefits generated from sustainable workplaces have created significant interest within commercial organisations. Whilst this has been a key selling point for sustainable workplaces business leaders today are more aware of the broader benefits of a sustainable workplace. In particular the opportunities and value successful sustainable workplaces provide in terms of employee and community engagement with sustainability and emerging opportunities for highly sustainable outcomes alongside changing community values.

In this paper a number of recent Australian sustainable workplaces are reviewed. In addition we discuss the organisations that inhabit these workplaces and their commitment to progressing sustainability within their community. The workplaces reviewed include: Sustainability Victoria, Melbourne; HASSELL Studio Melbourne; and Investa, Sydney. Two of these projects have undertaken productivity studies utilising Business Outlook and Evaluation (BOE) to further evaluate outcomes. The productivity studies are compared for perceived employee and organisational outcomes to determine if they achieved cultural change in employee values. The 'lessons learned' are also reviewed in terms of endeavours to improve culture change needed to support sustainable communities. Finally, we consider how we can affect a more meaningful future workplace utilising the designed environment and cultural change.

1. Introduction

Entrenched cultural expectations are driving building energy demand beyond sustainable consumption. Fueled by tighter parameters of workplace 'comfort', increasing use of information and communication equipment and expectations of 24/7/365 operation our expectations have created exponential demand for workplace lighting, ventilation, heating and cooling; which in turn puts upward pressure on both electricity resources and global greenhouse gas emissions.

As with all cultural change, awareness and education of the challenges and opportunities is critical to creating the change in community attitudes and actions. Whilst the demand for sustainable workplaces is driven by the need for healthy and environmentally responsive workplaces, the process of creating a sustainable workplace requires employee engagement and a level of awareness and education. There is an opportunity to provide not just a workplace that reduces operational costs whilst increasing staff productivity – a sound business case; but to engage the community in pursuing a responsible approach to our environment; providing the opportunity to change cultural behavior on a daily/life basis throughout the workplace and broader community.

In the growing global movement towards corporate social responsibility the incentive to reduce the demand on our finite earthly resources and share the benefits with our community is a global imperative and something increasingly aware employees demand in a potential business employer. Through education and awareness Generation X, Y and Z employees seek employers who are environmentally responsible and provide a healthy supportive workplace allowing them to function at their optimum ability. Gen X, Y and Z expect their employees to provide a workplace that operates on a minimum carbon footprint with an optimum indoor environment quality which includes fresh air, no indoor toxins, renewable onsite energy and low energy demand.

1.1 Sustainable Workplaces – Sustainable Organisations?

Sustainable workplace outcomes are maximised when designed and operated as integrated components of living buildings. This requires not only that the workplace is designed to operate as a sustainable workplace; but for the workplace to be located within a building that is designed to operate sustainably; and for the organisation to apply sustainability principles to their organisational values and operations. A successful sustainable workplace lives within a sustainable built environment, within a sustainable community.

Sustainable workplace design will incorporate:

- A healthy indoor environment i.e. the provision of clean, fresh air; flexible and appropriate lighting and heating and cooling solutions; comfortable thermal conditions (protected against weather extremes); a safe and community-orientated environment; and
- The provision of amenities which support equitable and accessible local transport and encourage physical and mental health and wellbeing.

Living Building design will incorporate:

- Solar passive designed building with building façades built to suit the climatic conditions and aspect of the building;
- Building systems which operate passively as well as actively, and are flexible to allow reduced energy demand;
- Onsite renewable energy generation;
- Onsite water capture and recycling; and
- Onsite reuse / recycling of waste.

Organisations sustainable operations will incorporate:

- An environmental management system (EMS) that is transparent, responsive to local environmental needs and takes a cradle-to-cradle approach for energy, water, materials procurement and waste;
- Carbon Reporting, Sustainability Reporting and a commitment to a zero carbon strategy for the organisation;
- Support and engagement with the local and global community to pursue sustainable resourcing i.e. Corporate Social Responsibility (CSR).

To achieve sustainable workplaces as integrated components of living buildings we need to do more than change the way we design, create and use our workplaces: we need to change our community values, lifestyles and culture.

Successful, sustainable workplaces require:

- Visionary clients who are in touch with changing values and current global and regional needs;
- Business leaders, regional and global leadership engaging/driving the transition to a more sustainable community;
- Passive and active design elements which support the health and wellbeing of employees while minimising toxins and emissions; and
- Passive and active building operation which is allied to the local environment in terms of energy, water and waste.

1.2 Local Resources

Australian and regional research has done much to stimulate the uptake of sustainable activity.

At a national level, the Green Building Council of Australia (GBCA) is a key industry body in terms of the provision of education, rating tools and policy for sustainable commercial buildings. The 'Your Building' website is an national online forum providing research information and case studies on sustainable built environments throughout Australia and internationally.

At the local level the Melbourne City Council (MCC) and Sustainabiltiy Victoria (SV) offer fast turn around programs and education for facility managers, building owners and tenant representatives with the objective of reducing energy demand in existing Melbourne tenancies/buildings. For example, the Melbourne City Council's Sustainable Lighting Guide and associated seminars enables interested parties to understand the sustainability rationale and financial incentives behind improving lighting systems. It also provides funding to facilitate early uptake. SV actively educates and provides financial incentives to businesses to reduce their energy and water demand and to reduce waste outputs and impacts.

1.3 Global Issues and influences

It is the global and regional challenges of our time which drive the transition to a more sustainable community. The critical challenges of global climate change, provision of drinkable water, greenhouse gas emissions reductions and the issues we face in relation to the health of our people as well as our planet are seen as keys drivers.

International research has contributed significantly to the body of knowledge required to demand behaviour and cultural change in relation to the procurement of the built environment. International targets for the reduction of carbon emissions globally have been proposed over the last 30 years. The development of living buildings integrated with their environment will further support a reduced onsite energy demand and onsite renewable resource generation. Operational cost savings enabled through reduced energy and water demand in addition to reduced waste resource management have recently been proven.

With the advent of new research and better understanding of global climate change and Emission Trading Schemes (ETS) the business case scenario of purchasing carbon credits to offset carbon emissions is seen as beneficial for short term goals only. The long term view requires we change our cultural expectations and dramatically reduce energy and greenhouse gas emissions.

Sustainable workplaces utilise passive and active design elements to support the health and wellbeing of employees and their local community through the provision of increased indoor environment quality for improved health and productivity.

Current research demonstrates the link between productivity and indoor environment quality and the disproportionate organisational costs of sick leave compared with the provision of environmental 'comfort' i.e. employee salaries exceed building energy and maintenance costs by a factor of approximately 100 and exceed annual construction or rental costs by almost as much (Woods, 1989 USA). Even the achievement of a 1% increase in productivity should be sufficient to justify an expenditure equivalent to a doubling of energy or maintenance installation costs or large increases in construction costs or rents. Productivity increases of 1% correspond to reduced sick leave of two days per year, reduced breaks from work or increased time at work of 5 minutes per day, or a **1%** increase in the effectiveness of physical and mental work (Fisk and Rosenfeld, 1998).

With improvements in employee health come improvements in overall community health easing the burden on our communities and economy. Whilst this is not an obvious economic incentive for companies, it is an economic incentive for governments and local communities. An improvement in overall health of our community will contribute to stronger and greater global economic capability.

2. Sustainable workplaces

2.1 Cultural expectations within the workplace

Changes to lifestyle and culture have a rapid and sustained uptake if underpinned by education. Low cost changes with demonstrated benefits and little lifestyle impact can be absorbed rapidly in both the work and private arenas. However to affect the degree of change required lifestyle and cultural changes must occur.

The question from the broader community is "will these changes improve our lifestyles?" In many instances the changes required actually improve the quality of our natural and built environment, offering a better lifestyle; the challenge is whether we can affect change quickly enough for the planet.

Cultural change will occur where the community is educated, actively engaged and can influence the process and outcomes. It will occur fastest if the community is aware of the current opportunities and benefits to their lifestyle if they make immediate changes.

2.2 Current sustainable measures for workplace

So what are the measures of a successful sustainable workplace? Here caution is required, for any review of a sustainable workplace design and construction is but a snapshot in time; and we know that sustainable workplace design and the way the workplace is operated evolves with time dependant on the organisation. So when we review a sustainable workplace of an organisation it is important to review the organisation and any changes occurring within it.

The sustainable workplace performance review looks at the base building selection and a number of organisational sustainability measures.

Key base building measures include:

- energy efficiency, water efficiency and sustainability rating (and/or certification)
- commitment to achieving greenhouse has emission reduction/neutrality
- renewable energy generation.

Key organizational measures include:

- Environmental Management System (EMS)
- Occupational Health &Safety System (OH&S)

— Carbon accounting and Sustainability reporting

— Commitment to achieving a carbon balance (carbon neutrality/zero carbon).

2.3 Sustainable Workplace Performance

When large, multinational organisations embrace the need for sustainable workplaces the opportunities for cultural change can occur rapidly with a global reach. The importance of grasping these opportunities and delivering successful outcomes is critical.

Since 2000 in Australia opportunities for cultural change due to sustainable workplaces have been growing. Table 1 below outlines the sustainability initiatives by workplace, building environment and organisation. Two organisations have undertaken productivity studies conducted by Business Outlook and Evaluation, which is discussed in Item 2.5. SA Water is currently under construction and, in this review, is used as a current comparison of sustainability initiatives to the earlier workplaces (refer to Table 1 of the Appendix).

In addition to reviewing Sustainability initiatives and the use of rating tools Table 1 below looks at two additional components: the selection of the base building and respective Sustainability rating and initiatives; and the ongoing commitment to sustainable business management practices.

2.4 Sustainable Workplace Outcomes

Of the workplaces/organisations reviewed the majority have implemented key Sustainability initiatives in respect to indoor environment quality and in the provision of supportive amenities. Many organisations referenced or applied the Green Star rating tool for both fitout AND base building which improves overall energy, water and waste reductions. Sustainable buildings have the potential to minimise toxic emissions, provide more flexible building operating systems; increase fresh air rates; provide monitoring of resources and thereby allow improved energy, water and waste efficiency. Sustainable buildings provide greater opportunities for the creation of a sustainable workplace with potentially less cost.

In addition to building design considerations many organisations demonstrate a commitment to sustainability within the broader community through thought leadership, community education and engagement programs. For example, Investa has gone on to produce the Green Lease Guide in conjunction with a number of other local organisations. This publicly available document assists business in understanding how they too can create a sustainable workplace. SV and HASSELL have implemented Environmental Management Systems certified to Australian/International standards. Both have also conducted productivity studies and have implemented carbon reporting with a commitment to achieve carbon neutrality (Zero Carbon) in the near future. These initiatives have occurred since the establishment of their sustainable workplaces. Whether this is a direct outcome of sustainable workplace initiatives or the continuing evolution of a sustainable organisation is not clear from this review. What is clear, and fundamentally important, is that the continual process of education and awareness which occurs in the process of establishing a sustainable workplace does not stop. It continues through the organisation via the employees to create a sustainable community.

2.5 Productivity Study Outcomes for Melbourne Sustainable Workplaces

All reviewed workplaces indicated a high level of end-user satisfaction. Productivity studies conducted on three workplaces/buildings included both preoccupancy and post occupancy evaluation. This allowed a more detailed evaluation of employee satisfaction health and productivity indicators. In these surveyed workplaces, many employees indicated the new work environment was a major contributing factor to improvements in their job satisfaction.

The productivity survey results from HASSELL and Sustainabiltiy Victoria (which include indoor air quality and HR data) are compared in Table 2 below Productivity survey results from a tenant within 500 Collins Street (also undertaken by Business Outlook and Evaluation) offer a third set of comparative indoor environment Sustainability initiatives within the Melbourne context. In this context the survey was undertaken within the same building, pre and post base-building refurbishment (the tenant temporarily relocated within the building during this period) Refer Table 2. The 500 Collins St building is also reviewed in context of the new Melbourne office of the GBCA (see Table 1).

Investa did not conduct an independent pre and post occupancy productivity studies. Instead they conducted internal qualitative surveys which identified significant benefits had been achieved by implementing sustainable workplace initiatives. These included decreased absenteeism, increased productivity and staff satisfaction. Investa is currently participating in a University research project on productive and sustainable workplaces which will, in the near future, provide further data on this subject.

The three productivity studies of sustainable workplaces found significant improvements across a range of workplace indicators including staff health, productivity, reduced sick leave, and better staff concentration and engagement in meetings. Table 1 clearly shows that within SV and HASSELL both organisations have ongoing commitments to sustainability, including the management of their workplace and resource usage and the ongoing education and engagement of staff. From the outcomes of the productivity studies we can see a clear indication that where an organisation successfully implements Sustainability initiatives within their workplace, they will also see improved employee satisfaction, and improved employee productivity and engagement.

Attraction and retention of staff is also increasingly important in an era of professional skills shortage. The benefits of a sustainable workplace in attracting and retaining employees through the provisions of a healthy and environmentally responsible workplace are also implied through the productivity study results.

However the ability to activate cultural and behavioural change within a short space of time is most critical particularly as cultural change can take one or more generations to occur. We do not have the luxury of an extended timeframe. Many would say that the requirement to change our cultural behaviour and reduce our energy consumption and greenhouse gas emissions has been known by a section of our community for the last 30 years. Environmentalists and scientists have been conducting research and publishing reputable papers on this topic for most of the second half of the last century i.e. the Kyoto Protocol was activated in 1990 and the current definition for Environmentally Sustainable Development drawn from the Bruntland Commission in 1988.

3.0 The Cultural Change in Sustainable Workplaces, Organisations and Communities

Many of the organisations reviewed here have fulfilled their early vision by creating a more sustainable workplace, supporting the health and productivity of their employees and minimising their resource demand and environmental impacts. A number of organisations however have continued to evolve along their path towards greater sustainability by committing to carbon neutrality, incorporating carbon reporting mechanisms, certifying their Environmental Management System (EMS) and creating meaningful cultural change within their employees, client and industry groups.

Organisations commencing the process to deliver better productivity and lower operational costs for the business should seize the opportunity for the organizational culture to influence broader community change. Large employers in particular have the ability to affect change in thousands of employee households. In this way organisations demonstrate corporate social responsibility and assist the government in their educative role.

4.0 Conclusion

If we are to change our communities' mindset towards an environmentally responsive culture and lifestyle we need our governments and organisations to educate and support the changes for all of our community. Leadership by Governments, organisations and industry professionals is critical to make the policy and cultural changes required to significantly reduce our energy usage, greenhouse gas emissions and provide us with a healthy and sustainable lifestyle.

Sustainable workplaces, like sustainable buildings act as a mechanism for broader cultural and behavioural change within our community. To ensure we as a community move forward at the speed which is now imperative, we need to populate the creation of sustainable workplaces globally as a catalyst for cultural change – change to an abundant and promising future.

PRODUCTIVITY STUDY	**HASSELL** Sustainable Workplace	**Sustainability Victoria[1]** Sustainable Workplace	**500 Collins Street** Sustainable Building Refurbishment
Satisfaction index	Previous office -16; new office +46	69% more comfortable office(light, air quality/temperature, ergonomics)	Previous office -11; new office +16
Air quality	Previous office: -42 rated as stuffy or variable; New office: +24 rated as normal or fresh	Meeting room Air Quality index rose15%; meeting room ambience rose 19%.	Previous office: 73% rated as stuffy or variable; New office: 77% rated as normal or fresh
Temperature	Previous office: 50% rated as too hot or too cold; 60% rated as normal		Previous office: 45% rated as too hot; 59% rated as normal and none rated it too hot
Workplace ambience	Previous office 43% found it tiring; New office 48% of staff found it 'invigorating'	Meeting room concentration index rose 43%; Meeting room engagement index rose 41%	Previous office 64% found it tiring; New Office 40% of staff found it 'invigorating'
Health / Sick leave:	Significant falls (8-27%) in the frequency of headache, sore throats, sore eyes, fatigue, colds and flu and feeling 'off-colour'. Sick leave fell by 0.2 days per employee/per year. (Sick leave in conjunction with significant increase in project workloads experienced in the first 8-10 months this is seen as a successful reduction.	Sick leave fell by approximately 2 days per employee per year. Or by 30% in average sick days per employee Sick leave reduction represents a financial saving of approximately $76,080pa	Significant falls (10-25%) in the frequency of headache, sore throats, sore eyes, fatigue, colds and flu and feeling 'off-colour'
Staff self-assessment of productivity:	Increased by 3%. (productivity improvements occurred at a time of increased workloads / administrative requirements)	Increased workplace performance 13%	Increased by 11.7%
Business impact	Consulting work increased by 20% in the first 8-10 months after relocation. Staff involvement in sustainability programs increased significantly.	Significant savings in other sectors of the new fitout were achieved. 96% of respondents say the new workplace represents the Sustainability Victoria values.	

1 The Sustainability Victoria Productivity Study utilised two productivity measures: Sick leave as a quantitative indicator of organisational performance; and self assessed staff performance in meetings. Air quality measures were undertaken separately utilising Deakin University's MABEL technology.

2 Productivity Studies were conducted by Business Outlook and Evaluation (BOE).

PHYSICAL PROPERTIES OF THE ENVIRONMENT-FRIENDLY PAPER FOAM INSULATOR BY CELLULOSE AND STARCH, POLYPROPYLENE

Jae-Sik Kang[1]

Keywords: Foam Insulation, Recycled Paper, Thermal Conductivity, Physical Properties

Summary

The annual CO_2 emission in Korea is 4.1 million tons (CO_2 tons)/year. It increased by 75.5% during the past 10 years, and by 6.5% on average annually. Accordingly, in consideration of high oil prices and for the purpose of reducing the environmental load on Earth, it will be necessary to establish energy-saving policies and develop energy-saving technologies.

The main ingredients of the foam insulator suggested in this study are cellulose and starch. Cellulose comes from recycled paper, and starch is natural. Unlike other insulators, the foam is made using the steam foaming technique which does not use foam gas. Accordingly, this foam insulator has little environmental load occurring in the production process, and is environmentally friendly from product distribution to scrapping.

Foamed products show a vertical texture, but most cells are close types. It is low in absorptiveness, and high in moisture permeation resistance, i.e. 0.07 g/m3 hr mmHg. This foam insulator can be easily processed at a density of 20 kg/m3~ 30 kg/m3, and the thermal conductivity under this condition was 0.034 W/mK ~ 0.037 W/mK.

1. Introduction

With the insulation materials recently used in buildings there have been extensive developments in diverse technologies and materials, and many new products with increased insulation performance have been released into the market. The paper foam insulation proposed (hereinafter referred to as "paper insulation") in this study consists mainly of cellulose and starch. The cellulose is extracted from the incinerated paper and used as foam material, and plant materials are used as starch.

The cell formation to secure insulation properties in the paper insulation, that is, the foam to form very fine spaces is produced using the steam foaming method unlike the standard insulation production process which uses foam gas.

Thus, the environment load arising from the raw materials in the production process is low and possesses environment friendly properties from product distribution to the disposal process.

This study seeks to examine the physical properties of the environment friendly paper insulation made from recycled paper as insulation for buildings, and to devise application possibilities.

2. Paper Insulation Overview

The core material of the paper insulation proposed in this study is cellulose extracted from paper. Cellulose can freely be extracted from waste paper in which the fiber is destroyed or grinded, that is, paper that cannot be recycled and is normally incinerated. To summarize the production process, firstly the waste paper and starch are mixed, and then polypropylene resins are mixed in, and after the expansion using steam and the press molding process, it is produced into insulation material in the form of a board or filling type particles.

The cell structure of the paper insulation is comprised of elements that act as the nucleus during expansion and the outer cover that covers the nucleus, and possesses the advantage and characteristics in which the cell image and membrane do not physically or structurally change after expansion.

The expanded product shows a perpendicular direction grain, but the cell is in a closed form which has low absorption while possessing high water vapor resistance of approximately 0.07 g/m3.hr.mmHg. The paper insulation has relatively easy density control depending on the expansion proportion, and as a building insulation material, a density of 20 kg/m^3 ~ 35 kg/m^3 would be the most economical for application.

Apart from the polypropylene resin additive, the paper insulation comprises mostly of natural materials, so it is free from harmful gas emissions in the case of fires during the summer season, and it does not contain harmful substances such as formaldehyde, VOC etc.

Figure 1 shows the density and molded image of the product sample, and Figure 2 shows the product as a building insulation and a detailed sectional diagram. Figure 3 shows the application of both the internal insulation system and the external insulation system on an actual building.

3. Performance of Paper Insulation

3.1 Thermal Conductivity Test Overview

For the thermal conductivity measurement the test methods of ASTM C 518(Standard Test Method for Steady-State Thermal Transmission Properties by Means of the Heat Flow Meter Apparatus), ISO 8301(Thermal Insulation-Determination of Steady-State Thermal Resistance and Related Properties), KS L 9016 (thermal conductivity measurement method for heat insulation materials) were applied. Table 1 and Figure 4 show the measurement principles and composition of the heat flow meter.

For the thermal conductivity test the high-end temperature was set at 33℃ and the low-end at 7℃ while the average test temperature was set at 20± 0.5℃, and measurements were taken of the high-end & low-end temperatures in the insulation sample (T_u, T_l), the heat flow quantity using the heat flow meter (Q_t), and the thickness of the insulation sample (d). The measurements were taken 5 times in 10 minute intervals after the temperature and heat flow reached normal conditions.

Subsequently, 4-6 types of samples were used for each of the 5 paper insulation types, and by conducting 5 repetitive tests on each sample, a total of 115 tests were performed. The test was conducted in a constant temperature & humidity room with the test temperature set at 23± 1℃ and relative humidity at 50 ± 5%.

3.2 Heat Conductivity Test Results

In order to determine the physical properties according to the foam composition & proportion of the paper insulation, the heat conductivity test was performed twice on the samples after setting each foam composition & proportion. Table 2 & Figure 5 show the test results of the paper insulation produced through the phase 1 expansion process.

3 sample types with densities 0.02 g/㎤, 0.026 g/㎤, and 0.031 g/㎤ were produced for phase 1, and the average thermal conductivity rates according to density were 0.037 W/mK, 0.035 W/mK, and 0.034 W/mK respectively.

The densities of the 2 phase 2 sample types after setting foam composition & proportions were approximately 0.024 g/㎤ and 0.026 g/㎤, and the average thermal conductivity rates according to density were 0.035 W/mK and 0.034 W/mK respectively. Table 3 & Figure 6 show the test results of the paper insulation produced in the phase 2 expansion process.

Table 1. Outline of the Thermal Conductivity Measurement Device

Thermal Conductivity(λ) Measurement Scope	0.015 ~ 0.43 W/mK

Figure 4. Test Device & Test Room

3.3 Insulation Performance Estimation & Comparison

Figure 7 shows the thermal conductivity correlation of the paper insulation according to density based on the phase 1 & 2 test results. The thermal conductivity according to the densities of the phase 1 & 2 samples in the figure reveal a largely different fluctuation pattern, and in the case of the phase 2 sample there was a decline in thermal conductivity with the increase in density, so this shows improved thermal performance compared to the phase 1 sample.

Thus, when the foam composition and proportion is optimized, thermal conductivity of 0.032 W/mK or less can be secured under a density condition of 0.031 g/㎤.

Table 4 makes a comparison between the thermal conductivity of the paper insulation calculated from the correlation graph in Figure 7 and the thermal conductivity of the EPS insulation prescribed in the current KS standards. As shown in the table, the paper insulation shows more superior thermal performance than the EPS-1 insulation for both the phase 1 & 2 samples when density was 0.015 g/㎤ or higher, and with density of 0.03 g/㎤ or higher it had similar thermal performance to EPS-2 (graphite content) number 4 (density 0.015 g/㎤). In the case of the high density paper insulation with density over 35 g/㎤, the thermal conductivity is estimated to be under 0.030 W/mK, and this level of performance can secure overall superiority over the performance of existing insulation materials.

4. Physical Properties of the Paper Insulation

Figure 9 shows the test process to examine the absorption properties of the cell interior and perpendicular texture of the paper insulation. In the absorptiveness test the paper insulation was immersed for 68 hours into a container with coloring materials, and by cutting a section, the degree of water penetration and absorption was examined by the capillary tube phenomenon on the perpendicular grain.

Test results showed that no water was absorbed within the cell as the entire paper insulation had closed cells rather than open cells, and especially, there was no water penetration through the openings between the cells. However, there was water penetration between the openings of the perpendicular grain, but there was no water absorption past the water penetration boundary surface due to the capillary tube phenomenon.

Table 5 shows the results of gas composition when fire was applied to the paper insulation. There was CO 130mg/g, and CO_2 610mg/g, but other harmful gasses such as Cyan, hydrogen chloride, ammonia, nitrogen oxide, sulfur oxides etc. were not detected.

In the meanwhile, quantitative tests are currently in progress for other physical properties required in building insulation materials such as tensile strength, compressive strength, combustibility, permeability, and emission of chemical substances that can affect air quality.

Table 2. Phase 1 Thermal Conductivity Test Results

TYPE	density (g/㎤)	Average Thermal Conductivity (W/mK)

5. Conclusion

The total annual emission of CO_2 in Korea is approximately 410 million CO_2tons/year. There was a 75.5% rise over the past 10 years which is an annual average increase of 6.5%. Thus, with the high oil prices and to reduce global environmental load, developments are required for energy related technology, as well as technologies for resource regeneration and recycling.

The results of this study are as follows.

1) The paper insulation is comprised of closed cells, so absorptiveness is low and resistance to water penetration is relatively high. Also, there is no absorption due to the capillary tube phenomenon in the openings between the perpendicular grains.

2) Results of analysis for gases on combustion revealed that apart from CO and CO_2 there were no emissions of harmful gasses such as hydrogen chloride, sulfur oxides etc.

3) The paper insulation density control according to the expansion multiple is relatively easy, and a density range of 20 kg/㎥ ~ 35 kg/㎥ was found to be applicable as building insulation materials.

4) Thermal conductivity of the paper insulation has high correlation to density, and the test results showed thermal conductivity of 0.034 W/mK ~ 0.037 W/mK according to density.

Physical property tests are currently in progress in relation to diverse items required in building insulation materials, and especially because paper insulation is comprised mainly of recycled materials and no global warming related gasses are emitted in the expansion process, comprehensive direct & indirect economic evaluation taking into account these physical properties and analysis of the environmental load reduction effects will continually be conducted.

Keywords: small-diameter hydraulic heating pipes, slim ondol system, thermal performance, energy consumption

Summary

Ondol, the Korean traditional floor heating system for houses has undergone many changes, and has been used as the heating system for most residential buildings until now. The biggest change to Korean ondol was the introduction of the hot water ondol system with pipes in the mid-1970's. The structure and heat-supply principle of the ondol system greatly changed, but few comprehensive and systematic studies have been conducted to improve the technologies related to the design, construction and operation thereof. Accordingly, typical examples of unreasonable installation of the current floor heating system are the excessive heat collection capacity, the imbalance of the floor surface temperature, and the insistence on the wet construction method, which in turn result in the increased structural load, the difficulty of renovations and maintenance, and the waste of resources and energy.

Meanwhile, the energy-saving policies of the government to reduce the environmental load, such as global warming caused by greenhouse gases, and the high oil prices in recent years are highlighting the importance of the energy consumption and efficiency of the ondol system. Accordingly, various studies are underway to develop a new ondol system and increase on-site application with the aim of reducing the energy consumption of buildings which account for about 30% of domestic energy consumption.

The purpose of this study is to develop an energy-efficient ondol system capable of heating at a relatively lower temperature by eliminating the imbalance of floor temperature, which is the weakness of the most common wet-type ondol, and by increasing the radiation capacity per unit area. In this study small-diameter hydraulic pipes (Ø 8mm), which replace the existing hydraulic pipes 20mm in diameter, were installed at intervals of 75mm. A unit model experiment was conducted to evaluate the thermal performance and energy consumption characteristics by examining the radiation characteristics according to the hot water supply temperature and supply flux.

1. Introduction

Ondol, the Korean traditional floor heating system for houses, has undergone many changes over the years, and has been used as the radiation panel heating system for most residential buildings until now. Currently most high-rise apartments have the district heating system or the local heating system using city gas, and the heating system most widely used for houses in Korea is the hot water circulating ondol. This is a wet type. That is, an insulating resilient layer is installed at the bottom. After the filled layer based on autoclaved light-weight concrete is installed above the insulating resilient layer, heating pipes are installed and mortar is applied. Then, boards, room carpets or ondol floors are laid.

Meanwhile, the national energy-saving efforts to reduce environmental loads in response to the continuation of high oil prices and global warming due to greenhouse gases highlight the importance of energy consumption and efficiency of ondol. Accordingly, diverse researches are being conducted to develop new high-efficiency ondol systems and to increase their application as part of the effort to reduce building energy consumption, which accounts for about 30% of domestic energy consumption. In addition, it will be necessary to develop a 3R (Reuse, Reduce, Recycle) ondol system capable of reducing environmental loads and pollution by using environment-friendly building materials derived from waste materials.

With the purpose of developing a slim ondol system capable of eliminating the imbalance in floor temperature, which is the shortcoming of an ordinary wet-type ondol system, and heating with relatively less warm water and improving energy efficiency by increasing the radiating capacity per unit area, this study evaluated the radiation and energy consumption characteristics of unit model test specimens in relation to the temperature and flow rate of supplied hot water.

2. Outline of the slim ondol system using small-diameter hydraulic pipes

2.1 Core technology

1) A 3R-type ondol system that substitutes the key component materials of the ondol system with wood, plastics and rubber by replacing those materials hard to recycle and reuse, such as autoclaved light-weight concrete and cement mortar.

2) Using dry-type and industrial members for on-site assembly to lengthen the life of apartments, and turning the structure of the ondol system into infill when the design is variable.

3) Adopting small-diameter hydraulic pipes (Ø 8mm) to improve the radiation capacity of the conventional dry-type ondol.

4) The entire ondol system, including slim panels, will have an ultra light-weight structure so that the load of the ondol layer will be reduced to 1/5 or less when the structure of the building is designed.

5) A dry-type ondol system which is comparable to the wet-type cured with cement mortar in terms of amenity and sensitivity of walking.

2.2 Outline of the system

The slim ondol system, using small-diameter hydraulic pipes, replaces the XL pipes of the existing wet-type ondol and places small-diameter hydraulic pipes on modular panels at narrow intervals of 75mm. It is a dry-type/prefabricated modular radiation panel system that increases energy efficiency by maximizing the radiation area and thus increasing the radiation capacity per unit area. The cross-section and unit panel of the slim ondol system are shown in Figures 1 and 2 respectively.

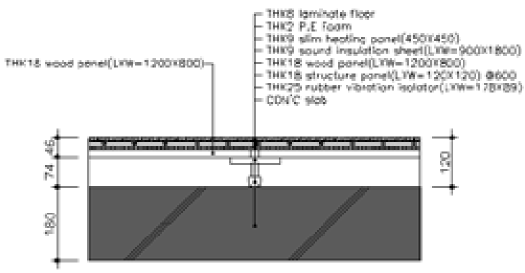

Fig 1. Cross-section of the slim ondol

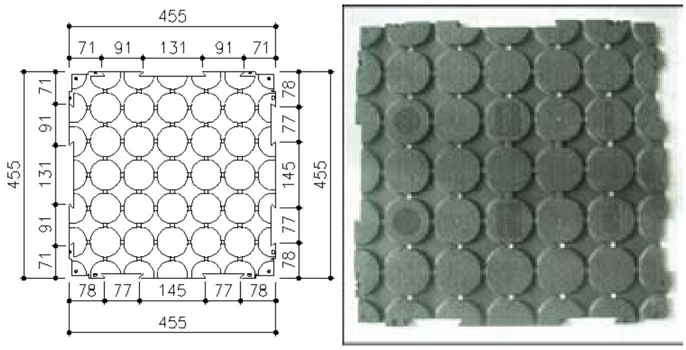

Fig. 2 The dimensions and shape of the slim ondol panel unit

3. Evaluation of the thermal performance and energy consumption characteristics

In an artificial weather laboratory where precise control of thermal environment elements, such as indoor temperature, humidity, air velocity and air distribution, the performance of the slim ondol system, i.e. the heat release and energy consumption characteristics, was evaluated against the heating conditions (room temperature, supply water temperature, etc.) of the apartment ondol system.

1) Evaluation of the changes and uniformity of the floor surface temperature in relation to supply water temperature and flow rate under continuous and intermittent heating conditions,

2) Evaluation of the energy consumption properties vs the wet-type ondol

A heatproof cover is installed in the ondol system to be measured to ensure its temperature is different from the temperature of the temperature setting (20℃) inside the laboratory. The energy consumption necessary for maintaining the same indoor temperature was measured to compare and evaluate the energy consumption characteristics of the wet-type ondol and the slim ondol system.

3.1 The results of the evaluation of thermal performance in case of continuous heating

On condition that 45℃ water is supplied continuously at the flow rate of 3 Lpm, Figure 6 illustrates the changes of the mean floor surface temperature directly above (0/4 pitch, 4/4 pitch), in the middle (1/4 pitch, 3/4 pitch) and the center (2/4 pitch) of the wet-type ondol system and the slim ondol system, whereas Figure 7 illustrates the changes of the floor surface temperature in different parts of the pipe.

Table 1 shows the changes of temperature from 8 hours after hot water supply till the stop of hot water supply (floor surface temperature stabilization) in the thermal performance experiment in case of continuous heating. The mean temperature difference (ΔT) directly above and in the center of the pipe was 0.6K for the slim ondol system and 3.9K for the wet-type ondol system. The ΔT of the slim ondol system was about 3.3K smaller than that of the wet-type. Overall, the mean temperature of the floor surface of the wet-type ondol was about 1.5K higher than that of the slim ondol system.

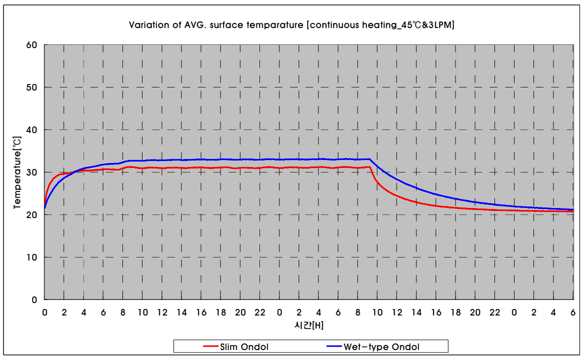

Figure 6. Changes in the mean floor surface temperature (continuous heating)

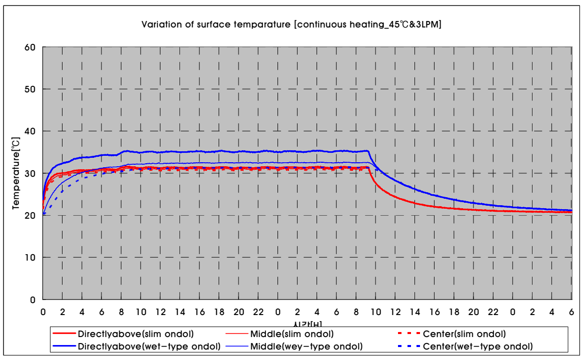

Figure 7. Changes of the floor surface temperature in different parts of the pipe (continuous heating)

Table 1. Changes of temperature under continuous heating conditions

Classification		Minimum	Mean	Maximum
Wet-type ondol	Directly above	34.8	35.1	35.4
	Middle	31.7	32.4	32.6
	Center	30.5	31.2	31.4
	Mean floor surface temperature	32.4	**32.9**	33.1
	ΔT (directly above-center)	4.3	**3.9**	4.0
Slim ondol system	Directly above	31.2	31.4	31.6
	Middle	30.8	31.0	31.2
	Center	30.6	30.8	31.0
	Mean floor surface temperature	30.9	**31.0**	31.3
	ΔT (directly above-center)	0.6	**0.6**	0.6

3.2 The result of the evaluation of thermal performance in case of intermittent heating

On condition that the 45℃ water is supplied for two hours at the flow rate of 3Lpm, and then cooled down for two hours, i.e., hot water was supplied intermittently three times in total (stage 1; 0 ~ 2 hours, stage 2; 4 ~ 6 hours, stage 3; 8 ~ 10 hours), Figure 8 illustrates the changes of the mean floor surface temperature in the wet-type ondol system and the slim ondol system. In case of intermittent heating with 45℃ water, 2 hours after hot water supply, the floor surface temperatures directly above, in the middle and center of the pipe were 32.48, 27.52 and 25.23 ℃ respectively for the wet-type ondol system. The temperature difference between the part directly above the pipe and the center was 7.25K. In case of the slim ondol system, the floor surface temperatures were 30.27, 29.77 and 29.40 ℃, showing a temperature difference of about 0.87K. The hourly increase of the mean floor surface temperature of the slim ondol system was 8.15 ℃/hour, while the hourly temperature decrease was 6.09 ℃/hour, whereas the hourly increase of the mean floor surface temperature of the wet-type ondol system was 7.20 ℃/hour, and the hourly temperature decrease was 2.60 ℃/hour.

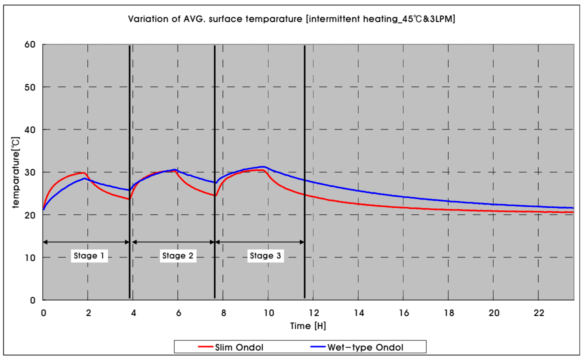

Figure 8. Changes of the mean floor surface temperature (intermittent heating)

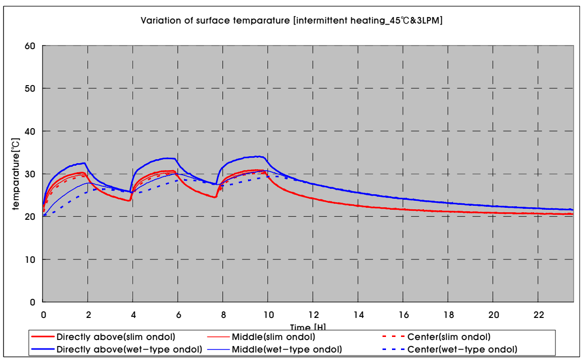

Figure 9. Changes of the floor surface temperature in different parts of the pipe (intermittent heating)

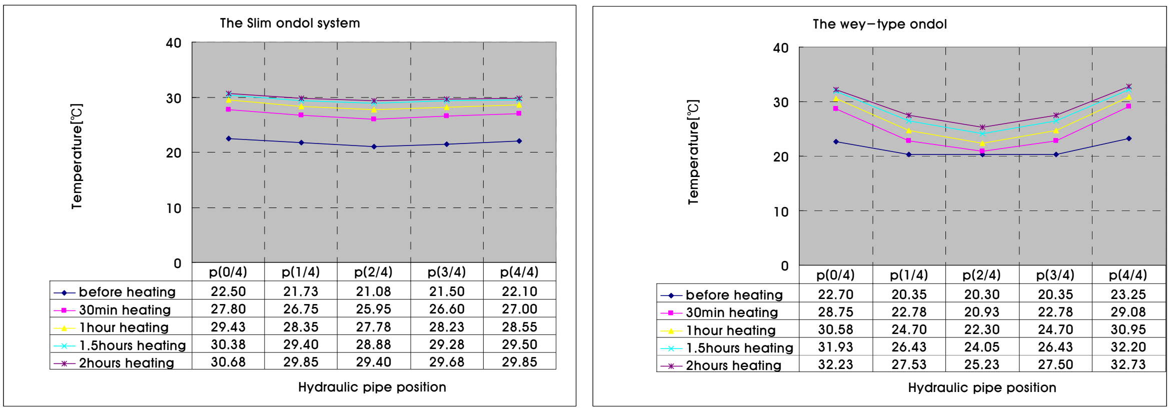

Figure 10. Slopes of the floor surface temperature (for stage 1 of intermittent heating)

3.3 The result of the evaluation of energy consumption characteristics

60℃ water was supplied for the wet-type ondol, and 45℃ for the slim ondol system to ensure that the indoor temperature of the artificial weather laboratory (outer room) was 20℃. The heatproof cover was installed in both the wet-type ondol and the slim ondol system, and the heating energy consumption necessary for keeping the indoor temperature inside the heatproof cover at 24℃ was measured. It was 8.60kW/h for the slim ondol system, and 9.10 kW/h for the wet-type ondol system. The heating energy consumption of the slim ondol system was about 5.5 % less than that of the wet-type ondol system. At this time, the indoor temperature inside the heatproof cover was almost the same for both ondol systems: i.e. 24.0℃ for the slim ondol system, and 23.8℃ for the wet-type ondol system.

Table 2. The result of the heating energy consumption characteristics experiment

Classification	Slim ondol system			Wet-type ondol			Remarks
	Minimum	Mean	Maximum	Minimum	Mean	Maximum	
Indoor temperature (℃) inside the heatproof cover	19.9	24.0	24.5	20.4	24.1	24.6	
Directly above (℃)	20.1	29.6	30.5	20.1	32.0	36.7	
Middle (℃)	20.1	29.6	30.5	20.1	29.4	30.3	
Center (℃)	20.2	29.3	30.3	20.1	28.7	29.0	
Mean floor surface temperature (℃)	20.1	29.6	30.5	20.1	30.0	31.6	
Heating energy consumption (kW. h)	8.60			9.10			24 hours

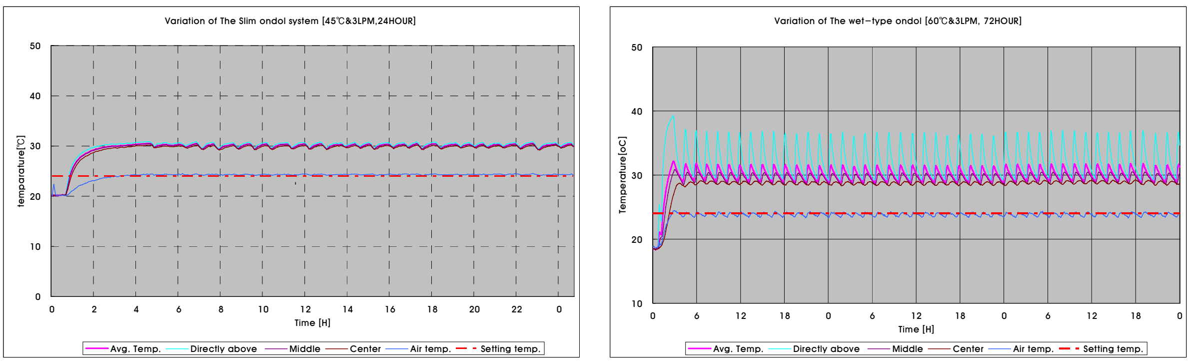

Figure 11. Changes of surface temperature in different parts of the pipes

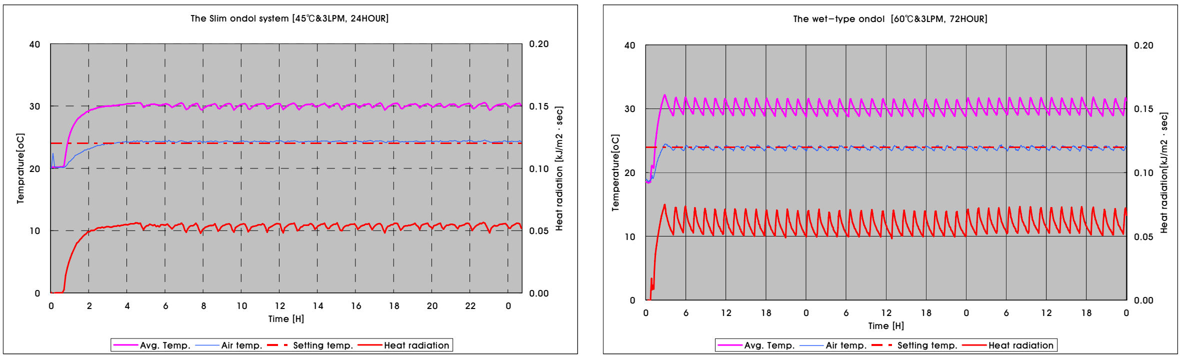

Figure 12. Changes of the mean floor surface temperature and heat radiation of the upper part

4. Conclusion

This study evaluated the radiation and energy consumption characteristics of the unit model test specimen, which is capable of heating with relatively lower-temperature water and increasing energy efficiency by solving the problem of the general wet-type ondol system, i.e. the imbalance of the floor temperature, in relation to supply water temperature and flow rate.

1) The mean radiation capacity of the upper part of the slim ondol system was 0.057 kJ/㎡ sec, better than or equal to that of the conventional wet-type ondol system. Meanwhile, the floor surface temperature difference of the slim ondol system was less than 2.5K for the entire floor surface, solving the uneven floor surface temperature distribution (over 6K) of the conventional wet-type ondol system, and the temperature deviations of the dry-type ondol system (over 10K).

2) On condition that the supply water temperature is 45℃, the mean floor surface temperature of the slim ondol system was greater than 29℃, indicating that it is capable of low-temperature water heating with the supply water temperature being lower than 50℃.

3) The heating energy consumption necessary for keeping the indoor temperature constant was measured with the unit thermal performance test specimen. The energy saving effect in case of low-temperature water heating (supply water temperature 45℃) was about 6% as compared to the wet-type ondol system (supply water temperature 60℃). Accordingly, in consideration of the heating load characteristics, such as the energy saving effect in the boiler due to low-temperature water heating and the heat storing, the energy saving effect of the slim ondol system is believed to be greater than in actual buildings.

Meanwhile, in consideration of the high oil prices constantly rising past the 100$ mark and energy consumption which accounts for about 80% of greenhouse gas emissions, this technology, capable of reducing energy consumption and environmental load at the same time by improving the efficiency of energy use while maintaining the same thermal environment, is thought to be of great significance.

A HIGH STANDARD OF SUSTAINABILITY FOR NEW ZEALAND HOMES

Lois EASTON MSc[1]
Megan HOWELL PhD[2]

[1] Beacon Pathway Limited, Gisborne, New Zealand loise@beaconpathway.co.nz
[2] Independent consultant, Auckland, New Zealand, mjhowell@ihug.co.nz

Keywords: sustainable, building, evaluation, benchmark, assessment methods

Summary

Why is it that we know more about the performance of our cars than we do about our homes? Homes are typically New Zealanders' largest single investment, and the place where we spend most of our time. Yet the performance of New Zealand homes is generally poor, with high economic, health and environmental costs for occupants and for New Zealand as a whole. Research shows that it doesn't have to be this way. New homes can be built to a much higher standard of sustainability and existing homes can be similarly retrofitted.

To support the shift to warmer, healthier and more resource-efficient homes, Beacon Pathway has identified a series of benchmarks that define a High Standard of Sustainability™ for New Zealand homes. This paper discusses key design choices made in developing the High Standard of Sustainability™, and argues for a performance-driven benchmark approach to both identify the sustainability potential of a home and to educate occupants about the effect of their behaviour on whether that potential is achieved or not. It identifies some of the challenges inherent in defining a High Standard of Sustainability™ for New Zealand homes, as well as the anticipated benefits.

1. Introduction

Why is it that we know more about the performance of our cars than we do about our homes? When we buy a new car, we think about how much it will cost to run – the rate of fuel consumption, cost of servicing and replacement parts, how long the car will last, and how safe it is. Performance data is an important part of the decision-making process. So, why don't we ask the same kinds of questions when we buy a new house?

Homes are typically New Zealanders' largest single investment – the New Zealand Reserve Bank estimates that approximately 90 percent of New Zealand households' net worth is represented by housing assets (Department of Building and Housing, 2007a)[1]. Houses are also where people spend 75 – 90% of their time (Beacon Pathway et al., 2007).

Yet the performance of New Zealand homes is generally poor, with high economic, health and environmental costs for occupants and for New Zealand as a whole. Research shows that it doesn't have to be this way. New homes can be built to a much higher standard of sustainability and existing homes can be similarly retrofitted.

Beacon's objectives are: 'creating homes and neighbourhoods that work well into the future and don't cost the Earth.' Through its research and advocacy, Beacon is working towards a goal 'that 90% of New Zealand homes reach a high standard of sustainability by the year 2012.' Fundamental to this goal is establishing what, exactly, a high standard of sustainability is. How should such a house perform?

This paper discusses key design choices made in developing the High Standard of Sustainability™ (Easton, 2006), and argues for a performance-driven benchmark approach to both identify the sustainability potential of a home and to educate occupants about the effect of their behaviour on whether that potential is achieved or not. It identifies some of the challenges inherent in defining a High Standard of Sustainability™ for New Zealand homes, as well as the anticipated benefits.

[1] The housing sector underpins much of New Zealand's economy. Approximately half of the building and construction industry activity in New Zealand is residential. The building and construction sector contributed around 5% of GDP and 8% of employment in the March 2007 financial year (Department of Building and Housing, 2007a).

2. New Zealand's Housing Stock: the Need for a High Standard of Sustainability™

There are approximately 1.6 million houses in New Zealand, with an additional 25,000 dwellings built each year (Beacon et al., 2007). The majority of the population will continue to live in houses that have already been built, and were not designed to achieve a high standard of sustainability.

Achieving a high standard of sustainability across New Zealand's housing stock – both new and existing, and at all socioeconomic levels – is important for several reasons, leading to health and economic benefits to residents and the wider community, as well as environmental benefits.

2.1 Health Benefits

New Zealand enjoys a temperate climate, but the country's houses are for the most part cold, damp, and hard to heat in winter (Howden-Chapman, et al., 2004). About 65% of the current housing stock was built before 1977, when there was no requirement for insulation to be installed as part of the construction process. Furthermore, many homes built since 1977 are known to still not meet basic insulation standards.[2]

Common problems identified in New Zealand homes – across all socioeconomic groups – include (Phipps, 2007):

- **cold:** New Zealand homes are on average 6°C below World Health Organization recommended minimum temperatures in winter;
- **damp and mould:** 45% of all New Zealand homes are mouldy;
- **poor air quality:** approximately 300,000 New Zealand homes have an unflued gas heater and the air inside New Zealand homes can be more polluted than outdoor air; and
- **presence of fungi and dustmites:** triggering allergenic reactions and asthma, rates of which are increasing.

These problems are significant contributors to illnesses, such as asthma and bronchial diseases. New Zealand has the second highest rate of asthma in the world, with one in six adults and one in four children experiencing asthma symptoms (over 600,000 New Zealanders), conservatively estimated to cost New Zealand $825 million per year (Asthma and Respiratory Foundation of New Zealand, 2002).

Research shows evidence of health returns well in excess of the investment in housing improvements, and the New Zealand Energy Efficiency and Conservation Authority have identified that health is a more persuasive driver for homeowners to upgrade their home than climate change or energy efficiency.

Direct health benefits to residents also contribute to substantial wider benefits to the nation, such as reducing illness-related absences from employment and education (key drivers of productivity) and reducing hospitalization and heath-care costs (Beacon et al., 2007).

2.2 Environmental and Resource Efficiency Benefits

New Zealand homes generally require substantial inputs of energy, water and materials, and generate large amounts of waste. Households directly consume 32.4% of national energy (including transport energy) (Energy Efficiency and Conservation Authority, 2007). Construction and demolition waste – a good proportion of it from residential construction and demolition – is thought to represent up to 50% of all waste generated in New Zealand (Ministry for the Environment, 2006).

Some of the country's infrastructure is nearing the end of its functional life and, with the additional load from growth in population and per capita demand, it is reaching critical capacity constraints. For example, electricity supply has relied on hydro power stations commissioned throughout the twentieth century. As demand has grown, the proportion of electricity supplied by hydro generation has declined from 85% in 1980 to 60 – 65% today, with the deficit met with a mix of gas, coal, geothermal and wind (in declining order of contribution) (Parliamentary Commissioner for the Environment, 2005). Given environmental sensitivities it will be extremely difficult to commission any further hydro power stations.

Demand side management can go some way to offsetting the need for further investment in supply. New Zealand's Electricity Commission calculated that installing 3 million compact fluorescent light bulbs[3] in New Zealand homes would save enough electricity to power up to 30,000 homes a year, generate annual household savings of around New Zealand $45 million, and reduce CO_2 emissions equivalent to taking 40,000 cars off the road (Electricity Commission, 2006).

As a signatory to the Kyoto Protocol, New Zealand has made a commitment to stabilise its greenhouse gas emissions at 1990 levels. Unfortunately, rates of emissions are continuing to accelerate, and the country now faces a significant bill for carbon offsetting. The National Value Case (Beacon et al., 2007) suggests that around 22 PJ of household energy consumption could be saved per year through simple

---

[2] Minimum insulation standards in the Building Code were raised in 2007, with expected reductions in the order of 30% of energy necessary to stay 'comfortably warm' (Department of Building and Housing, 2007b). Even fewer existing homes meet these new, higher standards.

[3] This equates to replacing five standard bulbs with five CFLs in every second home in the country.

measures. That is enough energy to power over 500,000 New Zealand homes for a year, and would offset around 3,600kt of CO_2 emissions. Allowing for take-back effects (warmer, healthier homes, spending household energy savings on travel and other commodities), CO_2 savings of 1,600kt are still produced.

2.3 Consumer Expectations, and Sustainability as a Marketing Tool

After several decades of small-scale initiatives, New Zealand is now experiencing a rapidly growing level of consumer interest in all things sustainable. Energy efficiency is still the major focus of most of the schemes underway, including the Energy Wise retrofit programmes available throughout the country since the mid-1990s, and the newly launched voluntary Home Energy Rating Scheme (HERS) run by the government Energy Efficiency and Conservation Authority.

However, the scope of initiatives is beginning to extend beyond energy, with various tools and rating schemes being released to support home owners to make informed choices in all aspects of their home's design and operation, including the Smarter Homes and Homesmarts websites.[4] Other tools are also being developed, for example rating tools by the New Zealand Green Building Council. There has been very low uptake of rating schemes in the past (the most notable New Zealand example of a rating scheme being the Green Homes Scheme run by BRANZ), so it will be interesting to see if increasing consumer interest leads to greater uptake.

The marketing of building products is certainly responding to increasing consumer expectations (or may even be driving them), with companies claiming energy efficiency, healthy homes, future-proofing and the like for their various products. Yet, as sustainability becomes something of a marketing tool, there is the potential for a great deal of confusion – just what makes for a sustainable home? How can homeowners make the best choices for their specific needs?

All of these factors point to a need for New Zealanders to be able to define what achieving a High Standard of Sustainability™ in a home means – how the home should perform, and what features are necessary to deliver that level of performance.

3. The High Standard of Sustainability™

The High Standard of Sustainability™ (HSS) developed by Beacon identifies a set of benchmarks by which homeowners can:

a. understand the performance of their homes; and

b. gain insight into the effect of their behavioural choices (that is, the gap between the home's design potential and its actual performance).

Five key performance areas have been selected to define the HSS: energy, water, indoor environment quality, waste and materials (Easton, 2006). These are underpinned by issues of affordability and future flexibility (consistent with Beacon's objectives, introduced above). In combination, these performance areas ought to demonstrate whether a home is performing sustainably or not.

Beacon's focus is on the homes of ordinary New Zealanders rather than any particular income or demographic group. For this reason, the HSS is defined within the confines of *what is reasonably achievable for the mass market today*. This tempers the level of the benchmarks, down from what might be achieved with excellent design or significant capital investment, to a level that is more reasonably aligned with the potential of 'mainstream' design, industry expertise, and consumer acceptance. It is anticipated that the HSS will be staircased to require higher levels of performance over time, as sustainable design is increasingly employed.

Affordability was a significant consideration in setting benchmarks. The cost of implementation (whether retrofitting or new development) and length of payback period were taken into account to set benchmarks which are practically achievable. Future flexibility was also a concern. Benchmarks and features were selected so as to be adaptable to changes in dwelling use, household structure, and the changing ethnic and socio-economic mix of the population.

Initial benchmarks have been established as a "first cut" starting point from which to assess Beacon's high standard of sustainability for houses, and are set out in figure 1. The benchmarks were established based on the best available national information. For example, this included the Household Energy Enduse Project and the ALF3 model for setting energy benchmarks (BRANZ, 2006), and work

[4] The Smarter Homes website (www.smarterhomes.org.nz) is an initiative of the government Department of Building and Housing and is 'aimed at home owners and renters, people looking to buy or build houses, and at building and property professionals who want an overview of smart home and building issues.' Its intent is 'to provide clear, independent, factual information about sustainable home design, building and lifestyle options.' This is supported by the Homesmarts tool (www.homesmarts.org.nz), which provides a more detailed level of advice, including a Smart Home Tour and Home Health Check, modelled on the findings from Beacon's Now Home® research programme.

commissioned to assess national levels of domestic water consumption (on a per capita basis) for the water benchmark (Lamborn, 2006).

The benchmarks provide a baseline of information for researching Beacon's hypothesis that it is possible to build new homes and retrofit existing homes to achieve a high standard of sustainability within a framework of affordability and use of existing technology. It is entirely expected that the benchmarks will be revised over time as data sets improve, and work is already underway in this regard.

As a set of benchmarks, the HSS is intended to operate as the *underlying standard* that is promoted through a range of tools, including the Homesmarts website and Beacon's design guidelines for construction and renovation of new and existing homes. It may also be used as an underpinning common reference point for the various home rating tools that exist in the New Zealand market-place (or are currently in development). It must be underlined that the HSS is not a rating tool in its own right, and there are no plans to develop it as such. The intention is for the HSS to work with rating schemes, ensuring compatibility rather than competition.

Energy

- New homes: 7,600 kwh/yr (climate zone 1), 8,500 kwh/yr (climate zone 2), 9,800 kwh/yr (climate zone 3)
- Existing homes : 9,050 kwh/yr (climate zone 1), 11,000 kwh/yr (climate zone 2), 12,000 kwh/yr (climate zone 3)

Water

- 180L/person/day

Indoor Environment Quality

- temperature: 16° C bedroom mean min temp; 18° C living room mean min temp
- ventilation: 0.4 -0.6 air changes/hour (new homes), 0.5 – 0.75 air changes/hour (existing homes)
- relative humidity: mean relative humidity 20 - 70% in bedrooms and living space
- checklist: mechanical extract ventilation of kitchen, bathroom and laundry; windows with passive venting; no unflued gas heaters; Environmental Choice certified paints and finishes; no air conditioning

Waste

- Provision for kitchen waste composting or storage space for kitchen waste collection
- Space for recyclables storage
- No in-sink waste disposal unit
- New building construction or renovation in accordance with REBRI construction guidelines

Materials

- New homes checklist: materials which promote good indoor air quality, have minimal health risks during construction or retrofitting, are durable and have low maintenance requirements, incorporate recycled content or can readily be recycled, reuse existing or demolished building materials or can readily be reused, are made from renewable or sustainably managed resources, have low embodied energy including minimal impacts due to transport, choices, construction (waste) guidelines, have low impact on landfill or are biodegradable, have third-part certification (e.g. NZ Environmental Choice, Forest Stewardship Council.
- Existing homes checklist: applies principles from new homes checklist to retrofit or renovation, where appropriate.

Figure 1 The High Standard of Sustainability™

4. A Whole-of-House Approach

Many of the sustainable housing initiatives that exist in New Zealand are focused only on one issue – particularly energy efficiency. It is a key Beacon assertion that the sustainability of a home is an interdependent web of features/performance areas (see fig 2). It is not possible to address only one resource stream and call the house sustainable.

Focusing on a single issue can lead to compromises and under-performance in other aspects of the home. Energy efficiency can be achieved through under-heating the home, but this compromises indoor environment quality. Conversely, heating the home for IEQ reasons (without also improving the dwelling's thermal performance) can lead to high energy demand. High water use also has energy implications - approximately 30% of typical New Zealand household energy consumption is spent heating water. Plus, there are infrastructure costs for collection, storage, transport, treatment, use and disposal of water.

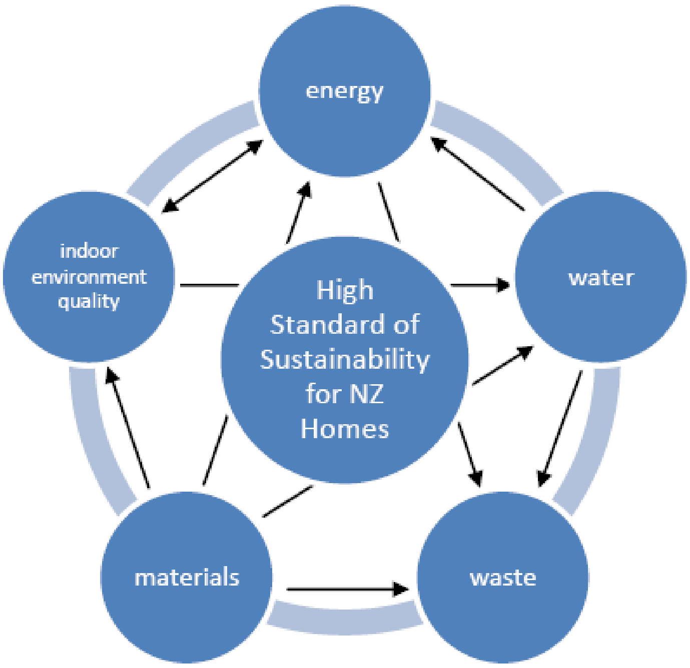

Figure 2 Sustainability as an interrelated web of features

5. A Measurable Approach: Benchmarks versus Checklists

As far as possible, the HSS benchmarks have been established as measurable units, rather than as checklists of features. Providing checklists of features is an extremely useful approach for identifying the range of options available to improve a home's performance, however checklists tend to lack a connection to performance outcomes – particularly due to the variable effect of occupant behaviour.

Preliminary data from Beacon research indicates that a sustainably designed home will perform better than a conventional one, regardless of occupant behaviour, but that the extent of the improvement is dependent in large part on the behavioural choices of the occupants.

Following a checklist should make a home warmer, healthier and more resource efficient, but once the features are installed, checklists may not support improved occupant practices. For example, leaving taps running and drapes open can undermine the intended benefits of these features.

By specifying measurable benchmarks, the HSS identifies the design potential of a home and establishes a simple feedback loop between occupant behaviour and home performance. Occupants can regularly measure their performance against the benchmarks, and better understand where they can make improvements. For some performance areas, such as reticulated energy, the measurement can be easily obtained from power bills. The same applies to reticulated water in places where it is metered. Indoor environment quality is a more complicated set of measurements, and a simple monitoring tool for New Zealand homes is in development as part of Beacon research.

For the IEQ, materials and waste performance areas, the HSS has had to rely on checklists - due to the nature of the performance being measured and the lack of available data to set measurable benchmarks. As research progresses, it may be possible to specify measurable benchmarks for these areas.

6. Application in Beacon's NOW Homes®

As part of developing and testing approaches to increase the sustainability of New Zealand homes, Beacon is building a series of NOW Homes® – resource efficient homes defined to be affordable to most New Zealanders. Beacon is also currently monitoring retrofits of nine "average" homes to increase their level of sustainability – this number will increase significantly in the immediate future.

The Waitakere NOW Home® was completed in August 2005. The home was designed and built to budgets and constraints typical of "ordinary" New Zealand housing rather than aimed at the top 5% of the market more typical of other "ecohomes". Passive solar design, resource efficiency, minimisation of hazardous materials and future flexibility were all key considerations in designing and building the home. As a result less than 2.5 tonnes of construction waste was produced, compared with a study of 'conventional' new 3-bedroom homes, which each produced 6 tonnes of construction waste (Kazor and Koppel, 2007).

The first twelve months of monitoring from the Waitakere NOW Home® demonstrated that the house can meet the HSS benchmarks. The home used 7400 kWh/year of electricity, with supplementary space heating being required for only two days. When compared to the occupants' previous dwelling, this was 45% less electricity than they used in their previous home (French et al, 2007). There has been an increase in the second year, with the occupants using 8500 kWh/year. Analysis shows that this "take back" has been in the form of additional hot water use (longer and more frequent showers) and additional appliances being introduced into the home – an important illustration of the home's design capability versus the effect of its occupants' behavioural choices.

In contrast, water usage has declined, from 100L/person/per day reticulated water (a total of 189L/person/day including rainwater) in the first year, down to 85**L**/person/day reticulated water (and a total of 172L) (Pollard et al, 2008). In addition, the quality of the indoor environment and occupant satisfaction is very high, and the health of the family living there has improved (French et al, 2007).

7. Challenges for Design and Implementation

Measuring the performance of New Zealand homes and establishing generally relevant benchmarks is not a simple task. Accounting for variability, and finding meaningful methods of communication are two of the key challenges.

7.1 Variability

Variability is one of the greatest impediments to establishing appropriate, generally applicable benchmarks. The challenge arises in terms of:

- Significant variability in the performance of the housing stock, due to climate, construction type, size, etc. resulting in a wide range of starting points and potential for improvement;
- Major issues over the availability and reliability of existing data; and
- Wide variability in the effect of operator influence.

7.1.1 Housing stock variability

There will always be differences arising from climate conditions and housing typologies. A brick and tile unit in Auckland (climate zone 1) cannot be equitably benchmarked at the same energy performance levels as a draughty villa in Invercargill (climate zone 3). This is recognised to an extent in the HSS, with differential benchmarks according to climate zone and whether the house is new or a retrofit.[5] It is anticipated that greater levels of differentiation will be developed over time and as data becomes available (for example, setting benchmarks for different housing types).

7.1.2 Data variability

A key issue for the HSS is the variability – and in some cases simple lack – of data on which the HSS benchmarks rely. For example, data relating to average domestic potable water consumption is extremely variable, with no accepted national average. In a country where water has been a relatively abundant resource, there is little knowledge about where our water actually goes. Some of this variability may be due to regional differences in water use (due, *inter alia,* to climate, soil type and water charging practices) and some due to different measurement methods (with some places measuring only gross per capita consumption, including agricultural and commercial uses, as well as losses due to leaky supply infrastructure). However, it makes it difficult for Beacon to determine an appropriate baseline benchmark. For this reason, the benchmarks have been specified as 'first cuts' that will need to be reviewed as Beacon and other research organisations develop a stronger evidence base.

[5] Similar performance differences occur for water (particularly due to garden watering), and indoor environment quality (due to humidity levels). These benchmarks are currently set at a relatively low threshold and apply nationwide. Further research underway may suggest a more fine-grained approach, setting benchmarks to better reflect local conditions.

7.1.3 Operator variability

As noted above, occupant behaviour has a marked influence on home performance. The HSS benchmarks focus on the performance potential of the physical fabric of the home, based on best available data (related to both the particular dwelling and to average data). Benchmarks need to be carefully defined to ensure that the HSS is not seen as an accurate prediction of actual consumption or a guarantee of performance, but rather as an indication of design potential. This issue is not unique to New Zealand. Comparable international standards (e.g. the UK Code for Sustainable Homes and New South Wales' BASIX tool) all come with provisos that their measures are established to be design tools rather than a guarantee of operational efficiency (BREEAM Centre at the Building Research Establishment, 2007, p. 70, Centre for International Economics, 2005, p. 2).

7.2 Communication

A further challenge for the HSS is in communicating a wide range of information simply and meaningfully. Using actual measurements is important for the educational and management purposes of the HSS, but the range of units – litres per person per day, kilowatt hours per year, rate of air changes per hour, degrees Celsius – could potentially be overwhelming. At this stage it is proposed that the HSS be communicated in two layers – a first, simpler layer of percentage savings compared to conventional dwellings of a similar style and location (as is done in BASIX and other such tools), and a more detailed layer for application once users are more familiar with the range of issues and measurements.

8. Anticipated Benefits

The High Standard of Sustainability™ is a key measurement tool for Beacon to establish, pursue, and monitor its objectives. Successfully defining and applying the HSS through its research programmes should help to deliver a better understanding of the sustainability of New Zealand's housing stock, with an improved data set, gathering and comparing performance data about New Zealand homes against a simple set of measures for sustainability. It should also provide an improved evidence base for investment and decision-making at both household and national levels. Perhaps most importantly, the development of a simple measurement tool should help to improve New Zealanders' understanding of:

- their home's performance – in the first instance, this is likely to be an awareness of the substandard nature of the majority of our homes;
- the effect of their behaviour on their home's performance; and
- the sustainability features to look for when buying or renovating a home.

Achieving the HSS in a growing proportion of New Zealand homes will generate benefits for residents, the housing industry, the public sector and the environment, including improving New Zealanders' quality of life through healthier homes, reducing the demand for valuable resources such as energy and water, and reducing carbon dioxide emissions. It will help to increase productivity and make more efficient use of New Zealand's resources, and improving the resilience of the New Zealand housing stock to global challenges such as climate change, resource availability, and population change.

9. Further research

As identified above, the benchmarks identified within the HSS are a 'first cut' – largely due to the poor understanding of housing performance in relation to sustainable development. As more data becomes available, it is expected that the HSS will be reviewed and recalibrated accordingly.

There will be an ongoing challenge to ensure the HSS strikes a balance between 'stretch' and achievability (that is, setting the benchmarks high enough to make a notable difference in the sustainable performance of dwellings but not so high that the HSS is out of reach of the mass market). The variability of New Zealand's housing stock – in terms of design and climate, means that setting appropriate benchmarks for some performance areas, particularly energy, needs to be more fine-grained.

Further research is also needed to support implementation of the HSS – for example, conducting life cycle analysis on systems used in construction to inform materials choices, and developing packages of features that can be expected to achieve the performance benchmarks.

There is potential for the HSS to expand to include other performance areas, e.g. more specific provisions around stormwater, wastewater, ecology, and social sustainability dimensions such as building homes that are adaptable to changing resident needs. How wide the scope of the HSS should be is a question of finding an appropriate balance between comprehensive cover and ease of use.

10. Conclusions

The poor standard of the majority of New Zealand homes, combined with increasing consumer awareness of the benefits of more sustainable homes, means that the HSS is a much-needed benchmarking tool – communicating possibilities, establishing expectations, and leading change. The High Standard of Sustainability™ is a way of establishing how New Zealand homes can be expected to perform – equipping residents with information to benchmark their homes, to understand what they can achieve within their home, and to signal where improvements can be made.

Providing a simple means to measure – and consequently to manage – is also fundamental to Beacon achieving its goals nationally: creating homes that work well into the future and don't cost the earth. It provides the information necessary to understand the condition of New Zealand homes, and to make a business case for change, enabling the nation's housing stock to be progressively improved over time.

Establishing appropriate benchmarks – that is, benchmarks that are measurable, achievable and yet also lead to a significant improvement in housing quality – is an ongoing challenge for Beacon. The HSS benchmarks are expected to be made more stringent over time, as data improves and as it becomes easier to incorporate sustainable features into the majority of homes.

Keywords: daylight, tropics, facade, office, building, design, case study, zero energy, zeo

Summary

The tropical Zero Energy Office (ZEO) building in Malaysia is nearly 100% daylit without causing glare and over-heating to the building occupants. This key daylight design strategies were 1) orientation of the building facades North and South to take in diffuse light and block direct sun light 2) facade with split window design and lightshelf 3) development of a daylight window with a fixed blind that allows light entry and prevents glare 4) development of roof lights and 5) a daylight response electric lighting system. The split window design ensures that the daylight performance is maintained even though occupants by the facade engage the roller-blind, as it only covers the lower viewing window.

All workstations were given task lights to give the occupants individual control of their lighting environment. The lighting control strategy for the general lighting is 'automatic off' and 'manual on', so the electric lights only are switched on when needed.

Despite the lack of a culture of working in a 100% daylit environment, the Malaysian occupants of the ZEO building found the work environment pleasant and use minimal electric lighting.

1. Introduction

1.1 Overview of Cast Study Building

In October 2007 the Malaysian Energy Centre (Pusat Tenaga Malaysia) moved into their new headquarter building, the Zero Energy Office building, which is a cutting edge demonstration project for energy efficiency and renewable energy in a tropical office building. The zero energy design (3270 m² air-conditioned floor space) married super low-energy building designs/technologies with 92 kW_p building integrated photovoltaic panels. While typical Malaysian office buildings have an energy index of 175 kWh/m² floor area per year, the ambitious energy index of the ZEO building is 35 kWh/m² per year (EAEF, 2006). An international team of expert consultants collaborated with the Malaysian Energy Centre and local consultants to meet the target; fine-tuning of the building is still on-going. One of the key features for achieving the low building energy index was the extensive use of daylighting throughout the building.

Figure 1 Zero Energy Building photographed from entrance and at photovoltaic roof

1.2 Daylight Availability

Tropical Malaysia has an abundance of daylight. At latitude of 3.15° North the change in weather is very minor across the year. Daylight hours are from 7 – 19 o'clock. Diffuse sky radiation, which is best suited for daylighting purposes, accounts for about 60% of the global radiation, which means the sky often is overcast or partly overcast. The average diffuse radiation reaches a peak mid-day value of 50,000 lux, whereas it drops to 15,000 lux at 8 o'clock in the morning and 17 o'clock in late afternoon; see Figure 2. The annual sun path, also shown in Figure 2, comes close to zenith all year with a slight tilt of the sun to the North in the summer months and a slight tilt to the South in the winter months.

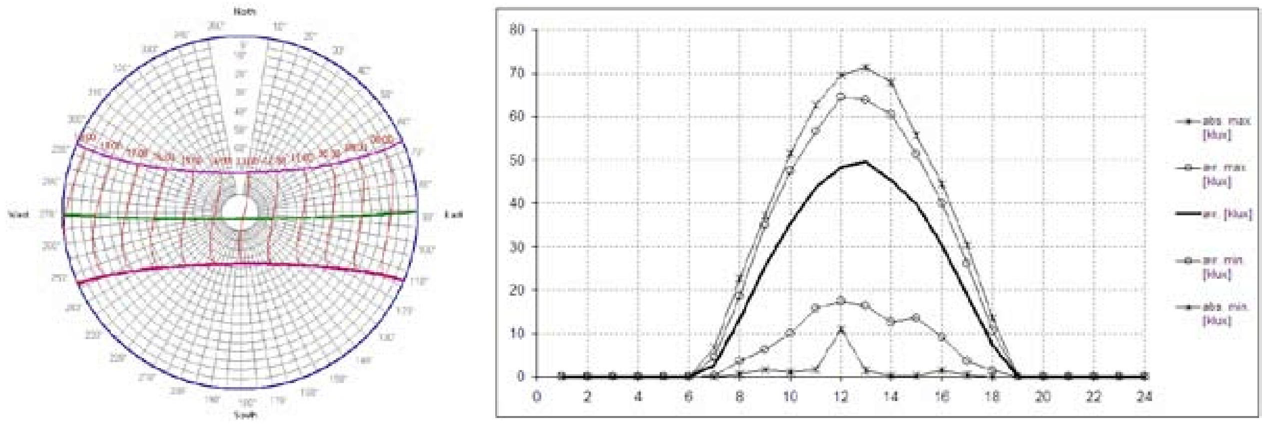

Figure 2 Annual sun path (left) and annual average diffuse sky radiation for Kuala Lumpur, Malaysia

The Malaysian building code (MS1525) recommends an office task light level of 300 - 400 lux. This is only a fraction of the outdoor lighting level, as can be seen in Figure 2. Daylit buildings are often designed to meet a certain daylight factor. A daylight factor is the amount of diffuse daylight measured horizontally indoors divided by the amount of diffuse daylight measured outdoors on a horizontal unshaded surface. For Malaysian office spaces it is recommended to have a daylight factor of 1 - 2% on the desk table top. This means that the at an outdoor diffuse illuminance level of say 20,000 lux top, the light level on desk table top with be 200 - 400 lux. It is worth noting that most people can work comfortably at indoor illuminance level of down to 150 lux or lower – particularly if they are doing computer work. Figure 3 below illustrates the frequency by which the lighting requirement of 300 lux is met by different daylight designs in Malaysia.

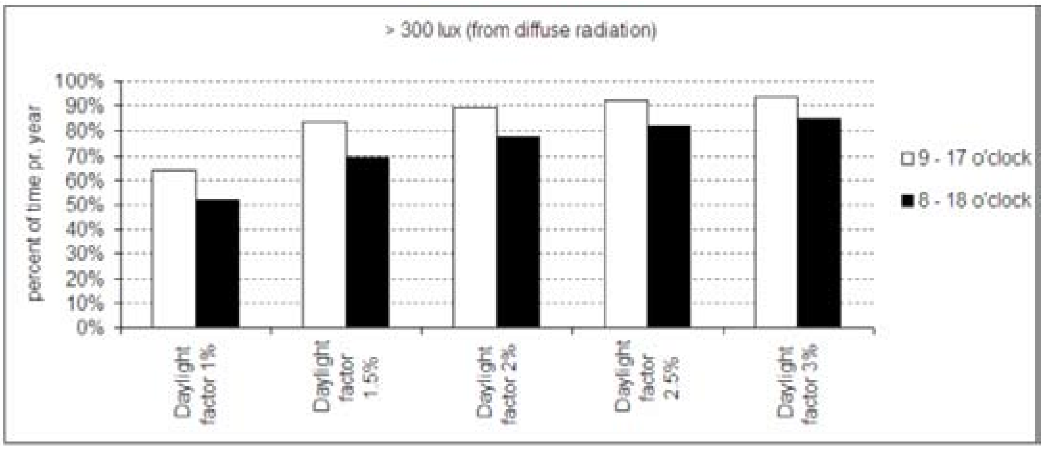

Figure 3 Annual frequency by which the 300 lux requirement is met at for rooms of a different daylight factor in Kuala Lumpur, Malaysia.

Figure 3 shows that for a room with a daylight factor of 1.5% the 300 lux requirement will be met 83% of the time between 9 – 17 o'clock and 70% of the time between 8 – 18 o'clock. Keeping in mind that people often accept working at lower light levels, a daylight factor of 1.5% seems like a reasonable design target to achieve a high annual daylight utilisation without providing excessive daylighting. The daylight factor should not be too high, as increased light levels might cause glare and/or wash-out of the computer screen. For these reasons, Nabil and Mardaljevic (2006) recommends for office daylight values to stay below 2000 lux. Moreover, an increase in light entry also means a higher solar gain, which – unlike in temperate climates – always is undesirable in the tropics.

1.3 Tropical Daylight Design: Building Orientation

Diffuse daylight is the preferred light source for daylighting because it varies less than direct sunlight, it is softer and it has a slightly higher lumen efficacy than direct sunlight. In tropical countries the North and South facade orientations are both well suited for daylighting purposes because these facades easily can be shaded completely by a limited horizontal overhang (see Malaysian sun path diagram in Figure 2).

1.4 Tropical Daylight Design: Room Depth

Daylight can only reach so far in side-lit rooms. Therefore, the room depth should not be too deep. The general rule of thumb is that rooms can be daylit corresponding to 2.5 times the window height; see Figure 4 below.

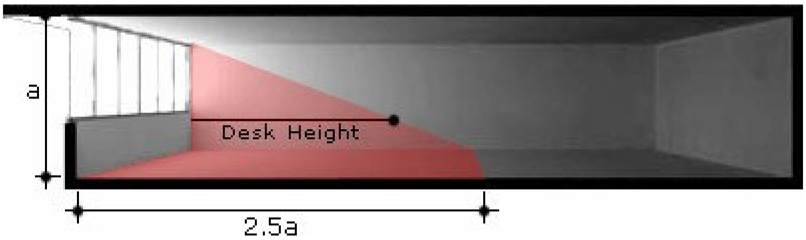

Figure 4 Rule of thumb for reach of usable daylighting for side-lit rooms (Square One, 2007).

Workstations should be placed along the facade where the daylight is found and circulation spaces, which have a lower lighting requirement, should be located towards the back of the room where daylight levels are dimmer. People should face parallel to the facade when working and care should be taken that their workstation cubicle walls do not block the daylight, for example by using transparent or translucent partitions as is done for the Zero Energy Building (see Figure 7).

1.4 Tropical Daylight Design: Glare Prevention

The combination of strong tropical sun and a light cloud cover can make the sky very glary. A direct view to the sky should therefore be limited in order not to cause visual discomfort for the building occupants. The alternative of choosing a heavily tinted glazing (light transmittance < 30%) is not a good option as it cuts away too much of the daylight. A split-window design is therefore recommended, where the upper daylight window is fitted with a dual function (fixed) blind or optical glazing that both directs light onto the ceiling and blocks a direct view to the sky. This allows the light transmittance of the upper daylighting window to be high. The lower viewing window – that typically would run from the floor or parapet wall and up to a height of approximately 2 meters from the floor – can have a lower light transmittance and a manually operated blind for glare prevention and/or to ensure privacy. It is recommended to have an external lightshelf between the upper and lower windows in order to shade the lower window at direct more light through the upper window.

1.5 Tropical Daylight Design: Glazing Properties

The following performance is recommended for the glazing listed in order of priority:

1) Spectrally selective coating (light passes through, infrared and UV light is reflected)
2) Low-e coating (heat radiation from window is reduced)
3) Double pane window (thermal gain through window is reduced)

Soft coats work most efficiently and they have to be applied to the protected pane surfaces inside a sealed double-pane window. The lumen efficacy of daylight is about 200 lm/W when spectrally selective windows are used. For comparison, the best lumen efficacy of fluorescent light is only about half.

1.5 Tropical Daylight Design: Daylight Responsive Lighting System

The electric lighting system must be zoned and daylight responsive to benefit from the daylighting design.

2. Daylighting in the Zero Energy Office Building

2.1 Facade Design

The facades of the ZEO building are facing North and South. They are perfectly shaded from direct sunlight because the building is self-shading by stepping out 1 meter for each consecutive floor as shown in Figure 5.

Figure 5 Section of typical facade (left) and section of self-shading building stepping out 1 meter each floor (right)

In Figure 5 the substantial 1.4 meter deep lightshelf give able shading for the lower viewing window. The mirror lightshelf also reflects diffuse light through the upper daylighting window and onto the ceiling as illustrated in Figure 6 below. The lower window has a manually operated blind that does not impair the daylight performance of the facade if left engaged, as 80% of the daylight in the office comes (> 2 m from facade) comes from the upper daylighting window.

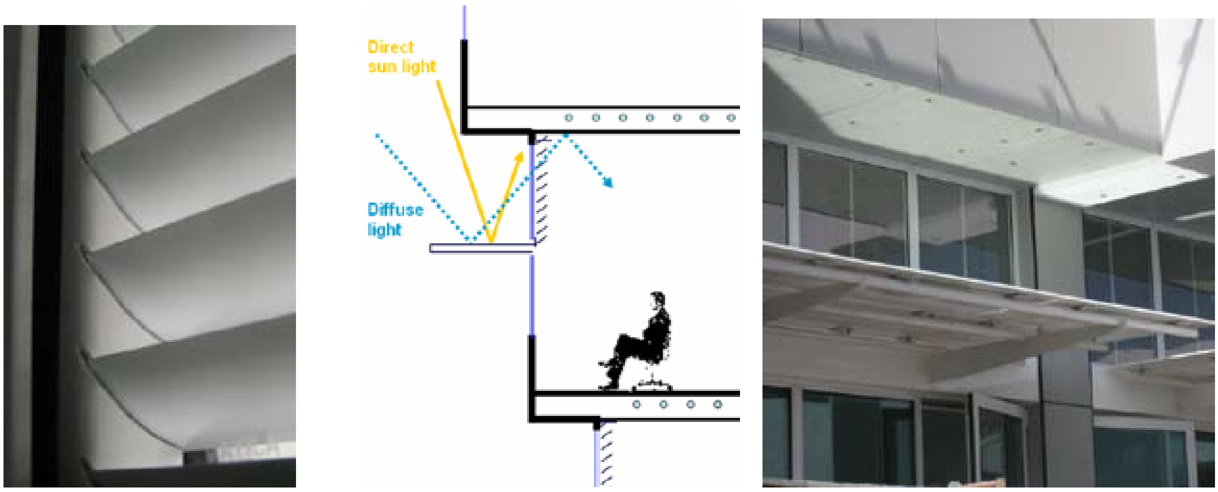

Figure 6 Close-up of fixed blind for upper daylighting window (left). Illustration of how facade lets lower angle diffuse light pass through and blocks off higher angle direct sunlight (middle). Photo showing that the facade design intent works (right).

The right-hand photo of Figure 6 shows direct sunlight is seen deflected from the mirror lightshelf and onto the bottom side of the overhang. The photo was taken on 12 June, i.e. almost at the maximum North tilt angle of the sun, so since no direct sunlight enters the upper daylighting window at this time it will also be the case the rest of the year. The fixed blind for the upper daylighting window (Figure 6, left) is mounted inside the double pane window. The blind has been designed exactly to block the view out of the window when seated at the last row of workstations 5.2 meters from the facade. This allows for a gradually increasing blind spacing from bottom blind to top blind such that the blind spacing is 24% higher at the top to maximise daylight entry. It is also worth mentioning that the lower side of the blinds, which can be viewed from the inside, is painted matt white to avoid veiling reflections and visual discomfort, whereas the upper side of the blinds are specular reflective to maximise daylight. Key data of the facade daylighting system is given in Table 1 below.

Table 1 Material properties for daylighting facade system

Item	Light transmittance	Reflectance	Specularity	Comment
Upper daylighting window, no blind	0.71			
Lower viewing window	0.5			
Lightshelf, top surface		0.85	0.8	Mirror
Fixed daylight blind, top surface		0.85	0.8	Reflective aluminum
Fixed daylight blind, bottom surface		0.85	0.05	White matt paint
Tannenbaum ceiling, no clear lacquer		0.85	0.7	10° tilt angle profile
Ceiling		0.85	0.05	White matt
Walls		0.85	0.05	White matt
Floor		0.5	0	Light brown carpet
Manual blind	0.25			For lower window

The 1st floor has the least daylight towards the back of the room because it has not roof light. A so-called Tannenbaum reflective sheet was mounted on the ceiling in a 2.5 meter deep perimeter to increase light reflection towards the back of the room. The Tannenbaum has a small 10° profile engraved into its semi-specular surface, such that glare from the ceiling is avoided because reflected light is directed downwards at a sufficiently steep unlike for a flat semi-specular sheet (Figure 7).

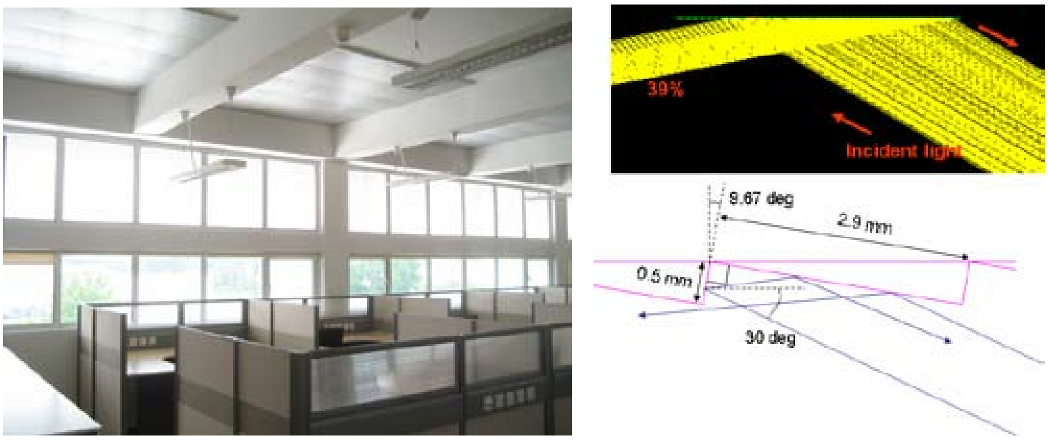

Figure 7 Reflective Tannenbaum ceiling panel for 2.5 meter perimeter of 1st floor

Daylight measurements from all three rows of workstations from the facade are show below in Figure 8. The measurements show that indoor light levels are adequate and not overpowering for a wide range of outdoor lighting conditions. The daylight levels in workstation rows 2 and 3 is very stable and are not affected much by variations in outdoor lighting conditions and/or use of the curtain (i.e. roller blind for the lower viewing window). This means that occupants in workstation row 1 can use the roller blind without obstructing the daylight concept for the rest of the office.

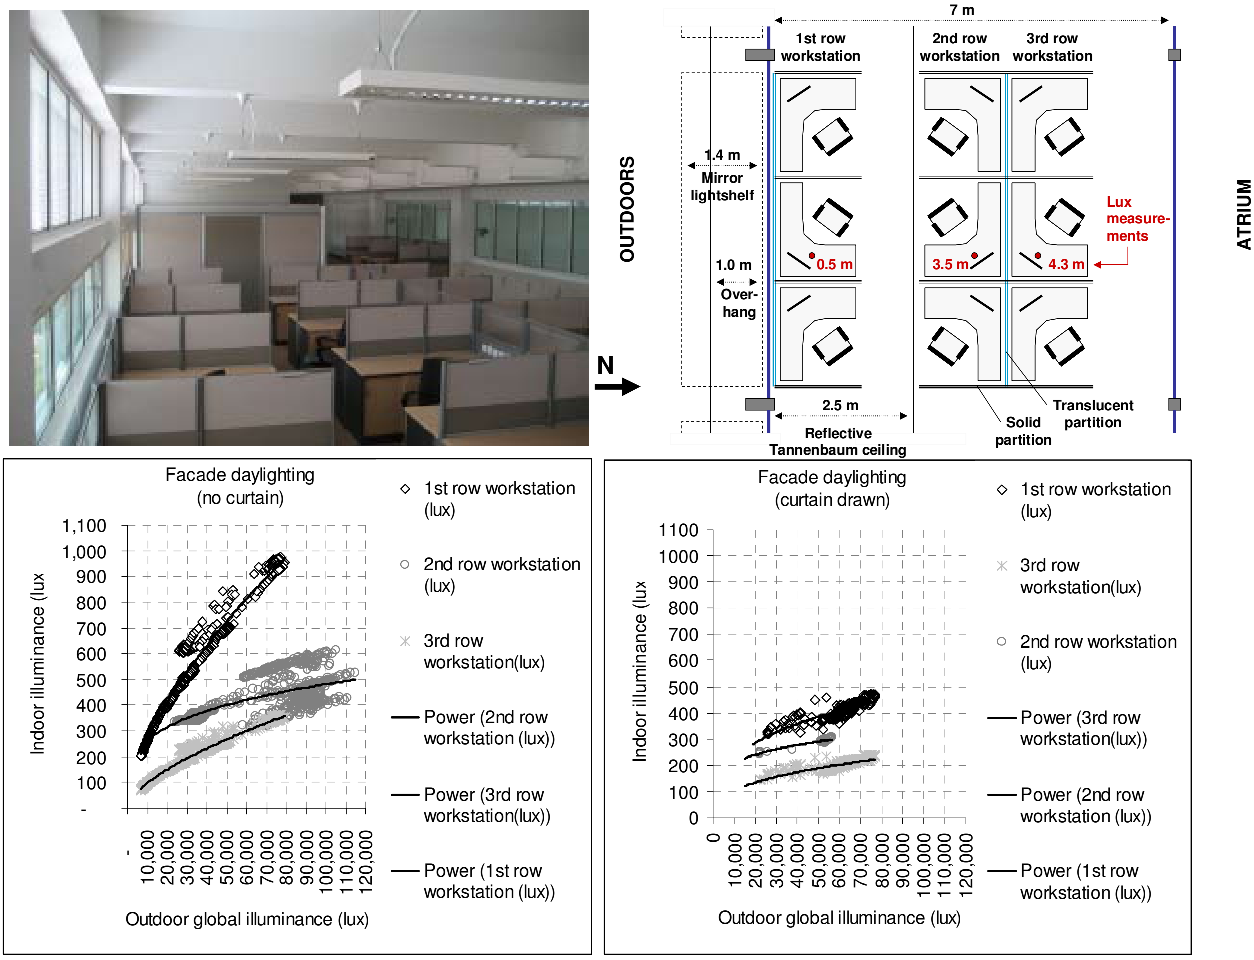

Figure 8 Daylight measurements in three rows of workstations from the facade in the 1st floor open plan office of the ZEO building.

The 300 lux code requirement for office lighting is met most of the day for workstation rows 1 and 2, whereas workstation row 3 often falls a bit short with only 200 lux, which in practice has not posed a problem. People often work at daylight levels down to 100 lux – especially for computer work – before deciding to switch on the electric light. Efficient 6.2 W table lamps are provided for each workstation giving each building occupant the possibility of supplementing the daylighting. The general lighting can only be switch on when outdoor daylight levels are low.

The measurements show that the facade daylighting system works well. Electric lights are off in the office areas except during the dim early morning and evening hours – or during the occasional thunderstorm. The installed lighting power is 4.8 W/m², but the measured lighting consumption is less than 1 W/m²; see Figure 9.

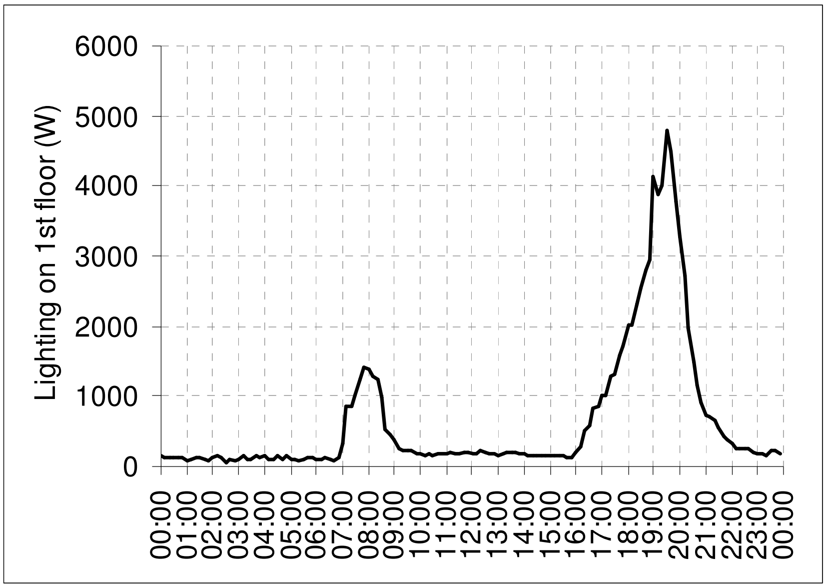

Figure 9 Average electric lighting consumption for the 1st floor (3 months data)

The electric lighting consumption in Figure 9 shows a minimal consumption during the day and some consumption in the morning and in the later afternoon / evening when there is little/no daylight.

2.2 Roof Light Design and Light Tube

The roof has several light scoops that only allow entry of diffuse daylight in from the North. Reflective cladding inside the roof light directs the daylight downwards. From inside the building the roof lights look like an ordinary light fixture. Measurements below the roof lights show that the 300 lux requirement on average is met between 8:30 and 17:30 o'clock; the maximum measured light level is 1250 lux.

Figure 10 Roof lights oriented to the north photographed outdoors and indoors

Two roof light tubes were punched through the 1st floor to provide daylight to the entrance at ground floor level. Each light tube has a cross sectional area of about 1 m² and are clad with spectrally reflective aluminum on the inside. They look similar to the roof lights (Figure 10) but have a weaker light output due to the longer shaft. Moreover, they have the disadvantage of taking up floor space in the levels above.

2.3 Daylight Atrium with Integrated Photovoltaics

Solar cells were sandwiched in between the laminated atrium glazing to yield both daylighting and power production (12 kW_p).

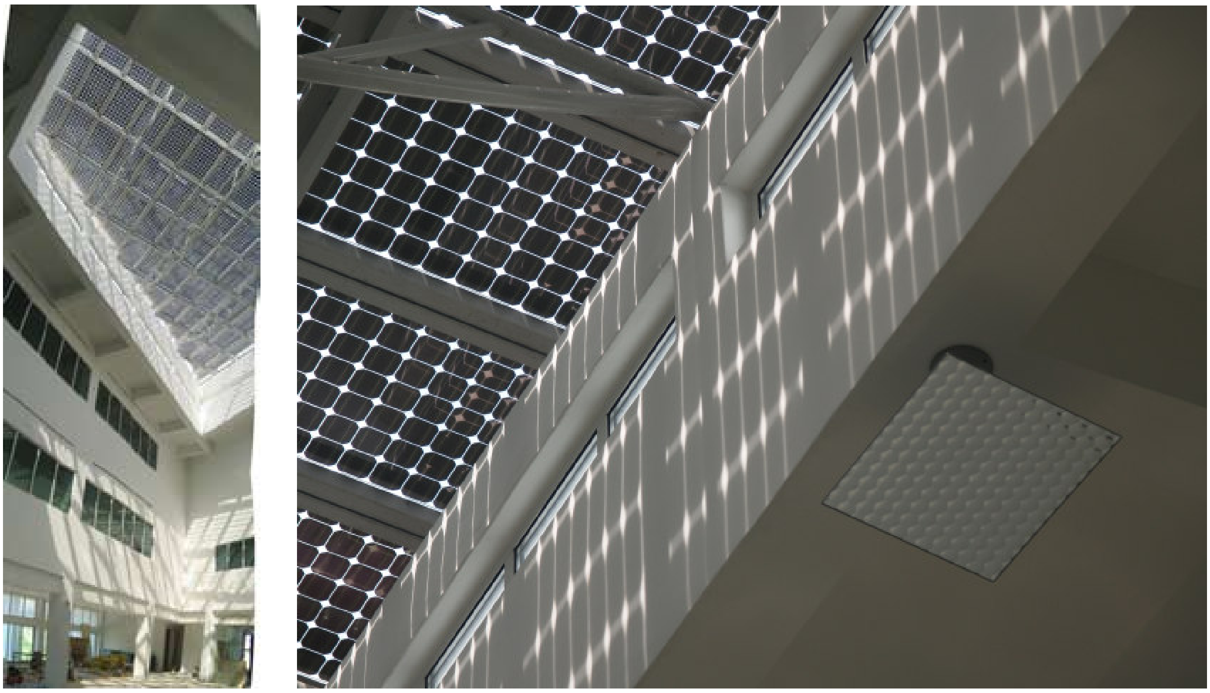

Figure 11 Atrium with integrated solar cells

About 13% of the roof was open to daylight penetration giving a pleasant light level (1% daylight factor) and giving beautiful sunshine patterns on the atrium floor and walls

3. Conclusion

The ZEO building has successfully employed innovative facade and roof daylighting technologies to off-set nearly all electric lighting. Since the building was occupied in October 2007, the electric lighting consumption during office hours has been less than 1 W/m². In the tropics there is no culture of working in 100% daylit office environments. Nevertheless, the occupants are happy to work in the daylit environment with typical daylight levels of 200 – 1200 lux.

The daylighting design for the office spaces relies on diffuse sky radiation whereas direct sun light is blocked out. This gives a stable indoor light level despite big changes in the outdoor lighting level. Measurements from the second row of workstations show that a 5-fold variation in the outdoor light level only causes a 2-fold variation in the indoor lighting level.

SUPPORTING AND GUIDING DESIGN TOWARDS A GREEN BUILDING

Roberto Lollini
Italo Meroni

ITC-CNR Construction Technologies Institute of the National Research Council, www.itc.cnr.it

Keywords: guideline, manuscript, sustainable, building, conference, green, frame, structure

Summary

A 100-meter high big transparent parallelepiped combining lightness and a strong capacity to characterize the surrounding territorial environment: that's how Roman architect Massimiliano Fuksas imagined and conceived the new headquarters of the Piemonte Region.

The complex will consist of two elements: the 100-meter tower that will house the Region's offices and a lower building that will develop horizontally and will serve as a congress centre to accommodate up to 150 people and will be the headquarters of other services of the city of Turin.

The sustainability level of the building will be evaluated throughout the different steps of the project by means of a methodology based on the ITACA protocol, which is in turn based on the GBC methodology.

The methodology was defined and applied by ITC-CNR and iiSBE-Italia with the main purpose of defining performance guidelines to steer design, right from its early steps, towards constructive and technological solutions able to enhance the environmental quality of the building once they are integrated into it.

The evaluation system was used in synergy with common design tools in order to increase designers awareness of the fallout on energy-environmental performances of the architectural and technological choices of what will become one of the symbols of the city of Turin.

The paper describes in particular the practical issues related to the integration of the tool, largely depending on the interaction of two distinct processes such as design and verification of sustainability and the results obtained in terms of analyzed performance indicators.

1. Introduction

The assessment of the new Piemonte Region headquarters was carried out in compliance with a well structured approach, extensively used for residential buildings, but still quite experimental with regard to tall buildings.

Anyway, in the context of the accreditation process of the Italian chapter to the WGBC (World Green Building Council) a deep change of the so far used methodological approach is under way, towards a real building energy-environmental sustainability certification system, with rigorous rules, organized in the form of certification procedures, where the activities and the responsibilities of the several involved actors are specified.

Such a system is growing around the well proven assessment tool "Protocollo ITACA", Italian version of the known SBTool, through the following actions:

- identifying the organizations, which shall assess/certify the building by the application of the already defined evaluation procedure;
- defining the qualification and independence criteria of the assessors who shall work in compliance with the procedures defined for the building certification;
- defining the accreditation criteria for the organizations, which shall work within the framework of the defined certification system.

On the contrary, as stated above, the assessment tool is ripe enough form the conceptual and methodological point of view, though it requires the planning of R&D activities aimed at the optimization of the weighting, benchmarking and criteria analysis procedures, identifying suitable calculation tools for the determination of the performance indicators on the basis of the normative and legislative framework in force and of the technical-scientific literature.

Even in this very dynamic context that is going through a reorganization phase, the case study carried out allowed to verify the usefulness of the assumed methodological approach, in particular for designers, forced to face a wide set of performance targets, partially dependent from each other, in directly or inversely proportional way. This provided incentives to the interaction among the different professionals involved in the design team and the identification of an interdisciplinary connection technical figure able to communicate with the assessment team using a 360 degrees vision.

Also, the performance-based approach used to measure the building quality showed how the construction market could be naturally boosted towards the realization of buildings with a high environmental sustainability level, if only the final user or the investor were aware of the reachable performance targets and of the consequences in terms of performance (with regard to both resources consumption and indoor environmental quality) for the building they are using or purchasing.

The "Italian system" is complex and structured, all the more so over the last years due to the so-called "devolution", that transferred several governmental powers from the Central State to the Regions, not always ready to plan and manage the new technical issues. In this picture, though starting from a common tool as the "Protocollo ITACA", applications diversified both in terms of rules and contents were experimented. The assessment of the new Piemonte Region headquarters, due to its meaningful institutional role and representativeness, would also be a reference case study in order to exemplify that it is possible to structure a transparent and repeatable assessment process regarding a difficult subject like environmental sustainability, above all when the building typology shows very complex peculiarities too.

2. "Protocollo ITACA" for tall buildings

A specific assessment tool was defined for the building analysis, allowing to evaluate the peculiar aspects of tall buildings, that very often have unique constructive and technological solutions, which are hard to include into a too rigid evaluation scheme.

Such a tool was part of a certification process involving all the stakeholders: the buyer (Piemonte Region), several institutional organizations, the designers, the local utilities with regard to energy matters, obviously the Italian GBC (Green Building Challenge) chapter, and somehow also Turin's citizens (who will have the skyline of the city they live in, changed) with some public assemblies for the presentation of the project.

The buyer fixed the building's synthetic performance target, the assessors set the assessment tool, defining weights, benchmarks, criteria analysis methodologies, legislative and normative references. Together with the instructions for the use of "Protocollo ITACA" specific sheets were defined for the collection of data and design documentation, in order to facilitate the information exchange among the involved actors, allowing the designers to identify the essential information in order to characterize the solutions chosen for the assessment.

Actually the design team self-assessed the building project by calculating the performance indicators with regard to the several criteria of the assessment tool, providing at the same time the data and documentation necessary to control such a self -assessment.

Considering the still experimental condition of the certification system the objectives were essentially two:

- to define a methodological approach that could be a support/guide for the design process, towards a performance target fixed by the buyer;
- to devise the methodological calculation approach of the performance indicators with regards to the several criteria used to verify the design solutions quality.

From the point of view of the assessment tool the main issues faced concerned the weighting system and the definition of reference performance ratings (benchmarking), which are general issues for all the assessment tools, even more important in this case where an ambitious performance target was fixed.

3. Case study

3.1. The building

The assessed building is a big transparent parallelepiped, that rises up to a height of 100 m and brings together lightness and a strong capacity to mark the urban land: that's how Roman architect Massimiliano Fuksas imagined and conceived the new Piemonte Region headquarters.

The building will be built in the so-called "Spina 1", in the former Materfarro area (a surface of about 40,000 m^2) also marked by the railway link and it will contribute to redefine the image of the regional capital of Piemonte which, over the last years, has made strong efforts to carry out important architectural projects.

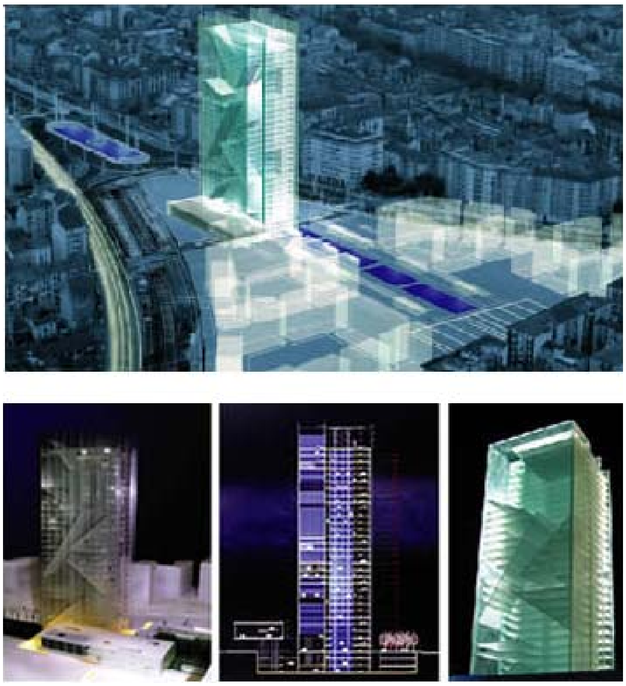

Figure 1. The new Piemonte Region headquarters

The arrangement of the indoor “big void”, the emphasis of the structural blades that partition the atrium space at full height and the personalization of some special internal functions are marks of a language directly referable to the latest architectonic avant-garde. Then the 100 m tower will be an evident sign in the Turin landscape, though without wanting meaning to attract attention on itself at all costs. It is of course a symbolic building, but its integration in the surrounding urban tissue is clear and recognizable. The belonging to the citizens community is underlined by the entrance hall, that is forced access to the different parts of the system: the Piemonte Region offices, the boardrooms, the congresses center and, significantly, the garden in front of the tower, as a point of confluence of Turin’s “Spina Centrale”, the 12 km boulevard stretching from South to North. Finally the architectural solutions seem to find a natural and unstrained harmony with the technological systems of which they are the legitimate precondition both for the ordinary arrangement of spaces and for the progressively and always different discovery of the big “chimney” rising from the entrance hall.

Besides, its realization was conceived within the framework of a strengthening plan regarding the area where it will be built, both from the functional and from the architectural point of view.

The overall cost of the works, also including the construction of a big car park, was estimated to be 100 millions euros.

The new glass building will host 1,300 employers, distributed in seven Councillor’s offices and twenty Directorate-General offices.

3.2. The assessment tool

The assessment tool used consisted of around twenty five assessment criteria, subdivided into the following issues:

1. resources consumptions;
2. environmental loads;
3. Indoor Environmental Quality (IEQ);
4. service quality.

A serious effort was made in order to reduce the tool complexity and to tailor it considering the preliminary design phase of a very complex building. Some assessment sheets are reported below as examples.

1. Resource consumption
- 1.1. Annual non-renewable primary energy expected for heating
- 1.2. Cooling
  - 1.2.1. Solar radiation control
  - 1.2.2. Thermal gain time shifting and attenuation factor
  - 1.2.3. Annual non-renewable primary energy foreseen for cooling
- 1.3. Renewable energy: foreseen production of energy by PV systems
- 1.4. Potable water consumption
- 1.5. Eco-compatible materials
  - 1.5.1. Use of recovered or recycled materials
  - 1.5.2. Use of materials by renewable source
  - 1.5.3. Embodied energy

2. Environmental loads
- 2.1. Equivalent CO_2 emissions
- 2.2. Centralized area for the solid wastes separate collection
- 2.3. Permeability of external areas
- 2.4. Liquid wastes
- 2.5. Heat island
  - 2.5.1. Heat island effect – landscaping and paved areas
  - 2.5.2. Heat island effect – covering

3. Indoor Environmental Quality
- 3.1. Thermal comfort
- 3.2. Visual comfort
  - 3.2.1. Daylighting
  - 3.2.2. Illumination
- 3.3. Acoustic comfort
- 3.4. Indoor Air Quality
- 3.5. Electromagnetic pollution

4. Service Quality
- 4.1. Controllability of the technological systems
- 4.2. Ability to modify facility technical systems
- 4.3. Adaptability to future changes in type of energy supply
- 4.4. Maintenance of building envelope performance
- 4.5. Creation and maintenance of a building log

Figure 2. The assessment criteria

Criteria 1.2.2. is an example of how a classic criteria of the "Protocollo ITACA" was transformed in order to suit the skyscraper, which is a building typology with light envelope, keeping unchanged the requirement to be satisfied, modifying the performance indicator, no more related to the envelope (thermal gain decrement factor and time shift as calculated in compliance with EN ISO 13786), but to the effect on building performances (indoor temperature without air-conditioning plant). The reference standard is the recent EN 15251, that defines dynamic comfort limits as a function of weather conditions.

Criterion 1.3 was tailored on the recent developments of the Italian power production market, that has lately started a liberalization process and allows the final user to choose the supplier or to self-produce on his own on-site. With respect to the structure and configuration of the SBTool, the on-site and off-site production was evaluated at the same time, in general rewarding the electricity production using renewable sources.

Also criterion 4.4 was modified as a function of the analyzed building typology, introducing in the qualitative scenarios some tests specifically defined for light envelope elements.

SUB-CRITERION: 1.2.2 – Thermal gain time shift and decrement factor	
Issue: 1 – Resources consumption	
Criteria: 1.2 - Cooling	
Requirement: to maintain good thermal comfort conditions in the built environment during summer, avoiding air overheating.	**Performance indicator**: indoor temperature without cooling system.
	Unit: °C

Method e and calculation tools

In order to assess the criteria the following procedure has to be used:

- Calculation of the external average dynamic temperature from 20th to 26th of July by the following equation:
  Trm= (Ted-1+0.8*Ted-2+0.6*Ted-3+0.5*Ted-4+0.4*Ted-5+0.3*Ted-6+0.2*Ted-7)/3.8
  Where:
  Trm = External average dynamic temperature (°C)
  Ted-n = Average temperature of the n-th previous day (°C)
- Calculation of the average operative temperature in the occupational period without a mechanical cooling system
- Calculation of the weighted average operative temperature:
  $To = (To_1 Surf_1 + To_2 Surf_2 + \ldots\ldots + To_n Surf_n)/(Surf_1 + Surf_2 + \ldots + Surf_n)$
  Where:
  To_n = Indoor average operative temperature n (°C)
  $Surf_n$ = Net room surface n (m^2)
- Identification of the comfort zone using the graph below.

Performance scale	Score
Beyond class III	-1

Technical Literature, Legislative References and Normative References

EN 15251 "Indoor environmental input parameters for design and assessment of energy performance of buildings addressing indoor air quality, thermal environment, lighting and acoustics".

Sub-criterion weight	40	%

Documentation

Provide a Technical Report for the assessment of sub-criterion 1.2.2, containing the following information:

- Reference weather data and description of the calculation carried out aimed at the determination of the whole building performance indicator.

Notes

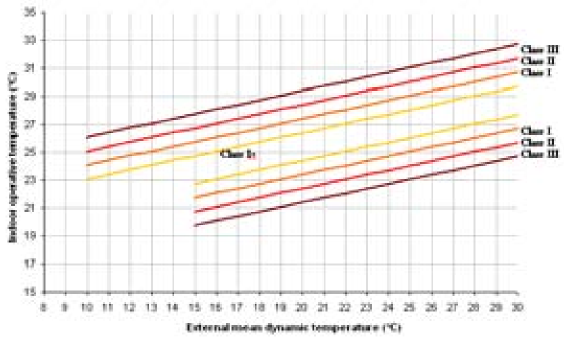
- The graph below is referred to buildings without mechanical cooling system.
- The operative temperatures reported in the graph apply to office rooms or similar, where sedentary activity is essentially carried out (activity from 1,00 to 1,30 met) and where the user may control window openings.
- According to statistic data the yearly warmest week for the city of Turin is from 20th to 26th of July. If simulation tools with different weather data are used, the simulation itself has to be carried out in the week with the warmest average temperature.
- The equations representing the straight lines in the graph are:

Class I+ Upper limit: $To_{max} = 0.33T_{rm}+18.8+1$
Lower limit: $To_{min} = 0.33T_{rm}+18.8-1$

Class I Upper limit: $To_{max} = 0.33Trm+18.8+2$
Lower limit: $To_{min} = 0.33Trm+18.8-2$

Class II Upper limit: $To_{max} = 0.33Trm+18.8+3$
Lower limit: $To_{min} = 0.33T_{rm}+18.8-3$

Class III Upper limit: $To_{max} = 0.33Trm+18.8+4$
Lower limit: $To_{min} = 0.33Trm+18.8-4$



CRITERION: 1.3 – Renewable Energy: foreseen production of electricity by Renewable Energy Sources

Issue: 1 – Resource consumption

Requirement: Promoting the use of electricity by renewable sources	**Performance indicator**: CF_{res} – Renewable Cover factor: estimated percentage of electric energy need covered by renewable sources
	Unit: % (kWh/kWh)

Method e and calculation tools
In order to assess the criteria the following procedure has to be used:
- calculation of the amount of electricity produced by renewable sources with regard to the power supply contract, the design and constructive choices for possible on-site renewable sources production systems, the weather data of the specific location;
- calculation of the ratio between the overall electric energy by renewable sources and the total estimated electric consumption;
- comparison of the calculated CF_{res} with the benchmark scale and assignation of the score.

Performance scale	**Score**
-	-1
16	0
19	1
22	2
25	3
28	4
31	5

Technical Literature, Legislative References and Normative References
Directive 2001/77/EC of the European Parliament and of the Council of 27 September 2001 on the promotion of electricity produced from renewable energy sources in the internal electricity market.

Criterion weight	25	%

Requested data
Provide a Technical Report for the assessment of criterion 1.3, containing the following information:
- characteristic of the power supply contract;
- components technical specifications and characteristics of the RES on-site production system, if present;
- Net building surface (m^2).

Documentation
Annexed to the Technical Report containing the requested input data necessary in order to evaluate the criteria 1.3, provide the following documentation:
- description of the analysis carried out for the possibly rough dimensioning of the power production system from renewable sources, if present;
- sketch of a cost-benefit analysis with the calculation of the payback time.

Notes
The reference electric load is 20 kWh/m^2year (source: EN ISO 13790).
In the case of off-site production by photovoltaic system, report the technical characteristics of the supply plant.

CRITERION: 4.4 – Maintenance of building envelope performance	
Issue: 4- Service quality	
Requirement: To ensure that detailed design minimizes the risk of moisture accumulating in the building envelope, where it is most likely to shorten the lifespan of building elements.	**Performance indicator:** surface relative humidity **Unit:** qualitative indicator

Method e and calculation tools

In order to assess the criteria the following procedure has to be used:

- calculation of the performance indicator in compliance with the standards UNI EN ISO 13788 and UNI EN ISO 10211-1 for low thermal inertia elements and other opaque envelope components next to thermal bridges;
- description of possible tests and analyses to be carried out during the construction phase;
- choice of the scenario that best describes the building characteristics and score assignment.

Performance scale	Score
The surface relative humidity of the low thermal inertia elements (transparent envelope components or opaque envelope components with surface mass lower than 230 kg/m^2) is greater than 0,8, while the surface relative humidity of the opaque envelope components with mass greater than 230 kg/m^2 or next to thermal bridges is equal to 1.	-1
The surface relative humidity of the low thermal inertia elements (transparent envelope components or opaque envelope components with surface mass lower than 230 kg/m^2) is lower than 0,8, while the surface relative humidity of the opaque envelope components with mass greater than 230 kg/m^2 or next to thermal bridges is lower than 1.	0
	1
	2
The surface relative humidity of the low thermal inertia elements (transparent envelope components or opaque envelope components with surface mass lower than 230 kg/m^2) is lower than 0,6, while the surface relative humidity of the opaque envelope components with mass greater than 230 kg/m^2 or next to thermal bridges is lower than 0,8.	3
	4
The surface relative humidity of the low thermal inertia elements (transparent envelope components or opaque envelope component with surface mass lower than 230 kg/m^2) is lower than 0,6, while the surface relative humidity of the opaque envelope components with mass greater than 230 kg/m^2 or next to thermal bridges is lower than 0,8. Pressurization tests and thermograph analysis for the evaluation of thermal bridges are scheduled for the operative phase in compliance with standard UNI EN 13829 and UNI 9252.	5

Criterion weight	25	%

Requested data

Provide a Technical Report for the assessment of criterion 4.4, containing the following information:

- average external minimum temperature (calculated on a daily basis) from December to February;
- external RH at the reference external temperature;
- indoor air temperature in compliance with the legislation and regulations in force for the specific building typology (report also the reference legislation or regulations);
- indoor RH.

Documentation

Annexed to Technical Report containing the requested input data necessary in order to evaluate criterion 4.4, provide the following documentation:

- technical report containing graphs and calculations with regard to the surface and internal condensation control for all the envelope components including the construction elements described in the technical sheet 1.1 (external envelope, roof, floor);
- description of the possible experimental plan and of the methodological approach.

Notes

- The satisfaction of the minimum requirements reported in standard UNI EN ISO 13788 has to be verified for all the construction elements described in the technical sheet 1,1 and for the structural nodes that could be thermal bridges.
- Low thermal inertia elements are the transparent envelope elements (note that the requirements have to be met both by glass and frame) and the opaque envelope elements with surface mass lower than 230 kg/m^2.
- For the definition of thermal bridges see standard UNI EN ISO 10211-1 at paragraph 3.1.1.
- For the definition of surface relative humidity and its calculation methodology see standard UNI EN ISO 13788 at paragraph 5.

The examples stated above would demonstrate the need to have an assessment system tailored on the specific building typology and placed in a specific context, considering the local rules and practice frameworks. Although the overall assessment tool structure and the methodological approach remain unchanged, weights, benchmarks, and criteria calculation references (theoretical picture and tool) should be accurately chosen in order to optimize the communication of the several involved stakeholders, increasing the awareness of the target and specific building performance that determine the final synthetic score for the building environmental sustainability level.

4. Discussion

Many criteria were assessed more on the basis of the designers' intentions than on the detailed description of the constructive and technological solutions, because design itself is still at an early phase.

It is then necessary to continue until the realization of the building, updating the criteria depending on the phase and verifying that a high level of sustainability is maintained first through a simulation software and then through an appropriate environmental monitoring.

Main lessons learned

- It is important to coordinate the design team and to identify a specific professional figure or group of experts able to prepare the data necessary for the assessment on the basis of the design documentation.
- Tall building is a peculiar building typology and there is still a big amount of work to do on the matter of environmental sustainability assessment: the tool has to be more and more tailored on this building typology and the design team must start thinking that they will have to interface with such a tool needing synthetic data, that could efficiently describe the designed solutions; the procedures used to produce and record the design documentation have to be thought in a new way, in order to be used to demonstrate effectively the building expected performances. The documentation currently prepared to "display" the building and to demonstrate the compliance with the legislation in force should be aimed also at this new communication intended both for the user and/or investor and for the assessor of the environmental sustainability level.
- Using clear performance indicators solves a lot of communication problems among the involved stakeholders.
- It is very important to underline the different building analysis phases: design, diagnosis, assessment/certification. In fact, the building performances analysis implies several activities each one with specific objectives, relevant methodological approaches and support calculation tools:
  - New building design;
  - Energy/environmental diagnosis;
  - Retrofit.

  The different building analysis phases must not be thought in straight lines, even if led by different persons who should, on the contrary, be given enough time to schedule meetings and discussions. As an example, the energy diagnosis results obtained by auditing and dynamic simulation are necessary data for the planning of energy retrofit actions; finally the assessor will use synthetic parameters derived from design documentation and from the use of products' technical sheets aimed at assessing the building energy potential. A subsequent collection and elaboration of actual consumption data will allow to verify the proper realization and management of the building, which might lead to suggesting suitable actions in order to fully exploit the building's potentials.

5. Conclusions

The case study carried out underlines the need for a connection among the institutions managing the certification system at national level, because by now design companies, investors and real estates, and builders are companies that operate at global scale and they should be able to face as uniform and consistent as possible assessment approaches to optimize performance indicators recognized and really representative of the environmental quality of the chosen constructive and technological solutions.

What's stated above is neither meant as a criticism to the assessment methods market, nor as a promotion of a tool rather than another; the main point is concentrating on the only really important target, that is the promotion and realization of buildings with a high environmental sustainability level, optimizing and enhancing the virtuous choices of designers and builders so as to turn some specific performance targets into common practice.

If on the one hand the commercial promotion of certification systems and tools has stimulated all the stakeholders to deal with building environmental sustainability, on the other hand it risks to choke down the objective to reduce the environmental impact of this sector, satisfying at the same time the final user performance requirements in a rat race to the certification market.

The path covered far for the new Piemonte headquarters assessment produced rewarding results for all the involved stakeholders who expressed the wish to continue walking this path mainly because the interaction among the parties was based on the use of a methodological objective, referenced, transparent and repeatable approach, giving guarantees both to the user and to designers with regard to the final building performance and the correct assessment of the solutions pointed out, respectively.

A PROCESS-ORIENTED SUSTAINABILITY APPRAISAL FRAMEWORK TO INFORM PLANNING FOR A SUSTAINABLE URBAN RENEWAL AT EAST LAKE, CANBERRA

Petra OSWALD MSc[1]
Guy BARNETT BSc Hons.[2]

Keywords: Integrated Assessment Framework, Sustainability Appraisal, Sustainable Urban Renewal, Participatory Action Research, Transdisciplinary Urban Research, Social Learning, Decision Support Tool, Discourse Analysis

Summary

Many existing sustainability assessment tools for urban planning lack a scientifically sound framework and urban systems context for sustainability evaluation and appraisal. In fact existing decision-support-tools are often rather technical, limited in their scope, and insufficient to meet the complex process, integration and communication requirements of real-world planning and the challenge of implementing sustainability.
This paper argues for a more comprehensive, process-oriented sustainability appraisal framework of collaborative research that offers several capacities of supporting urban planning and its decision-making for sustainability. Such an innovative approach has been developed for the East Lake Urban Renewal in inner Canberra, Australia, and is based on a transdisciplinary research partnership involving science, policy and the community. Designed as a participatory action research process that is "learning by doing", the project has been developing and testing an "Integrated Urban Planning and Assessment" approach that is flexible and adaptive to the local context and creates systems-based, integrated knowledge on sustainable urban development. A key part of this approach is a continuing stakeholder engagement and deliberation process to identify different needs and experiences, to induce social learning and to inform research and planning. Qualitative and quantitative urban research combines stakeholder knowledge with the latest scientific insights and delivers integrated, community-supported planning documents and a set of process guides, methods and tools to test different urban planning scenarios and to explore the various flow-on consequences of planning decisions with stakeholder groups.

1. Introduction and Background

Many cities around the world are increasingly focusing their attention on urban renewal as a process for revitalizing poorly managed or neglected inner urban locations, often typified by industrial decline. While the drivers for this style of development are often the social and economic factors associated with convenience and lifestyle preferences, urban renewal is also increasingly being seen as a means for producing higher density and more compact cities reducing resource consumption and thus helping address climate change. While there remains considerable debate about the various environmental costs and benefits of 'greenfields' versus 'brownfields' urban development, this only acts to highlight the growing need for policy-relevant approaches to provide integrated and evidence-based information on planning processes.

1.1 Sustainable Development and Decision Making under Uncertainty

As with many other policy fields, urban planners are charged with developing policy responses to problems that are often characterized by a high degree of complexity and interconnectivity where *"typically facts are uncertain, values in dispute, stakes high and decisions urgent"* (Funtowicz et al. 2002). Take for example, the pressing challenge of how best to deliver sustainable urban development in the context of a changing global climate and a national housing affordability crisis. In the face of such dilemmas, many urban planners are now turning to scientists for practical methods of sustainability appraisal to better inform their decision making on issues characterized by a multiplicity of perspectives, complex systems interactions and a high degree of uncertainty.

This paper examines the emerging role for applied science in urban planning processes, as explored through the development and application of an Integrated Urban Planning and Assessment Framework (IUPAF) to support decision making for the sustainable urban renewal of East Lake in Canberra, Australia.

1.2 Planning the Sustainable Urban Renewal of East Lake

East Lake was identified in the Canberra Spatial Plan (ACT Government 2004) as a significant area of the city that is suitable for future infill urban development. It is located within inner Canberra, close to central employment nodes and major transport routes. Nearly half of the 471 hectare East Lake site is dedicated to the Jerrabomberra Wetlands Nature Reserve, with the remaining areas comprising predominantly mixed industrial and commercial uses including the Canberra railyards and Fyshwick Fresh Food Markets. There is also a small area of residential development known as 'The Causeway', which is primarily public housing.

In September 2007, coinciding with the public release of the East Lake Draft Planning Report, Planning Minister Andrew Barr announced a partnership between CSIRO and the ACT Government to showcase sustainable urban renewal in the East Lake area. Implemented through CSIRO's Sustainable Communities Initiative (SCI) which brings together participants from across the public, private and civil society sectors, the partnership is focused at the nexus between sustainability research and policy implementation, with the aim of working closely with the community to develop innovative solutions to key urban sustainability challenges.

The foundation for the partnership is based on the premise that neither a standard consulting nor classical scientific research approach is sufficient to tackle the many challenges and opportunities associated with implementing sustainable urban development. Munda (2006) arrived at a similar conclusion stating that *"… scientists cannot provide any useful input without interacting with the rest of society and the rest of society cannot perform any sound decision-making without interacting with the scientists".* As such, new modes of partnerships between science, policy and the community are required, that deliver context-driven research for stakeholders, residents and policy-makers, building capacity and producing broadly accepted outcomes.

2. Towards an Integrated Urban Planning and Assessment Framework

For the East Lake project an Integrated Urban Planning and Assessment Framework was developed that is based on Participatory Action Research (Whyte 1991). This approach was adopted because it is a way of capturing 'real world' understanding of the issues and policy implications of a change process such as urban renewal. Our framework aims to inform East Lake planning decisions through a process that acts to deliver a common understanding and integrated knowledge-bases. These outcomes are pursued by combining, interpreting, integrating and communicating systems-based knowledge derived from stakeholder engagement, science-policy collaboration as well as qualitative and quantitative urban analysis (see Figure 1).

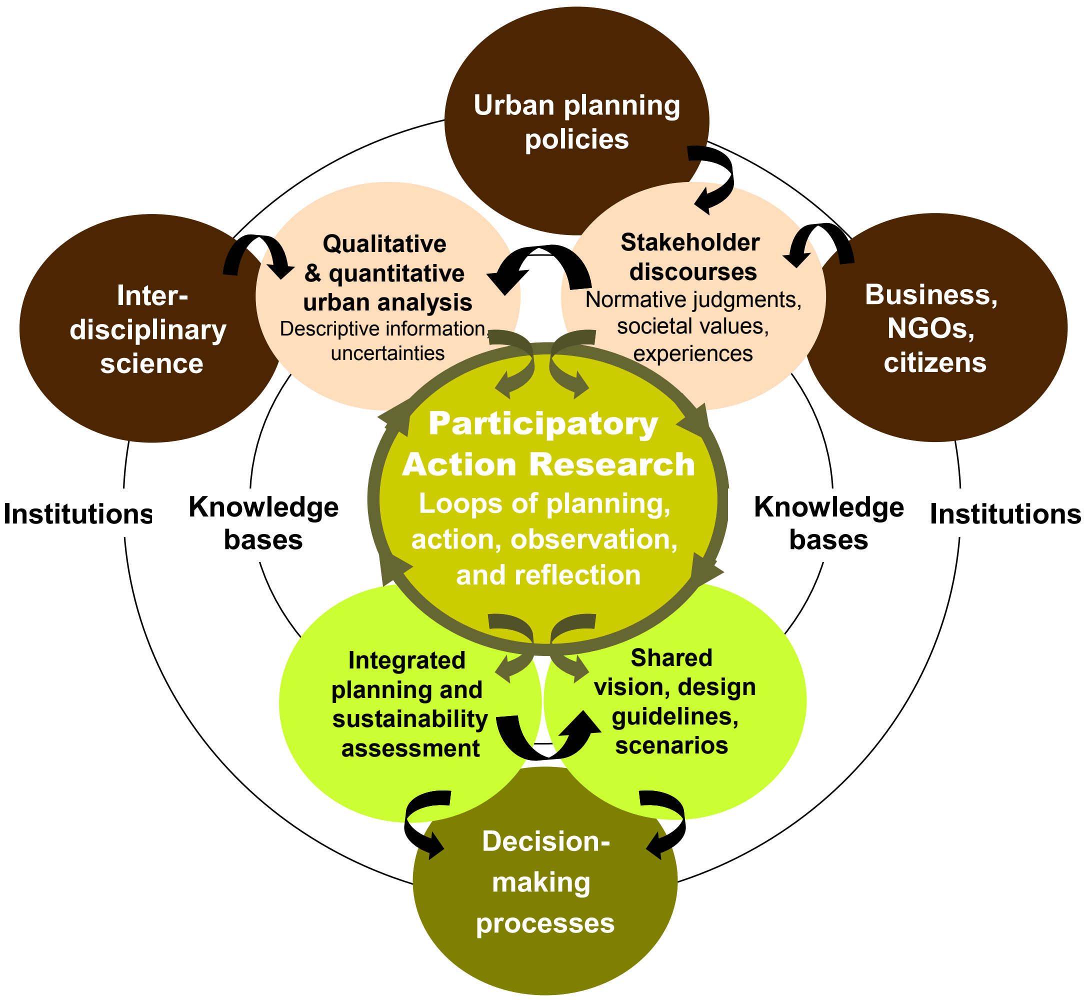

Figure 1 Integrated Urban Planning and Assessment Framework to inform planning for East Lake (based on Rotmans and van Asselt (2002) with own amendments)

The Integrated Urban Planning and Assessment Framework developed for East Lake is process-oriented with active dialogue among science and local stakeholders that enables social learning throughout the research process. The aim is to develop a set of techniques and tools to analyze, explore and evaluate various alternatives for sustainable urban planning in terms of plausibility, desirability and feasibility (Rotmans and van Asselt 2002). Context-driven outcomes are intended to inform policy and support decision making.

The project was implemented in an iterative and 'spiral' procedure with several loops of planning, action, observation and reflection. Participatory elements ensured that those traditionally the subject of 'research' are involved in some or all stages of the research as active participants (Pain 2004). Knowledge sourced from different institutional perspectives (science, public and private sectors) was also fed into the research process and outcomes were shared with participants and policy partners. It therefore created open dialogues in which stakeholders, experts or citizens could communicate their knowledge, experiences and views, thus establishing a degree of ownership over the process. As such, it is important to recognize that sustainability research does not only rely on the contribution of scientific knowledge from different disciplines but must also integrate the highly valuable and legitimate local knowledge of policy-makers, practitioners and lay persons.

This form of research goes beyond multidisciplinary and interdisciplinary approaches and is often referred to as transdisciplinary research (Bergmann et al. 2005, Müller et al. 2005). Transdisciplinary research recognizes that scientists' theories of local issues are no longer more valid than the everyday experiences of local experts, businesses and citizens (Elden and Levin 1991). This refers to a new scientific paradigm called 'Post-Normal Science' (Funtowicz and Ravetz 1991) that considers in particular science and policy challenges associated with implementing sustainable development (Ravetz 2006). Post-Normal Science emphasizes the collaboration of scientists with 'extended peer communities' to enable issue-driven research outcomes, to generate publicly shared knowledge, and to raise broad commitment for resolving complex policy issues.

As a holistic framework, the objective is not to optimize one aspect of sustainability (e.g. energy efficiency) by blanking out all the others (e.g. economic feasibility or social equity), but rather to focus the attention on the multiple dimensions of urban sustainability and to increase awareness and understanding of the flow-on consequences of decision making, technical indeterminacies and system uncertainties (Ravetz 2000).

3. Participatory Action Research and Discourse Analysis

A defining feature of this project and fundamental tenet of the Integrated Urban Planning and Assessment Framework was to achieve meaningful participation and involvement of East Lake stakeholders from the early stages of the project onwards. What this means is that participants are able to actively contribute to the research and development of new ideas and options. This participatory action research approach contrasts with other rather passive forms of stakeholder consultation which often only give participants the opportunity to comment on ideas experts have developed with limited scope for influence (Tippett et al. 2007).

With the above in mind a Participation Strategy was developed for the East Lake project outlining the major goals of the stakeholder participation:

(1) Making the planning process for East Lake more transparent and inclusive by ensuring all relevant stakeholders are informed on the ACT Government's initial thinking for the future of East Lake (embodied in their Draft Planning Report) and then explicitly asking stakeholder's for their views, feedback and inputs,

(2) Raising awareness and building capacity for sustainable urban renewal by conducting facilitated workshops and group discussions with various stakeholders and experts thus stimulating social learning processes and an appreciation of multiple and diverse viewpoints concerning pathways to sustainability, and

(3) Creating a growing sense among participants of belonging to a "community of interest" that is working together in a broad and inclusive partnership for a sustainable East Lake by exploring a common vision and emerging design principles that can form the foundations for all follow-up planning activity within East Lake.

The East Lake stakeholder participation process was comprised of three stages; identification, mobilization and integration. Relevant stakeholders for East Lake were identified by conducting an institutional analysis (Munda 2006). These stakeholders were then grouped into four clusters: Individuals and representatives from the *'local community'*, general *'interest groups'* relevant to the East Lake area, *'professional bodies'* representing business and industry, and *'government agencies'* relevant for planning a sustainable East Lake. A focus group was facilitated for each stakeholder group to mobilize different players and engage them in an East Lake discussion. The focus group method is an approach that is often used in sustainability assessment. It consists of a focused interview encouraging group discussion (Kasemir et al. 2003).

A series of guiding questions was used to structure the East Lake focus group discussions, firstly, focusing on the qualities and values of East Lake now, then on the various visions and concerns held for the future, and finally, on the process of getting from where East Lake is now to where stakeholders would like it to be in the future. Follow-up interviews with similar structured questions were applied to elicit the views of underrepresented stakeholders. A fifth focus group discussion was held with a particular citizens group of mainly public housing residents at The Causeway precinct to gain additional insights and perspectives.

The East Lake stakeholder participation and its analysis were based on a discourse approach (Dryzek 2005) which aims to identify various debates between stakeholders as well as possible interconnections between different debates. Such discourses provide us with stories from multiple perspectives which help to unravel characteristics of a complex systems problem. They represent shared narratives of how issues concerning the East Lake urban renewal are understood, illuminate the various interconnections, and can inform urban planning on discourses to which decision making should respond in order to foster sustainability transitions.

A key step in the process of integrating these disparate views from science, business and community, was the facilitation of a design principles workshop where representatives from different stakeholder groups and professional backgrounds were brought together to explore the development of a common vision and design principles for East Lake. This workshop provided the first opportunity to begin to integrate the many and diverse stakeholder views and to facilitate a social learning process for urban sustainability at East Lake.

4. Social Learning Approach Applied at East Lake

Social learning is a specific, collective form of learning from past experiences, different patterns and various ideas (Holden 2008). A key focus of social learning is to understand policy changes and therefore it is significant in urban planning, in particular to achieve and accelerate sustainability processes. In this project we adopt a transdisciplinary social learning approach which conceives planning, science and deliberation as learning processes (Müller et al. 2005) which follow several related learning cycles (see Figure 2).

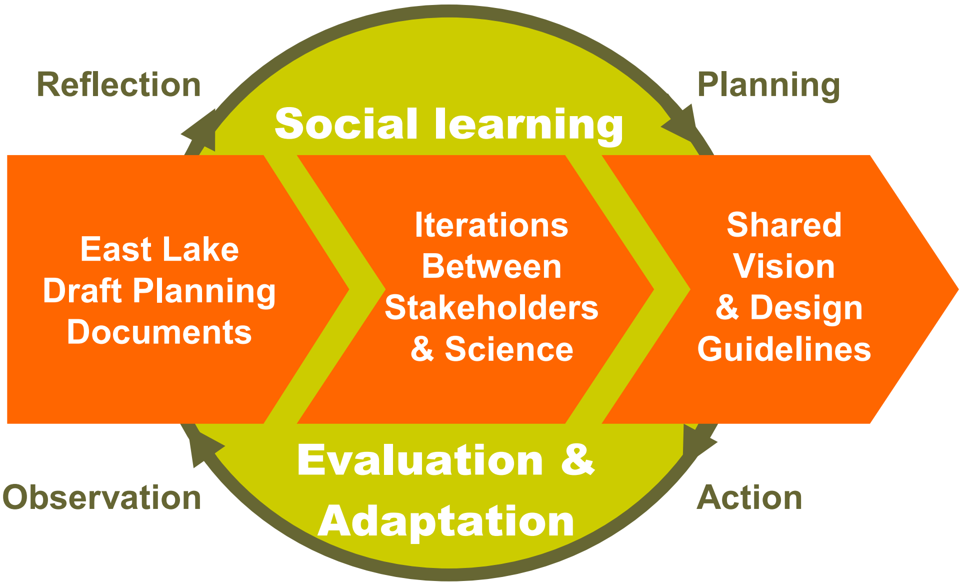

Figure 2 The related learning cycles of a transdisciplinary social learning approach applied at East Lake

Social learning, evaluation and adaptation were cross-cutting themes throughout the East Lake project. The project team applied several innovative methods to analyze when and how learning for sustainability occurs:

(1) A social scientist was employed as a 'learning facilitator'. In this role the learning facilitator observed all stakeholder engagement processes and team processes in order to analyze how groups deal with different discourses, associated conflicts and how compromise and a common understanding emerges in the process.

(2) 'Interim learning evaluations' were conducted by interviewing project team members (researchers and planners) and other involved stakeholders in the process on their insights, understandings and opinions. The results of this learning evaluation were fed back to the research and planning team in order to reflect actions and pick up identified learnings for the next planning and research phase (adaptation). This refers to an iterative and 'spiral' research procedure with several loops of planning, action, observation and reflection.

(3) Members of the project team (researchers and planners) also conducted 'shared learning and evaluation trips' to sustainability case studies within Australia that were relevant to the urban renewal of East Lake. The focus was not so much on visiting sites, but rather meeting and learning from associated project managers and researchers on their common experiences. After each of these trips, the project team would meet again to reflect on shared learnings and to discuss innovations in planning, design, governance and implementation that could be applied at East Lake.

5. Results So Far and Emerging Insights

The ACT Government's 'East Lake Urban Renewal Draft Planning Report' was used as a key input for stakeholder participation. The following results are based on focus group discussions and personal interviews with professional bodies, interest groups, Government agencies, and the local community.

Most frequently mentioned issues and shared narratives deal with preserving the ecological value of the Jerrabomberra wetlands, followed by a need to provide for affordable accommodation in such a premium location and to maximize benefits from the market attractiveness of the land by applying long-term investment strategies and new business models to foster sustainability innovations. Other frequently mentioned narratives refer to improved access and connectivity within and across the East Lake area and the need for rapid transport networks, mobility concepts and logistics management. Maintaining and integrating all heritage sites and existing social infrastructure, such as Fyshwick Markets, Kingston Railway Station, industrial heritage sites or The Causeway, is suggested to ensure preserving the historical sense of the place. It is argued that for East Lake to become a showcase in urban sustainability that planning approaches must go well beyond current practice in Canberra in order to position East Lake as a catalyst and exemplar for sustainability. High land prices are seen as a major driver of development costs and there is some concern that this may hinder a developer's ability to deliver sustainability. In general, the ACT Government is seen as a major developer who has the responsibility to arrange binding development guidelines and expected outcomes, to provide seed funds by partly reinvesting profits from land sales and to coordinate an ongoing evaluation and monitoring process. It is argued that desirable design for diverse user groups might be more likely if socio-demographic changes and needs of different target groups and future residents are addressed more explicitly, via strategies for social integration, employment and community.

The ACT Government's 'East Lake Urban Renewal Draft Planning Report' reflects most stakeholder perceptions, but could outline more explicitly the implementation process related to governance and management processes that guarantee the transparency and integrated character of the process required to foster greater stakeholder commitment.

One of the collective learnings for sustainability is that social interaction and stakeholder engagement is needed to access and make use of different forms of knowledge relevant to sustainability, to broaden more narrow individual perceptions on planning challenges, and to enable the social environment for arriving at integrated planning solutions. Another important aspect of social learning for sustainability refers to the local context of planning challenges and the need to identify integrated sustainability strategies and measures adapted to local characteristics and development needs. Sustainable urban planning of any neighbourhood needs to be plausible, desirable and feasible for a range of stakeholders in the local area. To identify most plausible, desirable and feasible planning scenarios for sustainable development, applied science needs to deliver beyond environmental technologies or sustainability assessment tools – it needs to embed these "hard aspects" into policy-driven, socially sound research processes including social interaction and deliberation between relevant stakeholders to arrive at both meaningful and acceptable local sustainability outcomes. Moreover in a policy-driven approach, the collaboration process not only needs to effectively garner understandings from the stakeholders to be an effective process but also needs to be timely to influence planning outcomes. In the case of East Lake the emerging insights from the process need to meet the timelines for releasing land in order to be considered and inform the packaging of the actual product put to sale (i.e., scope, scale, features, targets, development requirements).

6. Summary and Next Steps

An Integrated Urban Planning and Assessment Framework has been developed to inform the planning processes for sustainable urban renewal of East Lake. Several techniques and research methods, both qualitative and quantitative, were combined to facilitate and analyse a participatory action research process.

Aspirations and concerns of local stakeholders have been reflected in a stakeholder participation report that identifies important planning issues and challenges for East Lake. This input has been fed into the process of developing an integrated vision and design guidelines that provide the foundation for the sustainability directions of the East Lake planning process. An integrated sustainability assessment software tool has been developed as part of the project to assist stakeholders explore sustainability implications of decision-making.

The project is now nearing the first year of completion with future activities to involve refinement of the Integrated Urban Planning and Assessment Framework and associated tools and outputs, with a view to incorporating more focused design expertise and investigations as the project gets closer to implementation.

Keywords: Chicago, carbon, reduction, high-performance, buildings, architecture, environment, strategies

Summary

The American Institute of Architects Chicago Chapter Committee on the Environment (AIA Chicago COTE) launched the "Carbon Reduction Strategies for the Chicago Region Pilot" in November of 2007. The CRS Pilot is a matrix outlining sixty strategic action items in four categories: Immediate, Short-Term, Middle-Term, and Long-Term. Action items indicate policies, design strategies, and existing technologies to be implemented in design, construction and operation of existing buildings, renovation and new construction.

The CRS Pilot matrix is envisioned as an open-source tool for defining pragmatic steps aimed at improving energy efficiency in buildings and reducing the carbon footprint of existing or newly built structures. While created mainly for use by architects, the CRS Pilot has flexibility that lends itself to any building industry professional interested in reducing their carbon footprint: architects, engineers, contractors, developers, and building operators.

The AIA Chicago COTE's CRS Pilot references the "Architecture 2030" initiative and carbon reduction goals set forth by the US Conference of Mayors "Challenge 2030". The CRS Pilot is formatted to address climate issues specific to the Chicago metropolitan region. Once implemented, proposed actions would help decrease global warming and its impact on the Chicago region by reducing carbon footprints of buildings through energy conservation and "smarter," high-performance design.

1. Global Warming and Climate Change

1.1 Impact of Global Warming on Large Urban Centers

Existing scientific evidence and global consensus continues to strengthen the idea that global warming and climate change represent a real threat to the environmental, social and economic health of global communities, especially those located in highly populated urban areas and those along the coastal areas.

Our ability to effectively address and mitigate the effects of global warming and climate change will have significant impact on human activities and overall living and economic conditions, particularly in the large urban centers. Many urban centers, in the U.S. and abroad, are already developing climate change-specific local policies, action plans or have comprehensive programs put in place, aiming to reduce global warming pollution and to mitigate the effects of impending climate change. However, more action is needed at the local, state, and federal levels to meet the future challenges of global warming and the climate change.

1.2 The Kyoto Protocol

On February 16, 2005, the Kyoto Protocol - the international agreement to address climate disruption caused by global warming, became law for the 141 countries that have ratified it to date. The Kyoto Protocol now covers more than 170 countries globally and more than 60% of countries in terms of global greenhouse gas emissions. The treaty expires in 2012, and international talks began in May 2007 on a future treaty to succeed the current one. The advocates of the Kyoto Protocol state that reducing global carbon emissions is critical, as the current increase in carbon dioxide levels is directly related to the heating of the earth's atmosphere and therefore global warming.

2. The Kyoto Protocol Implementation in the Cities of the United States of America

As of December 2007, the U.S. and Kazakhstan are the only signatory nations not to have ratified the act. The United States, although a signatory to the Kyoto Protocol, has neither ratified nor withdrawn from the

Protocol. The signature alone is symbolic, as the Kyoto Protocol is non-binding on the United States unless ratified. At the end of 2007, the United States remains the largest single emitter of carbon dioxide resulting from the burning of fossil fuels.

2.1 U.S. Conference of Mayors and the American Institute of Architects Act on Climate Change

On February 16, 2005 in the United States, Seattle Mayor Greg Nickels launched the U.S. Conference of Mayors (USMC) initiative to advance the goals of the Kyoto Protocol through individual leadership and coordinated action by at least 141 American cities. This initiative was strongly supported by the American Institute of Architects (AIA), which provided significant research and guidelines for planning and design of energy-efficient and environmentally friendly cities. By the U.S. Conference of Mayors annual meeting in June 2005, 141 mayors had signed the USCM Climate Protection Agreement – symbolically, the same number of nations that ratified the Kyoto Protocol.

In early 2006, the AIA issued “The AIA Green Cities Toolkit” and the “AIA 50to50” document, intended to serve as a set of policy and design guidelines to the U.S. Conference of Mayors’ Summit on Energy and the Environment, held in Chicago in 2006. The AIA simultaneously launched the “Architecture 2030” initiative aimed at exploring the strategies for reducing carbon emissions in U.S. cities.

The U.S. Conference of Mayors’ Resolution 50, sponsored by the mayors of Chicago, Seattle, Miami, and Albuquerque, specifically cited the AIA sustainable practice initiatives and called on the U.S. Conference of Mayors to endorse a goal of carbon neutrality for all city-funded buildings by 2035. The mayor’s group organized the Chicago Summit on Energy and the Environment in May 2006, in response to the nation’s ongoing energy crisis. The AIA cosponsored this groundbreaking event, and two architects presented at the meeting: Ed Mazria, AIA, who gave a keynote address on the relationship between buildings and climate change; and Vuk Vujovic, Assoc. AIA, who presented on energy efficiency and carbon reduction strategies related to new and existing buildings.

Mayors’ Resolution 50 was subsequently approved during the U.S. Conference of Mayors annual meeting in June 2006, which resulted in adoption of the U.S. Conference of Mayors’ Climate Protection Agreement in 2006. By the April 2008, the number of U.S. mayors who signed the agreement has reached 830, representing variety of municipalities throughout the 50 states, the District of Columbia and Puerto Rico, on behalf of a total population of over 79,535,702 citizens.

2.2 U.S. Conference of Mayors Climate Protection Agreement

Under the initial USCM Climate Protection Agreement, participating U.S. cities commit to take following three actions:

- Strive to meet or exceed the Kyoto Protocol targets in their own communities, by implementing actions ranging from anti-sprawl zoning, land-use policies to urban forest restoration projects and public information campaigns focused on sustainable development;

- Urge their state governments, and the federal government, to enact policies and programs to meet or exceed the greenhouse gas emission reduction target suggested for the United States in the Kyoto Protocol: 7% reduction from 1990 levels by 2012;

- Encourage the U.S. Congress to pass the bipartisan greenhouse gas reduction legislation, which would establish a national emission trading system.

2.3 Chicago Climate Change Related Initiatives

2.3.1 Climate Change Impact on Chicago Metropolitan Area

Cold winters and humid summers in Chicago would seem to describe the general weather patterns experienced over any given year during the last century. There are some exceptions, such as unseasonable extreme temperature conditions during winter and long periods of hot weather experienced during summer months. These intermittent climatic anomalies are considered to be precursors of the more extreme climate changes that are possible in the future and which are being taken seriously by the Chicago municipal government.

Climate researchers predict that Chicago’s climate over the next few decades will grow increasingly hotter. Recently, the Chicago metropolitan area was reclassified from Climate Zone 5 into a hotter Climate Zone 6, indicating the potential and type of impact impending climate change could have on Chicago Metropolitan area. The City government is concerned about the impact this climatic changes would have on the general population of Chicago, and about what those changes would mean for its citizens, especially the young and elderly, the City infrastructure, energy and food supply, and local economy.

With such serious issues facing Chicago, the municipal government is looking into the ways to mitigate some of the effects of the climate change, and is looking into active measures that could be taken early, such as greening their vehicle fleets, improving the energy efficiency of municipal buildings, introducing drought-resistant native vegetation and promoting public transit use and alternative transportation throughout the City.

2.3.2 Chicago Climate Protection Strategy

The City of Chicago began development of the Chicago Climate Agenda in 2006 and the associated Chicago Climate Strategy and Implementation Plan in 2007. In partnership with the Global Philanthropy Partnership and with the support of The Joyce Foundation, the Lloyd A. Fry Foundation, the Grand Victoria Foundation and the Clinton Foundation, the City has been able to engage three different research teams to answer the following questions:

- What will be the specific impact on the Chicago's infrastructure, buildings, emergency services, energy, food and water supplies, and local ecosystems?

- What are Chicago's current baseline carbon emissions and where are the best opportunities to reduce those emissions?

- What are the environmental, economic and social impacts of any climate change related action?

The Chicago Climate Strategy is intended to enable the Chicago municipal government, various design, real estate and construction industry professionals and Chicago residents to take proactive steps to combat climate change by understanding its key sources and most critical impacts. The climate change related policies and measures instituted today will make a critical difference in the City of Chicago for generations to come. The City government intends to engage thousands of local residents through the public information and education process to understand what's most important to Chicagoans and how the Climate Change Strategy can be of most use to them.

3. The Role of the Design Professionals

U.S. design professionals have the unique opportunity to address and help mitigate the effects of global warming and climate change on buildings and cities. Through the implementation of readily available building technologies, high-performance building systems and materials, and through the education of general public and the municipal governments, architects and engineers can highlight the opportunities for change in existing codes, regulations and policies, and propose actions and measures that could start the change today.

3.1 American Institute of Architects, Chicago Chapter Sustainable Initiatives

The American Institute of Architects, Chicago (AIAChicago) is a professional organization of licensed architects, architectural interns, and allied professionals expressing their commitment to excellence in design and livability in our nation's buildings and communities.

The AIA Chicago supports the AIA's global position statement on climate change, calling for the immediate energy reduction of all new and renovated buildings to 50 percent of the national average for a particular building type. The increased reductions of 10 percent every five years so that by the year 2030 all buildings designed will be carbon neutral, meaning the future structures would use no fossil fuel energy for production, construction or demolition of buildings.

3.1.1 AIA's "50to50" Guidelines

The AIA's "50to50" resource is intended to assist architects and the construction industry professionals in moving toward a minimum 50 percent reduction of fossil fuel consumption in buildings by 2010 and carbon neutrality in buildings by 2030. The AIA recognizes that built structures are responsible for approximately 48 percent of energy consumption in the U.S. The ongoing operation and maintenance of built structures account for approximately 76 percent of U.S. electrical use. Given the above facts, it is not difficult to establish that built structures represent one of the primary sources of the greenhouse gases contributing to global warming and climate change. This realization has established carbon reduction as the top priority of the AIA's sustainable design initiatives and for design professionals nationwide.

3.1.2 AIA Calls for 50 Percent Carbon Reduction in Buildings

The 50 carbon reduction strategies proposed by the AIA have been selected to provide readily available and effective tools and techniques that will have an effective and immediate impact on an architects' ability to achieve significant carbon reduction. The strategies span a spectrum from broad-based site and building planning objectives to specific, building-based concepts. Each strategy includes an overview of the subject, typical applications, emerging trends, links to information sources, and important relationships to other carbon reduction strategies.

3.2 AIA Chicago's Committee on the Environment

AIAChicago's Committee on the Environment (AIA Chicago COTE), promotes the design and construction of sustainable and high-performance buildings in the city of Chicago and the region. AIA Chicago COTE is committed to educating local architects on sustainability principals by bringing local and national experts to Chicago to discuss strategies, policies and methods of implementing sustainable architectural design, metrics to obtain such design, as well as reinforcing the multidisciplinary collaboration approach true sustainability demands.

Through its work with the City of Chicago and the Department of Environment, AIA Chicago COTE represented a broad group of local design professionals and provided information critical for the success and implementation of the Chicago Climate Change Strategy. The AIA Chicago COTE's "Carbon Reduction Strategies for the Chicago Region" (CRS) Pilot is a direct result of the cooperation between the AIA Chicago COTE and the City of Chicago's Department of Environment.

4. AIA Chicago COTE's "Carbon Reduction Strategies for the Chicago Region" (CRS) Pilot

4.1 Initial Development

The AIA's CRS Pilot was envisioned as a matrix-based resource tool incorporating practical action items grouped in four time and project phase specific categories based on typical project delivery phases.

The AIA Chicago' s Carbon Reduction Strategies Pilot is envisioned primarily as a tool for defining pragmatic, actionable steps that can be taken to reduce the energy use and/or carbon footprint of any existing or newly built structure. While created mainly for use by architects, the CRS Pilot tool has a built-in flexibility to lend itself to any building industry professional interested in carbon footprint reduction: architects, engineers, contractors, developers, and building operators.

The CRS Pilot relates to the "Architecture 2030" initiative's carbon reduction goals and the AIA Sustainability Discussion Group's "50to50" recommendations but is formatted quite differently in order to address issues specific to the City of Chicago and the wider urban region. If implemented on a global scale, proposed actions would help decrease global warming impact on Chicago region by reducing the carbon footprints of buildings through energy conservation and "smarter," high performance design.

4.2 Cooperation with the City of Chicago's Agencies

Through AIA Chicago COTE's cooperation with the local municipal agencies such as Chicago's Department of Environment (Chicago DOE), proposed policies could be implemented throughout the City on both public and private buildings, also on the existing structures or the new construction. The widespread use is intended to reduce energy consumption and measure proposed design and policy effectiveness on a broad scale. The Pilot tool matrix incorporates some of the broad policy ideas and expands them into strategies that can be used on all building types.

AIA Chicago COTE's relationship with Chicago Center for Neighborhood Technology (CNT) was established with the assistance of the City of Chicago, and was instrumental in getting early energy and cost information incorporated into the matrix. With this information, AIA Chicago COTE was able to establish preliminary cost scale, approximate energy savings, and estimate potential carbon reduction levels for each action item.

4.3 Carbon Reduction Strategies Pilot Structure

The AIA Chicago COTE's Carbon Reduction Strategies Pilot matrix is comprised of four strategic categories with sixty specific actionable items. The proposed strategies correspond to building design and construction timelines defined by the political, economic, and ecological relationships already in place.

AIAChicago COTE has received extensive input from the committee's membership, and the Carbon Reduction Strategies Pilot Sub-Committee. The sub-committee incorporated local experts and building industry professionals, including lighting professionals, building system engineers, and the City officials.

If implemented, the actions proposed in the AIA Chicago COTE's Carbon Reduction Strategies Pilot would help decrease global warming by reducing carbon footprints of buildings through energy conservation and "smarter," high-performances design.

5. Carbon Reduction Strategies for the Chicago Region Pilot: Strategies

The matrix divides strategies into four implementation categories: Immediate, Short-Term, Middle-Term, and Long-Term. Actionable items indicate possible policies, design strategies, building systems, materials and existing technologies to be implemented in building design, construction, operations and maintenance, on existing buildings, renovations and new construction.

The Pilot tool matrix incorporates some of the broad policy ideas discussed with Chicago Department of Environment and expands them into actionable strategies and measures that can be used on existing and new buildings of all types.

Since the target audience is quite diverse, comprised of building industry professionals, city officials, building owners, and general public, non-technical language was used as much as possible throughout the matrix to allow the reader to use or combine the action items for implementation or further discussion. The intention was to include specific links for each item to ongoing initiatives already in place or explanation of the specific approach.

5.1 Immediate Strategies

These approaches are achievable virtually without cost. It is recommended that the user starts with these strategies first.

5.1.1 Turn off lights when they are not required

5.1.2 Program computers and office equipment to "power-save (sleep) mode"

5.1.3 Reduce overuse of space heaters

5.1.4 Reduce programmed HVAC temperature setbacks

5.1.5 Adjust common area Lighting

5.1.6 Check the economizer cycle

5.1.7 Regulate air-conditioning temperatures

5.1.8 Change the furnace filters at the preset schedule

5.1.9 Secure all the cabinet panels

5.1.10 Regularly clean air condenser coils

5.1.11 Check the register airflows

5.2 Short-Term Strategies

The short-term approaches are achievable with low first costs and require little or no design integration. They can be implemented today or incrementally over short period of time.

5.2.1 Replace and/or relamp light bulbs or lamps with the most efficient available products

5.2.2 Install programmable thermostats

5.2.3 Add insulation to plumbing supply piping

5.2.4 Lobby Local and National Legislature for Green Tax Incentives

5.2.5 Include ceiling fan/Light combination fixtures

5.2.6 Purchase U.S. Environmental Protection Agency's (EPA) "Energy Star" rated appliances and products.

5.2.7 Provide bicycle parking in all private and public buildings

5.2.8 Provide dimming and photocell controls on light fixtures

5.2.9 Seal leaks in HVAC ductwork

5.2.10 Install most efficient light fixtures available on the market

5.2.11 Purchase carbon emission offset credits

5.2.12 Change building and/or zoning codes to performance based model

5.2.13 Implement building commissioning

5.2.14 Provide recycling and composting space

5.2.15 Utilize car and bicycle sharing programs

5.2.16 Design efficient site and amenity lighting

5.2.17 Use "smart" lighting design in parking lots – do not provide more that what is required.

5.2.18 Implement preventive maintenance programs

5.2.19 Increase all building and/or energy codes to follow best practices in the country/region

5.2.20 Use deconstruction / material salvage when demolishing buildings

5.2.21 Give incentives to green design during building code reviews

5.2.22 Implement advanced thermal envelope design (exterior wall)

5.3 Mid-Term Strategies

The approaches listed below are achievable with moderate cost and most require modest design integration. These strategies can be incorporated as upgrades and/or during renovations.

5.3.1 Achieve fully integrated architectural and building engineering services design process

5.3.2 Install radiant heating and cooling systems

5.3.3 Upgrade roof insulation to R-49

5.3.4 Give tax incentives for smaller, higher density, more proportionately sized homes

5.3.5 Utilize heat recovery ventilation in HVAC systems

5.3.6 Update exit signage with energy-efficient LED bulbs/fixtures

5.3.7 Design using daylighting and daylight harvesting principles

5.3.8 Include demand-controlled ventilation (DVC) systems or CO_2 monitoring in HVAC systems

5.3.9 Install evaporator fan controllers and modulating ventilators in commercial kitchens

5.3.10 Install point of use water heaters

5.3.11 Install geothermal heat wells and HVAC systems

5.3.12 Sequester carbon emissions on site

5.3.13 Replace windows with triple glazed units, up to R-10

5.3.14 Tie property taxes to benchmark CO2 emissions for individual building types

5.3.15 Install low flow (minimum 1.25 gallons per minute) or dual flush toilets

5.3.16 Utilize natural ventilation and "stack effect" to supplement HVAC system

5.3.17 Mandate use of energy modeling to design building systems

5.3.18 Utilize U.S. Environmental Protection Agency's (EPA) "Energy Star" high albedo ("cool") roof systems

5.3.19 Use off-peak cooling for larger commercial or industrial buildings

5.3.20 Install brise soleil or sunshades on building exterior to eliminate heat gain and glare

5.4 Long-Term Strategies

The approaches listed below are achievable with moderate cost and do require higher design integration. These strategies are most applicable for new construction and are readily available today.

5.4.1 Increase building energy "independence" by providing on-site power generation

5.4.2 Create neighborhood based (sized) infrastructure

5.4.3 Integrate building's energy production systems

5.4.4 Design fully automated building systems

5.4.5 Incorporate "intelligent building design" into all disciplines throughout design and construction

5.4.6 Implement "smart growth" based urban design and planning

5.4.7 Mandate policies that promotes longer lasting buildings

6. AIA Chicago's Carbon Reduction Strategies for the Chicago Region Future Development

The development of the AIA Chicago CotE's CRS Pilot tool is envisioned as an on-going process. During this process, the AIA Chicago COTE intends to expand the 2007 Pilot matrix by continually developing and refining the information and post the final version as an open-source, interactive online tool by January, 2009.

AIAChicago CotE is interested in receiving and integrating into an online tool any constructive feedback from both AIA members and the wider building industry community, especially those operating in the Chicago metropolitan region. The final online version will be posted on the AIA Chicago website as an online interactive tool available to all.

The matrix was Inspired by the AIA's Green Cities Toolkit, Architecture 2030 initiative, the "U.S. Conference of Mayors Climate Protection Agreement" and is aimed at significantly curbing carbon emissions in U.S. cities across the nation.

Summary

Energy efficiency in air-conditioned buildings for tropical climate has been a subject of much discussion, especially among the building construction practitioners such as the architects and building services engineers. There exist many myths about the efficacies of various features in the building as energy flows in building remains largely unfamiliar to most. This is because even a simple building has a very complicated energy transfer process converting electrical energy into things that are useful to the building occupants, such as lighting and computational need and then into heat, where electricity is used again to provide comfort by removing heat from the space, and all this while, the climate outside is influencing the space by radiating solar gain, conducting heat and infiltrating air into the building.

This paper addresses the need for an easy method of understanding energy efficiency in buildings by providing a simple and yet comprehensive picture of energy flows in buildings by providing the 8 fundamental steps for energy efficiency for air-conditioned buildings in tropical climate. This 8 fundamental steps covers all the energy components to achieve an energy efficient building, from architectural, mechanical, electrical and energy management point of view for an air-conditioned building. Steps 1 to 7 are building design steps that are listed based on its amount of energy consumptions with the highest energy consumer listed first and the lowest energy consumer listed last, simply because, it would be the most important to reduce the energy consumption of the item with the highest energy consumption first before focusing effort on less important items that would contributes a smaller amount to the total energy consumption of the building. Step 8 is for energy management, that is to ensure that step 1 to 7 are being practised correctly in the actual building after the completion of construction.

The 8 Fundamental Steps Towards Energy Efficiency in Air-Conditioned Buildings for Tropical Climate are:

1. Chillers System Efficiency
2. Lighting Efficiency
3. Small Power Efficiency
4. Fan Power Efficiency
5. Control of Infiltration (Moisture Control)
6. Control of Solar Radiation
7. Control of Conduction Gain (Building Insulation)
8. Energy Management.

1. Introduction

The 8 steps towards energy efficiency for air-conditioned building in tropical climate is a resultant of the re-evaluation of the Overall Thermal Transmittance Value (OTTV) in Malaysia in 2005-2006.

The Overall Thermal Transmittance Value (OTTV) was first developed for Malaysia in 1987. The OTTV was developed using computer simulation to provide an easy method for architects and engineers to manually calculate the average heat gain that is being transmitted into a typical office building via the building fabric due to orientation, windows to wall ratio, wall properties and glazing properties. Since 1987 (a time when personal computer is not wide spread yet), there have been no re-evaluation of the OTTV until this study in 2005 undertaken by the Danida project for Energy Efficiency in Malaysian Buildings.

The re-evaluation of the OTTV was conducted using computer simulation to get a fundamental understanding of the behaviour of a typical building thermal and energy characteristic based on Malaysia's climatic data. The results of this study provided remarkable insight into the thermal and energy performance of air-conditioned buildings in tropical climate that not only provided valuable input for the updates of the Malaysian MS1525 (Malaysian Standard for Energy Efficiency in Non-Residential Buildings), but it has also provided a key summary of the steps required for an air-conditioned building to be energy efficient a tropical climate.

The re-evaluation of OTTV was conducted with a simulation of more than 40 case scenarios by varying different properties of the building. The results showed that the variation of the building envelope properties have a small effect compared to the variation of different internal load of a typical building on the total energy consumption of the building. Therefore, the development of the 8 steps towards energy efficiency for air-conditioned building was largely based on the results of 3 case scenarios that varies the internal energy load of the building while keeping the building envelope constant. This would simplified the complexities of energy flow in building to a manageable analysis while providing enough useful information. The 3 selected case scenarios are:

1. Worst Case Building Scenario
2. Base Case Building Scenario
3. Ministry of Energy, Water and Communication (MEWC)'s Low Energy Office Scenario.

2. The OTTV Model

Three (3) case studies were set up and simulated to get an understanding of how energy is used in a typical office building today. These case studies were:

1. Worst Case Scenario (2005)
2. Base Case Scenario (2005)
3. MEWC's Low Energy Office (2005) - calibrated to an air-conditioned space of 5,200 m2 instead of 19,000 m2

The worst case scenario describe a building with high energy consumption due to high internal load. An internal lighting load of 21 W/m² and a small power consumption of 24.5 W/m² is allocated for this building. In addition, this building is also assumed to have a bad energy management with an approximately 40% of lights and small power still running during non-occupied hours. It was also assumed that the building is very leaky with an infiltration rate of 2 air-changes per hour (ach).

The base case scenario attempts to describe a building with the most likely scenario of current buildings in Malaysia. It has a lighting load of 18W/m² and a small power load of 19 W/m². A moderate scenario of energy management is assumed for this building where approximately 30% of the lighting and small power load is still running during non-occupied hours. It was assumed that this building is also leaky with an infiltration rate of 1 ach as Malaysia do not have a culture of providing air-tightness in buildings.

The Low Energy Office (LEO) scenario is based on the actual measurements obtained from the Ministry of Energy, Water and Communication's Low Energy Office building after approximately 9 months of operation. A lighting load of 5.5 W/m² and a small power load of 6 W/m² was measured in this building and is used for LEO case scenario. During non-occupied hours, approximately 20% of the lighting power is still being consumed, while the small power consumption during these hours represented approximately 54% of the peak daytime load. No measurement of air-tightness was made for the LEO building, however, based on the fact that fresh air is not required for the building from the system (CO_2 sensor controlled) and the measured CO_2 in the building range from 400-500 ppm, it is rational to assume that the infiltration rate is 1 ach for this study to represent a fairly leaky building.

The shape and properties of the Malaysian Base Case building in 1987 was retained in this initial study, while the internal loads were varied as shown in the table below. The base case office building shape and dimension of the simulation model in 1987 has the following properties:

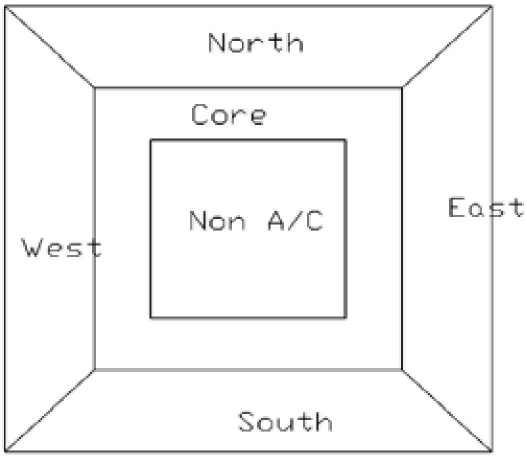

Figure 1 Plan View of the Malaysian Base Case building with 10 floors and 5200 m² of total conditioned floor space.

Table 1. Base Case Building. 10 Story office building, perfect square

Descriptions	Key Numbers Used
Air-Conditioned Space	5200 m²
Core Space	1000 m²
Windows to wall Ratio	0.4
Shading Coefficient of the Glazing	0.69
Brickwall U-value	2.6 W/m²/K
Roof (Highly Insulated)	0.001 W/m²K
Lighting Load	21 W/m²
OTTV	66 W/m²
COP of Chiller	4.1
People Density	9m²/person
Small Power Load	5.35 W/m²
Infiltration	1 ach
Fresh Air	3.3 lit/sec/person
Variable-air-Volume Air Conditioning System	50% minimum flowrate

The roof was simulated with a high insulated value to remove the effect of roof from the simulation, as the OTTV equation only describe the façade of the building excluding roof.

Table 2. Description of input data for 3 different case scenarios.

Descriptions	**Proposed Worst Case (2005)**	**Proposed Base Case (2005)**	**MEWC LEO (2005)**
Lighting Load (W/m2)	21	18	5.5
Lighting Operation Hours	100% 8am to 5pm 40% 5pm to 8am	100% 8am to 5pm 30% 5pm to 8am	100% 8am to 5pm 20% 5pm to 8am
People Density (M2/person)	10 as stated in UBBL	10 as stated in UBBL	60
People Working Hours	1% 7:30am-25% 8am 25% 8am-100% 8:30am 100% 8:30am-5pm 100% 5pm-5% 10pm 1% from 10pm-7:30am	1% 7:30am-25%8am 25% 8am-100% 8:30am 100% 8:30am-5pm 100% 5pm-5% 10pm 1% from 10pm-7:30am	1% 7:30am-25% 8am 25% 8am-100% 8:30am 100% 8:30am-5pm 100% 5pm-5% 10pm 1% from 10pm-7:30am
Small Power Load (W/m2)	22.14 W/m2	17.67 W/m2	4.5 W/m2
Small Power Operation Hours	100% daytime 45% nightime	100% daytime 29% nighttime	100% daytime 54% nighttime
Computer Load per person (W/person)	180 (18 W/m2) 100% Daytime, 35% night	150 (15 W/m2) 100% Daytime, 15% night	120 100% Daytime, 15% night

Server Room, Load/AC Area (W/m2)	2.5 100% 24 hours	1.5 100% 24 hours	1.5 100% 24 hours
Shared Office Load (W/m2)	0.5 100% 24 hours	0.25 100% 24 hours	0.25 100% 24 hours
Core Load (W/m2) of Core Area	5 100% Daytime, 50% night	4 100% Daytime, 50% night	4 100% Daytime, 50% night
Fresh Air	AC hours: 2 ach 20 l/s/person (10500 l/s) approx. 650ppm CO2 level Off AC: 1 ach	AC hours: 1 ach 10 l/s/person (5250 l/s) approx. 920 ppm of CO2 Off AC: 1 ach	AC hours: 1 ach 60 l/s/person (5250 l/s) Off AC: 0.5 ach
Fan Static Pressure	1250 Pa	750 Pa	250 Pa
Chiller COP	4.1	4.1	4.1
Air Delivery	VAV	VAV	VAV

Notes on the LEO case:

1. Lighting load of 5.5 W/m2 was based on actual monitored usage. Installed lighting capacity is 12 W/m2.
2. Occupant density in MEWC is approximately 60 m²/person.
3. Small power load of 4.5 W/m2 was also based on actual monitored usage.
4. Computer load of 120 W/person was computed from the small power load and occupant density of MEWC.
5. Server Room, Shared Office Load and Core Load of MEWC were all calibrated based on actual monitored values in the current MEWC office.
6. Fresh Air intake is also calibrated to the CO2 sensor reading in the building. 1 ach rate is required to keep office CO2 reading below 460 ppm. Monitored CO2 reading in the MEWC is between 400 – 500 ppm in most areas.

3. The 8 Steps Toward Energy Efficiency in Buildings

The simulation results of the 3 case scenarios were tabulated in a bar chart (displayed in Figure 2) to provide an overview of the various breakdown of energy consumption in a building.

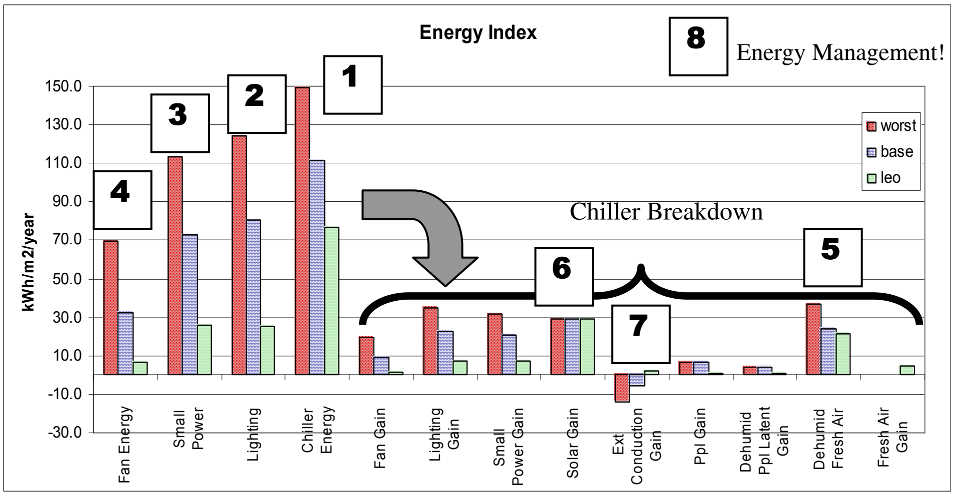

Figure 2 Energy Index breakdown of 3 different types of building scenario.

The energy index breakdown in Figure 2 shows that there are basically 4 major energy consumption in an air-conditioned building in tropical climate. These are:

1. Fan Energy
2. Small Power Energy
3. Lighting Energy
4. Chiller Energy

Usually the chiller energy and fan energy are combined and called as air-conditioning energy; however, for the purpose of understanding the energy flow in building, it is useful to it split up in order to provide a breakdown of chiller energy into each heat element that the chiller is required to remove from the building.

The chiller energy breakdown showed the following heat element that is removed by it from an air-conditioned space:

1. Fan Sensible Heat Gain
   - The fans have a motor that drives it. The motor would then generate waste heat. This heat is introduced directly into the air-conditioned space.
2. Small Power Sensible Heat Gain
   - All equipments that are plugged into the powerpoints constitute of small power energy use. As a law of energy conservation, all electrical energy used by these equipment will end up as heat in the air-conditioned space.
3. Lighting Sensible Heat Gain.
   - Similar to the small power sensible heat gain, all electrical energy used by lighting will end up as heat in the air-conditioned space.
4. Solar Radiation Sensible Heat Gain
   - The heat gain due to solar radiation through the building windows are known as solar radiation sensible heat gain.
5. Conduction Sensible Gain due to External Facade
   - The heat gain due to conduction through the building façade excluding the roof space.
6. People Sensible Heat Gain
   - The sensible heat gain from people is the heat emitted by people in the air-conditioned spaces.
7. Dehumidification of People Latent Heat Gain
   - The latent heat gain from people is the moisture emitted by people in the air conditioned spaces.
8. Dehumidification of Fresh Air Ventilation
   - The infiltration of fresh air (outside air) into air-conditioned spaces bring along moisture content of the outside air.
9. Fresh Air Ventilation Sensible Heat Gain
   - The infiltration of fresh air (outside air) into air-conditioned spaces bring along heat/cooling content of the outside air.

The chiller energy is used to remove all the heat generated in the list described above in order to maintain the comfort temperature and humidity in the air-conditioned space.

The chiller energy is the highest contributor to the total building energy use for all the cases. The electricity used for lighting is consistently the second highest, followed by small power and lastly the fan energy that is used to deliver cold air into the spaces.

Figure 2 is a very insightful chart. It shows that in the worst case scenario the heat generated by lighting and small power is higher than the heat from solar radiation or conduction heat gain in the building.

More interestingly is the fact that the worst case scenario, the net conduction gained over a year is negative, meaning that heat is being conducted out of the building more than being conducted in. This is due to the reason that in a worst case scenario, a significant amount of small power equipment and lighting system are still running during non-occupied hours (e.g. night time to early morning), at hours where the outside temperature is low. The air temperature in the office space during night hours would then be higher (due to the internal equipments and lighting that are still in operation) than the outside air temperature. Therefore, heat is being conducted out of the fabric of the building, helping to cool the building during night time. This chart also shows that conduction gain is high for the base case in 1987 due to the reason that the building in 1987 does not have night load inside the building because it does not have equipments that are running during night such as computers, fax machine, server room, control room and etc.

The dehumidification of fresh air in the worst case scenario is also shown to contribute more energy to the chiller than the solar radiation heat again. This is largely caused by the high moisture content of a hot and humid climate such as Malaysia. In addition the removal of moisture from the air is phase-change process that requires large amount of energy to convert moisture in vapour form into water in liquid form.

It is also interesting to note that the air-conditioning that is used for the primary purpose of providing comfort to the building occupants (people). However, the sensible and latent heat gain from people represented only a fraction of the chiller energy use.

It is also shown in Figure 2, that the heat generated internally by lighting and equipment (small power) represented a significant amount of heat removed by the chiller, clearly indicating that the reduction on energy consumption of internal loads such as lighting and equipments will also lead to significant saving on chiller energy consumption.

Finally the chart shown in Figure 2 allows the following general interpretation to be made to provide a sort of checklist of priorities for energy efficiency features in building starting from the items that consumed that highest amount of energy to the item that consume the least:

1. **Energy efficient chiller system.** A low efficiency chiller system will increases the total energy use within a building significantly as it increases the energy used to remove heat from the air-conditioned space. The term 'chiller system' consist of the chiller, chill water pumping system, chill water piping system and condenser system such as the fans for the cooling tower and the pumping system of the condenser system. Energy efficiency of the whole 'chiller system' is required in order to gain efficiency in this area.
2. **Reduce artificial lighting load.** Natural daylighting is the best because it provide the highest amount of light with the least amount of heat. Other methods include the use energy efficient lighting system, proper zoning of lighting circuit and etc. Night lighting should be carefully considered and should never be over provided.
3. **Reduce small power load.** This would means that energy efficient computers, servers, and control system should be used. Nighttimes energy consumption of small power should be closely monitored.
4. **Minimise fan power**. The fan is used for the air-conditioning system. The energy use by the fan is mainly contributed by two factors, fan efficiency and ductwork total pressure. Selection of fan with high efficiencies will reduce the energy use by fan significantly, while larger duct sizes will have lower pressure loses and therefore lower overall static pressure and thereby reducing energy use of the fan.
5. **Control of fresh air intake and infiltration.** Air-tightness of building is now shown to be more important than preventing solar radiation heat gain as the infiltration of humid air into air-conditioned spaces contributes significantly to the energy used by the chiller. In addition, it is highly recommended to install CO_2 sensor in the air-delivery system to control the amount of fresh air introduced in air-conditioned building in this climate. The CO_2 sensor will ensure that the quality of air is maintained adequately without over providing fresh air via the air-delivery system to minimise the energy used to dehumifidy outside air.
6. **Control of solar heat gain.** Building orientation, exterior shading devices and glazing properties should be carefully considered by the architects to minimize heat gain from the sun.
7. **Insulation of building fabric.** Building fabric should only be well insulated when night load in the building is well controlled. Otherwise, the insulated fabric will trap the heat generated during night hours. It is also possible to use vegetation (greeneries) outside the building to help to keep the micro-climatic surrounding the building to be cooler.

A low energy building design need to address all these 7 steps, as these are the fundamental steps towards energy efficiency for air-conditioned buildings in tropical climate. It should also be noted that in each proposed step there are many possibilities to achieve the same intended objective as every building is built unique. It is up to the designer of the building to be creative to provide the most appropriate solution for their client while addressing these 7 fundamental steps for energy efficiency in air-conditioned building in the tropical climate.

Step 8 is energy management of the building after construction. This is to ensure that steps 1 to 7 are being practised in the building during the actual operation of the building to achieved the intended effect of a low energy air-conditioned building in tropical climate.

4. Summary

The re-evaluation of the OTTV offers an opportunity for an insightful analysis of typical energy consumption in buildings. As energy flow in building is often a matter of great complexity, this analysis simplified and put in perspective of the relationship and quantity of the possible energy saving potential of each element of a typical building into 8 fundamental steps. More importantly this analysis aided in providing a form of general checklist of priorities in the design of energy efficient buildings for the building designers such as the architect and engineer.

ENVIRONMENTAL ASSESSMENT OF BUILDING MATERIALS – BVB, A SWEDISH TOOL FOR SUSTAINABLE CHOICES.

Mia Torpe[1]

[1] HSB, Fleminggatan 41, Box 8310, 104 20 Stockholm, Sweden, mia.torpe@hsb.se

Keywords: Building materials, sustainability, environmental assessment

Summary

BVB is a Swedish database tool for environmental assessment of building materials. This system developed as a voluntary measure of the construction industry to incorporate environmental concern in housing construction. One of the main environmental impacts of housing comes from the materials that are used for construction and interior design of buildings. In order to support builders in making sustainable choices, a system has been developed by the major building companies and owners, for environmental assessment of building materials and chemical products in Sweden. The following paper presents the tool and the work behind it. On a globalized market there is a need to coordinate processes such as the assessment of building materials. The authors hope that this presentation of the BVB tool will enable exchange of ideas for fruitful cooperation and development of environmental concern in the building industry.

1. Introduction

One of the main environmental effects of housing and construction is related to the materials and products used in the construction and maintenance of buildings. If today´s main environmental question is climate, then the second is surely the existence of chemicals and hazardous substances in the environment. In the construction industry, thousands and thousands of products are used, resulting in long term consequences for humans and environment. Asbestos, freon, cadmium and PCB are examples of building material composites that have been used but are now not approved in the construction business for environmental reasons.

In order to coordinate and streamline efforts, the major housing companies together with the major construction companies in Sweden, most of them based in Stockholm, joined forces to establish a mutual system for environmental assessment of building materials. HSB, one of the founders of the BVB, is a housing cooperative which was set up in 1923 with the aim to provide quality housing for its members. In Sweden one home in ten has been built by HSB. A few of the parties involved, including HSB, had already made attempts to establish systems of their own. Hence a large part of the initial work with the BVB was to coordinate and synchronize. The needs of the market for quantitative, environmentally related information are increasing, especially in the construction sector. Therefore, systems for environmental declarations based on ISO and LCA methodologies are developing in Sweden and Europe.

In February 2008, a press release was issued stating that the BVB was launched and operative. The tool is comprised of a database containing to date 5 000 of the most frequently used products in the Swedish building industry. The basis for information in the database is a building product declaration supplied by the producer of the product according to a format developed by the Ecocycle Council in Sweden.

In a globalized world, building materials are transported all over the world, and building companies carry out jobs abroad. The standardization of building product environmental assessment would be an efficient aid to the development of environmentally sound construction methods.

2. Criteria

The building materials are assessed according to criteria developed in a wide group of experts. Seven categories of criteria are set:

- Declaration of content
- Raw materials, origins
- Stages in the life cycle:
    - Construction
    - Use
    - Deconstruction
- Waste and byproducts

- Interior environment

All of these components are valued according to a three part scale: Recommended, Accepted and To be avoided. Apart from the three categories, there are zero-tolerance criteria for certain substances. These include specific metals, toxic, carcinogenic, mutagenic and persistent substances, and producers of construction materials shall certify that the materials do not contain the specified substances.

3. Process

Construction materials producers and suppliers produce BVB through a form that is filled in and submitted to the BVB owners for introduction to the database. Today, about 5 000 building materials are part of the system, and have BVB declarations. This is only a minor part of all constructions materials available on the Swedish market. However, the use of the BVB is growing, with the increasing awareness of health and environment in relation to construction and maintenance of buildings, as well as the demand from construction companies.

The criteria are published on a website for transparency. After assessment takes place each product is assigned a color; green for “recommended”, yellow for “accepted” and red for “To be avoided”. Producers can comment on the result of the assessment. All assessments of building materials are stored in a database with a date assigned to the product since building materials change over time. This will insure that a retroactive assessment can take place for buildings that are already constructed.

The database is set up with a searchable website application. The system is user-friendly and can be adapted for specific building projects. The tool is available to all who sign up for a user license at a set fee, as well as a demo version. There is a format introduced in order to facilitate searching the internet for BVB available on the web.

The system is financed through licenses that are sold for access to the assessment. A licensee can apply to have the building materials assessed, and the producer of a building material can also apply to have the product assessed.

4. Results

Two important applications for BVB can be discerned:

- Environmental assessment of new construction materials. BVB can be a part of assessment of construction materials in the planning phase, and the purpose of the assessment is here to support the choice of a suitable construction material in the planned application.
- Documentation of already built-in construction materials. BVB can be used as a tool to document the buildings environmental effect for future needs, for example at deconstruction, or for decision support regarding exchange of products.

The system will grow as producers of building materials supply building materials declarations to the database, and as construction companies start to demand environmental information when buying products.

5. Discussion and conclusions

The system has not been running long enough to generate data that can be subject to evaluation. However, some initial observations can be made:

- The amount of building materials assessed and presented in the BVBs does not yet meet the expectations of the founders of the BVB. One reason could be that the BVB are perceived as difficult to fill in, and that it entails some work to find all the data that is demanded.
- Suppliers of construction materials are sometimes perceived as uninterested due to lack of interest among customers. The coordination between demand by the industry on one hand, and the willingness of producers to supply information has not gone hand in hand during the start-up phase of the BVB.
- Another aspect that has hindered the growth of the system is lack of competence to value the information presented in the BVB. The tool is intended to simplify for construction companies, hence a simple scale and coloring scheme has been introduced where green stands for “recommended”, yellow for “accepted” and red for “to be avoided”.

The information presented in the BVB was initially of a qualitative character; however, as time went on, more and more quantitative figures were presented. This is one aspect of the maturation of the system, since the information on chemical products is difficult to value. As time goes, more detailed information will be available, on a more and more quantitative scale.

BVB is not yet a suitable tool to value energy consumption and emissions. In Sweden a process is under way to implement energy declarations, which is seen as a credible tool to assess energy demand. BVB has so far not seen a need to incorporate the energy use.

The technical capacity of the construction materials is not included in the assessment, nor is occupational hazards or legal aspects. However, there is synchronization between the information in BVB and the security data sheets supplied according to chemical regulations.

Summary

In this study the thermal properties and heat transfer properties of rooftops, based on the light-weight green roof method in consideration of the characteristics of Korean buildings and ordinary rooftops, according to the materials and the cross-sectional configuration were analyzed through on-site experimentation on experimental houses and real buildings over a period of 4 years.

The analysis found that 1) the soil in the green roof case obviously deferred heat transfer and heat insulation during air-conditioning. As compared to concrete rooftops, those with tree planted on the rooftop decreased the daily average room temperature by about 2K. 2) The green roof system saved heating energy by about 6%~10% as compared to concrete rooftops during heating, and reduced energy consumption by about 12%~15% during air-conditioning. 3) The thermal and energy effectiveness were also analyzed according to the types of soil, the configuration and location of heat insulating materials, and the characteristics of the drain system. This study is an output of the long-term research conducted to develop the best green roof system suited to the buildings and weather conditions in Korea, and objective research results will be obtained by continuously expanding demonstration projects and application to more diverse buildings.

1. Introduction

In December 1997, a protocol was adopted indicating the beginning of the environment round in accordance with the‘United Nations Framework Convention on Climate Change.’This became an opportunity to again raise global consciousness on the importance of environment and energy in the viewpoint of Earth environment preservation. Accordingly, the developed nations are raising the pace in developing technologies for energy savings and environment friendly alternatives across all industries including the buildings sector.

In city concentrated countries like Korea green roof systems are being noticed as a realistic alternative that can simultaneously resolve the urban ecological problems as well as energy issues. That is, the green roof system holds the meaning of restoring the ecology damaged by construction & urbanization on the building exterior. In the viewpoint of energy also, it is known to relieve the urban heat island phenomenon, which has recently been recognized as a significant problem, and have great reduction effects on the rising energy requirements for building cooling purposes.

Apart from this, the green roof system is being recognized as an alternative that possesses air & water purification effects and can rationally and fundamentally resolve flooding and underground water problems.

This study seeks to construct a database through objective and quantitative performance evaluation in relation to the various properties and effects held by the green roof system, and based on this propose the optimal green roof system appropriate to the Korean buildings, climate conditions, and other general matters.

2. Thermal Performance Test

In this study onsite tests were conducted in the test housing and actual buildings over 4 years in order to evaluate thermal properties, heat transfer properties in accordance with material & sectional composition of the green roof system developed with low management & light-weight rooftop greening methods and the current pressed concrete roof systems.

2.1 Test Outline

Thermal performance evaluation in relation to the roof systems was conducted in 8 blocks of test housing located in Ilsan, Gyeonggi-do and actual buildings (Asan Medical Center, dormitory buildings).

With the results from the test housing, 1 pressed concrete roof system and the green roof system applied test housing number 7 were analyzed as the main subjects.

2.2 Test Method & Details

In the case of the green roof system, thermal performance evaluation was conducted on the soil layer composition, soil layer thickness, application of storage & drainage systems, internal & external insulation methods in accordance with the position of the insulation material as these are the major factors that affect thermal performance.

The test was conducted measuring the indoor temperatures of the test housing and temperatures in 128 points by attaching T-type temperature sensors to the structures comprising each roof system. For the energy performance, the heating & cooling energy consumptions needed to maintain identical indoor temperatures were measured for the periods (1 month) in winter & summer with the highest load.

Table 1 shows the measurement details and methods, and Table 2 shows the major test details.

2.3 Test Housing

The test housing was constructed to possess solar radiation effects from nearby buildings and satisfy climatic factors such as wind direction and wind velocity conditions, and the spaces between the blocks were designed to ensure identical solar radiation conditions.

The dormitory building where the onsite test was performed is a 2 floor building with 6 units, and centering on the central corridor, a green roof system was constructed on 3 units (east direction) and comparative tests were conducted in identical indoor temperatures as the existing roof (west direction).

Preliminary tests revealed that there was no significant difference in building load due to solar radiation etc. in each of the units during the test period, and in order to maintain more similar solar radiation conditions for the external wall, black anti-sunlight barriers were installed for the entire wall with a 1m interval.

3.1 Surface Temperature of the Roof System Facing the Open Air

Figure 2 shows the upper part temperature of the pressed concrete (test housing 1) facing the open air during the cooling period, and the surface temperature of the soil layer in the green roof system (test housing 7). During the test period the outside air temperature was about 20℃ ~ 40℃, and in the period August 10 ~ 17, the maximum temperatures increased everyday ranging 37℃ ~ 40℃.

During the 8 days of the highest outside temperature the surface temperature of the pressed concrete in the daytime was 47℃ ~ 50℃, approximately 10K ~ 12K higher than the air temperature, and about 28℃ was maintained during the night time. The surface temperature of the soil layer in the green roof system during the daytime was about 35℃, approximately 3K ~ 5K lower than the air temperature, and during the night time temperatures about 3K ~ 5K higher than the air temperature were maintained.

When we examine temperatures according to time, on August 12th and 13th the pressed concrete rose to 50℃ by about 14:00 in accordance with the rise in air temperature, and in the early morning at 3am when temperatures dropped to about 24℃ a high temperature of 30℃ was sustained. On the other hand, the upper surface of the green roof system rose to 37℃ which was similar to the air temperature at 14:00, but decreased below 30℃ with the drop in air temperature from about 20:00.

The surface temperature of the roof system facing the open air influenced the inside temperature of the structure with a time lag, and consequently as shown in Figure 4, the surface temperature of the lower slab section in the pressed concrete roof system increased to a maximum of 40℃ between 18:00 ~ 22:00, whereas the green roof system maintained a temperature about 10k lower measuring approximately 30℃.

Eventually, due to this temperature reduction effect it is expected that the movement of heat passing through the green roof system structure will decrease considerably. The inside temperature of the green roof system applied test housing during the same period showed a maximum of 36℃ in natural conditions without operation of any internal cooling systems, and this was about 2K ~ 3K lower than the daily maximum of 39℃ under the pressed concrete system.

As a result, the green roof system can effectively reduce cooling load from solar radiation at the soil layer surface, and this reduction in cooling load is expected to have been jointly influenced by the solar radiation blockage effect including the reflection in the green layer situated on top of the soil layer, the latent heat effects from the evapotranspiration in the vegetation section, and the physical insulation function held by the soil layer.

Figure 3 shows the test results during the heating period where the outside temperature range was -12℃ ~ 10℃, and from January 7 the outside temperature dropped drastically where the design air temperature (-11℃, based on central heating) of the heating system in the building was reached in the period of January 8 ~ 13.

According to the figure, the surface temperature of the pressed concrete showed an overall similar fluctuation pattern to the outside temperature (-12℃ ~ 10℃) without time-lag, and although the soil layer surface of the green roof system (soil depth 0cm) was similar to that of the pressed concrete, when the outside temperature dropped drastically in the period January 8 ~ 10, it maintained a temperature of -7.5℃ which was about 5K higher than the minimum of -12.5℃ on the pressed concrete surface.

The 0.5cm depth point from the soil layer surface maintained a temperature of about 0℃ even though the outside temperature dropped to approximately -7℃ in the period January 1 ~ 7, and on January 8 ~ 10 it held a temperature about 7K higher than the pressed concrete surface after which it gradually decreased. However, from the 11th it showd a similar fluctuation range to the outside temperature and the upper soil layer surface temperature (soil depth 0cm) indicating that the soil layer froze down to the measurement depth.

Figure 2. Fluctuation in Temperature of the Surface Facing the Open Air (cooling period)

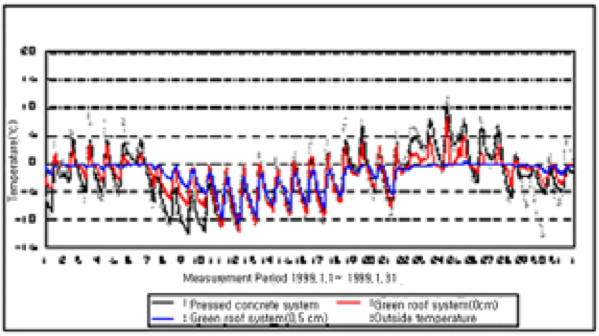

Figure 3 . Fluctuation in Temperature of the Surface Facing the Open Air (heating period)

3.2 Surface Temperature of the Lower Slab Section (upper section of the insulation material)

Figure 4 shows the fluctuation in the lower slab section surface temperature of the pressed concrete system and the green roof system (test housing 7) during the cooling period.

The lower slab section is the part that directly influences the ceiling surface and inside temperature as it borders the insulation layer in buildings with large scale insulation systems, and according to the figure, in the period August 8th to the 10th when the outside temperature rose to the maximum, the pressed concrete system showed a 5～6 hour time-lag in relation to the outside temperature during the daytime (about 14:00) when the temperature was the highest indicating a temperature distribution of about 35℃. However, at about 20:00 when the outside temperature dropped below 30℃, the lower slab section surface temperature remained at close to 40℃ due to the time-lag. Moreover, in the night time also when the outside temperature dropped to 22～23℃, the lower slab surface maintained a high temperature at about 33℃.

The lower slab section surface of the green roof system had a daily fluctuation rate of about 3K (28℃～31℃), and during the entire cooling period except for the days of rainfall (Aug 20th～23rd, 27th～28th), it maintained maximum temperatures of 8K below that of the pressed concrete system and minimum temperatures of about 2K～3K below that of the pressed concrete system.

Therefore, the pressed concrete roof system with large scale insulation systems continually maintains temperatures higher than the green roof systems in the lower slab section which is the upper section of the insulation material, and especially due to the time-lag, it causes the highest cooling load during the night time at about 20:00.

In real building if the insulation works are poor done or the connection points such as the joints are large, this high slab surface temperature directly affects the building's cooling load, so the difference in cooling energy consumption between the 2 systems is expected to be higher.

Figure 5 shows the test results during the heating period with the inside temperature kept constant at 18℃, and the pressed concrete system had a fluctuation range about 1/2～1/3 below the outside temperature fluctuation range while maintaining a similar fluctuation pattern.

The green roof system was found to maintain temperatures of about 4℃～8℃ during the test period when the minimum temperature range was -12℃～-5℃, and especially when the outside temperature continually stayed below 0℃, it maintained a temperature of about 5℃.

Because the insulation works were solid in the test housing, the maintenance of the constant internal temperature in the structure was not due to the heat transfer from the indoors, but rather due to the thermal properties of the soil layer comprising the green roof system. That is, it is positioned above the insulation material with sufficient insulation capacity, and the fact that the lower slab surface (lower section of the soil layer) maintained a temperature of 5℃ during the 12 days with outside temperature range -12℃～-5℃ was not solely attributable to the heat accumulation and insulation properties of the soil layer but also due to the existence of a temporary heat source that can somewhat counteract the outside temperature fluctuations.

Heat sources that can exist within the soil layer during the heating period first include microorganisms that produce heat through biochemical reactions. Generally, it is known that temperature increases from biochemical reaction are about 2K, and the vegetation rooted in the soil can also influence the overall thermal performance of the soil layer. However, it is difficult to see that these factors can maintain consistent temperatures when the outside temperature fluctuates as low as -12℃. Thus, it is judged that the sudden outside temperature fluctuations are first blocked by the soil layer surface, the heat insulation effects of the frozen layer created, and the effects of the thermal capacity in the soil layer. Moreover, apart from the insulation & heat accumulation effects of the soil layer, temporary thermal factors like the latent heat effects of moisture based on the frozen layer seem to have a greater influence on the maintenance of constant temperature.

Ultimately, as shown in Figure 5 the green roof system was found to be more advantageous in terms of heat than the pressed concrete system during the entire heating period of the test from January 1st to January 31st.

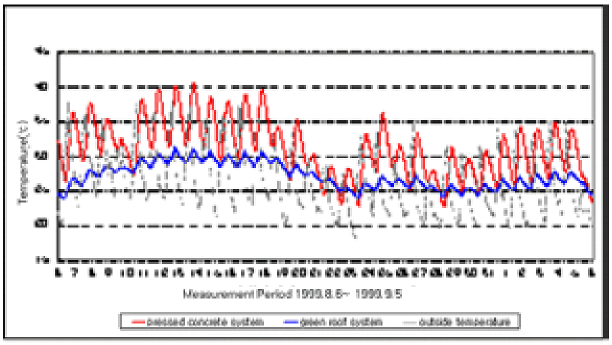

Figure 4. Lower Slab Section Surface Temperature Fluctuations (cooling period)

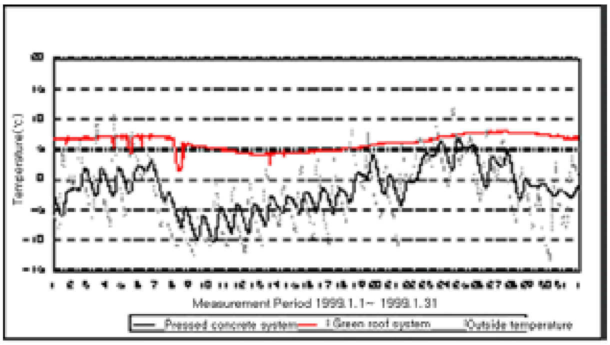

Figure 5. Lower Slab Section Surface Temperature Fluctuations (heating period)

3.3 Thermal Properties in Accordance with Soil Layer Thickness

Figure 6 shows the temperature fluctuations of the lower most soil layer section in the green roof system (onsite test located in Asan) in accordance with changes in soil depth.

As seen in the figure, the temperatures in the lower soil layer section (upper slab section) showed clear differences according to the thickness of the soil layer. When the soil layer was set at 10 ㎝, the daily maximum fluctuation range was 2.5K˜3K, and the maximum temperature 28℃, but the soil layers with thickness of 20 ㎝ and 30 ㎝ had relatively lower fluctuation ranges. The 30 ㎝ soil layer showed a temperature distribution under 25℃ with outside temperatures rising to 38℃ during the cooling period, and with daily fluctuation of less than 1K, it was found to maintain a very stable temperature.

3.4 Thermal Properties in Accordance with Soil Layer Composition

Figure 7 a) shows the temperature fluctuation within the soil in accordance with the soil layer composition during the heating period. As seen in the figure, the temperature within the soil consisting mainly of volcanic rock shows the largest fluctuation range in accordance with the outside temperature fluctuation, and especially around January 7th when the outside temperature dropped drastically, a similar fluctuation pattern was seen.

The perlite and natural soils maintained their internal temperatures at about 0℃ until January 7th gradually decreasing from the 8th, and from about the 11th a similar periodic fluctuation pattern to the outside temperature was seen. After the 18th when the outside temperature was again maintained above 0℃ the perlite and natural soils maintained their internal temperatures consistently at about 0℃ whereas the volcanic rock soil layer rose above 0℃.

Therefore, under identical conditions clear differences were seen in the soil layer internal temperatures depending on the soil composition, and these differences are expected to be influenced by whether a frozen layer has formed and the depth of the frozen layer. Furthermore, it was revealed that 1) physical thermal performance of the soil particles (insulation & heat accumulation performance of the particles), and 2) the amount of heat accumulation in the soil layer (soil moisture content - the shape, rate , and numbers of apertures in accordance with the particle size and structure) were revealed to be the major variables affecting the frozen layer.

In the case of the perlite soil used in this study, the soil itself has excellent insulation properties, and compared to the light-weight soil like volcanic rock, it has larger retention capacity, so the amount of heat accumulation increases relatively higher indicating more superior thermal properties during the heating period.

Actually, in the case of the volcanic rock soil layer during the analysis period, the entire soil layer was frozen until January 21st, whereas the perlite and natural soils contained relatively higher levels of moisture and the lower soil layer section did not freeze until January 7th. In the case of the perlite and natural soils, there is heating energy reduction effects for a period of time with the sudden drop in outside temperature, but the opposite effect could occur when the outside temperature rises due to the inherent heat accumulation properties.

Figure 7 b) shows the temperature fluctuation within the soil in accordance with the soil layer composition during the cooling period. As seen in the figure, the temperatures within the perlite soil layer showed the lowest fluctuation indicating the maintenance of stable soil temperature, and just like during the heating period the volcanic rock soil showed the highest temperature fluctuation with relatively higher temperatures.

In terms of the soil layer composition, the type & growth of plants, management performance of the greening system, building load etc. must also be taken into account together with the many factors discussed in this study, and in this study the perlite artificial light-weight soil was proposed for the low-management light-weight green roof system.

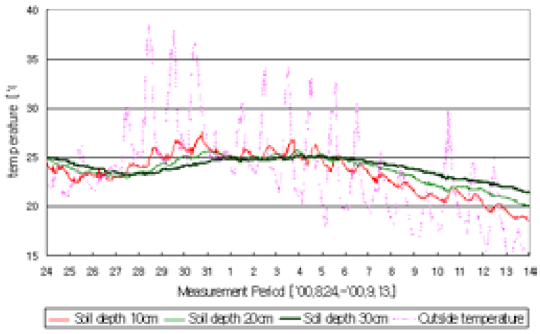

Figure 6. Lower Soil Layer (upper slab section) Surface Temperature Fluctuations According to Soil Layer Thickness (cooling period)

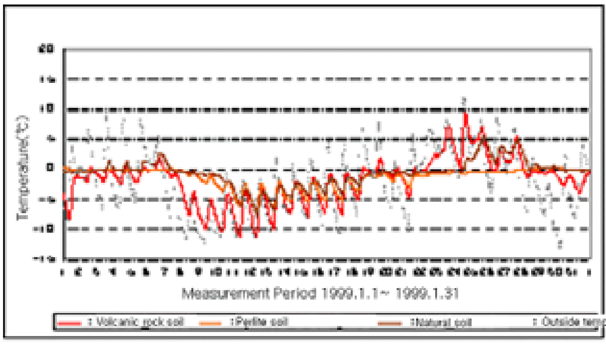
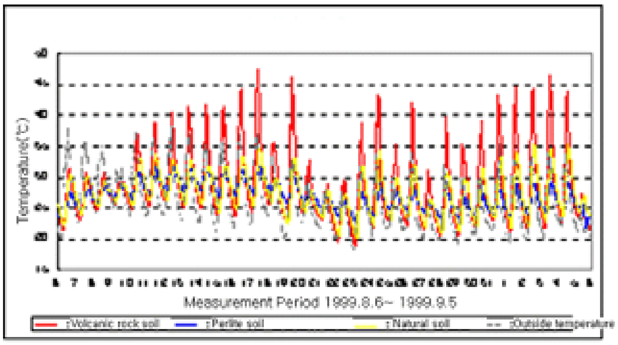


a) Heating Period Test Results



b) Cooling Period Test Results

Figure 7. Soil Temperature Fluctuations According to Soil Layer Composition

3.5 Thermal Properties in Accordance with the Drainage System

Figure 8 shows the lower drainage system section surface temperatures for the 4 test houses with different drainage system applications. Firstly, if we examine the case where drainage soil & water permeability plate were applied and the case where the storage & drainage plate developed for this study was applied, from January 10th when the daily minimum outside temperature remained under -10℃, the water permeability plate fell below 0℃ and froze, and under the same conditions the surface temperature of the storage & drainage plate fell to about 0℃ but did not freeze.

Moreover, the storage & drainage plate developed for this study showed similar thermal properties to the existing storage & drainage plate (D company of Germany), and the drainage mat which includes the air layer had moderate thermal performance lower than the storage & drainage plate but higher than the water permeability plate, and like the water permeability plate the lower section surface froze when the outside temperature fell over a long period of time.

Therefore, the 4 drainage systems each have different thermal properties, and in terms of thermal property, the storage & drainage plate containing expandable polystyrene was found to have the highest heat resistance, and the drainage mat also was found to have superior thermal performance compared to the existing drainage and the water permeability plate systems.

3.6 Thermal properties of Internal & External Insulation Systems

Figure 9 a) & b) shows the temperature inclination after measuring the temperatures over a 24 hour period (16.1.1999) in 20 minute intervals for the major layer boundaries of the green roof system with internal & external insulation under constant room temperature conditions.

With the external insulation system in a) the difference between the daily average room temperature and the temperature of the lower insulation section (upper slab section) was found to be about 3K, and the surface temperature difference between the upper and lower slab sections was less than 1K, so the slab holds thermal properties as a heat accumulation layer without heat resistance. The heat that passed through the slab makes contact with the green roof layer bordering the insulation layer, and here, the temperature difference between the upper & lower section of the insulation material ranged 10K ~ 12K showing a high temperature inclination. Moreover, the lower section of the storage & drainage plate on the upper section of the insulation material recorded temperatures 2℃ ~ 4℃ and did not freeze when the outside temperature dropped to -12℃, and the upper section of the storage & drainage plate fluctuated in the range -8℃ ~ -1.2℃ together with the soil layer.

In the internal insulation system of b) there was a temperature difference of about 10K bordering the insulation layer, and the upper section of the slab in contact with the green roof system layer recorded 1.4℃ ~ 1.9℃ showing a temperature distribution about 0.6K ~ 2K lower than the external insulation system. Therefore, the internal insulation system showed a lower frozen layer depth in the green roof system than the external insulation system under identical outside temperature conditions.

Generally, the probability of dew condensation inside a structure increases at the point of large temperature difference and when the inside temperature is low, so in identical humidity conditions the internal insulation system has higher probability of dew condensation occurrence on the slab and insulation material compared to the external insulation system. In existing buildings it is common not to incorporate a damp proofing layer on the interior ceiling, and if the connecting parts of the insulation material are not firm, internal dew condensation can occur on the boundary between the insulation and slab.

In the case of the external insulation system also, the moisture infiltrating into the structure through the slab can give rise to internal dew condensation on the boundary between the insulation and slab, that is why when the external insulation is incorporated into the green roof system in countries such as Germany and Japan, a damp proofing layer is always applied to the lower section of the insulation material.

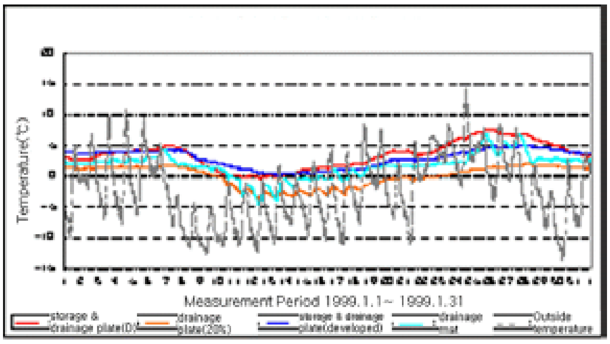


Figure 8. Fluctuation in the Upper Slab Section in Accordance with the Drainage System

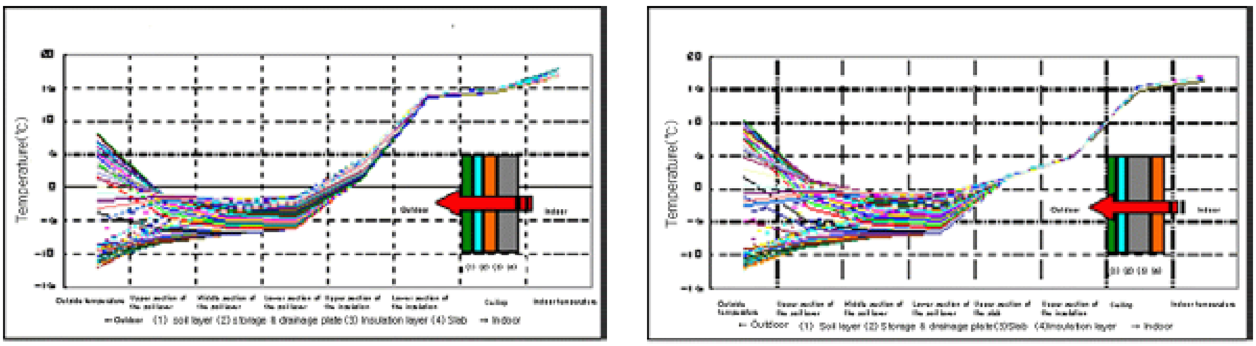

a) External Insulation System b) Internal Insulation System

Figure 9. Sectional Temperature Inclination in Accordance with Insulation Material Position

4. Energy Performance Evaluation

4.1 Heating Energy Performance Evaluation

Table 3 shows the heating energy consumption in maintaining the constant room temperature for the test housing during the heating period from January 13th to the 23rd (phase 1 test). The total energy consumption in the case of the pressed concrete system was 17.5[kWh] while the green roof systems recorded 16.4[kWh] and 15.2[kWh] respectively. Consequently, it can be seen that the green roof systems have energy saving effects of about 6.4% ~ 13.3% compared to the existing pressed concrete system.

Figure 10 shows the measurements of heating energy consumption in the low management light-weight green roof system introduced in the phase 2 test. Test housing number 2 was comprised of perlite artificial light-weight soil (soil depth 100mm) and water permeability plate (20%) & drainage soil as the drainage system, and with the same structure, test housing number 7 incorporated the storage & drainage plate developed for this test.

The total average daily energy consumption in the case of the pressed concrete system was 1.27[kWh/day] while the green roof systems recorded 1.19[k Wh/day] and 1.14[kWh/day]. The total energy consumption during the analysis period in the case of the pressed concrete system was 36.7[kWh] while the green roof systems recorded 34.6[kWh] and 33.1[kWh].

Therefore, it can be seen that the green roof systems introduced in this test have heating energy saving effects of about 6% ~ 10% compared to the existing pressed concrete system.

Table 3. Heating Energy Consumption (Test Housing)

Item		Pressed Concrete Roof System (Number 1 House)	Green Roof System	
			Number 2 house	Number 7 house
heating Energy Consumption [kWh]	Phase 1 test (13.1.1998 ~ 23.1)	17.5 (100%)	16.4 (93.6%)	15.2 (86.7%)
	Phase 2 test (24.12.1998 ~ 1.22.1999)	36.7 (100%)	34.6 (94.3%)	33.1 (90.2%)

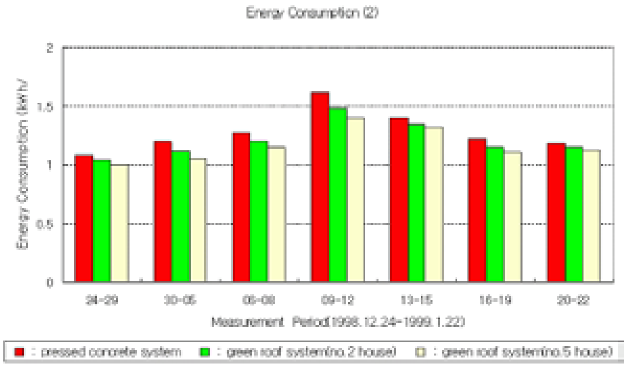

Figure 10. Heating Energy Consumption (Test Housing)

4.2 Cooling Energy Performance Evaluation

Figure 11 shows the daily cooling energy consumption in maintaining the constant room temperature for the actual building during the cooling period.

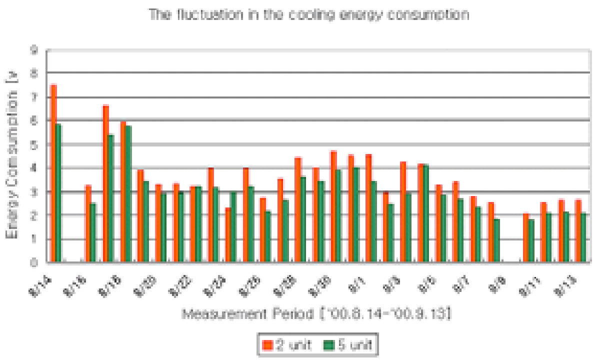
The onsite test was done on the 2 floor dormitory building located in Asan, Chungnam Province, and of the 6 units on the same floor, the green roof system was applied for 3 units and the existing pressed concrete roof system was maintained for the other 3 units.

Room air conditioners with cooling capacity of 1,800kcal/h were installed in each unit, and the room temperatures were maintained at 23.5℃ with no temporary adjustments. As a result, the room temperatures of each unit satisfied the constant test conditions of 23.5℃±0.3℃.

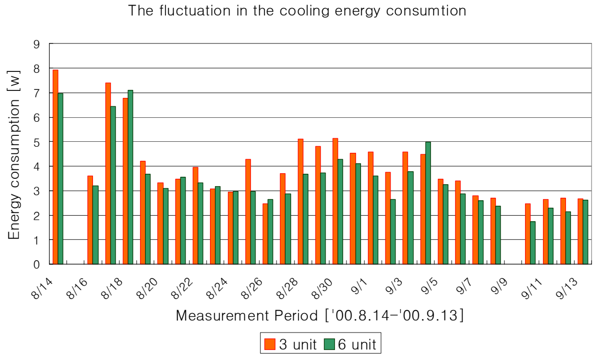
a) shows the fluctuation in the daily cooling energy consumption for the number 2 unit (pressed concrete system) and the number 5 unit (green roof system) whose side walls do not face the open air. Throughout the entire cooling period, the unit that applied the green roof system showed more than 15% less energy consumption than the pressed concrete unit. Especially when the outside temperature rose above 35℃, the difference in energy consumption between the green roof system and the pressed concrete system reached up to 17%.

b) shows the fluctuation in the cooling energy consumption for the number 2 unit (pressed concrete system) and the number 5 unit (green roof system) whose side walls face the open air. The unit that applied the green roof system showed about 10% less energy consumption than the pressed concrete unit.

During the analysis period, the total energy consumption in the pressed concrete units 2 & 3 was 108.82 [kWh] & 116.92 [kWh] respectively, and under identical load conditions, the green roof system applied units 5 & 6 showed energy consumption of 91.63 [kWh] and 102.62[kWh] respectively. Therefore, it was found that the green roof system gives rise to about 12% ~ 15% cooling energy reduction compared to the existing pressed concrete system.



a) Units that do not Face the Open Air



b) Units that Face the Open Air

Figure 11. Cooling Energy Consumption (onsite test)

Unit Position	Internal unit	Side wall unit	Internal unit	Side wall unit
Particulars	-	-	Soil depth 200mm	Soil depth 300mm

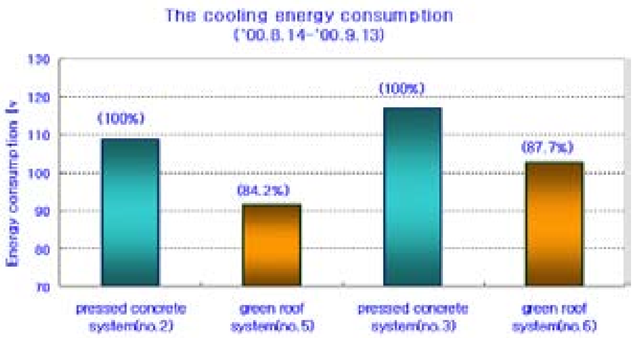

Figure 11. Total Cooling Energy Consumption (onsite test)

5. Conclusion

1) In the cooling period the soil layer of the green roof system clearly showed heat transfer time-lag as well as insulation performance, and without any separate cooling or heating source it showed a daily average room temperature reduction effect of about 2K. During the heating period also, unlike the existing recognition, the soil layer showed to possess sufficient thermal effect due to the heat insulation effect and heat accumulation properties.

2) In order to evaluate energy performance held by the green roof system, thermal performance tests were conducted on test housing and an actual building. The results suggest that the green roof system (perlite soil layer) gives rise to about 6% ~ 10% heating energy savings effect compared to the existing pressed concrete roof system, and during the cooling period it was able to secure energy saving effects of about 12% ~ 15%.

3) The test results of the major composition in the green roof system revealed that the physical properties of the soil particles and the moisture content had significant effects on the thermal properties of the soil layer during the cooling period. Especially during the heating period, it was shown to directly affect the degree of frozen layer occurrence within the soil and the subsequent thermal insulation effects. With the soil layer with the major constituents applied in the test (Perlite paraso soil, volcanic rock soil, natural soil), it was found that the perlite artificial light-weight soil had relatively superior thermal properties and performance.

4) With the drainage systems, it was found that the expandable polystyrene storage & drainage plate had the most superior thermal performance along with its storage & drainage functions. With the insulation system, it was found that the external insulation system was more effective in terms of internal dew condensation occurrence. Moreover, when the external insulation system and the storage & drainage plate was applied simultaneously, it was found that a more superior insulation performance could be secured.

Keywords: green roof system, rainwater , flood

Summary

The purpose of this study is to quantify the rainwater storing and leakage reduction effect of green roof system as a realistic solution to urban ecological problems, and lay the theoretical foundation for analyzing the effect of green roof system on the improvement of urban climate. To this end, rainwater leakage experiments were conducted on experimental houses with trees planted on the roofs and with paved roofs whose rainwater leakage can be measured. As for the materials and configuration of the green roof system, a model, determined in consideration of vegetation and energy-effectiveness, was applied.

The result of the performance evaluation of the rainwater leakage reduction effect of the green roof system, made of perlite artificial light-weight soil is summarized as follows: 1) The green roof model used in the experiment was found to be excellent in rainwater leakage reduction, around 70%, thanks to the water-retaining and evapotranspiration ability of the soil and vegetation. 2) The amount of rainwater leakage differed depending on the precipitation per hour, and the amount of water contained in the soil, but the green roof model was able to retain 20 ~ 30 kg/m2 of the initial rainfall without any leakage. 3) In case of a severe rain storm with more than 80mm/hr precipitation, the system was found to reduce rainwater leakage, and defer rainwater for at least 3 hours.

1. Introduction

The ecosystem maintains stability and balance with the continuous circulation of energy and substances. Likewise, water circulation is also in a closed form consisting of rainfall, soil saturation & storage, evapotranspiration, and precipitation. 65% of the rain falling to the ground is temporarily stored in soil, rivers, lakes, and plants after which it evaporates, and 35% flow into the sea in the form of surface water and underground water.[1)] The 65% of rainfall which evaporates from the ground has a governing effect on the local climate as well as Earth's climate control.

According to W. Geiger and H. Dreisei, the rainwater leakage rate in paved areas including the roofs of standard buildings is 90 ~ 100% and is much faster & higher than areas with natural soil and vegetation which have a leakage rate of 0 ~ 20%.[2)] This clearly explains the effect of pavement on rainwater leakage, and indicates the necessity of rainwater leakage reduction measures for paved areas for the maintenance of water circulation system balance. In other words, the loss in storage & permeation in soil & vegetation, as well as evapotranspiration due to excessive surface pavement are the fundamental causes of serious ecological problems such as the urban heat island phenomena, urban flooding etc.

With this background, green roof systems gained attention from the mid 1990s as the most economical and realistic measure against urban ecological problems due to the loss in the ecological function of soil and water circulation functions. There were especially great expectations in relation to the contribution green roof systems can have to rainwater storage, leakage reduction effects, urban climate improvement, and prevention of urban flooding.

Therefore, detailed studies are required for the quantification of green roof system rainwater storage and rainwater leakage reduction effects in order to scientifically examine the effects of pavement & green roof systems on urban climate as the realistic measure to resolve urban ecological problems.

Ground surfaces in urban areas are mostly paved by impermeable materials such as concrete & asphalt. Seoul, Korea has been transforming into an impermeable region with 48% of the total area covered by extremely urbanized areas consisting of 70% or more paved in impermeable materials. When we examine the soil coverage type in this urbanized area, 70% or more is comprised of buildings with flat roofs. Even if we examine the whole area of Seoul, there is approximately 254 ㎢ of flat roof areas taking up 42% of Seoul.[3)] These large scale pavement areas are the major cause of current urban ecological problems while having the potential space for green roof systems indicating that this must obviously be done and the high possibility of its success.

Consequently, the development of green roof systems is needed and must obviously be conducted, and we must commence with the existing flat roofs for which the technical difficulties and cost burden are relatively low.

However, in order to apply the green roof system to existing buildings, the problem of structural safety must first be dealt with. To solve this problem we can consider building repairs and reinforcement, but this only causes a rise in green system costs, so this can become an obstacle preventing the application of green roof systems. As a result, developing an light-weight roof planting system within the scope of the allowable load for the building was judged to be the most realistic method.

In this viewpoint, this study set the research scope with the light-weight roof planting system[4)] which was judged to have the highest utility to realistic requirements and potential application. The major details are as follows.

- Quantification of the rainwater leakage effects with the light-weght roof planting system
- Comparative analysis of the summer season aggregate rainfall and rainwater leakage rate
- Analysis on the effects of the drainage system on the rainwater leakage reduction effect

2. Rainwater Leakage Test

2.1 Test Facilities

The test on rainwater leakage effects was conducted by separately installing a $4m^{(L)} \times 4m^{(W)} \times 0.25m^{(H)}$ sized test roof as the test area on a roof not affected by nearby buildings. Also, in order to analyze the effects of drainage system differences on rainwater leakage reduction, the test roof on the upper part of the test area was constructed as two separate lengthwise test roofs sized $4m^{(L)} \times 2m^{(W)} \times 0.25m^{(H)}$. The short side slope of the test roof was set at 2/100 and while constructing a 10 ㎝ wide drainage canal, a ø35 ㎜ drain was incorporated into each of the 4 corners in order to optimize the similarities with the standard light-weight roof planting system construction conditions.

In order to prevent loss of reliability due to leakage, a PVC sheet waterproof material for green roof systems was used, and after the waterproofing work, the effectiveness was verified through a water test.

Photo 1. View of the green roof system test model

2.2 Composition of the Light-Weight Roof Planting System

The Light-Weight Roof Planting System model applied in the test is as shown in Photo 1. The system model consists of the drainage layer, soil layer, and the vegetation layer, and especially to examine the rainwater leakage differences between the drainage systems, 2 other different drainage system models were applied. Figure 1-1 is the system model combining the drainage soil and the drainage layer having an excusive drainage function, and Figure 1-2 is the model that has applied the storage & drainage layer which also has the storage function. The first model takes up 20% of the total area and after covering it with the soil particle filter the section (the remaining 80%) without the drainage layer was filled with drainage soil to an identical height (35 ㎜). On the other hand, the second model consisted wholly of the storage & drainage layer.

The soil layer comprised of the most standard perlite, an artificial soil made with plastic, and taking into account the allowable loads in existing buildings and the minimum soil depths for grass vegetation, the depth of soil was set at 10cm. The allowable stress on the roof of existing buildings is generally 200 ㎏/㎠, and considering that the moisture proportion for the artificial light-weight soil produced in Korea is 0.8 ~ 0.9, the depth of soil for the applicable light-weight roof planting system could only be limited to 10cm.[1)]

In order to minimize effects to the test, the vegetation layer was comprised of carpet type roll grass.

Figure 1. Roof Planting System Model 1, 2

2.3 Test Method

The rainwater leakage from rainfall was measured for the 2 green roof system models and the concrete roof surface, and a comparative analysis was conducted.

With the rainfall amount and the leakage amounts from the green roof system models the rainwater storage performance was evaluated, and by also measuring the time delay from the start of rainfall to the point of actual leakage, the rainwater leakage delay effects were analyzed.

From June to July the rainfall amount and the leakage amounts that passed through the green roof system test area were simultaneously measured, and the analysis of rainwater leakage reduction effect by the green roof system was conducted based on 24 hours of rainfall measurement results. The 24 hour periods were classified into rainfall amounts of 30mm or less, 60mm or less, and 80mm or less which calls for heavy rain advisory

he precision level of the rain gauge used in this test was ±0.5%, and it was a tipping type gauge (ø20cm, 0.5mm/pulse) approved by the meteorological administration, and the system was arranged so that automatic measurements were taken in 20 minute intervals with the rainfall converting into pulse signals.

3. Results & Observations of the Rainwater Test

Figure 2 shows the fluctuations in rainfall and rainwater leakage amounts that passed through the green roof system model within the period June 23 ~ 24. According to the figure, the rain started from 10am on the 23rd and ceased at 00:20 on the 24th. and the total rainfall amount was 33.5 kg/m^2(33.5mm) which was the aggregate of the 8.5 kg/m^2(8.5mm) for the previous day and the 25 kg/m^2(25mm) of rain over 14 hours during the analysis period.

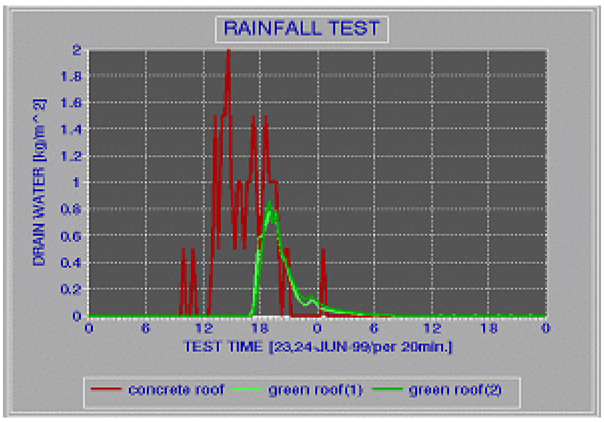

Figure 2. Rainwater Leakage Reduction Effect Case Study (Ⅰ) (Analysis Period: June 23 ~June 24)

As seen in the figure, the rainwater leakage that passed through the green roof system models 1 & 2 showed approximately a 7 hour delay from when the rain started with the leakage occurring from 15:00. Especially, the entire rainfall amount was held in the green roof system until the initial rainfall amount reached approximately 24.5 kg/m^2(24.5mm), so the rainwater leakage did not occur at all.

The total rainfall amount until the time when the rainfall amount and leakage amount was fully exhausted during the analysis period (based on 0.1 kg/m^2 or 0.1mm) was 33. 5kg/m^2(33.5mm) while the rainwater leakage amounts for test models 1 & 2 were 7.9 kg/m^2 & 8.1 kg/m^2 respectively. Therefore, the difference between the rainfall amount and the leakage amount, that is the rainwater leakage reduction effects (aggregate of the retention amount and evaporation amount) due to the green roof system in the 2 test models were shown to be 25.6 kg/m^2 and 25.4 kg/m^2 indicating that the rainwater leakage reduction rate is approximately 76%.

The water content in the green roof system models was not measured in this test, but if we take into account that there was virtually no rain within 10 days of the analysis period with rainfall measurements recording only 10mm, the maximum rainwater leakage reduction effect of the 10cm light-weight roof planting system is expected to be 25 kg/m^2 or more per unit area.

Figure 3 shows the fluctuations in rainfall and rainwater leakage amounts that passed through the green roof system model within the period July 28th to 29th. As seen in the figure, rain started falling from 4am on the 28th and by 16:00 of the same day the per hour rainfall amount reached 5 kg/m^2(5mm) and the total rainfall amount over the 2 days was 30 kg/m^2(30mm).

The rainwater leakage amounts for the green roof system test models 1 & 2 were 7.8 kg/m^2 & 8.9 kg/m^2 respectively, so the rainwater leakage reduction amounts in relation to the total rainfall were 22.2 kg/m^2 and 21.1kg/m^2 and reduction rates 74% and 70.3% respectively. The time delay effect from the beginning of the rainfall to the time of rainwater leakage occurrence after passing through the green roof system was approximately 11 hours. Here, the rainfall amount until the occurrence of rainwater leakage, that is the total rainfall amount that can be retained in the green roof system is approximately 19 kg/m^2(19mm).

The reason why the total water retention amount without leakage in the green roof system test models is different to that of 76% (25.4 kg/m^2) in figure 2 is firstly due to the intensity of rainfall, that is the scope of time in rainfall occurrence and the water content in the soil layer were under different conditions. Actually in the case of Figure 3, rainfall of 88.5mm occurred 5 days prior to the analysis period (July 22 ~ July 23), so the water content in the soil layer would have been relatively higher than in Figure 2.

However, the overall rainwater leakage fluctuation curves in figure 2 and 3 show similar patterns, and it was noticed that the green roof system models released the water slowly over time after the rain had ceased. Moreover, even after the rainwater leakage had occurred, the overall leakage fluctuation pattern moved in accordance with the changes in rainfall amount, but the leakage amount was relatively lower. At 16:00 when the per hour rainfall amount was highest, the rainwater leakage was shown to be less than half of the rainfall amount.

Figure 4 shows the fluctuations in rainfall and rainwater leakage amounts that passed through the green roof system models 1 & 2 within the period July 9th to 10th, and this analysis period was amidst the 15 days where rainfall did not exceed 0.1mm in the test area.

As seen in the figure, approximately 2.5mm of rainfall occurred from 6am to 12 noon, and during this period there was hardly any rainwater leakage. Also, the actual continuous rainfall occurred on the 9th from 20:00 recording a total of about 57 kg/m^2(57mm) until 12.

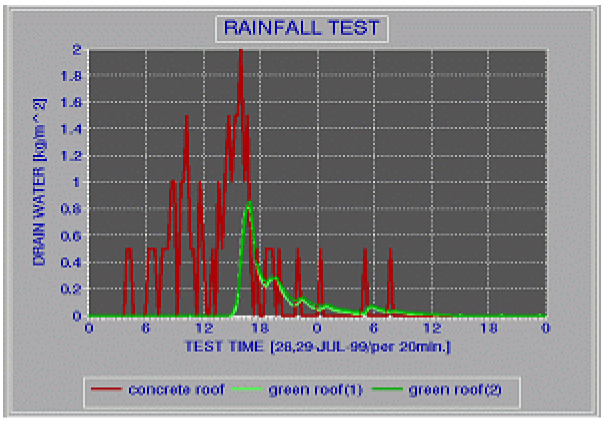

Figure 3. Rainwater Leakage Reduction Effect Case Study (Ⅱ) (Analysis Period: July 28 ~July 29)

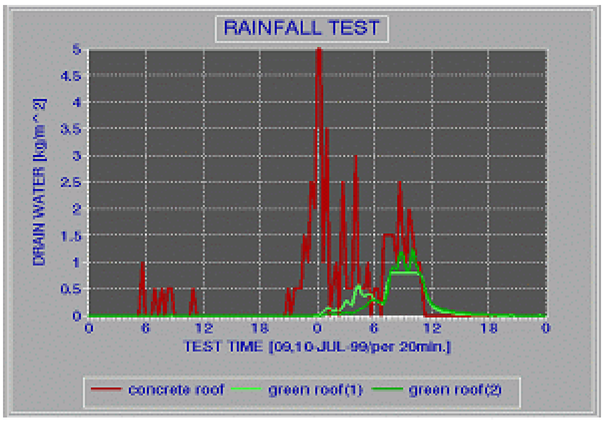

Figure 4. Rainwater Leakage Reduction Effect Case Study (Ⅲ) (Analysis Period: July 9 ~July 10)

In the figure, there was an approximately 6 hour leakage delay effect with rainwater leakage occurring from 2am on the 10th. Rainwater leakage in the green roof system models 1 & 2 did not occur until the initial rainfall reached 22.5 kg/m^2(22.5m m) and 32 kg/m^2(32mm) respectively.

Therefore, the total rainfall amount until the time when the rainfall amount and leakage amount was fully exhausted during the analysis period (based on 0.1 kg/m^2 or 0.1mm) was 57 kg/m^2(57mm) while the rainwater leakage amounts for test models 1 & 2 were 15.8 kg/m^2 & 15.2 kg/m^2 respectively. Therefore, the difference between the rainfall amount and the leakage amount, that is the rainwater leakage reduction effects (aggregate of the retention amount and evaporation amount) due to the green roof system in the 2 test models were shown to be 41.2 kg/m^2 and 41.8 kg/m^2 indicating that the rainwater leakage reduction rate is approximately 73%.

Because the analysis period was amidst the 15 days where there was hardly any rainfall, the maximum rainwater reduction effect of the light-weight roof planting system with soil depth of 10mm was over 41 kg/m^2 per unit area which is higher than the 19 ~ 25 kg/m^2 in figures 2 & 3.

Ultimately, the retention capacity of the soil layer depends on the rainfall amount, the rainfall intensity, and the amount of water content in the soil layer, but it can be confirmed that the rainwater leakage reduction rate in relation to the total rainfall amount is more than 70%.

Figure 5 shows the fluctuations in rainfall and rainwater leakage amounts within the period July 22nd to 23rd when a total rainfall of 88.5 mm was recorded within a 12 hour period. The rainfall during the analysis period exceeded the heavy rain advisory point, and especially around 9am on the 22nd the rainfall amount per hour was over 25mm.

As seen in the figure, rainwater leakage from the green roof system test models occurred approximately 3 hours after the commencement of rainfall, and until this time the water content without leakage in the soil layer was approximately 26.5 kg/m^2(26.5mm).

Therefore, the total rainfall amount until the time when the rainfall amount and leakage amount was fully exhausted during the analysis period was 88.5 kg/m^2(88.5mm) while the rainwater leakage amounts for test models 1 & 2 were 28.1 kg/m^2 & 29.1 kg/m^2 respectively. Thus, the difference between the rainfall amount and the leakage amount, that is the rainwater leakage reduction effects (aggregate of the retention amount and evaporation amount) due to the green roof system in the 2 test models were shown to be 60.4 kg/m^2 and 59.4 kg/m^2.

Moreover, the rainwater leakage amount in each green roof system model was about 4 kg/m^2 (4mm) when the per hour rainfall was at its maximum recording 25kg/m^2(25mm), so it could be seen that the green roof system is highly effective in terms of rainwater leakage reduction during times of short-term heavy rain.

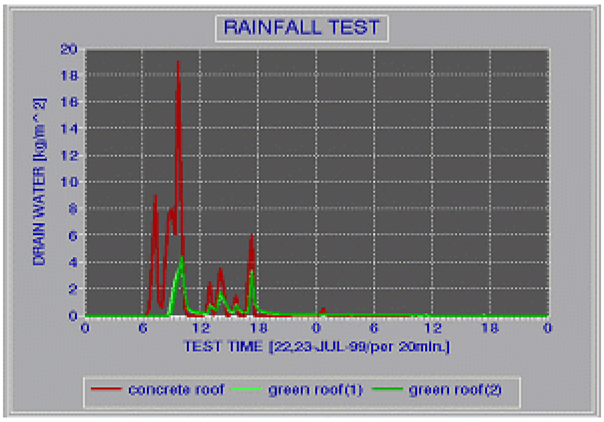

Figure 5. Rainwater Leakage Reduction Effect Case Study (IV) (Analysis Period: July 22 ~July 23)

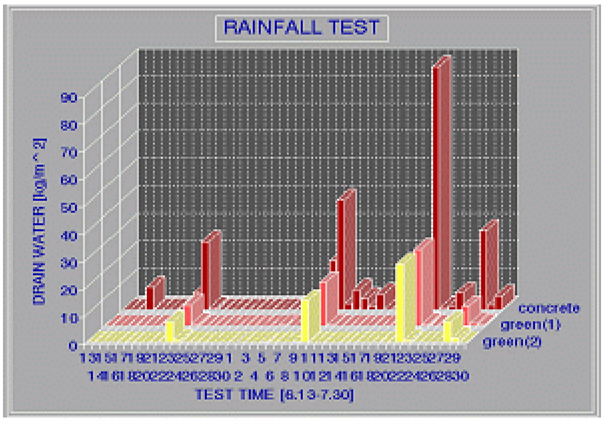

Figure 6. Comparison of the Overall Rainfall Amounts and Rainwater Leakage Amounts (Analysis Period: July 13 ~July 30

From the above results, it was found that light-weight green roof systems with soil depth of 10cm have about 70% rainwater leakage reduction rate through the retention capacity of the soil layer and the evaporation amount.

Furthermore, there were differences in the time delay effects relating to the rainwater leakage from the green roof system depending on the water content existing within the soil layer, but overall, it was found that an initial rainfall amount of 20 ~ 32 kg/m^2 (20mm/m2) could be held. Especially as seen in case IV (88.5mm rainfall in 24 hours) along with the rainwater leakage reduction effects during times of short-term heavy rain, it was found that the green roof system delays the leakage time by at least 3 hours.

The total rainfall amount for the entire analysis period (June 13 ~ July 30, 48 days) was 249 kg/m^2(249mm), and the rainwater leakage amounts for the 2 green roof system test models were 59.6 kg/m^2 and 61.3kg/m^2 respectively. Therefore, the amount of rainwater leakage reduction in relation to the total rainfall amount was 189.4 kg/m^2 and 187.7 kg/m^2 indicating a rainwater leakage reduction rate of approximately 75%.

Table 1 shows the total rainfall amount, rainwater leakage, and reduction rates for each case, and Figure 6 shows the daily rainfall amounts and the rainwater leakage amounts for 48 days from June 13 to July 30.

Table 1. Total Rainfall Amount, Rainwater Leakage, and Reduction Rates for Each Case

Category	Total Rainfall (kg/m^2)	Rainwater Leakage from the Test Models (kg/m^2)	Leakage Reduction Amount(kg/m^2)	Reduction Rate (%)	Particulars (Precipitation Conditions)
Case Ⅰ (6.23 ~ 6.24)	33.5	7.9 ~ 8.1	17.1 ~ 16.9	75.8 ~ 76	Total precipitation of 10mm or less over 10 days
Case Ⅱ (7.28 ~ 7.29)	30	7.8 ~ 8.9	21.1 ~ 22.2	70.3 ~ 74	5 days after the 88.5mm precipitation
Case Ⅲ (7.9 ~ 7.10)	57	15.2 ~ 15.8	41.2 ~ 41.8	72.3 ~ 73.3	No precipitation for 15 days
Case Ⅳ (7.22 ~ 7.23)	88.5	28.1 ~ 29.1	59.4 ~ 60.4	67.1 ~ 68.2	Approx 10mm precipitation over 9 days
Total (6.13 ~ 7.30)	249	59.6 ~ 61.3	187.7 ~ 189.4	75 ~ 76	Total over 48 days

Note) The precipitation is generally expressed as the height of rain (mm) per m2 unit, but the rainwater leakage amount is kg per m2 unit, so in order to enable comparison the rainwater proportion was assumed to be 1 and the precipitation unit was expressed as kg/m^2.

4. Conclusion

The summary of the performance evaluation in relation to the rainwater leakage reduction effect on light-weight roof planting system using perlite artificial soil is as follows.

1) It was found that the green roof system test models possessed approximately 70% rainwater reduction effects due to the retention capacity and evapotranspiration capabilities of the soil and vegetation layers. Moreover, the green roof systems show differences in rainwater leakage amounts depending on the rainfall amount and water content in the soil layer, but overall, they were able to absorb 20 ~ 30 kg/m^2 (20 mm/m^2) of the initial rainfall amount without leakage.

2) As seen in the case with the short-term concentrated heavy rain (88.5mm of precipitation in 12 hours), the green roof system was seen to have a minimum leakage delay effect of 3 hours along with the rainwater leakage reduction effects.

In order to make the data proposed in this study more realistic there needs to be large scale long-term onsite tests rather than the small scale model tests, and to raise theoretical comprehensiveness, supplementary studies on test conditions that can achieve consistency with the site conditions must be conducted.

Summary

The Ewha womans university Campus Complex (ECC) is designed to be a completely eco-friendly underground campus building that will symbolize the vision of sustainable design for the 21st century. In order to achieve this objective, the building is planned to reduce energy costs and the environmental load as well as to promote energy/water efficiency by applying optimal eco-systems such as a thermal labyrinth, geo-thermal energy, concrete core activation and others in order to use less primary energy. Furthermore, the envelope is effectively designed to save energy required for cooling and heating by providing an earth berm, a massive construction and a green roof system for the top of the building. In addition, windows that can be opened located on the valley side (opposite side to the earth-sheltered envelope) will improve natural ventilation during mid-season. Various water sources such as ground water, rainwater, and de-watering, etc. will also be applied to the building complex. As explained above, the ECC is a low-tech building designed with a focus towards saving energy and water and maximizing the recycling of the spent energy and water.

Figure 1 Ewha womans university Campus Complex (ECC) in Seoul, Korea (January 2008)

1. General Building Description

Table 1 Building information

Project	Ewha Campus Complex		
Architects	DPA Dominique Perrault Architecture (France) and Baum Architects (Korea)		
Engineers	HLPP Consult (Germany) and HIMEC (Korea)		
Location	Seodaemun-gu, Seoul, Korea		
Services	- Academic program: learning and sport-term project space, libraries, cafeteria - Administration - Commercial area: cinema, theatre, shops as well as external sporting spaces and car parks (20,000 ㎡)		
Site area	19,000 ㎡	Built-up area	70,000 ㎡
Structure	RC + SS	Estimated completion	2008

Above and below the land previously occupied by the Ewha square and the athletic field, the new campus valley provides both Ewhaians and prospective female leaders with the much-needed space for continuing education and student services. The concept design proposed by Dominique Perrault (France) was accepted at an international design competition held by the Ewha womans university in 2004, in order to develop the massive educational-cultural complex. The campus complex to be constructed is designed to offer a new sense of direction for higher education in the 21st century. It will establish organic relationships between the new building and the surrounding areas of the campus as well as between the above ground and underground spaces. The entire campus complex comprises six floors of underground structure. The 20m wide x 300m long campus valley connects the front gate and the main building and is composed of two floors of parking lots and four floors of educational-cultural welfare establishments.

2. Central Plant and HVAC Systems

The central plant systems of the ECC are designed as ecosystems that maximize energy and water saving. The various eco-friendly systems are also organically unified.

Cooling systems comprise heat pump type chillers, absorption chillers and a thermal storage system. In the night charging mode, the cooling system is operated by storing heat in the thermal storage tank using the less expensive night thermal storage power service during the night and using the discharging mode in the daytime. It is intended that the cooling systems will be operated in the order of the stratified thermal storage tank, the absorption chiller and the heat pump type chiller, according to the rate of the cooling load.

Heating systems serve the heating spaces and the heat pump units, which are reversed in the operating mode into the heating and the hot water boilers, produce domestic hot water. Numerous heat exchangers are installed separately in accordance with the amount of hot water required for each area, while the primary loop pumps are constant speed pumps and are controlled by the return water temperature in order to reduce the pump power. The secondary loop pumps are adapted to a variable speed either by the inverter control or by the quantity-related control, according to the heating load.

Table 2 Designed as a highly efficient heating and cooling system to deliver services

Equipments		Capacity	Quantity	Operation	Services
Cooling	Geo-thermal energy	100 kW	-	24 hours	CCA (concrete core activation)
	Ground water	40 kW	-	24 hours	CCA & condensate water
	Absorption chiller	1,266 kW	1 EA	24 hours	Day time: AHU, CHR & CCA Nighttime: CCA & nighttime zone
	Heat-pump type chillers	745 kW	2 EA (Stand-by)	24 hours	Daytime: AHU, CHR & CCA Nighttime: thermal storage tank
	Water thermal storage system	6,680 kWh	750 ton	24 hours	AHU, CHR & CCA
Heating	Geo-thermal energy	150 kW	-	24 hours	Heat-pump type chillers (chilled water)
	Hot water boilers	1,163 kW	2 EA	-	AHU, CHR, CCA & domestic hot water
	Heat-pump units (hot water)	958 kW	2 EA (Stand-by)	-	AHU, CHR & CCA

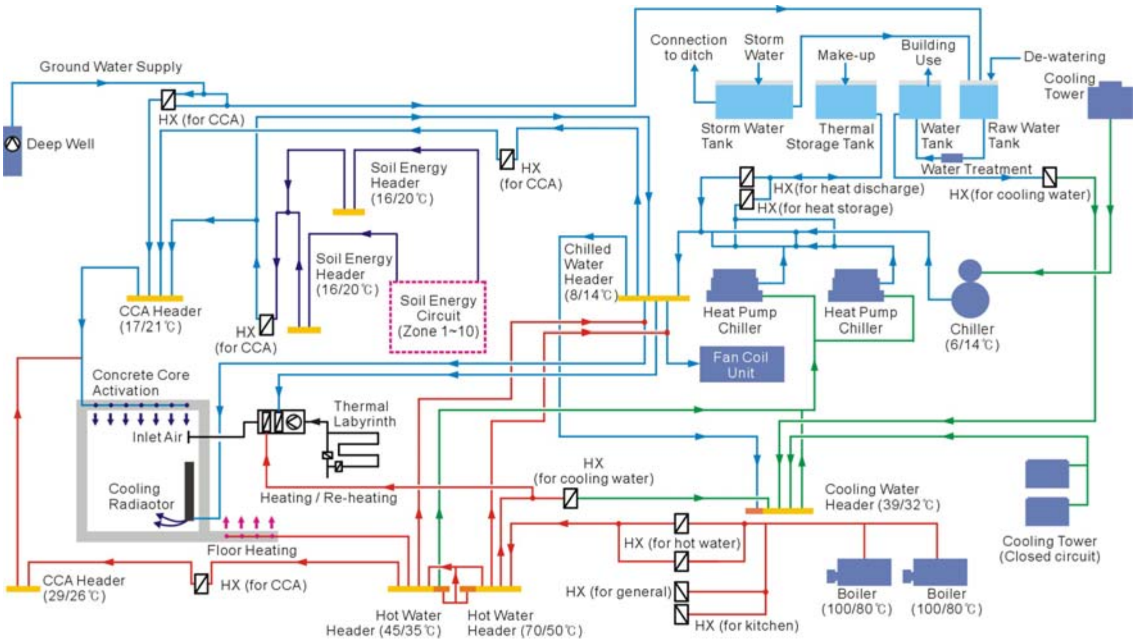

Figure 2 Central plant system diagram and equipment used for energy and water recovery

Re-cooling systems are prioritized to supply the condensate water that is exchanged with the domestic cold water and to use the waste heat from the AHU re-heating system in the summer season. In addition, if there is an insufficient capacity, the system is built to be able to control the quantity-related control of the closed circuit cooling tower.

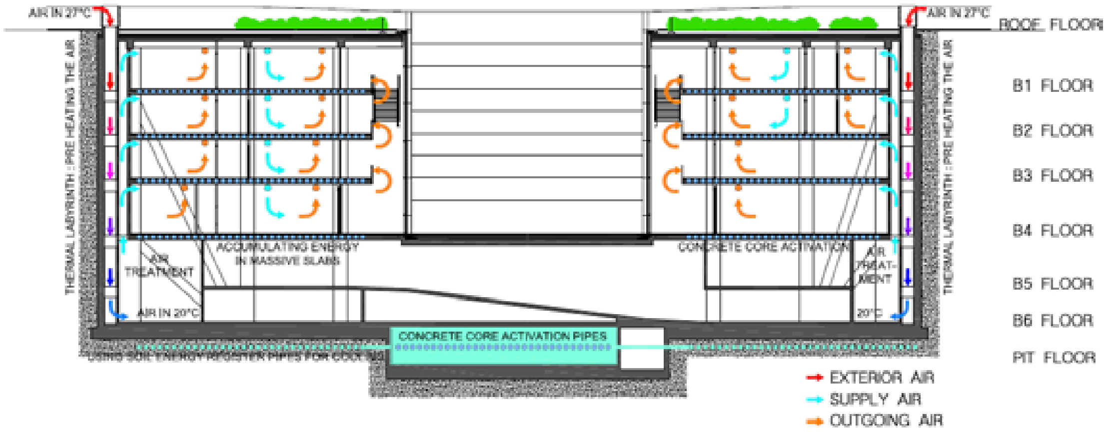

Figure 3 Section of ECC and how the design provides paths for air (cooling mode)

3. Eco-friendly and Energy Conservation Technologies

3.1 Thermal Labyrinth

The thermal labyrinth is a pre-cooling and pre-heating system supplying fresh outdoor air by taking advantage of building underground where there is a regular temperature all year round. There is no burden of extra construction cost for labyrinth structures because of the saving made in the use of a double layered space, which is necessary to install for the base structural system of earth coupled buildings. An analysis revealed that there is an approximate 10℃ pre-heating effect in winter and a 7℃ pre-cooling effect in summer, demonstrating that this system can save the energy that is otherwise required in HVAC systems for the pre-cooling and pre-heating of fresh outdoor air and can downsize the capacity of the boilers and chillers of central plants. Due to the air resistance of the labyrinth concrete structure, these benefits are greater than those gained by increasing fan power consumption.

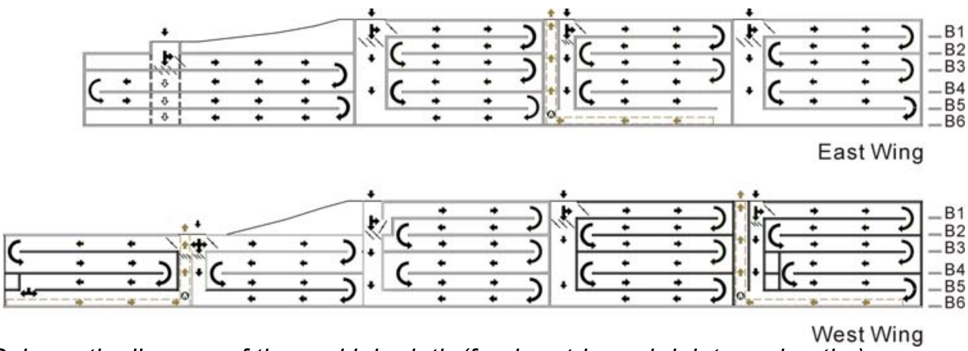

Figure 4 Schematic diagram of thermal labyrinth (fresh outdoor air inlets and paths)

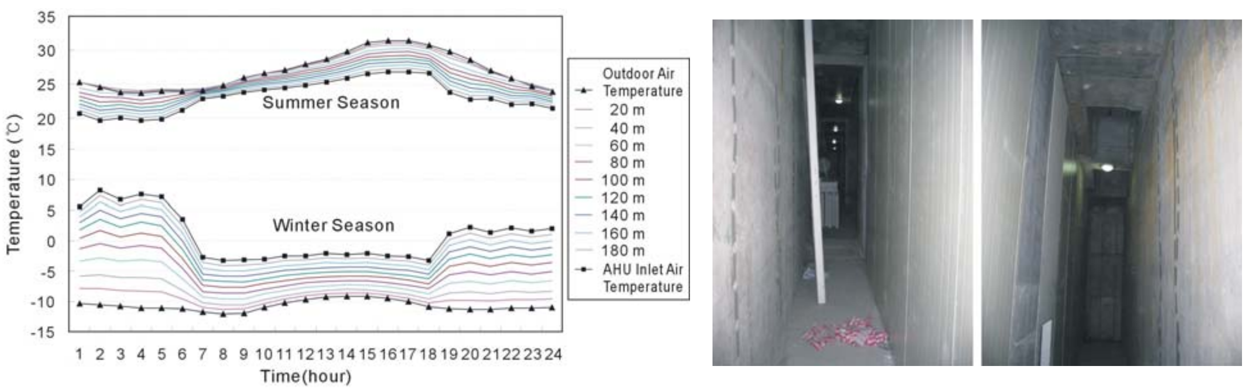

Figure 5 Effects of thermal labyrinth in summer / winter and actual figures of thermal labyrinth

For HVAC systems, during mid-season, when the outside temperature ranges from 12 to 18℃, the outdoor air is directly introduced through the vertical shaft. Conversely, a thermal labyrinth is composed of nine sections and eight outdoor air inlets. Because the ECC comprises a west wing, an east wing and a valley in the middle, the thermal labyrinth is divided into five sections in the west wing and four sections in the east wing. It is designed so that the fresh outdoor air is supplied to the two-storied mechanical room in the 6th underground floor and the heat is exchanged with the earth via the approximately 240m long soil duct connecting to the air handling units. The factors that affect the efficiency of the thermal labyrinth are thermal conductivity, density, heat capacity of the soil and the superficial area on the soil surface, resistance, the duct path of the thermal labyrinth, and the speed of air, etc. The results of an energy simulation taking these factors into account, demonstrate that it is possible to reduce the approximate 411kW peak heating load and the approximate 324kW cooling peak load. The equipment capacity of both the boilers and chillers can therefore be downsized.

3.2 Geo-thermal Energy

The main concept of the geo-thermal energy system is the use of cooling and heating source energy obtained from heat exchanged with the soil via the buried small-caliber pipes in the concrete floor slab of the 6th underground floor. During the summer season, the chilled water that has been heat exchanged with the soil is used for part of the cooling systems of the CCA and should be operated within 24 hours for thermal mass storage. The geo-thermal energy system comprises 10 different zones. In the cooling mode, the chilled or hot water is supplied through the CCA pipes for thermal mass storage and will be supplied to the hot water supply header in the heating mode. In Korea, it is known that the underground temperature regularly ranges from approximately 14 to 15℃ above a soil depth of 6~7m. The building was therefore designed so that the cooling system uses heat exchanged by the buried pipes between the concrete floor slab and the sand and gravel above the building foundation under the 6th underground floor. The temperature of the water is estimated to be about 16℃ after passing through the buried pipes and is supplied at about 17℃ via geothermal heat exchange before it is supplied to the CCA. The diameter of the pipe for the geo-thermal energy buried under the floor slab is 25mm and the pitch is 500mm.

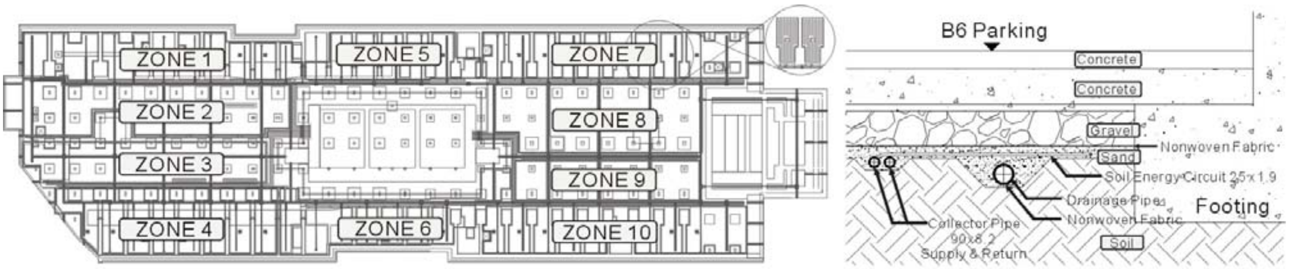

Figure 6 Plan of the geo-thermal energy system zonings and detailed schematic diagram of buried pipes

Figure 7 Construction pictures of geo-thermal buried pipes and supply header (B6F)

3.3 CCA (Concrete Core Activation)

The CCA system is the radiation cooling/heating system that controls the inside temperature by using the surface temperature of the radiation of the thermally activated building system. The system was proposed in order to save energy and to shift the peak load times due to the effect of thermal storage. Since the CCA system controls the space cooling/heating by using the radiation of thermal mass, residents are able to feel more comfortable at a higher indoor set temperature than when the conventional all air HVAC system is used. In addition, because of the low airflow rate compared to that of all-air systems, the duct works could be downsized along with the air delivery system energy. A total of four CCA zones are accommodated in accordance with the different load profiles between the inner zone and the outer zone. The inner zone is the valley area that faces the outside, while the outer zone faces the soil and the chilled/hot water loop pump zoning is separately installed. The CCA pipes buried in the concrete slab are of polyethylene material with a 20mm pipe diameter, a 150mm pitch, and are buried at a depth of 125mm from the ceiling (350mm of the thickness of the slab). It is intended that the entering/leaving chilled water temperature will be 17/21℃ for cooling and that of the entering/leaving hot water temperature for heating will be 29/26℃. Each zone area of the CCA is approximately 50~60 ㎡. From the results of simulation, considering the day time discharge efficiency (30W/㎡) and the night time charge efficiency (10W/㎡) at the early stage of design, a 60mm burial depth for the CCA in the concrete slab was proposed. A CCA system that utilizes various eco-friendly and natural energy methods uses geo-thermal energy primarily for the chilled water supply. When geo-thermal energy has insufficient capacity to serve the system, the chilled water will be supplied from the ground water or chillers. The reverse valves will control the exchange between chilled water and hot water seasonal supply in each season. In addition, a regular temperature of the CCA chilled water is maintained by primary variable speed pumps and 3-way valves in order to prevent dew condensation forming on the ceiling surface. In each room, the CCA that has buried pipes in the concrete slab controls sensible cooling and heating loads, while OHUs (outdoor air handling units) control the latent loads that are related to ventilation and dehumidification. VAV units control the airflow rate of ventilation according to the number of people in each area.

Figure 8 Detailed schematic diagram of CCA and construction pictures of CCA pipes

Figure 9 Indoor spaces of CCA system and cooling radiator

Using this method, any direct drafts from the cold air and shock from the difference in temperatures between the indoors and outdoors can be prevented. In addition, the heat generated from the human body is not rapidly eliminated, as it is with forced convection HVAC systems. Furthermore, this system can reduce the risk of dew condensation, via the latent heat load removal and ventilation. The finishing method for the ductwork is designed to reveal the ceiling in accordance with the interior concept, while the supply and return air ducts are arranged in a row. The VAV units are installed in the mechanical room in order to harmonize with the interior concept and to improve the convenience of maintenance.

3.4 Total Water Recycling System

Ground water maintained at a regular temperature is used for the heat source of the CCA operating 24 hours; after the ground water has been used for the CCA, it is collected in the water tank and is finally used for the domestic water through various steps, after being used for the heat sink of the condensate water of the cooling towers. As using ground water, the rainwater and de-watering are collected in the raw water tank, since after water clarification the heat sink for condensate water can save energy within the system. Using ground water also helps to improve the COP (coefficient of performance) of the chiller because the chiller can generate a lower temperature than that of the normal entering/leaving water temperature of cooling water. During the design stage, it is intended that the well sinking capacity will be 8.5 tons per hour and it is anticipated that the de-watering will be about 150 tons per day. The re-cooling capacity generated by the total water resource-recycling system is expected to be about 500kW.

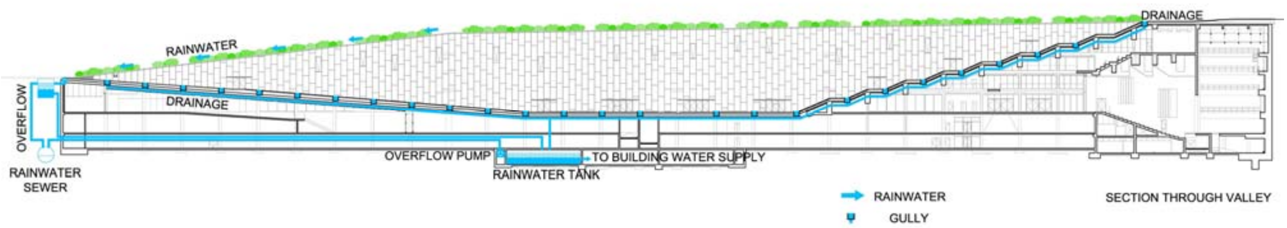

Figure 10 Use of rainwater for flushing toilets, irrigation, vegetation watering

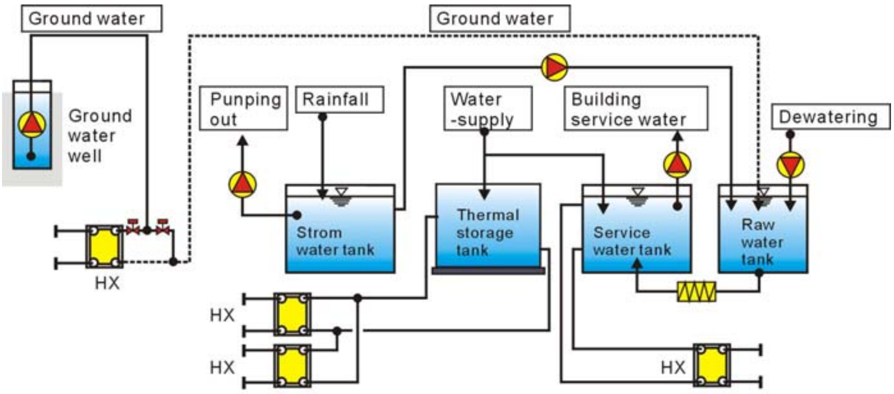

Figure 11 Schematic diagram of total water recycling system

3.5 Earth Berm: Earth-sheltered Building

As mentioned above, the optimum feature of the ECC is its massive construction for thermal storage and the application of soil energy as the source of energy. Because most of the exterior walls of the ECC are underground, the solar radiation and envelope load are effectively reduced. From an analysis of the building peak load, it is estimated that the load will be reduced by more than 20% of that of a similar sized building constructed above ground and that it is possible to reasonably downsize the capacity of the central plant equipment.

3.6 Waste Heat (from Exhaust Air) Reuse of Underground Car Parks

The air in the 6th underground floor car park is composed of the exhaust from the AHU and the fresh outdoor air for ventilation. In order to recycle the exhaust (waste) heat from the AHU into the re-cooling heat sink of the heat pump type chillers, the cooling towers for the chillers are installed on the 6th underground floor. To prevent an increase in the indoor temperature of the 6th underground floor, it is charged by heat-exchange of the soil with the underground car parks. The results of the simulation considering this condition show that during rush hour, when the maximum heat is generated from car engines, the indoor temperature of the underground car parks is maintained at under 27℃, which is the same as the entering wet bulb temperature of the closed circuit cooling tower. Therefore, the entering/leaving water temperature for the cooling tower is set at 32/39℃ and the re-cooling capacity is about 1,000kW.

Figure 12 Louvers for the waste heat reuse of the HVAC and the closed circuit cooling tower in the underground car parks

3.7 Re-heat System and Heat Recovery System for AHUs

Humidity control is very important in order to prevent dew condensation on the surface of the concrete slab, which is one of the problems of the CCA system. Dehumidified and over-cooled air is passed through the cooling coil in order to control humidity during the summer season. Hot and wet outdoor air is supplied to the indoors after again passing through the re-heating coil to meet the indoor set temperature. The re-heating energy is the recycled waste heat from the heat pump type chillers and the capacity of the re-heating coil is designed to be about 200kW.

3.8 Natural Ventilation and Green Roof System

At the main entrance of the ECC, the glass walls that face the valley are designed to facilitate natural ventilation. In addition, the green roof system on the top of the building is designed to provide places for relaxation and to reduce the cooling and heating envelope load of the indoors through the roof.

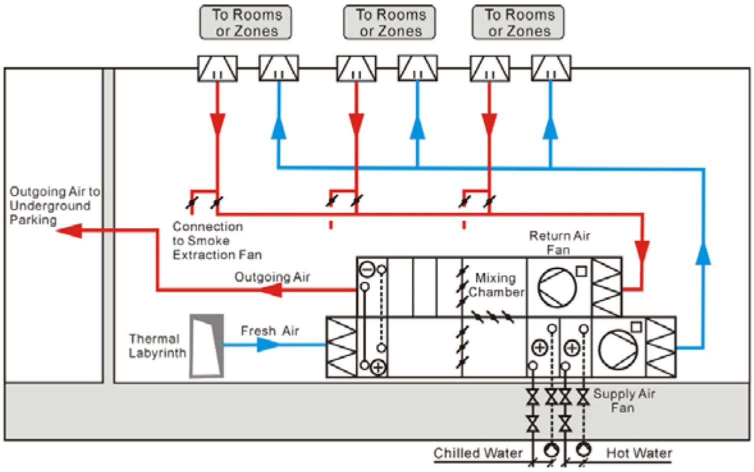

Figure 13 Schematic diagram of the re-heat and heat recovery system for air handling units

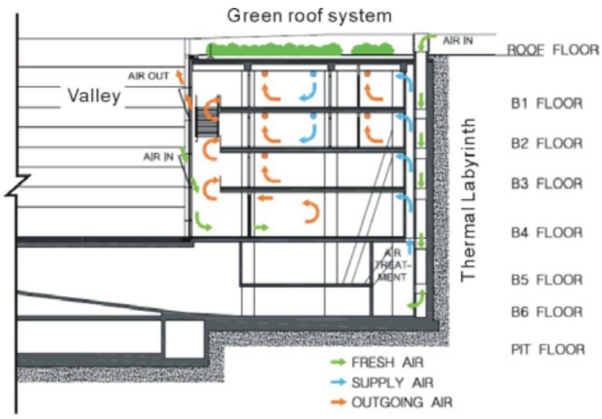

Figure 14 Outdoor air inlet windows for natural ventilation and green roof system of ECC

3.9 Water Thermal Storage System

The water thermal storage system stores (and charges) the chilled water, which is heat exchanged with the low temperature chilled water generated by the heat pump type chillers, in the stratified thermal storage tank installed under the 6th underground floor. This helps to reduce the operating cost by using the less expensive night thermal storage power service and by rapidly reacting to the load profiles. The temperature of the stratified thermal storage tank is charged at under 6℃ by the heat pump type chillers. A heat exchanger with a capacity of 840 kW for discharge is adapted.

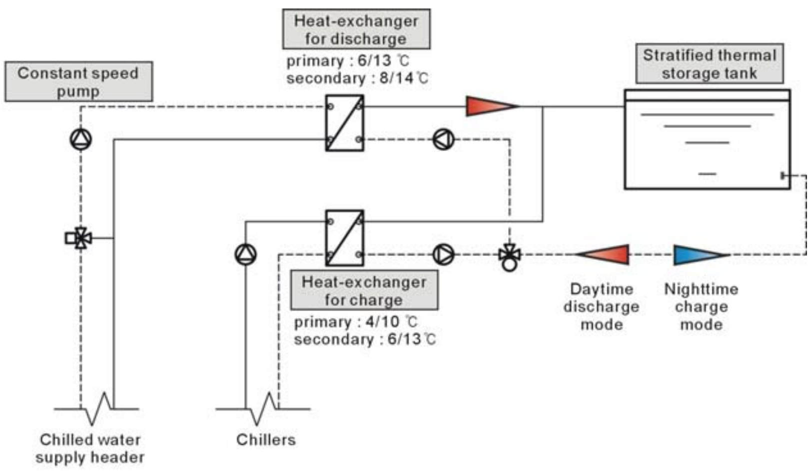

Figure 15 Schematic diagram of the water thermal storage system

4. Conclusion

In this study, the Ewha womans university campus complex (ECC), which organically connects eco-friendly and energy saving systems, is briefly introduced. The sustainability initiatives used in the design of the ECC encompass a range of well-integrated energy and water saving approaches, as well as a number of innovative techniques, such as a thermal labyrinth, CCA, and a geo-thermal energy system. Because the systems adapted in this building are somewhat unfamiliar, it is important to determine a method that will maximize the capacity to meet the climatic requirements and to be able to continuously monitor and analyze the operating data. Therefore, tests and verification of the systems are continuously required, as outlined below.

Firstly, the estimated capacity of the systems where eco-friendly and natural energy system design strategies have been integrated should be compared to the real capacity after the system has been in operation in order to detect and resolve any problems.

It is necessary to detect any problems related to the building control method by estimating the input/output energy of each organically connected system and to resolve such problems in order to create optimal operating systems.

In order to establish the concept of the design and construction of eco-friendly and sustainable buildings, it is necessary to investigate methods to improve such systems and to reduce the initial costs by improving the method of construction in order to protect the eco-system.

It is possible for eco-systems to be recovered to stable energy and water flows as macro environmental problems are solved through the removal of micro environmental problems within buildings. Consequently, when an integrative sustainable design is carried out, not only energy saving factors but also environmental factors need to be practically examined.

Acknowledgement

Technical support for this project has been provided by DPA (Dominique Perrault Architecture), HLPP Consult, Baum Architects, Samsung engineering & construction and Ewha womans university. Without their supports, this study would not be successfully achieved.

Summary

The term “sustainable construction” could be defined as a building contractor’s involvement in a sustainable development or simply the instigation of sustainable practices on a project. Understanding the associated risks, rewards and lessons learnt all come from that experience.

Understanding the levels of responsibility, cost and time can be defined as quantitative concerns. Understanding material selection, procurement processes and delivery techniques are qualitative concerns in the sense that they are of greater quality and should provide a superior result.

This paper attempts to summarize some lessons learnt over a number of sustainable or “green” projects.

1. Introduction

This paper is written from the view point of a main building contractor. It applies most pertinently to major construction projects with a sustainability agenda. However, some messages in the following would be pertinent throughout the building design and construction industry. My experience, for the most part, is that in office and hospital buildings with a sustainability agenda, some of which have pursued a *Green Star* rating.

Today’s building contractors are now involved in projects in different capacities than that of the traditional builder. It could be at the development instigation phase or, as part of a development consortium. The involvement can continue as facilities managers actually operating the facility, sometimes for up to 30 years. Building contractors are becoming involved in the whole of a building’s life.

In order to participate in the different phases of a building’s evolution, the building contractor must provide greater skills, knowledge and information than that traditionally offered.

The following provides an overview as to some of the challenges faced in sustainable construction.

2. Risk

Risk can be viewed as a challenge; it can also be viewed as an opportunity. It is all about understanding the issues presented.

A building contractor has to determine what level of responsibility they will be accepting.

There are many different contracting methods including Lump Sum, Alliance, Managing Contractor, Design and Construct (D&C) and now Public Private Partnerships (PPP). Each infers a different level of responsibility.

Many building contracts are now requesting the contractor be responsible for the sustainability outcome. This maybe measured through the *Green Star* tools, the ABGR or NABERS tools.

The Green Building Council of Australia’s (GBCA) suite of *Green Star* tools are formulated based on the building contractor being engaged on a lump sum basis with no design responsibility. Utilizing these tools under a design and construct contract can pose interpretation challenges.

The office building market is serviced by the Australian Building Greenhouse Rating scheme (ABGR) and National Australian Built Environment Rating System (NABERS) output based tools, whereas *Green Star* is an input based tool. In order to achieve an ABGR score the building must operate for a minimum of 12 months, most likely 18 months. This poses some complications to contracts with a standard 12 months defects liability period.

Risks can be seen throughout the delivery process of a commercial building, most of this paper is dedicated to the risks associated with sustainable construction.

Risks can differentiate you from your competitors, who are less informed or willing to accept the challenges.

3. Cost

Sustainable or “green” buildings typically contain 3 levels of features over that of a basic building.

(1) The ‘bolt on’ accessories typically associated with technology, such as co-generation, rain water storage or blackwater treatment.

(2) The 'increased specification' items, such as AAAA in lieu of AAA tapware, higher performance glass, substitute materials for piping, low Volatile Organic Compounds (VOC) and formaldehyde products.

(3) The 'inherent building form' items such as sun shading, thermal mass and orientation.

The 'bolt on' accessories are quite simply quantified and costed.

The 'increased specification' item can be analysed to determine any premium. However, depending on the cost drivers, this may not be undertaken for all projects.

A 'lump sum', project for example, with a clear specification for materials would not warrant a contractor performing a cost comparison. A D&C project, where the contract maybe on a guaranteed maximum price would warrant the comparison in order to determine the best value for money inclusions.

The 'inherent building form' items are more difficult to quantify.

Assumptions are made as to building mass and shading based on previous building projects versus the sustainable project in order to determine a premium. This is risky as the 'previous' project may not have suited the site. The orientation is normally accepted as good design.

As contractors continue to have more early involvement, they find themselves providing earlier and earlier cost advice. This is often termed cost planning. To do this on a "green" building requires some experience, as new technologies and methods can be difficult to quantify with out a full design.

Another aspect to "green" buildings and some others, is the concept of Whole of Life (WOL) based selections. This is where a low capital cost item may not be adopted due to higher ongoing costs. This type of analysis is commonly calculated, but once again not traditionally by a building contractor.

Some aspects within the *Green Star* tool are difficult to quantify due to the immature market. This applies to the role of the Independent Commissioning Agent whose role could vary from a $5,000 engagement to a $100,000 engagement dependant on the brief.

Our experience in commercial office buildings supports recent findings by Quantity Surveyors, Davis Langdon Pty Ltd and the GBCA, who find that a 4 star *Green Star* project attracts no cost premium. A 5 star attracts a premium between 3-5% and a 6 star project somewhere in the order of 10-15%.These findings assume that the projects obtain an as built rating and an ABGR score. It depends very much on the delivery method and scale of the project. A large design and construct project may attract less premium than a small 'lump sum' project in percent terms.

4. Materials

Sourcing materials to comply with an Ecologically Sustainable Development (ESD) brief or specification has challenges.

Initially, these challenges involve understanding the technical drivers, then locating suppliers and then verifying technical compliance. This is where the term "green wash" is real and causes building contractors confusion.

The selection of materials typically forms 3 types

- Materials with low emissions
- Materials with recycled content
- Materials with stewardship measures

Some of the lessons learnt throughout a selection of "green" building projects are that;

- Zero Ozone Depleting Potential (ODP) insulants, 20% fly ash in concrete, low VOC paints, sealants and adhesives and low formaldehyde, E1, MDF panel board are commonplace.
- Forestry Stewardship Council (FSC) certified timber and recycled structural steel is very difficult to source.
- Peak energy reduction plant like cogeneration, the use of an Independent Commissioning Agent and effluent treatment systems are expensive inclusions.

There needs to be more feedback to Suppliers, Architects, Engineers and organizations like the GBCA, from the construction industry, if the market is to respond effectively on sustainable materials. For example a tool such as *Green Star*, should in my opinion, reward best practice and some innovation. Whereas how things stand today some credit is provided for business as usual and then the rest of the criteria requires market transformation.

The best way of saving the amount of material wasted in the construction process is not to have it in the first place. By performing a waste minimization review with your design team; issues like minimizing off cuts can be reviewed by using standard sized items.

As a practical measure, a sustainable materials database with real selections can assist. Subcontractors maybe responsive to an actual complying selection.

What is mostly unknown in the construction sector, is the amount of embodied energy or water contained within our selected materials. Consideration must eventually be given to whether a product includes the transport energy from China or whether it is sourced locally.

Perhaps we should take a lead from the hospitality industry who are embracing a "locavore" principle, meaning to source produce locally, in their case from within a 10 mile radius. Can the construction industry construction source the materials required for a building is a similar manner?

5. Procurement

These days, the building contractor for a commercial property development can be contracted in many different fashions. For larger scale developments in is less likely they will be purely "The builder" working on a traditional lump sum contract with no design risk. They are more likely to be on a D&C, guaranteed maximum price (GMP), managing contractor, alliance model or now within a PPP.

These different models allow greater flexibility in procurement of subcontractors. For an outline of these different risk profiles refer section 2 of this paper.

Early subcontractor involvement can achieve tangible cost, time and quality improvements. For a "green" project the subcontractor may bring experience in the issues faced by the design and construction teams. They will also certainly bring another perspective to the discussions.

My experience in green building has shown me that all parties must cooperate in a collaborative environment. All parties will, of course, have varying viewpoints and agendas, but with the right leadership this can develop into organized teamwork which is most healthy when reviewing potential features and solutions. The suite of *Green Star* Tools certainly helps with this alignment, as long as they are not treated too much as compliance measures.

With the main contractor employed under a collaborative framework, there should then be consideration to selected specialist subcontractors joining your team. Not in a fixed price, lump sum, deemed to have included for everything model, but in an aligned collaborative model. Lump sum models can tend to lead to confrontation over allowances, diverting your focus from the real agenda.

A relationship model starts out collaboratively and can allow the subcontractors to understand the projects objectives, the main contractor's drivers and input into the desired timeframes.

This is certainly worth considering for the services trades, such as mechanical, electrical, fire protection and hydraulic services. Other useful considerations are the façade contractor, the flooring contractor and the waste removal contractor.

The services trades' impact can be over 30% of the total cost and they have more impact on the projected energy use than any other sector.

The façade contractor can assist in analyzing window selections for shading and will provide build-ability advice. The flooring contractor could range from a raised floor contractor, in a displacement ventilation project, where leakage and programming are critical issues. They could also be a floor finishes supplier who through innovative purchasing methods or products who could bring better sustainable solutions to the project. These range from increased recycled content, no PVC, whole of life modeling of selections and return the supplier end of life products.

The waste removal contractor can monitor and measure your construction waste and hopefully direct portions to varying reuse schemes in order to ensure that high waste by weight percentages are achieved. On site separation is an important consideration, it can increase your percentage recycled, but also instill a culture on site to separate. Separation could be a concrete bin, steel bin or plasterboard bin all of which would be removed by different parties and reused in entirely different applications.

The perceived resistance from subcontractors to these sustainable measures is actually based on a lack of understanding and guidance. My experience is that most parties embrace the opportunity to do improve their practices if they know the parameters of their obligations and responsibilities.

Of more relevance is the trade availability. Finding basic structural trades who want to embark on something non standard can be challenging in a heated market.

Some procurement takes more research and involvement, for example to obtain FSC certified timber. This is a chain of custody scheme of which may not have all products you require, or may require you to negotiate with a timber mill as well as a merchant.

Contracting with subcontractors can include sustainability considerations. One such method is contracting the subcontractor to the site Environmental Management Plan. Ensuring the subcontractor implements and reports on their appropriate parts on the plan, will certainly achieve a better than business as usual outcome. The subcontractors will also provide ideas and advice based on their experience elsewhere which will help the main contractor continually improve their methods.

Contracting such that packaging is returned to the supplier is also a clear message. The main contractor does not want the packaging and certainly does not want to dispose of the waste. Sending the packaging back to the supplier and hopefully the manufacturer may also promote less packaging or more innovative techniques.

6. Programming

"Green" projects can be more innovative than some other projects and as such could be more complex. This complexity needs to be considered when approaching the scheduling of the project. Questions like the lead time on unfamiliar products, the increased quality assurance and the increased commissioning and tuning all require review on standard delivery timeframes. The building may include more built form or activities with longer durations.

Depending on the method of building contractor engagement is the time taken to analyze sustainability design options. Continual modeling of options with your team is required to ensure the best for project outcome. It is acknowledged that this time is well invested up front, however must be considered on the scheduling of a "green" building.

Specific issues for consideration are; Raised floors used for displacement ventilation require a rethink on standard processes. As services are installed below the floor and access equipment cannot cross these pipes, trays and ducts, the ceiling must be installed first. Then the under floor services can be carried out, then the floor. The floor cannot typically support the weight of access equipment so any work from this new level must be performed from scaffolding.

The use of fly ash in concrete is now becoming commonplace. However the more fly ash the longer the curing times. It the case of precast panels this may leave them "on the bed" for more time which equates to higher cost.

Another specific example is the installation of black water treatment or sewer mining systems. These systems treat effluent into non potable water. For the systems to be commissioning they need the effluent to process, which will not exist until the building is occupied. A typical building contract includes "practical completion" prior to building occupancy. In a project with effluent treatment it could be 6 months before the system is operating correctly.

One issue mentioned previously is the risk of achieving the desired ABGR score. Commissioning is crucial to ensure the building operates as designed. Especially when using an Independent Commissioning Agent who reports to your Client. Depending on the project's contractual arrangement the building contractor could be responsible for ensuring or even just obtaining the ABGR score. The score cannot be achieved for a minimum of 12 months (most likely 18 months to 2 years) from building occupancy. This is necessary as the building needs to operate, as designed, through all 4 seasons. Typical building contracts include for a 12 month defects liability period which would have expired by the time obtaining a rating was applicable.

7. Auditing

Specifying the environmentally friendly products and services is one thing. Ensuring that the subcontractors are using the products is another.

Continual checking and reviewing is required to ensure the as built solution will be equal to that specified. This auditing can be done using many methods. My experience has contained some of the following;

The "green" clauses can be hidden within specifications and subcontractors may not appreciate their relevance. So highlighting their commitments in a separate document helps clear the agenda. Depending on the delivery technique the tenderer will most likely appoint a Project Manager, unfamiliar with the documentation, and an ESD precommencement meeting assists to ensure the Manager understands the subcontractor's commitments.

The collation of *as built* data, i.e. Concrete mix designs or recycling percentages should happen progressively. Obtaining the information after the subcontractor has completed their works and is on another project is difficult. Also auditing the content of this information progressively, helps you ensure correct procedures are undertaken, that your format of reporting is appropriate, and that targets will be met come the end of the project.

It is important to develop an effective management system, in order to standardize reporting. Obtaining and collating information needs a structure.

Actually contracting the subcontractor to your Environmental Management Plan somewhat empowers them to play a role in the overall solution. Auditing that compliance is then a teamwork issue.

Instigating your own environmental initiatives on site also shows leadership. Sensors in lunchrooms, bottle and can recycling, bike parks for site workers, site education and branding creates a sense of ownership and helps other "green "issues seem standard.

8. Commissioning

Building commissioning is not often done well. The activity includes testing, balancing, witnessing, record keeping and "putting to work" the systems as designed. The activity often comes under time pressure as it is the last activity often undertaken on the program.

The inherent risks of not commissioning a building correctly are exacerbated in “green” buildings as their energy use is closely monitored.

If the building is attempting to achieve an energy rating, such as the office system ABGR, ensuring the systems operate concurrently, in unison and as a whole of building would in reality, is crucial. Then ensuring they are operating as efficiently as possible to ensure the best result.

It is for these reasons the GBCA’s rating tools include for the use on an Independent Commissioning Agent to oversee the commissioning management process. This engagement should begin with reviewing the design, to ensure the team understands the time required and to oversee that the activities are undertaken in accordance with best practice. The scope of the agent’s role is still a little vague in the market place and the fees paid for such activities are not commensurate with the level of risk mitigation being employed.

The level of planning, monitoring and record keeping is often greater on a “green” project as unfortunately best practice techniques are not always implemented on other projects. It is also because “green” projects often incorporate a higher level of new technology and are inherently more complex.

Some specific issues associated with commissioning include;

- The air sealing of plenums and the building. Under floor plenum systems inherently leak, however this need close attention around the perimeter and between the zones or air highways. The façade system should also be closely inspected for leakage points.
- Daylight control systems. The systems typically involve automatic dimming and interface with an automatic blind system. The blinds close to reduce glare based on the sun angle however then the lighting levels increase to compensate.
- Metering and energy monitoring. The building’s energy data will typically be collected by the building management system (BMS). This capture of the metered energy use will correspond to the carbon dioxide output for the building. The metering can be extensive, needs to be calibrated and may need to be added to some “standard” equipment not usually remotely read i.e. authority meters.

Finally performance testing during the right climatic conditions is the only real test. Functional trials involving the running of all equipment as it should and then simulating occurrences is the best preparation for real occupancy.

9. Handover

A successful project is often measured by the handover from the building contractor to the user. This handover is no longer simply, handing over the keys. It includes training or more correctly orientation of all the features, submission of all the building records including operation and maintenance manuals, warranty schedules and *as built* drawings.

Training infers a transfer of skills with the trainee demonstrating some proficiency. Training in the building sector is more accurately described as orientation for which specialist trade subcontractors will explain the features to designated Client personnel. “Green” buildings bring another dimension to these orientation sessions. To start with the building may have employed a separate Facilities Manager (FM) who will not be aware of any of the features and will require orientation. Also, the building is likely to incorporate new technology which will be unfamiliar to those under instruction. The building contractor is more often facilitating formal sessions to ensure the activity is performed correctly and effectively. Facilitating training such that trainees take on an empowered level of ownership will ensure some transfer of responsibility.

The *Green Star* tool also includes for the provision of a building users guide, designed for the building occupant, not the building manager. This is in order for the staff and occupants to become familiar with the sustainability elements of the building’s design and for them to be more environmentally aware by i.e. commuting by public transport or where to deposit their recycling.

A method of reducing the environmental impact of all the *as built* paperwork is the use of electronic manuals. These can be scanned versions of manuals or proprietary online manuals. The manuals can save vast amounts of paper, but are also more secure; as it is less likely the manual will be removed and not returned.

As owners and tenants are becoming more aware of the cultural change new premises can deliver, the main contractor can be requested to facilitate or at least input into the successful transition of staff from one location to another.

10. Post Completion

These are activities performed after occupancy. They can include full facilities management, preventative maintenance of systems, essential services testing and reporting, building tuning and rectification of any outstanding defects.

It is also, on reflection, a time for analyzing what you have gained from the experience. Such an analysis might consider the capitalizing of marketing potential, the compiling of cost data and energy data, a more educated workforce and hopefully the establishment of a better profile in the marketplace.

The impact of an external FM contractor, employed by the building owner, on the running cost and energy rating of the facility must be considered. Various assumptions are made when modeling the building's performance. These assumptions maybe operational times, set points and demand. Modifications by the FM contractor could affect the building's eventual energy rating.

The *Green Star* tools also include for the provision of building tuning for 12 months. This is to ensure that set points are aligned to the design specification and that systems are operating to suit climatic conditions. This is a quarterly activity over and above maintenance. It is good practice for the building contractor to forward results of this tuning via the Consulting Engineer and the Independent Commissioning Agent for input and advice. This extends the involvement of the building contractor, albeit as required, throughout the defects liability and maintenance period.

Introduction

After a long period which can be qualified as an acculturation time all the Construction Sector agrees to wish an instrumentation of the sustainable development concept. The practitioners want to be able to make technical choices as well as to take architectural or urbanistic options in accordance with a more balanced development of the urban fabric.

We do not wish there to devaluate the tools implemented during this learning process for environmental grading. But it is time to rethink the construction process and to encompass a real sustainable approach of measurement.

To progress in this direction we must take a two steps reflexion.

1. How to structure the sustainable development dimensions?

Within the several attempts to improve a sustainable urban development we can find the same requirement: we must harmonize the different decision scales.

1.1 The urban context

Everybody recognize that a single sustainable building is not able to fulfil the sustainable requirement for a city block. It is not enough to build a friendly environmental construction to be sure that the building answers the social need of the neighbourhood.

The building must also improve the urban services and the attractivity of the area to achieve the end-user satisfaction.

These global requirements are not issued from the construction supply chain. They are basically the result of urban planners who respond to the political power. And this decision process is established at the city level.

The construction professionals cannot influence this political choice. They only can answer this will in a better way. We must conclude that the main period to improve a sustainable construction in the brief.

1.2 The construction process

We are not saying that the professionals should not contribute to a sustainable development. They only can improve the initial choice. They can help the decision making process without to disturb it. The builders are able to optimize the technical solutions for a specific use of the project.

So the more significant attitude for an improvement of the construction process is to contribute to a more lisible fitness for use.

Saying that we confirm that the professionals are not concerned by the destination of the construction but they must show to their clients the consequences of the initial decision.

At the building scale the sustainable assessment needs a functional review.

2. Towards a coherent measurement frame

To implement the previous principles we need to combine two aspects of a building: the fulfillement of use requirements and the consecutive sustainable impacts during the life cycle.

2.1 The functional approach

For a sustainable development of the urban fabric each building must be designed to support the end users activities.

To assess the result it is possible to determine how the construction fulfils seven use functions answering seven questions:

Does the building:

1. Provide space?
2. Provide an indoor climate?
3. Provide safety and security (integrity)?
4. Allow use of goods and tools?
5. Control the nearby relationship (privacy)?
6. Take advantage from the site without damaging it?
7. Provide sense (semiology)?

These use functions have been defined by a working group in 1980 using a functional analyse methodology[1].

2.2 The deployment impacts

They characterize the building in use during its life cycle.

Another working group has defined the criteria which can elicit and cover the three dimensions of a sustainable development: the economic issues, the social issues and the environmental issues.

This think tank proposed in 1990 the following nomenclature[2].

Characterizing the initial construction phase

- Permit technical and economical optimization:
  - Ability to fulfil the functions (1)
  - Impact on the financial capacity (2)
  - Logistics for the setting up (3)
- Provide it with acceptable setting up conditions:
  - Working conditions on site (4)
  - Impact on the personal valuation and on employment (5)
  - Pollutions due to the construction site (6)
- Reach minimized resources withdrawals:
  - Impact on the raw materials withdrawals (7)
  - Impact on the energy resources withdrawals (8)

Mastering the operation phase

- Guaranty the preservation of the use functions:
  - Service life duration (9)
  - Optimized up-keeping and maintenance (10)
  - Limited consumptions and rejections (11)
- Control the management of the interfaces:
  - Access cost to collective services (12)
  - People safety and health (13)
  - Immaterial features (new technologies networks) (14)
- Take part and contribute to the urban life:
  - Interconnections, transportation means (15)
  - Integration of short distance services (16)
  - Integration of avoided costs (17)
  - Impact on the patrimonial value of the place (18)
  - Impact on the natural environment (19)

Managing the upgrading, the retrofitting and the dismantling phases

- Permit refurbishing and retrofitting:
  - Ability to adaptation (20)
  - Ability to shift to another use (21)
  - Feasibility of upgrading the performances (22)
- Authorize dismantling:
  - Ease for demolition (23)
  - Ease for dismantling, sorting, re-use (24)

Therefore we obtain the sustainable assessment frame as the matrix defined by the two views of analysis: (a) the functional aspect and (b) the sustainable dimension

	Sustainable criteria (24)
Functional requirements (7)	Assessment matrix (7 x 24)

The main interest of this proposal is to provide the frame analysis of the building efficiency.

This concept has been introduced by the WBCSD. It is defined as the ratio ($\sum$ values/$\sum$ impacts)[3]. The assessment matrix answers this definition and allows new development to produce a significant indicator for a sustainable building. The values are brought by the performances level of each use function. The impacts for each value are defined as the level of responding to the sustainable criteria.

In another hand this proposal is in discussion within the ISO/TC 59/SC 17 sustainable building construction.

Conclusion

We believe that the improvement of the construction sector should be the result of three assertions:

- A building contributes to a sustainable development, when designed and operated for just matching the appropriate fitness for use, through the fulfilment of use functions, with minimum adverse environmental impacts, while encouraging improvements in economic, social and cultural aspects at local, regional and global levels.
- As a first statement, it means that a sustainable building is a building whose technical performance must be seen as an answer to a social demand: a building makes sense when and only when it is undertaken in order to meet objectives expressed by or for the users. It should be planned to provide the expected services, and this long term view can only be due to the owner, either local authority, or housing builder for social renting, or private investor. The designers and constructors come in a second step, and their role is to suggest technical solutions to meet the programme, but always considering the impacts of the technical choices on the three aspects of sustainability: environmental, economic and social/cultural.
- Consequently, as a second statement (and provided that the first one is achieved), a building is the one for which the relevant questions addressing all the stages of its life cycle have been raised at the initial stage by the owner, and answered through the technical and process choices described in the brief.

We hope promoting these principles to act as responsible professionals involved in a reengineering approach of construction.

Keywords: area-wide energy utilization, decentralized combined heat and power (DCHP) , load levelling, business and living continuity plan (BLCP), benefit-cost ratio (B/C), non-energy benefit (NEB)

Summary

To achieve the Kyoto Protocol target, the concept of area-wide energy utilization system is proposed in terms of sustainability of the built environment. The key items of which are; 1) electric and thermal load levelling by block-scale load aggregation, 2) installation of decentralized combined heat and power (DCHP) system, 3) installation of private electric wire and thermal interchange pipelines in the block
Total energy performance is expected to be remarkably improved along with contributing business and living continuity in emergencies such as disasters within the block. This paper proposes policy measures to promote building block scale DCHP systems based on feasibility studies conducted to some existing blocks in a highly-density city such as Tokyo.

1. Study background and objectives

In Japan, the formation of sustainable cities requires measures on various scales, including buildings, blocks, and districts and cities. To achieve the targets in the Kyoto Protocol is a particularly urgent task for mitigation of global warming. In the building field, approaches on the level of individual buildings are not enough and initiatives for area-wide energy utilization are required to make cities save more energy and emit less carbon dioxide (CO_2). Meanwhile, all cities share the agendum of improvement to heighten their safety, comfort, and resiliency to disasters, and increase their vitality.
Based on this background, this research considered steps that would enhance urban sustainability in the aspect of energy systems.

2. Major national policies and focused tasks

The promotion of "CO_2-saving urban design" was positioned as one of the key policy directions in the Kyoto Protocol Target Achievement Plan[1)], which was prepared in 2005. National policies[2), 3)] announced in 2007 set forth area-wide energy utilization and balanced linkage between decentralized combined heat and power (DCHP) systems and large central grid power networks. The New National Energy Strategy[4)] formulated in 2006 and the National Plan for the National Land Sustainability Plan[5)], on the other hand, emphasized the importance of efforts to heighten the sustainability of the life and business basis in cities. More specifically, they called for response to diversifying risks associated with accidents and natural disasters, and approaches to self-help, mutual aid, and public assistance measures to assure safety and security.
In light of these policies, this research focused on the energy supply, both in normal times and in emergencies, centered around extensive application of DCHP systems, and took up the following two tasks as subjects of priority action.

1) Promotion of initiatives in cities to mitigate global warming
   Promotion of area-wide energy utilization and load levelling on the block scale which is effective for saving energy and reducing CO_2 emissions
2) Contribution to the continuity of business and life functions in cities in emergencies such as disasters
   Promotion of the spread of power source equipment for use in both ordinary times and disasters, and multiplexing of power sources in order to prevent and mitigate disasters

The target energy system rests on the installation of certain city blocks with DCHP systems that would convert primary energy (in forms such as natural gas and natural energy) to heat and power (i.e., thermal energy) for utilization on an on-site, on-demand basis. Their operation in coordination with the large central energy supply networks would contribute to the formation of cities with a higher overall sustainability.

3. Feasibility study of DCHP systems

3.1 Concept for introduction of DCHP systems

This research included a feasibility study (FS) conducted for blocks where area-wide utilization of DCHP systems for the aforementioned reasons could be expect to induce significant effects. The purpose of the FS was to check those effects and ascertain tasks for actual installation. It was premised on system construction with technology currently available on the commercial level, and considered types of technology that could go into diffusion with proper policies for support to this end.
The main concept is described below.

1) Heat and power interchange within building blocks
The ability for interchange of electrical heat and power among buildings on the block level could be expected to assist load levelling, which is difficult to achieve through action in units of individual buildings, and improve load efficiency. It could also be anticipated to enable avoidance of low-efficiency partial-load operation of facilities and equipment and allow efficient operation even in the face of fluctuation in respects such as weather, times of building operation, and amount of natural energy supply.
2) Medium- and large-scale gas engines with a high generation efficiency
Central city blocks have a significant scale of energy demand, and this demand is usually characterized by a high proportion of electrical energy relative to thermal energy. In such cases, the installation of DCHP systems powered by engines fuelled with natural gas with a medium or high generation efficiency (some models have an efficiency of over 40 percent (HHV basis)) would enable high-efficiency operation at a favourable load.
The above mentioned concept is shown in Figure 1.

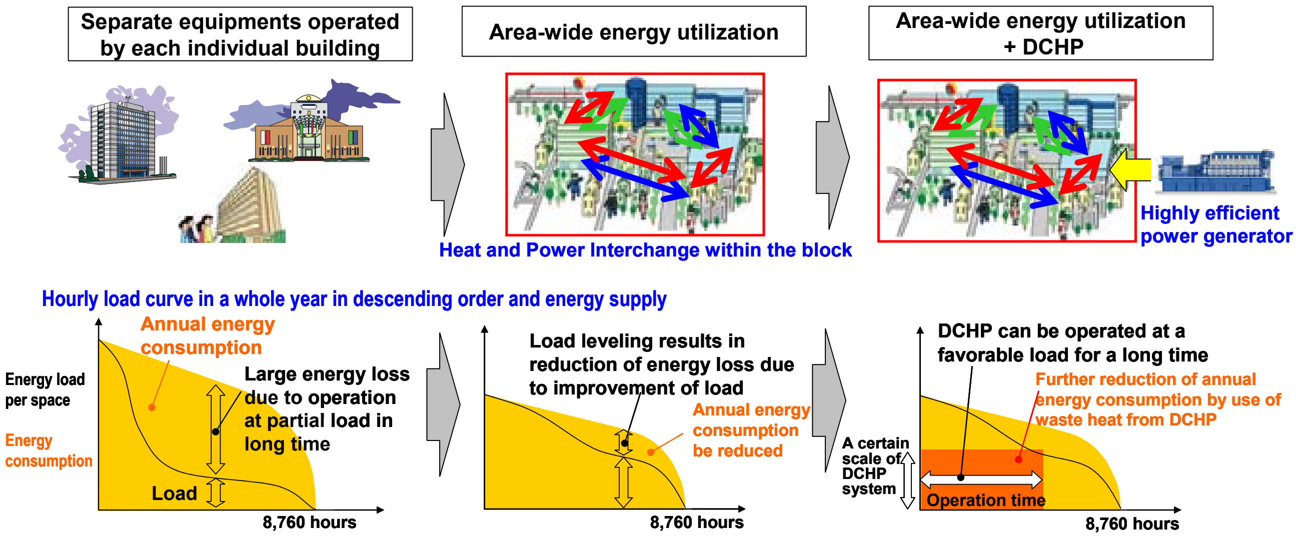

Fig.1 Image of area-wide energy utilization and with decentralized combined heat and power systems

3) Connection with the large central energy supply networks
The DCHP systems would be used to generate power in both normal times and emergencies. This would make it possible to have power sources fuelled with city gas (supplied by high-reliability medium-pressure networks) to back up the power supply, and thereby help to prevent and mitigate disasters on the block level. Figure 2 presents an image of this proposal.

3.2 Building blocks models in the FS

The FS took up a few actual city blocks which have a certain density of business/commercial buildings and apartment buildings. From the perspective of energy system planning, the blocks were classified with reference to differences in the following three aspects: 1) development status (new/existing), 2) presence/absence of district heating and cooling (DHC) facilities, and 3) character (business only/business-residential hybrid).

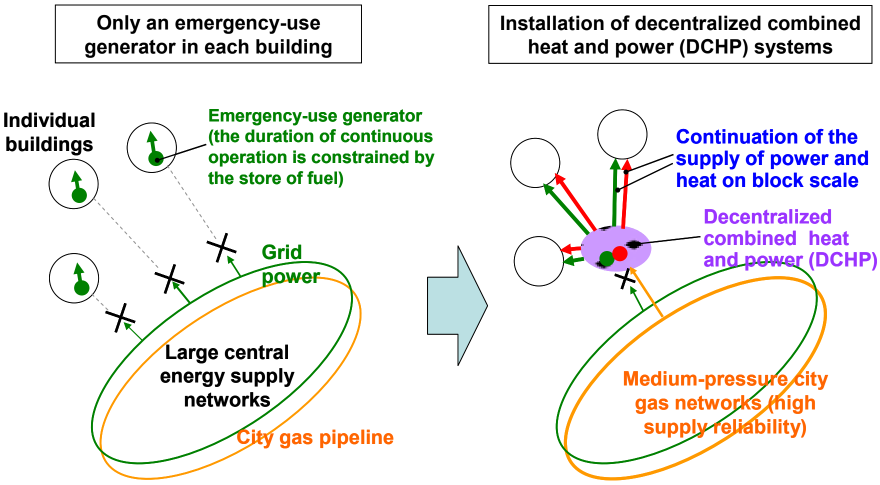

Fig.2 Image of power supply backup in emergencies

Of the blocks examined in the FS, this paper describes the findings for the three noted below. Table 1 shows the main data for each block, and Figure 3, models for area-wide energy utilization including our concept by extended use of DCHP systems in each block.

Table 1 Major data for the blocks in the FS (example)

Category	New	Existing	
	Block A	Block C	Block E
	New area-wide development	Interconnection of existing DHC systems	Connection of existing building
Block area	5.2ha	15.1ha	0.9ha
Total floor area	328,000 m^2 (4 buildings)	856,000 m^2 (15 buildings)	49,000 m^2 (4 buildings)
Block characteristics	Newly developed multiuse block with public facilities designated as evacuation shelters	Proximity of 2 zones served by DHC and 1 point heat supply (to hotels, office buildings, etc.)	Established urbanized district with a mixture of housing and business/commercial facilities
Heat load density	18,200 GJ/year･ha	36,000 GJ/year･ha	10,400 GJ/year･ha
Maximum power demand (at an emergency level of 2)	Normal times: 9,700 kW Emergencies: 2,743 kW	Normal times: 42,695kW Emergencies: 13,691kW	Normal times: 1,627kW Emergencies: 237kW
Energy system concept	Top runner model providing for a mix of uses with consideration for load leveling in the entire block, also taking into account use of natural and as yet unused energy	A model based on connection of the adjacent existing DHC systems with heat interchange pipes and a micro grid, for expanded area-wide utilization	A model for area-wide utilization based on heat interchange and a micro grid among adjacent buildings, upon rebuilding of residential facilities
Postulated case	A1 (Comparison standard) Grid power + single-building heat sources A2 Grid power + area-wide heat interchange A3 Decentralized energy systems + grid power + area-wide power and heat interchange (Decentralized energy system generation capacity: 1,840 - 9,700 kW in cases A3-1 - A3-3)	C2 (Comparison standard) Current systems C3 Decentralized energy system + grid power + area-wide interchange of heat (use within the DHC areas) C4 Decentralized energy system + grid power + area-wide interchange of power and heat (entire block) (Decentralized energy system generation capacity: 22,300 - 43,300 kW in cases C4-1 - C4-3)	E1 (Comparison standard) Current systems Grid power + single-building heat sources E3 Decentralized energy system + grid power + area-wide interchange of power and heat (Decentralized energy system generation capacity: 250 - 700 kW in cases E3-1 – E3-3)

Block A: New area-wide development

As an example of city blocks that are subjects of redevelopment plans, we selected a block anticipated to undergo integrated improvement that contains facilities also designated as evacuation shelters (a primary school and a sports center).

Block C: Interconnection of existing district heating and cooling (DHC) systems

This block contains some DHC facilities installed adjacent to each other, has one of the highest demand densities in central city, and lacks DCHP systems. It offers good prospects for remarkable improvement of energy performance around the building blocks as a whole.

Block E: Connection of existing buildings
This block is a mixture of business facilities and housing. It is smaller than blocks A and C, but is a typical case found in central city.

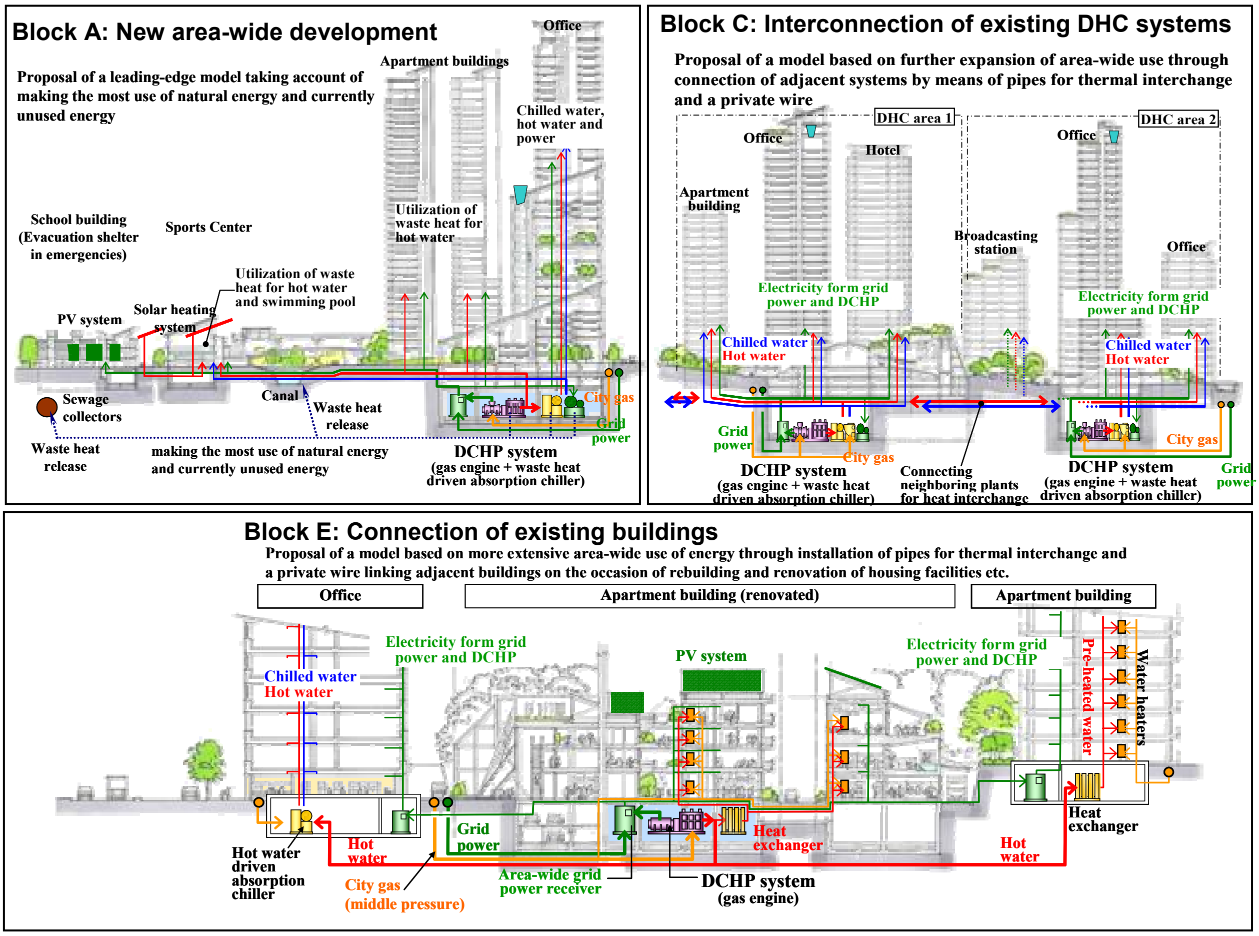

Fig.3 Characteristics of the model of building blocks and DCHP systems proposed in the FS

4. Feasibility study overviews

4.1 Assessment procedure

For the energy demand in each block, we assembled the prime units of demand and load fluctuation pattern in each category of use within each block based on the findings of preceding studies. This provided basis for the preparation of fluctuation patterns for the load demand in each time period on typical days (weekday/holiday) in each month for the block as a whole. This was followed in turn by appropriate selection of the division of capacity/number of units of DCHP systems and various heat source equipment in correspondence with these patterns, calculation of items related to the gas engine operation in each period (such as the amount of power generated, amount of waste heat utilization, amount of heat supplied by the various heat sources, and auxiliary equipment), and calculation of annual totals.
For each block, we postulated a baseline case of mutually separate heat sources in each building, and some cases of DCHP system capacity. These cases were studied to ascertain effects for energy conservation, CO_2 emission reduction, contribution to business and living continuity plan (BLCP; to be described below) for preparedness in emergencies, and benefit for cost.

4.2 Results of the energy conservation and CO_2 emission reduction

Figure 4 shows the effects for reduction of primary energy consumption and CO_2 emissions in each case studied. Basically, the calculations yielded energy-conserving effects of 10 - 20 percent and CO_2 emission reduction effects of 15 - 25 percent.
Key findings are that the effects for reducing energy consumption and CO_2 emissions rise with the capacity of the DCHP system and that the effects are also higher in blocks that are newly developed or otherwise offer a higher degree of design freedom (e.g., Block A) or have a larger subject area (Block C).

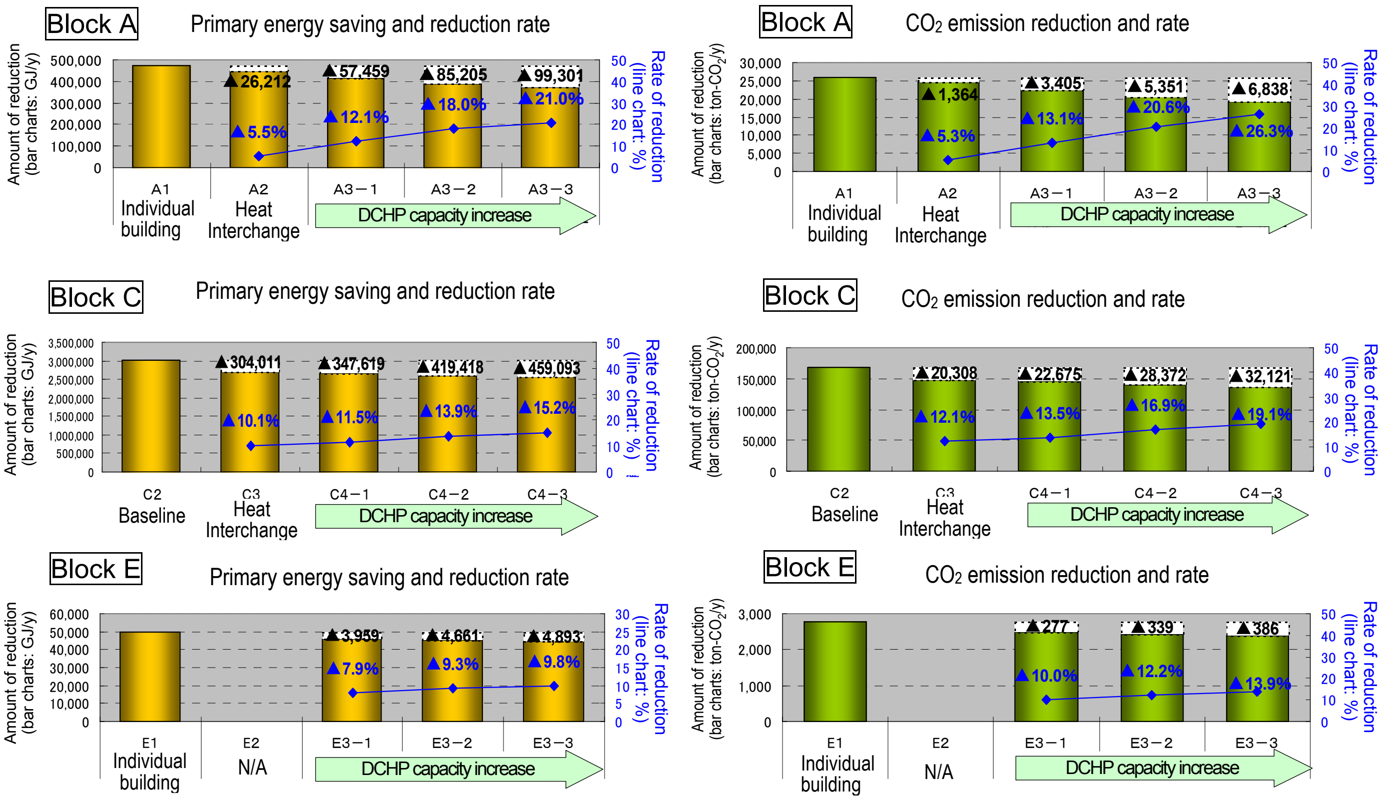

Fig.4 FS results - Rates of reduction of primary energy consumption and CO_2 emissions in each case

4.3 Assessment of energy related to BLCP contribution

Adding the element of consumer life to the well-known concept of business continuity plan (BCP), this research assessed the degree of contribution to business and living continuity plan (BLCP) in the energy aspect. BLCP was defined as the determination of systemic and environmental arrangements on the block level enabling the maintenance and prompt restoration of the minimum requisite business and life activity functions, in preparation for disasters and other emergencies.

Differences of disaster magnitude are reflected in differences in respect of the degree of lifeline damage and restoration and the functions sought on the demand side. We distinguished the following emergency levels based on the duration of energy (power) supply suspension, by referring to data from sources such as the tables of disaster statistics released by the Cabinet Office[6].

Level 1: Temporary suspension due to damage from wind/water, snow, human accidents, etc. (duration of suspension: in the range of a few hours to about 1 day)

Level 2: Long-term power outage due to earthquakes, etc. (duration of suspension: in the range of 1 day to several days)

First, we estimated the power demand required for each building in emergencies of each level. This was done by calculating the power capacity rate by application for each activity. For the power demand in emergencies, we tentatively set levels of power supply to buildings as a whole by dividing demand and totaling the amount for each component.

Next, a totalization was made for the requisite continuous energy demand in emergencies in the entire block. This was followed by a trial calculation of the extent of coverage of this demand by DCHP systems fuelled with medium-pressure city gas and capable of use in normal times as well as emergencies. This extent was taken as indicative of the emergency energy supply rate (degree of power self-sufficiency in the entire block), and was calculated as follows.

$$\textbf{[Power self-sufficiency]} = \frac{\textbf{[Continuous supply capacity in emergencies (in the entire block)]}}{\textbf{[Continuous power demand in emergencies (in the entire block)]}}$$

Figure 5 diagrams the situation in the event of a Level 2 emergency in Case A3.

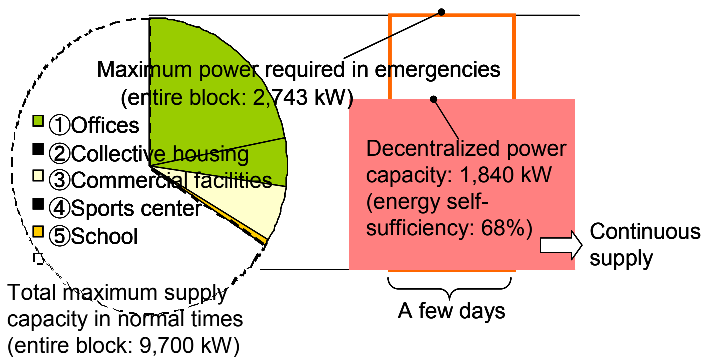

Fig.5 Example of power self-sufficiency in the entire block in emergencies

Calculation of the emergency energy supply rates in the representative cases in blocks A - E yielded rates of about 180 percent for Case A3-2, 200 percent for Case C4-3, and 105 percent for Case E3-1. In each of these cases, the system composition is an excellent one in terms of environmental performance and benefit-cost ratio (to be described below). This research confirmed that the proposed energy system concept with a power self-sufficiency rate of over 100 percent would make a vital contribution to BLCP as well.

4.4 Assessment of B/C taking account of diverse benefits

The FS found that the installation of DCHP systems on the block level could be expected to yield reduction effects for energy consumption and CO_2 emissions beyond those on the level of individual buildings. To promote such approaches, it is essential that the concerned parties in the block have sufficient economic motivation. This research consequently made an assessment of the benefit for cost (B/C) with a focus on non-energy benefits (NEBs).
According to documentation[8)], NEB is a collective term for various indirect benefits that are distinguished from the direct energy benefit (EB) of reduced utility costs and tend to be neglected in assessment of initiatives, such as the indirect economic benefits and environmental preservation benefits induced by the initiatives.
While it would be difficult at present to make a quantified assessment of all NEBs in an assessment of the effects of area-wide utilization of DCHP systems, the items of assessment in the limited scope that can be immediately examined are as follows.

1) Reduction of power, heat, and water costs (EB)
   The ability to avoid operation of various facilities and equipment at partial load and operate them on a long-term basis at favourable load would presumably increase the efficiency of energy utilization and lower these utility costs.
2) Reduction of facility management costs (EB)
   Conservation of labour due to the consolidation of facility management capabilities could be expected to lower the operation and maintenance costs for energy facilities and equipment in buildings.
3) Contribution to mitigation of global warming through CO_2 emission reduction (NEB)
   The reduction of CO_2 emissions accompanying energy conservation would contribute to efforts to mitigate global warming, which is an urgent international agendum. It would also engender an economic benefit due to emission reduction in the event of a future allocation of emission quotas in units of companies.
4) Contribution to BLCP in emergencies (NEB)
   The installation of DCHP systems would lead to the formation of highly reliable systems supported by back-up power sources and other elements. As such, it would contribute to enhance BLCP in emergencies such as storm and earthquake disasters, and consequently alleviate the economic loss.

The following equation was applied in assessment of B/C. Here, C refers to the sum of the initial and running costs.

Benefit-cost ratio (B/C) = (EB + NEB) / C

When the ratio exceeds 1, its size may very well determine the degree of priority for adoption. The following are the assumptions applied in the B/C calculation.
- Service life of facilities and equipment: 15 years
- Service life of heat interchange pipes: 45 years
- Discount rate: application of a rate of 4 percent, which is generally applied in society as a whole
- Applied period of B/C calculation: calculated in 5 years, 10 years, 15 years and 45 years respectively

- Market price per ton of CO_2 emission reduction: 2,000 yen/t-CO_2
- Probability of occurrence of emergencies in Tokyo (levels 1 and 2)
  Level 1 (Temporary suspension due to damage from wind/water, snow, human accidents, etc.)
  Division of the total number of lighting and power customers by the average number of households that experienced outages due to damage from wind/water or snow over the three-year period beginning in 2004 based on data from sources including the disaster information tables of the Cabinet Office [6] yielded an occurrence probability of 0.057.
  Level 2: (Long-term power outage due to earthquakes, etc.)
  Corresponding calculation based on data from sources including Source [9] yielded a probability of once every 115 years (= 0.0087).
- Outage cost: based on the source[7] documented data The saving from avoidance of this cost was added to the NEB quantification.
- Other initial and running costs were set on appropriate levels based on various design cases.

Figure 6 shows the example results of the B/C calculation for Block A, A3 cases as an example of trial calculation. It is thought that area-wide utilization of DCHP systems would increase the benefit and afford a B/C significantly higher than 1. While the aforementioned effect for reducing energy consumption and CO_2 emissions rises along with the capacity of the DCHP system, there is a trade-off with B/C, which may peak at a certain level of capacity.

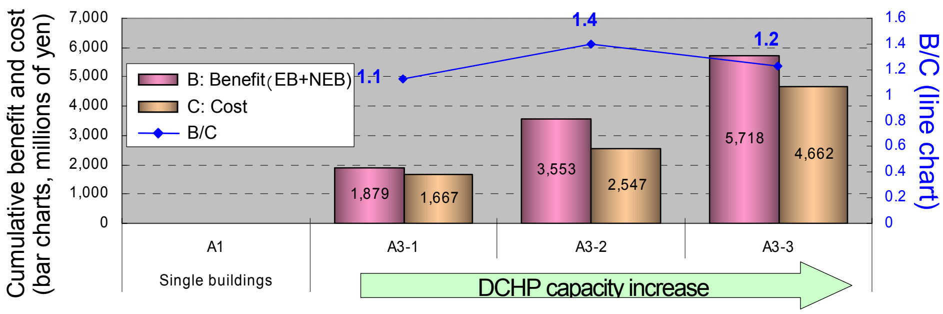

Fig.6 Example of FS assessment of benefit-cost ratio (A3 cases)

5. Policy proposals to promote initiatives for area-wide energy utilization

5.1 Business structure and role of stakeholders

Area-wide energy utilization as described in this paper cannot be achieved without proper plan and operation of projects on a foundation of cooperation by the stakeholders in the block. We therefore examined incentives for the stakeholders based on actual recent projects which are regarded as successful cases, and on the knowledge of persons with experience in promoting such projects.

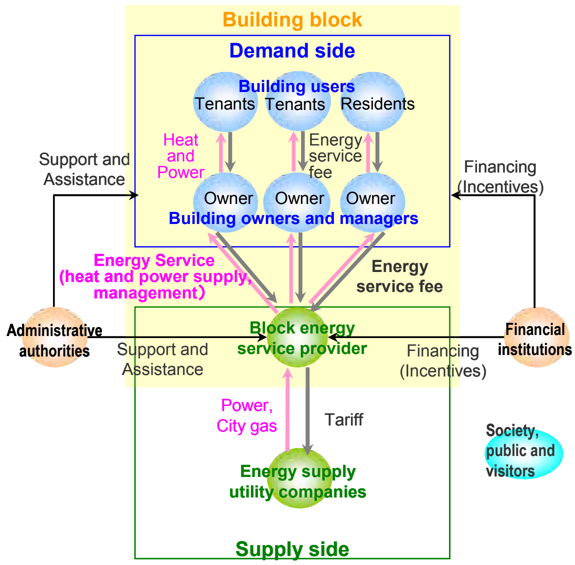

Fig.7 Conceptual diagram of stakeholders and roles in area-wide energy utilization

Table 2 Example of EB and NEB

Benefit / Stake-holders	Energy Benefit	Non Energy Benefit (Example)		
		Effect on global environment	Risk reduction against disease	Others
Demand side	• Reduction of heating and lighting expenses	• CO2 emissions reduction	• contribution to BLCP* in emergencies	• additional rentable space • improvement of landscape
Supply side	• reduction of supply cost • improvement of service standards		• adding options of energy supply in emergencies	• load leveling • flexible utilization of natural energy
Government and society		• contribution to deal with global warming	• realization of town well prepared for emergencies	• motivation of people by showing advanced model

(*BLCP: Business and Living Continuity Plan)

Figure 7 presents a conceptual diagram of the roles of stakeholders in the context of such cooperation. Besides the energy utility companies (i.e. electric power and city gas companies), we assume a block energy service providers (ESPs) supplying power and thermal energy within the building block.
Table 2 shows sample results of a tentative identification and classification of EB and NEB to encourage each stakeholder. In addition to disaster prevention and mitigation, the NEB presumably includes an increase in the efficiency and sophistication of energy system management, and reduction of project risks due to commitments by the national government and other authorities. Other NEBs should be considered further in the future study.

5.2 Proposal of policies for support

Based on the results, it formulated the following proposals to be considered for designing policy in five aspects to assist the resolution of these problems and rooting of the business model in the market.

1) Mechanism for consensus-building: offer of incentives to stakeholders (building owners, tenants, residents, etc.), assessment of the applicability of DCHP systems, and establishment of verification technology
2) Deregulation and regulatory modification: incentives such as deregulations on cubage rates for initiatives that greatly conserve energy and reduce CO_2 emissions on the block level
3) Provisions for support (project certification/administrative support): support to promote active use of the existing urban infrastructures (underground pedestrian passageways, subways, etc.) for installation of pipes for heat interchange, etc.
4) Provisions for financial assistance: assistance with enterprise investments, support for reduction of risks, and assistance beginning with the stage of studies of area-wide energy utilization.
5) Guidelines: formulation of guidelines for urban improvement to encourage application of DCHP systems

6. Conclusion

This paper proposes policy measures to promote area-wide energy utilization by extended use of DCHP systems on the block level with a view to mitigating global warming. Through FS for some cases, it is confirmed that such utilization would have effects for conserving energy and reducing CO_2 emissions which could not be induced by mutually separate systems on the level of individual buildings.
It was also shown that the proposed DCHP systems would contribute to business and life continuity plan (BLCP) for emergencies by investigating the degree of energy self-sufficiency. In addition, to design the policy measures, it suggested the importance of taking account of such non-energy benefits (NEBs), and indicated the possibilities for a further increase in benefit-cost ratio (B/C).

Acknowledgment

This paper represents a part of the activities of the Sustainable Town Study Committee (chaired by Shuzo Murakami), whose secretariat is the Institute for Building Environment and Energy Conservation (IBEC). The authors would like to acknowledge their indebtedness to all concerned for their assistance with its preparation.

TITLE: MEETING THE ENERGY CHALLENGE OF CITIES: FINDING SOLUTIONS THROUGH DISTRICT ENERGY AND GREEN BUILDING

Brent GILMOUR M.Sc.Pl.[1]
John WARREN P.Eng. [2]

[1] Project Manager, Education and Research Division, Canadian Urban Institute, Toronto, Canada, bgilmour@canurb.com
[2] Senior Associate, Canadian Urban Institute, Toronto, Canada, jwarren@canurb.com

Keywords: district energy, high performance building, sustainable development

Summary

In response to increases in the cost of fuel and concerns over greenhouse gas emissions, there is renewed interest across Canada for the potential to integrate district energy and high performance (green) buildings to achieve a transition to a more healthy, balanced and sustainable way of building communities. To illustrate how district energy can contribute to emission reduction targets, as well as achieve community economic growth and land-use objectives, nine best practices in Canada were assessed for their capacity to achieve sustainable urbanization objectives. The review included an assessment of how district energy systems could be effectively integrated with high performance building. For communities to capture the mutual advantages and goals of district energy and high performance building, three key steps were identified including assessing sustainability at the community level, use of integrated energy planning and working to ensure local building rating systems account for the efficiencies provided by district energy.

1. Introduction

As world demand for fossil fuel increases and as energy supplies become harder to access, the price of energy is expected to rise. It is also anticipated that jurisdictions without a secure and steady supply of indigenous energy sources will be vulnerable to unpredictable energy markets. The implication for local governments and businesses is that inexpensive energy for use in heating, cooling, industrial processes, transportation and electricity generation will be at a premium. To help cities maintain a high quality of life for residents and an attractive investment environment for business, changes will be required to how we heat, cool and power buildings and communities. In Canada, there is renewed interest in the application of district energy by all levels of government and the development community to address rising energy costs, meet increasing energy supply demands, encourage the use of local alternative and renewable fuels, and lower greenhouse gas and other air emissions.

To assist communities with addressing their energy supply and infrastructure challenges, the Canadian Urban Institute, Canadian District Energy Association, and the Toronto Atmospheric Fund formed the Urban Energy Solutions (UES) infrastructure research partnership. The UES initiative set out to identify the challenges to the advancement of district energy across Canada, and demonstrate how district energy could contribute to local community infrastructure and energy conservation in urban regions.

This paper examines how applications of district energy studied during the UES initiative are contributing to community sustainable development by highlighting several best practices in Canada. The paper also outlines how district energy can be incorporated with high performance (green) building development to achieve improved energy efficiency. It concludes with a set of steps that can be used to assess the contribution of district energy and high performance building for achieving sustainable development objectives.

1.1. Managing Energy in Cities and the Role of District Energy

Cities represent less than one percent of the earth's total surface; however, urban activities around the world generate close to 80 percent of all carbon dioxide (CO_2) emissions, and use nearly 75 percent of all energy produced (United Nations Environment Program and United Nations Habitat, 2005). More than three-quarters of Canadians currently live in cities, and it is estimated that by 2020 that number will increase to 85 percent or more (Canadian Urban Institute, 2008). The current 80:20 ratio is the exact opposite of the urban-rural split a century ago. Although a significant portion of energy consumed and greenhouse gases (GHGs) emitted in cities is due to transportation, the built environment accounts for almost 30 percent of all energy consumed in Canada (Government of Canada, 2006) and nearly 30 percent of all GHGs emitted (Canada Green Building Council, 2006).

In response to the continuing growth of cities, many communities are attempting to incorporate sustainable urbanization practices such as creating land uses that support higher density populations, encouraging localized energy generation and distribution, enhancing local ecosystem integrity, minimizing air and water pollution, encouraging the use of public transportation, improving energy efficiency in the built environment and industry practices, as well as use better community energy management strategies, such as district energy (Williams, 2004).

District energy systems work to manage the energy needs of a community at the building level. By linking buildings and industrial activities together, district energy systems can aggregate the varying energy requirements into a steady heat load that can be effectively managed (Church, 2007). A typical district energy system includes one or more individual plants that use one or more types of fuels and can incorporate a combination of different heat sources and technologies (Gilmour, 2008a).

In Canada, modeling for the UES initiative identified that if every building were connected to a natural gas-fired district energy system that used combined heat and power technology, nearly 57 million tonnes of $C0_2$ emissions (almost 10 percent of Canada's $C0_2$ emissions) could be reduced, and nearly 897 million GJ of energy (11 percent of Canada's total energy consumption) saved every year (Gilmour, 2008a). These reductions arise not only from increased efficiency of combined heat and power systems compared with centralized generation, but include energy savings from avoided losses associated with transmission of electricity over long distances.

2. Achieving Sustainable Development – District Energy Best Practices

To identify the key attributes of a district energy system that contribute to community sustainable development objectives, a scan was conducted of nine district energy systems operating in Canada. The scan involved the review of each system to assess the contribution to community sustainable development with a specific focus on: intensification, re-urbanization, community economic development and sustainable energy planning. These categories were selected based on a review of relevant literature on sustainable urbanization and to test common claims made about the community social, environmental and economic benefits of district energy (Moffatt 2001; Newman 1999; Pivo, 1996; Seasons, 2004).

For seven of the district energy sites, an independent modeling analysis was conducted during the UES initiative to identify the potential reduction of GHGs and energy relative to local conventional operating practices. During the analysis, it was noted that there were regional variations in energy intensity and mixes of conventional fuels used in Canada that can have a direct impact on the GHGs and energy efficiency comparisons. These factors were incorporated into the modeling. Table 1 provides a breakdown of the systems in terms of location, system size, energy technology used, primary fuel source and the type of sustainable contribution made to each community.

2.1. Identified Contribution of District Energy

During the review process, it was observed that district energy systems had the capacity to lower GHGs, reduce energy consumption for a community and displace the use of fossil fuels. It was also noted that district energy systems could enhance local economies, contribute to the creation of compact urban communities and help revitalize urban centres through infrastructure investment and by creating an attractive development opportunity. Several of the district energy systems studied are explored in more detail in this section for their contribution to community sustainable development.

Table 1 Profiled Canadian District Energy Systems

Location	Facility	System Size	Energy Technology Used	Primary Fuel Source	Greenhouse Gas Avoided tonnes/year	Energy Use Reduced GJ/year	Contribution of DE
Halifax, Nova Scotia	Purdy's Wharf	1,250 tons cooling	Titanium plate heat exchangers; Electrically driven centrifugal chillers	Sea Water Cooling	2,000	9,720	Community Economic Development
Charlottetown, P.E.I.	PEI District Energy System	51MW	High efficiency boilers; Back pressure boilers	41% municipal solid waste; 42% sawmill residue; 17% oil	4,883	1,749	Sustainable Energy Planning
Becancour, Quebec	Becanouver, TransCanada Energy	550MW	Combustion Turbines	Natural Gas	--	--	Community Economic Development
Markham, Ontario	Markham District Energy Inc.	12 MWt 3.5 MW electricity 4600 tonnes	High efficiency boilers; Centrifugal Chillers; Spark-ignited engine; Reciprocating Engine	Natural Gas	4,893	88,902	Intensification
Toronto, Ontario	Enwave Energy Corporation	75,000 tons cooling	Cold-energy transfer loop	Deep Lake Water	13,348	355,573	Sustainable Energy Planning
Hamilton, Ontario	Hamilton Community Energy	12.5MWt and 3.6 MW electricity	High efficiency boilers and Reciprocating Engine	Natural Gas	4,403	45,431	Intensification
Okotoks, Alberta	Drake Solar Landing Community	1.5 MW	Thermal solar panels, gas furnaces, borehole storage	Solar Radiation and Natural Gas	152	3,0444	Sustainable Energy Planning
North Vancouver, British Columbia	Lonsdale Energy Corporation	6 MW	Condensing high efficiency boilers	Natural Gas	3,713	44,797	Re-Urbanization
Revelstoke, British Columbia	Revelstoke Community Energy Project	1.5 MW	Biomass burner and backup propane	85% wood waste; 15% propane	--	--	Community Economic Development

2.1.1. Intensification

The movement towards intensification within developed areas and on green field sites (virgin areas of land) is a trend of growing importance. Between 2002 and 2007, Canada had over 1.3 million new housing starts across the country (Gilmour, 2008b). The majority of this new development commenced on tracts of land outside cities. This pattern of growth is placing additional stresses on communities by consuming more land than does compact development, using more energy, increasing transportation needs and increasing infrastructure costs for various services including public transit. To address these growth challenges, communities are striving to encourage intensification through mixed-use development. Mixed-use development – the concentration of land uses and built form such as residential, commercial, industrial, office, and institutional – is an established approach for creating urban environments where people can live, work, and meet everyday lifestyle needs.

The Markham District Energy Inc system illustrates how district energy can contribute to creating more compact urban environments that support mixed-use development. Since the late 1990s, Markham, Ontario has added over 110,000 people to its community. Although the Town has developed quickly, it adopted a planning vision based on the principles of New Urbanism of compact and land-efficient urban form, higher density development, a wide range and mix of land uses, a pedestrian friendly and connected grid pattern of streets and high quality urban design. Although Markham was recognized for its innovative planning approach, the Town identified that while planning objectives where being met the impact of new development in terms of GHGs and energy reduction was not being adequately dealt with.

For the Town's largest development project, Markham Town Centre, emphasis was placed on creating a complete, self-contained community with minimal impact on the environment. In addition to setting high standards for promoting mixed-land use and encouraging design that reduced dependency on the automobile, the Town also set a goal to lower energy consumption by 20-30 percent. Early into the development process, the Town identified district energy as an important component for achieving expected energy reduction and land use development objectives in the Town Centre. For Markham, district energy provided the capacity to promote compact, mixed-use development by concentrating development through piped infrastructure, while ensuring that all of the heating and cooling requirements for new development could be met. The Town also worked with the local development community to ensure new buildings connecting to the district energy system incorporated advanced high performance building standards to further lower the level of energy consumed in the community and improve the overall efficiency of new buildings.

2.1.2. Re-urbanization

Private sector investors have avoided investment in brownfield sites (former industrial or otherwise potentially contaminated lands) where real or perceived issues of environmental concern exist. The challenge for communities is to improve sites to a state where investors find them attractive to develop. Traditional strategies have included investment in infrastructure, such as the development of stacked parking facilities, various financial incentives such as tax breaks and loans, and creating innovative partnerships that mitigate risk for the private sector.

An example of the capacity for district energy systems to be part of a regeneration and economic development program for industrial lands is the Lonsdale Energy Corporation district energy system. In the City of North Vancouver, British Columbia, Lower Lonsdale was characterized by vacant or under-used lands that created a discontinuous space in the centre of a busy urban area. In the early 1990s, the City launched a planning process to redevelop the municipally owned waterfront and urban area. The initiative called for the establishment of higher-density, mixed use development that could contribute to the development of a vibrant downtown and lead to job creation. Local officials for the City, who participated in an energy study tour to Europe, recognized district energy as a promising opportunity to help achieve municipal objectives for the reduction in GHGs, as well as provide an important incentive to developers and potential employers to purchase and invest in the waterfront lands.

For the City of North Vancouver, district energy offered an additional level of investment incentive for developers and investors by reducing the need for capital investments in building heating and cooling systems, lowering building costs associated with operation and maintenance, and improved returns by removing space needed for mechanical systems and allowing the area to be used for more efficient revenue generation.

2.1.3. Community economic development

Across Canada, communities have experienced the impacts of national and global economic change. In some cases, communities have adjusted to the potential for little or no growth in terms of population and investment, while others have experienced a reduction in employment opportunities from the introduction of productivity technologies. Canadian communities that have adjusted well to economic change, largely as a result of finding the right balance of infrastructure investment, human resources, creative talent, and location advantage (i.e. proximity to markets), are continuing to receive higher levels of population settlement and economic growth. However, the impact of economic change has been widely uneven among Canadian communities, with some having to adopt and contend with a variety of challenges that can negatively impact economic viability and the quality of life of a community.

The opportunity for district energy to be incorporated as part of a strategy for community economic advancement and retention is illustrated by the Revelstoke Community Energy Corporation. In the late 1990s, the Town of Revelstoke in British Columbia was faced with several significant and interconnected economic challenges including the potential closing of the Town's sawmill, a major employer and supporter of many local industries, and the continuing decline of the population. As a result of a change in regulations concerning the burning of wood residues, sawmill operators across the province of British Columbia where faced with the potential of having to use alternative heating methods to dry wood for processing or relocate operations closer to advanced wood residue processing operations. With over 25 percent of the local economy supported by the forest industry in Revelstoke, the threat of a move, closure or reduction in operational size of the mill had the potential to severely impact the Town's economic vibrancy and health.

For the Town of Revelstoke, maintaining the presence and economic integrity of the sawmill became a priority and resulted in the formation of a public/private partnership between the Town and the owners of the sawmill to develop and operate a renewable fuelled (wood biomass) district energy system. The district energy system served to meet the economic needs of the sawmill operator by providing a needed and affordable heat source to operate wood drying kilns and supply the Town with a largely free source of heat for local businesses, institutions and municipal operations, including schools and a community centre. For the Town, district energy offered the economic benefit of reduced operating costs for local businesses and contributed to securing the long-term operation of the sawmill. The district energy system also provided the Town with the added benefit of reducing reliance on the truck delivery of propane as the main source of heat fuel.

2.1.4. Sustainable energy planning

Across Canada, communities have traditionally given minimal consideration to the role of energy in terms of supply and use. However, as the price of fuel rises, the demand for energy grows and the potential for power outages due to severe weather become more frequent, there is renewed interest in assessing the opportunities to minimize energy waste, reduce reliance on centralized grid generation, increase local energy supply security and apply advanced land use development practices that reduce energy consumption. Today, long-term planning for municipal growth and economic vitality is requiring an approach that looks beyond traditional areas of concern. For municipalities, planning for population growth no longer just includes potential increases in revenue from property taxes or the requirement to adjust development charges to cover investments in new infrastructure. It also requires an understanding of how a community can plan to reduce GHGs and energy use, ensure the secure supply of energy, and substitute fossil fuels with alternative and renewable sources of fuel.

The Drake Solar Landing Community in Okotoks, Alberta provides an innovative example of how sustainable energy planning can be incorporated into the design, development and operation of communities. In the late 1990s, Okotoks was the first community in North America to establish growth targets in a master plan based on the local carrying capacity of the watershed to treat and dispose of effluent. As part of the plan, a sustainability vision was developed that outlined the objectives for development in the Town, including energy use in the community. Additional sustainable design objectives where also set including reducing reliance on the centralized electricity grid system and encouraging the use of localized solar energy production.

To help advance the plan, a partnership was established between the Town, a local land developer and the federal government of Canada to develop a solar power district energy network for a new residential subdivision in the Town. By developing all of the homes connected to the district energy network based on Canada's highest standard for energy efficient homes (R-2000), nearly 90 percent of all space heating needs for the homes are now met by solar energy. The district energy system has also contributed to allowing each home to reduce its GHGs by nearly 6 tonnes and energy consumption by 110 GJ per year. For the Town of Okotoks, the use of the district energy network contributed to enhancing the overall sustainability of the community by reducing energy costs, lowering the reliance on fossil fuels and mitigating the overall environmental impacts associated with new construction.

3. Compatibility of District Energy and High Performance Building

In less than a decade, high performance "green" building has become synonymous across Canada with achieving sustainable development principles and having a measured impact on greenhouse gas reduction. As a result of the increase in general awareness and importance of incorporating high performance design and development standards into buildings, there is a need to better understand the compatibility of district energy systems with high performance designed buildings. This section reviews the suggestions and experiences of operators across Canada, provided during the UES initiative, with high performance buildings and district energy systems.

3.1. Applying Integrated Design

Traditionally, energy planning for communities has resulted in keeping the optimization of district energy systems and improved environmental performance for buildings separate. Today, there is an increasing understanding that to ensure the successful integration of district energy systems to achieve the highest efficiency levels possible requires that design engineering teams for a high performance building be encouraged to also consider the performance metrics of a district energy system from day one of a project and evaluate the performance of proposed buildings and energy supply systems as a single integrated system with the goal of minimizing energy use and emissions production from that integrated system. Keeping informed on the latest advancement in the application of district energy can be a challenge. Design teams not familiar with district energy might apply "conventional rules of thumb" when evaluating efficiencies of various systems that do not account for currents costs or performance considerations.

In order to achieve the benefits of a high performance building and to ensure that known attributes are applied, district energy design teams need to work closely with owners' or developers' design engineers during the construction of a high performance building to avoid multiple iterations of design concepts. An integrated design process sometimes involves redesigning various distribution systems and reviewing the building envelope design to achieve consistent thermal loads/balances. This close interaction of the design teams can lead to improved system efficiencies, as well as a better environmental building design while reducing the overall design effort and cost.

3.2. Moving Beyond the Building Envelope

Most of the building rating systems applied in Canada are designed to achieve improved building envelope performance, reduce overall energy consumption in a building and ensure that in-building heating, cooling and circulation systems have a high level of operational efficiency. Generally, the building rating community in Canada has been concerned that rewarding the energy supply savings from a district energy system could compromise progress on the level and extent of energy-efficiency measures incorporated into a building. Great strides have been made in building energy efficiency design and implementation. The concern that a systems approach to building energy emissions might blunt progress in building design improvements is legitimate.

The achievement of equivalent reductions in emissions through the use of district energy generally has not been recognized as equivalent to improvements in the building envelope in most building rating systems, which often focus on building envelope energy cost savings rather than system emission reductions. However, there is growing consensus within the U.S. and Canada that energy efficiency evaluations should put less emphasis on cost savings and more emphasis on reducing the environmental impact of a specific building, especially in terms of GHGs and other air pollutants.

In order to achieve the most economic method for minimizing energy use in a building, the efficiency of energy supply as well as the efficiency of the building envelope needs to be considered equally and consistently. Carrying out such an assessment on an objective basis can result in the cost effective method for achieving green building performance and the lowest life cycle costs. This process should be carried out in a manner that continues to encourage improved building envelope design so that the total potential reduction in energy use, GHGs and other air emissions can be captured.

4. Transferring Lessons From Canada: Steps For Advancing District Energy and High Performance Building

Although there are many successful district energy systems across Canada in operation, municipalities and businesses continue to experience challenges to using district energy to achieve sustainable development and energy efficiency. Overcoming challenges to the wider application of district energy can require innovative approaches to determine community interest in sustainability, the use of advanced planning practices and encouraging broad community support from the green building community. Suggestions for how district energy and high performance buildings can be better integrated to achieve sustainable community development objectives are discussed below.

4.1. Assess Sustainability at the Community Level

Among the key determinants for assessing the potential for district energy and high performance development to be successful in any community is the importance placed on reducing GHGs and energy consumption. Municipalities across Canada are responding to the impact of climate change by developing comprehensive action plans that provide clear targets for GHG and energy reductions through the environment, while other communities are enacting new guidelines and legislation that encourage decentralized energy production. Municipalities that have identified energy as part of their long-range planning or a central objective of managed community growth are likely to be more receptive to the potential application of district energy and high performance building development. Influential leadership from the public and private sector can also improve the potential for a community to consider district energy and high performance building for meeting sustainable development goals. Key considerations:

- When an Official Plan or equivalent municipal statement references energy or GHGs reduction, this can contribute to broader community awareness and can encourage policy decision makers to explore how district energy and high performance building can be used to meet sustainable development objectives.
- Official Plans should also address energy supply security and overall sustainability issues for the community. These issues are integral to community long-term well being, but are often given less

prominence than the achievement of shorter term goals such as economic growth and job creation. Awareness of the need to truly include these concepts in Canadian municipal planning is increasing.

4.2. Use Integrated Energy Planning

To help achieve a high level of energy performance in buildings, building design teams now use an integrated design approach (IDP). IDP provides the ability to ensure that all aspects of a project are assessed at the concept stage and decisions are made throughout the design and implementation process that support sustainable design. A similar process is also being applied to communities in the form of integrated energy planning. This process can allow a community to identify how district energy can serve as an energy broker to collect, generate and distribute energy in an efficient and economical manner. Integrated energy planning can enable communities to meet energy demands by examining opportunities to lower energy use across an entire community, improve the energy efficiency and operating performance of buildings, capture excess energy from industrial process, and determine how district energy can contribute to sustainable development.

When applying an integrated approach to the planning and development of district energy, consideration should be given to developing a catalogue of thermal resources – types of alternative, renewable, fossil and waste heat fuels used in a community – for heating, cooling and electricity needs. The use of an inventory can allow a community to better assess the potential applications and location for a district energy system. For instance, municipal services can provide sources of heating such as heat from sanitary wastewater and cooling from naturally extracted cold drinking water sources that can be used in a district energy system. Key considerations:

- Understand the role, types and distribution of energy within a community and assess how to accommodate growth in the built environment that would not dramatically increase energy consumption;
- Encourage compact urban form and mixed land uses (such as commercial, institutional, office and residential) that support district energy;
- Use regulation, such as zoning controls to create energy zones that encourage building developers and owners to use high performance building standards, meet energy efficiency targets and consider the use of a district energy system to meet heating and cooling requirements;
- Consider the opportunity to require that terms of reference for land use planning studies and infrastructure development (i.e. new waste treatment facility or new sewer systems) assess the inclusion of district energy applications with high performance building; and,
- Encourage municipal officials to document and provide access to energy data that can be used to forecast heating and cooling demands. This information can be used to make a more accurate assessment of energy requirements for new development and assist developers of high performance buildings and district energy facilities to better assess the integration of thermal systems.

4.3. Build Partnerships and Work with the “Green” Building Community

Many of the challenges experienced while initiating a district energy system or a high performance building result from a lack of public and industry awareness concerning the ability of district energy and high performance building to meet the energy and sustainable development objectives of communities. Developing partnerships with local building organizations, various levels of government, utilities and non-government agencies to assist with funding and implementation is important for creating a local community that is accepting and capable of implementing district energy and high performance building. Partnerships between various organizations, whether public or private, can contribute to overcoming knowledge gaps and assist directly with the implementation of strategies to develop and deliver education programs and implementation tools. Key considerations:

- Explore the opportunity to use public private partnerships. Private sector partners can bring needed expertise and, in many cases, provide “turnkey” services to the design, build and operation of a project. In these arrangements, the community may become a financial stakeholder in the project or simply the purchaser of services provided. This can allow for the challenges for integrating district energy and high performance building to be assessed early on in the design stages and financial risk lowered by the municipality through activities such as providing access to public right of ways, securing commitment for connections and encouraging density of built form.

- Work with local building rating assessment systems to integrate a process for evaluating green features, such as district energy systems that use alternative and renewable fuels, which can contribute to reducing the environmental impact at the community level and at the building site level. The development of a transparent process that reflects the full life-cycle cost benefits and energy enhancement capabilities of district energy can contribute to improving the overall design and energy efficiency a new building and lead to the reduced dependence on non-renewable fuel sources.

5. Conclusion

Across Canada, district energy systems are providing the heating, cooling and electricity requirements needed to meet the growing energy demands of cities and businesses. At the same time, high performance building development is helping communities to reduce overall energy consumption. When integrated with sound community planning and modern urban design strategies, district energy and high performance buildings can assist communities to use less energy, keep energy dollars local, address energy security and resiliency concerns, contribute to brownfield remediation and, overall, allow communities to achieve their sustainability development objectives.

The use of integrated energy planning to connect district energy and high performance buildings may also be one of the greatest and most economically attractive opportunities available for reducing energy use and emissions on a local, regional and national basis. To fully recognize this opportunity, there remains a need for the building and district energy industries to work together to ensure that policy makers provide the appropriate incentives and regulations to maximize the uptake of improved energy efficiency building design, as well as improved building energy supply efficiency.

ABSTRACT: A vertical planting system is equipment that wraps up the peripheral of Archilife Symbiosphere 1 Center. Plants may play an important role in buffering the disaster induced by drastic climate change. The records of sampling survey of container indicate that average fresh weight of plants on each container is 801g, and the average dry weight of plants on each container is 82g. The TOC-5000A in the experiment is adopted to sense the carbon storage content in plants on VPS. The average of carbon content is 41% which depends on the different kinds of plants. The carbon content of the medium on VPS ranging is higher than uncultivated medium. Through the calculation with photosynthesis formula, the AS1C is compared with the buildings without any plants absorbed more 1024 kg of CO_2.

KEYWORDS: Sustainable building, Vertical Planting System (VPS), Archilife Symbiosphere 1 Center (AS1C), Plants, Carbon Dioxide (CO_2), Climate Change.

1. INTRODUCTION

A vertical planting system (VPS) adhering to the experimental has been designed to evaluate the feasibility of food production and additional ecological benefits to the inhabitants of the sustainable building (figure 1) [2], [6]. VPS forms a small nature symbiotic ecosystem [2], [6]. Base on the changes of CO_2 and temperature of the earth in foregoing 400,000 years [5], the period climate change was around 100,000 years. We are going to experience the change of next period, which follows by violent change of climate. The diversity of dry regions displayed the greatest increase in diversity due to increased CO_2 [4]. Plants may play an important role in buffering the disaster induced by drastic climate change [1], [3]. And, the major source of energy on the earth is the radiation of the sun. As the life of humankind is heterotrophy, they are necessary to choose symbiotic species. Consequently, humanity can choose solar-energy-transformable plants as symbiosis species.

Figure 1. A VPS was introducing ecology into Sustainable buildings.

2. MATERIALS AND METHODS

Plants material

Taiwan is rich in its indigenous flora. Some 564 species have been found within an area of a radius of 500 meters around the AS1C. Among these species, 124 are edible. We were collected and propagated either reproductively or vegetatively on the VPS in the AS1C [2], [6]. After three year, a great part of the plantings showed good symbiotic effects. We were collected Samples (figure 2) from the VPS in the AS1C. We were collected 38 kinds of plants (Sep, 2006~Jan, 2007) [6].

Figure 2. There were much symbiotic plants on the VPS in AS1C.

Preparation of samples

The VPS comprises 17 planting towers, each again comprises 80 containers. Each container is 94cm in length, 23cm in width and 24cm in height for plants growing. There were 1,360 containers in the AS1C [2], [6]. As the planting by sampling 1 from 100 says, which harvested chose 15 containers continually. The first step in the procedure for preparation of plants was cutting each part separately. After drying 70°C over 72 hours, samples milled 10~30 seconds at room temperature, and then stored at 70°C for further analysis [6]

Figure 3. The simple procedure for preparation of plants as show in the pictures.

TOC5000A analysis carbon storage content

The TOC5000A (total organic carbon analyzer) in the experiment is adopted to sense the carbon content of the plants on the vertical planting tower. The first procedure for analysis carbon content was warming-up 30~45mins (Figure 4**)**.

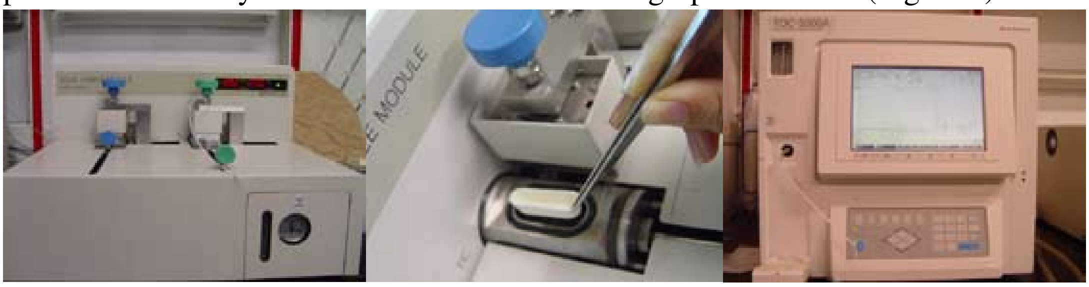

Figure 4. The simple procedure for TOC5000A as show in the pictures.

3. RESULTS

The records of sampling survey of container indicate that fresh weight and the dry weight of plants on each container (Figure 5).

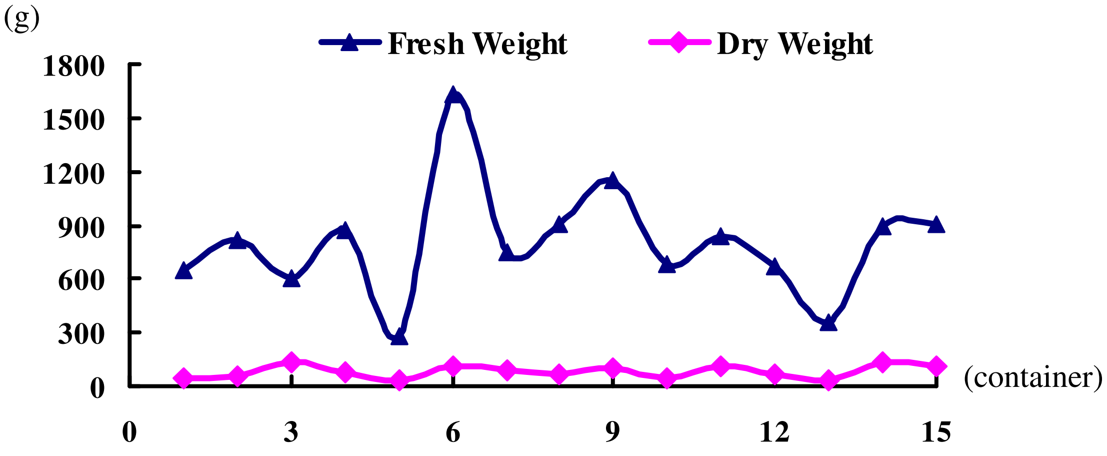

Figure 5. Each container has the fresh weight and the dry weight of plants.

We were cutting plants from root, steam, leaf, fruit, seed and etc. The carbon storage content in the different parts of plant was show as Figure 6.

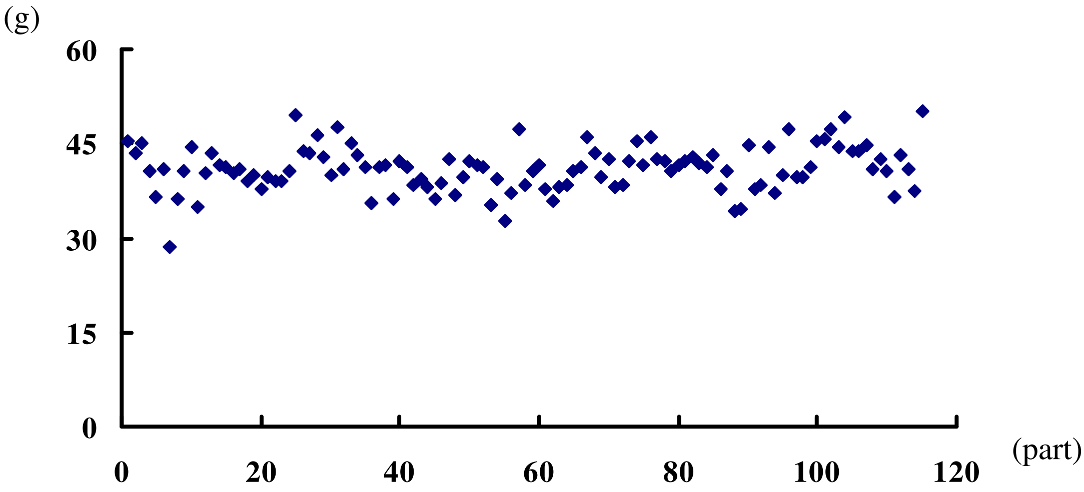

Figure 6. The carbon content measured in the different parts of plants.

We measured the carbon storage content of the medium with different position in AS1C (Table1). The carbon content of uncultivated medium was 35.89%.

Table 1. The carbon content measured in the different positions of mediums.

	Position	Plant Types	Medium Average TC%	Medium Average pH
VPS	East	3	39.20	6.6
	South	4	36.61	6.2
	West	4	35.66	6.2

4. CONCLUSIONS

VPS is equipment that wraps up the peripheral of AS1C. This forms a small nature symbiotic ecosystem. The records of sampling survey of container indicate that average fresh weight of plants on each container is 800.76g, and the average dry weight of plants on each container is 82.24g. The TOC5000A in the experiment is adopted to sense the carbon content of the plants on the VPS in the AS1C. The range of carbon content from 28.69% to 50.09% depends on the different kinds of plants, and the average carbon content is 41.03%. The carbon content in the fruits & seeds is especially high. In the root of the *Composite* is higher than leaf and steam. The carbon content (like that in the taros) turning into amylum is fixed. The literature review shows that the C4 plants has the stronger ability to fix CO_2. The fixed carbon has been taken into crops is decomposed back into the circle. In this always changing balanced carbon circle, a little more weight on the end of fixed carbon is useful to slacken the climate change. The carbon content of the medium on the planting tower ranging from 33.64% to 40.90% depends on the different positions, and the average carbon content is 37.19%. The carbon content of the medium on the planting tower is higher than that of the never planted medium at 35.89%. Therefore, the fixed CO_2 should have come from the air. Through the calculation with photosynthesis formula, the AS1C is compared with the buildings without any plants absorbed more 1024.27 kg of CO_2. The result of the next study should be compared with that of this study for the correlation. Another kind of measurement is recommended next time so that

ACKNOWLEDGEMENT

We are grateful to Professor Cheng Cheng-yung for helpful guidance in using TOC5000A. This research was supported by Archilife Research Foundation.

Keywords: thermodynamics, profit, exergy, stakeholders, building process, life-cycle costs

Summary

In the Netherlands three technical universities are participating in a new research project "Exergy in the built environment", that aims to contribute to sustainable building by investigating the potential financial benefits of exergy saving techniques. Exergy is a concept used in thermodynamics to express the maximum amount of mechanical work that can be obtained from an energy flow or a change of a system in relation to its environment. In contrast to energy, exergy can be destroyed and by that means exergy can express the finiteness of resources better than energy can.

In the building process investors currently use life cycle costing to calculate the returns on their investments in buildings. The life cycle costing method however does not take into account an important organizational issue. Namely, that the stakeholders who benefit from exergy saving techniques not necessarily include the investing stakeholders. The aim of the research on the profit of exergy in the built environment is to develop an improved model to predict the potential added value of exergy saving techniques by linking this thermodynamic concept to building processes and to investment appraisal. In this proposition paper the objectives, methodology and theoretical framework will be explained.

1. Introduction

Since stated by the World Commission on Environment and Development in 1987, sustainable development receives world wide attention. In the building industry the term sustainable building is used to address all techniques and approaches in terms of source efficiency, quality improvements and pollution reduction, *which not compromise the ability for future generations to meet their own needs* (Brundtland et al., 1987).

Within sustainable development and sustainable building the reduction of energy use and lowering the pollution have much attention. In the Dutch building industry innovative techniques, like solar chimneys, heat pumps and mechanical ventilation systems with heat regeneration, are introduced to supply heat efficiently during winter and to keep the heat inside as long as possible by using new types of insulation and heat exchangers. It is even possible to build houses that offer comfortable temperatures without the necessity of any external energy infrastructure to supply them of resources or heat at all; autarkic houses.

However, the Dutch building industry seems to see the national Building Code, with its explicitly stated energy performance, as a guideline for the maximum level of necessary performance. The Building Code should although be considered as a minimal required energy performance. The building industry is rather reluctant to apply these necessary energy saving techniques. Contractors often do not know which broad range of energy saving techniques is available and the direct costs of some of these existing techniques are simply too high, so it seems.

One method to get something implemented in the building industry is to enforce it by law (e.g. building codes, regulations). Another method to get something implemented in the market is by showing its commercial value. A logical motivation will lie in making this task easier to reach by pointing out the financial advantages of the techniques and approaches. Research is therefore needed to explain the financial benefits of exergy saving techniques (including the formerly known energy saving techniques).

Exergy is a concept based on the first and second law of thermodynamics. Exergy is the maximum amount of mechanical work that can be obtained from an energy flow or a change of a system in relation to its environment. In contrast to energy that is only based on the conservation principle of the first law of thermodynamics, exergy can be destroyed. Therefore, exergy can express the finiteness of resources better than energy can. In other words exergy expresses the quality of the quantity energy. The relation between energy and exergy can, according to Ala-Juusela et al (VTT, 2003), be embedded in a quality factor (see Eq. 1 in combination with Table 1).

$$Exergy = Energy \times Quality\ \ Factor \tag{1}$$

Table 1 Quality factors for multiple energy sources based on an ambient temperature of 20°C (VTT, 2003)

Source	Quality factor
Mechanical energy	1,00
Electrical energy	1,00
Solar radiation	0,95
Nuclear fuel	1,00
Fossil fuels	0,90
Thermal at 100°C	0,21
Thermal at 40°C	0,06
Thermal at 20°C	0,00

Although there is much thermal energy needed in the built environment to generate a comfortable indoor climate, the exergetic value of heat in an indoor environment of twenty degrees Celsius is very low. When it is twenty degrees Celsius outside, the value even equals zero, because there is no temperature difference between the analyzed system and its environment.

To generate the proper indoor climate of approximately twenty degrees Celsius, a fossil fuel named natural gas is commonly being used in The Netherlands. This fuel can be burned at high temperatures; therefore the generated thermal exergy will almost equal its formal internal energy. However, the generated high thermal exergy does not match the needed low thermal exergy for the indoor climate. The principle of using high quality sources in degrading steps, so called cascade principle, can be introduced to make efficient use of fossil fuels. Another possibility is, of course, to use alternative (renewable) sources for heating residential and commercial real estate.

2. Research objective

The planned research is aimed to contribute to the adoption of exergy saving techniques in the built environment by giving insights in their financial consequences. These techniques will help to lower the amount of harmful emissions and can provide the correct quality (in terms of the ability to generate mechanical work) and quantity of energy, expressed by exergy, in a more effective way. The relation between thermodynamics, economics, and sustainable development has been described most challenging by Valero et. al. (1993):

Developing techniques for designing efficient and cost-effective energy systems is one of the foremost challenges energy engineers face. In a world with finite natural resources and increasing energy demand by developing countries, it becomes increasingly important to understand mechanisms which degrade energy and resources and to develop systematic approaches for improving the design of energy systems and reducing the impact on the environment. The second law of thermodynamics combined with economics represents a very powerful tool for the systematic study and optimization of energy systems.

In a time of governmental deregulation, improvements in adopting exergy saving techniques need to be facilitated by specifying the financial benefits for the stakeholders in the building process. The main research question can be stated as a single line question in the following way:

What are the financial benefits of exergetic optimization of real estate?

Although there is a common awareness of the ecological and social benefits or other externalities of exergy saving techniques, the financial costs and benefits will be the major point of concern in the decision making process on investments in real estate. In the process of addressing this concern the financial benefits of exergetic optimization will be mainly approached from the investor's and user's point of view.

The appraisal of exergy saving investments does take the benefits during utilization into account (for example in the method of life cycle costing), but stakeholders in the building processes often do not communicate about, or take the time to weigh, the costs and benefits of life cycle investments. Furthermore the methods for calculating the yearly cash flows do not incorporate all benefits of exergy saving techniques yet. The main contribution of this research can be found in offering a model to overcome these two aspects.

3. Societal relevance

Given that many modern (starting somewhere during the industrial revolution) emissions harm the environment and given that the supply of fossil fuels is finite, the adoption of exergy saving techniques is of great importance. It can help to use the supply of fossil fuels more effective or to use sustainable sources that do not harm the environment.

The fact that the building industry and the built environment as a whole are, according to the EPBD (EC, 2002), responsible for at least forty percent of the total energy consumption, and the given fact of an increasing number of restrictions on the energy consumption of buildings, make it interesting and wise to stimulate techniques that can reduce the exergy consumption in a cost effective way.

The Return on Investments (RoI) in exergy saving techniques will mostly benefit the user of the building. This user is in most cases not the same person or corporation as the constructor who paid for the investments during the construction phase. During the habitation of a dwelling or the use of an office some actions will be undertaken by the user to lower the energy consumption. Until 2003 there were different subsidies to trigger these users e.g. to insulate their buildings, most users however do not know which level of adoption of energetic techniques is attractive from a financial and/or energetic point of view.

Current developments that can stimulate customer awareness on the energy consumption of buildings, involve the Dutch Energy Performance Coefficient (EPC) and the European Energy Performance Building Directive (EPBD):

- The EPC expresses the energy efficiency of buildings and is included in the Dutch Building Code (2003) regarding building licenses for new buildings. Its introduction was in 1995 for dwellings and it gradually lowers the building related energy use of all new buildings by lowering the numerical value of the coefficient from 1.5 in 1995 to 0.8 in 2006. The energy performance of offices and other utilities has been regulated and lowered since 1998.
- The EPBD passed the European parliament and council at 16 December 2002 and should have been converted in laws by the member states since 4 January 2006. Twenty one European countries were however not able to finish the preparations in time. The Dutch government has introduced the derived laws on the certified energy performance of existing buildings and inspections of heating and cooling systems at the first of January 2008.

The certification of the energy performance of existing buildings can result in recognition of their energy use. An appreciation of a good energy performance can positively affect the market value and therefore the financial benefits of an exergy saving measure will be higher.

4. Scientific relevance

By focusing on the financial benefits of exergy saving measures in real estate objects the research takes place in an area, in which three scientific fields overlap; building processes, economics and thermodynamics (see Figure 1). The relevant theories for these three fields shall now be addressed.

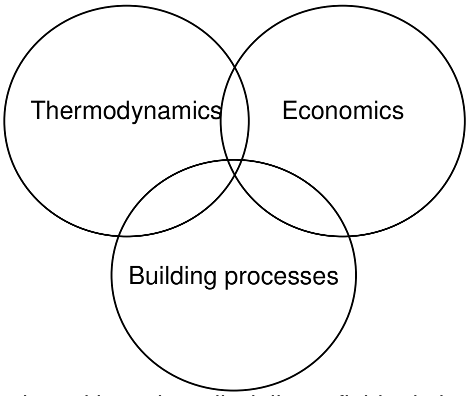

Figure 1 The research will be conducted in an interdisciplinary field relating thermodynamics and economics in interaction with the building process.

4.1 Building processes

In the Netherlands the implementation of energy saving measures in real estate is at this moment mainly enforced by law (Building Code, 2003). Although investments by commissioning commercial organizations or private persons are mainly weighed by their financial returns and technical aspects (Vermeulen et al., 2006), it seems that the goal realization or development in sustainable building by the temporary organization of the building process also can be stimulated by respectively transactional or transformational leadership (Bossink, 1998). It is not only important to do research on the financial benefits and technical aspects, but also on the organization of the stakeholders in the building process.

Research of Van Soest (2005) e.g. shows, that an increase of environmental taxes and quotas does not necessarily induce early adoption of energy saving technologies in firms. This seems to conflict with the findings of Vermeulen et al. (2006), where the economic assessment is one of the main variables. According to their findings the use of subsidies effected especially the economic assessment of young innovations. The research of Van Soest had a focus on one single firm that is both the investor and user of the object. However, in case that user and investor are different parties the cost benefit considerations might be different for both parties. As a consequence their decision to adopt specific energy saving technologies and techniques will most likely also differ.

In the first part of the research a stakeholder analysis needs to clarify where in the process the objectives for reducing the exergy consumption are developed and where their financial consequences are addressed. It is important to know at which moments in the design, construction and utilization phase, intervention to adopt the exergy saving technologies is possible. The influence of the stakeholders and uncertainty in the early phases of the building process in relation to the project's value generation has been studied before by Kolltveit et al. (2004), but this research did not specifically focus on energy or exergy saving techniques. Therefore this research can make an innovative contribution by specifying the opportunities and restraints in adopting energy saving techniques in building processes.

4.2 Thermodynamics

The basic methods of energy and exergy analysis from the field of thermodynamics are generally used to optimize the designs of power plants, but in recent years some building related installations have been analyzed, for example heat pumps (Ozgener et al., 2005; Ucar et al., 2006). Methods to address the costs and benefits of exergetic optimization processes are referred to as thermoeconomics (Szargut, 1988) or exergoeconomics (Tsatsaronis, 1985).

The possibilities to reduce energy consumption and to save exergy in the built environment are numerous. An average dwelling in the Netherlands uses for example 1,736 m^3 natural gas and 3,346 kWh electricity each year (SenterNovem, 2006). The efficiencies of many exergy saving techniques have been addressed e.g by Gustafsson (2000), Xiaowu et al. (2005) and Nagano et al. (2006). A preliminary literature study on exergy saving techniques however shows that so far, little research has been done on passive solar systems. This research will contribute to this research on exergy saving techniques by conducting an experimental study of a passive solar system.

4.3 Economics

A basic method to specify the financial costs and benefits of real estate investments is Life Cycle Costing (LCC). It recognizes that the total cost of ownership of a product is not solely reflected in its purchase price. The purchase of certain products should in other words be considered as an investment for which both benefits and additional costs are incurred over the life of the product (McEachron et al., 1978). Although there are some difficulties still to overcome (see e.g. Gluch et al., 2004), this method can be used for the analysis of design options regarding conventional energy efficiency. Lutz et al. (2006) used it for example for weighing the costs of residential furnaces and boilers and Gustafsson (2000) optimized insulation thickness.

LCC has been improved from an environmental point of view by integrating the product's or investment's results from Life Cycle Analysis (LCA) and the customer's willingness-to-pay for the related environmental improvements (Bovea et al., 2004, Banfi et al., 2006). However, despite these improved LCC methods, there are still possibilities for further improvements. The application does not take into account the possibilities of increasing the value of real estate by means of improving its efficient energy performance. Although this aspect is related to the willingness-to-pay principle, it is the first time that financial data from the existing building stock can be related to energy performance certificates based on the European Building Directive on Energy Performance.

Furthermore, in the case of residential real estate the availability of fuel resources are not accounted for in LCC yet, although the prices of car fuels for example are strongly related to their availability. Alanne (et al., 2006) performed a first study on the reliability of decentralized energy systems and Awerbuch (2000) already addressed the urgency to improve the traditional valuation models by introducing the Capital Asset Pricing Model (CAPM) for investments in photovoltaics. CAPM explains the relationship between risk and the investor-required return rate for an asset. Awerbuch's statement "by ignoring financial risk, lenders and investors understate the value of PV projects relative to fossil alternatives" and his suggested solution to use the portfolio theory of Markowitz (1952) to relate cost and risk contribution of alternative resources, offer a basis to investigate the value of the quality of energy; the so called exergy. At this point the economic aspect of the research can be linked with the already mentioned thermoeconomics or exergoeconomics.

5. Research methodology

Three research questions regarding the building process, the field of thermodynamics and field of economics are defined to achieve the objective of the research. This research methodology is based on Verschuren et al. (1999). The first research question will focus on the building process and the relevance of (conventional) energy saving techniques for stakeholders within this process.

Question 1: Which opportunities and restraints during the development of real estate can be distinguished in adopting energy saving techniques?

To combine the advantages from the collective thermodynamic and economic approach on exergy saving techniques the building process and its stakeholders need to be described. Four different project types in describing the processes can be distinguished:

1. Residential real estate developed by private ownership;
2. Residential real estate developed by housing corporations;
3. Commercial real estate developed by investors;
4. (Commercial) real estate developed by the government.

Research on building processes for residential real estate in relation to sustainable measurements has been done by De Man (1983) and Bossink (1998) for example. Research of Vermeulen et. al. (2006) has a focus on commercial real estate. To reflect on the international context of this first research question it is possible to use the research of Lo et al. (2006) on the opinions of building professionals in Hong Kong and Shenyang on sustainable measures.

The interaction between the stakeholders can be based on different management structures; traditional management structure, construction management structure and project management structure (Best et al., 1999). Is it the customer or client who makes the decisions or is the adoption driven by the design of the architect? Relations between the stakeholders will be overviewed to identify certain bottle necks or changes for the implementation of sustainable techniques in building processes.

This first question refers also to the possibilities for the stakeholders to introduce certain techniques to save exergy in the building process. The building process is described by the Jellema series (Woude et al., 1997) for the Dutch situation for example. Internationally reference can be made to Pietroforte (1996), Arditi et al. (1998), Winch (2002) and Turin (2003). The possibilities to interfere in the design and building process are often bound to the first phases of the project (Kolltveit et al., 2004).The quality of the product resulting from the building process is strongly driven by the Dutch Building Code. This law specifies a minimum quality level for all buildings and is therefore an important aspect in the adoption of energy saving techniques in the built environment (Building Code, 2003; NNI, 2004). Buildings must have a certain energy performance, which makes investments in energy saving techniques necessary. Which techniques are being used for which reasons? What are the best practices in relation to these regulations?

By conducting a literature study and interviewing stakeholders the necessary insights will be collected for answering this first research question. The content of the interviews will be based on mentioned theoretical references. An interview is one of the most important sources for case study research (Yin, 2003).

Question 2: What is energetic and exergetic optimization of real estate objects?

It has already been mentioned that more than forty percent of the energy consumption in Europe can be assigned to the building industry. The second research question will focus on the possibilities of lowering this energy consumption and of applying exergy saving techniques to match the provided quality of energy with the quality needed. The appropriate science for this goal can be referred to as thermal-fluid sciences, which can be studied under the subcategories of thermodynamics, heat transfer, and fluid mechanics (Çengel et al., 2005).

The first law of thermodynamics on conservation of energy is commonly known, but the second law is less familiar. Society needs to become more familiar with the possibilities of exergetic analyses in the built environment. A literature study on this concept will be conducted. Important sources are the thesis of Cornelissen (1997) on "Thermodynamics and sustainable development" and the "Fundamentals of thermal fluid sciences" written by Çengel et al. (2005).

The exergy consumption of the built environment can only be reduced effectively, when the current conventional energy consumption of buildings is known. To get a grip on the potentials of exergy saving in the existing building stock a preliminary study has been made of three commercial real estate objects. For the explorative research among residential real estate there are eight houses available constructed in the years 1913, 1925, 1939, 1948, 1964, 1972, 1982, 1992. By using the standardized data on energy consumption (Novem, 2003, SenterNovem, 2006), the normalised method to compute the building related Energy Performance Coefficient (NNI, 2004) and the actual energy consumption data, it is possible to analyse the potential energetic benefits in real estate objects. It is important to reflect on the effectiveness on past policies and regulations which influenced the physical state of buildings.

There are many studies available on specific energy and exergy saving technologies. The Network of International Society for Low Exergy Systems in Buildings listed many possibilities to lower the exergy consumption of buildings (VTT, 2003), however several of these techniques have not been tested or analyzed yet. This research can contribute to existing studies by performing an energy and exergy analysis on an exergy saving technique that has not yet been analyzed. A literature study will be made of the existing energetic and exergetic analyzed parts of buildings (e.g. Gustafsson, 2000; Xiaowu et al., 2005; Ucar et al., 2006; Nagano et al., 2006). In this research one promising and innovative technique will be thermodynamically analyzed and tested to address the benefits of the concept of exergy in practice (this technique will also be used for testing the model on financial benefits of exergy saving techniques). A first scan of the available theory showed that passive solar (ventilation) systems are not well represented yet. An experimental case study on a passive solar system seems promising.

Question 3: What model can be developed to express the financial benefits of exergy saving techniques?

The third research question will refer to the economic element of the research. As a basis standard investment appraisal methods will be used. In this research the focus will be on, like expressed in Figure 2, (1) the stakeholders involved at the moment of the decision to invest and (2) the variables that form the cash flow. Two new variables will be introduced in the second in depth study: (A) the actual market value of the real estate object and (B) the price of the reduced form of exergy as a result of the depletion of fossil fuels.

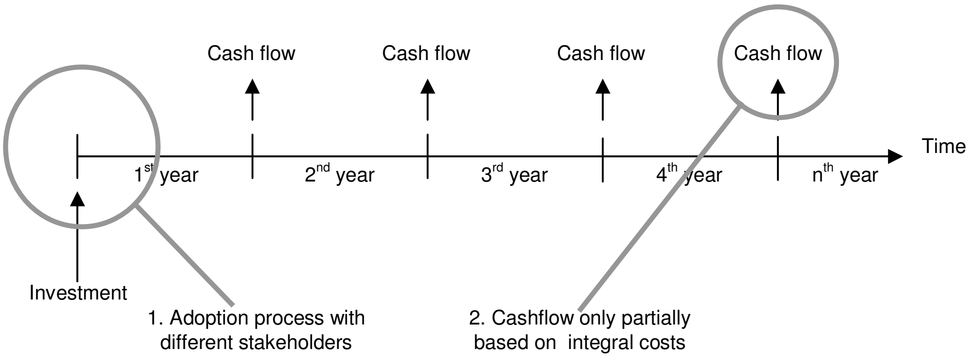

Figure 2 Model showing two problems regarding investments in exergy saving techniques.

When the principles of conventional capital budgeting methods are used on building related investments, they are commonly referred to as life cycle costing. Life cycle costs can be used for the appraisal of exergy saving investments by taking into account the direct costs, the yearly costs of maintenance and the yearly costs of (fossil) fuels. A conceptual discussion given by Gluch et al. (2004) offers important shortcomings to overcome, before adoption of life cycle costing in the building industry can be further stimulated. Not withstanding these shortcomings, the LCC method is commonly used for comparing designs in civil engineering projects (e.g. Noortwijk et al., 2004; Zen, 2005; Singh et al., 2005; Ugwu et al., 2005) and it is also used for environmental orientated investments (e.g. Reich, 2005; Nakamura et al., 2006). Theory on the basics of life cycle costing (originally developed at the American Department of Defense) is offered by McEachron et al. (1978) and Stern (1978).

Two financial benefits of exergy saving techniques are not yet addressed in the theory on the traditional life cycle costs. The first is the willingness-to-pay for real estate that consumes less exergy than conventional real estate. Research on the value development of real estate regarding their energy performance in the past will be conducted by comparing the actual market values of the case objects with the investment costs of specific energy saving techniques. Papers in the field of willingness-to-pay are for example Banfi et al. (2006) and Bovea et al. (2003). The second category of financial benefits is related to the depletion of fossil fuels. With a fixed demand for fossil fuels; the scarcity will increase and therefore the price. By analyzing the energy prices it is possible to specify an interest rate for the yearly positive cash flows generated through exergy saving.

The third research question also involves the applicability of the model for the stakeholders in the building process. The costs and benefits of the exergy saving investment are not in the hands of one and the same stakeholder. In principle there are two possible solutions to deal with this aspect; (1) the model needs to incorporate this separation or (2) the building process needs to incorporate the exergy saving investment appraisal. Depending on the results of the first research question a solution or manual can be offered as a spin off of this research.

6. Conclusions

Based on the existing debates in society on the depletion of fossil fuels, energy consumption, and carbon dioxide emissions, the time is there to introduce the concept of exergy within a broader community. The national Dutch research project "Exergy in the built environment" will introduce this concept in the building industry by providing tools and catching applications, that give insights in the advantages regarding comfort (people), the environment (planet) and economy (profit).

The presented research will focus on the financial benefits. At this moment the prices of multiple energy forms are based on a combination of production costs, governmental surcharges, and market principles. The quality of the energy form, expressed by exergy, is not incorporated in the price setting.

Furthermore, building processes are in general not accommodated to stimulate investments in techniques that reduce the energy and exergy consumption. Stakeholders that invest in a lower energy consumption and stakeholders that financially benefit from these investments, should be brought together within the buildings process or the indirect financial relation should be brought to the surface.

By offering more insights in the cash flows that are generated by installed energy saving techniques in existing buildings and by smoothening building processes, we expect to be able to stimulate the adoption of more and newer exergy saving techniques. Summarizing, this research will comprise:

- Investigating the possibilities to save exergy in the built environment by conducting an experimental study on passive solar systems;
- Investigating decisive considerations to adopt exergy saving techniques to adopt exergy saving techniques from a multiple stakeholder perspective;
- Developing an improved model to estimate the added value of implementing exergy saving techniques, considering their life-cycle costs and benefits.

Acknowledgements

The authors would like to express their gratitude to the SenterNovem for providing financial support of the present research.

Paper Title: Regional Strategies for the Development of Sustainable Building

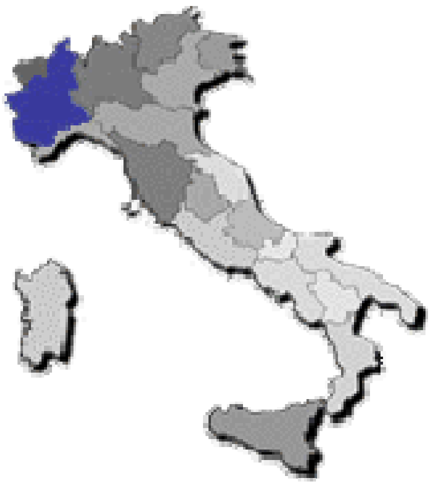
SB08 Abstract/Paper Reference: ABSN7 –LE527 – ZM2X6- QCFT4

Relevant Topic Code(s): 4.2

Summary
The Italian Regions have developed a sustainability assessment tool called "Itaca Protocol".
Piedmont Region is experimenting the assessment tool and developing policies and projects for urban reneval and building sustainability.

Keywords: Sustainable Building Certification System**,** Itaca Protocol, Green Buiding Challenge, iiSBE Italy, Piedmont Region**,** Social Housing Program, Skyscrapers, Sustainable District, Municipalities, Sustainable School Building, Sustainable Health Building.

1 Introduction



Piedmont is an Italian region, part of north-western Italy, bordering France and Switzerland. It is economically prominent amongst the twenty Italian regions.
Piedmont and its capital city, Turin, are focusing on urban renewal as the main way to develop sustainable building practices.
With the industrial areas' displacement, the regional government and the local administrations have found a way to redeem the mistakes in architecture and urban planning made from the 60s through the 70s.
Parts of the former factories are destined to new functions (i.e. museums); other industrial buildings are replaced by new areas, which will reweave the urban fabric and remove its rifts.

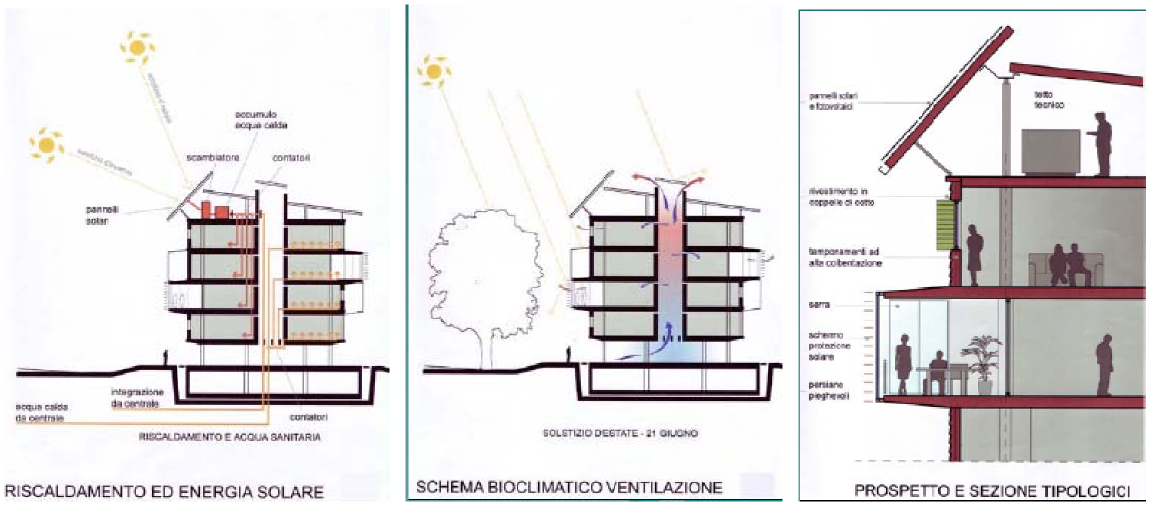
In such context, Piedmont promotes sustainable building through its policies and incentives. The Region works towards sustainable building through strategies such as urban renewal and industrial reorganization; the projects include new buildings which will be models for future realizations.
For these projects Piedmont allotted 4 billion euros, to be used over the next 6 years.

2 Urban renewal and the territory

Urban renewal involved 17 important Piedmont municipalities.
The urban planning choices have been made towards redeveloping industrial areas transformation; these projects notably include a strong support to sustainable building, through increased investments in sustainable building.
The regional funding contest requires the application of the ITACA Protocol (based on GBC) to assess buildings. This requirement encourages qualified design, emphasizing the use of new materials, and a focus on water reuse and renewable energy.
These programs, called "district contracts", require investments for ca 700 million euros; 54% of these investments (375 millions euros) are made by private funds.
The second version of the district contracts' program required the application of the abridged version of ITACA Protocol. This version evaluates twelve criteria, and is the most commonly used adaptation of the system approved by the regions.
On a stronger take on the subject of sustainable building, Piedmont launched the "Regional housing program: 10.000 apartments within 2012". This program requires the application of ITACA Protocol.
The regional housing program covers:

- 6063 apartments to rent, destined to social housing;
- 1973 apartments partly in permanent location, partly redeemable in 15 years;
- 300 flats for people over 65 years old;
- A warranty fund up to 60.000 euros for apartment, granted to the buyers of apartments realized by builders which took part in the program.

The assessments are carried out by iiSBE Italy. The certifications issued grant a reimbursement for additional building costs, covering 4%-8% of the total cost; the overall allocation sums up to 56 million euros.
The first results of the housing program are now available; the program has generated investments for over 1 billion euros, involving about eighty Piedmontese municipalities, working with builders, housing cooperatives, and ATCs (Agenzie Territoriali per la Casa - Territorial Housing Agencies, formerly Social Housing Independent Institutes) (Fig. 1, 3).
Another group of projects, launched in some of the main towns of Piedmont, will allow the realization of new districts; these areas will mainly house the families of army staff and police officers. Each of these projects will include housing for ca 1000 people, and the realization of new commercial areas and services. Currently 6 of these projects are planned. Before the building phase starts, the projects must be assessed by iiSBE Italy through ITACA Protocol; every project must achieve a score of at least 2 points on the Protocol scale. The total investment for these projects is ca 500 million euros (Fig. 2).
The effort towards sustainability goes beyond housing projects; the Region launched a new plan for 2007-2009, concerning schools. The school building involved in the plan will be refurbished, focusing on high structural and service standards. The assessment will be carried through an experimental version of ITACA Protocol, which will evaluate the fulfilment of eco-efficiency standards. The main areas of assessment include energy performance and indoor air quality. Piedmont allotted 25 million euros on this plan for schools' renewal.
In the town of Novara (near Milan, with ca 90.000 inhabitants) the Region has placed its "Health City", a new hospital, research and university complex. This project received a fund of ca 360 million euros; every building in the project must fulfil the requirements of ITACA Protocol, which will be adjusted by iiSBE Italy to suit these peculiar building typologies.
An interesting application of the ITACA Protocol will be carried out in Valdieri, a small thermal centre near Genoa. The thermal complex will be designed to achieve a score of 2 on the Protocol scale.



(fig.re 1)

(fig.re 2)

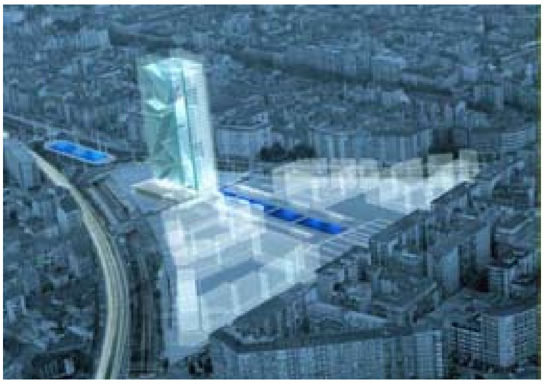
3 The skyscrapers

As of today, the Piedmont Region has 15 departments, each with its head offices, all in Turin.
In order to concentrate all the activities in one headquarter, the Regional Executive Committee has planned the realization of two towers designed by Massimiliano Fuksas; one of the towers will be 220 metres tall, and will be linked to the second through a lower building, destined to lodge an indoor garden (Fig. 4a).
The area will also include residential buildings, shopping centres and underground parking lots; the project will renew the former Fiat Avio area, close to Lingotto (previously hosting the Fiat group headquarters, known for its roof track for test drives). The area's ground level will be destined to public park, for pedestrians only.
The Regional Executive Committee resolved to apply ITACA Protocol to the whole area, requiring a minimum score of 2.5. Due to the complexity of the area, the protocol will be adjusted by iiSBE Italy and I.T.C.-C.N.R.[1] to ensure the fulfilment of the sustainability requirements by all buildings.
The regional investment for the towers alone adds up to 200 million euros.
On the other side, the Intesa-San Paolo banking group has chosen the Porta Susa district for its headquarters. Porta Susa is planned to become Turin's main train station, and will be displaced underground. The new Intesa-San Paolo headquarters will be hosted in a skyscraper, 219 m tall, designed by Renzo Piano (Fig. 4b). The project's highlights are the use of geothermal power, coupled with an highly insulated envelope, and the use of the stack effect during summer. Every floor of the building will host an indoor garden facing south.

---

[1] *Istituto Tecnico Delle Costruzioni – Centro Nazionale Ricerche (Building Technical Institute – National Resarch Centre)*

This building as well will be assessed through ITACA Protocol, to evaluate the performance of the systems and techniques used.
On a side note, the Group Intesa – San Paolo has recently created a new financial product, called Aedifica-Bioedilizia, to encourage sustainable building. Both the builder and the buyer will receive funding, upon verification of the bulding's eco-efficiency level.
A third skyscraper will be built close to the Intesa – San Paolo one, by the insurance society Sai – Fondiaria. The tower, 140 m tall, will collect most of the society's offices in a place conveniently close to the Porta Susa station, in the renewed area called "Spina 2". This building too will follow energetic and environmental criteria.



(fig.ra 4)

(fig.ra 5)

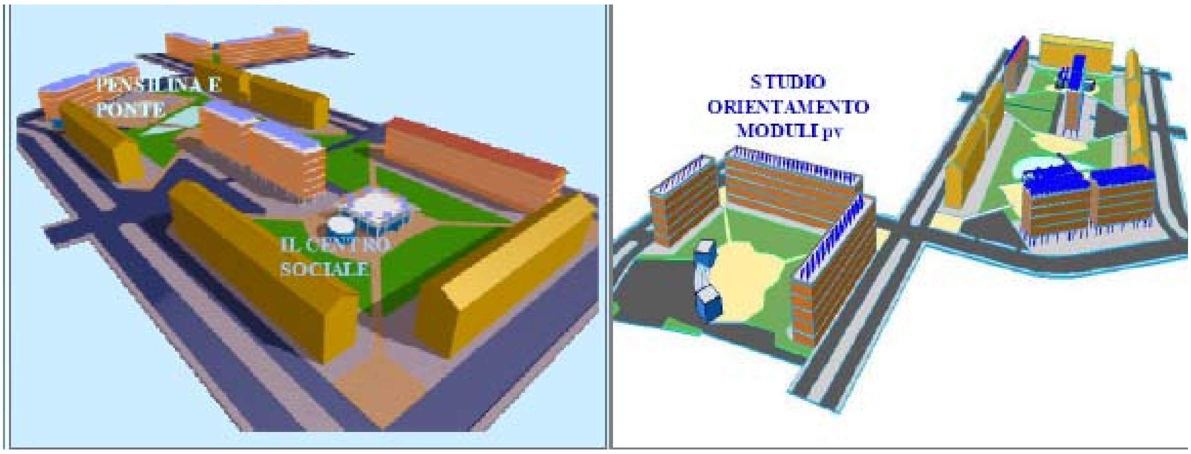
4 The sustainable district and the wood manufacturing process

The paradigm shift towards sustainable building happens in part through the aforementioned programs (including social housing, incentives, notable buildings such as skyscrapers); but these projects need a strong technological backup, which must be developed on the territory.
Piedmont will use 800 million euros from the F.E.S.R. (European Found for Regional Development) to encourage the design of sustainable materials and technologies, and to help the former industrial processes to take part in the production of such new materials. The aim is to develop and produce sustainable technology in Piedmont.
In the Monregalese area, in southern Piedmont, a similar project is under way. The effort is to create a productive network in the whole area, which will cover various steps of the wood manufacturing; the Monregalese area will host the production and the first stages of wood processing. The following steps up to the final product could be made in the province of Alessandria (southeastern Piedmont, ca 70.000 inhabitants) which is renowned for its wood processing industry.

5 The agreement protocols

The Region, whishing for a correct application of ITACA Protocol and its sustainability principles, promotes work agreements with the municipalities; one of this agreement protocols has been concluded with the Alessandria province and municipality. The Region's target is to allow the drafting of local energy and environment management plans and building regulations.
The protocol includes tutoring by iiSBE Italy to assist the municipalities in drafting new projects for sustainable building.

Piedmont has also arranged an agreement with iiSBE Italy (control body of ITACA Protocol) to provide training and technical counselling to builders enrolled in the "Regional housing program: 10.000 apartments within 2012".



(fig.re 3)

(fig.ra 3)

6 Sustainable building examples in Piedmont

- Vercelli: renewing Sambonet industrial area (Fig. 1);
- Torino: new district for security corpses' families (Fig. 2);
- Alessandria: new photovoltaic village (Fig. 3);
- Torino: Regional headquarters' skyscraper (Fig. 4a);
- Torino: Intesa- San Paolo banking group skyscraper (Fig. 4b).

7 Conclusion

Every Country has its own problems, but undeniable common need are: developing strategies to manufacture new ecological materials, building reference projects to boost future sustainable realizations, and strongly supporting sustainable building wherever possible, through public financial support.
Piedmont and Itaca, through iiSBE Italia's activities, strive to set a pattern for sustainability policies.

SUSTAINABLE DESIGN; ECOLOGY, ARCHITECTURE AND PLANNING

Daniel E. **Williams, FAIA, MURP**

Fellow in the American Institute of Architects; 2003 Chair, Committee on the Environment, COTE; 2006 Chair, AIA Sustainability Task Force; Former Director, University of Florida, Center for Urban Research and Education

Keywords: ecologic models; watershed planning; sustainable design and planning, bioregionalism; biourbanism; carrying capacity; climate change.

Summary

The significant impacts on urban settlements due to climate change require a similar scale of design intervention. The problems associated with housing and feeding an additional billion people or transporting them out of harms way, are not solvable on the architectural scale alone. Designing at the urban and regional scale is central to this need.

Design as the regional scale begins with applying the knowledge of the region's ecology as it is the form and structure created by large and sustainable energies. This approach recreates synergistic connections between the design and the sun, soil, air, water, and gravity. Design at this scale enhances the regions' social, ecologic and economic health and is the forcing function of sustainability at the neighborhood scale. The removal of these connections has decreased the quality of life as it has exponentially increased taxes and stress on the global social, ecologic and economic systems.

Integrating the knowledge derived from systems ecology into the design program illustrates a systems approach to resource protection, quality of life and sustainable community design. These designs use the "free work" of nature and provide better places at lower costs and impacts.

Community designs that incorporate renewable resources and are respectful of the natural cycles create compelling neighborhoods while protecting the resource base. Solar driven urban and regional design creates a community that is efficient, economical and compatible with the regions resources.

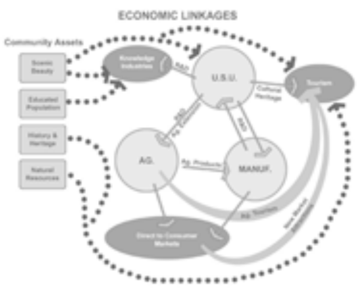

Figure 1. An ecological systems model of community, economy and environment

1. Issues of Sustainability

Land has a purpose and function over and above its real-estate value and that purpose and function needs to be understood, valued, preserved, protected and integrated into our planning and design efforts. Planning on a regional scale is one of the most effective methods of assuring available natural resources for future generations.

Figure 2. Regional “systems” planning includes economic development, social equality, and environmental protection while assuring a future desired.

1.1 Water as the Common Denominator

In the book *The Last Oasis*, the author Sandra Postel states, "Although water is a renewable resource, it is also a finite one. The water cycle makes available only so much each year in a given location. That means supplies per person, a broad indicator of water security, drop as population grows. Thus per capita water supplies worldwide are a third lower now than in 1970."

For example, in the United States even Florida is running out of water. Despite more than two decades of growth management, the health of the State's fragile ecosystem continues to decline. This decline is the subject of intense scrutiny ranging from the 1998 Governor's Commission for a Sustainable South Florida to the many Army Corps of Engineer restoration projects, which seek to mitigate the negative impact of landuse development. Although the causes of this decline are many and complex, clearly growth management has failed to successfully integrate landuse and water management planning.

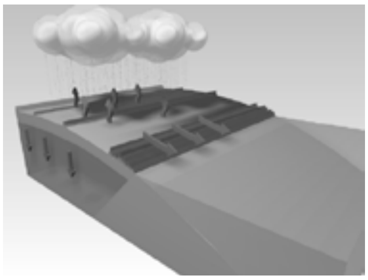

Figure 3. The hydrologic cycle is a free water distribution system

Land use affects water supply as well as water quality. South Florida's water shortage problems are not so much an allocation problem as a problem of where to store the abundant wet season rainfall so that it can be used during the dry season. Land use decisions ultimately affect the amount of water that will be stored on the land and in aquifers. As more and more land becomes developed, recognizing the influence of land use on water becomes more important.

Water is a renewable but limited resource. In most communities, water is used at a far greater rate than it is being supplied by natural rainfall or is available by annual storage capacity. Fresh, clean water is increasingly scarce and costly. Globally we are not using water resources are a rate that is sustainable for the future.

Water is often the most invisible yet critical limit to growth and development. Areas of the country are now restricted in their development due to insufficient water supply—a situation that can only get worse. Development outside of existing urban patterns increases demand and decreases land area available for recharge. Present-day development trends are inviting water shortages on a scale that is unsustainable, with near and long-term impact the economy, the environment, and the quality of life.

Buildings, cities, and communities are as dependent upon water as upon electricity. All buildings and materials, construction processes and labor forces rely on water. Once built, a building cannot function without water—it is no longer useful. Drinking water sustains human health. Water is used to clean the building, to cool equipment and space, to irrigate landscape and to remove wastes from the building. After a building's useful life, water is used to deconstruct the building. Dust control and biodegrading of many of its materials is reliant on the availability of water. Without water there is no construction, no building, and no community.

For all of human history, we have used clean water for all water uses, not only drinking, but for every other convenience, including transport of sewage. The wasteful use of water is very similar to our use of fossil fuel—we perceive the supply as unlimited. The "work" that water does for society is enormous. Its energy value is greater than that of gasoline. Water shortages are more critical than fossil fuel shortages.

1.) Water supply is among the least understood and yet critical factors of sustainable development. The global hydrological cycle supplies and distributes water, but with great variation, subject to location and seasonal weather patterns. In some arid regions of the globe, the sole and increasingly costly sources of water are importation from afar, deep well digging deeper into once plentiful but now dwindling aquifers, and desalinization. In contrast, all water in the United States for all practical purposes comes from rainfall.

2.) Annual rainfall of a region determines its water income or budget that is available on any reliable basis to support natural landscape and human requirements. Annual rainfall varies, especially in arid drought-prone regions, so that sound planning for water needs has to extend over many years, if not decades.

3.) Peak weather events establish the severity and risk from local natural weather hazards. In some regions, hurricane, storms and flooding are the foremost natural disaster threats. In other regions, lack of water, drought and resulting forest fire hazards pose the greatest risk, while in the same regions flashfloods need to be anticipated and mitigated. With the global climate trending toward more severe weather events, regional landscape and infrastructure need to be enlarged to anticipate greater peaks and variations. These preparations need to be made part of every regional and municipal watershed plan and infrastructure.

4.) Water storage, either in natural water bodies and available aquifer, or structured storage systems, is essential to a sustainable approach to providing for present and future water needs. Currently, water storage systems globally are for the most part inadequate to meet future demands of their regions and communities.

This presents a design opportunity for watershed planning: critical relationships between how we build, where we build, and how we preserve the water supply have not been studied or implemented as an integrated system. Techniques for water storage are available and affordable for projects at every scale. Implemented together within a region, they can quickly restore and improve the quantity and quality of a community's water independence.

Figure 4. Architecture can create its own water supply by receiving, collecting and storing precipitation. The very form of the building can also capture renewable energy such as solar and thermal ground energy.

1.2 Living within the Carrying Capacity of the Region and Site

The local rainfall represents the most readily available and predictable *"income"* for water supply in a region. Regions where annual rainfall can meet annual demand require effective ways to store and disperse that income. Arid regions where the annual rainfall is insufficient have to invest heavily in transport from afar, with greater cost of infrastructure and management, which increase as fresh water supplies become scarcer. In both instances, conservation and reuse are far more effective.

The local aquifer and man-made storage represents the *"bank account"* for a regional water resource. The quality and availability of the aquifer represents its "water wealth." The water infrastructure at regional, community and building scale represents the means of investing that resource—determining the cost and "budget" of water on which to live. When primary needs are met, the balance represents its "disposable income."

The design and technology of water use—how we design and construct the landscapes and structures of the built environment— represent our *"spending habits,"* determining rate at which we expend our water budget. Currently, too many of our practices are profligate, and without any saving plan. In every region, community and building project, there is room for improvement, conserving while also improving life and water quality.

Recovery and reuse of water after primary use represents the *"savings and investment plan."* Without one, the water account is soon depleted. With planning and designing for water conservation and quality improvement, we create a *"water endowment."* In the terms given by the goal of sustainability, that endowment should last forever. Water supply is best thought of as a savings account where using the interest – water over the required need for the system – is good practice. Using the principle is not advisable as it reduces the overall system supply and stresses or degrades the future supply.

We know that we are able to create a *"water budget plan"* appropriate for each region, community and building, to conserve and improve water resources and to provide a higher quality of life for the greatest number.

1.3 Watershed Principles

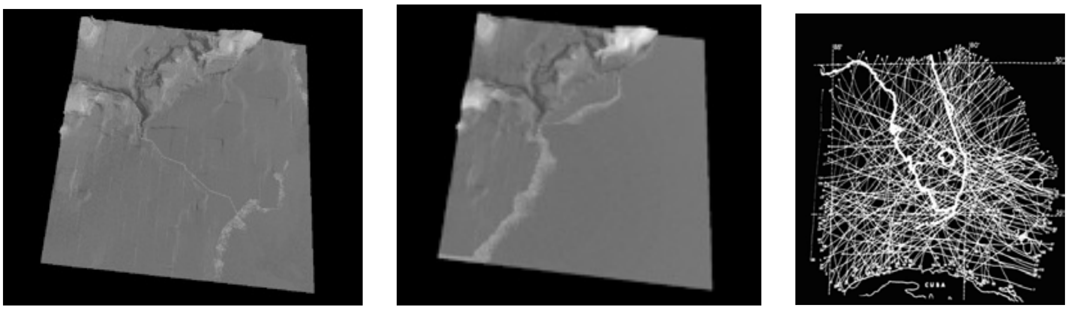

Figure 5, 6, 7. Changes in sea level greatly impact ground water storages and consequently supply. The regional natural disasters can greatly influence urban and regional form and inform sustainable patterns.

Consumption and demand for water are increasing globally. Population growth and continued expansive regional development has, most notably in the arid regions where water resources are already strained, relied upon water imports from other regions or from vanishing storages. Due in part to planning, fresh water, a free gravity-distributed resource, is now a costly commodity. Water is needlessly costly in cases where there is no water budgeting and no savings plan or water endowment for the future. Urban design with watershed planning as its ecological systems planning tool provides opportunities that are of high value for all systems:

(1) Reducing water consumption, to live with the regional and local water budget.
(2) Increasing water storage systems that mimic natural system hydrographs,
(3) Creating water green-infrastructure that cleans and reuses water, uses gravity to distribute it and be responsive to climate change and sea level changes.
(4) Improving water quality and storage at each step.

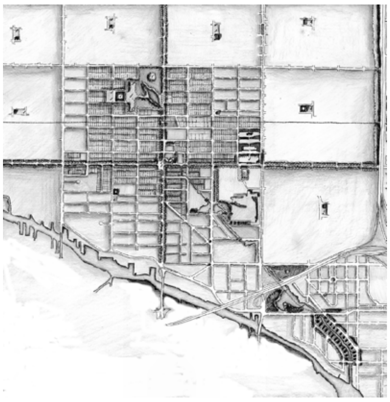

Figure 8. An illustration of an urban pattern retrofitted to provide a sustainable water supply, walkable neighborhoods and economic vitality.

These four steps that protect the water resources are appropriate at all scales: regional and urban planning, landscape and community design, building and plumbing technologies. By establishing large planning efforts that are detailed with the knowledge of the hydrology of the region, a future with water can be assured all while creating livable-desirable communities – without this planning it is assured the result will not be desired.

Keywords: concrete composite, durable material, sustainable construction, seismic desert, weight reduction.

Earthquakes annually cause big economic and human impacts on world's society such as losses of energy (causing depletion of natural resources in a large scale), efforts, and lives. Declining the vulnerability of inhabitants in a building is a major ambition for designers and the construction industry as well as for politicians and decision makers. With building destruction in seismic areas, the collapse of construction materials and their weight is the main reason for fatalities and severe injuries. Houses as the major inhabited buildings are the main subject of the collapse or damages in earthquakes. Therefore, appropriately materialization of houses is highly important in seismic areas.

This study concentrates on the reconstruction of houses in a seismic desert city. To ensure the sustainability, by an integrated design and a qualitative building system, materialization is the main subject in this work. A concrete composite will be the basic material of the structure. As concrete is relatively heavy, the focus lies on decreasing the weight by options such as replacement of the heavy ingredients in the composite. The aim is to investigate the influence of such materials on the durability of the concrete composite for this particular application in a sustainable approach.

1. Introduction/ Reconstruction and materialization

Housing was and always will be the most concerning factor (related to buildings) for humans (Oliver, 1969); therefore it is a major ambition for the building industry (Habraken, 1998). Earthquakes are happening frequently. For instance, since1900 (until 2007), around 919 strong earthquakes (i.e. magnitudes 5 and more) were registered. This includes 224 earthquakes with magnitude of 5, about 370 with magnitude 6, magnitude 7 about 283, magnitude 8 about 38, and magnitude 9 or more 4 earthquakes (USGS, 2006). As houses form the major part of the built area, to decline vulnerability of the inhabitants of buildings, designing and materialization of houses in seismic areas are very important. Therefore, for increasing the efficiency in the construction industry, the durability of materials for houses (Hendriks, 2002) should be seriously taken into the account as an essential contributor for economic and human safety.

The other important concern of this study is the desert climatic condition, because the reconstruction of the houses will occur in a desert circumstance. Deserts include 1/3 of the surface of the planet Earth, while only 15% of the world's populations live in deserts (Gradus, 1985). This unequal dispersion of population with the land area is due to the harsh climatic and land condition (Pyper, 2000). Durably materializing the houses in the desert cities in addition to the economic and social efficiency (Newman et al., 2003), will end with material minimization (Groot, 2005). This results in less depletion of natural resources being distracted for raw materials (Yu, et al. 2006). Consequently, the pollution which may be results of the production process of construction materials will decrease and thus the virtual pollution prevention costs such as eco-costs will decline (Vogtlander et al. 2004).

For reconstruction in such a situation, the study was confronted with two contradictory phases. For a seismic design decreasing the weight is important. However for the desert situation the thermal mass helps to save more energy which will be used for the cooling in the summer and the heating during the winter. Besides the temperature difference between the night and the day time in these circumstances is high. Therefore, the weight of the materials can be decreased as much as it does not affect the required mechanical and other properties. However, to compensate the extra burden from the climate when the thermal mass is decreased, insulation capacity of the material will be a crucial factor. This weight decreasing in a concrete composite is possible by using substitution materials for the ingredients of a conventional concrete. For such purpose some alternatives are available. For example decreasing the amount of the cement in the composite by replacing it with a light weight material or finding an appropriate replacement for the conventional aggregates and for the conventional reinforcement method will help to reduce the weight; because concrete is a very flexible material to be combined with a large range of materials (Li, 2005). These methods have also positive effects on the sustainability of the materialization in the construction/reconstruction, not only by directly declining the environmental impacts but also by improving some of its mechanical properties. With this background, this study investigates the influences of some substitutive and additives on the durability of a concrete composite in a sustainable framework.

3. Approach and methodology

The broader research, of which this study is a part, is divided into the three levels of: Macro (urbanism), Meso (building, component, and element), and Micro (materials dividable in sub-levels). Thus the work presented in this piece is placed in the micro level of the general research on sustainable houses for seismic desert areas. However, the material investigation, itself, has been worked in different scales. To ensure sustainability of a reconstruction in a desert area decreasing the weight by using the sintered clay and fly ash was the general assumption. Furthermore, the influence of some fibers (as the substitutes for the steel reinforcement) on the durability of a concrete composite has been investigated. Although in order to achieve more sustainability of the final composite, replacing the aggregates with recycled materials was another concern during the investigations, it is not the issue of this paper. As the first concepts of the design for the reconstruction were dome concepts for houses; the concrete composite was casted in the dome form. These have been shown in the table 1.

For laboratory tests and observations, in addition to the building elements and panels, two models of the complete houses were materialized with the concrete composite in a time difference of about 1.5 years, using the earth-casting technique for the molding (i. e. figure 1.).

Figure 1. a, b, and c

Models were made in a scale of 1:25 with the circle plan as the footprint of radius of about 5m. They were materialized with a concrete composite based on a conventional mix of the Portland cement, normal fine and coarse aggregates. A shell structure was the main concept for the modeling with the thickness of more than 8 mm for both of the models. Table1. shows the models and the related characteristics). The sizes of the clay particles were various, but mainly according to the thickness of the shell structure; because, it needed to be covered by the cement in the matrix like a thin sheet all around the particle. Therefore the sizes are scaled and so they are relatively smaller than the range that can be used in an application into the 1/1 scale structure.

Table 1. the two models of the dome concepts materialized with the concrete composite including the expanded clay particles

Specifications	Model number 1	Model number 2
Figure		
Age of the composite	25 months	7 months
Size range of the clay particles (Ø mm)	2 – 5 2-5 mm	2 – 7 2-7mm

The concepts were modeled and cured in an indoor environment with the mix of a water/cement ratio of about 1/3. The time difference between the models was about 1.5 years, and the tests and observations were done more than a half year after the second model was built. For preparing the test samples thin-sections have been done in the Micro lab of the TNO Delft in two consequent processes. The specimens were made by first cutting the samples to an appropriate size (ca. 0.5 mm), thereafter stabilization using resin impregnation under vacuum, and then cutting these into thin sections (25-30 μm) using a diamond roller (DBT) and grinder (Grinder/86). UV-light was used to cure and harden the resin whereby these could then be ground and polished. Observation and analysis of the composite on a micro-scale was undertaken using both polarized light and UV-fluorescence light microscopy. These are shown in the figure 2. a, b, and c. Moreover, the snapshots of the microscopic observations were made with different magnifications and are used here to show for comparison.

Figure 2. a, b, and c . parts of the sample preparation by impregnation and polarization.

4. Results

The produced composites (liquid phase and the solid phase) of sintered clay, which was mixed with an approximation, were lighter in weight in both cases. The weight difference is shown in the table 2

Model number one		Model number two	
Basic concrete	With expanded clay	Basic concrete	With expanded clay
100%	92.5%	100%	91.01%

Table 2. the comparative weight reduction in the different aged models

The other part of the main results from the tests and observations can be summarized as:

- Carbonation was observed, distributed irregularly. However, in the samples from the second model carbonation defected zones were relatively ignorable

- Model two (the younger model) showed a better zonnation around the lightweight aggregates in the matrix (i.e. figure 3. a, b, and c).

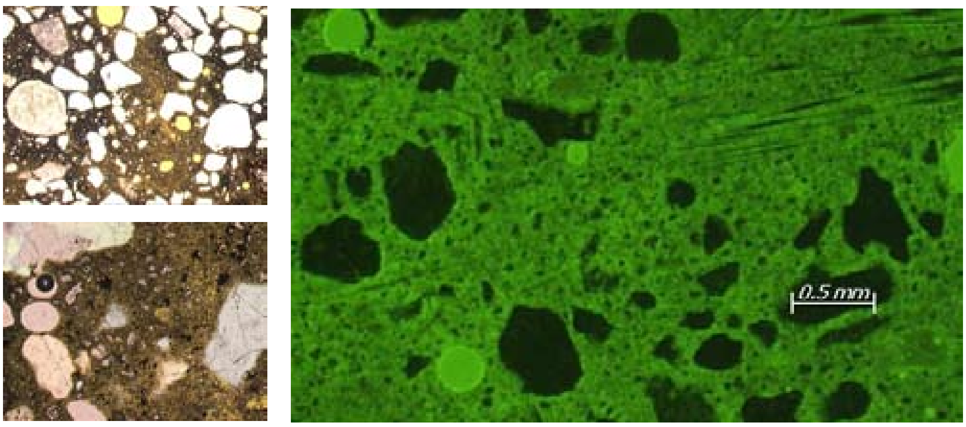

Figure 3. a, b, and c

- Porous zones are more distributed in the samples from the model one, in which carbonation was the consequence.

- Although the matrix in the second model was more homogenous (from the mix), the interfacial structure in the matrix between the expanded clay, fibers and the bulk was still heterogeneous and problematic (i.e. porosity)

- In the area around the expanded clay particles, some iron look areas were observed (i.e. figure. 4)

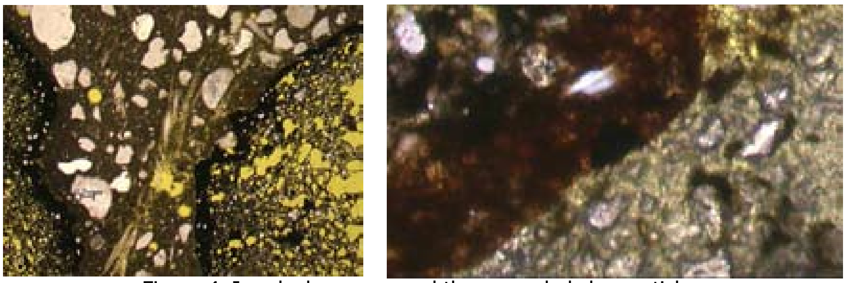

Figure 4. Iron look area around the expanded clay particles

- The compaction problem was not seen in the parts where fly ash was added in the mix neither the porosity problem. The results were homogenous bulks.

- Exceptional crack about 15 mm long was observed (i.e. Figure. 5), in addition to the partially distributed interfacial and internal curing problems in the model one.

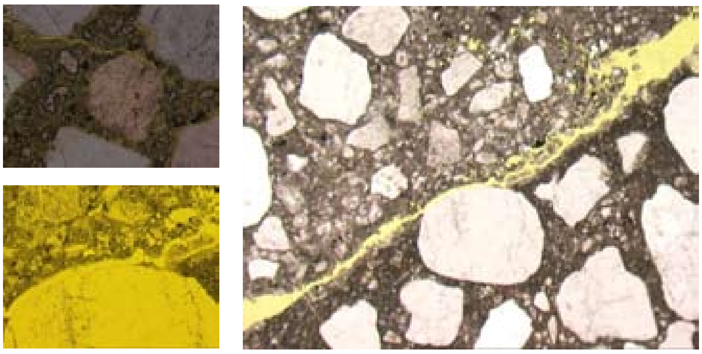

Figure 5. the exceptional crack observation in the microphotographs

6. DISCUSSION

Although seismicity is a big threat to the buildings, it is not the only important concern. The environment is a very important issue for the construction industry. According to the book of WCED (1987) and the Brundtland-report (UN, 1987) the construction industry is an important contributor in world's economy. It contributes on average 10% of GNP and about 50% of the capital investment in most countries world-wide (Durmisevic, 2006). CICA (2002) reported that the building industry includes the largest industrial employer with 111 million employees. In a global perspective the construction industry poses 40% of the air pollution, and 50% of the waste (Durmisevic, 2006).

Despite the impact that this industry may directly cause on the environment, it can highly influence some other aspects, ending in serious problems such as desertification. As a global problem, desertification threats a vast range of desert areas. This is a problem with which a land loses its biological potential 'ultimately leading to the desert condition' (Pachaury et at., 1997). For example the Sahara desert is expanding southwards, degrading grasslands at a rate of 30 mils every year. However, deforestation as an important phenomenon, which can also lead to the desertification, is happening in a larger variety of lands (than only desert areas). It can also ultimate the soil instability and consequently flooding (Kibert, 2005). Besides, with diminishing the forests (i.e. about 20 million hectares of rain forest are cut down every year), the amount of carbon emission, which can be stored in the trees' masses, releases in the air (CCAP, 2007). Thus, places that are located in the vicinity of deserts are considered as more endanger. Therefore, construction/ reconstruction in a desert land is highly sensitive and needs extra attentions. As the dominate buildings, design and materialization of houses in an efficient system will not only help the land from desertification, but also incorporates with the other aspects of sustainability (Shahnoori et al., 2008). With this, durability of the material plays a major role, because using durable materials can end with very efficient results such as decreasing in the depletion of the natural resources, air pollution, and the eco-costs.

As an available construction material in a large range of places in the world, concrete with the required mechanical properties is a durable material (Hendriks, 2002). However, a conventional concrete composite makes a rather heavy structure. On the other hand materials' weight is important because the structure (materialized with heavy materials) should carry more dead load. Besides, transportation and performance related costs increase as the weight increases (Beukers et al. 2005). Moreover, in seismic design for houses the weight can lead to additional problems such as more vulnerability of inhabitants in the next earthquake, when the structure meets the load bearing limits (Booth et al., 2004). However, as another important quality of concrete, this material is very flexible to be combined with some other materials to upgrade particular mechanical and other properties (Li, 2005).

Cement is the basic material in a concrete mix, which is responsible for most of the environmental impact (Hendriks et al. 2000) that is the main part of the impact of concrete. Because, in the conventional production process to produce one ton cement approximately1.25 ton carbon emission releases in the air (CCEC, 1993). Therefore, an important method that is being worked out is to find substitution materials for cement with the same or similar mechanical properties. This substitution material can also be lighter in weight than the cement, such as fly ash (Anderson, et al. 2007). Similarly to the study of Anderson et al. (2007) fly-ash used in this study models not only did not have negative influence on the durability of the concrete composites, but also the matrix in the areas around the fly ash particles showed a homogenous bulk, and no failure was observed. Apart from the specific properties of the fly ash, this can be assumed as a result of the lower water/cement ratio required for the workability of the concrete composite (i.e. using the fly- ash). Also the early shrinkage cracking and generally the cracking were relatively low (especially in the second model), and in the case of the exceptional cracking, large dimension cracks were not observed. One reason to introduce the micro or macro cracking and thus impairing the concrete quality is autogenous shrinkage (Lura et al. 2002). Therefore, using the fly ash in the concrete in the current tests similar to the study of Ridging et al. (2008) with reducing the heat of hydration of the cementitious materials may decline the risk of cracking.

Working on these substitution materials mostly concentrates on obtaining optimal mechanical properties such as strength while decreasing the cement in the composite. With which the fly ash is a good alternative as it results also in less weight for the final composite (van Breugel, 1999). Many of these materials (substitutes) are basically subjects to pollute the environment as they are counted as waste (i.e. mostly by products), such as blast furnace slag or silica fume. In about thirty years ago manufacturers who produced silica fume as by products had to pay for removing this by products from their site. However, regarding to the potential qualities, as the demand for this material has enormously increased, they are not counted even as cheap materials. Because for instance adding the silica fume to the mix increases the strength and reduces the porosity (Lura et al., 2002). However, it also increases the relative humidity (RH) drop in the mix (Jensen et al., 1996). Besides, as it was stated in the study of Jensen (1993) adding 6% silica fume to the pastes of different w/c ratio led to two times higher shrinkage (about 1000 μstrain vs. 500 μstrain, for w/c ratio 0.35). Therefore, to avoid carbonation problem in a normal situation it can be a good alternative substitution.

Another example that results in a more environmentally friendly approach for concrete producers, although it is not the focus of this paper, is replacing the aggregates (or reducing their ratio) with recycled items (Lauritzen, 1998). With this not only natural resources will be preserved (for more/future demands) but also processing and reusing the stony construction and demolition waste decreases the impact on the environment. For example it has been estimated that by the year 2002 in Europe, about 200-300 million tones of building and demolition waste was land filled or used in road foundations (Symonds, 1999). Using the recycled aggregate in a more efficient way is vastly increasing in some countries such as Japan and European countries by applying special policies. For example in the Netherlands in 1990 about 60% of this kind of waste was recycled, but after establishing the tax policy for the landfill, this amount increased to above 95% (Pietersen et al., 2002). However, this percentage was only used in the road construction, but since 1995 Dutch standard VBT (NEN 5950, 1995) recycled concrete (or mix) aggregates can be applied for 20% of the natural aggregates (Pietersen et al., 2002). Although, it has not been used in High Performance Concrete (HPC) properly, yet, for the concrete industry it is still a very efficient way to decline the negative impact on the environment (UEPG, 2006).

The weight of a concrete composite can also be lowered by appropriately replacing the aggregates as heavy segments in the mix (ESCSI, 2004). An alternative which is considered as a sustainable, available material is clay. Clay is available in a vast variety of places across the globe. If it is not being used in a huge scale, the use will result a sustainable construction (Videla et al, 2001). With great characteristics, clay can be worked out into different products for various applications such as Nano-clay, sintered and expanded clay. Moreover, because the materialization of the houses as a purpose of this study is being used for a seismic desert area, clay is an affordable material for using in the concrete composite. Besides it has a good thermal insulation capacity. However using various clay products (e.g. sintered clay) may have different effects on the concrete.

As several involved factors make the prediction of the durability of a concrete structure difficult (Jones et al. 2002), more investigations are necessary to increase reliability of this prediction. For example carbonation is not considered as a fatal problem for concrete (Yu et al., 2006). However, in a reinforced concrete structure it will defect the durability by generalizing corrosion, which induces failure of pre-stressing or generally the steel (Proverbio et al., 2002), mainly by depasivation. Passivating stainless is to remove the iron from the surface and create a nickel and chrome- rich surface that is not the subject to rust (Brwer, 2001). In the current tests, the porous areas around the clay particles which were appeared to be more dispersed in the older model (the first model of the concrete composite presented in this work) may be due to the characteristics of the sintered clay. The extremely fine particulate clay minerals (i.e. normal) and the activity of their surface generally increase the required water for the workability of the concrete. This is a reason that clay is supposed as a harmful material in the fine aggregates inside the concrete (Yool, et al, 1998). In the presented samples, although carbonated zones were almost dispersed in the older model, they were mostly concentrated around the lightweight aggregates, which can be assumed as a result of more permeability of the matrix due to the porosity.

As it was indicated before the carbonation- induced corrosion is harmful mostly for the steel reinforced concrete, where the moisture saturation level of the capillaries is suitable for supporting both CO2 ingress and steel oxidation (Jones et al. 2002). Therefore 2/3 of steel reinforced structures (which are exposed to the rain) are subjected for such corrosion (Parrot, 1996). With this background Hobbs et al. (1998) counted the service life of most reinforced concrete buildings structures to be governed by cover carbonation and subsequent reinforcement corrosion. On the other hand, the Concrete Society (1996) claimed that carbonation- induced corrosion is rarely catastrophic. However, this is a major issue in the tropical deserts (Shahnoori, 2000), but not for the dry desert areas. Jones et al. (2002) concluded that the potential carbonation resistant of concrete is dependant on permeation and alkalinity of the cover concrete. It can again be concluded that it is not harmful for the non-reinforcement segments (directly). Therefore, as this study is concentrated on using mainly fibers to increase the ductility of the concrete for an application in the seismic desert areas, this problem is not a fatal issue for such purpose. Although fiber-matrix interface problem was also observed, it was mainly due to the typology and geometry of the fibers that have been used, which is beyond the scope of the presented work.

7. Summary, conclusion, and recommendations

The sintered clay in the version that was used in these mixes resulted in relatively light weight concrete. The insulation capacity of the sintered clay is also considerable. However the durability of the concrete was susceptive to be influenced. Therefore, by using the sintered clay in the concrete for load bearing structural elements in seismic areas, apart from the strength, the durability of the concrete composite will not be guaranteed. For such purpose in a sustainable reconstruction further treatments may help to deprive the negative influences of the sintered clay on the strength and durability of the concrete composite. This needs further researches.

The positive effects of fly-ash (and silica fume) on the strength and durability of the concrete was also observed. Using fly-ash in the concrete mix for the structural load bearing purpose can result in a sustainable reconstruction. Besides preference of polymer and glass fibers than the natural fibers (i.e. no chemical treatment were used), inside the concrete mix, which was the subject of the former study, were observed. For these fibers longer fibers showed better potentials for durability to be used in such a composite.

ACKNOWLEDGMENT

Many thanks to Dr. Timo Nijland of the Micro-Lab, TNO Delft, for his generous supports, guidance, and helps. Thanks as well to Dr. Joe Larbi of the Micro-Lab, TNO Delft; Prof. Mick Eekhout for his supervision; and to the Hormozgan University for sponsoring this research program.

Keywords: Building Technology, Energy conservation, Sustainability issues, Building Services.

Summary

The built environment is an integral part of the infrastructure necessary for human survival. Current concerns over the environmental sustainability of our biosphere for future generations are being scrutinised on the fringes of the higher education. The focus of this paper is on the teaching approaches of academicians of a public university in Malaysia, specifically on the integration of building technology and sustainability issues into the subjects offered. Architecture teaching involves not only the teaching of art and aesthetics but also the science of building. With the increased use of high-rise construction, intelligent building features as well as the use of building services to make the buildings habitable, it becomes imperative that the students of architecture understand and appreciate the complexities of the engineering systems to make the buildings sustainable and energy efficient, so that their carbon footprint is minimal. The process of architectural design starts with the sketch design as well as a statement of design intent including sustainability and targets by the architectural student. At this point several major decisions are being made with respect to the orientation, fenestration, service cores, environmental control systems etc. These preliminary design decisions would affect the overall energy efficiency of the building as such. It is thus necessary for the architectural student to comprehend and assimilate advanced building technologies. This paper presents a novel approach adopted in the Department of Architecture at the University of Malaya for the teaching of Building Analysis to year 3 students as well as Advanced Building Technology to Year 4 students in a five year Architectural programme.

1. Introduction

Buildings are increasingly becoming more complex and more sophisticated due to advances in building technology, construction and engineering (Gyula Sebestyen 2003). Thus the Architect needs to depend upon a team of specialists who can handle the different aspects of the design and construction of the buildings. Unlike in the earlier days the architect and hence the architecture student should be aware of the latest technological developments and their adaptation for the successful design as well as running of the buildings

2. Architecture through the ages and the building envelope

The "Pre-Industrial" architecture was characterized by abundant resources and limited technology. During that period the architects necessarily had to use the building envelope as the modulator and filter for the harsh outdoor climatic conditions. The building envelope was the PRINCIPAL means of controlling the visual and indoor thermal environment in the buildings. The luminous environment in the buildings was by day lighting in most instances.[1] The "Industrial revolution" markedly changed the above parameters. The advent of new materials coupled with advances in mathematics, structural engineering, building services engineering etc., has immensely contributed to the growth of the modern day skyscrapers and intelligent

[1] We require from buildings, as from men, two kinds of goodness: first the doing of their practical duty well: then they be graceful in doing it. (John Ruskin: The stones of Venice,1851).

buildings. The exterior wall now simply becomes a member supported by structural framework at each floor. The exterior wall thus becomes a skin to exclude wind and rain water penetrations into the buildings. The concurrent developments in air-conditioning, lighting, lifts and escalators allowed the buildings to become deeper and deeper in plan as well as to be designed to greater heights (Fuller Moore, 1993, Gyula Sebestyen 2003)

The "Modern movement"[2] used the freedom thus gained by the technical and engineering developments to explore new building forms. Economy of structure, space, labour and construction became the characteristics of the new International style. The concurrent developments in the horizontal and vertical transportations in buildings allowed the buildings to be designed to greater heights. Hence the new buildings are designed to be heavily dependent on electrical energy for their sustenance. This can be construed as "energy dependent" architectural style (Fuller Moore, 1993, Gyula Sebestyen 2003)

3. Architecture studio teaching

In the Architecture Studio, Design projects are the main vehicle by which all the subjects taught in the lectures, seminars as well as from fieldwork are integrated to enhance the learning and creative design skills. (Esa 2002).Figure1 is a simplified illustration of the architecture educational process. The project becomes the central objective for students. (Tony Brown 2001)

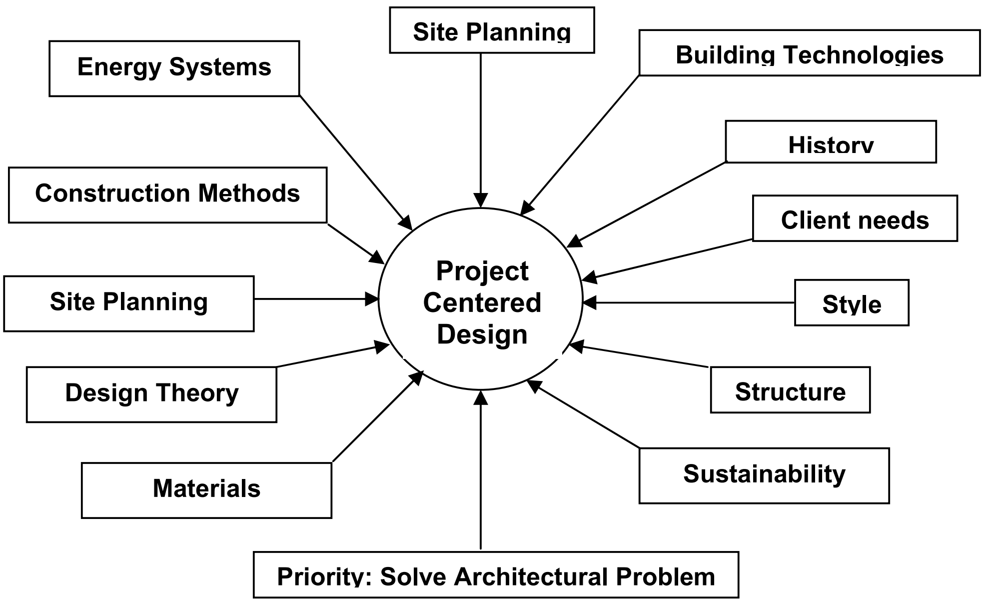

Figure 1 Architecture Studio Teaching Process (Tony Brown 2001)

Project based learning as a subset of Problem-Based-Learning techniques are often used in teaching as a method of achieving deep learning and simultaneous mature participation within the education process. Project-based techniques may range from the search for an optimal solution to precisely framed problems through to scenarios more akin to complex real life situations where the principal difficulty is one of identifying and framing the appropriate parameters (Peter Skinner 2002).

4. Teaching of sustainability issues to students of Architecture in the University of Malaya

The ambience in and around buildings is the result of the built environment. The responsibility for this falls squarely on the architect (Flynn et al, 1992). The extent and contents of the requirements has grown more complex in recent times as shown in Figure 2 ((Gyula Sebestyen 2003)

[2] This is expressed, perhaps, as the new spirit of the 20th century in the claim by Gropius that the designer was released at last from the "tyranny of the wall", which had become merely a boundary between the outside and inside of the buildings.

The architectural curriculum in the University is based on Design as a vehicle for integration of all the taught subjects. During the first three years of their course the students are given inputs on environmental physics, building structures, building materials, and construction as well as building services. As part of this exercise, students are set to solve practical problems, which would involve environmental sustainability issues. The students are encouraged to be proactive in their research and presentations. The students are taken on field trips as well as practising architects are invited to the studios to show how they tackle sustainability issues. The Faculty is fortunate to have eminent architects assisting the students to understand and design environmentally sustainable buildings.

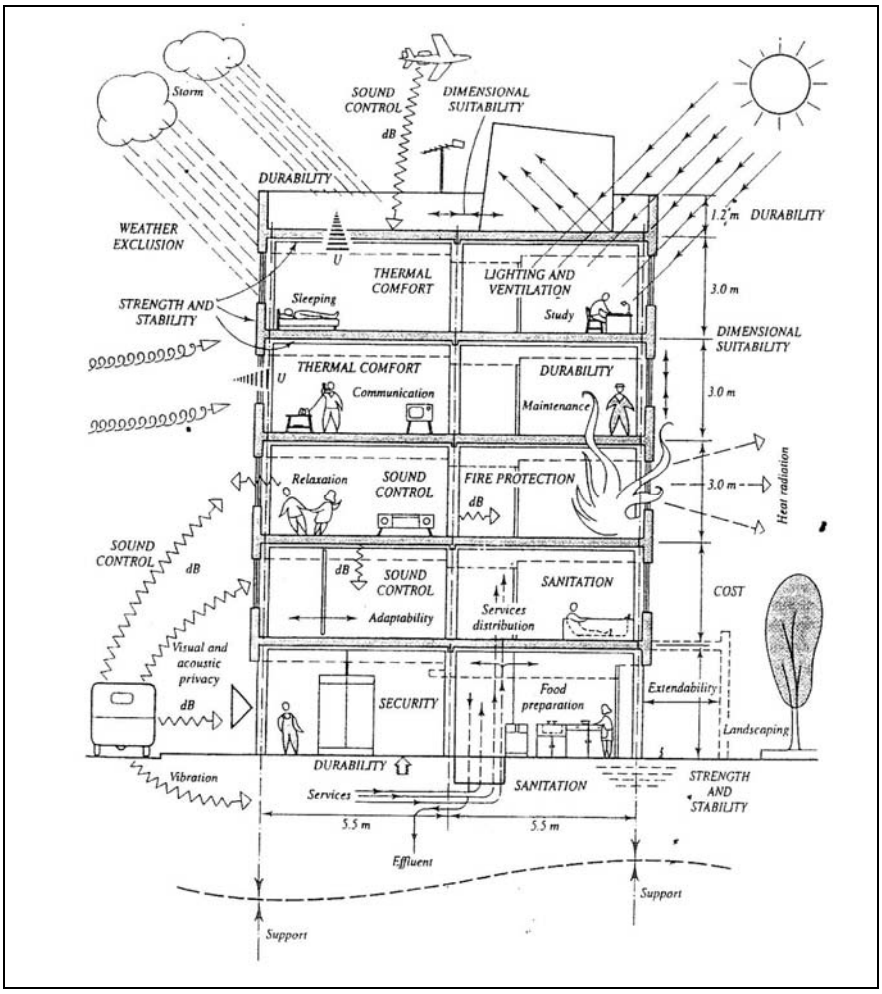

Figure 2 Performance requirements for buildings (Gyula Sebestyen 2003)

The University's research facility on renewable energy is to be used as a test bed to test new ideas in the future. The facility is being used at present to monitor the performance of some of the building integrated photovoltaics. The students are encouraged to have meaningful discourses in the studio setting for achieving an environmentally sustainable building.

In year 3 studio one of the assignments encourages the student to include the passive and active architecture aspects in their design showing the cause and effect of the sustainable features chosen to the occupant by doing virtual studies of their proposal. They are also exposed to site visits to the internationally known Low Energy Buildings.

5. Innovative teaching of Building Technology at the University of Malaya

The modern day skyscraper is dependent on energy resources and engineering services systems for its daily operations. These services are commonly grouped under the generic heading of "Building Services". Figure 3 shows some of the major components of the Building services for an Intelligent Building.

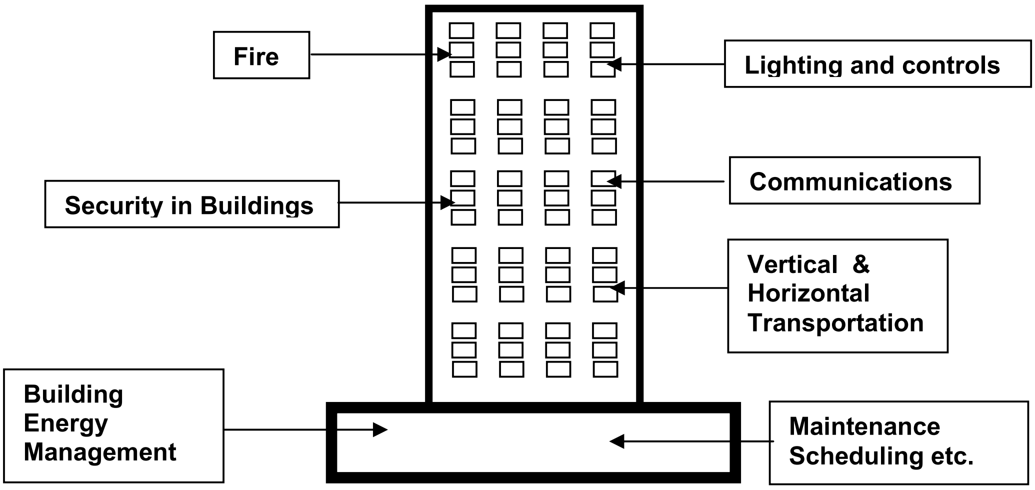

Figure 3 Components of an intelligent building

The scope, complexity, value, use and installation of the specialised building services machinery are increasing rapidly with the advent of the intelligent buildings. An architect is expected to have a basic understanding of the building services so that proper space allocations for plant rooms, ducting, cooling towers and other equipment are made during the initial design phase. Any miscalculations at the sketch design stage are detrimental to the servicing and maintenance of the buildings, leading to Indoor Air Quality (IAQ) problems in the buildings.

5.1 Building Analysis & Report

The arrangement discussed above seems to be satisfactory at first. The studio based assignment does achieve the object of integration. However, it was felt that the students were not benefiting fully from the programme, as it was largely left to the lecturers to integrate the assignments and lectures with the studio. The students were bogged down by the lectures rather than learning on their own.

One of the strategies adopted by the authors is to introduce a special subject 'Building Analysis & Report' in year 3. The subject is introduced in semester 6, the last semester of the first tier programme. It consists of two parts combined together in our effort to maximize the possibility of fulfilling the overall goal of integrating the various subjects.

To achieve the goal, this subject has been formulated with two objectives:

i) To train students in making critical assessment of an existing building from various aspects, covering site suitability, structures, environmental physics, method and detail of construction, use of materials, building services, landscape, etc.
ii) To give guidance in the preparation of a technical report that will accompany their Comprehensive Design Project, covering all the above aspects.

In consonance with the objectives, the subject combines the following two components,

5.1.1 Component 1

This component is a group work, for which students are divided into several groups, each comprising 4-6 persons. The formation of the grouping takes into consideration ethnic, gender and individual performance of the student to ensure that all the groups are more or less of similar composition and strength. Every group is required to select an occupied building of not more than 4 storey-high of acceptable complexity, which must have been in use for at least one year, since brand new buildings are considered unsuitable for this exercise. After their choice has been approved, students have to make a critical analysis of the building, covering all the above mentioned aspects. As a general guide to write the report, they should respond to the following questions and instructions, which by no means are exhaustive.

i. Explain briefly the function of the chosen building.
ii. Is it appropriately located on site in terms of orientation and context?
iii. Look at pedestrian movement, car parks and landscaping and give comments.
iv. How does the building respond to the tropical climate?
v. Is the structural system suitable for its function?
vi. What do you think of the construction of the building?
vii. How about the choice of materials?
viii. Study the engineering services used in the building
ix. Fire prevention and fire fighting systems etc., their strengths and weaknesses?
x. Suggestions to improve the sustainability aspects of the building?
xi. Are there any serious defects on the building? Is it because of the inappropriate choice of materials or faulty detailing?

The 'Building Analysis' exercise requires a holistic and comprehensive approach, which will inevitably touch on design issues. However, it is not meant to be a design analysis per se. The students' progress is monitored through weekly seminars and they are required to submit their report at the end of the seventh week. The product of this exercise will be in the form of a detailed report containing the building records, such as drawings, photographs, sketches, and an analysis that critically describes the coordination and integration of various aspects of building with the plans and elevations. Students are also required to give suggestions for the improvement of construction details that they consider to have caused problems or undesirable effects to the building performance and users. The analysis should contain not less than 5000 words, complimented with pictures and sketches with proper annotations. The power point version of the report will be used by each group in presenting their work in a series of seminar conducted during the second half of the semester.

5.1.2 Component 2

This is an individual work in the form of 'Technical Report' that every student shall prepare during the second half of the final semester and hand in at the end of the 15th week. Having gained experience from the preparation of 'Building Analysis' previously, he/she is expected to be able to write the report that will complement his/her Comprehensive Design Project (BAEA 3276) which is meant to be the culmination of his/her project solving ability at the end of the first tier programme (Part 1 level of the Malaysian Board of Architects as well as Part 1 RIBA)

The report shall contain,

i. Site analysis and site studies
ii. Project brief/Client brief
iii. Compilation of initial sketches, concept/intention, massing and photos of initial models
iv. Summary of relevant clauses in Uniform Building Bye Laws related to the building needs
v. Building purpose group, travel distance, fire fighting appliances, etc.,
vi. Local Authority's guideline concerning planning, plot ratio, plinth areas, parking
vii. Calculation of plot ratio, plinth areas and parking requirement of your project
viii. Land use diagram, site planning and landscape
ix. Building services: water, electricity,& electronic, sanitary, telephone, lift & escalator, solid waste disposal system, etc.(Drawings must be in ACAD).
x. Structure and Elevation studies
xi. Interior design
xii. Photos of final model in context

5.2 Advanced Building Technology

The aims of teaching technology to the architecture students in the upper years can be itemised as follows,

- To explore and understand technological possibilities and limitations,
- To learn various aspects of building design and construction
- To integrate technology into design and
- To understand the roles of consultants amongst others.

There has been a conscious effort to integrate technology subjects into architecture design in recent years (Lim 1999, Rao et al 2003). Specialist technology tutors have been traditionally invited into the studio to understand and aid the design process. The mathematical content of the technology subjects are kept to a minimum and integration and exploration of technology subjects are encouraged. At the Department of Architecture, Advanced Building Technology has been traditionally taught over two semesters at the Year 4 level. During both the semesters, the students are given eight lectures on specialist topics by in-house lecturers as well as by visiting experts and from the trade. The students are also taken on site visits and are required to complete two assignments during the semester, to show their understanding of the design and operation of tall buildings under the Malaysian climate. One of the assignments is set in the context of studio design.

Starting from academic year 2004-2005 onwards, it was decided to bring all the lectures for the building technology to semester one. Thus, the students will get concentrated inputs on building services, structures and construction technology. Various specialist lecturers were invited to talk about their specialities and its application to the high-rise building with special reference to Malaysia. A simple 2-week assignment was set to understand the concept of service cores and their utilization. A second assignment was set in the context of Putra Jaya, the new administrative capital of Malaysia, to give a feel for technological developments.

In the Second semester, the students were introduced the innovative teaching of technology subjects. Figure 4 shows the buildings that have been utilised for the study since 2004, they are: the Securities commission building, the Telecom Tower, the Putrajaya Convention center and the Low energy office building in PutraJaya.

The Securities Commission Building Kuala Lumpur, Malaysia	The Telecoms Building Kuala Lumpur, Malaysia	Putra Jaya Convention Center, Putra Jaya, Malaysia	Low Energy Office Building Putra Jaya, Malaysia

Figure 4 Buildings chosen for study for advanced building technology since 2004.

These are very unique buildings both for their architecture as well as for their innovative technological features. Three of the buildings have won international awards for energy conservation and for innovative design features. The technology aspects of the buildings were itemised and introduced to the students in the inaugural session. The students do a study of the overall building and its design as well as to individually do a deeper study of their chosen topic. The students had to organise their study methods and site visits. They have to liaise with the various consultants and specialist contractors. All this has to occur within a period of eight weeks. The students regularly meet-up in a discussion session with the coordinators once every two weeks to discuss the materials collected, analyse their utility and share the knowledge across the class. The coordinators acted as facilitators and gave directions for further work as well as explained any new concepts and ideas the students encountered. The students have milestones and targets to meet during the semester. The whole process is perceived to be a student-led educational adventure and learning experience.

6. Conclusions

A new and innovative concept of teaching advanced building technology is described. The students are required to do an in-depth study of a building with reasonably complex structures, services as well as construction features. They have learned fast and seemed to find the teaching process more exciting and useful. The teaching process has met its intended objective of creating enthusiasm and excitement for learning of technology amongst the students. The students appreciate the building technology aspects of design as it is based on a real building ably assisted by the consultants and experts involved in its design as well as in the operation of the building.

7 Acknowledgements

The authors acknowledge the assistance given by Hijjas Kasturi Associates, SNO Architects as well as the various consultants and maintenance engineers involved in the projects. Acknowledgements are also made to the students involved in the teaching process for their unstinted cooperation and enthusiasm.

Keywords: Sustainable buildings, Partial air-conditioning, total energy systems.

Summary

Tropical climates are thermally uncomfortable and are mostly unhealthy to the occupants of the modern skyscrapers, both residential and commercial buildings. The outdoor air dry bulb temperatures are on the hot side coupled with high relative humidity's. The population living in the tropics, especially in countries like Malaysia, is affluent and can afford to air-condition their residences and offices. Installation of air-conditioners is almost synonymous with prestige. This way of living leads to increased electricity usage and energy consumption in the buildings. However, switching-off the air-conditioning is not an option for the modern day buildings, as it would affect the health of the people as well as their productivity. This paper proposes innovative indoor units that will contribute to energy conservation by utilising principles of partial air-conditioning. The outdoor units could be utilised for clothes drying or for providing hot water to the occupants of the building of residential buildings, thus reducing the energy requirements in the buildings. Thus the utilisation of partial air-conditioning will lead to enormous savings in energy consumption in the buildings.

1.0 Introduction

In the humid tropical climate of Malaysia, the differences between indoor and outdoor air temperatures are not high. Sun is the single most important natural element to be considered in the building design. It affects almost every design decision and has a direct impact on the energy budget of the building. Thermal Comfort analysis may be used to assess a given environment and is important in determining an energy management strategy in buildings. The human body temperature regulation determines the physiological thermal comfort of the occupant of a room, as the human body exchanges heat with the environment. Heat is exchanged by radiation, convection and evaporation. The heat is primarily produced by metabolism. During normal rest and exercise, this results in an average temperature of the vital organs of near 37 deg C. The body's temperature control system tries to maintain this temperature in the varying thermal environment.

2.0 Climate of Malaysia

The main features of a hot-humid climate like that of Singapore and Malaysia are the relatively uniform temperatures, small variations in the diurnal temperature variations (approximately 7 deg C). However the associated high relative humidity is high. Also, there is abundant rainfall due to the maritime exposure and proximity to the equator. Throughout the year the temperatures are fairly uniform. The mean monthly temperature does not vary by more than 1.1 deg C from the mean annual value of 26.6 C. The average diurnal variation of temperature is about 7.0 deg C. Excessively high or low temperatures are rarely experienced. For the period 1934 to 2007 the highest temperature recorded is 35.8 C and lowest is 19.6 C. The mean annual R.H. over the period 1934 to 2007 is 84%. However, there are large diurnal variations from 60% to 95%. The mean daily maximum and minimum values are 96% and 64% respectively. There are no distinct seasons and rainfall occurs during every month of the year. December is usually the wettest month of the year with an average monthly rainfall of 280 mm and July if the lowest with an average monthly rainfall of 160 mm.

Thus, the salient features of a hot-humid equatorial climate are,

- high rainfall and high humidity, associated with a low diurnal range
- a relatively high and even temperature throughout the year

- light winds and long periods of still air
- high radiation intensities.
- rain usually in afternoon often accompanied by violent thunder-storms (Sumatra's)

2.1 Solar radiation intensities (Lim et al, 1979, Rao 1994)

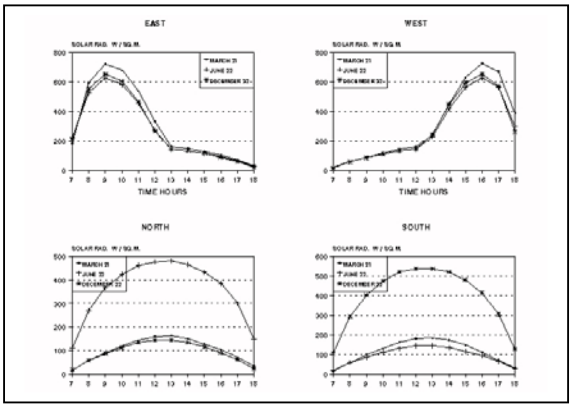

Figure 1 Typical Solar Radiation Intensities in Singapore measured data (Rao 1994)

Figure 1 shows the measured solar radiation intensities for Singapore. Table 1 (Mohamed Ali. 2004 and Malaysian Meteorological Office) is a summary of 30-year average of dry bulb temperatures, relative humidity's and mean wind velocities for various months in Kuala Lumpur, Malaysia. It experiences high relative humidity, varying from 67% to 96 % with an average value of around 80%. The outdoor air temperature varies from 24 deg C to a maximum of 33 deg C. There is no dominant wind direction.

TABLE 1 Monthly Means of Outdoor Air Temperatures, Relative Humidities and Wind Speeds Kuala Lumpur, Malaysia. (Mohamed Ali. 2004 and Malaysian Meteorological Office)

	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Mean Temp.deg C	26.9	27.2	27.5	27.6	27.7	27.8	27.3	27.3	27.1	27.0	26.6	26.6	27.23
Mean Max. Temp deg C	32.5	33.3	33.5	33.5	33.3	33.1	32.6	32.7	32.5	32.5	32.1	31.9	32.79
Mean Min. Temp deg C	23.1	23.4	23.8	24.2	24.3	24.1	23.7	23.7	23.6	23.7	23.6	23.3	23.71
R.H %	78.4	78.2	79.3	81.5	80.6	78.9	78.9	78.9	80.6	81.6	83.6	81.9	80.20
Mean Wind Speed (m/s)	1.02	1.10	1.06	1.00	1.00	1.07	1.17	1.15	1.03	1.16	0.97	0.90	1.05

2.2 Thermal comfort in the Hot-humid climate (Ellis 1953, Humphreys 1975, Lim et al 1979,Mohamed Ali 2004, Rao et al 1979,Rao 1993, Webb 1959)

Creating a thermally comfortable environment is one of the parameters to be considered when designing buildings. Thermal comfort has been defined as the condition of mind that expresses satisfaction with the thermal environment. The reference to mind emphasises that comfort is a psychological phenomena too. There is a wide variation in thermal requirements and in thermal sensitivity between individuals in a given group. The aim should be to create conditions for optimal thermal comfort to satisfy the highest possible percent of the group. Probably at best only 80% of the occupants would be comfortable at any one time under the best possible conditions. The individual differences in preferred temperatures would arise in part from the differences in the clothing, activity and acclimatisation to the local climate. Hence results of comfort studies made elsewhere may not necessarily be applicable to the Malaysian conditions.The factors, which affect indoor thermal comfort, are the air dry bulb temperature, humidity, air movement and solar radiation. In order to combine the effect of these factors several thermal comfort indices have been proposed. These indices attempt to combine the effect of two or more variables into a single variable on humans. Several such indices have been developed for the tropical climates.

2.2.1 Thermal comfort studies in Malaysia (Abdul Malik et al 1993, Zain Ahmed 2000, Mohamed Ali 2004)

For comparison purposes, the results of the criteria from several sources are summarized in Table 2. For example, the temperature range obtained from Zain is between 24.5-28.0 deg C, which is lower than Abdulmalik, but higher than the range suggested by the Ministry of Energy, Telecoms and Posts [13]. This table comprises eight thermal comfort studies, four of which have been carried out on Malaysians either in climate chambers or as field studies. The outcomes of the studies differ slightly due to different test procedures. However, most of the studies seem to agree on a Malaysian comfort zone of around air temperature of 25 deg C.

Table 2 Thermal Comfort Studies in Malaysia (Mohamed Ali. 2004)

Study	Comfort Zone (°C)	Type of Study	Humidity range (%)	Air Velocity (m/s)
Zain Ahmed	24.5-28.0	Field Study	72-74	0.3
Abdulmalik	25.5-29.5	Climate Chamber	45-90	-
Davis	24-28	Field Study	-	-
Ministry of Energy, Telecom and Posts, Malaysia	22.0-26.0	Field Study	-	-
Abdul Rahman	27.4	Climate Chamber	54 -76	0.1

3.0 Air-conditioning

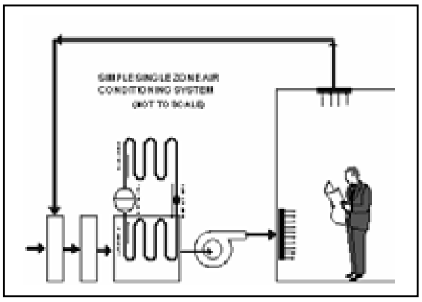

Figure 2 Simple Single zone air-conditioning system

Air-conditioning is defined as a process that heats, cools, cleans and circulates air and controls its moisture content. Ideally, it does all these simultaneously and on a year round basis. Thus air conditioning makes it possible to change the condition of the air in an enclosed area. Figure 2 shows a simple air-conditioning system.

3.1 Chilled water air-conditioning systems for typical tall building structures

Figure 3 shows a schematic layout of a chilled water system. In this system heat from air passing through the air-handling unit is collected by chilled water and is transferred to the refrigerant passing through the evaporator coil. The heat from the refrigerant is transferred to the cooling water in the condenser. The cooling water carries the heat away to the cooling tower where it is dissipated in the atmosphere. Thus the chilled water system is an indirect system where the refrigerant chills water, which is then circulated through pipe work to the air-handling units which can be located anywhere in the building.

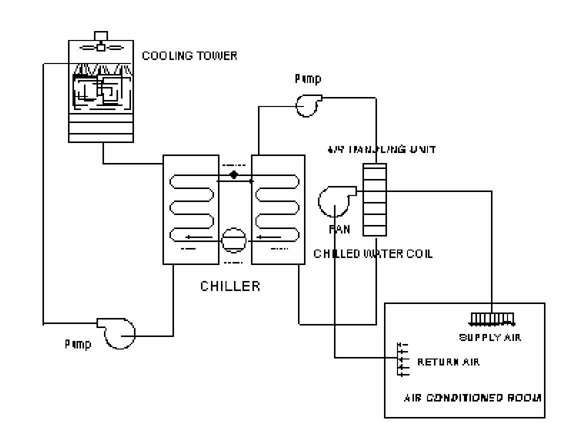

Figure 3 Chilled water air-conditioning system

3.2 Air-conditioning for residences in the hot-humid tropical climate

Figure 4 A typical split-system air-conditioning system for both high-rise and low rise residential units

Almost all of the split system air-conditioning units utilise the mechanical vapour compression refrigeration cycle shown in Figure 2. The split unit system contains two major elements: one is the indoor unit that blows the cool air, called fan-coil unit, second is the outdoor unit as shown in Figure 2, called a condenser unit. These two are linked with copper piping that carries the refrigerant gas. The out door unit work as chillers, where the refrigerant is compressed and pumped back to the indoor unit. The outdoor unit contains an electric motor to blow away the heat as a result of the mechanical vapour compression of refrigerant. It is worthwhile to study the various potential of this reusable energy, as it is has significant impact on the architectural design and environment such as in Malaysia

4.0 Concept of Partial air-conditioning

This section investigates the possibilities of raising the set temperatures in the air-conditioned space with appropriate increase in air-velocities by supplementary fans, without sacrificing occupant thermal comfort.

4.1 Cooling effect of air movement (Aynsley 2006)

The manual of Naval preventive medicine covers the cooling effect of air movement on people. Figure 5 is redrawn from the original, amplifying the region of air velocities of 0 to 2 m/s. There are several other sources indicating the cooling effects of air movement.

Figure 6 shows the effects on the Predicted mean votes (PMV) due to air movement at various dry bulb temperatures for air velocities of 0.1 m/s and 0.3 m/s. It can be observed that the DBT can be raised to 25 deg c in an air-conditioned office, provided the air velocity is held at 0.3 m/s. This will reduce the energy for cooling the supply air. This is the concept of partial air-conditioning.

Large ceiling fans can mix the air in atria to a uniform temperature. Aynsley (2006) demonstrates a system of de-stratification fans in an air conditioned atrium as shown in Figure 7.

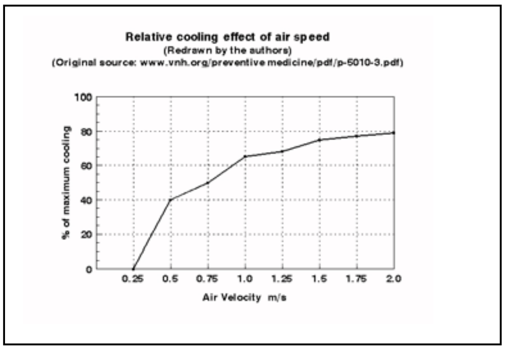

Figure 5 Relative cooling effect of air speed (redrawn from www.vnh.org/preventivemedicine, p3-7)

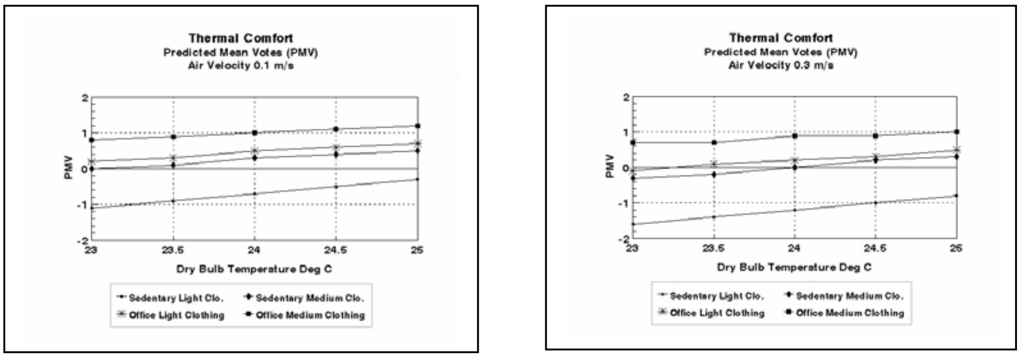

Figure 6 Predicted Mean Values for air velocities of 0.1 m/s and 0.3 m/s (based on Fanger 1972)

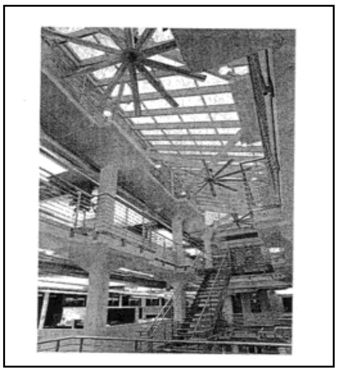

Figure 7 De-stratification fans in an air conditioned atrium (Aynsley, 2006)

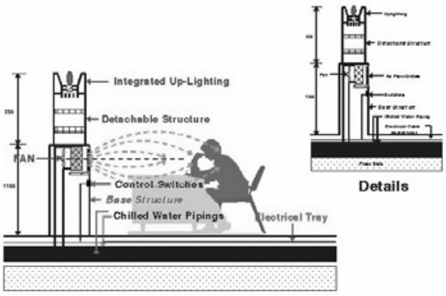
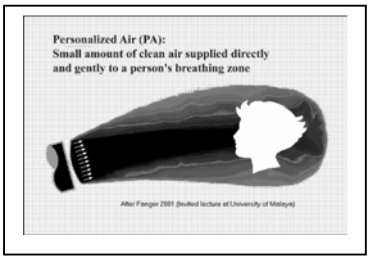
4.2 Modified personal air-conditioning fan-coil units (Personal air-conditioning Systems) for effective partial air-conditioning

The concept of partial air-conditioning is proposed by the authors to provide adjustable personal environments to individual work stations in open plan offices. This involves the provision of individual air-conditioning outlets and delivery systems. Personal air-conditioning allows every office worker to gain control over their immediate thermal environment (Fanger 2001, Pan et al 2005). The air is delivered at a slightly higher velocity of 0.3 m/s and at a dry bulb temperature of 25 deg c at 60%R.H. The office worker could be provided with controls to control the air temperature as well as the air speed. As shown in Figure 6, this will still be within the thermal comfort zone as it is closer to PMV values of +1.00, which is comfortably warm. This would lead to conservation of energy by reducing overcooling of the space. This concept has been reinforced by the latest statement by Rob Traynham about the new Nissan headquarters in USA “Air conditioning and heat are controlled through outlets at each work station: You heat the people and not the space” (Yahoo News: Nissan goes green in new US headquarters, 8 March 2008). This firmly reinforces the authors' proposal of partial air-conditioning with the delivery of the conditioned air directly at the workstation and not through the conventional ceiling outlets. Figure 8 demonstrates the modified fan-coil units for air delivery at the work stations.



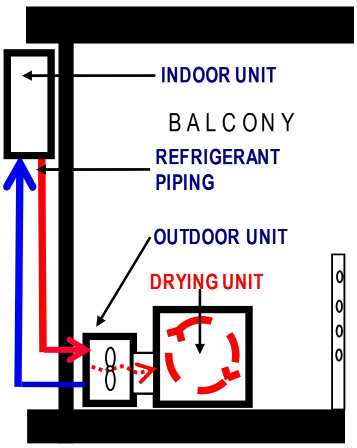


Concept of personalised air delivery (after Fanger 2001)

Figure 8 Personal air-conditioning for office work stations (authors proposal)

5.0 Using the waste heat from the condenser for drying clothes in residential units.

Currently the out door units are installed at the discretion of installer. The maximum length of the refrigerant copper pipes governs the limit of furthest distance. Usually there are no problems in selecting the location for the outdoor unit for the detached houses. It is easy to gather outdoor units together to collect the hot air from it. In comparison to the apartment unit, the designer usually would allocate a drying yard near the kitchen for laundry or general cleaning facilities. Out door unit could be placed in the drying yard and if the waste heat is channelled properly to help speed up drying the laundry. Tests have shown that temperature of the waste heat is about 40 ° C with the corresponding humidity of about 38 %. (Zunaibi et al 2002 and Rao et al 2005). Placing the outdoor units in the yard will help in reducing the number out door unit arbitrarily installed on the building facades. The average size of out door unit for 3 TR air-conditioning split unit systems is 1030x850x 400mm. Individual units of drying facilities can be placed in the drying yards. Re-channelling by capturing the hot air could reduce to muffle the noise created by the units. One unit of 1 hp outdoor unit could produce a noise level of about 60dB



CONCEPT:

- It consists of a standard commercially available electrical tumble-dryer unit.
- The heater module is disassembled from the tumble-dryer.
- This modified tumble-dryer is coupled with the condenser unit of the split system, by using suitably designed ducting.
- The whole assembly is designed to be arranged in the balcony to provide an aesthetically pleasing environment.

Figure 9 Use of condenser units for drying clothes in an apartment unit.(Zunaibi et al 2002, Rao et al 2005)

6.0 Conclusions

This paper proposes an innovative concept for the indoor units that will contribute to energy conservation by utilising principles of partial air-conditioning coupled with the personal air-conditioning systems. It has been proven that the air dry bulb temperatures can be raised upto 25 deg c with an accompanying air velocity of 0.3 m/s This does not compromise thermal comfort of the occupants of the office spaces. Because of the increase in the set-point temperature there will be a corresponding reduction in the air-conditioning cooling loads, leading to energy conservation. Also, the outdoor units could be utilised for clothes drying to the occupants of the residential buildings.

This will lead to enormous savings in energy consumption in the buildings and can be summarised as follows,

i. The utilisation of the principles of partial air-conditioning will lead to savings in energy for air-conditioning.

ii. There is no need for the Air-handling units (AHU) as they are no longer required. This saves valuable FLOORSPACE in a building.

iii. There is no need for the false ceiling, as there are no air-conditioning ducts. This will lead to a better interior architecture as the ceiling spaces can be exposed. The space saved can be utilised to provide additional rentable space in the building, for a given plot ratio.

iv. The personalised air-conditioning system is the most energy efficient system. The system will guarantee the best possible indoor air quality to the occupant of the space. (Most healthy environment).

v. Gives freedom to the architects and interior designers of office buildings to organise the workstations more efficiently. This in turn, will lead to better aesthetics.

vi. The waste heat from the Split-system air-conditioning units in residential units are used to dry clothes. This will eliminate electricity consumed for drying clothes in a tumble dryer. Also, it will lead to a more aesthetically pleasing building exterior. This will lead to a better quality of life for the residents

SOCIAL INDICATORS FOR SOCIAL HOUSING PROJECTS IN BRAZIL

CARVALHO, Michele Tereza Marques MS.c[1]
SPOSTO, Rosa Maria, Dra.[2]

[1]PhD student of the Postgraduate Course of Structures and Civil Construction, University of Brasília, Brasília, Brazil, micheletereza@brturbo.com.br
[2] Professor of the Postgraduate Course of Structures and Civil Construction, University of Brasília, Brasília, Brazil, rmsposto@unb.br.

Keywords: social indicators, social housing projects

Summary

A worldwide need to solve problems related to social housing has been observed alongside the evolution of the concept of sustainable construction. In the majority of Latin American countries, social housing is produced by informal self-construction. This fact highlights the importance of encouraging the community's participation and strengthening as well as the formalization of constructive processes, materials, and local components in order to provide greater environmental comfort at a low housing cost. This paper aims to develop and reveal social indicators for social housing projects in Brazil according to the local reality by means of categories of essential and characterization criteria. The results shown will provide data for the development of an evaluating tool for social housing projects.

1. Introduction

Agenda 21 charter for sustainability in developing countries such as Brazil shows the necessity of reducing social and economic inequality as well as the crucial necessity of balance between environmental costs and benefits.

As far as Brazil's sustainable development is concerned, it is necessary to correct one of its most noticeable social problems: the lack of low-income population housing. Furthermore, there is a need to integrate the various dimensions of sustainability - social, economic, environmental, spatial, and cultural - in order to produce social-interest housing. Only then the solution would be effective and efficient, providing performance optimization throughout the housing's useful life.

According to Choquil (2007), in order to solve the problem of sustainable housing and to make it economically viable, socially acceptable, and characterized by a workable and environmental compatibility with housing policies, the following are required: (1) Community participation in all stages in search of cost reduction, satisfaction of all those involved, and quality guarantee; (2) Good quality material and accessible costs related to environmental preservation; (3) Minimum performance standards such as health, hygiene, fire performance, flexibility, and security demands; (4) Elongated funding; and (5) Proper land availability for construction by means of social soil recovery. Such standards may be obtained by indicators.

ISO/TS 21929-1 (ISO 2006) defines *Indicators* as elements which are able to extract simplified information from complex phenomena, such as social, economic, and natural impacts, in a relatively easy way to use and understand. The main functions are quantification, simplification, and communication. According to OECD (1993), an indicator is directly related to a value.

An indicator needs to be relevant and its value needs to be found by appropriate ways, thus capturing tendencies to inform decision agents such as managers, employees, and designers; guide the development and monitoring of policies and strategies; and facilitate the report of measures adopted when establishing the sustainable construction.

This study has as its main objective the establishment and presentation of social indicators for Social Interest Housing (HIS) in Brazil.

The performance indicators set by this study have the purpose of evaluating social interest housing projects and allowing comparisons between individual projects.

2. Social Indicators

According to Silva (2007), sustainability indicators first appeared internationally as a response to Agenda 21. Several levels of indicators were established: national indicators OECD, UN, World Bank, CSD[1]); civil construction sustainability sectorial indicators (CIRIA[2], CRISP[3]); organizational sustainability indicators – construction and design companies (Global Reporting Initiative Guidelines) and project/building indicators (LEED, BREEAM, GBC). Indicators defined in more restricted evaluation spheres have to be aligned to indicators and goals of sustainable development on both national and worldwide levels.

Social themes for sustainable construction in the United Kingdom are: (1) Respect to staff: (1.a) effective training provision and staff evaluation; (1.b) equality of terms and conditions; (1.c) equal provision of staff opportunities; (1.d) health, security, and appropriate work conditions; (1.e) support for staff morale and satisfaction; and (1.f) participation in decision-making; (2) Relationship with local communities: (2.a) minimization of local disturbance; (2.b) construction of effective ways of communication; (2.c) contribution to the local economy; and (2.d) delivery of buildings and structures that improve the local environment; (3) Establishment of partnerships: (3.a) construction of a long-term relationship with clients; (3.b) construction of a long-term relationship with suppliers; (3.c) corporative citizenship; (3.d) conclusion of buildings and structures that increase satisfaction, welfare, and value for clients and users; and (3.e) contribution to global sustainable development (CIRIA, 2001)

At building level, ISO/TS 21929-1:2006 (ISO,2006) defines a framework for sustainability indicators for buildings based on the premise that sustainable construction achieves the required technical performance of the construction with minimum environmental impact. At the same time, sustainable construction encourages economic, social, and cultural improvement at a local, regional, and global level.

Social indicators are used to describe how buildings interact in relation to themes regarding sustainability with the local community[4]. As for social aspects, ISO/TS 21929-1:2006 (ISO,2006) suggests that indicators should consider the following themes: (1) quality of buildings as a place to live and work; (2) building-related effects on health and user safety; (3) barrier-free use of buildings; (4) access to services needed by users of a building; (5) user satisfaction; (6) social cohesion and participation of users and other interested persons in the building process; (7) architectural quality of buildings; and (8) protection of cultural heritage, which may also be expanded.

Mahammad and Amato (2006) have defined sustainability indicators for public housing in Hong Kong and established a criterion that determines a great area of concern subdivided in specific key questions, such as: (1) Social preconditions for ecological sustainability (values, habits, rules, lifestyle, environmental consciousness, regulations); (2) Equitable housing distribution and consumption (housing equity, housing standards, affordability, government role, housing subsidy policies); (3) Harmonious social relations (landlord and tenant relationship, existing or not relationships, housing subsidy policies); (4) Quality of housing and living environment (internal housing conditions, immediate environment); (5) Cultural preconditions conducive to environmentally sustainable housing (values, habits, rules, lifestyle, environmental consciousness, regulations); (6) Acceptable quality of housing conditions (internal housing conditions, immediate environment); (7) Preservation of housing heritage (internal housing design, external housing design, housing structure, reflection of the way of life of people from past to present, cultural identity, collective memory, and location of a contemporary society in its traditional context).

Benett and Sattler (2004) performed a research amongst low-income families in Brazil in order to identify popular housing sustainability indicators. The following themes were pointed out for

---

[1]Internationally, CSD Theme Indicator Framework organizes indicators into four dimensions (social, environmental, [……])

[2]CIRIA - Construction Industry Research and Information Association. Sustainability indicators for construction industry in the United Kingdom (CIRIA, 2001).

[3]CRISP - Construction and City-Related Sustainability Indicators. Sustainability Indicators for construction industry in the European Union. (CRISP,2001)

[4] [4]Community-level issues which may be relevant are urban sprawl, mixed land use, access to basic services including public transport, availability of green and open space, attractiveness of city centers, development of brownfields, housing availability, social segregation, cultural quality and protection of cultural heritage, safety, noise, and air quality. (ISO,2006)

social indicators: public transportation, security, public phoning, nurseries, and medicine access.

This study reveals the necessity to include social and cultural indicators in project decision in order to avoid a series of problems concerning management, conservation, and maintenance of housing projects, as well as a need to reach an improved quality of life for the people involved.

3. Method

In order to obtain the proposed indicators, an extensive research has been done through this project, taking in account national and international authors, looking for reported concepts on this subject, and after some questions related to social aspects have been formulated:

1- What existing necessities concerned to social aspects are to be contemplated?

2- How can social aspects be measured?

3- Are social aspects applicable in social-interest habitation?

4- Are social aspects applicable in project phase?

5- Can these aspects be arranged in a checklist form?

All aspects which have obtained positive answers were joined in categories and subcategories, like one can see in table 1.

Table 1 Division in categories and subcategories of the selected aspects

Category	Subcategory
Social	1.Infra-structure 2.Comfort and health 3.Quality of product/habitation 4.Relashionship with local community 5.Participation
Cultural	6.Cultural heritage
Political/ Institutional	7.Public policies 8.Environmental education
Generating income and social responsibility	9.Construction companies 10.Designer companies 11.Sellers to enterprises of projects 12.Users
Security	13.Security

Inside each category, questions (subjects) were developed to check how the project contemplates the selected aspects, as exemplified in table 2. The next step in order to set the indicators was to define a essential criteria of determination and characterization [5], like below:

Table 2 Example of questions (subjects) defined to each subcategory

Category	Subcategory	Subjects
Social	4.Relashionship with local community	4.1 Are there coexistence grounds to stimulate the community strengthening and coexistence? 4.2 During the project execution, have social relationship promotions been done? 4.3 During the project execution, have the cohesion among social necessities been reached? 4.4 Has the neighborhood analysis to implant the entrepreneurship been done? 4.5 Does the entrepreneurship bring benefits to the neighborhood? 4.6 Is the entrepreneurship to be implanted harmonious with the neighborhood?

[5] Essential criteria: were obtained from positive or negative (yes/no) answers; characterization criteria: are obtained from quantification answers.

The indicators were obtained from this criterion: the essential indicators are that ones measured according to quantity of positive answers (yes) among total number of questions. The characterization indicators were obtained from quantifications, of questions, in math fractions, like, for instance: number of bus stops and distance between them. The objective of obtaining characterization indicators is to develop *benchmarks*.

In brazilian specific case, the number of questions (subjects) defined to each subcategory are shown in tables 3 to 7. This quantity can vary according to local necessity, goals established to reach continuous improvement and excellence and sustainability standard aimed.

4. Results

4.1 Essential Indicators of Social Category

The essential indicators of social category are defined and shown in table 3, which vary from zero to one.

Table 3 - Essential indicators of social category

Indicators	Equations [1]	Number of questions (subjects) for each subcategory
4.1.1. Infra-structure indicator (IF)	$IF = QS/QT$ (1)	11
4.1.2. Health and comfort indicator CS)	$CS = QS/QT$ (2)	9
4.1.3. Quality of product/housing indicator (QP)	$QP = QS/QT$ (3)	10
4.1.4. Relationship with the local community Indicator (CL)	$CL = QS/QT$ (4)	6
4.1.5. Participation indicator (P)	$P = QS/QT$ (5)	8

[1] being:

QS= Number of answers 'YES' obtained from subject questions.
QT= total number of questions.

The indicator of social category is defined in equation (6):

$$Social\ indicator = \frac{IF + CS + QP + CL + P}{5} * 100 \qquad (6)$$

4.2 Essential Indicators of Cultural Category

The essential category of cultural indicators are defined and shown in table 4, which vary from zero to one.

Teble 4 – Essential indicators of cultural category

Indicators	Equations [1]	Number of questions (subjects) for each subcategory
4.2.1.Cultural heritage indicator (HC)	$HC = QS/QT$ (7)	8

[1] being:

QS= Number of answers 'YES' obtained from subject questions.
QT= total number of questions.

The indicator of cultural category is defined in equation (8):

$$Cultural\ indicator = HC * 100 \qquad (8)$$

4.3 Essential Indicators of Political/Institutional Category

The essential indicators of political/institutional category are defined and presented in table 5, which vary from zero to one.

Table 5 - Essential indicators of political/institutional

Indicators	Equations [1]	Number of questions (subjects) for each subcategory.
4.3.1.Public policies indicator (PP)	$PP = QS/QT$ (9)	18
4.3.2.Environmental education indicator (EA)	$EA = QS/QT$ (10)	3

[1] being:

QS= Number of answers 'YES' obtained from subject questions.
QT= total number of questions.

The essential indicator of political/institutional is defined in equation (11):

$$Pol/inst \quad indicator = \frac{PP + EA}{2} * 100 \qquad (11)$$

4.4 Essential Indicators of Income Generation and Social Responsibility Category

Essential indicators of income generation and social responsibility are defined and presented in table 6, which vary from zero to one.

Table 6 – Essential indicators of income generation and social responsibility category

Indicators	Equations [1]	Number of questions (subjects) for each subcategory.
4.4.1.Building companies indicators (EC)	$EC = QS/QT$ (12)	31
4.4.2.Design companies indicator (EP)	$EP = QS/QT$ (13)	35
4.4.3.Supplier indicator for project companies (F)	$F = QS/QT$ (14)	9
4.4.4.User indicator (U)	$U = QS/QT$ (15)	3

[1] being:

QS= Number of answers 'YES' obtained from subject questions.
QT= total number of questions.
The essential indicator of income generation and social responsibility category is defined in equation (16):

$$Inger/resp \quad indicator = \frac{EC + P + F + U}{4} * 100 \qquad (16)$$

4.5 Essential Indicators of Security Category

The essential indicators of security category are defined and shown in Table 7, which vary from zero to one.

Table 7 Security category essential indicators

Indicators	Equations [1]	Number of questions (subjects) for each subcategory.
4.5.1.Security Indicator (S)	$S = QS/QT$ (17)	4

[1] being:

QS= Number of answers 'YES' obtained from subject questions.

QT= total number of questions.
The essential indicator of security category is defined in equation (18):

$$Security\ indicator = S * 100 \quad (18)$$

The general indicator for social and cultural aspects (*Social and Cultural Indicator - SCI)*, generated from equations (6), (8) (11), (16) and (18), is defined in equation (19):

$$SCI = \frac{social + cultural + pol/inst + inger/resp + security}{5} \quad (19)$$

4.6 Characterization Indicators of Social Category

Characterization indicators (*IC*) of social category were defined only for social category. Hence, there are no obstacles to define new indicators, according to the necessity of regions to be eventually studied.

$$IC_a = \frac{\text{Proposed Actions to Mitigate Impacts}}{\text{Coverage Area}} \quad (20)$$

$$IC_b = \frac{\text{Number of Stops}}{\text{Coverage Area}} \quad (21)$$

being:

IC: Characterization Indicators

5 Final Consideration

The objective of the proposed indicators was to develop a comparison criterion among social-interest housing projects in order to select the one which presents the best rates from the social aspect. However, it is evident that environmental aspects also need to be considered towards a more complete evaluation about the sustainability of projects.

It is also noticeable that the number of proposed questions was defined in accordance with local reality, therefore updates and innovations are likely to occur.

Indicators defined by this study aim to provide the necessary feedback to their users in order to establish a performance benchmark, thus contributing to social awareness and establishing a comparison basis between a project's decision-making and strategic planning.

Keywords: ceramic block, concrete block, soil-cement brick, sustainability criteria

Summary

A built environment is one of the survival strategies of human beings and of local socio-economic development. Recently, there has been intense debate over environmental impacts related to its production and use. Studies regarding indicators and sustainability criteria which aid in the specification of materials and construction components are highly necessary, as well as comparative studies between existing solutions. Such studies aim towards an emphasis on cultural aspects, greater economic efficiency, and reduced environmental impact. In the Brazilian field of social housing, one may often observe users' preference for ceramic block in certain locations instead of concrete block or soil-cement brick. Therefore, this paper aims to present a comparative study of sustainability in the production of masonry for social housing projects via the use of ceramic block, concrete block, and soil-cement brick in Brazil, in the city of Goiânia - Goiás. The parameters under analysis in this comparative study were: incorporated energy in components, use of recycled materials, and potentiality for recycling

1. Introduction

The selection of construction materials and components has a strong influence on environmental comfort conditions as well as on the performance and useful life of buildings. Therefore, priority should be given to those materials which generate lower environmental, social, and economic impacts. The selection or specification phase is relevant in any sustainability study because the manufacturing processes of construction materials and components contribute decisively to the generation of greenhouse effect gases.

This study aims to contribute to impact quantification when using natural resources by considering energetic consumption, use of recycled material, and recyclability of masonry components. The functional unit considered is 1 m² of masonry for 50 years of performance for every subsystem. The selected components for this study are ceramic block, concrete block, and soil-cement brick. This information is useful to the formation of a database that will act as a sustainability evaluation tool in the conscious choice of materials and components.

This project's choice of masonry components is justified: (1) by the high quantity of material used in this subsystem, as may be seen in Pictures 1 and 2, which show the results of a research that investigated the mass quantity of the material used in several Social Interest Housing projects in Goiânia, Brazil; (2) by the fact that the subsystem in question frequently presents sharp losses[1]; (3) by the fact that these components reveal the majority of innovations and rationalizations of the field, (4) by the fact that the production of these materials generates many environmental, social, and economic impacts; (5) by the fact that they are responsible for a considerable part of the edification performance; (6) by their close relation with the occurrence of pathological problems; and (7) by their constitution, in many cases, of the building structure itself.

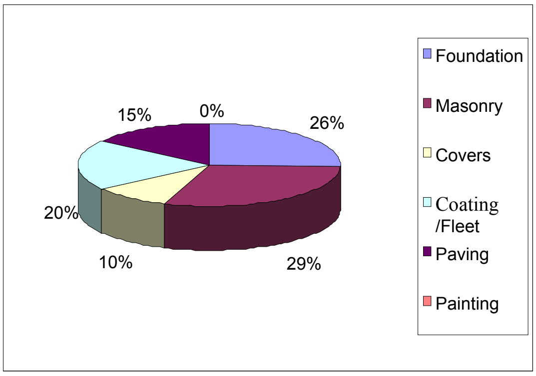
Sposto et al. (2006) studied energy consumption and loss of ceramic and concrete blocks that supply Brasilia's market. As regards energy consumption, the authors concluded that the production requires 3,92 MJ and 2,90MJ, respectively.They observed that the ceramic block case suffers the greatest loss due to its higher variation in the produced dimension.

Emmanuel (2004) quantified the environmental impact of five materials and components that constitute masonry walls in an attempt to identify, as regards the production and the reality of his country's (Sri Lanka)

[1] – The loss in this subsystem occurs due to the low quality of blocks and craft processes frequently used in the region under study.

.

characteristics, which were the most sustainable and of the lowest impact, including less energy consumption during production, highest recyclability potential, and lowest life cycle cost.



Picture 1 – Mass amount percentage (kg/m^2) for each subsystem related to an average of three projects in Goiania – GO – Brazil.

Picture 2 – Social Interest Housing - Goiania – Go – Brazil.

2. Method

The methodology used herein consists in a survey about energy consumption, usage of recycled components and recyclability potentiality, as shown in tables 1,2, and 3.

Table 1- Energetic Index Survey.

Component	Energetic Index MJ/kg	Reference
Ceramic block(9x19x19)	4.88	Sposto, 2007
Concrete block (9x19x39)	5.37	Barros; Sposto, 2005
Soil-cement brick	0.14	Silva, 2005

Table 2 – Recycled Material Usage Index

Component	Incorporates recyclabe input	Waste	Composition	Researched Industries	Reference
Ceramic (block, tiles and brick)	Depends on industry	- fuel material - Chamote (ground waste)	Several industries use sawdust, wood splinter, wood retails and rice bark as combustible. These are others productive processes waste, obtained with sawmills, timbers and furniture industry. Burn phase waste is also reincorporated to the mass by some industries, being ground and nominated Chamote.	Do not incorporate	MANFREDINI; SATTLER, 2005 GOUVEIA (2008)
Concrete block	Depends on industry	Cement with RDC additional.	CP II –E -6-34% of blast-furnace clinker CP III - 70% of blast-furnace clinker CP IV -50% of fly ash	Incorporate	FARIAS et al., 2005[1]
Soil-Cement Brick	Depends of the industry	Cement without additives.		Incorporate	-

.

Table 3 – Recyclability potential arise

Component	Recycling process	Impacts/ Limitations	Recyclability Potential	Reference
Cerâmic (blocks)	Knap/ Grinding to generate aggregate	Waste variability	Recyclabel	ZORDAN, 2001; CONAMA n° 307, 2002; WOOLLEY *et al*. 1997; HENDRIKS, 2000
Concrete and mortar	Knap/ Grinding to generate aggregate	Waste variability	Recyclabel	ZORDAN, 2001; CONAMA n° 307, 2002; WOOLLEY *et al*. 1997; HENDRIKS, 2000
Soil-cement brick	Knap/ Grinding to generate aggregate to be paving base and sub-base.	Waste variability	Recyclabel	CONAMA n° 307, 2002;

The block quantity necessary for 1m² of masonry have been considered as functional unit execution, for calculations. The second part of analysis uses a “value index”. For example, VI_e for embodied energy is derived from equation 1:

$$VI_e = (LV/E)*100 \quad (1)$$

where:

VI_e= embedded energy index value.

LV= embedded energy lowest value

E= embedded energy

The calculus of index value for usage in recycled material is:

$$VI_r = (LV/R)*100 \quad (2)$$

where:

VI_e= recycled materials index value.

LV= recycled materials biggest value.

R= recycled materials

The index value for recycling potentiality is calculated as:

$$VI_p = (LV/R)*100 \quad (3)$$

where:

VI_e= recycling materials index value

LV= recycling potential biggest value

R= recycling potential.

After index value calculations for each parameter, it has been calculated the Environmental Suitability Index (ES) in equation 4:

$$ES = VI_e + VI_r + VI_p \quad (4)$$

3. Results

3.1 Embodied Energy

In table 4 are presented the results of incorporate energy (to execute the functional unity – 1m² of masonry)

.

Table 4 – Energetic consumption of the material to 1² execution

Component	Functional unit (pç/m²)	Mass (kg)	Material quantity (kg)	Energetic index (MJ/kg)	Total (MJ)
Ceramic block (9x19x19)	25	2.6	65	4.88	316.88
Concrete block (9x19x39)	13	11.77	153.01	5.37	821.66
Soil-cement block	80	2.3	184	0.115	21.16

In table 5 are presented the VI of studied components.

Table 5 – Incorporated energy Index Value for studied components.

Component	VI_e
Ceramic block (9x19x19)	6.7
Concrete block (9x19x39)	2.6
Soil-cement brick	100.0

3.2 Use of recycled materials

In table 6 are presented the results of components which use recycled material.

Table 6 – Mass quantity of recycled material used for component manufacturing

Component	Functional unit (pç/m²)	Mass (kg)	Recycled content	Which content	Quantity of recycled material for one block (kg)	Total Kg
Ceramic block (9x19x19)	25	2.6	no	-	-	0
Concrete block (9x19x39)	13	11.77	yes	cement[1]	1.97	25.61
Soil-cement brick	80	2.3	no	-[2]	-	0

1 In the factory studied, to produce one concrete block, 5,64kg of cement are consumed; the cement is CP II, which has 35% of blast-furnace clinker.

2 In the factory studied, it has been used the soil-cement brick, produced with cement CP1.

In table 7, also is presented the Index Value of studied components.

.

Tabela 7 –Index Value for recycled material of studied components.

Component	VI_r
Concrete block (9x19x39)	0.0
Ceramic block (9x19x19)	100.0
Soil-cement brick	0.0

3.3 Recycling Potentiality

In table 8, results of mass quantity of material and components related to recycling potentiality are presented:

Table 8 – Results of mass quantity of material and components related to recycling potentiality

Component	Functional unit (pç/m²)	Mass (kg)	Recycling Potential	Total kg
Ceramic block (9x19x19)	25	2.6	yes	65
Concrete block (9x19x39)	13	11.77	yes	153.01
Soil-cement brick	80	2.3	yes	184

.

In table 9 are presented the index value VI_p for recycling potential of studied material.

Tabela 9 – Index value for recycling potential of studied material

Component	VI_p
Ceramic block (9x19x19)	100.0
Concrete block (9x19x39)	42.5
Soil-cement brick	35.3

In table 10 is presented the calculation of environmental sustainability index (ES) for studied components, considering the parameters submitted to analysis in comparative study, which are: incorporated energy in components, use of recycled materials and potentiality for recycling.

Tabela 10 – Environmental sustainability index

Material	VI_e	VI_r	VI_p	ES	Environmental Sustainability Rank
Ceramic block (9x19x19)	6.7	0	35.3	42.0	3
Concrete block (9x19x39)	2.6	100	83.2	185.7	2
Soil-cement brick	100.0	0	100.0	200.0	1

As noticed, the best index for the analyzed parameters has been the soil-cement brick, followed by concrete block.

4. Final Consideration.

This study attempted to gauge the environmental sustainability of the most commonly used wall components in Goiânia, Goiás, Brazil: ceramic block, concrete block, and soil-cement block. Environmental suitability is estimated on the basis of an E which depends on embodied energy, use of recycled materials, and potentiality for recycling.

One of the crucial findings of the present study is that the concept of “environmental suitability” is a relative phenomenon. We cannot truly say in the present context that material “A” is better than material “B”. Thus, a definitive statement such as “Material ‘A’ is the most suitable wall material” cannot be made.

One of the most evident limitations is the number of parameters under consideration. There is a necessity to include others, for instance energy on transportation, CO_2 emissions generated during production and transportation, socio-cultural and economic aspects, among others.

In addition to the features considered in this study, there are certain limitations involving the collected data, which are characterized by the current research stage regarding sustainability. This data will be more complete once the life cycle analysis (LCA) of construction materials and components is effectively performed.

The final goal of an exercise such as the present study is to develop a decision-support tool enabling building design professionals to make rational decisions about the environmental consequences of their choice. This research is only a tentative beginning in this direction in Brazil.

Keywords: Chinese kang, elevated kang, thermal storage, energy saving, DeST

Summary

Heating of rural houses now constitutes 25% of total building energy consumption in China. Hence, the transition and new technologies for rural home heating is considered as the top priority for managing future building energy consumption in China. Chinese kang, the most traditional and widely used heating and sleeping bed system, has been regarded as a potentially sustainable and energy-saving solution.

In this paper, we integrated a macroscopic heat transfer and airflow model of an elevated kang system into the existing Chinese building environmental system simulation and analysis software-DeST. The new integrated software can serve as a design and energy analysis tool for rural houses with the elevated kang heating. The basic methodologies and mathematical model for the elevated kang are presented and some preliminary results obtained from simulations of a typical house in northern China are also discussed.

1. Introduction

With the rapid economical development and urbanization in China, the living environment of people in rural areas has received increasing attention. Rural house heating (including biomass energy) constitutes now 25% of total building energy consumption in China. Hence, transition and new technologies for rural home heating is considered as the top priority for managing future building energy consumption in China.

The Chinese kang has been used for home heating for more than 2500 years (Men 2004). There are currently nearly 200 million people using this kind of heating system in northern China. Figure 1 illustrates a typical arrangement of an elevated kang heating system. It utilizes the residual heat of fume from the cooking stove, and uses the kang body to release heat to indoor environment. Kang plates, often made of materials with high thermal storage capacity, can store heat and maintain a heating period of several hours or more and also create local warm climate under the blanket for sleeping. Chinese kang has been regarded as a kind of potentially sustainable heating system, although its design has been mainly based on the experience of craftsmen. Investigations have shown the potential of energy-saving while providing a comfortable indoor thermal environment by the elevated kang, the latest design of kang (Chen et al. 2007). The performance of some of the buildings using these systems has been reported by, among others, Yang (1963), Deguchi and Sanda (2002). These reports, however, often lack the information about the likely effect of key parameters on the heating energy requirements of a building with such a system. For example, there appear to be no studies that identify clearly the contribution of the kang alone to the overall energy savings of the building. Thus, a thermal analysis tool for buildings with kang systems is needed for designing the kang in a house.

In this paper, the macroscopic thermal and airflow model of the elevated kang is developed at the first, and the approach of integrating the kang model with a building energy simulation software (DeST) is given. The thermal performance of the elevated kang and its effect on indoor environment in a typical house in northern China are investigated by applying the tool developed.

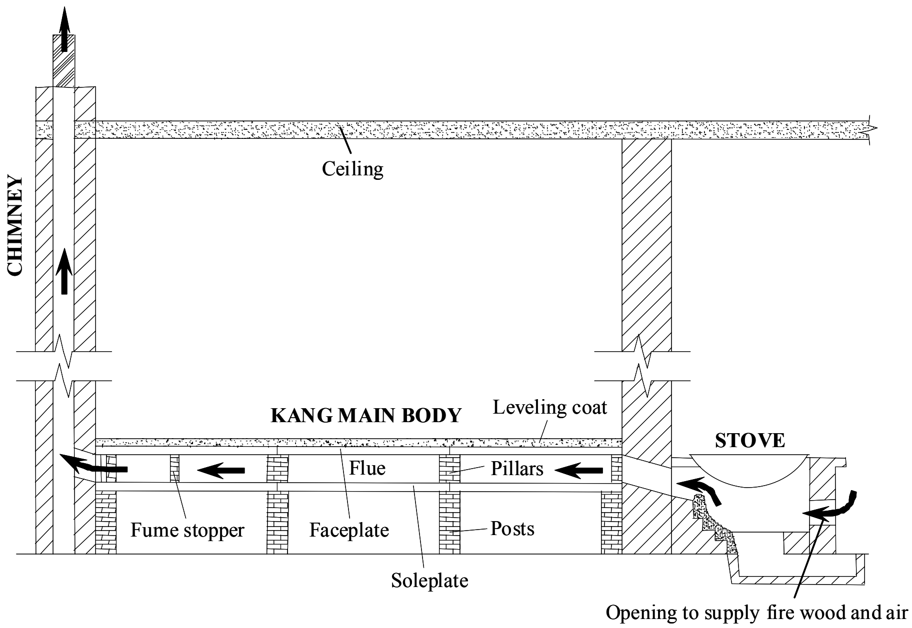

Figure 1 Schematic representation of a typical elevated kang system

2. Approach

A mathematical model for a house integrated with an elevated Chinese kang (HIEK) heating system has been developed for building energy simulation, which was validated using the test data (Zhuang, 2007). Because the heat transfer and airflow between smoke and kang plates is a coupling process, it is more adaptive to analyze the elevated kang using the macroscopic method. The entire elevated kang heating system is divided into three zones, Zone 1 (stove), Zone 2 (kang main body) and Zone 3 (chimney), as shown in Figure 2.

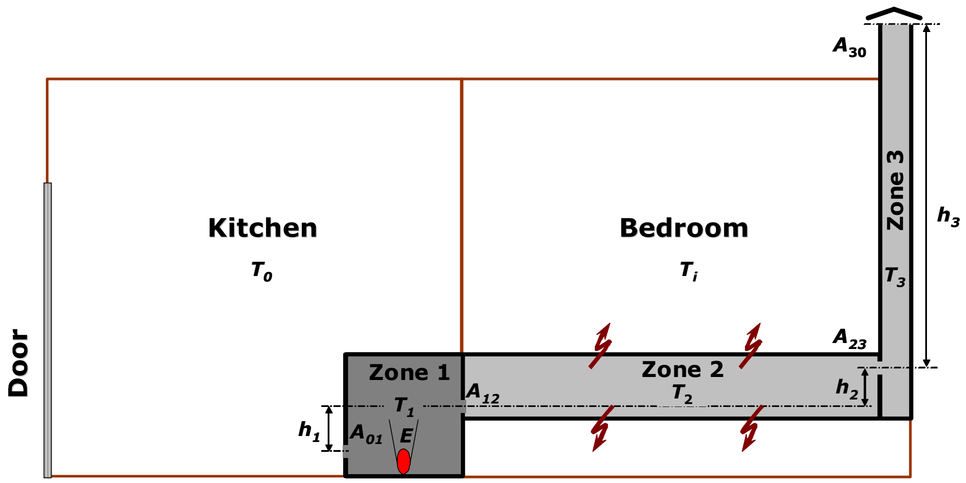

Figure 2 The general notation for the macroscopic model of elevated kang heating system

Considering the relatively small sizes of space in kang heating system, the uniform air temperature in each zone is assumed, which is often adopted in building thermal analysis. This approach enables relative, if not absolute, predictions of the effects on heating energy requirements to be made. The proposed program is mainly developed for researchers or experts. For building designers its use is, however, severely limited due to some shortcomings such as inconvenient input and output methods. If this model is integrated into available building simulation software, it can be used to investigate alternative operational strategies and to determine kang system performance for a range of climates. Due to the fully development of building energy simulation techniques over the past decades, several programs are widely used with mature techniques and friendly visual interface, like Designer's Simulation Toolkit-DeST (Tsinghua University DeST Group, 2006).

DeST is a simulation tool for building thermal performance & HVAC developed by Tsinghua University during 1990s, and now widely used in Chinese building industry. The approach taken in this project was hence to integrate the proposed kang model into the DeST software.

The core issues on integration are the input and output linkage between the kang model and the DeST software. The output parameters from DeST such as indoor air temperature, solar radiation and building envelope surface temperatures are used as inputs for the kang module. The heat release from a kang should be transferred to DeST likewise at each time step. Another item noticed is to deal with the inconsistent time step. In this project the outputs from DeST with the time step of 1hour are linearly interpolated into 60 parts and input the kang model with the time step of 1 minute. The integrated DeST-k can predict the indoor air temperature, heating load, heat release from kang plates, surface temperatures of kang plates, mass flow rate of kang system and so on.

3. Case setup and simulation details

The design for buildings with the elevated kang heating system is to achieve or check the two main aims: firstly people often lie on the kang plates to sleep, and the kang needs to be felt thermally comfortable. Thus the surface temperature of kang plates should be maintained within the range of 25-30°C (Guo, 1998). The heat input pattern can be controlled to regulate the surface temperature, such as changing the heat source power, firing time and firing duration. Besides, the kang configurations like plate thickness and materials also affect the surface temperature. The second design aim is to efficiently utilize the heat input of kang to improve indoor thermal environment. That needs to improve the heat release and heat storage capability of kang and the thermal physical level of building itself such as enhancing insulation, decreasing building air infiltration, or installing auxiliary heating systems. The integrated DeST-k can serve as a useful tool for energy analysis of buildings with elevated kang heating systems to obtain the design aims described above.

A base case house with elevated kang heating was selected for case study, see Figure 3. Note that this building was representative of commonly found homes in rural area in northern China from surveys (Zheng, 2007). The total building area was 66m^2, and the heating area was 33m^2.There were two bedrooms with one living room between them. The living room was mainly used as kitchen and dining place. The elevated kangs were placed in each bedroom for heating. The parameters of one bedroom are listed in Table 1. The TMY data provided hourly climate data. Shenyang, the capital city of Liaoning province in Northeast China, was chosen as the base location. The elevated kang was 3.0 m long and 2.0m wide with often used concrete kang plates. The base plate thickness was 60mm. For heat transfer from the slab surface to the room, a combined linearized radiation and convection heat transfer coefficients were used. The convection coefficients were obtained from recent experimental results, and the heat power of smoke into the kang body was fixed at 35KW during firing time (Zhuang, 2008). There were three firing times during a day, at 6:00 am., 12:00 am. and 18:00 pm., lasting for 90 minutes respectively. It should be noted that heat release from the stove is not included in the following simulations.

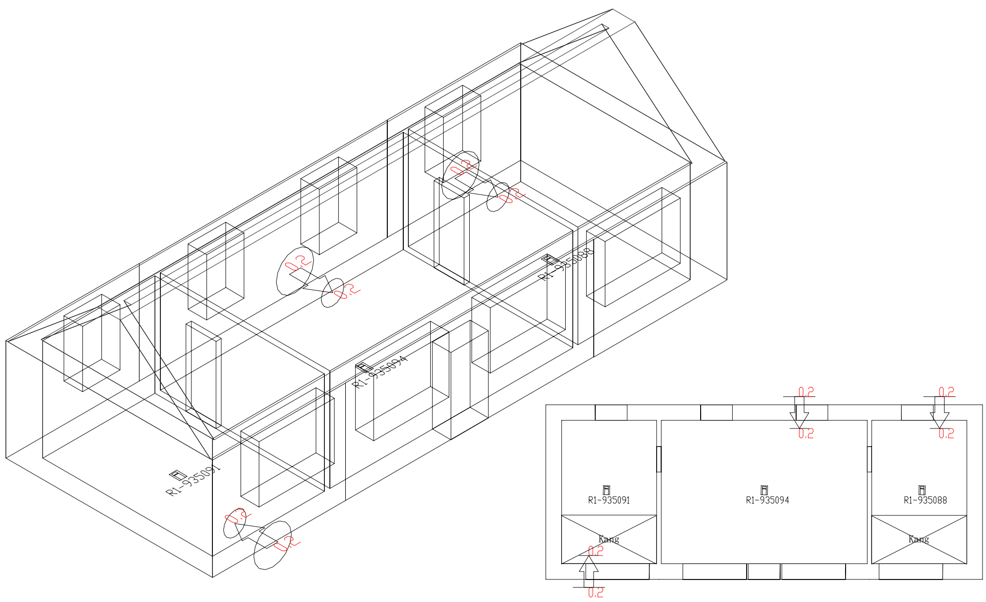

Figure 3 Layout of a typical rural house in northern China

Table 1 Materials, dimensions and assumptions used in the base room

Item	Description
Room size (L×W×H)	5.0 m×3.3m×2.7m
External wall construction	370mm clay brick with 20mm plaster layer
Internal wall construction	120mm clay brick with 10mm plaster layer either side
Roof construction	10mm tile, 160mm clay with 80mm straw
Ceiling construction	10mm plasterboard
Floor construction	50mm concrete with 100mm soil
South window construction	Single, 6 mm thick, plain, size: 2.0m×1.8m
North window construction	Single, 6 mm thick, plain, size: 1.5m×1.0m
External door construction	Timber framing, size: 2.0 m×1.0m
Internal door construction	Timber framing, size: 2.0 m×0.8m
People	2×64W/person, from 18:00 pm. to 6:00 am.
Lights	60W, from 18:00 pm. to 22:00 pm.
Air change rate	2 ACHs (ACH is a short of “air change per hour”)

Performance sensitivities to a variety of parameters were determined by changing the inputs to the base case model. Various simulations were performed to investigate the effects of kang configuration, building insulation, room air change rate and climate on indoor thermal environment and heating load. Three different plate thicknesses (40, 60 and 80 mm) were arranged. These dimensions are typical of the sizes used in an elevated kang. To evaluate the insulation effect, only the external walls were insulated by adding 100mm polystyrene panel outside. Four different room air change levels were assumed, namely 0.5, 1, 2 and 4 air changes per hour (ACH), to represent the range of ventilation rates most likely to be used in a residential building. The effect of climate on performance was investigated by running the models described above using climatic data for three different capital cities in northern China listed in Table 2. All the simulations were performed only in the heating season. Considering the low living level in most rural families in China, the design indoor air temperature for heating was fixed at 14 ^{o}C, which is often adopted in passive heating building design.

Table 2 The climate in three locations during the heating season (National Meteorological Information Center and Department of Building Science of Tsinghua University 2005)

Location	Shenyang	Beijing	Xi’an
Heating degree days (base 14^{o}C)	3063	1978	1572
Average temperature in the coldest month	-11.46 ^{o}C	-3.83 ^{o}C	-0.35 ^{o}C
Average temperature in the coldest day	-17.50 ^{o}C	-10.00 ^{o}C	-3.45 ^{o}C

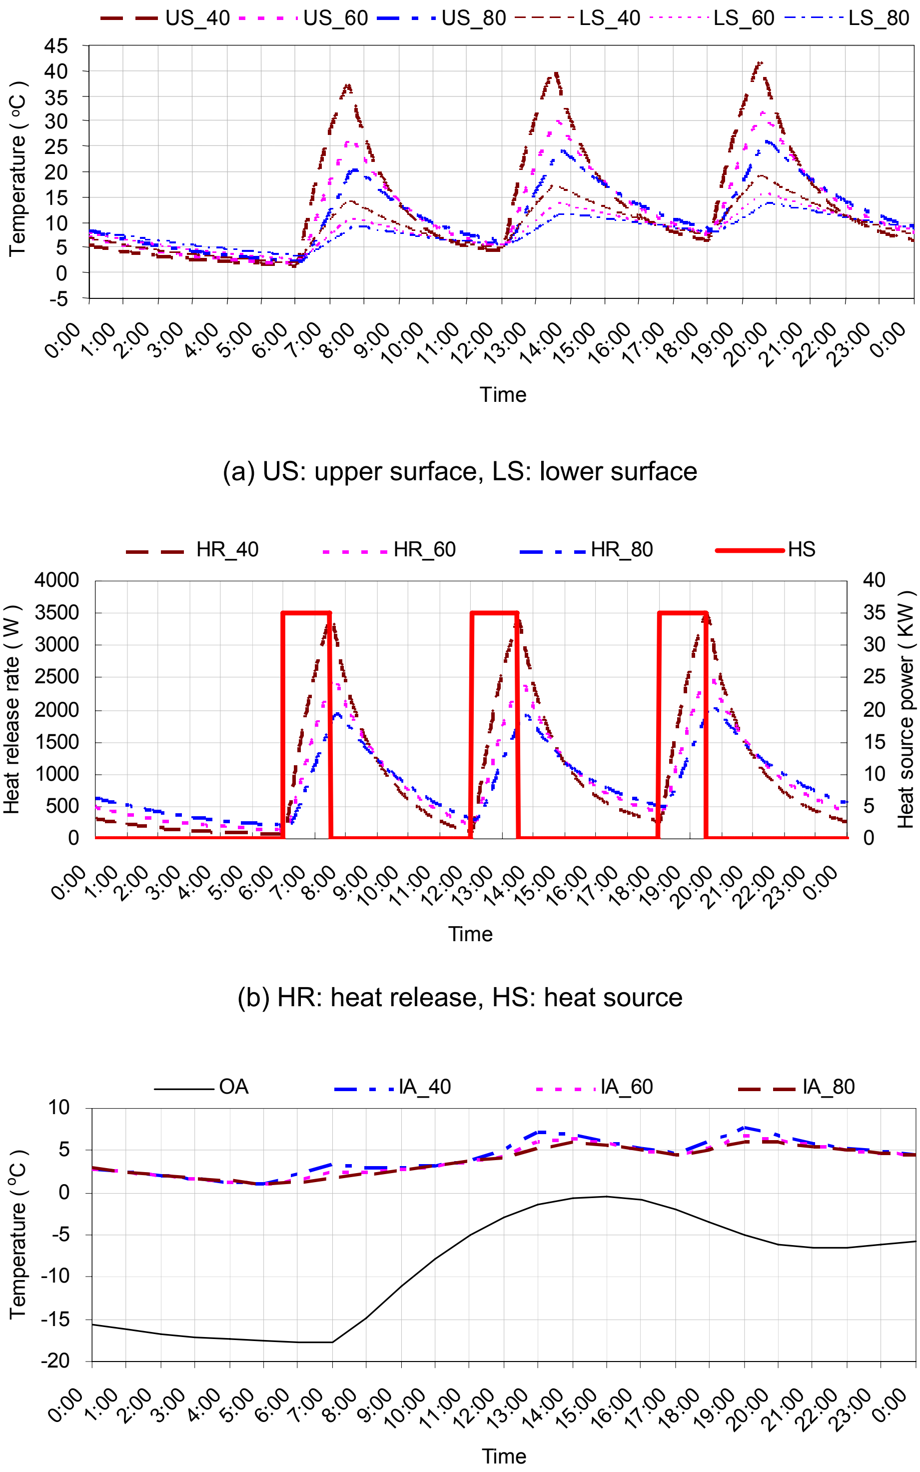
4. Results and discussion

4.1 Thermal performance of the elevated kang

The thermal performance of the elevated kang can be investigated from its thermal responses. The change of surface temperatures of kang plates with three different plate thicknesses during one day is shown in Figure 4(a). It can be obviously seen that the upper surface temperatures of top plate fluctuate a lot due to the firings. The amplitudes of them decrease from about 30 ^{o}C to 15 ^{o}C as the plate thickness increases from 40mm to 80mm. The thicker plate has more thermal capacity which helps to moderate the change of temperature. While considering body thermal comfort requirement, the recommended thickness is 40mm leading to upper surface temperature within the range of 25~30 ^{o}C in most of time. The amplitudes of lower surface temperatures of bottom plate are relatively small, within 10 ^{o}C in all cases. This is mainly caused by the low heat convective coefficient at the inner surface of bottom plate (Zhuang, 2008).

The heat release from kang plates directly describes the heating capability. From Figure 4(b), it is found that a decrease in plate thickness results in an increase of transient heat release during the firing periods. For example, the maximum transient heat release rates with 40, 60 and 80mm thick plates are 3500 W, 2596 W and 2070W respectively. By calculation, the heat efficiencies, the ratio of total heat release to heat source power, are 15.4%, 14.1% and 13.3% for the kang with plate thicknesses of 40, 60 and 80mm respectively.

Figure 4(c) illustrates that the indoor air temperature can be maintained above 2 ^{o}C under the kang heating despite of the lowest outdoor air temperature of -18 ^{o}C. The thickness of kang plates has little effect on indoor air temperature, which only changes somewhat during the firing periods. The main reason is that the change of total heat release from kang is relatively small comparing to building heat demand.



(a) US: upper surface, LS: lower surface

(b) HR: heat release, HS: heat source

(c) OA: outdoor air, IA: indoor air

Figure 4 Dynamic thermal response of the elevated kang during one day

4.2 Effect of the elevated kang on indoor air temperature

Figure 5 shows the indoor air temperature frequency distributions for different proposed cases. For case NIWK, the indoor air temperature is the basic result telling the current thermal level of rural building without insulation, and even 8.2% of indoor air is lower than -2.0 °C. There is an urgent need to improve indoor thermal environment. The effect of building insulation on indoor thermal environment can be evaluated with case NIWK and case WIWK. By adding wall insulation described above (for case WIWK), the indoor air temperature can be further improved by about 2.0 °C. Besides, the indoor air temperature distribution of case WINK is better than case NIWK. It can be said that insulation plays an important role in improving indoor air temperature, even better than using the kang heating system. For case WIWK, 13.5% of indoor air is still lower than 2.0 °C, which may be caused by the uniform heat input of kang at the fixed times. The heat supply is not completely based on the requirement.

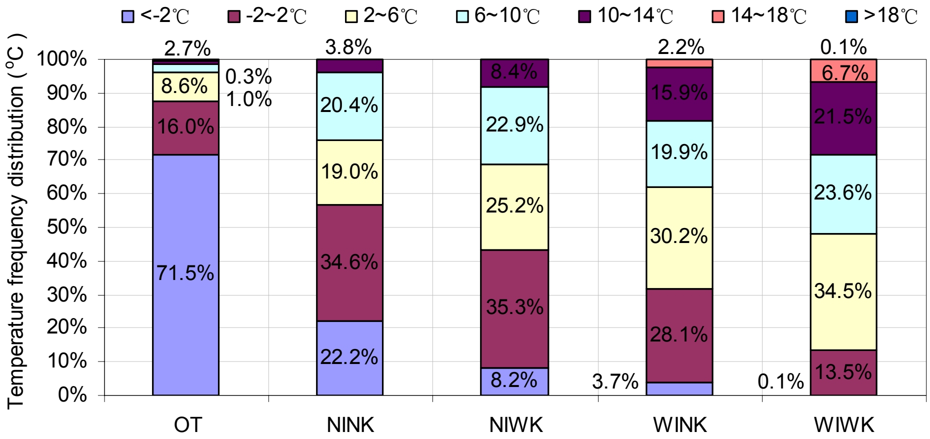


Figure 5 Indoor air temperature frequency distribution with and without kang heating and wall insulation (OT: outdoor air temperature, NINK: no insulation and no kang, NIWK: no insulation and with kang, WINK: with insulation and no kang, WIWK: with insulation and with kang)

4.3 Effect of ACH on indoor air temperature of room with elevated kang heating

Figure 6 gives simulation results of the room with four ACHs under the elevated kang heating. The air infiltration of room greatly affects the indoor environment in cold regions. For airtight room with ACH of 0.5, the indoor air can be kept above 6 °C in 99.5% of heating reason.

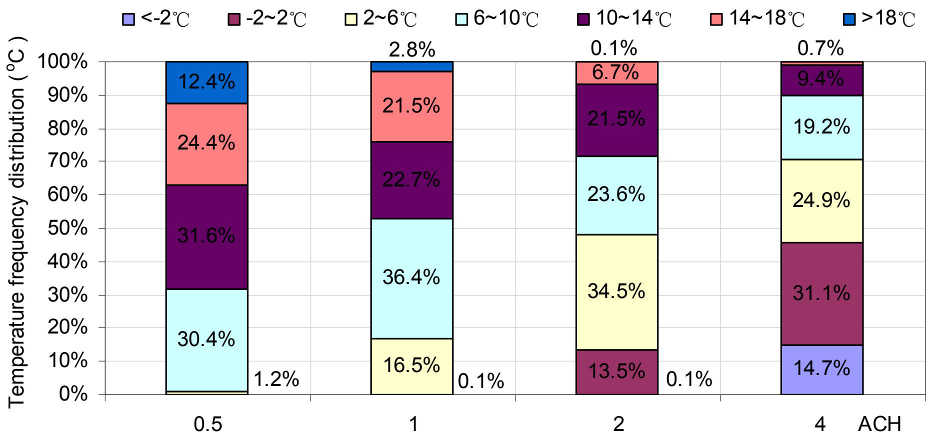

Figure 6 Indoor air temperature frequency distribution under different ACHs

4.4 Effect of the elevated kang on building energy consumption

Table 3 lists the cases of various simulations described above for the heating load prediction. Predictions of heating energy and peak demand as a result of using the kang heating system and wall insulation are summarized. A brief discussion of the use and meaning of the simulation results is presented below.

Table 3 List of simulation results for a room with an elevated kang system

Case	Location	ACH	Heating energy (KWh/m^2)	Peak heating load (W/m^2)
NINK	Shenyang	2	201.64	149.09
NIWK (base)	Shenyang	2	133.09	143.15
WINK-1	Shenyang	2	149.95	121.39
WINK-2	Beijing	2	66.01	83.37
WINK-3	Xi'an	2	67.37	66.40
WIWK-1	Shenyang	2	86.13	115.03
WIWK-2	Beijing	2	33.07	70.12
WIWK-3	Xi'an	2	19.2	53.41

Figure 7 compares the heating load index under kang heating and building insulation. The heating load index per square meter is decreased from 54.8 W/m^2 to 40.7W/m^2 by the elevated kang when the external walls have no insulation, saving 25.7% of heating load. By adding wall insulation, the energy saving by the elevated kang is improved by 5.8%, providing 31.5% of heating load. It illustrates that the elevated kang can contribute more energy savings as the building is better insulated. While the total heat release from kang is slightly affected by the building insulation, the heat efficiencies of the kang body are 14.22% for external wall with insulation and 14.24% for external wall without any insulation.

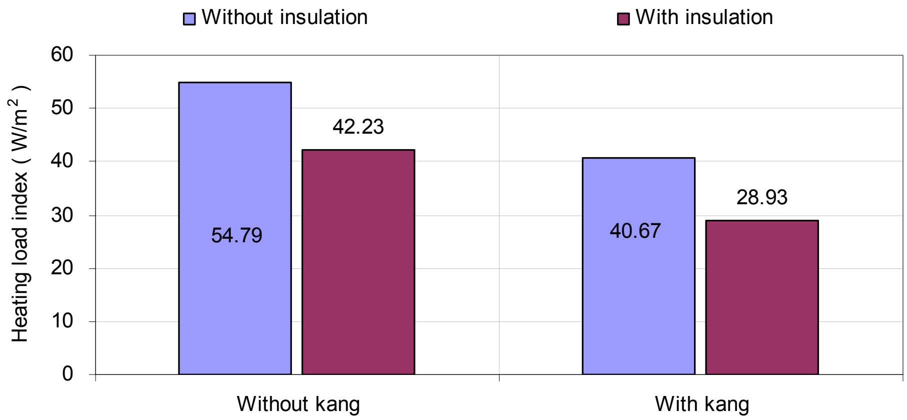

Figure 7 Comparison of heating load index under kang heating and building insulation

4.5 Effect of climate on building energy consumption of room with elevated kang heating

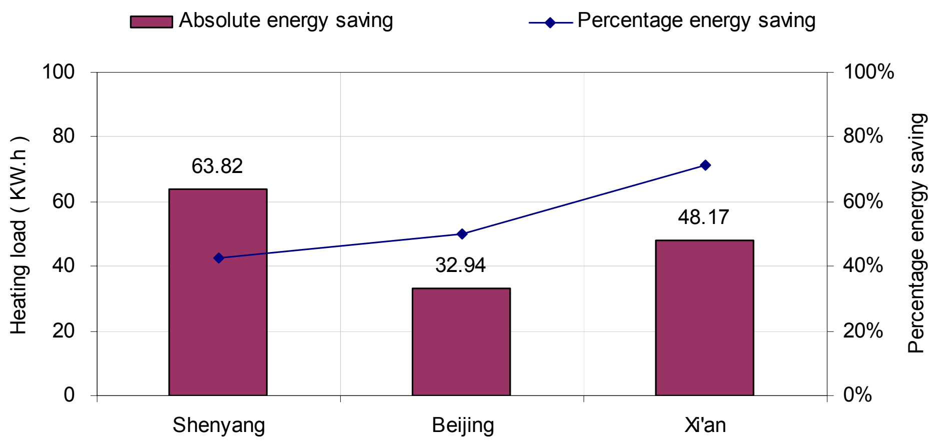

Figure 8 Predicted heating energy savings by the elevated kang in three climates

The heating capability of the elevated kang in various climates is investigated. Three representative regions in Northeast China, North China and Northwest China respectively are selected. Overall it is important to understand that it is not possible to identify a “best” system for any particular location. In this paper the judgment depends on how much the heating energy consumption is reduced. The absolute energy saving is defined as the difference between heating load for room using a traditional air-conditioning system and the auxiliary heat energy required as using the elevated kang to reach the designed indoor air temperature. The percentage saving is a convenient indicator of system performance, which evaluates the heating potential of the kang system. From Figure 8, the elevated kang is the most effective in reducing heating energy consumption in areas with the climate like Xi’an, 71.5% of heating load can be provided by the kang alone. It is also interesting to observe that 49.9% of annual heating load is saved for the Beijing climate. However, the annual heating load saving in this location is 51.6% of the result in Shenyang area.

5. Conclusions

Chinese kangs have been widely used in northern China as a potentially sustainable heating system. The elevated kang model has been integrated into a building energy simulation software (DeST) to predict the indoor air temperature and energy consumption for houses with the elevated kang heating. The performance of this system in a typical rural house has been predicted under different proposed cases to investigate the effects of kang configuration, building insulation, room air change rate and climate on indoor thermal environment and heating load.

The simulations show that the indoor air temperature can be improved under the kang heating, and building insulation plays an important role in further improving indoor air temperature. The heat supply of kang should be based on the requirement to maintain continuous indoor thermal level. The heating performance of the system is not very sensitive to the thickness of kang plates. The air infiltration of the room greatly affects the indoor thermal environment in cold regions. The elevated kang can contribute more energy savings if the building is better insulated. The elevated kang system offers either energy and/or peak load savings in almost all locations investigated. It is the most effective in reducing heating energy consumption in areas with the climate of Xi’an, 71.5% of heating load can be provided by the kang alone. These results support the general consensus that the elevated kang system is suitable for climates with not too cold regions. For the extreme cold regions, the design indoor air temperature cannot be achieved only by the kang heating system. Further research is needed to fully explore other controls parameters and strategies for kang system.

Acknowledgement

The work described in this paper was supported by a grant from the Research Grants Council of the Hong Kong SAR, China (Project No. HKU7154/05E) and A NSFC 2007 Young Researcher Award (No.50729803). The authors are grateful to Dr. Xie Xiaona, Mr. Wu Ruhong and Dr. Yan Da of DeST group from Tsinghua University for helping debugging the kang program in the DeST software.

Keywords: architecture, climate, user, energy, technologies, holistic, education, planning

Summary

The project integrates the fields of building climate, energy technology and building informatics in order to develop a holistic planning concept for administrative buildings in different climate zones. The aim is to create sustainable buildings that can afford a maximum of comfort with a minimum of energy and costs during the building life cycle. Architecture and building services technology can therefore not be planned as a uniform series, but need an interdisciplinary team to work out the relationships between the daylight situation, the facade concept, room conditions, technical systems and energy generation and to show the consequences of planning decisions.

Planning tools should be easy to handle and useful both in education and in the design process. Architects and engineers have to understand the interplay between user requirements, environmental potential and the building concept in order to activate synergetic effects and optimize the potential of the holistic building. This makes it possible to reduce the planning time and at the same time create sustainable buildings that take both the needs of the user on a given site and the overall ecology and economy into consideration.

1. Relevance of the Concept Phase

All over the world, the building industry is faced with ever tighter planning schedules and the need to minimise planning costs. This is compounded by time-consuming planning and increased costs for innovative concepts, which aim to increase comfort while simultaneously reducing energy consumption and technology investments (Hindrichs et al., 2007). If this challenge is to be mastered, additional planning methods and tools that provide fast, cost-effective guidance when making decisions during the conceptual phase, are called for.

Energy and room climatic objectives play a major role in architectural competitions. Principals and investors must often specify the requirements concerning the energy and the room climate. There is insufficient knowledge about the energy and technical consequences closely related to the particular requirement, e.g. the room operating temperature in summer related to the technical effort in the building (Hausladen et al., 2008).

In view of the level of detail involved, conventional simulation programs are of only limited use during this early planning phase. The many as yet unspecified parameters and the high initial number of variants cause (fig. 1) an enormous amount of work of limited relevance. Instead, there is a need for decision guides that restrict the number of variations worth pursuing. During the concept phase, it is not so much the acquisition of absolute values that is of interest, but the choice of planning variants, and this must take priority.

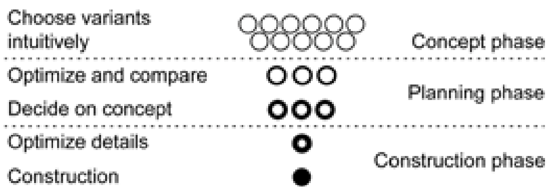

Figure 1 Requirements in the different planning stages

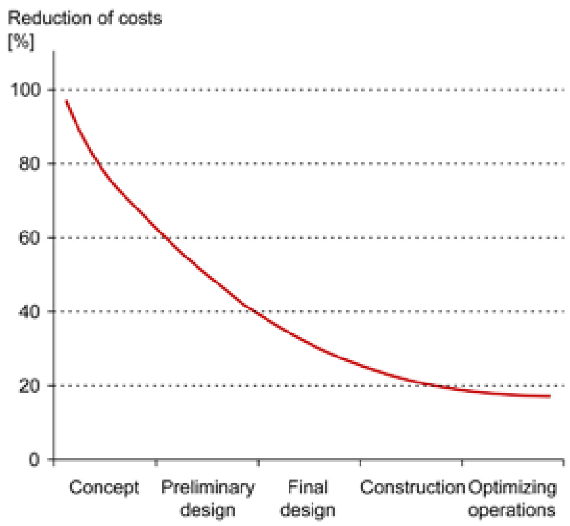

Figure 2 Potential reduction of costs in the planning process

2. Research Approach

The research approach treats buildings in different climate zones (tropical humid, subtropical, hot arid and Mediterranean) holistically, incorporating the building concept, façade planning, building technology, the generation of energy in keeping with the outdoor climate, user requirements, indoor climate and energy efficiency in a comprehensive context that highlights their interrelationship.

The participating institutes are (fig.3) Dept. of Computation in Engineering Steering, Prof. Rank, Dept. of Energy Management and Application Engineering, Prof. Wagner and the initiator, Dept. of Building Climatology and Building Physics, Prof. Hausladen. The initial point of the research project is the concept presented here, with the building representing a holistic system.

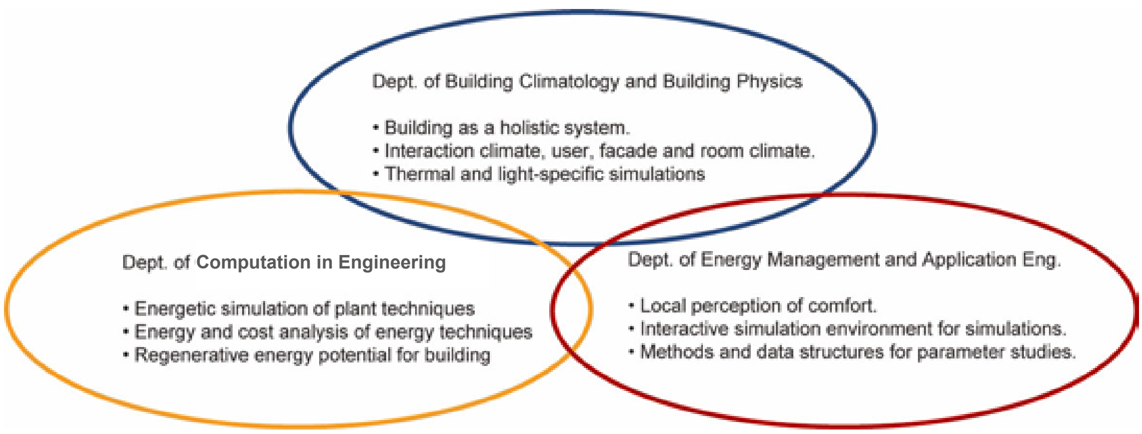

Figure 3 The interdisciplinary team and their core themes

2.1 Objectives

The research objective is to support architects and engineers during the conceptual phase of planning administrative buildings in different climate zones. During the draft concept phase, tools that that allow the energy and indoor climate requirements to be gauged in the absence of detailed planning data are essential, as professional planners are not normally involved at this stage.

In-depth knowledge of the climatic challenges and potential and the required standards of comfort is often lacking in building projects for other climate zones. An exact analysis of the climatic conditions and the site is, however, essential when planning buildings with optimised energy and indoor climate systems in order to align the structure of the building and the façade accordingly and to exploit the potential for the energy and room climate concept (fig. 4). A critical examination of the relevant utilisation and comfort criteria and an accurate analysis of the outdoor climate and site conditions support the development of appropriate room climate concepts.

In this way, it is possible to realise energy saving potential, achieve regenerative energy generation systems and reduce the building's technical installation costs. A good indoor climate is the basis for the well-being and performance of the users.

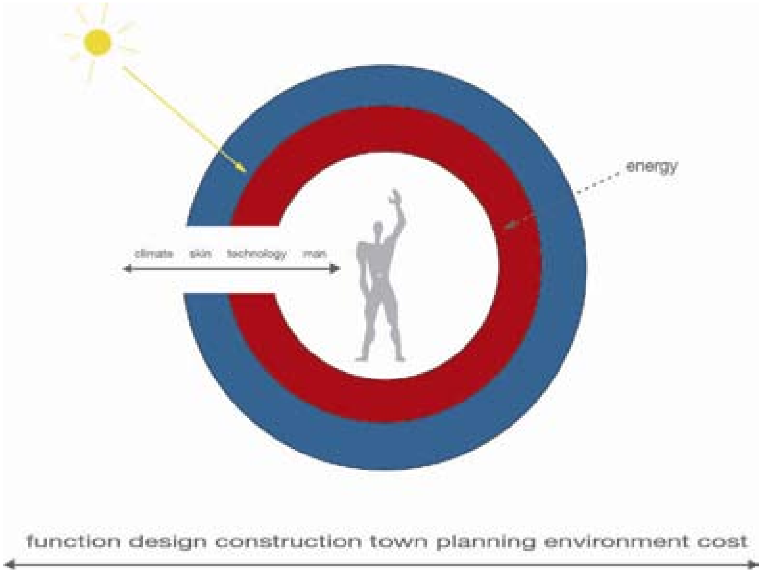

Figure 4 The building seen as a holistic system. The better the building reacts to outside climate conditions, the less technology and energy is required to achieve a comfortable thermal climate for the occupants

2.2 Support Of A Holistic Planning Basis

A holistic planning basis for building in various climate zones supports architects and engineers in education and planning practice.

Table 1 Support

Categories	Advantages
Building with the climate	Recognition of the potentials of the respective site Utilisation of regenerative energy generation systems
Specification of requirements	Depiction of synergetic effects and interaction in the building system Revelation of optimisation potential during the concept phase
Challenges in the planning process	Submission for international competitions Cutting planning time Systematic analysis of suitable energy technologies and combinations
Life cycle	Reduction in energy consumption and costs Holistic optimisation of the energetic and economic life-cycle balance by incorporating production, utilisation and disposal/recycling

3. Realization

The results of the research are to be implemented in straightforward planning tools and a planning manual designed to define and quantify the interaction between the outdoor climate and indoor/room climate as well as the engineering concept. The aim is for them to set out the basic principles of optimum climatic concepts in different climate zones during the conceptual phase by enabling a rough estimate of the indoor climate and energy consumption to be drawn up. By revising existing detailed surveys, these can be integrated into an overall context in such a way that interaction becomes visible.

3.1 Planning Tools

Planning tools that can be utilised after a reasonable period of familiarisation are to be devised for individual features. These include planning graphics, execution diagrams and tools for doing an initial (basic) draft of the building from the point of view of energy and room climate aspects. It is also planned to create a software tool that scans the relevant planning parameters at the concept phase and hazards an approximation of the building's future behaviour. The main aim is not so much to quantify an exact planning result but to make a quick comparison between diverse planning options.

Planning aspects that cannot be depicted directly in the software or are not immediately quantifiable are expounded in a supplementary planning guide, and their relevance is shown qualitatively. This planning manual for architects and planners depicts the inter-relationship between planning factors and the consequences of planning decisions in different climate zones, and is intended to allow a fast practical implementation. The themes are to be presented in a simple, easily comprehensible manner in order to lend assistance in planning decisions at the concept phase.

3.2 Interaction Matrix As An Example For A Planning Tool

The starting-point for developing a building concept is the needs and standards of the users. The planner responds to these requirements by designing the façade and choosing the air-conditioning concept. These two aspects together influence the desired indoor climate during the summer. Moreover, the façade determines the daylight situation. The air-conditioning concept affects the possible cooling systems.

The result is an inter-relationship between light, indoor climate and cooling system (fig.5), which works both ways. This in turn sparks reciprocal action between the cooling strategy and the availability of daylight.

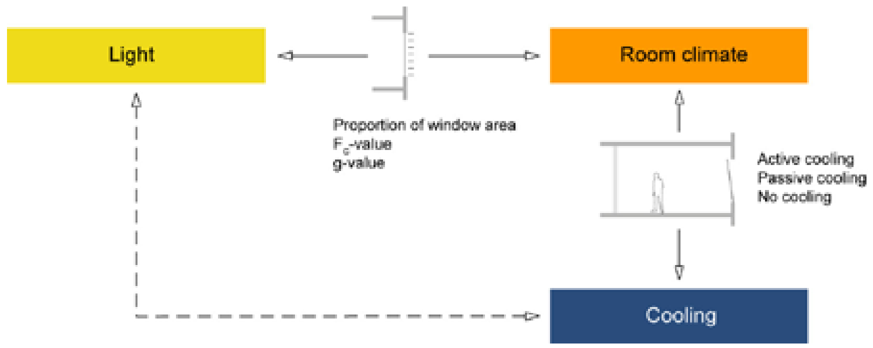

Figure 5 Inter-relationship between light, indoor climate and cooling system

For standard cases, a parameter study coupling the aspects of light, façade, indoor climate and building technology has been drawn up for the reference climate in Germany (fig. 6). This enables several fundamental simulations for the concept phase to be replaced. For a better detailed analysis of the connections, the results pertaining to light, indoor climate and energy have been summarised in an all-embracing matrix.

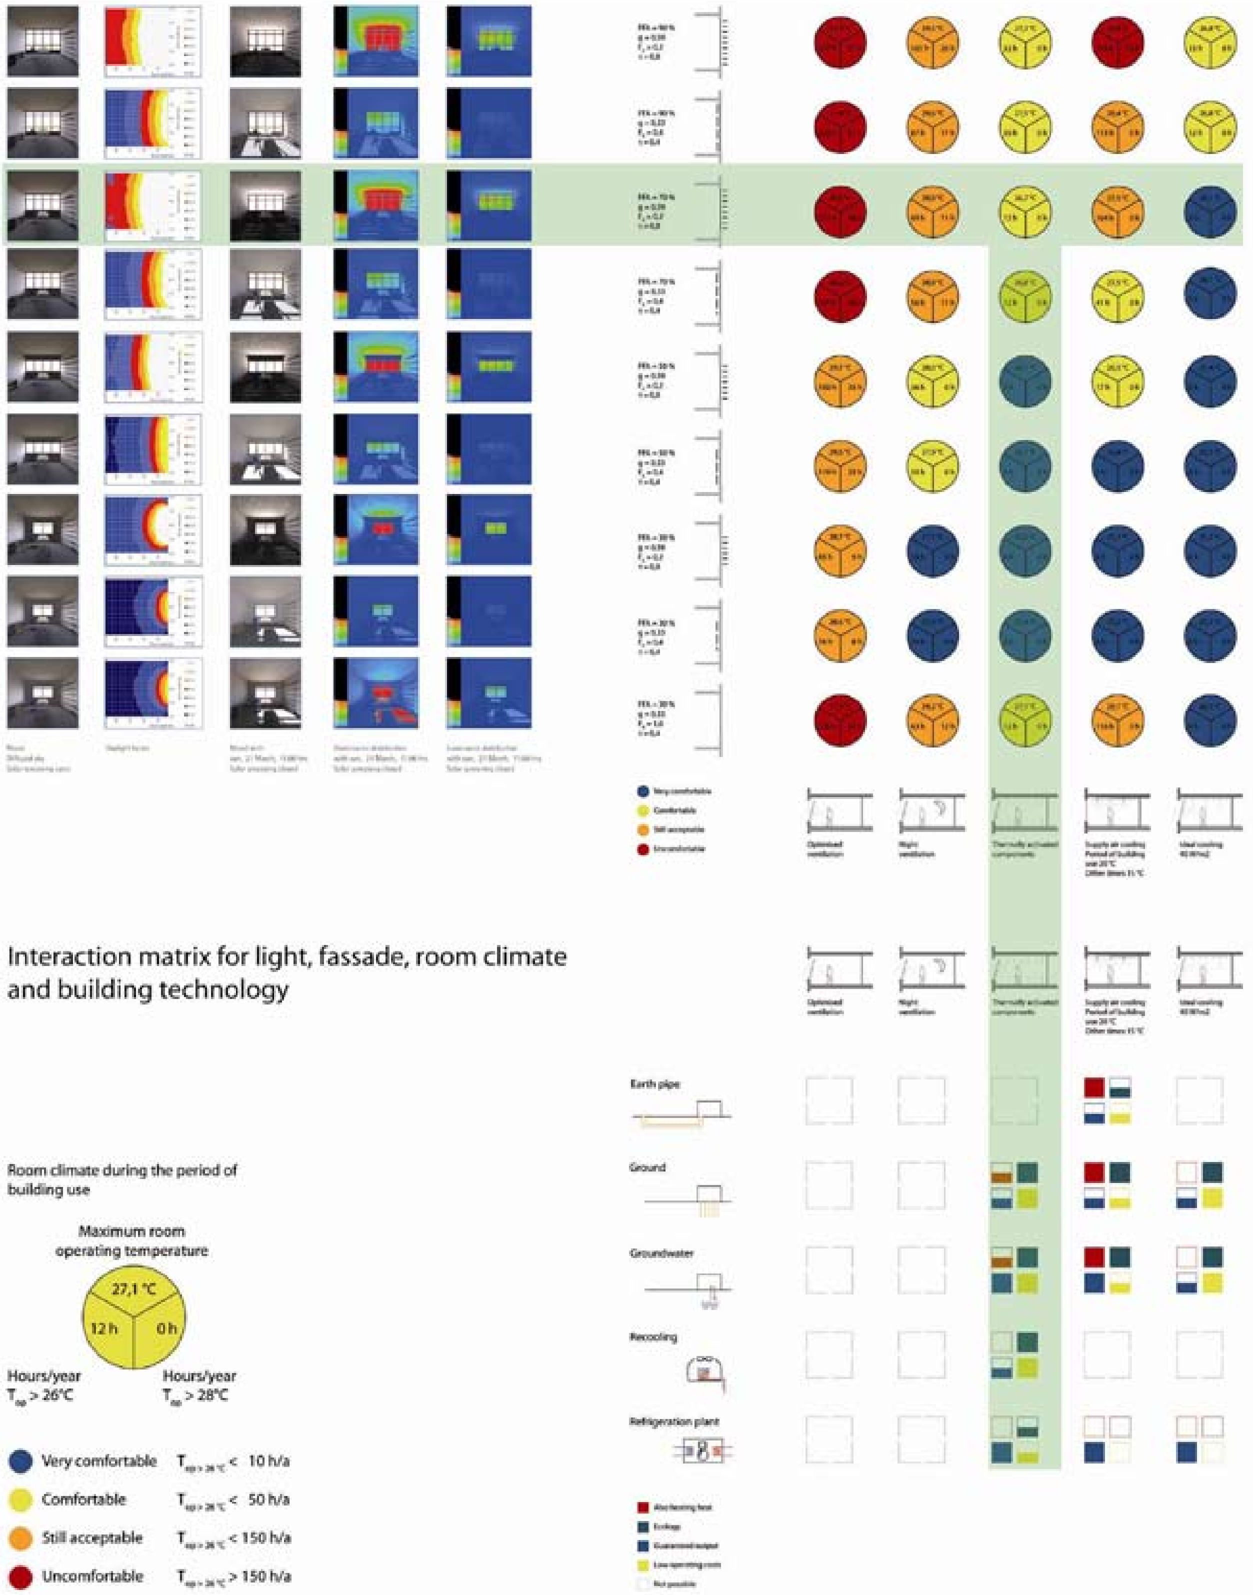

Figure 6 Interaction- matrix daylight situation, façade, indoor climate, air conditioning and energy generation and legend for the room climate

For better understanding, the interaction-matrix presented in figure 6 will be described by the following example (highlighted in green). If, very good daylight provision is desired, it can be achieved with a proportion of window area of 70% with conventional glazing. In combination with external solar screening, a good room climate (yellow circle) is achieved with thermally activated components, a very good climate (blue circle) with active cooling.

With thermally activated components, regenerative energy sources such as ground cooling, groundwater and night recooling are used. Regenerative cooling has low operating costs (filled yellow square) and is very ecological (filled green square). The output from groundwater cooling is always guaranteed to be available (filled blue square). With night recooling there is a dependency on night outdoor air temperature, ground cooling may become exhausted (half-filled blue square). Ground and groundwater can also be used for generating heat in winter by means of a heat pump (half-filled red square).

To ensure a very good room climate with active cooling, a mechanical cooling system would be required. The output is guaranteed (filled blue square). Operating costs with this option are generally high (empty yellow square). The interrelationships also work in the opposite direction.

3.4 Preview

Planners of building projects in other climate zones frequently lack a detailed knowledge of the climatic conditions and comfort criteria. But it is precisely at the early planning phase that a fast assessment of the interaction between the façade and building technology is essential. Detailed calculations are less practical because of the unverified boundary conditions and the large number of variations (Hyde, 2008).

Parameter studies for standard cases enable several fundamental simulations for the concept phase to be replaced. The Interaction matrix daylight situation, façade, indoor climate, air conditioning and energy generation makes it possible to record the effects of planning decisions using a holistic approach.

This planning tool serve as a starting-point for considerations in different climate zones and is currently being developed in the research project. In education and professional training (e.g. the international and interdisciplinary master course “ClimateDesign” started in October 2007) architects and engineers should be prepared for the new challenges and changes in the building industry with these tools and developed concepts.

Keywords: the Super High-Rise, the community facilities, the satisfaction, preference

Summary

This study aims to be a reference on the basis of residents' use of community facilities. And it is to suggest design guide lines for each community facility of the Super High-Rise Apartments.

The process of this study are as follows; 1. Varieties and sizes of the community facilities on the drawings of the nineteen cases, which are built in Seoul Metropolitan area, were analyzed. 2. Questionnaire was conducted to the dwellers that live in the four cases among those nineteen cases.

The results of this study are as follows; 1. Based on the analysis of the drawings, the number of residential unit is positively correlated with the size of the community facility area, whereas the family density in that building is not correlated per residential unit. 2. Sports facilities were found to be arranged in the most nineteen cases than in any other types of other facilities. The Sports facilities have the highest level for averaging the time-duration in use for a week basis among the community facilities of the Super High-Rise Apartments.

1. Introduction

After the Sewoon Commercial Apartment was built, and this was the first high-rise mixed-use building in South Korea, a new housing scheme was introduced in Seoul in the late 1980s. The high-rise mixed-use apartments were expanded which was based on easing regime in the mid 1990s and it settled down as a new style of urban residence. The high-rise mixed-use apartments were a center in the super high-rise traditions and it weighed a huge scale in the late 1990s. These days mostly people think the high-rise mixed-use apartments were as an elegant type of housing. The facilities for community and the commercial in the mixed-use apartments, they seem to have a trend, variety-featured and elegance in compared with the normal multifamily housing since risen income and changed life styles. Although the high-rise mixed-use apartments were high buildings with a high residence-density, in process of planning there were no accurate studies in terms of their size, variety and amenity that was to complement for poor outdoor spaces, and shared spaces, and other life services.

Recently in the super high-rise mixed-use apartments are studied actively based on above issues about community facilities, and many previous researches understand the characteristics of the plan that was through the literature survey, and the researches understand about residents utilizing the community facilities that was interviewed through the staff. It was surveyed on the residents for their satisfaction about the community facilities.

As the housing gets taller, the building emerges to have characteristics being high density housing, which is mostly recognized as one unit of one community. The community facilities in the Super High-Rise Mixed-Use Apartments have functions, which are semi-public space as a buffer zone (connecting unit house and outdoor space), defensible space (protection from outdoor threat) and amenity (upgrading for residents' convenience and welfare).

This study should be used as a preliminary data to draw the criteria for unit planning. The aim of the study was to find out the residents' utilizing the community facilities, the residents' satisfaction and their preference for community facilities in the super high-rise mixed-use apartments. The study is expecting for helpful designing the community facilities and for improving for residents' quality of life.

2. Methods

For choosing some cases in this study, we selected the buildings that were built after year 2000 and those that named by mixed-use apartment. They appeared on the real estate websites and on the authorized building lists. The study was geographically limited in Seoul Metropolitan and Bundang areas because in other cities, there were poor numbers of cases, different income level and density of residence.

The process of this study is as follows;

First, through the literature survey we considered concept of community facilities and space functions in the Super High-Rise Mixed-Use Apartments. The buildings were classified by types and functions of the community facilities from the analysis of the mixed-use developments.

Second, Variety and size of the community facilities were analyzed in which shown on the drawings of the nineteen cases in Seoul Metropolitan and Bundang areas.

Third, survey was conducted to the dwellers living in the four cases with variety of the community facilities and with good brand quality among all nineteen cases.

3. Results

3.1 Types

The community facilities in the Super High-Rise Mixed-Use Apartments include functions such as semi-public space which refers as a buffer zone between each unit and with outside and defensible space which is a safety function and amenity that is to improve for residents' welfare and their convenience.

From the analysis of the previous research on the community facilities, it was classified by their functions, residents' behaviors, indoor and outdoor. In this study it classified about the indoor community facilities into the followings, residential service, the residents' communication space, sports facilities, leisure-culture facilities, and education facilities.

Table 1 The type of community facilities in the Super High-Rise Mixed-Use Apartments

Functional index	Residential service	Residents' communication space	Sports	Leisure/Culture	Education
Community facilities	Hall/Lobby Living Center Storage Business room Laundry Guest room Indoor garden	Banquet Hall Meeting room Residential rest room Business room Club house Silver room Multi−use	Indoor golf Gym Aerobics Pool Sauna Tennis/Billiards	Exhibition room Habby Multimedia room Karaoke DVD room	Study room Kids room Library PC room

The Super High-Rise Mixed-Use Apartments is classified by three types and the types are residence and neighborhood, horizontal residence and office, and vertical residence and office which based on the location of community facilities and other non-residence facilities.

The residence and neighborhood type was made up of residence and commerce area that next to each other at low-level story and entrances were separated between each area. If there were no restriction for floor space index, there would had been some advantages for designing the user's path and make house comfortable, even if a flat and one-hall apartment was planned. For the type of the horizontal residence and office, if the office proportion weighed high it should separate the residence and office building in order to prevent from the residents being crowded. Then it can make community facilities comfortable by locating them at low-level in the residence building. The vertical residence and office type was subdivided by podium style and mixed style. The podium style distinguished the residence and the office vertically and the community facilities were located at low-level in the building. The podium style can have high floor space index in the tower shape, there are advantages for residents' amenity between the connections from the community and the commercial facilities. The mixed style which refers to the community facilities at low and middle floors of the building and it worked to make the residents convenient. This style can control about the proportion and the use of the semi-public spaces in low and middle floors in the building.

Table 2 The type of community facilities' location in the Super High-Rise Mixed-Use Apartments

Community facility types		Diagram	Name of complex
Residence and Neighborhood type (RN)			Royal Palace 1 (RN-1) Michellan Shervill (RN-2) Castle Ivy (RN-3)
Horizontal Residence and Office type (RO)			Park View (RO-1) Obelisk (RO-2) Royal Palace 2 (RO-3)
Vertical Residence and Office type	Podium (P)		Tower Palace 2 (P-1) Tower Palace 3 (P-2) Super vill (P-3) Acrovista (P-4) Gelleria Palace (P-5) I-park 1(P-6) I-park 3(P-7) Hiperion 2 (P-8)

3.2 Size

The means of the public space area were 5250.16m^2 and the numbers of the community facilities were 13.42 in the housing complex. Sports facilities were quite big proportions of the most complexes. Every complex had education facilities (study room and kids' playing room) and the life service facilities like lobby. Residents' community facilities such as meeting room, karaoke, guest room, club house, and so forth which were established for at least three in every housing complex.

The numbers of the residents correlated between the area of the leisure and culture facilities and the area of sports facilities in the super high-rise mixed-use apartments. Therefore the community facilities in the super high-rise mixed-use apartments, the facilities are as important like in the normal multifamily housings. If the community facilities were satisfied to be common level the expansions in the area of the community facilities were meaningless, because the number of residents had no correlation between education facilities, residential community facilities and residential service facilities.

Table 3 The area and number of community facilities

3.3 Use

The mean hours in utilizing each community facility were less than 2 hours per person in a week except for the study room, the lobby and the sports facilities; but aerobic room was used less than 2 hours. When comparing the utilization average hour for each room, study room, lobby, swimming pool, gym, golf lounge, sauna, and commercial facilities in low-level of the building and they averaged more than 2 hours. More than thirty percent of the respondents used all these facilities.

Community facility	Sum(hours/ people)	Utilization average hour	Community facility	Sum(hours/ people)	Utilization average hour

DVD room	15/11	1.4	Commercial	110/52	2.1

4. Discussion

There was correlation between the area of community facilities and the number of houses in the super high-rise mixed-use apartments but the area of community facilities per house did not correlate with residence density. Therefore the numbers of the houses were the most important issue about designing of community facilities when the facilities' size was considered.

The highest utilization from the community facilities was the sports facilities and the lobby, but residential community facilities were not used and the facilities had low satisfaction level even though there were many sorts of them. Therefore residential community facilities in the super high-rise mixed-use apartments should be simplified and have flexibility rather than make it various. The lobby with a high level of utilization is needed to make it-self comfortable and should design the mixed space based on the functions of the residential communication.

As for the education facilities, the study room was the highest level in utilization and satisfaction, but for the kids' playing room the utilization and satisfaction was low. There are a lot of teenagers who are more than children and who are not even entered into school living in the super high-rise mixed-use apartments, because these days the apartments were developed in a huge size of unit for the

residents. When planned for the education facilities, there are needs to analyze about the members of the residents thoughtfully, and check out any programs that needed for kids.
The needs for the facilities' expansion, and variety, elegance for the community facilities in the super high-rise mixed-use apartments were shown clearly, so such needs will be important for commercializing. When the community facilities are planned, it is important to understand the residents' needs and traits. The community facilities should concern about their flexibility in planning because of low-level of utilization in the facilities after had been occupied by the residents.

Keywords: Building envelope, Double Skin Façade, Residential building, TNRSYS

Summary

Recently, the interest in the green house gas problem keeps increasing. The international community is trying to reduce green house gas emission according to the Kyoto Protocol on Global Warming. As well as global warming issue, occupants' health in building is widely concerned as also important. Double skin façade is used in many sustainable building projects and well known as an innovative solution of ecological façade system. The aim of the facade is, on the other hand, to increase internal comfort and, on the other hand, to decrease energy consumption. Within this context, the necessity of developing optimized double skin façade system for specific building types, and the detailed behavior of such façade need to be understood.

The paper deals with development of window-type double skin façade which is optimized for sustainable residential building. The façade system is based on the box-type window for protection of privacy by sound transmission through the cavity spaces and to avoid dispersion of cooking smell. First of all, parametric studies on how to decrease energy consumption by changing depth and height of the cavity spaces are proceeded with TRNSYS simulation, which is validated by the mock-up test. Furthermore, the case studies on how to decrease energy consumption by the operation methods of facade are also examined. Finally, the reduction of energy use by applying optimized window-type double skin façade to a residential building is assessed by the TRNSYS simulation that is calibrated in the real energy consumption data.

As the results, the reduction ratios of gas and electricity use by applying optimized window-type double skin façade to a residential building with 0.7 times of air change rate are 10.78% in terms of annual gas consumption and 8.66% in terms of annual electricity consumption.

1. Introduction.

1.1 Background and starting point

Following the 1973 energy crisis, interest has rapidly increased in the possibility of designing buildings that incorporate passive building technologies and efficient mechanical systems and that use significantly less energy than do conventional buildings. In December 1997, the international community has decided to adopt 'Kyoto Protocol on Global Warming' in Conference of the Parties, to cope with aggravated global warming problem. The committee chose CO_2, CH_4, N_2O, HFC, PFC and SF_6 as the six main green house gases. Also, in compliance with requirements of the Kyoto Protocol, each country has to reduce the magnitude of the green house gas emission according to 5.2 percent less than in 1990. The protocol means that enormous green house gas market is appearing as well as war of new technology begins. Europe Climate Exchange, trades 80percent of world green house gas, said that their trading volume of the green house gas in 2005 had grown 2400 times more than in 2004. Also, they foresee that the market would grow to as much as $25 billion until 2012. In order to take over the market, government and industries form developed countries struggles to preoccupy the right of green house gas emission with various policies and technical innovations. CDM (Clean Development Mechanism) is a typical example.

In December 2007, the 13th Conference of the Parties was held in Bally in Indonesia and the committee adopted 'Bally Roadmap'. The roadmap insists a developing country to comply with voluntary negotiation for reduction of green house gas emission. Korea has not only got the most rapid increase in magnitude of CO_2 emission among the OECD countries but also, imports 97 percent of nation's energy from other countries. In addition, the construction of energy is mostly based on fossil fuel and nuclear. Experts prognosticate that if Korea becomes a country obligated under the Kyoto Protocol, $11.2 billion would be spent to purchase the right of green house gas emission in 2015. The foundation of Korean economy can be threatened by this heavy expense and rapid energy cost increase with the poor energy structure, similar to underdeveloped country. Therefore, Korea also has to prepare for the reduction of green house gas to survive in the international society, even though it is not obligatory at the moment.

Since buildings consume approximately 35 - 40 percent of a nation's energy for their operation as well as the load of a building is mainly related with the building envelope, which is a climate filter for the indoor environment, it becomes clear that the necessity of developing optimized double skin façade for specific building types is increasing. Moreover, the detailed behavior of such façade is needed to be well understood. In this regard, this study purposes a development of window-type double skin faced for residential building in Korea which is able to be widely adopted without a large initial cost increase.

1.2 Prototype model of the facade

Basically, a building façade should have enough air tightness and overall U-value. The overall U-value of a façade is influenced by the layer composition of the wall and the window, but mainly by the glazing ratio. External insulation is a good solution for improving thermal performance of a façade and for avoiding problems with thermal bridge. It does not only give advantages of easy maintenance but also, the room temperature fluctuation can be minimized by the large area of thermal mass inside. Opaque wall is only related with thermal flux, but transparent or open window is a pathway of heat, light and air. So that, window as a climate filter should be able to respond dynamically to the outdoor climate changes.

Double skin façade is used in many sustainable building projects and well known as an innovative solution of ecological façade system. The aim of the facade is, on the other hand, to increase internal comfort and, on the other hand, to decrease energy consumption. The paper deals with development of window-type double skin façade which is optimized for sustainable residential building in Korea. The façade system is based on the box-type window for protection of privacy by sound transmission through the cavity spaces and to avoid dispersion of cooking smell. Using dual window can help improving thermal performance and air tightness of the façade. The cavity space between window layers, with natural or mechanical ventilation devices, acts as a thermal buffer and introduces preheated air in winter. Also, the cavity provides room for shading devices and protects them. Those shadings functions as avoiding cooling load increase in summer as well.

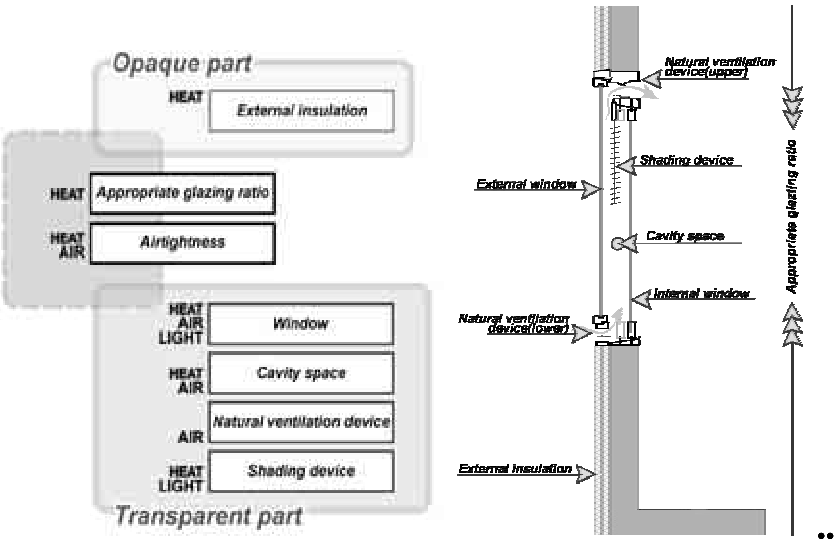

Figure 1 Concept and the prototype of window-type double skin façade.

Figure 1 shows the conceptual model of window-type double skin façade. Usually, increased depth of a double skin façade causes increase of thermal performance. The façade in this paper, however, is aiming widely adopted without a large initial cost increase. Hence, limit in the depth of the window is set to 250mm (depth of a typical wall). Also, the height of the window is restricted within the ceiling height (2500mm) because the façade is based on the box-type window

1.3 Process of the study

This paper describes a series of TRNSYS simulation for understanding thermal action in the window-type double skin façade, also finding appropriate window sizes and seasonal operation methods of the facade.

Firstly, a mock-up test with the prototype of the façade is proceeded for validation of the simulation. Actual air temperatures and surface temperatures of the cavity are observed with environmental conditions during the time of the test. After that, the TRNSYS simulation model of the mock-up test is coded and calibrated under the same environmental conditions of the test.

For better understanding of thermal action in the façade 4 sets of simulation cases are studied. Next, parametric studies with 36 cases on how to decrease energy consumption by changing depth and height of the cavity spaces are proceeded. Also, 18 kinds of operation methods were compared for finding the most efficient seasonal operation methods. Finally, the reduction of energy use by applying optimized window-type double skin façade with only natural ventilation devices to a residential building is assessed by the TRNSYS simulation that is calibrated in the real energy consumption data.

2. Calibrate the simulation model

Figure 2 shows the interior dimensions of the test cell, the dimension of natural ventilation device and installed window which was used in the mock-up test. The window of the prototype in installed at the 580mm high from the bottom of the facade. The window frame is made of aluminum, and the glass is 24mm double pane with 2.87W/m^{2}K of U-value and 0.74 of g-value.

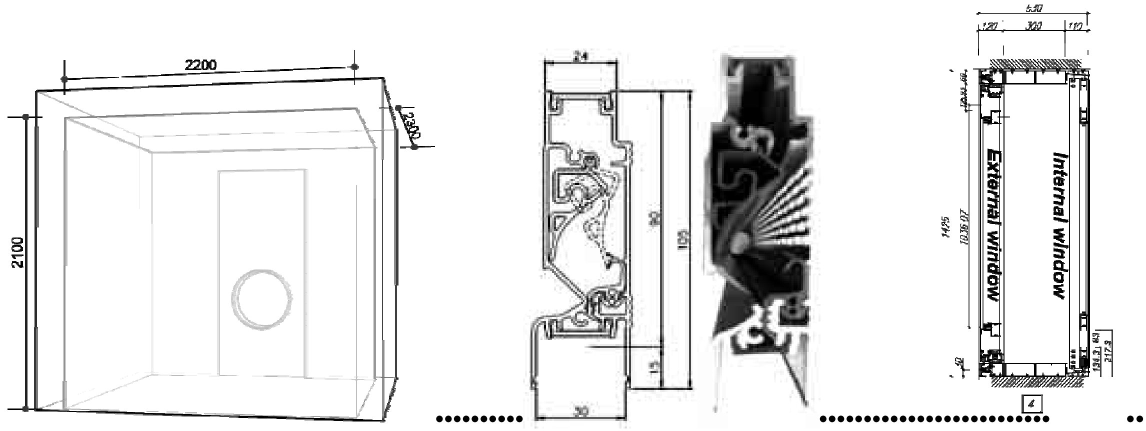

Figure 2 The test cell, the natural ventilation device and the window of the façade that was used in the test.

Figure 3 Thermocouples on the facade and the blower door with highly sensitive wind speed sensor.

9 points of the cavity air temperature, 15 points of the surface temperature of the each side of windows and 3 points of the outside and inside air temperature were observed with T-type thermocouples. Also, to make nearly constant air flow, blower door was used with minimum fan speed. Highly sensitive wind speed sensor was installed in a 300mm long pipe at the outlet of the blower door fan to measure the airflow. The test was at the nighttime from 05:00 to 06:00 in October 2007 when there is no influence of sunlight and is the coldest on the day. Under floor heating was used to maintain the indoor temperature. The set point was 30°C, because the outside temperature was not cold enough.

The cavity and the windows of TRNSYS simulation model is divided in parts at each 500mm high for more accurate analysis of the thermal action. Massless type layer is used on the connections of thermal zones, and the solar absorptance of the layer was set to 0. To calculate solar energy distribution to each zone accurately, an additional self-designed Geosurf module is used for the later use, because Type 56 does not calculate the geometry of a thermal zone. Especially in a dual window, with default Geosurf value 0, the insolated energy through a pane of glass is considered as diffused light, so the temperature of the cavity is exaggerated in the calculation.

As the simulation results, all the error between the median values of the measured and the simulation result is within 10%: the cavity temperature and each surface temperature at each 500mm high. Also, the error range is from -8.57% to +9.96%. *Figure 4* compares the measured data at the test to simulation result of cavity air temperatures at each height. With the results, the simulation model is reliable in the thermal action analysis of this type of the window.

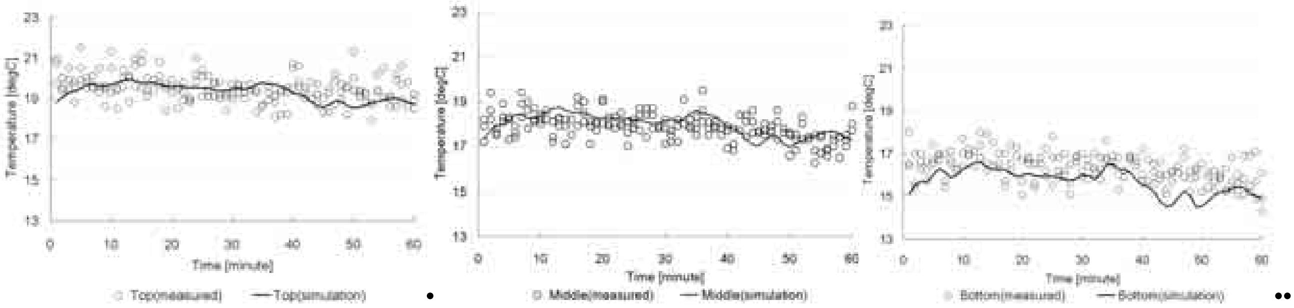

Figure 4 *comparisons the measured data to simulation results of cavity air temperatures at each height*••

3. Parametric studies

3.1 Heat flux at the window

For the better understood of heat flow at the window of the façade in winter, 8 cases according to existence and nonexistence of solar radiation, airflow directions and whether the air flows through the cavity or not are studied. *Figure 5* shows the analytical cases and the temperatures and heat transfer rates at the each height of the windows and the frames. Furthermore, it shows heating load, room air temperature, operative temperature and heat loss by ventilation of each case. The validated prototype simulation model is used. Ventilation rates are fixed to 15.38kg/hr for making similar conditions with real building: The regulation of ventilation rates in residential buildings in Korea is 0.7 ACH, and Window area to Volume ratio of the biggest room of a typical residential building is 0.125m^2/m^3. Accordingly, the ventilation rates follow the regulation, with the window which has dimensions of 2.29m^2 (window area at the test), is 15.38kg/hr. The boundary conditions of outdoor climate used in the simulation is shown at Table 1. The climate conditions are from the weather data of Sosan area in Korea in 2006. The set point is 20°C, and the simulation is conducted under the steady state.

Table 1 Climate conditions

Date/time	DBT	RH	Sky temp.	Solar incident angle	Total solar radiation	Direct solar radiation
12.22/12:00	6.3°C	74%	-7.61°C	32.04°	1746.96kJ/m^2	714.12kJ/m^2
12.22/00:00	-1.25°C	90%	-14.68	-	-	-

In contrast between Case A and B, the cold outdoor air is preheated by solar radiation and taken heat from the room while it passes through the cavity. We can see that the total heat loss to outside, in Case B, though the surface of the external glazing is smaller than Case A, despite the cavity air temperatures and inside glazing temperatures are lower. It is because that the temperature difference, in Case B, between the cavity and the outdoor is smaller than Case A. The similar thermal characteristic is shown in the contrast of Case C to B, even without solar radiation. In Case D, the heat flux to the cavity at the internal glazing is bigger than Case C, yet the heat flux to outside at the external glazing is smaller. The sensible heat is taken from the room through the internal glazing by the introduced cold air into the cavity; in the mean time the air in the cavity lose less heat to outside as the smaller temperature inclination between the outdoor and the cavity. Therefore, the heating load and the ventilation loss of Case D are smaller than Case C. From the result of the case E and F with outflow of air and solar radiation, the temperature of both the room and the cavity of Case E are higher than Case F. Since, the air in the cavity works as a thermal barrier, as the warm indoor air flows into the cavity constantly. We can find from Case G and H that the effect of the action is much bigger at the nighttime. The studies in this chapter consider natural ventilation only, buy the benefits from the inflow and outflow of the air through the cavity can be applied to a mechanical ventilation system. However, more specified studies are required for applying them to a mechanical ventilation system. For instance, if we use heat exchanger, it can make the cavity air temperature too cold at daytime which causes bigger heat loss and discomfort by cold draft.

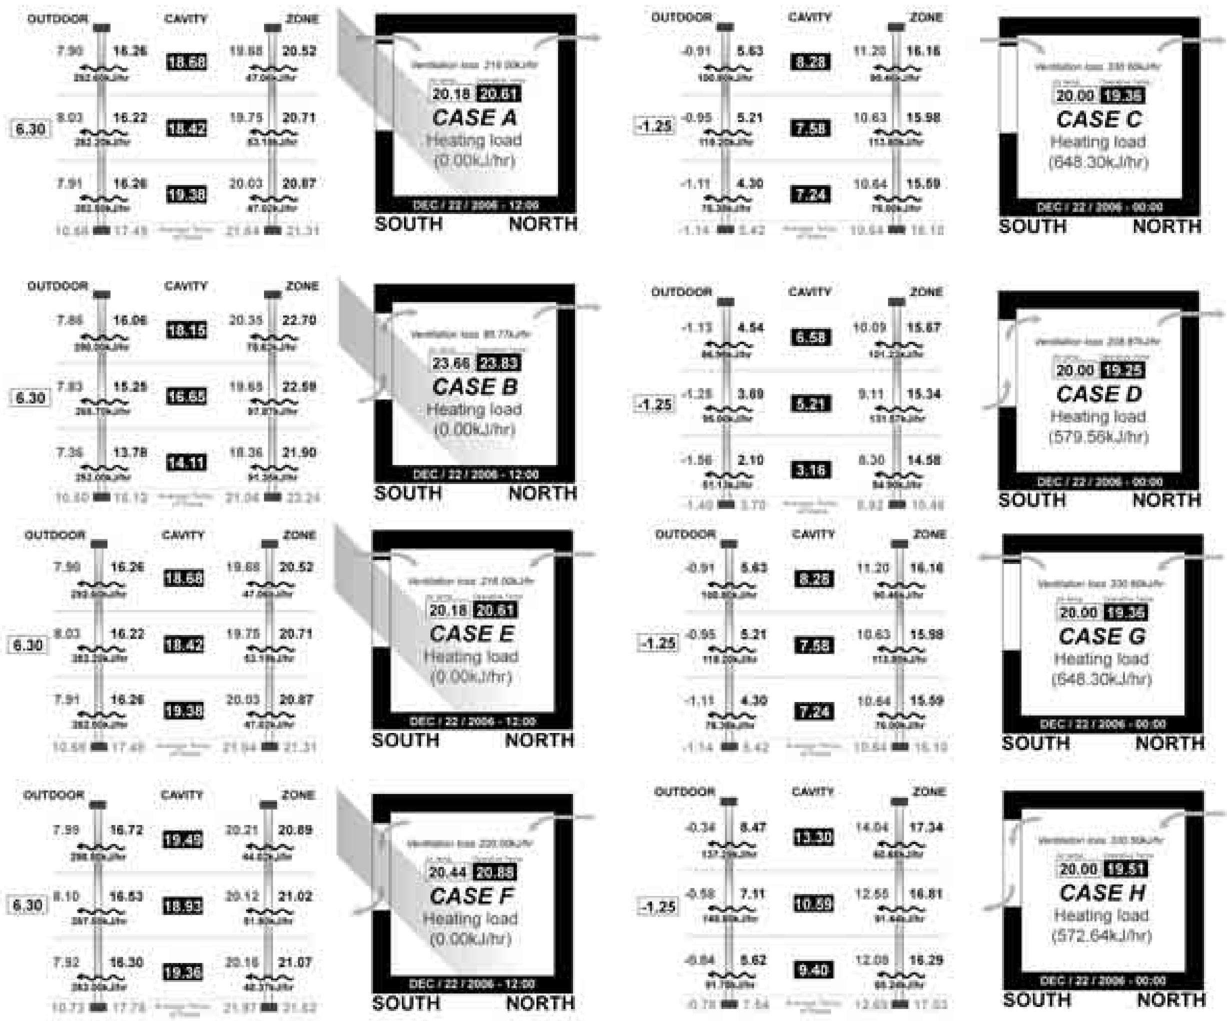

Figure 5 Heat flux intensity at the each part of the window according to cases.••

3.2 Depth and height of the cavity

Figure 6 shows 36 cases according to existence and nonexistence of solar radiation, airflow directions and heights and depths within the limit for finding the appropriate height and depth of the cavity. The simulation is conducted under the same climate conditions, the ventilation condition as well as set point condition as chapter 3.1 and under the steady state.

Figure 6 Analytical cases for depth and height of the cavity.••

As you can see from the result of Case A, there is no heating load when the height is 1500mm and the indoor temperature is 23.73°C. Although, it shows the biggest heat loss by ventilation and fairly big heat loss through the external window surface, yet it is because the indoor temperature is higher than the others. Also, the average heat losses through the external window surface are 298.33kJ/hr at the height 2000mm and 376.33kJ/hr at the height 2500mm. The values mean that heat loss through the external window surface is also increased even though the absorbed solar radiation is increased by increment of the height of the window. From the result, we can find that the longer height, the worse thermal performance under the circumstance. Besides, the result shows that increase of depth causes less heating load, but it makes little change in thermal performance. On the other hand, the additional simulations with the height 1000mm show relatively meaningful changes in heat loss through the external window surface. We could expect that the faster airflow prevents heat transfer by convection from the results.

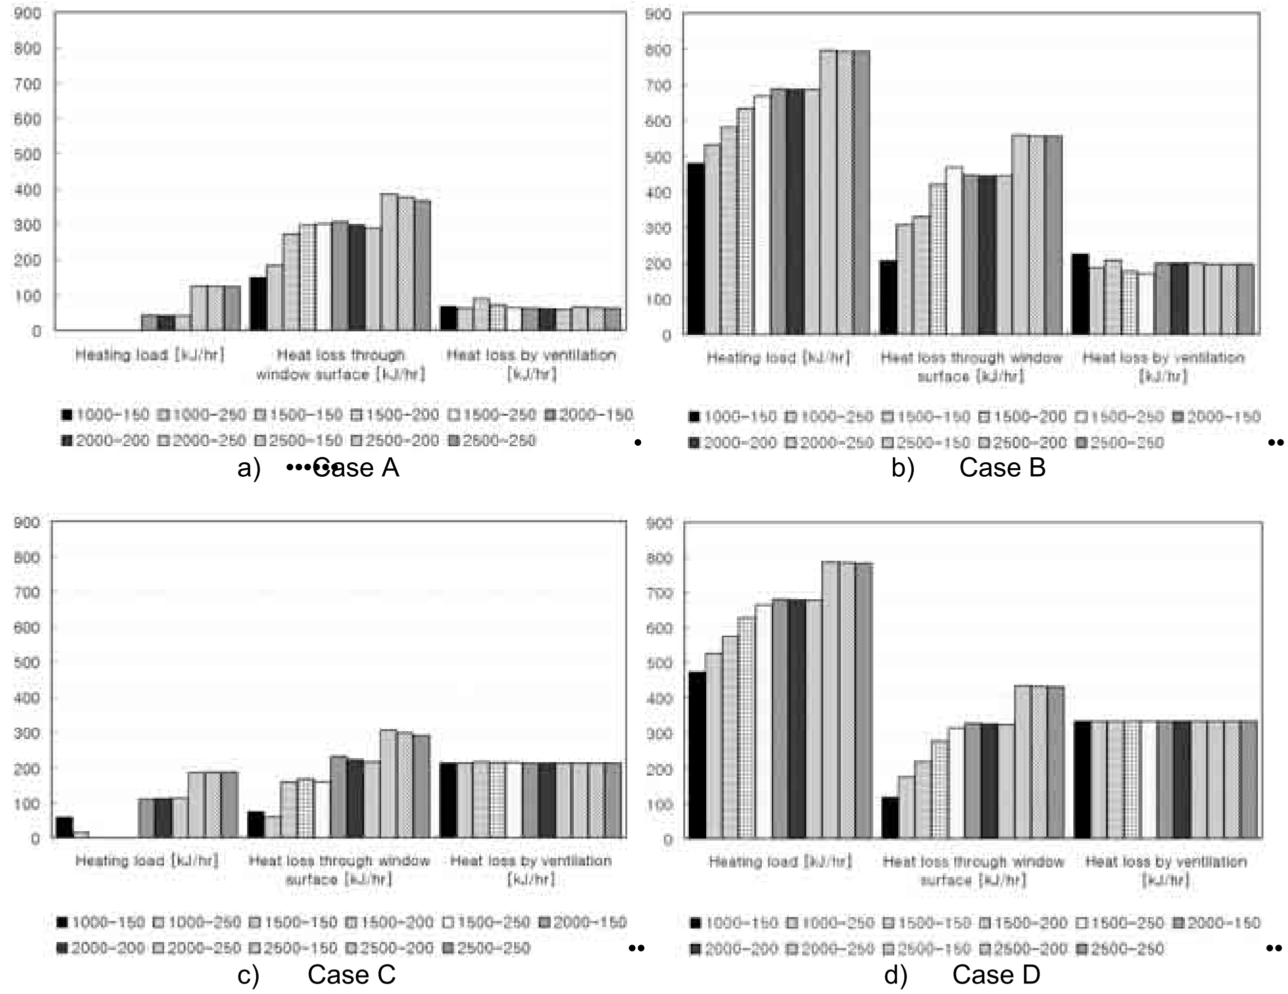

Figure 7 Simulation results of each case: heating load and heat loss through the surface and ventilation.

From the Case B, we could find the similar results in changing height with the Case A but not in depth. The heating load and the heat loss through the external window surface are proportionate to the glazing ratio. However, with the window height 1500mm, the heating load and the heat loss through the surface are in inverse proportion to the depth, also the influence is quite big especially when the height is short and there is no sunlight. This phenomenon is also able to be described by increment of convection current. Case C shows that no heating load is when the height is 1500m. Particularly, overall heat loss through the external window surfaces is smaller than Case A. It is supposed that the temperature of the cavity is kept higher enough to reduce heat loss by exhausted room air, which is nearly 20°C, through the cavity. The action of constant heat supply reduces heat loss through the window surfaces. Moreover, less heat loss does not mean less heating load. We can find it from the result of height 1000mm at Case C. For enough heat gain appropriate glazing ratio is required. Case D shows expected patterns from the previous cases. The surface heat loss is in proportion to the glazing ratio and is in inverse proportion to the depth.

As the results, increment of the depth within the limit decreases heat loss little when the cavity volume is big, but it shows contrary results when the volume of cavity is small. On the other side, the window area within the limit is proportionate to total heat loss. At the additional simulations of the window with height 1000mm, they do not show better results than the windows with higher heights under the conditions of Case A and C. However it shows better thermal performance under the condition of Case B and D. So that, height 1500mm, depth 150mm at the southern façade and height 1000mm, depth 150mm at the northern façade, consider the visual contacts, would bring a fine thermal performance.

3.3 Operation methods

Effective operations are essential to obtain the best possible performance from passive features. However, because of the nature of residential buildings, sophisticated controls are not well harmonized with them. The controls should be rather simple and easy. This study chooses 9 simple operation methods for natural ventilation according to use of ventilation flaps and opening or closing the windows. The analytical cases for various operation methods are shown in *Figure 8*. The simulation is conducted for comparing heating loads of each case in December and cooling loads in August with minimum ventilation rates.

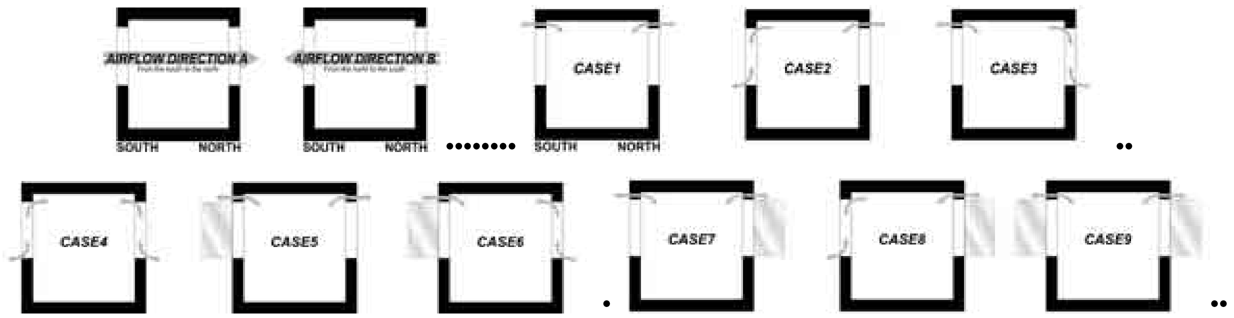

Figure 8 Analytical cases for operation methods.

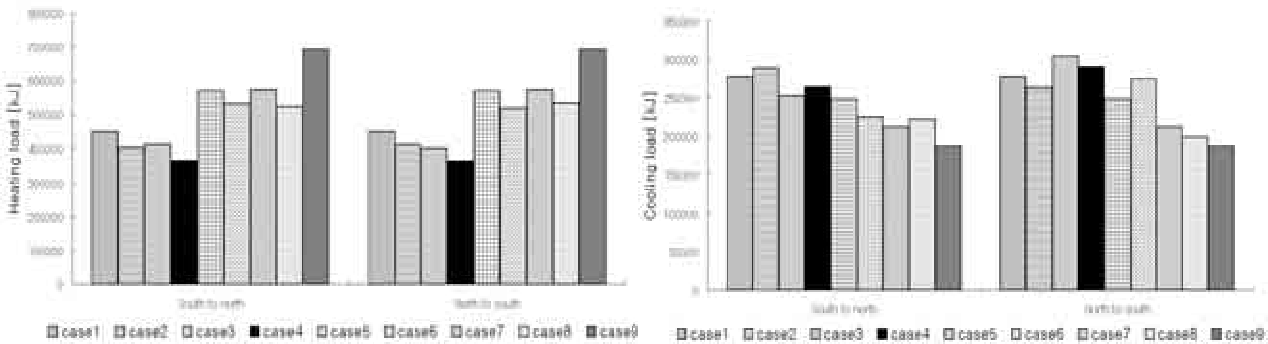
The results of the simulations are shown in *Figure9*. Heating load is found all through the month in the every case. Generally, Case 1 to 4, with closed window, show less heating loads than Case 5 to 9. Case 4 shows the smallest heating load independent of the direction of airflow. As we have seen in Chapter 3.1, airflows through the cavity in both directions dose not only show less heating load at the southern façade but also at the northern façade. The patterns of the average operation temperatures are analogous to the heating loads. Case 4 shows 0.3°C higher operation temperature than Case A. The cooling loads in August show that opening the external windows for prevention of overheating of the cavity decreases the cooling load.



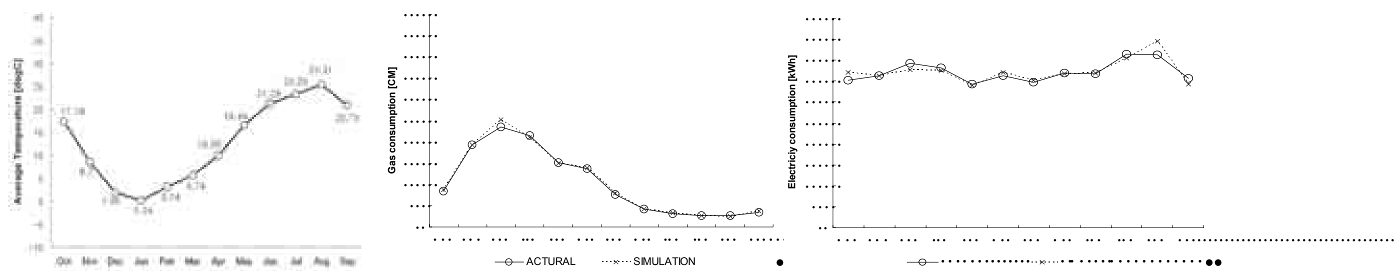
a) Heating load (December) b) Cooling load (August)

Figure 9 Simulation results of each case: heating load during December and cooling load during August.

4. Reduction of energy use by applying the façade

The reduction of energy use by applying the window-type double skin façade to a residential building is assessed by the TRNSYS simulation that is calibrated in the real energy consumption data. Before the assessment of energy use reduction by applying the façade, the existent unit of a residential building which has got balconies is modeled and calibrated at first. *Figure 10* shows monthly average temperatures of Sosan from October in 2006 to September in 2007 and the comparisons between simulations and actual data for gas and electricity consumption with the least 0.7 ACH of natural ventilation. The error ranges between the actual data and simulations of the gas consumptions and the electricity consumptions are within 10%. The range of the gas consumption is from -4.34% to 7.76%, and of the electricity consumption is from -4.07% to 7.66%.

The modified simulation models, to the balcony extended and the window-type double skin façade applied, are simulated to assess the reduction of energy use by applying the façade. The applied building façades are followed the conclusion of chapter 3.2, and the seasonal operations are followed the chapter 3.3.

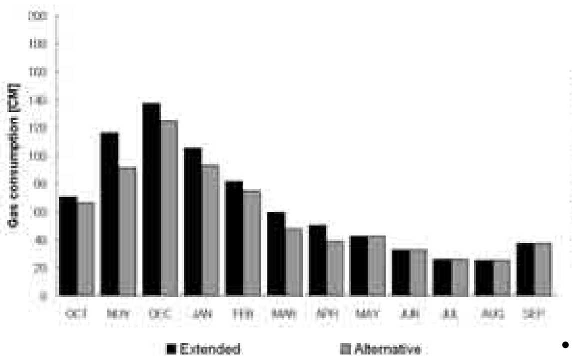


a) Average DBT(monthly) b) Gas consumption c) Electricity consumption

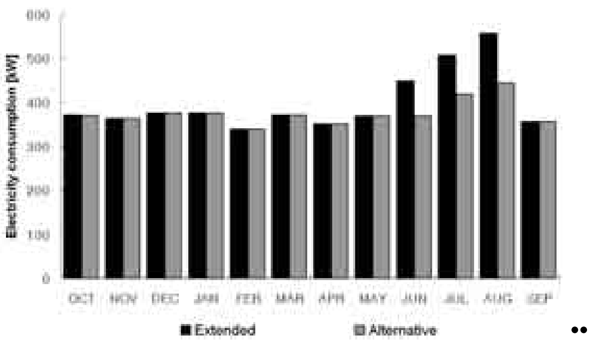
Figure 10 Annual temperature of Sosan and the comparisons between simulations and actual data.

The U-value of the aluminum window frame used at the balcony extended model and the façade applied model is three times bigger than the PVC frame of the existent model. The overall glazing ratio is reduced 11.19% and the window frame area ratio is increased 15% at the façade applied model than the balcony extended model. Also, the shading devices are used form June to August in the simulation of the façade applied model.

As the results (*Figure 11),* the reduction ratio of gas and electricity use by applying optimized window-type double skin façade to the balcony extended unit of the residential building with the least 0.7 times of air change rate are 10.78% in terms of annual gas consumption and 8.66% in terms of annual electricity consumption. ••



a) Gas consumption reduction



b) Electricity consumption reduction

Figure 12 Analytical unit plans: existent unit and balcony extended unit.

5. Conclusion

This paper deals with development of window-type double skin façade which is optimized for sustainable residential building. The façade is based on the box-type window and has got natural ventilation devices and shadings. Parametric studies for finding appropriate height, depth and seasonal operation methods are conducted. As the results, the reduction ratios by applying the façade to a residential building are 10.78% in gas consumption and 8.66% in electricity consumption.

This study focuses on heating load in winter season for the most. Further studies are required for more detailed thermal actions of the façade in cooling season. Also, it should be studied about prevention of heat transfers with smaller air volume of cavity by analysis of computational fluid dynamics or tests. Moreover, studies about integration of the façade with mechanical ventilation systems should be executed in detail.

Summary

The global warming has been raised as the most serious problem all over the world at the present and many countries have been working out to reduce carbon dioxide emission which is the main factor to occur the global warming. The carbon dioxide is generated in all industries and particularly, construction industry occupies 42% of all industry wastes. Therefore, it is sorted as the environment obstruction industry. So, the development of environmentally sustainable construction materials is required to reduce carbon dioxide on the stage of producing construction materials. In this study, the energy consumption and carbon dioxide emission in the object floor components are analyzed and compared to each other with SUSB-LCA ver 1.0. As the result, dry double floor has the best performance and dry radiant double floor has the worst performance in terms of environmentally sustainable performance.

1. Introduction

1.1 Research Background and Purpose

Global warming is one of the most terrible environmental disasters which the world faces at the present. Several countries including OECD recognize global warming as the most difficult problem that human beings should solve. Carbon dioxide occupies the most portions of greenhouse gases.

The construction industry which occupies 48% of material consumption and 40% of energy consumption in all industries is the mass consumption industry. It also occupies 42% of all carbon dioxide emission and generates 20% of all industrial waste and 60% of illegal waste. In terms of resource and environment, as the construction industry fatally affects environment of the earth, environmentally sustainable countermeasure against the problem has to be established as soon as possible. Therefore, the reduction of energy consumption and technology for development of environmentally sustainable materials are required at the stage of producing construction materials. As an effort to realize this, developing and utilizing a variety of construction materials and components based on compatibility of construction materials. However, as for a interior component of buildings, a quantitative study on the amount of energy consumption and the carbon dioxide emissions to know the environmental load in buildings have not been sufficiently performed yet.

Consequently, in this study, a floor component of buildings to be able to reduce energy consumption and carbon dioxide emissions was screened out by comparing carbon dioxide and energy consumption between existing floor component and several types of a dry floor component quantitatively. The results of the research would be utilized as a fundamental data to select the best environmentally sustainable components at the planning stage of architecture.

1.2 Research Method and Procedure

In this paper, the study is performed to reduce the energy consumption and carbon dioxide emissions of floor components through the procedure on figure 1.
Firstly, the method of the study is set up after choosing a building and floor components which become the subjects of the study through previous research. Secondly, the mount of materials is calculated through an on-the-spot survey and data research for the material requirement estimation in each floor component.

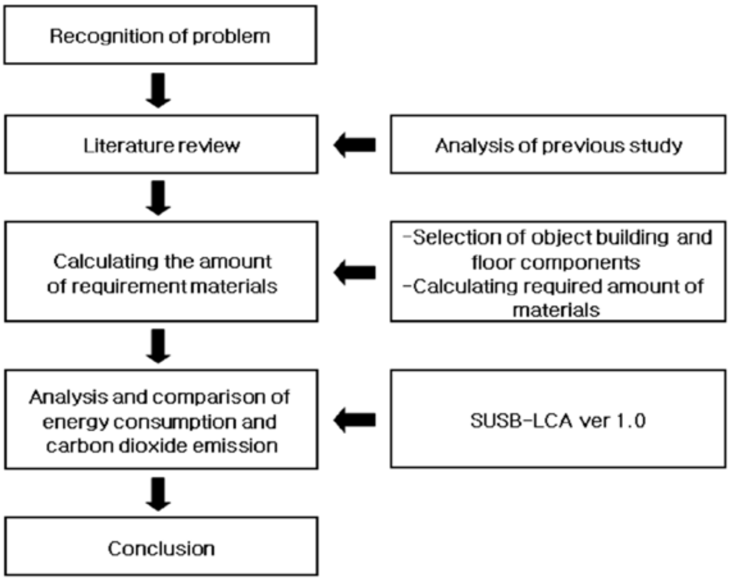

Figure 1 Research Process

2. Literature Review

In this study, to quantitatively and objectively evaluate the energy consumption, we used CO2 emission in floor components, SUSB-LCA ver. 1.0 and searched for energy consumption and carbon dioxide emissions of building interior component materials. In this study, SUSB-LCA ver. 1.0 which is the program to evaluate environmentally sustainable performance in buildings is used to quantitatively and objectively calculate energy consumption and carbon dioxide emissions of component materials.

2.1 Summary of SUSB-LCA ver 1.0

SUSB-LCA ver. 1.0(Sustainable Building Life Cycle Assessment ver. 1.0) is the useful program that can be used to calculate LCE(Life Cycle Energy), LCCO2(Life Cycle CO2), LCC(Life Cycle Cost) and assess environmental performance quantitatively. Moreover, SUSB-LCA ver 1.0 makes it possible to compare relatively environmentally sustainable technology-applied building with existing buildings built in terms of LCE, LCCO2, LCC, and assess comparatively reduction impact on LCE, LCCO2, LCC by application of environmentally sustainable architectural technology.

Major function of this program is calculating LCE, LCCO2, LCC over L.C.C of building, and it is possible for it to compare with the output of each object when environmentally sustainable technology is applied to objects. Furthermore, the by putting the data such as the amount of materials, energy consumption in operation stage and the amount of waste in removal stage into the program, the LCE, LCCO2, LCC can be output.

2.2 Assessment Method

The environmental load of building life cycle is evaluated with SUSB-LCA ver 1.0 in 3 stages divided which are construction stage, use and maintenance stage and removal stage.

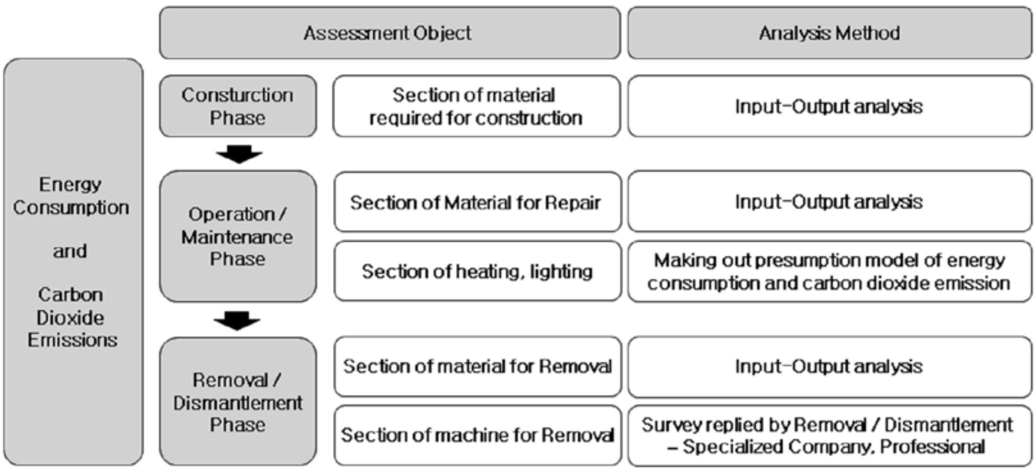

Figure 2 Environmental load assessment of building by SUSB-LCA ver. 1.0

The construction stage is divided into three stages such as material production stage, material transportation stage and onsite construction stage and the use and maintenance stage is divided into building use stage and maintenance stage. Besides, Removal/Discard stage is divided into Building Removal and Discard of building waste from removal work. The figure 2 below indicates the way to make assessment of environment load by SUSB-LCA ver 1.0.

3. Selection of Object Building and Floor Components

3.1 Object Building Selection

The object building is a normal apartment constructed in B district in Korea in 2004. Brief information of RC-structured Building is like table 1 below.

Table 1 Brief Information of Object Building

Category	Data		Category	Data
zoning district	Central commercial zone, urban planning district		Rate of building volume to lot	355.99%
Lot area	99,744 ㎡		Building coverage ratio	59.21%
Total floor area	Aboveground	355,075 ㎡	Structure type and scale	RC structure, 35 stories above and 3 stories below the ground
	Underground	82,654 ㎡	Building-covered area	59,061 ㎡
	Sum	437,729 ㎡	Gardening area	29,109 ㎡

3.2 Selection of Floor Components

As for choosing the types of floor component as an object, totally, 4types of floor are chosen, one of them is wet floor, which has been used from the past and is one of general types in housing, and the others are 3 types of a dry floor lately invented and used for construction. The table 2 below is for composing material according to each floor type.

Table 2 Composing material of floor components

Floor type	Composing Materials
Wet floor	fire insulating material(20mm) + bubbled concrete(60mm) + copper pipe +mortar(40mm)
Dry double floor	protection against dust + base panel(25mm) + floor finishing material(12mm)
Dry radiant double floor	sound insulator(20mm) + protection against dust(350mm) + plywood(12mm) + panel(30mm) + heatproof panel(2mm) + XL pipe +aluminum panel(2mm)
Dry radiant floor	fire insulator(20mm) + panel(30mm) + heatproof panel(2mm) + panel(12mm)

4. Energy consumption and Carbon Dioxide Emission of Floor Components

4.1 Output Standard of Required Materials in the Floor Components

The calculation of energy consumption and carbon dioxide emissions is progressed with focus on unit (width:1m, length:1m). And in order to calculate the amount of materials, the materials used for each component are searched through visiting site and data review. In addition, the amount of required materials is calculated at firsthand with integration method. The calculation of required materials is done by two professionals who have more than five years experience. Also, cross check is also performed not to make any omissions.

4.2 Comparison and Calculation of Energy Consumption and Carbon Dioxide Emission

4.2.1 Energy Consumption

By analyzing energy consumption classified by floor component type, the result as figure 3 is drawn.

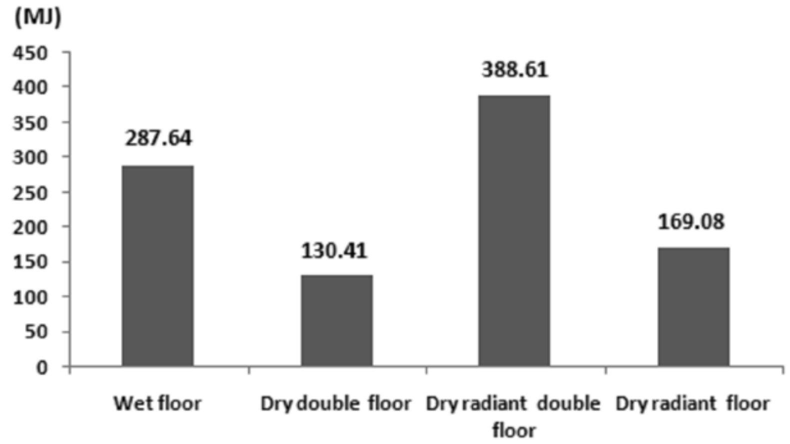

Figure 3 Energy consumption of the floor components.

First of all, dry double radiant floor occupy 388.61MJ as the most energy consumption of them. Next, wet floor has 287.64MJ and dry radiant floor has 169.08MJ. Lastly dry double floor has 130.410MJ as the least energy consumption.

As a result of showing percentage comparing three types of dry floor components to existing wet floor, dry radiant double floor is 135.1%. dry radiant floor is 58.8% and dry double floor 45.3%. According to this order, the dry double floor has a superior performance in terms of energy consumption as the least energy consumption.

4.2.2 Carbon Dioxide Emission

As a result of analyzing carbon dioxide emission of the components, the result is like figure 4 below.

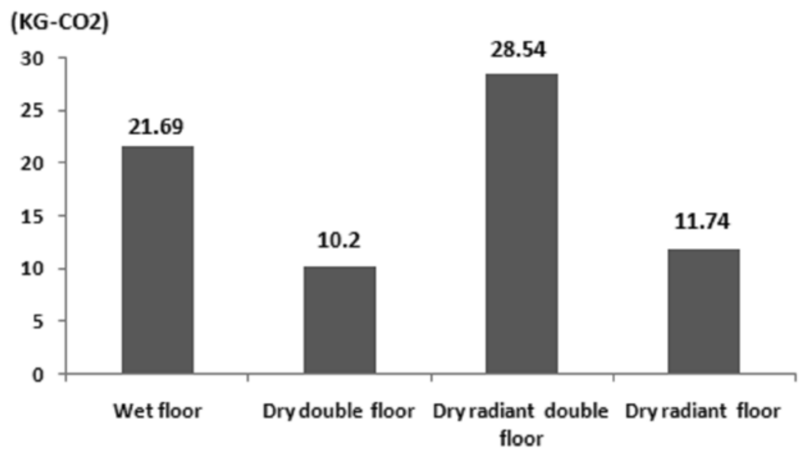

Figure 4 Carbon dioxide emission of the floor components

The result of the analysis classified by a floor type is like figure 4. It shows that Dry radiant double floor has 28.54KG-CO2 as the most carbon dioxide emission. As for carbon dioxide of the others, the existing wet floor has 21.69KG-CO2. Dry radiant floor has 11.74KG-CO2 and dry double floor has 10.2KG-CO2 as the least carbon dioxide emission. As the result of showing in percentage, dry radiant double floor has 131.6%. Dry radiant floor is 54.1% and dry double floor is 47.0%. It is proved that carbon dioxide emission of dry double floor is the lowest among them.

5. The Decrease Rate of Energy Consumption and Carbon Dioxide Emission in the Case that Alternative Components are used for Object Building.

The decrease rate of energy consumption and carbon dioxide emissions over Life Cycle are analyzed under applying each component to object building according to the standard of object building which has existing wet floor. The result is like the table 3 below.

Table 3 The decrease rate of energy consumption and carbon dioxide emissions in the case that alternative components are used for object building.

Floor type	The reduction rate comparing to the existing object	
	Energy consumption (%)	Carbon dioxide (%)
Dry double floor	0.51	0.41
Dry radiant double floor	-0.32	-0.28
Dry radiant floor	0.38	0.32

As a result of this study, energy consumption and carbon dioxide emission rate of dry double floor are 0.51%, 0.41% and it shows that it has the most reduction rates of energy consumption and carbon dioxide emission. Next, as the numerical values of dry radiant floor are 0.38%, 0.31%, it also has considerable decrease in energy consumption and carbon dioxide emission.

But in case of dry radiant double floor, the energy consumption has the increase of 0.32%. This means that energy consumption and carbon dioxide production of it increase more than the wet floor.

6. Conclusion

But in case of dry radiant double floor, the energy consumption has the increase of 0.32%. This means that energy consumption and carbon dioxide production of it increase more than existing wet floor. Continuous and comprehensive efforts to realize this are being promoted in building industry. Many components, which is based on development of various building materials and utilization of it, compatibility of building, are being developed. In this study, energy consumption and carbon dioxide emission of wet floor component which is the most general type of the several components is compared with dry double floor, dry radiant double floor, dry radiant floor component in terms of energy consumption and carbon dioxide emission. The result is like these followings.

Firstly, in respect of energy consumption, it is found out that wet floor component is 287.64MJ. Dry double floor component is 130.41MJ and dry radiant double floor component is 388.61MJ. Lastly, dry radiant floor is 169.08MJ. Therefore, the energy consumption of dry radiant double floor was relatively the most, and energy consumption of dry double floor is the least. Secondly, in respect of carbon dioxide emissions, wet floor is 21.69KG-CO2, dry double floor component is 10.2KG-CO2, dry radiant double floor component is 28.54KG-CO2, dry radiant floor is 11.74KG-CO2. Furthermore, when applying three types of dry floors to the object building which adopts the wet floor, in case of the reduction of energy consumption, dry double floor has the reduction rate of 0.51%. Besides, dry radiant double floor has the increase of 0.32% and dry radiant floor has the decrease of 0.38. In case of the reduction of carbon dioxide emission, dry double has the reduction rate of 0.41%. dry radiant double floor has the increase of 0.28% and dry radiant floor has the decrease of 0.32%.

The result of this study can be used as a basic data for selection of best alternative component by analyzing and estimating environmental impact in advance at the planning stage. In addition, this would be able to be used as a basic unit to assess environmental load of rebuilding for remodeling. And the order of priority to select alternative technology environmentally demanding materials could be judged. Dry double floor supposed proposed in this study is the component being developed continuously in respect of energy consumption and carbon dioxide emission. Particularly, if variableness, noise, disaster prevention and heating are pieced out by double floor system, it will be expected to increase the efficiency of building work and environmental amenity.

Keywords: the High-Rise, Health, Story, Apartment

Summary

This study aims to gather preliminary data for future high-rise apartment planning involving city-based residents in order to objectively understand their health condition. In this study, a survey was conducted that involved those who visited the general hospital for general checkup, and the survey limited its region to residents in the southern area of the capital city. The survey was structured with 13 sections and involved 107 symptoms.

In the study's results, the floor level on which residents live was determined to have no influence on residents of high-rise buildings' health conditions in the High-Rise building. On the other hand, the financial status seemed to have a general effect on the health of residents, and regular exercises seemed partially influential as well.

1. Introduction

The rapid increase in the number of constructed high-rise apartments (Super High-Rise Apartment, Mixed-use Apartment) is part of the drive to make efficient use of limited urban land. As people who live in the city consider the building's effectiveness and economic aspects, and because of the continuing improvements with high-rise apartments, our cities today have a thriving high-rise apartment communities.

Recently, there has been increasing interest in public health, which has spilled over in issues concerning high-rise apartment communities and other various highly concentrated residential environments. In a domestic study on high-rise apartments and related health issues, it was found that "those that live on the 16th floor or higher visit a healthcare professional twice more often than those who live on the fifth floor or lower (Choe et al, 1998).", "Those living on high floors get stressed out from fear and the sense of being isolated from the ground, from noise and accidents and crimes, and these seem to affect children more than adults" (Shim et al, 1996). Such findings indicate that living in a high-rise apartment has something to do with the residents' health. In one domestic documentary (Park et al, 1993) and quoting from findings in other countries, it was determined that living in a high-rise apartment had a correlation with residents' medical pathology.

However, considering cultural differences, systematic differences of buildings, and lifestyle, it is difficult to accept the findings and assertions of such studies made in other countries (Kang et al, 2003). There were, however, domestic partial studies, but these focused more on mental than physical stress, aggravated by the fact that insufficient samples were used.

Author	Main contents
Kim, Namgil (1996)	· A sense of isolation from the ground in high-rise residences has a psychological and physiological influence on dweller
Sim, Soonhee (1996)	· The noise and the use of elevator, and the perception of accidents in high-rise residences seem to contribute to the high stress level of dweller
	· The minimal social exposure in high-rise residences has a negative impact on the development of independence of the human child.
Park, Chulsoo (1993)	· Dweller in high-rise residence is exposed to allergy, respiratory diseases, impaired lung functioning, low physical strength, and the risk of gynecological disease.
	· High-rise building syndrome (ringing ear, headache, enervation, irregular menstruation, blurry vision, pain in the inner ear)

Kang, Inho(2003)	· Insufficient ventilation and dry air in high-rise residences influence the health of the dweller's respiratory system.

This study aims to build preliminary data for future high-rise apartment planning involving city-based residents to understand their health condition objectively. We also determined how economic status and regular, exercise.

2. Methods

The current study's context, we first analyzed the residents of high-rise and mixed-use apartments to determine the differences in health conditions depending on the city's residential type. Second, as there can be differences in the cities' environments depending on specific areas, we chose cities in southern Kyunggi-do in South Korea as target cities.

As for the targets of the study, we relied on the health questionnaire data obtained from the health center of a university hospital. The said data contained information on 21,199 residents, 34,000 people that had health-related general check-ups in the years 2005 and 2006, and those who live in selected high-rise apartments in southern Kyunggi-do.

As for the general medical examination by interview, we used self-reported health evaluations. This type of examination is performed by each participant responding to health-related questions. In studies in other countries, this self-reporting of one's health condition proved adequate in predicting health conditions, diseases, and death rate (Peter Franks et al, 2003). The tools of the current study were constructed with general symptoms in the respondents and consisted of 104 symptoms for 13 parts that were developed by the health questionnaire in the general medical examination.

In the analysis, respondents' health-related data as dependent variables were examined for architectural correlations such as with the dwelling's floor level. Furthermore, we studied possible influences to health, apart from the floor level factor, by analyzing the interrelations between expenditure and health.

3. Analysis

The group we studied mostly lived in the fifth floor or lower, 426 people who live higher than the 21st floor. It was shown that 98% of residents live below the 20th floor in South Korea, and it showed that living up to the 20th floor is common living floor. The studied target group of 77.4%, shown as the property owners, it is understood that they are capable of self-managing their property. In the part of the survey that asked the respondents their financial ability, 67.7% answered 'moderate', and 14.9% answered 'stable', which indicates that financial difficulty was rare, and the given financial situations were not relatively different from one another. On the other hand, monthly expenditures ranged widely, from less than 1 million won and to more than 6 million won.

Characteristics of Residents		Frequency	Percent
Living floor	Lower than 5th	6,647	31.4
	6th -10th floors	6,107	28.8
	11th -15th floors	5,289	24.9
	16th-20th floors	2,530	11.9
	21st floor or higher	426	2.0
	Nil	200	0.9
	Total	21,199	100.0
Type of dwellings	Renting	3,531	16.7
	Owned	16,405	77.4
	Monthly renting	230	1.1
	Nil	1,033	4.9

	Total	21,199	100.0
Financial stability	Stable	3,169	14.9
	Moderately stable	14,343	67.7
	Unstable	852	4.0
	Nil	2,835	13.4
	Total	21,199	100.0
Monthly expenditures	Less than 1 million won	1,718	8.1
	1-2 million won	4,038	19.0
	2-3 million won	3,708	17.5
	3-4 million won	1,342	6.3
	4-5 million won	957	4.5
	More than 6 million won	414	2.0
	Nil	9,022	42.6
	Total	21,199	100.0

The self-reported recording method by symptoms was existence or non-existence for those thirteen parts and the total of one hundred and seven of symptoms. Those thirteen parts were inclusive of the general medical examination (8), and dermatology (5), optical (5), auditory (6), breathing (9), vascular (5), digestive (15), kidney/urinary (10), gynecology (10), internal (7), hematology (5), skeletal (7), mental and nerve (12). For each medical part, it studied the frequency of symptom as for varied amount, and in all parts average per one person of symptom frequency did not exceed over two.

Series	*Symptoms*	*Mean*	*Std. deviation*
General Symptom	pale/fever/cold fit/cold sweat/sleeping disorder/lost appetite/fatigue/feeling stiff	1.623	0.985
Dermatology	skin rash/urticaria/tumefaction/boil/itching/	1.132	0.381
Optical	visual disturbance/dim-sighted/diplopia/sore eyes/dry eyes/ /eye mucus/inflamed	1.600	0.978
Auditory	hearing disturbance/sore ear/otorrhea/ringing ear/vertigo/dizziness	1.270	0.596
Breathing	sneezing, running nose, block nose/sore throat/substance in throat/husky voice/cough/phlegm/blood phlegm/hemoptysis/dyspnea	1.632	0.992
Vascular	dyspnea/palpitation/chest pain/chest discomfort/irregular pulse	1.385	0.699
Digestive	indigestion/belch/upper abdominal discomfort/epigastric pain/stomach pain after meal/nausea/gastralgia/vomiting/jaundice/lower abdominal pain/constipation/diarrhea/pain in bowel after emptying/blood in motions/melena	1.838	1.253
Kidney/ Urinary	frequent urine/irregular urine/dysuria/hematuria/pain in urination/urgency/oliguria/body swollen/lost sexual desire/incontinence	1.595	0.958
Gynecology	menstruation irregular/menorrhagia/dysfunctional uterine bleeding/longer duration of menstruation/excessive period /profuse menstruation/vaginal itching sense/vaginal rash/decreased secretion/pain from sexual activity	1.662	0.968
Internal	thirsty, increased urine/enlarged thyroid gland/hyperhidrosis/flushiong/increased appetite/anorexia	1.427	0.706
Hematology	vertigo/frequent nose bleed/gum-bleeding/easy bruise/hypertrophy of lymph gland	1.260	0.516
Skeletal	back pain/joint pain/restricted range of motion/neck stiffness/shoulder pain/numbness and pain	1.767	1.018
Mental/Nerves	headache/nervous /lacking concentration/sensitive nerves/memory impairment/struggling speaking/quadriplegia/syncope/depress/anxiety/insomnia	1.972	1.325

Each symptom and living floor by body parts, as results of scatted analysis on monthly expenditures and financial abilities, the living floor showed ineffective influence by different living floors. In contrast, the figure telling for financial stability and monthly expenditure showed a strong effectiveness, and the average of exercising per week had showed effective on the general medical examination, optical, kidney, urinary, gynecology, and internal. In those thirteen symptoms since the symptoms by the living floor did not differ, so the residents' health conditions and the living floor level do not correlate each other. As for the dwellers' financial stability, the average difference of ten symptoms out of that thirteen symptoms were analyzed to be meaningful and monthly expenditures were analyzed the average meaningful in the eleven symptoms. Especially, in the general medical examination the explanatory (F=20.330) appeared to be the highest. Although it did not reach as much as like by financial ability, regular exercising was decided partial influential on the inhabitants' health conditions.

Symptom Series	Dwelling Floor		Financial Stability		Monthly Expenditures		Weekly Exercises	
	F	Sig.	F	Sig.	F	Sig.	F	Sig.

4. Conclusions

The bottom line is, the living floor in the High-Rise Apartment is determined not influential for the residents' health related conditions and symptoms. In contrast, the financial level had generally shown meaningful influence for their health, and regular exercising was analyzed being partial influential. Despite financial level being a difficult factor to be enhanced by some physical environmental, that physical environmental factor that is in order to develop the residents' health conditions, then well-planning for easing access to regular exercises will be the best effective way.

This study has limitations that it did not reflect for the real health conditions which were supposed to have analyzed by the residents' self-reported survey for existence and non-existence of the symptom frequency. Therefore, in the future, the study will have to be implemented better in which based from the previous medical examination data. Moreover, because the ratio for those apartments higher than 25th floor level in the southern Kyunggi-do was very less number, and so the small gap between the living floors, this study was enable to result for its reliability.

Summary

This study aims to produce an optimized arrangement of apartment complexes that considers various factors such as the exterior finishing materials and the arrangement of apartment complexes that influences the outdoor thermal environment of cities, and also to draw a more realistic conclusion through actual measurements and simulation inspections. The results of actually measuring the air temperature around 2 pm when the temperature is the highest, by dividing the measurement points to concrete block space, water and tree space, and water space, showed the temperature to be in the order of block space (33.1℃) > green space (31.7℃) > water space (30.9℃). The simulation analysis results showed similar results to the measured results in which green space and water space had temperatures 4~5℃ lower than that of block space, and exhibited a similar pattern.

1. Introduction

As urbanization and industrialization rapidly progressed since the mid-20th century, our lives have become affluent. However, as the industrial activities focused on the urban area and economic activities and population increased, high density buildings were demanded around the urban center and various artificial heat and air pollutions generated from this changed the climate of the city. The urban heat island effect can also be seen as a result of such phenomenon and the global interest to examine and relieve this situation is increasing. The urban heat island effect refers to the phenomenon in which the temperature of the urban center increases compared to the outer areas since the amount of heat absorption and emission of the earth's surface has greatly increased and the emission of moist has also been intercepted due to the area expansion of concrete structures and asphalt roads within the city compared to the green area. The heat island effect appears more distinctly in a city that is tightly filled with cars, people and buildings. To prevent any more ecological destruction and preserve the land of Korea, finding a method to control the changes of the outdoor thermal environment of cities is urgently called for.

This study aims to produce an optimized arrangement of apartment complexes that considers various factors such as the exterior finishing materials and the arrangement of apartment complexes that influences the outdoor thermal environment of cities, and also to draw a more realistic conclusion through actual measurements and simulation inspections.

2. Outline for measurement

2.1 Outline of subject of measurement

The environment-friendly apartment housing complex of D Construction Company located in Sillim-dong, Seoul, was chosen as the subject for the measurements. The subject complex arranged the apartment houses to form a wind flow and secured green space and water space between the houses within the apartment complex. The proportion of green space is about 37% with a land area of 47,840 ㎡ and landscape area of 17,700 ㎡, and the green space is formed of broadleaved trees and grass.

The total number of residents within the complex is 853 households and the structure is reinforced concrete.

2.2 Selection of measurement points and arrangement of equipments

2.2.1 Selection of measurement points

The actual measuring points within the subject complex of measurement were measured by largely dividing the space into three groups that considered the physical environment factors of space: space finished with bricks; space densely filled with water, trees, and grass; water space that has an artificial pond. Block space were made of concrete bricks as the floor covering material, and receives sunlight directly and continuously during the afternoon. Green space is covered with broad-leaved trees and grass. Water space is of a sunken formation and the water is circulated. Figure 1 shows the main measurement points within the complex.

Fig 1 Measuring Points and Measuring space division

2.2.2 Arrangement of equipment

Multi-function measuring instruments were installed 1.5m above the earth's surface at three spots, and the temperature, relative humidity, glove temperature, and airflow velocity within the complex were measured. Thermo-hygrographs were installed at nine places in each space and measured for 24 hours, and the standard point for measurement was set at the height of 1.5m, same as the other equipment.

2.3 Period and method of measurement

2.3.1 Period of measurement

Measurements were gathered for three days from July 30 to August 1, 2007. The weather data of the Korea Meteorological Administration and the weather data through actual measurements are shown in Table 2.

Table 2. Weather data of the measuring period

Classification	Temperature			RH [%]		Velocity of air [m/s]			Solar radiation [MJ/m^2]
	Avg.	Max.	Min.	Max.	Min.	Max.	Avg.	Direction	
Actual measurement	28.7	31.2	26.4	77	54	5.8	1.4	West	15.23 (Meteorological Administration)

2.3.2 Method of measurement

The method of measurement consisted of dividing the housing complex into green, water, and block space, installing measuring equipment 1.5m high above the earth's surface, and measuring the temperature, humidity, velocity of air, and solar radiation and reflection rate that reached the complex. A weather station was constructed on the apartment roof in the center of the complex and measured the representative climate conditions. The measurement points were photographed every three hours to find out the reduced temperature effect by measuring the difference of the surface temperatures according to the exterior finishing material of the apartment complex space. Data measurement was fixed to measure every minute for all measuring instruments, and after the actual measurements, data was arranged to produce average values for every15 minutes.

2.4 Measurement results

2.4.1 Analysis of outdoor thermal environment

When the temperature data of block, green, and water space in Figure 2, excluding the globe temperature, was compared, the temperature distribution of the block space was the highest and the temperature distribution of green space and water space were low during the day. On July 31, the average temperature distribution for the day was block (28℃) > water and tree, water space (27℃). The block space was greater by an average of 1℃ with a maximum of 2.2℃ higher temperature. The temperature increase in block space progressed rapidly due to heat storage and radiation of concrete bricks, and for the green and water space, the temperature was judged to be low due to the evaporative cooling effect from the photosynthesis of trees and evaporative cooling effect of vapor. The reason why the temperature of the water space was the lowest is analyzed to be because the amount of evaporation of the pond was greater. When the airflow velocity of block, green, and water space were compared, the average airflow of the block space was the fastest with 0.87 m/s, and that of the green space was the slowest with 0.27 m/s. In the complex plane, since the block space actually does not have any apartment buildings around in the east and west direction, the flow of the airflow might seem to be smoother than that of the other spaces, but the green space and water space showed not much of a difference. When the relative humidity of block, green, and water space were compared, the relative humidity of the block points was the lowest during the day, and the humidity of the water space and green space appeared to be almost the same. Since the distribution of relative humidity is determined by temperature when it is similar to the absolute amount of humidity, it seems that the humidity was low because the temperature of the block space was relatively high.

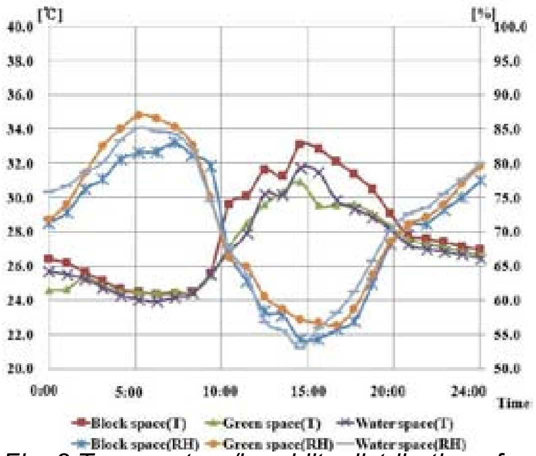

Fig. 2 Temperature/humidity distribution of each space

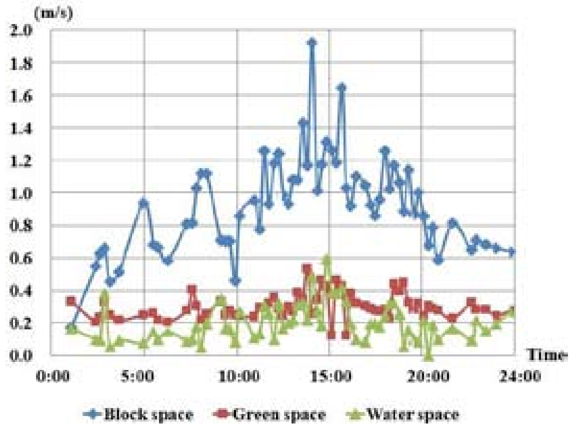

Fig. 3 Velocity distribution of each space

2.4.2 Analysis of surface temperature according to exterior finishing material

Figure 4 shows photographs of temperature distributions according to the surface finishing material during the day (3 pm, 6 pm) taken by infrared cameras. The surface temperatures according to the finishing material on a summer day appeared in the order of block > green > water. The reason why the temperature difference of the block space was large is judged to be because hot air was less stagnant despite the high surface temperature since the airflow velocity of the measuring locations were greater than that of other areas. The surface temperature according to the finishing material at night appeared in the same order as the day: block > green > water. Block space still had a higher surface temperature compared to green and water spaces, but the range of the temperature change decreased. Since the solar radiation effect was minimal, it seems the difference between the temperature of the block surface and the temperature of other points decreased. However, the reason why it still had the highest surface temperature is that the heat stored during the day was not completely emitted externally. Through the high surface temperature of block space compared to those of the grass and water space, it can be confirmed that the properties of the materials influence the heat island effect within the apartment complex during the summer.

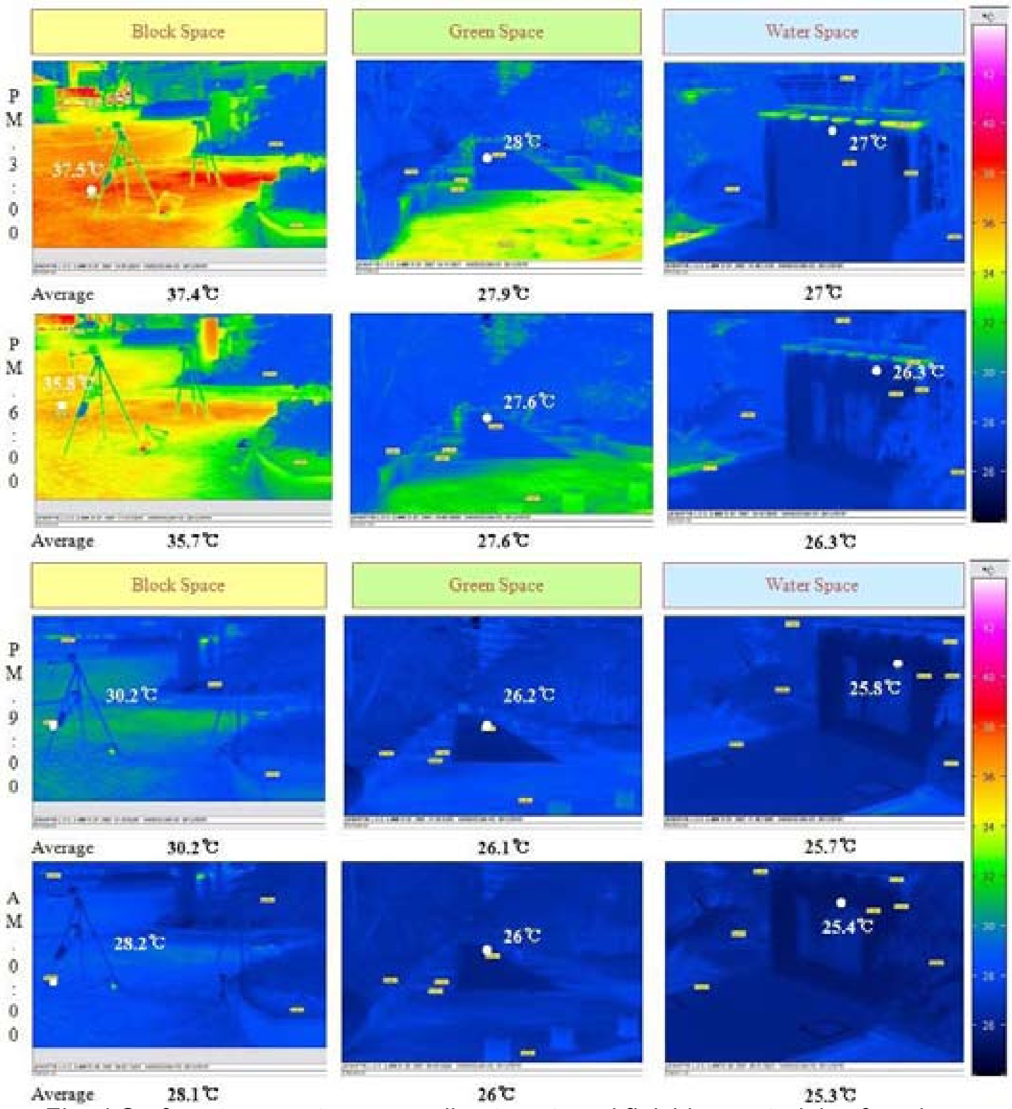

Fig. 4 Surface temperature according to external finishing materials of each space

3. Analysis of outdoor thermal environment using CFD simulation

3.1 Analysis model

This study attempts to quantitatively analyze the outdoor thermal environment of the subject complex for measurement, and compare and analyze the measured results and the simulation results in order to verify the outdoor thermal environment modeling method and simulation analysis method. The modeling subject is the subject complex for measurement and the modeling was carried out according to the characteristics of the space, such as buildings within the apartment complex, block space, water space, water and tree space, grass space, and roads. Figure 5 shows the modeling results of the subject apartment complex.

The arrangement of the building space was modeled identically to the location of the buildings within the complex and the modeling was carried out with buildings of equal height of 50m. The outdoor environment analysis area of the complex subject to analysis was modeled with a doubled the horizontal and vertical length of the subject complex and five times the height. The outdoor environment analysis area is shown in Figure 6.

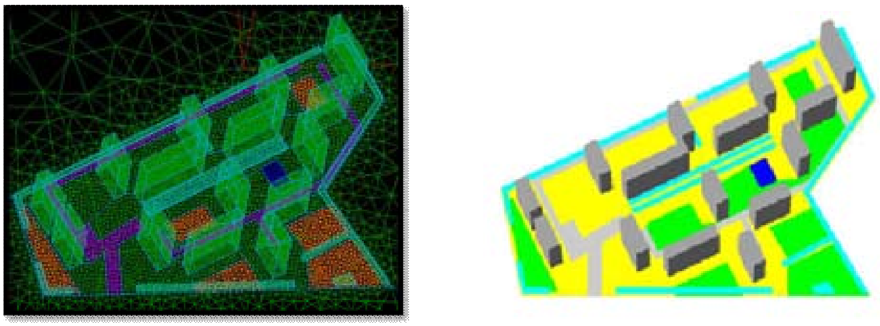

Fig. 5. Modeling of subject apartment complex

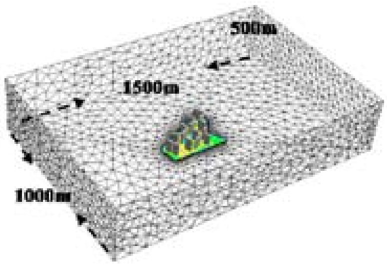

Fig. 6 Outdoor environment analysis area

3.2 Analysis conditions

The CFD method was used for the outdoor thermal environment analysis within the complex. Total space was divided into about 850,000 sub-spaces, the Korea Meteorological Administration data was used for diffuse radiation according to time, and direct solar radiation was calculated based on DIRN/HOR. For the amount of wind, the equation below was applied to carry out the CFD analysis.

$$v(z) = V_{\infty}(z/H)^n$$

z : vertical altitude from earth's surface (m)
H : height of air boundary layer (m)
V_{∞} : average wind velocity at air boundary layer altitude (z=H) (m/s)
v(z) : average wind velocity at arbitrary altitude z (m/s)
* Exponent n: roughness length of surface

In this study, surface roughness length was set at 0.3 considering that the analysis complex was located at the urban center and the fact that numerous tall buildings were located nearby. Table 3 displays the CFD simulation analysis boundary conditions.

Table 3 CFD analysis boundary conditions

Solar radiation	Total solar radiation of the horizontal surface (July 31)
	$594 W/m^2$
Amount of wind	$V(h)=V_0\times(h/10)^a$, a = 0.3(urban) V_0 : Wind velocity at height of 1.5m (=0.5m/s)
Wind direction	West wind (Weather station)
Temperature	temperature of influx of air 29℃

3.3 Analysis results

3.3.1 Airflow distribution

The measured data and the analysis results of the CFD simulation were compared. As the measured data is data measured 1.5m above the earth's surface, the CFD simulation results also attempted to compare the airflow velocity at 1.5m under the same conditions. Figure 7 shows the airflow velocity of the measured space. The simulation analysis results show the airflow velocity in the order of block space (1.19m/s) > water space (0.33m/s) > green space (0.32m/s). It is interpreted that a smooth flow of the airflow was achieved from the formation of a wind flow since there were not many trees in the block space. Overall, the simulation results of the airflow distribution according to block space, water and tree space, and water space appeared to be distributed in the same pattern as the measured results.

3.3.2 Temperature distribution

Block space was found to be about 5℃ higher with the simulation analysis results showing block space (37℃) > water space (32.8℃) > green space (32℃). It is judged that this greatly influences the thermal comfort the human body feels. A temperature reduction effect due to evaporation cooling and solar radiation blocking appeared when the outdoor was finished with water and trees, and for the water space, the temperature dropped due to a cooling effect caused by evaporation. The air temperature according to the spatial configuration was analyzed with an error percentage of less than 10% when compared to the measured values, and the simulation verification results also showed a similar pattern to the measured results.

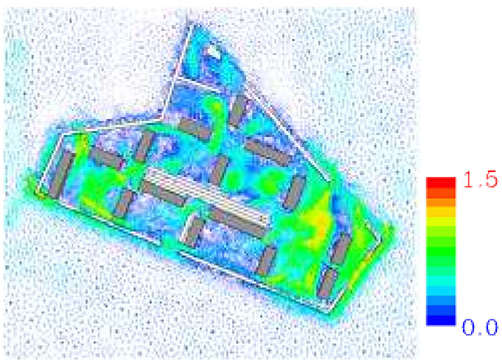

Fig. 7 Airflow distribution of analysis complex at 1.5m high (m/s)

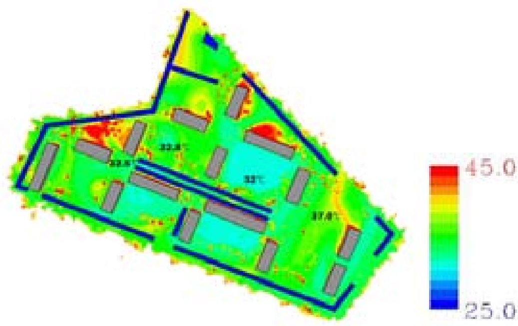

Fig. 8 Temperature distribution of analysis complex at 1.5m high (℃)

Table 4 Comparison of airflow distribution of analysis complex at 1.5m high

	Actual measurement	Simulation
Block space	1.00m/s	1.19m/s
Green space	0.30m/s	0.32m/s
Water space	0.30m/s	0.33m/s
Average	0.50m/s	0.58m/s

Table 5 Comparison of temperature distribution of analysis complex at 1.5m high

	Actual measurement	Simulation
Block space	34.0℃	37.0℃
Green space	31.7℃	32.0℃
Water space	30.9℃	32.8℃
Average	32.6℃	33.7℃

4. Methods to improve outdoor thermal environment of apartment complexes

4.1 Analysis model

Using the existing apartment complex that was measured as the subject, a method to improve and alleviate the outdoor thermal environment is proposed. CASE 1 modeled the actual apartment complex subject as it is, while CASE 2 carried out the modeling so that the block space of the subject complex was furnished with grass. The analysis conditions were made identical to the analysis conditions of the measurement of subject apartment complex and the verification stage of the simulation thermal environment.

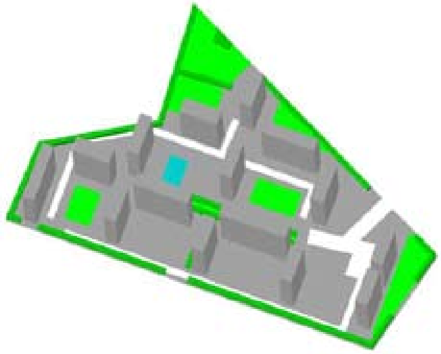

Fig. 9 Modeling of subject apartment complex (case1)

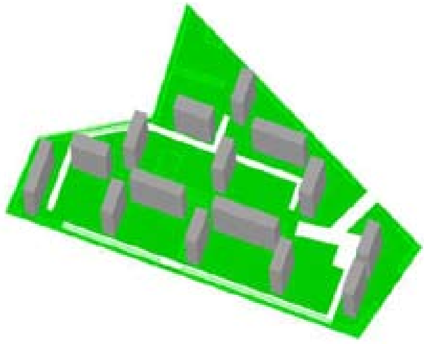

Fig. 10 Modeling of subject apartment complex (case2)

4.2 Analysis results

The air temperature of CASE 2 shows a notably low temperature distribution overall compared to that of the existing apartment complex (CASE 1). When observing the temperature distribution of CASE 2, most areas of the space show a temperature distribution between 28~31℃. The existing apartment complex (CASE 1) generally shows a temperature distribution that is 2~5℃ higher than that of CASE 2. The vertical surface temperature distribution of CASE 2 decreased remarkably compared to CASE 1. The whole complex showed a comparatively low temperature distribution due to a temperature reduction effect caused by a relatively high reflection ratio of grass and evaporation cooling effect. Such analysis results indicate that increasing the area covered by grass when planning apartment complexes allows the outdoor thermal environment of the complex to be controlled and to approach the comfort zone by mitigating the heat island effect.

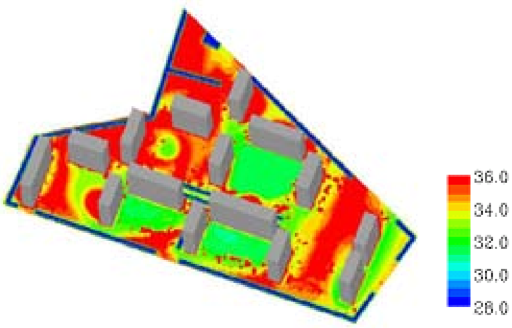

Fig. 11 Temperature distribution of analysis complex at 1.5m high(case1)

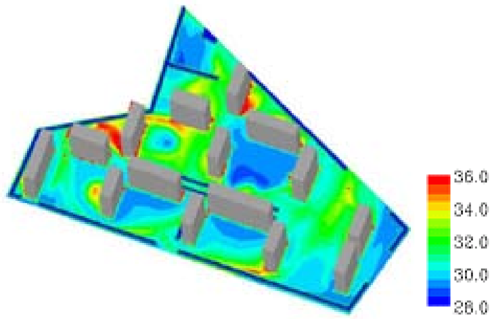

Fig. 12 Temperature distribution of analysis complex at 1.5m high(case2)

5. Conclusion

This study aimed to find a method to enhance the thermal environment within apartment complexes and mitigate the urban heat island effect using various variables by carrying out measurements of an actual apartment house complex and verifying them with simulations. The results of actually measuring the thermal environment confirmed that the microclimate of each space also differs according to the outdoor finishing materials. The results of actually measuring the air temperature around 2 pm when the temperature is the highest, by dividing the measurement points to concrete block space, water and tree space, and water space, showed the temperature to be in the order of block space (33.1℃) > green space (31.7℃) > water space (30.9℃). Furthermore, the results of measuring the surface temperature of each material by using an infrared camera appeared to be in the order of block space (37.4℃) > green space (27.9℃) > water space (27℃). It is analyzed that green space and water space have low surface temperatures compared to that of block space due to the evaporation cooling effect of moisture. The simulation analysis results showed similar results to the measured results in which green space and water space had temperatures 4~5℃ lower than that of block space, and exhibited a similar pattern. A temperature reduction effect by 2~5℃ is presented when arranging the block space of the existing apartment complex with grass space as a method to relieve the heat island effect. It is judged that planning methods that consider these factors that influence the thermal environment when designing environment-friendly outdoor spaces will alleviate the urban heat island effect and contribute to comfortable living.

Summary

Sustainable developments have always been a continuing goal and strive for Hong Kong Housing Authority (the HA) in its provision of affordable housing to the general public in terms of tens of thousands of domestic units a year. With management commitment, project team dedication and industry collaboration, the HA has successfully developed an Enhanced Precast and Prefabrication System (the System) with many innovations in precasting. The System comprises 11 types and about 10,000 pieces of precast elements per building that altogether bring the precast concrete volume to a record 60%. There are two precast innovations: firstly, precast structural shear walls that signify advancement from minor to major structural precasting, and secondly, large-scale volumetric precast components, i.e. from conventional planar to volumetric components. A pilot project was launched to try out the System. With its completion in March 2008, the project has demonstrated sustainability benefits of the innovative precasting: better quality of works, enhanced site safety and better environmental protection, and other potential benefits. Through exhibition to the general public and site visits and sharing forum to stakeholders of the industry, the significance of innovative precasting for sustainable housing developments was promoted. The System has not only contributed to sustainable construction but also advanced the frontiers of precast and prefabrication technology in the industry.

1. Introduction

Sustainable developments have always been a continuing goal and strive for Hong Kong Housing Authority (the HA) in its provision of affordable housing to the general public in terms of tens of thousands of domestic units a year. As precasting offers better quality, safer, less-pollution and quicker construction, and in turn makes a significant contribution to sustainable developments, the HA has been a pioneer in precasting in the local construction industry. Since its introduction of precast facades in the 80s, several types of precast elements have been conventionally adopted in public residential buildings – precast facades, semi-precast floor slabs, precast staircases, precast (non-structural) partitions and precast lintels. These precast elements total to about 20% of the total concrete volume of a building. The resultant benefits in built quality, site safety and environmental protection are obvious.

However, the HA was not complacent with this level of sustainability achievements and dedicated to further explore innovations in precasting with a view to bringing greater sustainability benefits to the public and proactively meeting increasing social needs of sustainable developments.

2. Management Commitment, Project Team Dedication and Industry Collaboration

Innovations mean changes – possibly changes from conventional materials, technology or practice that have worked well. It is understandable that any change has a risk of uncertainty and therefore the employer, the designer and the contractor are reluctant to change. Successful innovative development requires firstly, management commitment that will provide full support – financial, time and manpower. Secondly, it requires dedication of a project team that will follow through the innovations in their inception, formulation, trial and full implementation. Thirdly, it requires collaboration of the industry that will help actualise the precast innovations and provide realistic competitive bidding. The HA has possessed both committed management and dedicated project team. To start its pursuit of more sustainability benefits through precasting, the HA arranged a top-official delegation to Japan to obtain first hand information about the latest development in construction of high-rise precast buildings. Then it decided to try out new types of precast elements in large scale. The project team drew on overseas experience and in-house knowledge, collaborated with local academic institutes and consultants, conducted various discussions and meetings with the industry stakeholders including precasters and contractors, and executed a series of research, site trials and mock-ups.

All these efforts brought forth an Enhanced Precast and Prefabrication System (the System) with many innovations in precasting. The HA chose the Kwai Chung Flatted Factory Redevelopment Project as a pilot to try out the System. Evolution of the System satisfactorily progressed stage by stage – from planning of the project, design development, construction of a full scale mock-up on site to the construction of the precast buildings. The pilot project was completed in March 2008, which finally marked the successful implementation of the precasting innovations that once were ideas only.

3. Enhanced Precast and Prefabrication System

The System is adopted in two 41-storey residential buildings, each of 799 domestic units. Both buildings are basically of wall-slab structural form. For each building, the precast concrete volume is substantially increased from 20% to a record 60%, involving the following 11 types and about 10,000 pieces of precast elements (Figure 1):-

<u>Conventional Precast Elements</u>

- Stair Core

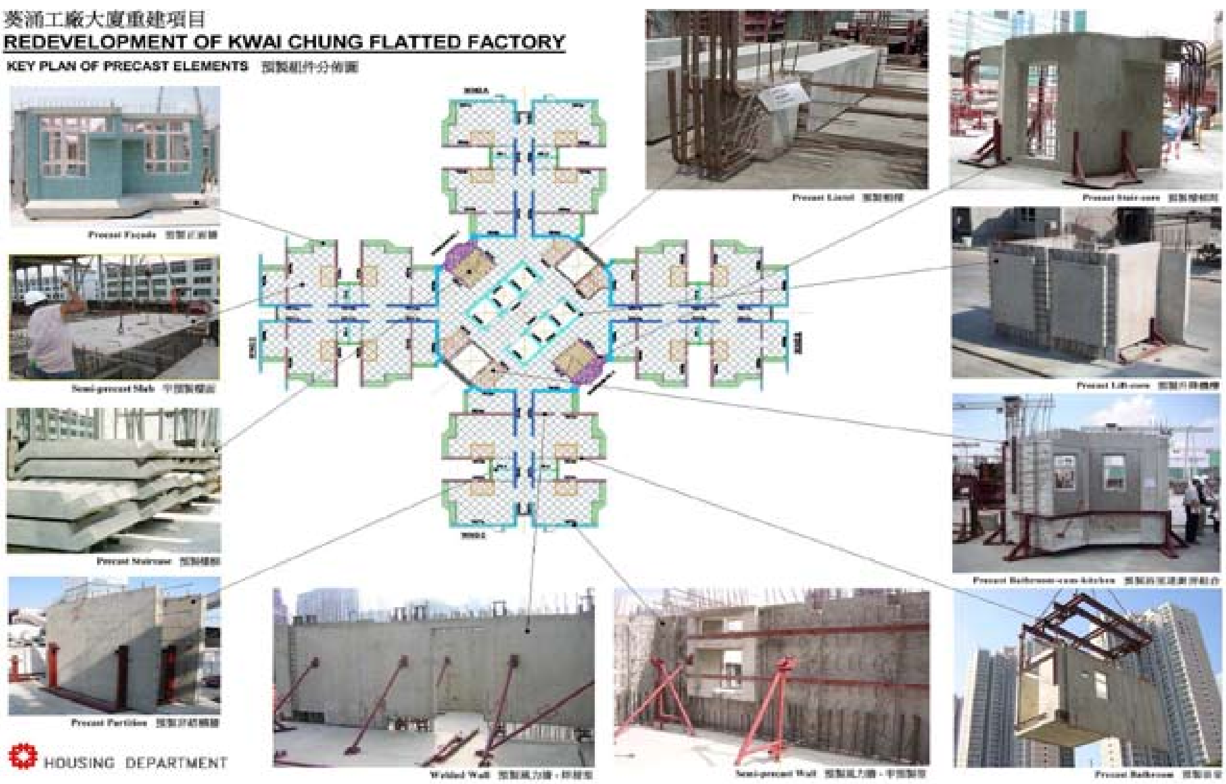

Figure 1 Layout of Precast Elements

3.1 Minor to Major Structural Precasting

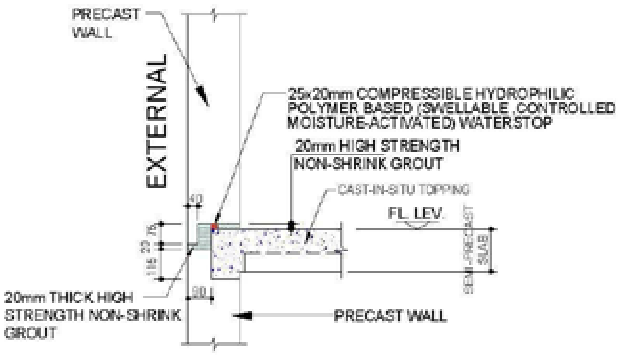
The System achieves a breakthrough development of Precast Structural Shear Walls, which signifies a great advancement from minor to major structural precasting. The conventional precast elements are all minor structural elements as they carry loads of one single storey and therefore concern local structural safety only. The design and construction are relatively simple.

In contrast, the precast structural shear walls are to carry all the gravity loads and wind loads (as Hong Kong is located in typhoon area, the buildings have to withstand winds of maximum hourly-mean velocity of 52 m/s or 187 km/h) from floors above and therefore impinge on global structural safety. The design and construction are relatively much more complicated. Besides structural aspects, waterproofing performance, buildability and cost are important design considerations for these precast walls as they are exposed, partly or wholly, to external and they are to incorporate architectural finishes and building services as far as practicable. There are two types of precast structural shear walls, namely Welded Wall and Semi-precast Wall.

3.1.1 Precast Structural Shear Walls – 'Welded' Walls

'Welded' Wall is a fully precast wall mostly used for external walls and specially designed with multiple waterproofing features at the joint – a 75x40mm downstand, a 25x20mm compressible hydrophilic waterstop and a complete filling with non-shrink grout (Figure 2). As compared to conventional insitu construction, this precast wall type can do away wall form and falsework and external working platform, not to mention that it will enhance the quality of the finished work and speed up the construction on site.

Given the unique conditions in Hong Kong that there are only a couple of suppliers of proprietary couplers for structural connections, joining upper and lower precast walls of this type is by welding of steel couplers embedded in the wall ends, i.e. structural steel sections at the two ends of the counterparts are welded together for load transmission. This connection requires neither special materials such as proprietary couplers nor special skills as qualified welders are commonly available in the market to carry out high-quality jointing work. Quality-wise it is comparable to proprietary couplers; cost-wise, it is more favourable. Besides, it has several more advantages: on-site quality control tests can be performed, and its price and supply position can be better controlled in contrast to proprietary couplers. Applying innovatively conventional welding to the structural connections is a key success to this type of major structural precasting.



JOINT DETAIL
(WITH ONE SIDE FACING EXTERNAL)

Figure 2 ' Welded' Wall

3.1.2 Precast Structural Shear Walls – Semi-precast Walls

Considering the normal lifting capacity of those tower cranes commonly available in the market and avoiding the need to upgrade the crane at an extra cost of few million Hong Kong dollars per crane, the weight of the precast components must be properly controlled. Semi-precast Wall is specifically designed for the gable end walls, furthest away from the tower crane that is usually located near the center of the block to keep the total weight within the lifting capacity of the tower crane (Figure 3). For similar lifting consideration, some of the walls of a precast bathroom-cum-kitchen are designed as semi-precast. The wall is made of an external precast wall panel and an internal in-situ concrete portion. It should be noted that the external precast panel is used as formwork for concreting the internal in-situ portion of the wall. The external precast panel is securely bolted onto the falsework at the internal side making use of the prefabricated threaded sockets cast in the stiffeners of the precast panel; thus the external wall form, falsework and working platforms are saved.

It must be stressed that the external precast panel forms an integral part of the structure to carry loads. As it is not a loss form, it will maximize the utlisation of the materials in place.

Figure 3 Semi-precast Wall

3.2 Planar to Volumetric Precast Construction

The conventional precast elements are generally planar, which are relatively easier to design, fabricate, transport and install than volumetric precast components that are sizeable in all three dimensions. The breakthrough achieved in the precast structural shear walls has enabled the development of large scale volumetric precast components integrated intelligently with shear walls (Figure 4), which satisfactorily overcome the design, fabrication and installation difficulties for such precast components of large size and weight (max 9.5 tonnes) and in large number (1,200 per block).

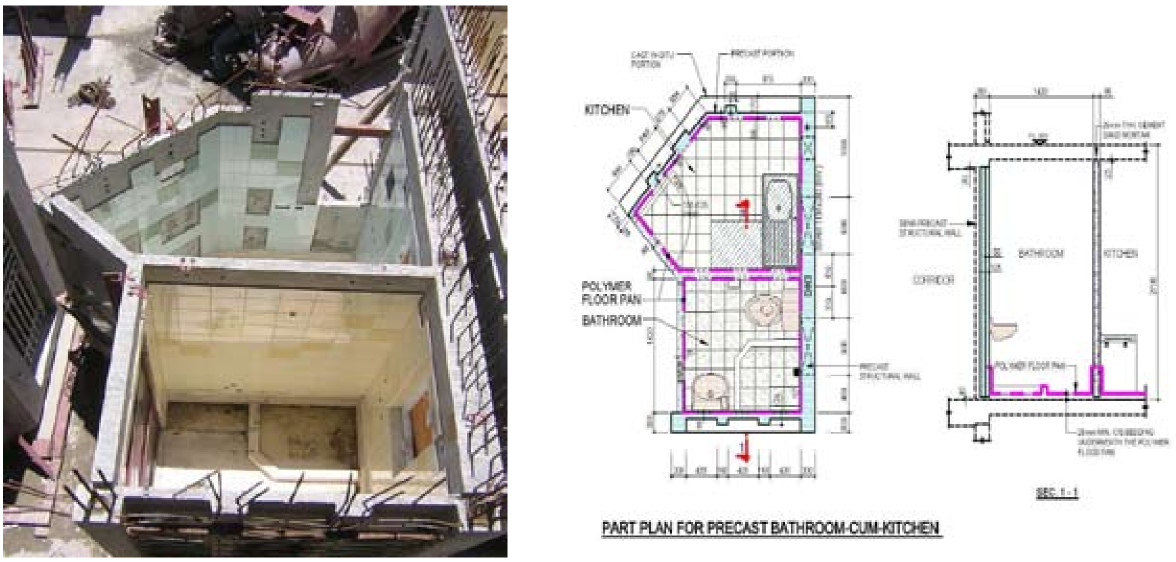


Figure 4 Framing Plan of Precast Bathroom-cum-kitchen

3.2.1 Precast Bathrooms & Precast Bathroom-cum-kitchens

The innovative precast bathroom (Figure 5) and bathroom-cum-kitchen have three special features. Firstly, they integrate intelligently with the adjoining shear walls, i.e. there will not be any double walls. Secondly, most of the architectural works are done in the precast factory, i.e. better quality control and less wet trades at working floor. Thirdly, a unique fibre reinforced polymer floor pan is used for the first time in Hong Kong to replace

- the traditional waterproof membrane,
- the floor finishes (the floor pan can be finished with different engraving, patterns and colours) and
- the base, which is normally required in proprietary products as a support for fabrication of the sanitary fittings,

Hence, there will not be double floor slabs. More usable space can be provided with less construction costs because no double walls or double floor slabs are used. The floor pan is a seamless machine-moulded pan encased into walls, which will prevent water leakage and associated concrete spalling problems. This will mean much less maintenance and in turn minimize nuisance or disturbance to residents. Besides, as most finishing works are prefabricated in factory, better quality is ensured.

Figure 5 Precast Bathroom

3.2.2 Precast Stari-cores & Precast Lift Shafts

For precast stair-cores and precast lift shafts, apart from saving of external working platforms, precast construction can achieve better quality by minimizing defects such as stepped joints commonly found in conventional cast-in-situ construction method.

4. Collaboration with Contractor in Implementation

4.1 The Mock-up

In view of the limited experience of local building contractors in the System, the HA tried out the System by constructing a two-storey one-wing mock-up structure at the Site before starting the main building contract. By process simulation, the HA could check out all the details involved in the fabrication, installation and testing. During the course of the mock-up construction, the HA worked closely with the contractor in identifying problems and developing feasible and practical solutions. The final, improved design was then let out for construction.

4.2 Building Construction

In view of their significance in overall structural stability, the precast structural shear walls were required to be fabricated on site for the purposes of close monitoring and better quality control (Figure 6).

The set up of the on-site fabrication yard took into consideration the logistics for production, the storage and erection of the precast elements with an aim to minimize double-handling in 'internal' transportation of the precast elements, which was costly. This was one of the major reasons for the awarded tender to win over other tenders.

During the course of the construction, the project team worked closely with the Contractor in overseeing the construction works, overcoming the construction difficulties and refining sequence of works and method statements.

Figure 6 Construction of the Residential Blocks

5. Achieved Sustainability Benefits

As the pilot project was completed (Figure 7), the whole construction process including the fabrication, transportation and installation of the precast elements has been thoroughly monitored and reviewed. The System has a number of major sustainability benefits and other potential benefits.

5.1 Better Quality of Works

Better quality was ensured. As precast components were mass-produced in casting yards, quality control was enhanced and construction errors were reduced. Under the System, not only were aesthetic finishes applied to the precast components, but also aluminum windows and building services devices were installed in advance. These greatly reduced potential damage to the materials arising from on-site installation while improving durability and cutting down future maintenance costs. In sum, the quality of concrete, architectural and building services works improved noticeably.

Further, by replacing the conventional waterproofing membrane with the seamless fibre reinforced polymer floor pan in bathrooms and kitchens, watertightness performance is better assured. Thus the repair and maintenance costs will be reduced.

5.2 Enhanced Site Safety

The System helped boost site safety as it re-sequenced the site works and reduced a great deal of site works at height (at working floors) such as reinforcement fixing, formwork erection and concrete pouring.

Due to the use of the System, the Contractor managed to bring down the accident rate to record low figure of 9.65 (per thousand workers), which was substantially lower than the average accident rate of 64.3 for all local construction projects in 2006. The Contractor obtained consistently high scores in their quarter safety audits carried out by external safety auditors. The Contractor had also won quite a number of safety awards in the years 2005, 2006 and 2007 for this contract[a].

5.3 Better Environmental Protection

The mechanized production of precast components in casting yards was much more environmentally friendly than conventional cast-insitu construction. With reduction in wet trades, it reduced both material wastage and construction waste. The Contractor reckoned that the average daily waste production for the project was 80% less than that for the Contractor's other projects.

At the same time, as less concrete pouring work was carried out on-site, noise, air pollution and other associated nuisance to nearby residents had been minimized and the workers were provided with a cleaner and more healthy environment to work in.

For this pilot project, the Contractor had won a number of awards on environmental protection in the years 2005, 2006 and 2007[b].

Figure 7 Completed Blocks adopting the System

---

[a] The Gold Award for Building Sites (Public Sector) of the Hong Kong Safety Award Scheme for the Construction Industry (2005); the Best Building Site Safety Record Award of the Hong Kong Quality Public Housing Construction (2006) organized by the Housing Department, HKSAR Government; the Gold Award of the Hong Kong Considerate Contractors Site Award (2006) organized by the Works Bureau, HKSAR Government; and the Hong Kong Considerate Contractors Site Award (2007) organized by the Works Bureau, HKSAR Government.

[b] The Gold Award of Hong Kong Eco-Business Award in the Category of Green Contractor (2005); the Gold Award of Outstanding Environmental Management & Performance Grand Award (2006) organized by the Works Bureau, HKSAR Government; and the Outstanding Environmental Management & Performance Grand Award (2007) organized by the Works Bureau, HKSAR Government.

6. Potential Benefits

6.1 Time Saving

For this pilot project, construction time of approximately five more months was required. This included three months allowed for on-site fabrication of precast structural walls and two months for resolving technical difficulties such as the fabrication details for the new precast components, the methods for assembly of the precast components, the dove-tailing details between insitu and precast construction. With the experience gained from this pilot project, the additional construction time may be trimmed down for future projects.

Volumetric precast components (integrated with precast structural walls) were used for the first time in public housing construction. Despite their sizeable dimensions and heavy weights, these components were installed quite expeditiously[c]. After the building industry has became familiarized with the System, it is anticipated that a shorter construction period can be achieved.

Time saving is also expected in the latter stages of the construction since as much as 36% of the originally on-site finishing works have been prefabricated onto the precast elements at the casting yard.

6.2 Cost Saving

The cost of the Building Contract was approximately 8% more than that adopting conventional construction method. When comparing costs on block basis, each building with the System was found to cost approximately 13% more than a conventional building. The comparatively higher cost was attributed to firstly, the additional cost for the new precast initiatives which demand substantial capital investment in design and manufacturing of the new steel moulds and extra cost for learning and mastering their production and installation, and secondly the set up cost for on-site fabrication of the precast structural shear walls (a specific requirement of this pilot project).

The extra cost is not surprising, considering this is a pilot project. We anticipate that the cost will go down if the new precast initiatives are widely used in future, as in the case for precast facades[d], and the scale for on-site fabrication is reduced. At the same time, lower maintenance cost due to better built quality is expected to make up for the higher capital cost, e.g. the fibre reinforced polymer floor pan will effectively prevent water leakage and the associated concrete spalling problems.

7. Promotion of Sustainable Construction Through Innovative Precasting

Through an exhibition of the System in the Innovation Expo 2005, Hong Kong, which was very well received by approximately 15,000 visitors, the HA successfully demonstrated to the public that the System was one of the HA's initiatives for sustainable public housing developments.

With so many new initiatives, the pilot project has indeed not only advanced the frontiers of precasting and prefabrication technology in public housing developments but also, through more than 30 site visits and experience sharing forums that involved more than 1,100 delegates from various stakeholders - academic institutes, public utility companies, consultants, contractors and government departments – from Hong Kong, China, Australia, Singapore, Korea and Japan, promoted awareness of the stakeholders on how the construction industry could contribute more to sustainable developments through innovative precasting.

8. Conclusion

Innovation in a public organization is not an easy task – stepping out from established conventional construction practice to trying out innovative precasting, putting down the innovation ideas and concepts on the drawing boards and finally turning them into reality. The success of this pilot project is indeed a result of the HA's relentless strive for sustainable public housing developments and collaboration with the industry, particularly the Contractor during the implementation stage.

The valuable precasting knowledge and experience in public housing developments will continue to be a prime mover for sustainable construction in the industry and will certainly contribute to the quality and sustainability of public housing developments and help to meet the ever-increasing expectation of the public.

---

[c] Installation (excluding post-installation jointing works) time for precast bathroom (9 tonnes), precast bathroom-cum-kitchen (8.5 tonnes), precast lift core (6.5 tonnes) and precast stair core (9 tonnes) are 8, 15, 10, 15 minutes respectively.

[d] Facade unit cost decreased from $11,520 in a pilot project in 1990 to $5,156 in 2002 (about 53% decrease). Since then the facade cost has increased because of firstly less competition with the shut down of a number of precast plants and secondly more market demand with the increasing need of precast units from the private sector. The latest facade cost in year 2006 was $6,799, which was still about 41% less than that of the pilot project.

SOCIAL DIMENSION OF SUSTAINABLE BUILDING

Keywords: social aspect, sustainable building, productivity, quantification

Summary

A brief history on the development of the concept of the sustainable building is presented and the relevant social aspects are identified and discussed. Social interaction, cultural enrichment, health of users, facilities for the disabled, security, productivity, public participation in decision making for the buildings are the elements identified. Public participation encourages individuals to be a part of decision making for issues that concern them about building. It ensures that the development is acceptable to society and promotes equity. The inclusion of social aspects in building sustainability assessment brings up the issue of its quantification. The social aspect is an intangible feature which presents difficulties in its quantification. Full cost assessment (FCA) is a decision making tool and may be used to estimate the cost of social aspects. The main barrier in its adoption is insufficient and poor quality data.

1 Introduction

The concept of sustainable building is far from being well defined, it is under constant evolution and new themes have been added to it since its emergence. There is no general consensus between different authors about the concept of sustainable building. Several terms are being used to describe the relationship of buildings with the environment such as energy-smart building, green building, intelligent building, sustainable building *etc*. Green building, as the term depicts, refers mainly to the environmental aspect. It involves minimisation of pollutants, reduction in energy use and environmental damages. The United Nations Commission on Sustainable Development in 1993, included economic aspects, as well:

> "to use the limited resources more efficiently and promote the solutions in economy and environment problems, further more to improve the living environment, is called the Green Building." (GBC 1998).

A statement or definition of sustainable building was described in the 2000 conference of Sustainable Building as:

> "A sustainable agenda operated on scales of materials, buildings, and urban regions, and must also include consideration of functional, social, economic and ecological factors. Strategies for reaching a sustainable built environment must reflect varied regional conditions and priorities, and different models for implementation: think global, act local." (SB 2000).

Thus, sustainable building presents a broader agenda encompassing several aspects. Therefore, to achieve a sustainable development in a community, the emphasis should be on sustainable building, which includes the community in decision making. A more comprehensive definition of sustainable building would be the one incorporating environmental, economic and social aspects and public participation.

2 Evolution of Sustainable Building

Before delving into the social dimension of sustainable building, a brief history of the evolution of the sustainable building concept is discussed. An early definition of sustainable construction was presented by Charles Kibert during the First International Conference on Sustainable Construction held in Tampa, Florida, US in 1994. "Sustainable construction is the creation and responsible management of a healthy built environment based on resource efficient and ecological principles" (Kibert 1994). It is evident that the foremost stress was given to resource efficiency and ecological principle as was justified by the Rio

Declaration on Environment and Development in 1992. With the passage of time, the concept of sustainable construction/building has evolved and a broader picture has emerged.

Figure 1 shows the evolution of sustainable construction concept over the passage of time. The traditional ideology was to consider time, cost and quality during the construction. Later on, issues such as resource depletion, emissions, and conservation of biodiversity took a forward step and a bigger picture encompassing these issues emerged as is supported by Agenda 21 on sustainable construction (CIB 1999). Finally, a broader concept evolved to covering economic, social and cultural issues as well. However, the social aspect has not yet gained sufficient recognition among the policy makers. The meaning of social sustainability must be recognised in order to identify the main social benefits and features of buildings.

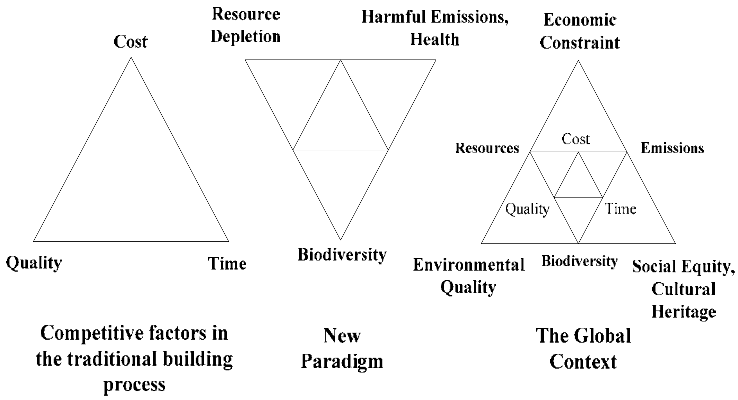

Figure* 1*: Traditional concept of sustainable construction (Source: Bourdeau 1999)

3 Social Sustainability

Black (2004) defined social sustainability as “the extent to which social values, social identities, social relationships and social institutions can continue into the future”. In terms of buildings it can be interpreted as social interaction, cultural enrichment, health of users, facilities for the disabled, security, productivity, public participation *etc*. Public participation in planning is a central issue and this concept has not yet gained its roots in the construction industry. Strong interaction among several sections of the construction industry is required. This may lead to modifications of the list of stakeholders who should have a say in built environment decision-making (Kaatz *et al*. 2005, p. 447). Public participation allows the views and concerns of all affected parties to be heard, thus satisfying the *equity* principle. Furthermore, it also increases the awareness within society about its responsibility towards sustainable development (Kaatz *et al*. 2005, p. 445). It may include architects, construction workers, engineers, owners, end users, property managers, facilities managers *etc*. It encourages the individuals to be a part of decision making for issues that concern them (Mitchell *et al*. 1995, p. 107). Its importance was realised at the Rio Declaration on Environment and Development (UNCED 1992) where it was added as the tenth principle and is as follows:

> “Environmental issues are best handled with participation of all concerned citizens, at the relevant level. At the national level, each individual shall have appropriate access to information concerning the environment that is held by public authorities, including information on hazardous materials and activities in their communities, and the opportunity to participate in decision-making processes. States shall facilitate and encourage public awareness and participation by making information widely available. Effective access to judicial and administrative proceedings, including redress and remedy, shall be provided.”

Public participation promotes equity by ensuring that the development is acceptable to society and does not create a monopoly for a certain section of a community (Kaatz *et al*. 2005, p. 442). Pearce (2003) published a report on the social and economic value of the construction industry and identified certain social values that need to be considered in the construction industry. This report realigned the concept of sustainable building by incorporating social and economic aspects. He argued the need to consider economic, environment and social issues alongside each other to better assess sustainability. The report brought forth the social dimension of the construction industry in terms of wealth, culture and ecology and highlighted the lack of quality data as a barrier in sustainability evaluation. He treated the built environment as a capital stock and sketched out a schema shown in *Figure 2* which gives an understanding of the wider social sustainable dimension in the construction industry and shows the capital approach to various aspects of sustainable building.

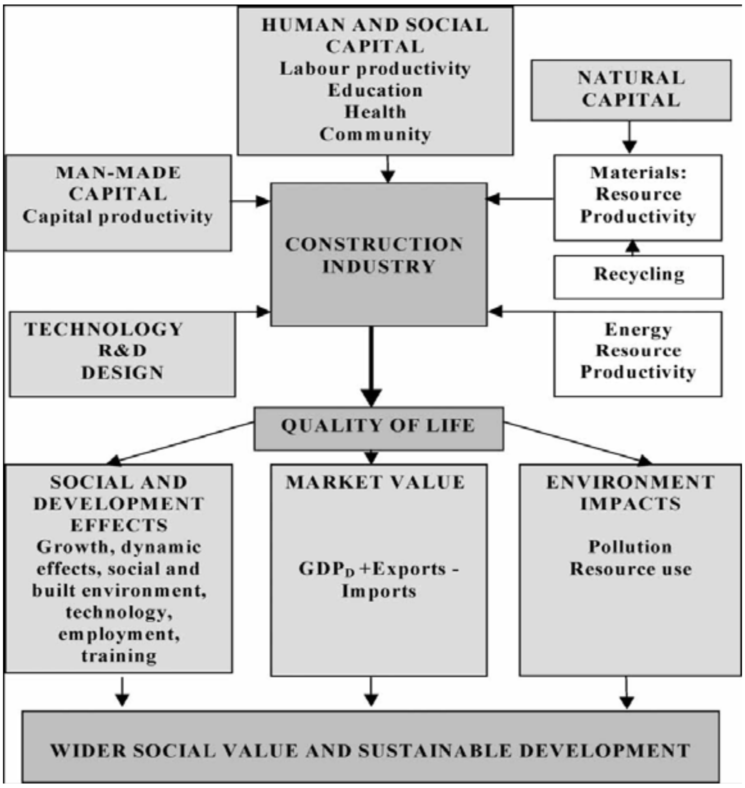

Figure 2: Pearce's Schema
(Source: Pearce 2003)

4 Importance of Social Aspects

Buildings should be seen as wealth generating stocks and in this context productivity of the occupants should be a major design consideration. Their productivity depends directly upon the indoor environmental quality (IEQ). As most of the people spend about 80% of their time indoors, IEQ needs to be monitored carefully and encompasses several areas such as ventilation, thermal comfort, lighting, noise, indoor air pollutants *etc*. Several researchers have shown a decrease in building occupant productivity with a poor IEQ. One such study revealed a high rate of employee sick leave in the face of poor ventilation conditions in office buildings (Kumar & Fisk 2002). The study was part of an occupational and environmental health evaluation at Polaroid Corporation, in which sick leave data and ventilation rates were analysed from 40 buildings. A low ventilation rate was found to be associated with a higher percentage of sick leave. An economic analysis revealed that the annual energy cost required to improve the ventilation rate would be more than compensated by the reduced cost of sick leave. There are several other studies which point towards the same direct relationship of poor IEQ with showing decrease in occupants' adverse health effects. Use of natural daylight in commercial buildings is not only energy efficient but also beneficial to the occupants' health. Landman (1999) cited a study in which the occupants of a commercial building reported 20% less sick building syndrome in occupants working closer to the windows. Other such factors affecting productivity include floor space, layout, noise *etc*. Sustainable buildings attract more tenants who extend their leases as a result of higher IEQ standards. The value of commercial buildings can be further enhanced by incorporating features such as showers, bike racks and proximity to public transport.

Lorch (2003) has discussed the benefit of social capital values in the community by providing social identity and complying with the basic needs of indigenous users. Heilbrun & Gray (2001) highlights certain social features which can be integrated into the built environment to improve its value and act as a source of revenue by attracting tourists (museums, art galleries *etc*.). A well planned housing community (open spaces, parks, bicycle tracks, accessibility to public transport *etc*.) can be a source of high capital return for the developers. More work is required to incorporate such features in neighbourhood design.

Including sustainable aspects of a building in its appraisal is likely to become a norm in the future and buildings with higher green star ratings may achieve higher prices and increased returns on equity. In 2000, New York offered an incentive package by passing a green building tax credit to encourage developers to incorporate sustainable practices. Such steps will further attract developers and investors to embrace sustainable building practices in future. Further value to the society can be added by adopting environmental practices such as using recycled materials and proper disposal of the waste to reduce the burden on landfills etc.

5 Quantification and its Barriers

The inclusion of intangible social aspects in building sustainability assessment brings up the issue of difficulties in its quantification. However, once made part of the assessment process, it can aid in bringing such issues to the forefront and making them part of managerial decisions and finding better alternative options both in terms of the economy and occupational health and safety. Full cost assessment (FCA) is a managerial decision making tool and may be used to estimate the cost of social aspects. The main barrier in its adoption is the insufficiency and poor quality of data. The estimation of full costs requires major effort and involves not only future forecasting but also occupants' environmental and health issues, productivity, loss or gain of revenue depending upon the reputation of a building or housing society (sick building syndrome may lead to poor reputation). Estimations can be made by studying past projects which have certain social sustainability e.g., museums, better security, open spaces *etc*. While designing the buildings, such productivity and wealth generation factors should be considered. There are a few building assessment tools that quantify certain social aspects - Green Star Rating Tool by Green Building Council of Australia and LEED. However, their effective use is limited by the input information and data availability.

6 Conclusion

The sustainability of building is a broad term encompassing various disciplines such as environment, society, economy. Buildings have a direct impact on society and can benefit society in terms of wealth generation, providing security, social capital and cultural preservation. Public participation in the decision making is identified as an important aspect of sustainability. Recognition and appreciation are needed by all the stakeholders to improve the occupants health and productivity and to incorporate flexibility in design for future modifications, accessibility *etc*. At this time full cost assessment (FCA) is limited by a lack of quality input data which should be developed in the future.

Keywords: computational design, internal thermal insulation system, heat and moisture transport, damage prevention

Summary

Sustainable design principles of interior thermal insulation systems are formulated and the appropriate design methodology is given in the paper. In a practical application of the methodology, an interior thermal insulation system on hydrophilic mineral wool basis provided with several types of water vapor retarders and applied on several types of different load bearing structures is subjected to a detailed computational analysis of coupled heat and moisture transport. Temperature, relative humidity and overhygroscopic moisture fields are calculated for the time period of several years using the computer code TRANSMAT 6.3 and the long-term hygrothermal performance of studied building envelopes is assessed. The results of computational design reveal that such a combination of hygric properties of water vapor retarder can be found which results in flawless hygrothermal performance of the interior thermal insulation system on hydrophilic mineral wool basis, no matter the type of load bearing structure. This means that the retarder with such properties can be considered as universal solution for the studied interior thermal insulation system. The mentioned properties of water vapor retarder can be met for instance using a common lime plaster or lime-metakaolin plaster with up to 25% of metakaolin as lime replacement.

1. Introduction

The application of interior thermal insulation systems on building envelopes is not a natural solution but sometimes there is no other option available. A typical example is a historical building, where the facade has to be kept in its original appearance mostly, and the exterior insulation systems are excluded for that reason. In that case the development of such an insulation system would allow to prevent moisture damages and to upgrade the thermal properties of the envelope as the only reasonable option.

A common solution to this problem consists in placing a vapor barrier just under the internal plaster, on the surface of the insulation layer, so that both the insulation layer and the load bearing structure are protected against water vapor. However, this is a solution, which can perform well on the theoretical level only. In the practice, it is not possible to avoid mechanical damage of water vapor barrier placed in such an inappropriate way. A sole nail or hook driven into the wall for instance if hanging up a painting can destroy the function of the barrier. In addition, even in the case that the barrier would perform without mechanical damage, the absence of water vapor removal from the interior through the envelope in the winter period, when the air ventilation in the interior is usually limited, would lead to undesirable increase of relative humidity in the interior and worsening of the internal microclimate.

The mechanical damage of water vapor barrier can be avoided by placing the barrier between the thermal insulation material and the load bearing structure. However, the amount of water condensed in the insulation layer would be also in this case for certain time period of year relatively high. It is naturally possible to design such a thermal insulation material, which cannot be damaged by long-term water exposure, but the presence of water will always have a negative effect on the thermal insulation properties of the material. In the climatic conditions of North and Middle Europe the danger of liquid water generation is concentrated to winter months mostly. Therefore, the worsening of thermal insulation function would occur just in the winter period of year when it is absolutely undesirable.

An alternative to the application of traditional water vapor barriers is using a vapor retarder instead, which permits a part of water vapor to diffuse further to the load bearing structure. Then, even if the retarder is placed between the thermal insulation layer and the load bearing structure, the amount of condensed water in the thermal insulation layer is lower, and the structure is not damaged because it is exposed to such a water vapor flux only, that can be transported through it without condensation.

The requirements to the thermal insulation layer in the above arrangement are quite high. It should have a low thermal conductivity in dry state, and the thermal conductivity even should not increase too much if moderate presence of liquid water appears. In addition, the material should have a high capillary activity because it is supposed to redistribute the condensed water backward to the indoor room as fast as possible in order to maintain a sufficiently low moisture level and corresponding sufficiently good thermal insulation properties of the layer.

The application of the capillary activity of insulation materials as a dehumidification method is a big innovative step in the building insulation/renovation technology and offers the possibility to develop new solutions for old, long-lasting problems, where expensive traditional renovation methods fail.

As it has been mentioned before, the retarder layer controls the outward directed vapor flux. The vapor flux must be adjusted according to the properties of the old construction and its climatic zone. Therefore, also the hygric properties of the retarder layer have to be chosen in an appropriate way. This design can be done most effectively by a computational simulation.

An exact specification of hygric properties is not the only requirement to the water vapor retarder. The retarder layer should keep together the thermal insulation layer and the load bearing structure to avoid appearance of air gaps. This can be achieved by an application of a glue, a mastic or a resin with an exactly specified workability, which should be long enough to allow the binding of both layers on a sufficiently large area. Assuming that this area could be for instance a wall of a living room, we arrive to a typical workability in the range of 2-3 hours. On the other hand, the hardening of the retarder layer should not be too long to avoid the movements of the thermal insulation boards after installation.

In this paper, sustainable design principles of interior thermal insulation systems are formulated, and design methodology is given. In a practical application of the methodology, an interior thermal insulation system on hydrophilic mineral wool basis provided with several types of water vapor retarders and applied on several types of different load bearing structures is subjected to a detailed computational analysis of coupled heat and moisture transport. The long-term performance of studied building envelopes is analyzed using a computer code. Temperature, relative humidity and overhygroscopic moisture fields are calculated for the time period of several years and the hygrothermal performance of the systems is assessed.

2. Basic principles of computational design of interior thermal insulation systems

Building envelopes always behave as systems and therefore, the properties of the parts of the system, of the particular materials have to be compatible. It is not sufficient to develop and employ one excellent material, but it is necessary to develop working multi-layer systems consisting of different materials. This is the most important feature of any computational design of a building envelope from the point of view of building physics. Therefore, we will consider a system consisting of internal plaster, thermal insulation material, water vapor retarder layer, the material of the load-bearing structure, and the external plaster in Figure 1.

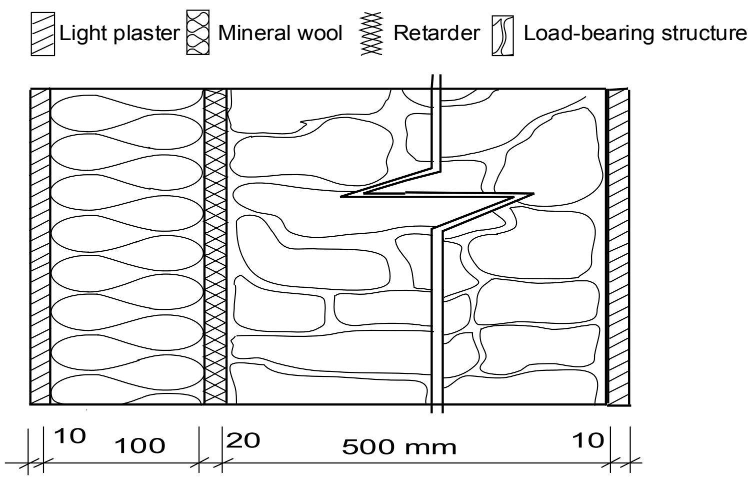

Figure 1 Composition of building envelope used to computational simulations.

An unavoidable preliminary condition for any reasonable computational design is the application of an appropriate mathematical model and the respective computer code. For the calculations we employed the computer simulation tool TRANSMAT 6.3 [Maděra J., Černý R. (2005)] which was developed in the Department of Materials Engineering and Chemistry, Faculty of Civil Engineering, Czech Technical

University in Prague. The construction of the code is based on the application of the general finite element computer simulation tool SIFEL (SImple Finite ELements). The moisture and heat balance equations were formulated in the simplified form suggested by Künzel [Künzel H.M (1995)].

It is necessary to perform the hygrothermal calculations in a sufficiently long time period. Under certain circumstances the hygrothermal properties of the system can worsen gradually, slowly, so that the damage can appear after a longer time period. Therefore, not only the actual values of main hygrothermal quantities are important but also their development in the subsequent years. The time period of 5 or 10 years appears as reasonable in deciding if the designed system will perform without substantial damage.

The proper initial and boundary conditions of the model are another crucial factor affecting the reliability of the calculations. Therefore, the calculations should be done for exactly the same situation as it will be done in the practical reconstruction on building site. First, the boundary conditions for the external side should be as accurate as possible. This can be achieved by using the meteorological data for the locality as close as possible to the real object. From the point of view of long term reliability, the application of so called “reference year” data should be preferred. Second, the initial conditions should be realistic. To this point, the calculations should be done first for the construction without the interior insulation system in order to find the long-term conditions in the wall before the reconstruction. The comparison of calculated data for two subsequent years in a longer time period can be an evaluation factor in this respect.

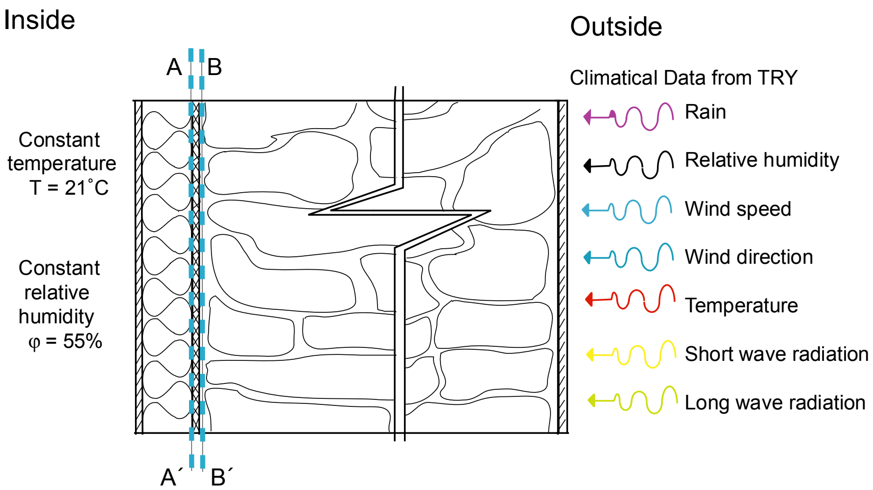

Figure 2 Boundary conditions for the studied envelopes.

Third, the calculations with the interior insulation system should be started exactly in the same time of year when the real reconstruction will begin.The long-term performance of the system should be characterized not only by calculated temperature and relative humidity. Also overhygroscopic moisture fields have to be determined, which decide about the real hygrothermal performance of the system. The critical places, where long-term water accumulation can appear, should be detected. This will make it possible to perform critical experiments in the semi-scale conditions in order to verify the model calculations and to perform the necessary inverse modeling.

The following basic criteria for the design of interior insulation systems can be formulated:

1. In the material of load-bearing structure, there should not appear any overhygroscopic moisture due to the moisture transport from the inside.
2. The thermal insulation material should have a high capillary activity, so that liquid water, which possibly condensed in the insulation layer, could be transported back to the interior in a short period of time.
3. Possible liquid water appearance in the thermal insulation layer should be limited to short time periods of year and small space intervals.
4. The water vapor retarder should have exactly specified hygric properties. First, it can allow to penetrate only such amount of water vapor that will not lead to the condensation in the load bearing structure. Second, it should be impermeable for liquid water.
5. The material of the retarder should have good glueing properties and exactly specified workability to keep together the material of the load bearing structure with the thermal insulation layer.
6. The thermal insulation layer should have besides good thermal insulation properties also good mechanical properties in order to resist mechanical damages.

7. The retarder should be placed in such a position in the system that any mechanical damage would be minimized.
8. The internal plaster should have an open porous structure in order to be able to evaporate a part of moisture, which was transported back from the thermal insulation layer, into the internal space.

3. Practical application of the methodology of computational design

We assumed three alternatives of the load bearing structure, the alternative No. 1 was the brick wall, No. 2 the concrete wall and No. 3 the sandstone wall. The thickness of the all types of wall was 500 mm. On the internal surface of the envelope, there was lime-metakaolin plaster. As the thermal insulation material, hydrophilic insulation boards on the mineral wool basis Dachrock with the thickness of 100 mm which were developed by Rockwool, SA, were used [Jerman et. al. (2007a)]. On the external side there was the same plaster as inside, with the thickness of 10 mm.

The basic parameters of materials of the described building envelope are shown in Table 1. Here, ρ is the bulk density, θ_{hyg} the maximum hygroscopic moisture content, θ_{sat} the moisture content corresponding to water saturation, λ_{dry} the thermal conductivity corresponding to dry sample, λ_{sat} the thermal conductivity corresponding to water saturation, κ the moisture diffusivity, c the specific heat capacity and μ the water vapor diffusion resistance factor.

Table 1 Basic properties of materials of building envelopes

	ρ [kg/m^3]	θ_{hyg} [m^3/m^3]	θ_{sat} [m^3/m^3]	λ_{dry} [W/mK]	λ_{sat} [W/mK]	κ [m^2/s]	c [J/kgK]	μ [-]
Plaster	1490	0.095	0.42	0.5	1.53	8.0e-9	1004	18
Brick	1746	0.015	0.33	0.69	1.9	3.0e-7	895	16
Concrete	2423	0.047	0.122	1.6	3.2	8.9e-10	801	25
Sandstone	1890	0.009	0.32	0.48	0.65	2.5e-6	850	7.5
Dachrock	170	0.0021	0.93	0.047	0.72	4.84e-5	801	7.1

The main aim of the computational simulations performed was to analyze the hygrothermal performance of the designed insulation system with different values of the water vapor diffusion resistance factor, moisture diffusivity and hygroscopic moisture content of the water vapor retarder. The basic material parameters of the retarder are shown in Table 2, the optional parameters in Table 3.

Table 2: Basic material properties of water vapor retarder

ρ [kg/m^3]	θ_{sat} [m^3/m^3]	λ_{dry} [W/mK]	λ_{sat} [W/mK]	c [J/kgK]
1500	0.5	0.5	2.0	1000

Table 3: Optional material parameters of water vapor retarder

	κ=1·10^{-6} m^2/s	κ=1·10^{-8}m^2/s	κ=1·10^{-10} m^2/s	κ=1·10^{-12} m^2/s
μ = 5, θ_{hyg} = 0.02 m^3/m^3	V1K1	V1K2	V1K3	V1K4
μ = 10, θ_{hyg} = 0.01 m^3/m^3	V2K1	V2K2	V2K3	V2K4
μ = 50, θ_{hyg} = 0.005 m^3/m^3	V3K1	V3K2	V3K3	V3K4

The sorption isotherm was assumed in the following simple form:

$$\theta_1 = \left(1-\sqrt{1-\varphi}\right)\frac{\theta_{Hyg}}{1-\sqrt{1-\varphi_{Hyg}}}, \quad (1)$$

and the water retention characteristic in a similarly simple form

$$\theta_1 = \theta_{Hyg} + \frac{\varphi-\varphi_{Hyg}}{1-\varphi_{Hyg}}\left(\theta_{Sat}-\theta_{Hyg}\right), \quad (2)$$

where φ is the relative humidity, φ_{Hyg} the maximum hygroscopic relative humidity.

The thermal properties of the water vapor retarder were not considered in a variant form in the final stage of computational design because preliminary calculations showed their negligible effect on the hygrothermal performance of the studied building envelopes.

4. Computational results

The long-term performance of the system should be characterized not only by calculated temperature and relative humidity. Also overhygroscopic moisture fields have to be determined, which decide about the real hygrothermal performance of the system. The critical places, where long-term water accumulation can appear, should be detected. We have chosen three critical profiles in the evaluation of the hygrothermal performance of the envelope, A-A´, B-B´, where the profile A-A´ was between water vapor retarder and insulation material, B-B´ between the load-bearing structure and water vapor retarder. In these profiles we calculated the dependence of the relative humidity, overhygroscopic moisture content and temperature on time. The results are organized according to the particular alternatives.

4.1 Alternative No 1 – brick wall

Figs. 3 a,b show the relative humidity in the A-A´ profile (the interface between thermal insulation and water vapor retarder). For all variants of retarder maximum relative humidity in this profile was far from the condensation limit.

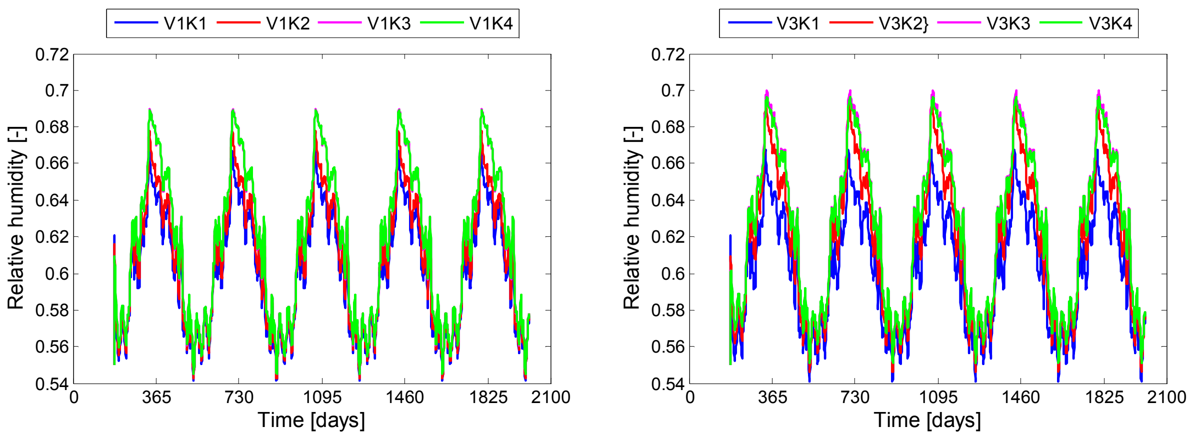

Figure 3 Relative humidity in A-A´ profile, brick wall - a) μ_{ret} =5 ,b) μ_{ret} =50.

Figs. 4 a,b show that also the relative humidity in the B-B´ profile (the interface between water vapor retarder and brick wall) was sufficiently low, and no risk of water condensation appeared there.

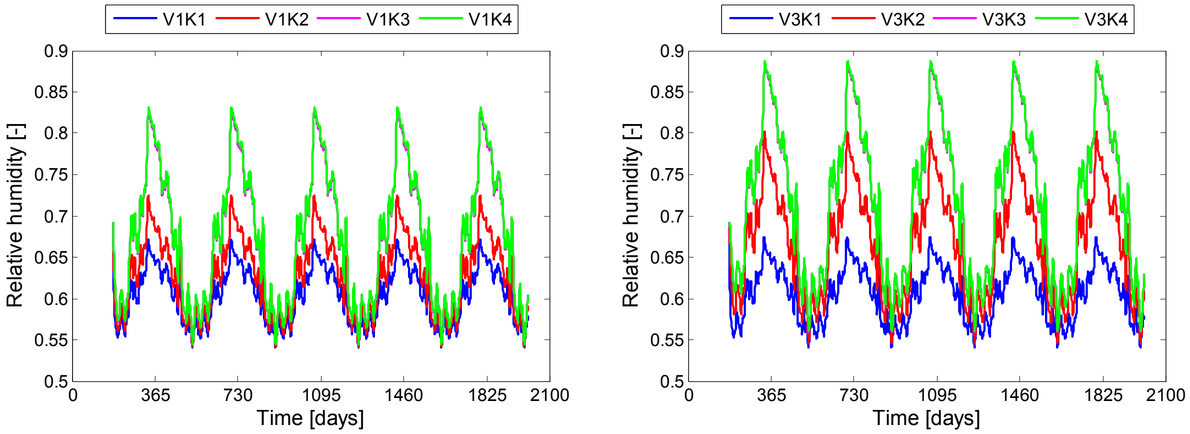

Figure 4 Relative humidity in B-B´ profile, brick wall - a) μ_{ret} =5 ,b) μ_{ret} =50.

4.2 Alternative No 2 – concrete wall

Figs. 5 a,b show the relative humidity in the A-A´ profile (the interface between thermal insulation and water vapor retarder), Figs.6 a,b in the B-B´ profile (the interface between water vapor retarder and concrete wall). For all variants of retarder the maximum values of relative humidity in both profiles were far from the condensation danger.

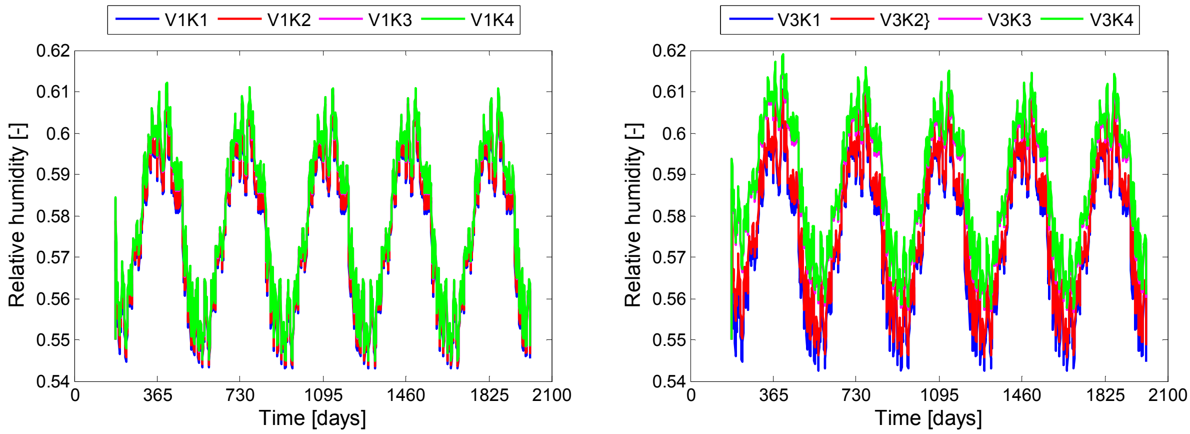

Figure 5 Relative humidity in A-A´ profile, concrete wall - a) μ_{ret} =5 ,b) μ_{ret} =50

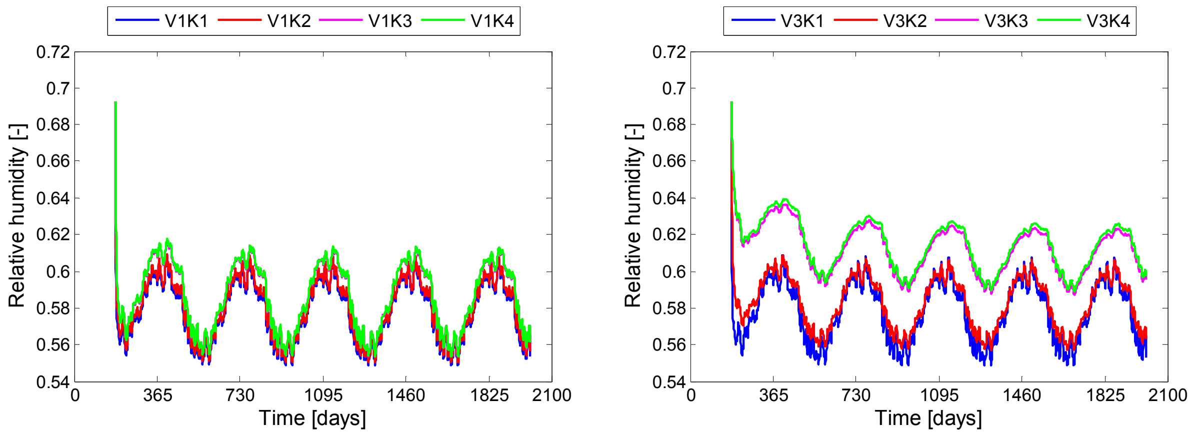

Figure 6 Relative humidity in B-B´ profile, concrete wall - a) μ_{ret} =5 ,b) μ_{ret} =50

4.3 Alternative No 3 – sandstone wall

Figs. 7 a,b present the relative humidity in the A-A´ profile (the interface between thermal insulation and water vapor retarder), which were far from the condensation limit. However, Figs.8 a,b show that in the B-B´ profile (the interface between water vapor retarder and concrete wall) for some combination of properties of water vapor retarder the risk of condensation may become real.

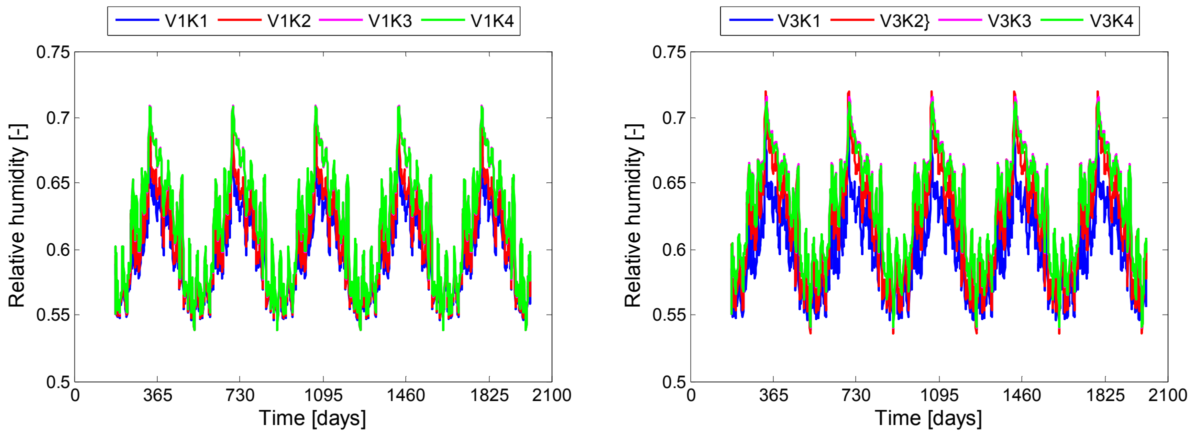

Figure 7 Relative humidity in A-A´ profile, sandstone wall - a) μ_{ret} =5 ,b) μ_{ret} =50.

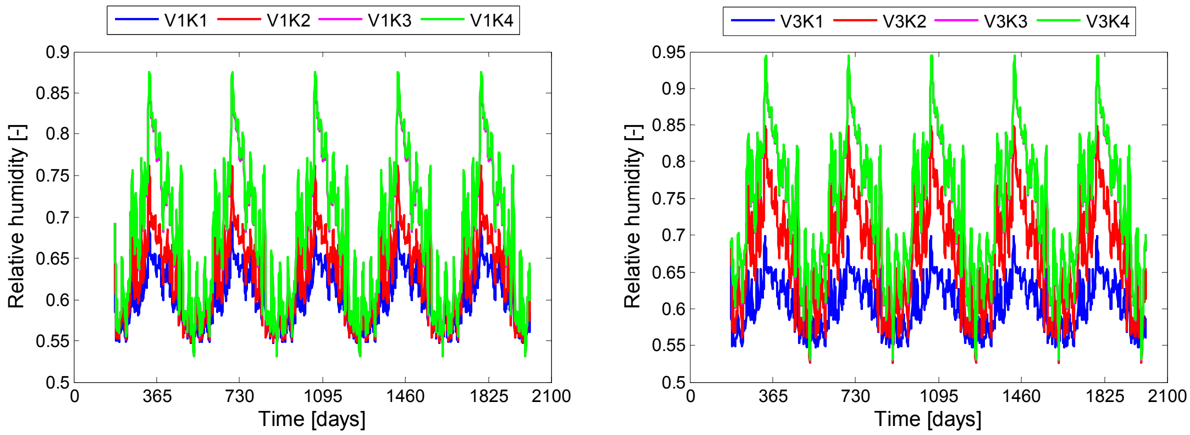

Figure 8 Relative humidity in B-B´ profile, sandstone wall - a) μ_{ret} =5 ,b) μ_{ret} =50.

5. Discussion

Computational results summarized in the previous section revealed that for the brick wall the optimum combination of hygric properties of water vapor retarder was: μ = 5, θ_{hyg} = 0.02 m^3/m^3, κ = 1.10^{-6} m^2/s. The maximum values of relative humidity in the whole envelope were during the five-year calculation time period lower than 68 %, which is safe from the point of view of possible water condensation. On the other hand, the combination with μ = 50, θ_{hyg} = 0.005 m^3/m^3, κ = 1.10^{-12} m^2/s resulted in maximum relative humidities on the interface between water vapor retarder and brick wall which can be considered as a critical place in the construction of about 90% - this does not mean water condensation yet but the RH value is already near the condensation limit.

In the concrete wall the maximum values of relative humidity were lower than in the brick wall, 64% for all studied variants of hygric properties of water vapor retarder. This was a consequence of very low water and water vapor transport rate in concrete combined with very high water and water vapor transport rate in hydrophilic mineral wool. For such combination of material properties of load bearing structure and thermal insulation layer the hygric properties of water vapor retarder apparently lost their significance.

For the sandstone wall the results were qualitatively similar as for the brick wall. The optimum combination of hygric properties of water vapor retarder was: μ = 5, θ_{hyg} = 0.02 m^3/m^3, κ = 1.10^{-6} m^2/s. The maximum value of relative humidity was 69% in this case. The other extreme in hygric properties of the retarder, μ = 50,

θ_{hyg} = 0.005 m^3/m^3, κ = 1.10^{-12} m^2/s, led to an increase of relative humidity on the interface between water vapor retarder and brick wall up to 95% which already meant that the condensation risk might be very high.

The results of computational simulations with very different properties of load bearing structures and water vapor retarders made possible to formulate some generalizations for the studied system. The combination of hygric properties of water vapor retarder in the form μ = 5, θ_{hyg} = 0.02 m^3/m^3, κ = 1.10^{-6} m^2/s resulted in flawless hygrothermal performance of the interior thermal insulation system on mineral wool basis with Dachrock mineral wool, no matter the type of load bearing structure. This is a very positive outcome of the computational design performed in this paper. The mentioned properties of water vapor retarder can be met quite easily; any common lime plaster or lime-metakaolin plaster with up to 25% of metakaolin as lime replacement have the required properties [Jerman et. al. (2007b)].

6. Conclusions

The computational results presented in this paper confirmed that computational design of hygric and thermal properties of materials in multi-layered building envelope systems can be considered as a good prevention of damage. In the computational simulations of hygrothermal performance of the studied interior thermal insulation system on hydrophilic mineral wool basis, an optimized universal variant of hygric properties of water vapor retarder was found which led to flawless hygrothermal performance of the system for all types of analyzed load bearing structures. In addition, proper materials with the hygric properties identified as optimal were found as already available on the market. This is a very prospective outcome because the designed solution can substantially reduce the risk of water-induced damage due to the improper use of materials in the interior thermal insulation systems in the building practice.

Some diversity for low income housing in downtown areas of São Paulo City

Lia Affonso Ferreira Barros. Arch. and City Planner, Master in Civil Engineering.

Abstract In contrast to Europe's inner cities, whose typological standardization instills a sense of coherence and harmony in its already built heritage, São Paulo's inner city landscape is contradictory, hybrid and contiguous. It has been continuously reconstructed, although its present configuration remains from the episodic 20's and 30's transformation, and to a certain degree, more accentuated, based on the 50's and 60's last century's changes.

São Paulo City's central area problems are related to its historical past, its geographic base, its urban development as a whole and its local economic context, which have gone through great changes in the last 40 years. The reconstruction of its buildings on the same nesting level in old urbanization areas mark the city's evolution aspects, the soil parcel which represent a specific period, as well as the consequence of the building code in effect, inside the limits of neighboring scale parameters.

Since the 1980s, inner cities in developing countries as Brazil have faced the deterioration in their living conditions. In such cases, low-income population lives in precarious housing conditions with the lack of proper ventilation and insulation for thermal comfort. However, all show characteristics of degraded dwellings, with high density population and cohabitation. The tenement houses occupied by squatters (*cortiços*) occur in old large houses of the central area, which have been transformed in collective dwellings.

Actions from an architectural project proposed vision are intended to meet the future users' needs. This housing complex, which is based on the Performance Program in Tenement Houses (PAC), deals with broad aspects rather than narrowing them down to city planning, urban opportunities and dwelling units to be offered to a population that prefers to live in the downtown area and needs dwelling solutions to suit their income needs.

Key words: urban renewal; public sector investments; low-income housing projects; sub dwelling.

1. Central areas

In contrast to Europe's inner cities, whose typological standardization and/or stylistic definition from the 19th century capital cities, São Paulo City instills a sense of coherence and harmony in its already built heritage, and its inner city landscape is contradictory, hybrid and contiguous. It has been continuously reconstructed, although its present configuration remains from the episodic 20's and 30's transformation, and, to a certain degree, more accentuated, based on the 50's and 60's last century's changes. This process resulted in a city that does not display a united architecture vision, but a sedimentary one, in terms of urban life accumulation (Benfatti *in* Schicci, 2004).

Problems in the inner central area are related to its historical past, its geographic base, the agglomeration urban development as a whole, the local economic context, the country and even the world. Today, evident problems are shown in different dimensions and with interrelated specific aspects that elapse the proper process of São Paulo City's urbanization.

The process of depreciation of downtown buildings, in a broad sense, is directly linked to the phenomenon of abandonment of the area by the elite city dwellers. This process started late in 1990's, with the city growth due to the coffee expansion. From 1870s, the urban expansion surpassed the limits of its historical peak, originally, the place where the city was founded. The elite land divisions had moved towards the West, which was topographically more favorable, and the Southwest, while the railway line and the flooding fertile valleys areas of the Tamanduateí and the Tietê Rivers depreciated the Northern and Eastern areas, where popular and/or industrial districts were established. In the subsequent decades, this dichotomy reproduced the structure of the wcity's central area. A new downtown area (known as the "New Downtown") was consolidated in the direction of the new elite districts and their surroundings. It consolidated a new Center (known as New Downtown), with the establishment of commercial, cultural, prestigious leisure activities, which are more significant than those from the old downtown area (known as the "Old Downtown"), that continued to house the business sector. There is nothing more emblematic about this transfer than the moving of the elegant department store named Mappin from Praça do Patriarca to Praça Ramos/ Rua Barão de Itapetininga (Silva *in* Schicci, 2004).

Up to 1950-1960, the downtown area, in general terms, continued to be an area of reputation and a symbol of identity for the metropolitan population, specially the upper class. During the coffee hegemonic economy period (from 1870 to 1930), the downtown was the object of interventions, "widening and realigning streets, creating representative public areas (Largo do Palácio, Praça da Sé, Praça Antonio Prado and Praça do Patriarca), stimulating the substitution of colonial houses for small commercial buildings and an eclectic architecture, prioritizing its tertiary and institutional use, adopting sanitary policies, remodeling and removing the "undesirable" bad customs and inhabitants such as tenement dwellers, laborers, sub dwellers and prostitutes. Construction works, demolitions and sanitary norms used to promote the urban segregation, differentiating the entitled urban sectors to assume prestigious functions, particularly in the central area.

In the 1980s, a new and serious shock was granted against the prestige of the Central Area: a consolidated competition between Avenida Paulista and a business center at Avenida Faria Lima was reinforced through the appearance of a fourth center around Avenida Luis Carlos Berrini. In the 1990s, it was the time of the Pinheiros River surrounding area. Thus, there were many new sites for rent, distant alternatives and relatively not entailed to the downtown area, especially for the branch offices of leading global corporations (Silva *in* Schicci, 2004).

On the other hand, the construction of the North-South subway lines (1968/1974) and the East-West lines (1975/1986), crossing themselves under Praça da Sé, and the consolidation of the bus terminals at Parque Don Pedro II and Praça da Bandeira, among others, guaranteed exceptional accessibility conditions to the historical center in terms of mass transportation. This contributed to modify the profile of the users from downtown, and this area became a point for trade and services. The low income population, which could once be found in the Old Downtown, after 1985 could also be seen in the New Downtown, when the subway access was facilitated by the extended lines at Anhangabaú and República stations on the East-West line, and by the bus corridors on Avenida Nove de Julho and Avenida Rio Branco. The higher income population, in turn, as well as the business and cultural related activities, migrated towards the southwestern area, abandoning the central area. It is also important to notice that the two first subway lines did not establish connection with the other financial centers and offices, contributing, thus, for downtown's isolation process.

One of the most emblematic elements of this elite center transfer of the City Hall and the state of São Paulo's government premises to Parque do Ibirapuera {1} and the district of Morumbi {2}, respectively. These geographic transfers, not by chance, followed the territorial saga of the middle and high income populations along the city's southwestern vector (Silva *in* Schicci, 2004).

1.1 Residential Evacuation

The demographic evacuation of city's central region constitutes an undisputed reality. In 1980, the administrative subdistrict of Sé, which corresponded nearly to 526 thousand inhabitants, continued to lose its dwellers in a way that it had about 355 thousand inhabitants in 2002. This administrative subdistrict shelters the districts of Sé and República, which once used to be densely populated, coexisting with the commercial, services and institutional activities. In the last two decades, these districts have been characterized by an important population loss, which is associated with a great percentage of empty residences and partly or totally abandoned buildings.

Many streets which had various traditional activities, now have become completely empty after the working hours, the same has happened to the districts. This residential evacuation constitutes a problem, for the urban vitality depends directly on its mixed activities. Beyond the negative implications regarding the optimization of the installed infrastructure, the residential evacuation constitutes an aggravating circumstance to the safety conditions, so that downtown is once again occupied after the commercial hours. Therefore, an important objective of the municipal urban policies is to repopulate the downtown area so as to prevent peripheral expansion and to strategically stimulate downtown's recovery, which will contribute to the sustainability of this process (Silva in Schicci, 2004).

2 Tenement houses in São Paulo: An Old and New Topic

The tenement houses (*cortiços*), appear in the City of São Paulo late in the 19th century, from the decade of 1870 due to the coffee industry expansion, when the city faced a significant population increase, whose demand for housings was unproportional if compared to the existing offers. The demand which was created in the city, consisted mainly of immigrants, and resulted in the

---

1 The headquarters transfer of the municipal administration from downtown at Rua Florêncio de Abreu, in Parque do Ibirapuera, was taken in a precarious way in 1955 and on a more effective way in 1956. The return to downtown happened in 1990, during with mayor Luiza Erundina's administration.

2 The headquarter transfer of the government state administration from Palácio dos Campos Eliseos to Palácio dos Bandeirantes was determined in April, 1964 by governor Ademar de Barros (Decree nº. 44.735). In the beginning, the new headquarters were used only eventually and they became definitive from 30/3/1970, during governor Abreu Sodré's management.

establishment of the improvised, profiting market for precarious housings for rent, most of which are collective dwellings.

The inadequacy of these houses' conditions allied to the city's precarious infra structure and the existing public services, composed a bad picture of the public health conditions, that opposed to the public power interests in promoting the necessary improvements for the urban downtown consolidation, in harmony with São Paulo City's attained economic importance at that time. The city's population, however, did not stop growing and in the first decades of the19th, the increase in the industrialization process provoked a new population growth. The industries started to be installed in the surroundings of the downtown area, stimulating the sprouting of new tenement houses in the intermediate areas such as Brás, Moóca and Pari, and even in more centralized areas, that already showed signs of deterioration, as Campos Elíseos (Silva and Caldas, 2005).

In 1934, the Arthur Sabóia Building Decree definitively banned the construction of the tenement houses in downtown and determined the demolition of the existing unhealthy ones. The objective of these legal measures was "to push away" popular dwellings from the central area offices and ended up determining the irregularity of this type of housings. Nevertheless, they continued to exist clandestinely (Bonduki, 1998). Between 1940 and 1950, the industrialization consolidation boosted Sao Paulo's City population from 1,3 to 2,2 million inhabitants, extending the demand for dwellings that started to be formed in the outskirt areas, which stressed the significant urban expansion of the city, and also stimulated the collective transportation provisions for more distant regions of the urbanized area {3}.

In spite of the restrictive legislation and the stimulation of the popular dwellings in the peripheral areas, in the decade of 1970, 8% of the city's population lived in tenement houses (Simões Jr, 1991). In 1986, the city's administrative office promoted a new research on the problems related to the tenement houses, whose final report (PMSP/SEMPLA, 1986), presented a broader approach to the urban status of the problem, pointing the confirmation of the following factors:

- *Most tenement houses which were researched were located in urbanized consolidated areas, 92.3% of the neighboring area's occupation rate was higher than 75%;*
- *94.3% of the properties which were originally considered tenement houses were located in areas that had been popular residential districts. Most of them were built during the establishment or consolidation of the districts, demonstrating that this category of tenement houses, in contrast to the adapted ones, followed the urban processes in such areas, and were not originated from them;*
- *Of the adapted properties, 90% were located in districts that, already in 1930, were densely or relatively occupied, which make us believe that this type of category of tenement houses is a characteristic of the old occupation in the districts, and that 56.6% of them occurred in districts considered of average residential standard at the time when they were created, such as Liberdade, Vila Mariana and Perdizes;*

3 For specific information about the City of São Paulo, see Bogus, L. and Pasternak, S.: *Como anda São Paulo,* in Cadernos Metropolis special number. São Paulo, 2004.

- *Therefore, it could imply the existence of two bind basic slum tenement processes at different times in the evolution of the districts: While the old urbanization areas, which had gone through transformations and led initially to the creation of slums, appeared in the districts as popular houses since their origin, and had already been conceived for this purpose. The districts which congregated both of these characteristics, that is, the old and originally popular patterns, as Brás, Pari and Moóca, have the two property categoriesf, although they appeared at different times.*

In 1994, the Institute of Economic Research (FIPE) promoted a research on the real estate of the tenement houses' characteristics and their occupants, complementing the data and consolidating the final report in 1997, with an inquiry on the terms of payment, stability and the relation between local work and housing of the target population. This research disclosed the magnitude of the problem: 600,000 people, almost 6% of São Paulo City's population, lived in 24.000 tenement houses. Late in the 1990's, São Paulo City had a lower demographic growth rate than those of the last decades. Its growth rate was 1,16% during 1980-1991, and just 0.85% during 1991-2000, according to the Brazilian Geographic and Statistic Institute's (IBGE) statistics.

2.1 Dwelling alternatives for São Paulo's low income population

Tenement houses represent a significant segment of habitation in São Paulo City, and portray the city's urban poverty as one of its oldest modalities. In 1896, the public sector (Law 286) defines the tenement houses as (Piccini, 1999):

Art. 13 – a tenement house can be defined as a set of two or more common dwellings in a same lot, that communicate with public streets with one or more entrances that serve more than one family.

Sole paragraph: each one of the tenement house's units is called room or cubicle.

Art. 14 – Cubicles are also defined as rooms from houses other than tenement houses, the ones that are divided into different rooms, each of them having a stove, and the ones that are added to them in these same conditions.

It could be perceived at that time a concern with the phenomenon of the existing conceptualization. In 1991, a century later, the Moura Law defined a tenement house according to these habitability conditions:

Art. 1 – A tenement house is defined as a collective dwelling unit, showing partly or totally, the following characteristics:

a) constituted of one or more buildings constructed in a single urban lot;
b) subdivided into many rented, sub rented or free to use;
c) a large number of people in the same room;
d) common use of not built spaces, sanitary facilities etc;
e) circulation and infrastructure in precarious physical conditions.

In the years following the metropolis expansion, the popular stratus had found another alternative, which became dominant, the tripod: one's own house, self-constructed and in irregular peripheral land division. Strengthened by the collective demand for bus transportation, substituting the trams, the city would follow a standard of expansive growth in a more distant direction towards the periphery, along the radial roads.

Table 1 shows that in last decade, central, interior and intermediate geographic rings had lost increasing population rates, while the periphery continued to grow, still in a less fast rhythm.

Table 1 – Taxes of population growth by geographic ring percentage. São Paulo City: 1960, 1970, 1980, 1991 and 2000

Geographic Ring	1960-1970	1970-1980	1980-1991	1991-2000
Central	0,69	2,23	-0,94	-2,05
Interior	0,08	1,26	-1,17	-1,78
Intermediary	2,79	1,28	-0,71	-0,79
Exterior	5,52	3,13	0,83	0,13
Peripheral	12,81	7,39	3,05	2,71
Total	4,79	3,66	1,13	0,92

Source: Pasternak, S and Bógus, L, (2004)

It can be observed that in the 1990s, the occupied lands in São Paulo City are the worst quality in topographic terms, areas with a lot of descending slopes with a precarious road system which is not articulated to the main city's. In this growth panorama of the periphery and significant expansion of the slums, the tenement houses are located mainly in the central area and continue to be an important dwelling alternative. There are several reasons and perhaps the most important question nowadays is the possibility of access to work {4}.

2.2 Characteristics of São Paulo City's tenement houses

The Santa Ephigenia Workers' Dwellings and Tenement Houses Examination and Inspection Commission Report of 1893, already presented the different typologies that had been found in that district and located each of its streets. It is possible to identify a relation between the tenement housing and the urban space organization processes in São Paulo City. In the type described as backyard tenement houses, which occupied the center of the blocks, with a small corridor for access, as reported in this Report from 1893, are associated with the formation of the industrial districts late in the 19th century and early in the 20th century and were mainly occupied by the workers population. These tenement houses appeared in the districts of Brás, Cambuci, Pari, Moóca and Barra Funda.

The tenement houses that had been created by the large houses' subdivision are a consequence of the gradual displacement of the upper and upper middle classes in direction of new areas with more prestige, abandoning the old districts as Campos Elíseos, Santa Cecília, Consolação, Vila Mariana and Aclimação. Some of these houses had been rented and gradually sub rented.

4 To understand São Paulo City's urbanization pattern, see Pasternak, S*: Dwelling alternatives for low income population: concept, measure and evolution in São Paulo City* in Synopsis no. 37I. São Paulo, 2002.

In 1975, the Social Welfare Secretariat, studying the phenomenon based on the municipality's real estate registration data, estimated that 9,3% of the population lived in tenement houses. The tenement houses' concept was of a collective dwelling unit for rent purpose, that is, "*it refers to the set of the existing constructions in the same urban lot, which can assume 3 forms: large old houses, basement used for living and precarious small buildings covered by lean-to roofs. These forms occur separately or in a combination. Another characteristic of these constructions is their subdivided rooms for rent (or sublet), although they rarely have a written rent contract (…).*

The book "Tenement Houses: face and reverse", published by SEMPLA (Municipal Planning Secretariat), describes the tenement house occupants' living conditions. It is estimated that there are 2.700.000 tenement house dwellers; which is nowadays considered overestimated. Regarding work hypothesis, it was known that the tenement house growth population rate grew as much as the slum population's due to the same impoverishment conditions. (PMSP, 1985).

The Institute of Economic Research (1991), by using the operational definition of tenement houses of Law 504/89, called Moura Law, made a research trying to up-to-date the data about tenement houses and to reduce the uncertainty from the estimates. This was a sample research, choosing randomly the people it was addressed to and based on the density of the tenement houses which were indicated by the municipality's real estate registration data from the Secretariat of Finance. There was an estimate that 23,688 properties were used as tenement houses in São Paulo, having 160.841 families and a population of 595.110 inhabitants, which corresponds to approximately 6% of São Paulo City's population. The data indicated that 46% of properties had been constructed for the main purpose of becoming tenement houses. The indicators showed this exiguity of space and comfort: the average area of the houses is 11.9 square meters, with 4.1 square meters for each person and 7.04 houses in each real estate; the number of people in each house is 2.90, 2.45 people in each room; there are 6.32 people for each shower, 9.25 for each sink, and 5.91 for bathroom. According to the Institute of Economic Research, in 1994, from all the people who lived in the tenement houses, 42.8% had a job. The workers' monthly income was, as it was already expected, very low: the great majority – 51.8% - earned from 1 up to 3 minimum wages. But 14.2% of the workers earned over 5 minimum wages (Moreira et al., 2005).

The rent paid by the dwellers for their houses, one month before FIPE's research late in 1993, was up to 0,5 minimum wages; the rent was between 0,5 and 1 minimum wages for 26% of the houses. The electric and water consumption, for the majority of the families in 1993 was less than 0,25 minimum wages.

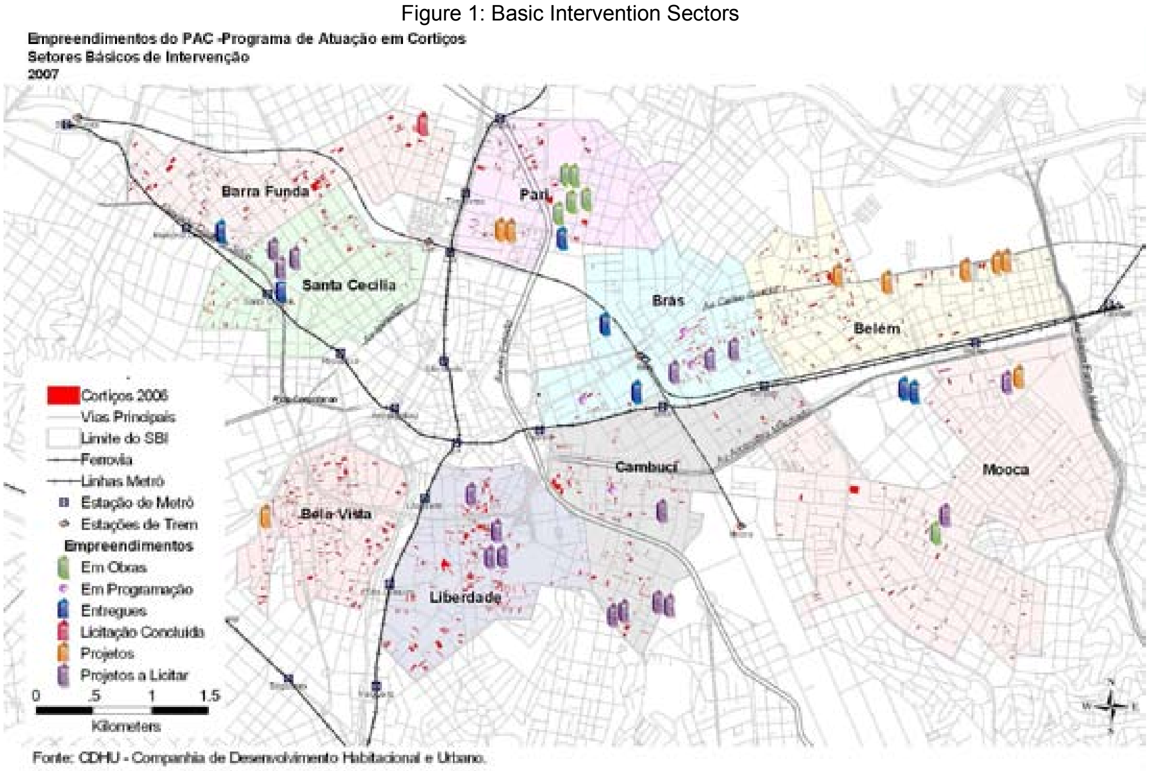
3. Action Program in Tenement Houses

PAC is the Housing and Urban Development Company of the State of São Paulo program (CDHU), a partnership with the Inter-American Development Bank (IADB). This financing program was created by the State Government's decree in 1998 in association with Inter-American Development Bank. It was effectively implemented in 2002 after a loan contract with the IADB had been signed, in the total amount of 70 million dollars in its initial phase. For the investment, USS 34 million came from IADB and USS 36 million, on the counterpart, from CDHU. For next phase of program, an additional investment of 150 million dollars is foreseen, USS 76 million from IADB and USS 74 million from CDHU, totaling a USS 220 million investment (Operational Regulation (PAC), 2002). Of the reimbursed expenditures of IADB, 21% is addressed to the management program; 50% is to the social work; 55% is to the institutional strengthening; 50% is to the credits and subsidies and 100% to the auditing activity. It is a multistage program, since it constitutes innovative introductory steps of the public social policies of the State Government. CDHU is responsible for the development and execution of Housing Programs in the State of São Paulo.

CDHU initiated its action’s strategic planning, delimiting priority areas for slum tenement population attendance, establishing defined space goals in favor of the slum tenement property concentrations, divided in Basic Intervention Sectors of (BIS). The objective of this space delimitation was essentially to program planning activities, project, group demand organization and the dwelling solutions management for the target families that would benefit from the program.

BIS comprehends these districts in São Paulo City: Barra Funda-Bom Retiro, Pari, Brás, Belém, Moóca, Cambuci, Liberdade, Bela Vista and Santa Cecília, whose total area is about 12 square kilometers. Its area of influence is estimated to be 44 square kilometers and it has a population of 516.000 inhabitants. PAC also acts in Santos, in the degraded area surrounding its port, in the district of Paquetá. In the BIS from Santos, (SEADE 2002) the totaling 340 tenement houses, with 2.992 residences and an estimated population of 7.802 inhabitants. Here, a tenement house is defined as an irregular one-family housing unit for rental purpose for the low-income class, subdivided into informal rooms for rent, which are located in areas with complete infra-structure - with precarious living conditions, having collective access, sanitary and laundry facilities. Tenement houses are private properties and have a known proprietor, through deed, although it may not be easy to contact the owner.

Figure 1: Basic Intervention Sectors



4. Objectives and features

PAC is aimed at promoting urban regeneration by recycling old buildings and by building new dwellings in downtown areas in order to improve the living conditions in degraded squattered settlements, optimizing their urban infrastructure, collective services and the public equipment already installed by the high public investments that were made in the past. In this first phase, CDHU, through PAC, privileges services to the low income families, who already lived in these downtown areas in São Paulo City and in Santos.

In the census registered property, it had confirmed the foreseen building types, as Picture 1.

Picture 1: Tenement building typology

Two-story houses 52,0%

Single level houses 47,4%

Multi level buildings 0,6%

Source: SEADE (2002)

High population density was verified, where 35 % of the tenement units have between 10 and 20 “residences”. The most preponderant physical characteristic in most of these residences is that the domestic activities such as rest, food preparation and hygiene, all take place one single space, harming the families’ quality of life. This lack of space makes some families, almost 15%, improvise internal thick partition walls, creating different environments to separate the "kitchen” from the "living room", as shown in Picture 2. However, more than 25% of the residences do not have windows in any of the rooms used as bedrooms, or they were obstructed by furniture that harms their internal ventilation. The collective use of the bathroom is for 85 % of the residences, and the shower is usually electric. To do the laundry, nine in every ten residences share the same washtub. The food preparation is made inside the residences and, since most of them have a few rooms, their occupants must use a stove (or a camping stove) in the same room which is also used as a living room or as a bedroom (SEADE, 2002).

Picture 2: Tenement houses

Photo: PAC/CDHU

4.1 Financing Resources

PAC, a dwelling financing program, provides credit for the tenement house dwellers through part of the ICMS tax (- a value added tax on goods and services – collected from specific industrialized products and services) and it is complemented with IADB's resources. In its first stage, PAC is aimed at helping 3.5 thousand families that will be living in tenement houses by 2009.The program always intervenes in existing buildings. CDHU acquires buildings to recycle or rebuild them, and lease them back to the same families, who had lived in them previously. IADB created the *self focus* concept to be introduced to PAC, where the beneficiary parts decide upon the credit options that are offered. As a result of the high population density in them, PAC must offer different credit options to families with different social-economic levels.

There are four credit options available: 1- *Individual Letter of Credit* to purchase a dwelling in the formal existing market, offering up to R$ 45 thousand, R$14 thousand of which (equivalent to US$ 5 thousand, in June 2002) are subsidized and financed to the families; 2- Financing an existing unit through CDHU's programs in other areas of the city; 3- Leasing a dwelling unit built by CDHU in downtown through the PAC program, for the first 5 years, to those earning up 3 minimum salaries, and the same US$ 5 thousand in subsidies, and after that period, the renter may become the borrower; 4- *Government Assisted Aid* provides a R$ 1.8 thousand aid for the temporary payment of rent for six months, for those families financially unable to take the previous options.

Table 2 PAC Production, in February 2008:

Table 2: PAC Production

Dwelling attendance		nº. UH
Commercialized dwelling units		**792**
Letters of Credit		**228**
TOTAL		**979**
Dwelling creation units	work in process	762
	project	465

Source: PAC/CDHU

In this production, 62% of the acquired properties through a letter of credit are located in the central area of the city. The amount spent on the dwelling access, already with the expenditures registered in the notary's office, corresponds to 30 % of the amount of the contract until February 2008.

PAC has an interface with the PMSP – São Paulo City's Administrative Office, by a Protocol of Intentions, signed between CDHU, SEHAB and COHAB, from December 19th 2003, whose objective is:

- to define performance ways that aim integrated action between State and the City Hall Administration;
- to integrate PAC (State Government) and *Live in Downtown,* a program from *the* City Administration Office's (PMSP) actions;
- to integrate and to articulate the municipal planning licensing and to verify the use to which the Program intervention will be object;
- to establish the creation of a partnership for the social dwelling which is focused on meeting the tenement dwellers' demands.

In respect to the accomplishment of the partnership, CDHU supported the technical actions from Moóca's regional administration according to Moura Law's enforcement, with the inspection of 450 tenement houses, foreseeing its recycling potential through refurbish.

4.2 The Target Public's Social and Economic Conditions

The social economic situation of this population living in all BIS researched tenement houses by the State of São Paulo Data and by the Analysis Foundation (SEADE) in 2002 (Table 3 and 4) are characterized by average young people aged up to 29, 55% of whom are male. Families are smaller than the usual standard, with 2.3 people, but with distinct composition, since only 25% of them are households with children. Half of the families with children in the researched area have only one child, followed by those with two children, with ages between 0 and 14. In terms of employment, 89% of the head of the households have formal jobs. However, the predominance for low income families is to earn 3 minimum salaries, from which rent payments represent 45% of the total income. Regarding formal instruction, the majority of head of households has no schooling and some have attended less than 4 years in elementary school.

Table 3: Some PAC research results: *cortiços* and *cortiço* inhabitants

5. Selection and intervention strategies

The Sectorial Projects were responsible for the diagnosis elaboration aimed at pointing the possibility of tenement houses' intervention. Focused on the appropriate use of the soil and the standard dwelling improvement of these existing properties, it provided a description of the urban characteristics and their dwelling conditions in the studied areas, with successive approaches, comparative analyzes, with the SBI's intervention formulating plan. The attainment of solutions for the dwelling took the urban, architectural, social and economic aspects into account.

The results prioritize the purchase of property complexes involving all the SBIs, as shown in Table 5. These addresses had been identified through the prioritization of intervention parameters and criteria, considering the tenement houses' specific construction and urban aspects. The confirmation of the prioritized enterprises was based on the performance level of evaluation, after a research identified *a priori* the estimated number of houses and units in each complex, according to PAC production rules (Table 6).

6. Projects

As PAC's objective is to promote the life quality improvement for the inhabitants of the central areas, by offering a dwelling solution for the tenement house's population, its premise is to develop differentiated housing solutions, tuned with the family incomes and their size.

The search for dwelling typologies to attend the tenement houses' population, with family incomes between 2 and 3 minimum wages, represent 50% of the demand for this dwelling attendance, and requires specific actions from this project in the context of the downtown area. For the development of this differentiated typological alternative, it was observed a great incidence of families with up to 3 people and a significant number of individuals living alone. Architecture projects not only inserted this concept into the Sectorial Project for all Basic Intervention Sectors, but contemplated the existing social reality and the impact of the enterprises establishment as well.

Dwelling unit areas had been adjusted to a production value that could meet the payment capacity of tenement house dwellers' demand, highlighting PAC's adopted commercialization plan, with concessionaires' services and condominium maintenance taxes added to the monthly payment amount value. For the architecture conception and the complementary development projects, the following information was provided - the urban characteristics about the use of the soil and their occupation, the neighboring area, address, physical data, area, zoning and these respective factors: soil use coefficient and occupation rate, City hall's specific policies, State registered historical heritage area: the Historical, Artistic, Archaeological and Tourist Patrimony Defense Council of the State of São Paulo (CONDEPHAAT) and the property which already is or is in the process of being declared a registered historical building by the municipal Council for the Preservation of the Historical, Cultural and Environmental Heritage of São Paulo City (CONPRESP) and the procedures of the Technical Project Manual (CDHU, 1998).

6.1 Project directives

The establishment of these dwelling solutions requires the development of projects which prioritize small enterprises and crowded dwelling units. The existing lots deed and the urban situation, the real exploitation of the property, under PAC's premises to keep the current families living in the same central region, and the analysis of the feasibility studies assure the decision of use for such properties.

The existing property existing typology, reflecting the use and occupation of the soil, the very low lot density, the used constructive technique and the precarious preservation and/or maintenance of the property general situation, as well as the economic viability simulation, generally led to the demolition of the existing properties at these addresses and consequently; the construction of a new venture. For the purpose of fulfilling the requirements of the new Master Plan and the capacity of the full use of the constructive potential of the current zoning, it was necessary to annex the selected lots in each of the complexes, attending the zoning demands. The low verticalization, the ground floor partly occupied by dwelling units for handicapped people , and the four-floor type of building, without vertical type mechanical circulation, was considered the building typology that best fits this social class, since nonexistent elevators in the buildings reduce the condominium tax in 50%.

The incorporation of CDHU's current directives related to individualized water, light and gas consumption measurement to the new public services concessionaires' norms and the remote measurement technologies, recently incorporated to the low income housing projects are present in these enterprises. The adoption of these individualized measurement readings minimizes the sociability conflict among the future users of these new enterprises, allowing better condominium management actions. The region where the enterprises are established is served with all urban infrastructures and with gas canalization.

All the projects were developed and contracted in accordance with the Federal Law n. º 8, 666 from June 21, 1993 that sets up norms for bid at auctions and contracts, since the CDHU is a public administration company.

6.2 The project program

The functional set, the dwelling unit architectural proposal, and even the complex have increased the supporting and condominium service area, the entertainment in the collective area (uncovered) and the entertainment collective and external area (open air), front desk, water, electricity and gas measurement shelters and other infrastructure installations. However, the essential uses were preserved with the creation of space, with dimensions that allowed a more appropriate disposal of furniture and objects for the development of the foreseen functional activities in the program of use of the dwelling construction.

The dwelling units' architectural proposal observed the project premises as follows:

- the concentration of wet areas, rationalizing the hydraulic installations;
- optimization of stairs and circulation in common areas;
- the best potential occupation use observed in the low income housing building legislation;
- vertical multifamily typology with 5 floors;

The complex viability was established from the lot use feasibility studies, providing a program of the project as shown below, in Table 7:

Table 7: Dwelling typology

Functional set	dwelling unit
Kitchen, laundry area, bathroom, integrated bedroom and living room;	efficiency apartment
Kitchen, laundry area, bathroom, living room, one bedroom;	1 bedroom
Kitchen, laundry area, bathroom, living room, couple's bedroom, single bedroom;	2 bedrooms

The architectural design proposal is based on the following recommendations from the Manual of Projects (CDHU, 1998): to distribute, in a balanced way, the necessary spaces for the performance of the dwelling program project's defined functions, and to search for cost compatible solutions for the specific use it is designed for, both for the construction of the building and for its maintenance.

The designs shall be in accordance with the City's construction legislation norms, the municipality's urban soil parcel and use, and other matters to be verified by the designer in the City's Administrative Office, State and Federal Departments. All the technical areas which are involved in the projects' conception complied with all the appropriate and up-dated norms and techniques from the Brazilian Association of Technical Standards (ABNT).

6.3 Projects' Characteristics

The presented solutions have maintenance and condominium low cost, and are compatible with the income of the target population, minimize the environmental impact, and do not harm the functionality, security, hygiene and the aesthetic maintenance of the buildings. The Program's differentiated actions of this project have shown different solutions, lot sites and the specification of the finishing materials, such as the use of ceramic floor in all dwelling units' rooms. Photo 3 describes some the original situations of these properties that are object of intervention in the case of extirpation of the tenement houses which are located mainly in the Basic Intervention Areas (BIS), and shows the projects designed for these lots, as well as their its electronic maquette.

7. Challenges and some special remarks

It is a challenge for the public sector to improve the provision of dwellings or to substitute the subnormal ones with physical delimitation in great cities' central areas, mainly in São Paulo City. The identification of the phases and evolution of this process, in order to better understand the broad context of the existence of the tenement houses, has allowed this recent diversity of dwellings of social interest which modify the characteristics of this universe to create data about the results which have been accomplished by this Program.

With the registration of some of PAC's actions in precarious tenements houses, it makes evident that the distinction between the Program's construction typologies and those designed for low income complexes of social interest located in distant consolidated central areas, since the urban lot and the differentiated zoning patterns allow it. The typologies proposed to meet the demands of the Program, which is characterized by new social groups, are crowded and completed dwelling units, which include: kitchen, laundry area, bathroom, living room conjugated with the bedroom, or an independent living room plus one or two bedrooms. In this recent universe of solutions, it is a novelty for CDHU to propose completed dwelling units with one bedroom or even a living room conjugated with the bedroom in vertical constructions and to commercialize dwelling units for people living alone, since one of the CDHU's requirements is addressed to people who have a family.

In the analysis of the procedures and development of these works, in some of the attained results, it was necessary to review CDHU's usual proceedings. The fact that the real estate selected for intervention is built in a small urban lot is a great challenge, totally different from the usual interventions. The materials' specification and specialized workmanship are other important aspects to be taken into consideration, as well as the construction to be installed in the site, which has specific characteristics and reduced dimensions, the addition to new routine tasks to be executed in civil engineering, for example, ready-to-use stucco that comes in packages easy to transport and to handle, among others.

The lots are not often located in registered historical area, which permits quick legal approval of the new enterprises in the competent departments. The necessary demolition of the existing properties in these lots was another novelty for CDHU, as well as the planning of the initial civil works and the attainment of the legal demolition conclusion document, followed by specific procedures from the City Hall, since CDHU used to intervene in great empty constructed or not constructed areas.

The project response to these central area proposals are the same as those of CDHU and other projects, in which the designer attempts to verify if it possible to adopt dwelling units with similar private area, with the rationalized optimization of the potential use of the lot. Both technological innovations and the individual water measuring for the vertical constructions were adopted, which besides meeting the demands of the new parameters of the water concessionaires, they minimize the social conflicts between the dwellers.

The commercialization of these dwelling units is made through the onerous concession contract for use during the first 5 years, and from that period onwards, this document is transformed into a contract of purchase and sell. Twenty-five years after the financing, the borrower becomes the proprietor. Such proposal aims at minimizing the dwelling unit sale process. The social work inserted into it is seen as a way to improve the dwellers' social living conditions and to make it possible for them to participate in the proposals to change their social and economic conditions and, consequently, their quality of life.

These punctual projects are a specific central area-related issue, and they have undoubtedly established a critical and creative dialogue with the existing city. City planning and project programs are based on traditional concepts and need a multidiscipline approach to meet the users' necessities.

The solution to fulfill these needs and the presented institutional responses shall have a long-term commitment.

A STUDY OF THE GREENWAY NETWORKS IN SEOUL

Ji-young, Choi PhD Student[1]
Ki-ho, Kim M.Arch[2]

[1]Urban Design Center, Seoul National University, Seoul, South Korea, voice134@snu.ac.kr
[2]Professor, Urban Design Center, Seoul National University, Seoul, kimkh@snu.ac.kr

Keywords: Greenway networks, Neighborhood greenways, Residential redevelopment

Summary

As the energy crisis becomes a matter of international concern, the Korean government hastens to institute green growth policies to conserve energy. Until now, environmental protection has been neglected for the sake of economic growth, and the quality of life in the major cities of Korea has been ranked lowest in the world. Furthermore, no energy efficiency system has been developed for the public. The Urban Design Center for the public considered greenways linking pedestrian ways as a solution to the city oriented automobiles. We divide the greenways into the hierarchy of pedestrian ways, city greenways, and neighborhood greenways. We also propose that housing be designed in harmony with the greenways. We are against the usual pattern of excessive development that does not consider the community and neighborhood. This study suggests, first, that separate redevelopment projects be designed so that they are synergistically integrated and, second, that the access to Han River be made easier with greenways. Such an approach to urban design will make Seoul become more hospitable to pedestrians and create sustainable and vibrant communities within the city. We hope that this endeavor will serve as an example to other countries in Asia as well.

1. Introduction

1.1 Background

Korea has advanced rapidly in industrial and technological developments in the past decades. The Korean economy has been ranked the 13th in the world. Advances in state-of-the-art-technology in electronic, IT, and shipbuilding have been exceptional.

However, the economic growth has negatively affected Korean society and the environment. As industry expanded rapidly since the 1960s, population density of Seoul rose to 17,108people/㎢, third highest in the world. Seoul is overcrowded and over-polluted and lacks open spaces. As a result, the quality of life in Seoul, and in other major cities, ranks low in the world index.

Urban Design Center, a non-profit organization at Seoul National University, has taken this situation seriously and started various projects, such as Greenway Planning and the Han River Waterfront Master Plan, to improve the urban environment. These projects have influenced the Seoul city government, which has begun to acknowledge that the condition of the public space is closely related to the quality of life in the city. Several meaningful projects are being spearheaded by the government: for example, the Han River Renaissance Project, the Pedestrian Improvement Plan in CBD, and the Gang-dong Greenway Project. The city of Seoul is embracing a new paradigm of urban design.

Figure 1 High-rise apartment districts have developed along the waterfront in Seoul

1.2 Purpose of Paper

Despite efforts by the government, the fundamental problem of making Seoul a livable city still remains. When large apartment complexes were first being built, they were looked at as a positive development, especially in supplying housing to large number of citizens. Soon, however, apartment buildings became convenient tools of landowners and tax collectors for yielding large economic gain, and the huge apartment complexes became the typical type of residence in Korean cities. (See Figure 1) This situation created a host of negative effects such as natural resources being in private ownership, haphazard and poorly integrated development, and large profits for private individuals in housing development. As a result, public space has almost disappeared, and no attention is being given to public interests.

The theme for the present study emerged from the question: "How can sustainable communities be design in residential redevelopment?" Beginning with an overview of current redevelopment methodologies in Korea, we discuss the elements and processes of a new planning paradigm. We would like to show a vision of Seoul through the pilot projects along the Han River and propose a way to make greenways through redevelopment of Seoul.

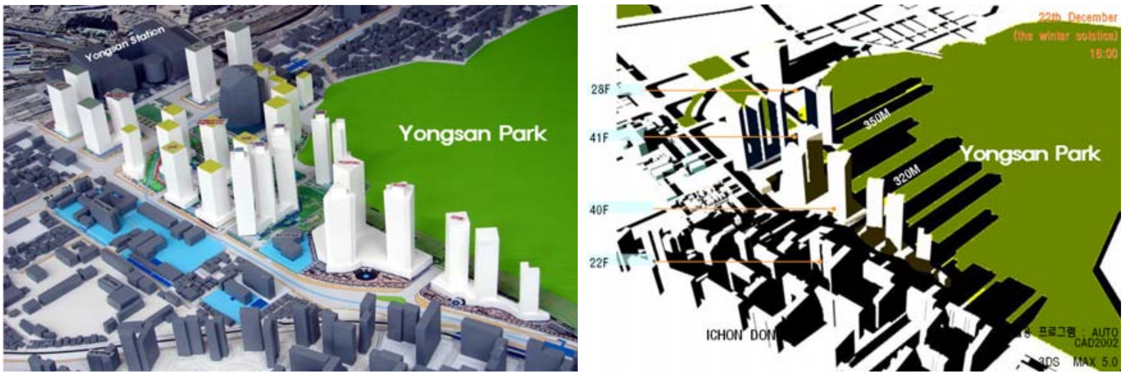

Figure 2 Despite significant investment in the area, the benefits are almost negligible in the areas adjacent to the key developments.

2. Concept of City and Neighborhood Greenways

2.1 Literature review

Greenway became widespread all around world. A fundamental factor that it has been developed is the desire to get away from the squalor, the congestion and the pollution of industrialized cities of the 19^{th} century. According to Searns (1995), Greenways help mitigate the loss of 'natural space' owing to development and provide a counter-balance to an expanding human dominated landscape. Open space planning including greenways has evolved to meet specific needs that have resulted from economic growth. (See table 1) With open space planning, neighborhood design has been studied in western countries. The concept of the neighborhood unit was formulated in the 1920s. This paradigm has been used widely as a design concept both in the United States and in other parts of the world. Korea was also influenced by this paradigm and applied it in building large apartment complexes. The method of placing schools and playgrounds in the center of districts has been a popular residential planning method until now.

Table 1 Advances in the History of Urban and Open Space Planning

Era	Urbanization by Industrialization (Mid-Late 1800s)	Development of Automobiles (Early-Mid 1900s)	Sustainability Smart Growth (Late1900s-2000s)
Problems	Poor public health and welfare in cities	Pollution and Urban sprawl	Traffic congestion and energy crisis
Urban Theory	Urban planning	Regional planning	Compact City, New urbanism
Open Space Policy	Boulevard Park	Parkway system Greenbelt	Greenway system

2.2 City Greenways and Neighborhood Greenways

The metropolitan Seoul is surrounded by a greenbelt with big mountains visited by many citizens every weekend. The greenbelt was established in 1971. The Han River is in the center of Seoul, and the waterfront is being revitalized through the 'Han river Renaissance Project.' Although amenities around the city are excellent, public open spaces of the inner city are run-down and have no access to outer city parks. Moreover, the prime locations along the Han River are the apartment districts where residential use is about 62%. Among the apartment units built in the late of 1970s are about 150,000 units all of which are designated as rebuilding districts. One recently rebuilt district is the Jam-sil apartment district. In this rebuilding project, the floor area ratio changed from 80% to 250%, and low rise (5 floors) buildings built for 30,000 units were remodeled to high-rise (30 floors) buildings for 50,000 units as shown below in Figure 3, Figure 4. Despite the waterfront is the importance public assets, the neighbor planning has not taken a broader view of the waterfront but only focused on the core of the building projects. Thus, the building districts are relatively self-contained, and the residents cannot access the waterfront easily. City greenways and Neighborhood Greenways are alternatives for improving the environment in neighborhoods. City greenways are regional-scale connections that link to natural resources and improve the accessibility of outlying areas for the public. Neighborhood Greenways are smaller-scale connections that fulfill local neighborhood needs. They connect local community amenities such as parks, schools, libraries, community centers, shops, and places of unique local significance: for example, historic sites, a group of heritage houses, or an interesting street. So the neighborhood greenways reflect local character and identity by providing opportunities for the residents to express the unique character of the area.

Figure 3 Before the redevelopment in Jam-sil

Figure 4 After the redevelopment in Jam-sil

3. The planning experience

3.1 City Greenways

The objective of city greenways in Seoul is to preserve the greenbelt and the Han River as links to natural resources. Our Greenway concept is 7 Rings and 50 trails linking the Han River and greenbelt. And provide linear parks whenever it happens to redevelop. Next picture is one of the rings in Seoul, especially central Ring. The second ring in the Gang-dong area is located in the upper zone of the Han River. The main hindrance to accessing the waterfronts is the highway constructed for the Seoul Olympics in 1988. So the Han River Renaissance Project attempts to make a mounding over the riverside highway so that the public can access the waterfront easily. (See Figure 5) And one of the bridges in the Gang-dong changed to a pedestrian bridge. The government has been trying to improve the environment and integrate all projects. Gang-dong city greenway is a ring-shaped multifunctional route that connects the waterfront park along the Han River to major parks in the greenbelt. 245million dollars was invested in this project to construct the greenway in 2 years.

Figure 5 Depressed the riverside highway and Mounding

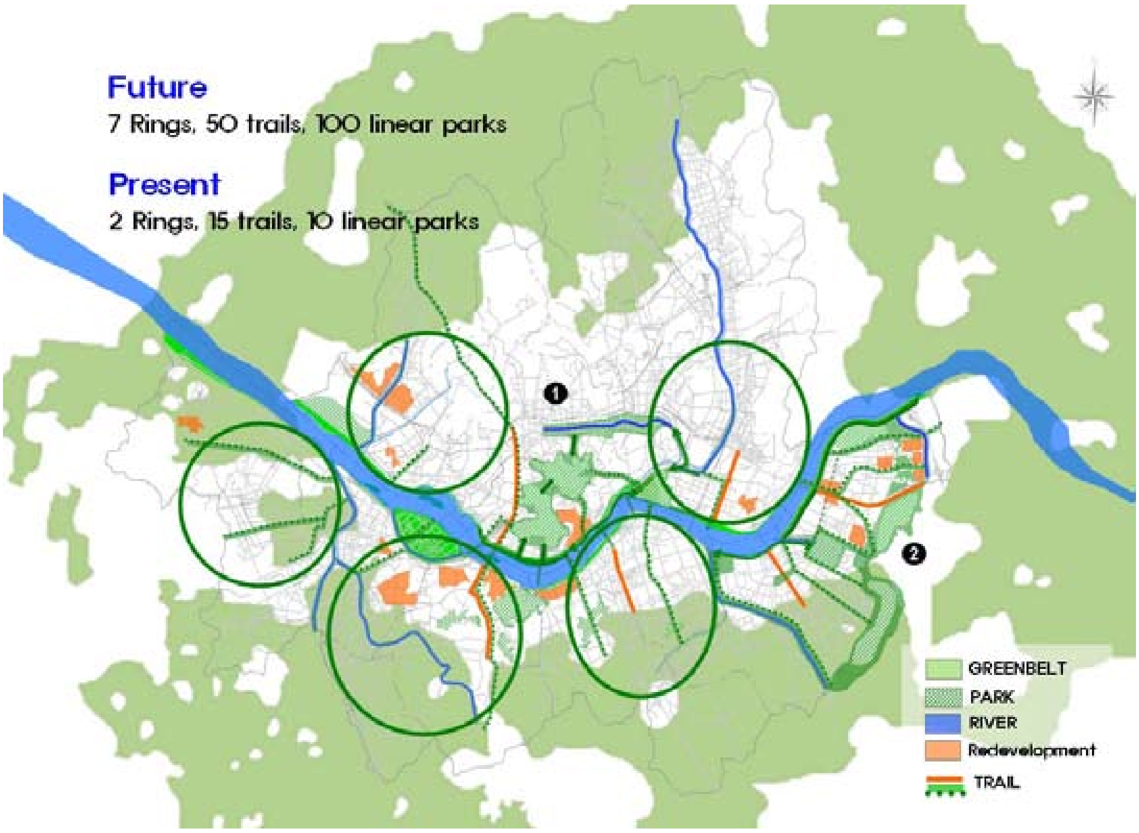

Figure 6 Seoul Greenways Concept Plan: Central and Eastern Greenways Plan completed

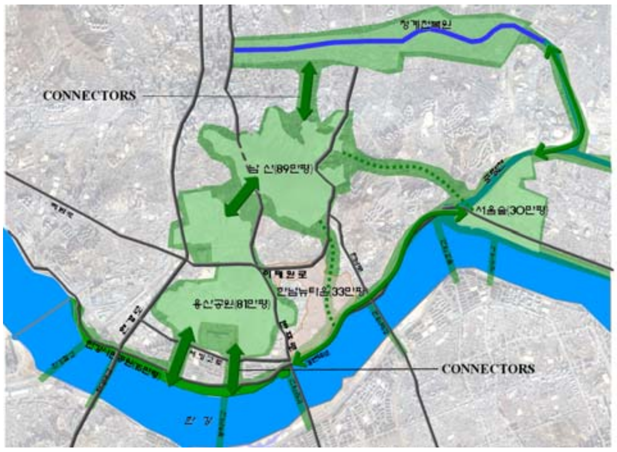

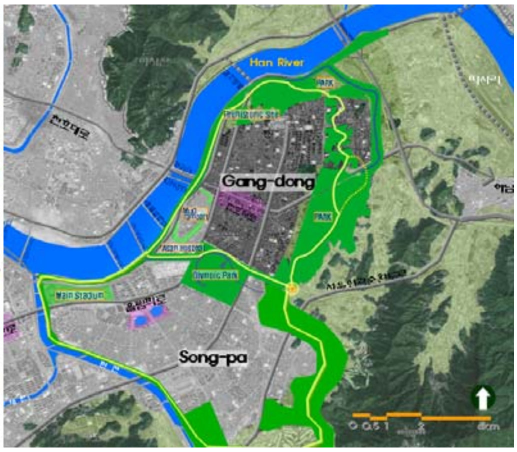

Figure 7 Central Ring① in the Yong-san Park Area *Figure 8 Eastern Ring② in Gang-dong*

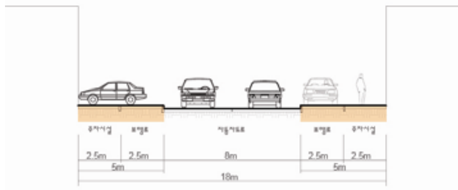
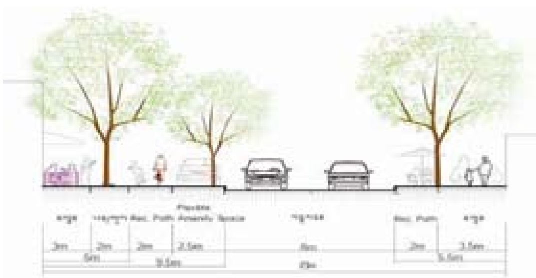
Figure 9 Gang-dong City Greenway linking of major parks and access points

3.2 Neighborhood Greenways

The object of Gang-dong neighborhood greenways is to provide the public with access to the Han River waterfront and parks in the greenbelt. Important components of a suitable greenway route are a main corridor connecting historic sites, redevelopment of over 50% of Gang-dong, the old way have been used from the Cho-sun dynasty, the roads having expansion plan and the pedestrian volume assignment. After a suitability analysis, neighborhood greenway routes were planned to enhance the waterfront access with historic corridors and boulevards and to include sidewalks, plazas, bicycle paths, and outdoor cafes.



Current Condition



Proposed Trail

Figure 10 Neighborhood Greenways in Gang-dong *Figure 11 A Plan of the street 'B'*

The area of study consists of the two parts: the old town that was established in the 1900s and the new town with apartment districts were built in the 1980s. The residential and official districts in the old town need open space for residents and office workers to be able to enjoy outdoor activities. As such, the Neighborhood Greenway Plan of the old town has a hierarchy that consists of public trails for citizens, semi-public linear parks in residential and business districts, and private courtyards in the residential area. This area also preferred to ride a cycle in Seoul. Thus it is recommended the mixed use development for cyclists around the public trail.

4. Discussion

As stated earlier in this paper, the purpose of this case study is to show how make greenways through the redevelopment site in Seoul. This is a new proposal against the typical development in Korea. For example, in the prime area of Gang-dong, a new town will be built with a business district and an apartment complex. Existing proposals by the government designed by Construction Corporation call for high rise buildings at the waterfront. Each planned project is designed separately without no consideration of the regional context, and therefore many problems remain, such as unbalanced land-use, disrupted communities, and lack of urban infrastructure. The proposed projects, if completed, would not be any different from existing neighborhoods, and the city environment would not be any different from existing neighborhoods, and the city environment would move even further away from livable and comfortable arrangements with built-in green areas. In contrast, new development with greenway networks, as we propose, would enhance the comfort for pedestrians and help create friendly and harmonious communities. Although the extent of development in the new town is the same in the two scenarios, the land use is more sustainable and varied in the new scenario proposed in this study. Fortunately, the city government has eagerly accepted our proposal, and our group and the city are cooperating in the city planning, the transportation, and the open space departments. Moreover, the city has imposed a greenway requirement for reconstruction projects for apartment complexes.

5. Conclusion

This pilot study is not yet complete, and therefore it is too early to compare the new projects with other cities in Korea. We look forward to establishing greenways in the cities of Korea, re-establishing the connection between people and nature. Until now, the control of urban planning has been in the hands of construction companies and land owners, so that excessive development for the sole purpose of profit has been the usual course of events. Citizens have had no choice in the type of housing. Recently, the city has been attempting to establish policies for creating a sustainable transportation system, including mass transportation, bicycle traffic, pedestrian circulation. Many regions are awaiting renewal and greening after the rapid urbanization in the past decades. Newly proposed green development will revive the public space and enliven communities destroyed by private development. Moreover, the Korean experiment in greenway planning and implementation, now under way, can serve as model for rapidly urbanizing cities in other countries for the recognition of various human and ecological benefits of urban greenways.

Keywords: ancient wisdom, modern technology, outside wall ventilation, breathing outside wall, medium-to-low-grade heat source and storage

Summary

A construction method is proposed to minimize the dependence on energy by combining ancient wisdom and modern technologies. The following three elemental technologies are introduced here:

1. Exterior walls with an air passageway between them, using double exterior walls to reduce the exterior skin load by virtue of their functions as ventilation, heat insulation, and heat storage, according to ambient conditions
2. Breathing exterior walls, to respond to constant changes in external wind conditions and to ensure that fresh air is taken in by virtue of the design of exterior walls and chimney shapes or by converting a draft route
3. Medium-to-low temperature heat sources and heat storage, in connection with treatment of a sensible heat load, to increase cold water temperature and co-efficiency of performance, and to equalize the load by using latent heat storage materials having potential for heat storage at the temperature

1. Introduction

We increasingly demand a better living environment and enjoy comforts that we cannot easily give up. In most cases, building equipment makes our environment more comfortable. For example, the thermal environment can be adjusted with air-conditioning equipment, and the light environment can be adjusted with lighting equipment. However, while energy efficiency has been improved, energy depletion and environmental destruction remain serious problems.

The authors of this report intend to construct a building designed to minimize energy consumption. The building concept is based on:

- Ancient wisdom used to adjust indoor environments without depending on equipment
- Provision of building components with equipment functions
- Use of new functional materials

Based on this building concept, we developed some technologies in cooperation with the designing department, aiming to be a help at an early stage of the design. We introduce the three elemental technologies of them in this paper.

2. Elemental Technologies

2.1 Ventilation Exterior Walls

Ventilation Exterior Walls are intended to reduce the amount of heat transmitted from exterior walls. These double exterior walls have openings that open and close to an air layer, and they have a heat storage function.

Since ancient times in Japan,• "Dozo" architecture has used roofs with natural air ventilation. Also, there is a type of termite that builds nests with a ventilation function to protect their living environment. Ventilation Exterior Walls imitate these examples.

The heat load due to transmission will be reduced by opening the openings and cooling the building structure with a natural air draft in summer, and by closing the openings to form an air layer in winter.

2.1.1 Details

Figure 1 shows a cross-sectional view.

In most dry construction methods for exterior walls, pre-finished metal panels are attached to the outside of dry-laid structural walls, such as ALC panels. The space between the metal panels and the structural walls can be made to function as an air layer. Openings and mechanisms to open and close them are provided at both the top and the bottom of the air layer.

In summer, while the opening is kept open, the temperature rises mainly due to solar radiation, resulting in a stack effect in the air layer. Ventilation can therefore be achieved without using power.

In winter, an enclosed air layer is formed by closing the opening. A higher heating load reduction effect is expected from a temperature rise in the air layer due to solar radiation. The open/close switching can be achieved by using shape-memory alloy.

These effects are expected to be more prominent for heat storage materials, which are used for areas to be exposed to the air in the air layer. This can equalize the amount of heat transmitted into a room and increase the heat insulation effect.

2.1.2 Effects Confirmed by Simulation

(a) Simulation Model

A 2D heat transfer model is developed for the exterior wall area, as shown in Figure 2.

Standard meteorological data for Tokyo is used for the ambient conditions. Based on the assumption that air-conditioning is switched on between 7:00 AM and 8:00 PM in the room, the temperature is set at 26°C in summer and 22°C in winter.

The non-stationary heat balance equation is solved at each mass point to determine the temperature change over time and the amount of transmitted heat.

(b) In Summer

Figure 3 shows the calculated results of the daily integrated cooling load. In summer, it is found that providing an air layer has the effect of an approximate 30% reduction in the load due to the effect of sun-shading and ventilation.

Furthermore, when phase change material (PCM) is provided at the air layer, the load reduction effect increases to about 50%.

(c) In Winter

Figure 4 shows the daily integrated solar radiation for a clear day in winter.

of the structure On clear days, solar radiation is blocked by providing an air layer, resulting in a decrease in the temperature. Consequently, the heating load increases. Under these ambient conditions, the load increases by about 20%. The transmitted heat can be slightly reduced by using PCM.

On cloudy days as shown in Figure 5, the air layer can function as a heat resistant layer, even when it is opened to the air. Therefore, the heating load can be reduced by about 10%. As a result of the adoption of PCM, the load can be reduced by about 20%.

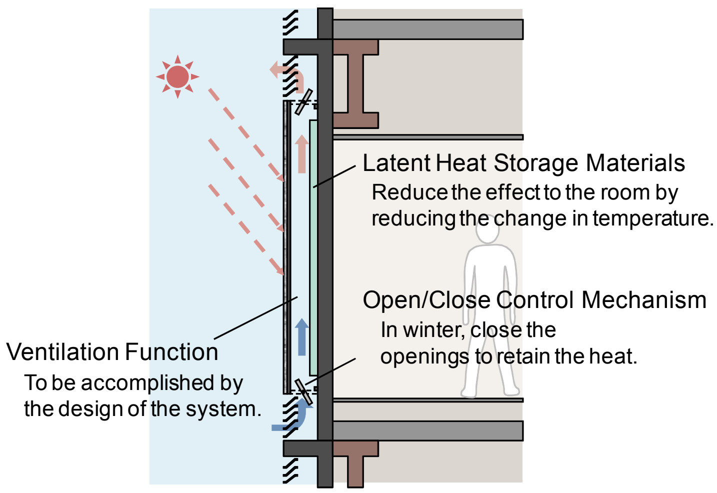

Figure 1 Cross-sectional view

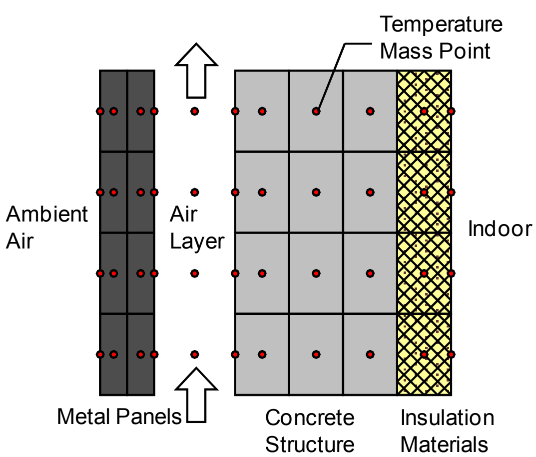

Figure 2 Simulation model

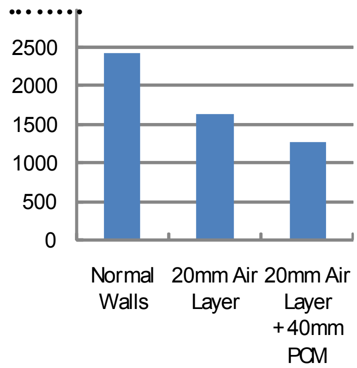

Figure 3 daily integrated cooling load in summer

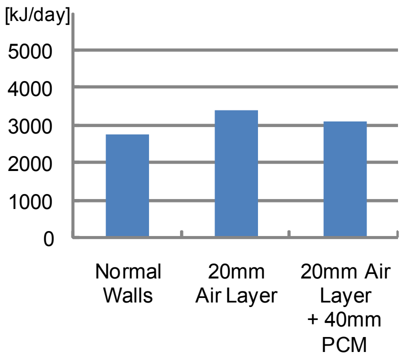

Figure 4 daily integrated heating load in clear winter day

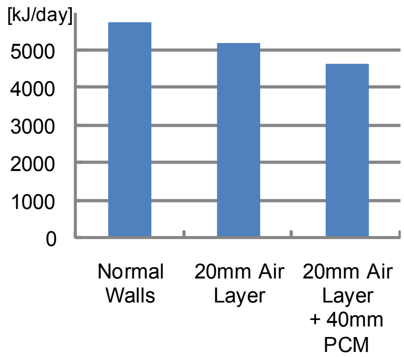

Figure 5 daily integrated heating load in cloudy winter day

2.1.3 Effects Confirmed by Actual Measurements

(a) Experimental Model

A test piece similar to the one shown in Figure 6 was measured outdoors in Osaka.

The exterior walls of the test piece comprise ALC panels with insulating material, having an air layer partially formed by being covered with metal panels. Measurements can be made under the same ambient conditions, because the part with an air layer and the part without an air layer are arranged side-by-side. The temperature measure points are located on the exterior wall as shown in Figure 7. The amount of transmitted heat is calculated from the surface temperature and heat resistance value.

(b) In Summer

Three different types of experiments were conducted for summer.

Case 1: Without an air layer
Case 2: With an air layer opened at both the top and bottom

Figure 8 shows the comparison of temperatures. In case 1, without ventilated air, the temperature rise is high (42°C) due to direct solar radiation on the surface of the ALC panels. The temperature can be reduced (33°C) in case 2 by ventilating the air space.

Figure 9 shows the amount of transmitted heat. It is confirmed that providing an air layer results in an about 40% reduction in the daily integrated load.

(c) In Winter

Three different types of experiments were conducted for winter.

Case 1: Without an air layer
Case 2: With an air layer opened at both the top and bottom
Case 3: With an air layer closed at both the top and bottom

Figure 10 shows the comparison of temperatures between Case 1 and Case 2.

In Case 1 without an air layer, the temperature rises on the outer surface of the ALC panel exposed to solar radiation in the daytime. In Case 2, the surface temperature rise is smaller due to the loss of absorbed solar radiation heat caused by air currents. However, providing an air layer has the effect of reducing heat loss due to nocturnal radiation at night, thereby increasing the surface temperature of ALC panel by about 6°C. The daily integrated amount of transmitted heat is shown in Figure 12, thus confirming the effect of reducing heat load by about 10%.

Figure 11 shows the comparison of temperatures between Case 1 and Case 3.

The temperature rise on the surface of ALC panel is more significant due to warm air enclosed by closing the opening. The effect of reducing nocturnal radiation in Case 3 is also more significant than in Case 2. The daily integrated amount of transmitted heat is reduced by about 30% from case 1 as shown in Figure 12 .

2.1.4 Conclusions

Providing a small space between a finished surface and the structure can have an effect on energy conservation. Although there were concerns about the potential increase in the heating load in winter, the results show that the effect of reducing nocturnal radiation is greater than the effect of heat from solar radiation in the daytime.

In this report, several options are available, such as using PCM or allowing the top and the bottom of the air layer to be closed. Adoption of these options can improve energy conservation, but careful consideration is required in terms of maintenance performance before adoption.

2.2 Breathing Exterior Walls

2.2.1 Outline

Before the existence of air-conditioning, building ventilation was an important means for reducing heat. Since ancient times in Japan, it has been said that "a building should be designed mainly for summer conditions," with many openings and systematically ventilated rooms with transoms. Outdoor temperatures are actually lower than indoor temperatures at most times of year, so it is important to take natural ventilation into account in order to enhance the cooling effect. Here, we introduce a support tool at the early stages of natural ventilation design and a practical design example.

2.2.2 Design Support Tool

We introduce a design support tool enabling designers to develop a general plan for natural ventilation in the early design stage. The tool is used with Microsoft Excel, and an overview is shown in Figure 13.

The designer inputs the building conditions (shape and location (meteorological conditions)) and the position and shape of the openings. The tool provides the national meteorological data, the wind pressure coefficient on each face depending on wind direction, and the measurement data from wind tunnel experiments (corresponding to chimney shape). Input conditions of the wind environment are determined in conjunction with CFD according to the surrounding terrain and block conditions.

In response to the input conditions given by the designer, the wind that enters and exists each opening is calculated in real time, and the effect of energy conservation is summarized and output. Based on a study using this tool, the designer can arrange the natural ventilation openings or set the amount of ventilation, allowing the effect of energy conservation to be determined in advance.

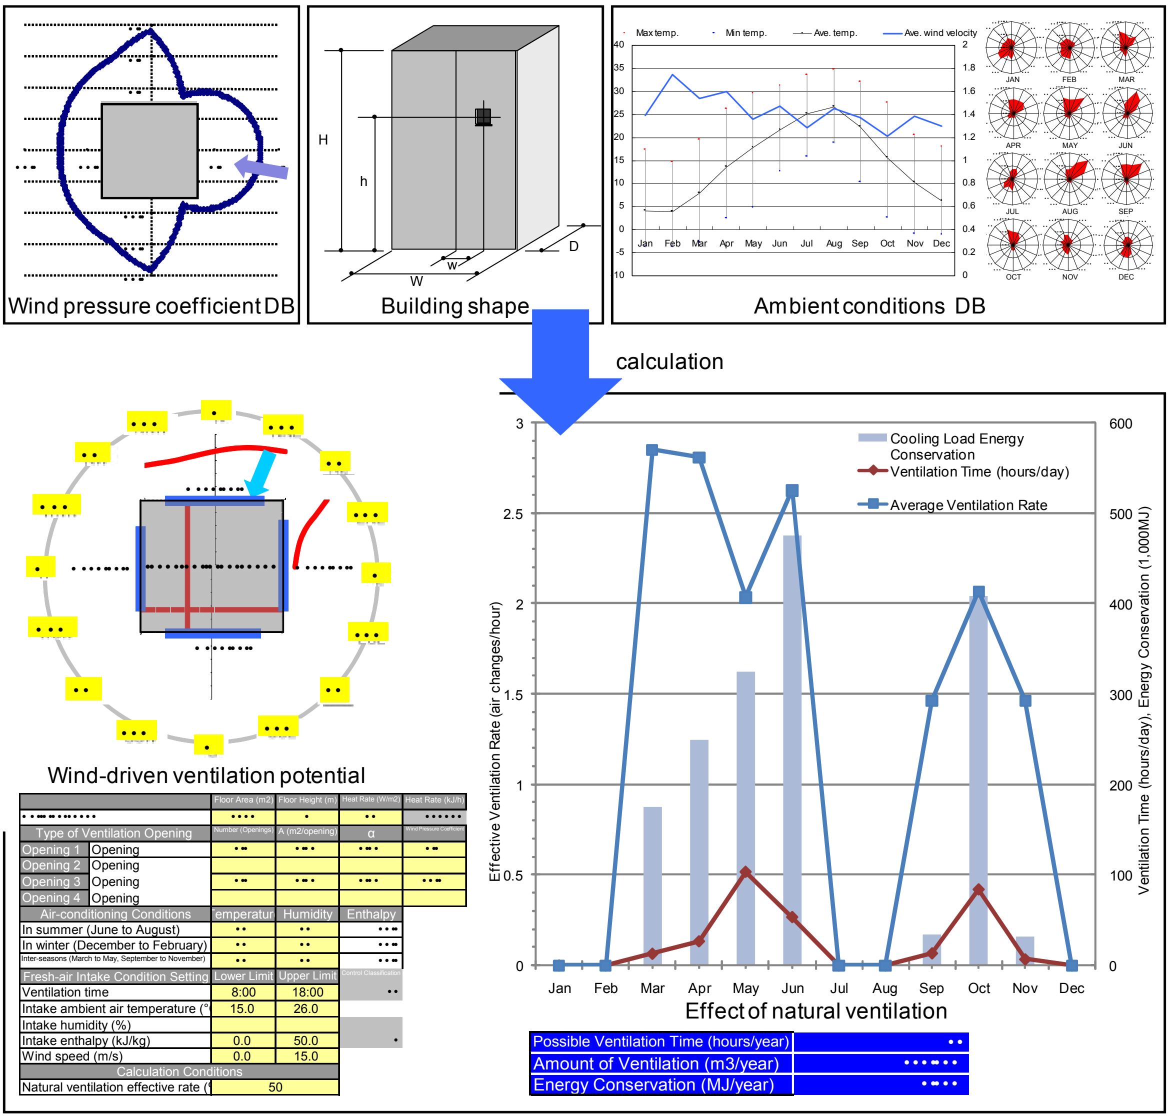

Figure 13 Overview of ventilation design support tool

2.2.3 Design Example

A design example calculated and designed in the manner above is shown here.

We introduce a university building in Shikoku. The building stretches from east to west, is composed of four floors above ground, and has laboratories lining both sides of a corridor. The building is located in a rich natural environment, and fresh air is expected to be actively introduced to promote energy conservation.

Under the local meteorological conditions, it is found that a prevailing wind blows in the longitudinal direction (east-west) of the proposed building. A natural ventilation plan is designed according to the following principal axes (see Figure 14 for outline):

- Considering the exhaust air from the top of the building, where there is constant negative pressure resulting from prevailing wind, use the staircases at both the east and west ends as exhaust routes
- Set the height to ensure sufficient induction effect and stack effect
- Provide sliding glass doors for each laboratory to directly supply fresh air as required

This building has only recently been completed, and the effect of energy conservation will be verified by future measurement study.

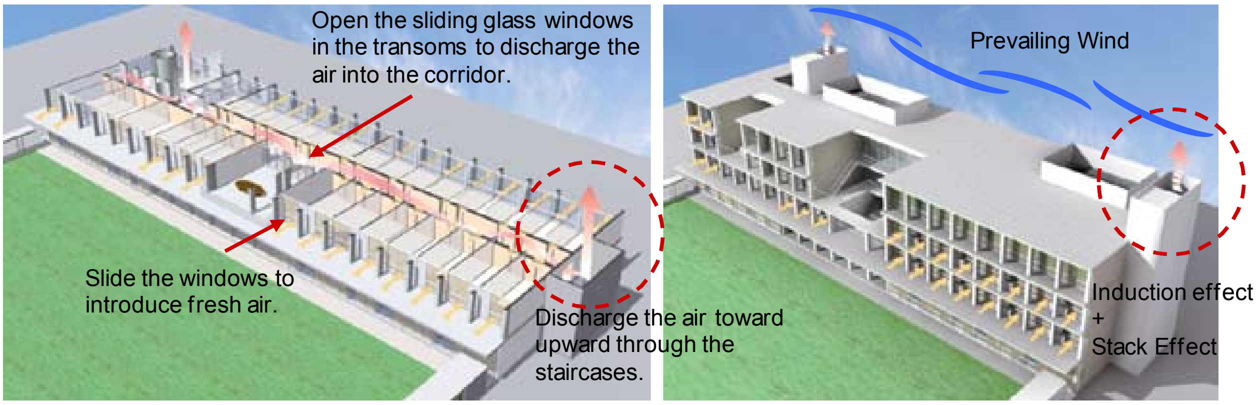

Figure 14 design example of natural ventilation

2.3 Medium-to-Low Temperature Heat Source System

2.3.1 Outline

As discussed above, it is possible to promote energy conservation by reducing or utilizing the ambient effects. However, we have to rely on mechanical air-conditioning to meet the thermal environment requirements. Here, we introduce an effort to increase heat source efficiency by using a new material.

Figure 15 shows the system concept.

The heat load can be separated into Latent Heat (LH) and Sensible Heat (SH). SH is treated by the medium-to-low temperature heat sources. It is possible to enhance the heat source efficiency, since the temperature of cold water can be increased. It is also possible to use nighttime power or natural energy and to equalize the load by storing heat in PCM for a medium-to-low temperature zone.

On the other hand, desiccant air-conditioning using water vapor adsorbent is available for LH. Heat utilization system can be designed rationally by using waste heat from heat pump for reuse of the desiccant.

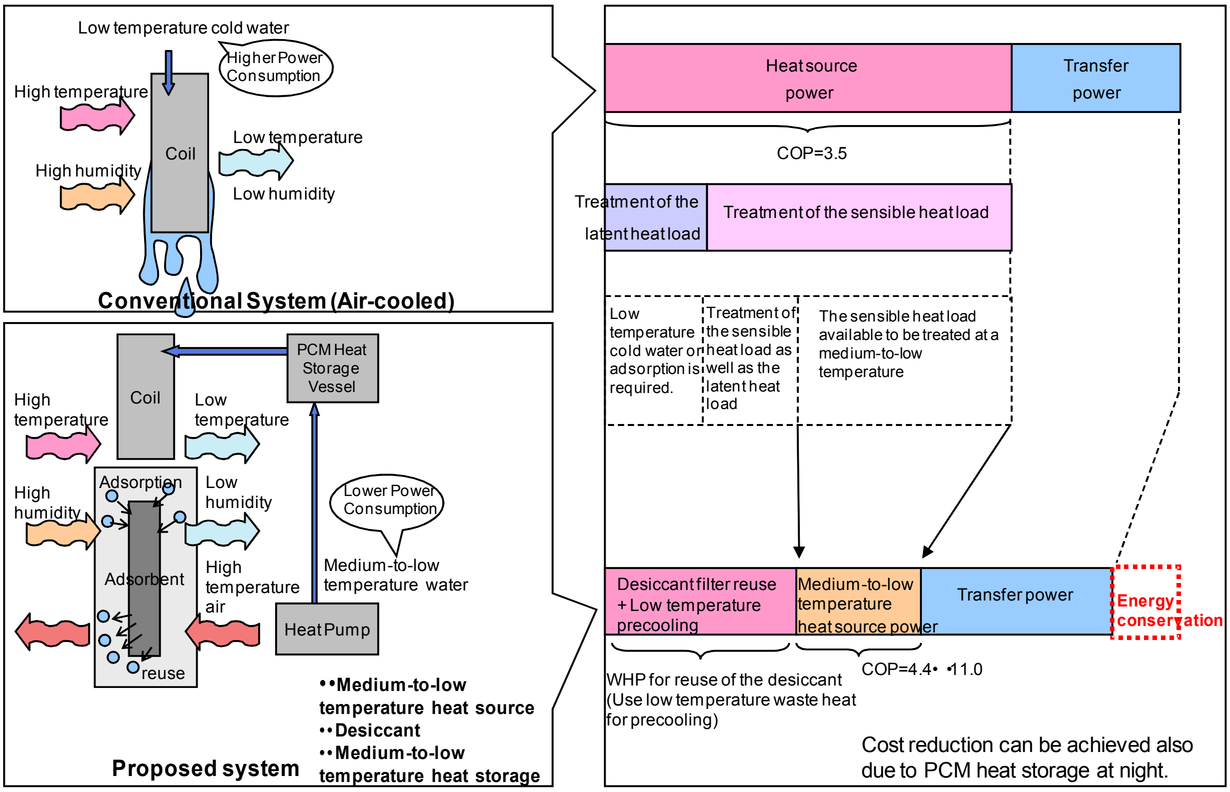

Figure 15 Concept of Medium-to-low temperature heat source system

2.3.2 Simulation

Simulations were performed for three different types of heat source systems (Figure 16).

Case 1: Ice Thermal Storage Unit
Case 2: Air-cooled Heat Pump
Case 3: Medium-to-Low Temperature Heat Source System

The subject building is a 10,000m2 office building (Table 1), and the calculation is performed under common ambient conditions based on the standard meteorological data for Tokyo. In the Medium-to-Low Temperature Heat Source System, the heat storage unit is checked and verified in advance by simulation and experiment. The desiccant dehumidification performance is checked by experiment and simulation, according to temperature and humidity conditions.

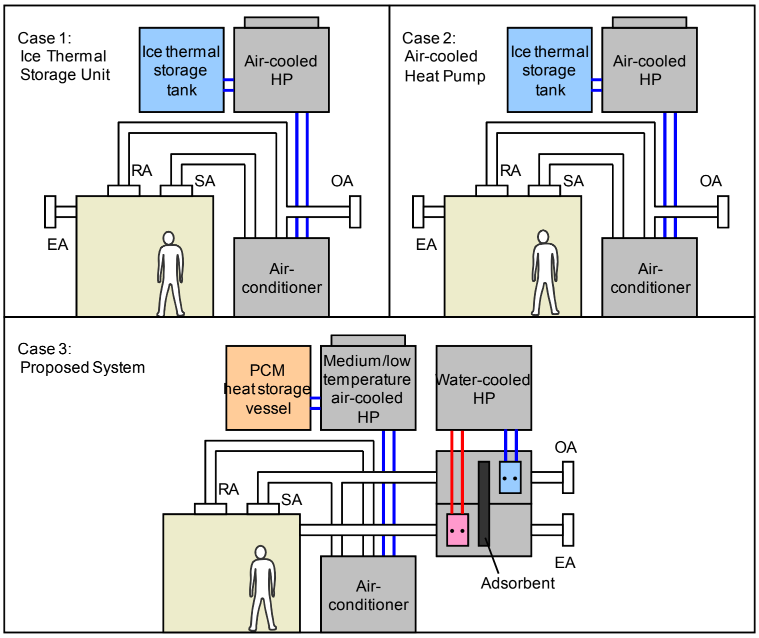

Figure 16 Three types of systems simulated

Table 1 subject building conditions

Building use			Office
Total floor area [m2]			10000
Air-conditioning area [m2]			7500
Building population density [persons/m2]			0.2
Required amount of fresh air [m3/h/person]			20
Maximum heat load	Cooling Load [W/m2]		140
	Heating load [W/m2]		80
Air-conditioning operating conditions	Operating days [days/year]		230
	Operating hours [hours/day]		10
	Set temperature [°C]	In summer	26
		Inter-seasons	24
		In winter	22
	Set humidity [%RH]		50

Figure 17 shows the calculated results of the daily variations in power consumption in July. For Case 3, it is confirmed that the load can be transferred to nighttime by heat storage and the demand is reduced compared to Case 2. The same considerations apply to Case 1. With respect to power consumption in the night heat storage time zone, the heat source COP is significantly improved compared to the Ice Thermal Storage Unit, accounting for about one third of Case 1.

Figure 18 compares annual primary energy consumption. In Case 3, although the amount of primary energy consumption is reduced due to the improved efficiency of the heat source, the power consumption of the transfer system increases as a result of pressure loss due to desiccant material and the fan power increases due to the increased number of coil rows. Consequently, the annual consumption is 3% higher than that of the Air-cooled Heat Pump. On the other hand, the power demand is 10% less than that of Air-cooled Heat Pump and approximately the same as that of the Ice Thermal Storage Unit, so the peak power cut is fully implemented.

In terms of energy conservation, further study will be conducted with the aim of reducing energy consumption more than that of the Air-cooled Heat Pump, for the purpose of increasing the efficiency of medium-to-low temperature heat source equipment and decreasing pressure loss due to desiccant material.

Keywords: commissioning, management, leased building, retrofit, Japan

Summary

This paper introduces project management strategies for continuous commissioning process to realize sustainable building. The key points are: 1) Extracting owners and occupants' latent needs, 2) Establishing mutual understanding among stakeholders including owners, occupants, facility managers, architects/engineers, and suppliers, 3) Enhancing communication among the stakeholders, 4) Visualizing process and effect, and 5) Developing continuable activities. The active commissioning approach is necessary for sustainable building, since the sustainable building needs are usually invisible and often less prioritized. The enhanced communication helps realize sustainable building goal while maintaining customer satisfaction.

Lessons learned from two case studies are described. The first case study site is a 193,000 square-meter multi-use leased office building where over 100 tenant companies reside. The challenge was to develop a communication scheme to establish mutual understanding among numerous stakeholders. Another case study site, a 37,000 square-meter research laboratory, achieved distinguished energy reduction only by operational improvement including occupants' spontaneous action. These actions were accomplished due to enhancement of understanding and motivation. Both case studies are examined with energy consumption trends, and occupant surveys as a factor of customer satisfaction.

1. Introduction

In Japan, due to its early experience with the oil shock in 70s, the first energy conservation law was established in 1979. Since this period, the government and industries have been taking a lead of energy efficiency. While the primary focus of energy efficiency was on industrial sectors and energy suppliers, large and mid-sized non-industrial buildings also became regulated since 2003. Under the regulation, the subjected buildings are required to submit periodical energy reports and energy saving targets. Leased buildings and research laboratories started to pay close attention to energy efficiency. Now, the primary driving factor for energy efficiency investment is the responsibility for the achievement of Kyoto Protocol target, and the sense of crisis.

Based on the above background, sustainable building design has become emphasized recently in Japan. Sustainable buildings should be designed to be sustainable by owners and architects. It is also equally important for occupants to understand the design intent and practically use the sustainable features.

Building commissioning, mainly discussed in this paper, is a procedure to achieve sustainable building's goals covering various issues from occupant comfort to natural environment, as well as energy conservation. It is a universal process to guide owners' investment decision making based on their building functionalities.

It has been only few years since the importance of commissioning started to be emphasized in common buildings in Japan. The market is yet premature at the moment. Currently, Japan is leaning from the experience in U.S. and Europe. In order to disseminate commissioning in Japan, the management process has to be well considered. Expensive, excess measurements and professionals' explanation with technical jargons are not practical to achieve owners' satisfaction.

In this paper, five key points to achieve successful commissioning management are introduced based on the authors' experience with two case studies.

2. Lifecycle Commissioning

2.1 Commissioning Management throughout Building Lifecycle

In Japan, most building owners have merely referred to concrete criteria of energy efficiency and indoor environmental quality during building operation. The efficiency of business activities (including office works, merchandise, and researches) has been most prioritized in building operation. On the other hand, various stakeholders are involved in building lifecycle, including planning; design; construction; turnover and operation. The stakeholders may not often communicate each other, or even within same roles over time. After all, no one understands the holistic performance throughout the building lifecycle. Under the situation, with the increasing awareness of global climate crisis, the importance of commissioning has become obvious. The activities to be done as the lifecycle building commissioning at each building phase are,

- Planning Phase: Define the building functionalities and materialize owners' needs.
- Design Phase: Quantify the owners' needs and develop specification. Define methodologies to verify the specification with articulate criteria.
- Construction Phase: Construct the building exactly as the design. Verify the building meets the predefined specification.
- Turnover Phase: Architects/engineers and constructors report the results of the verification to the owners. Provide an operational guidance.
- Operation Phase: With understanding the design intent, improve and retrofit the building to suite the current building use and the time.

One of the most important factors in commissioning management is to define and verify the owners' requirements at any building phase, and provide both the appropriate use and the best satisfaction. To achieve this goal, every stakeholder including owners must fully understand and be satisfied.

Building commissioning generally requires measurement and verification of the building functionalities, and documentation of the results. Although this is essential to fulfill the requirements in the contract, the documentations are often too complicated and barely understandable for some stakeholders who don't have technical knowledge. To achieve the aforementioned goal of everyone's satisfaction, it is important to have every stakeholder to fully understand the building systems and functionalities. This is in deed achievable with commissioning managers' skills, even without expensive measurements and analysis software tools, or expert labor costs.

2.2 Five Key Points for Effective Commissioning Management

1) Extracting owners and occupants' latent needs: In general, owners can neither express their needs as clearly defined specification, nor gather occupants' opinions. Architects/engineers materialize owners' needs. However, the communication only between owners and architects/engineers is often insufficient to cover all the aspects. In the process of commissioning, it is recommended to gather insights from various professionals.

To extract the latent needs, it is important to find out the adequate level of quality which owners desire. Comparisons and choices should be easy to understand for owners. Secondly, terms used to express the needs and the judgment criteria should be clearly documented. Architect/engineers should avoid explaining their thoughts to owners with figurative phrases and only documenting what is decided. This process affects the relationship among owners, architect/engineers, and constructors.

2) Establishing mutual understanding among stakeholders including owners, occupants, facility managers, architects/engineers, and suppliers: Owners make investment decisions by gathering insights from various stakeholders. It is important to accommodate a place where all the stakeholders can join the decision making process. This will make the process clear and fair. By keeping the place over the building phases, one can take over and understand the sequence of the process regardless of change of participating members. This place should be maintained over transition of time and needs through the building lifecycle.

3) Enhancing communication among the stakeholders: It is difficult to thoroughly understand each other only at series of meetings. Continuous effort to develop good relationship among stakeholders leads to positive outcomes in various situations. It is important to carefully extract underlying demands from abstract expression, and considerately arrange the opportunity for every stakeholder to freely express one's opinion.

4) Visualizing process and effect: Through the decision making process, it is often difficult to present how the decisions were made for each activity in an understandable manner. In order to clearly visualize the process and effect of an activity, it is important to extract key facts from series of the data and documentations. The decision-making criteria have to be well described. In fact, requirements for building functionality are often ambiguous, except when they are regulated by laws. Clear judgment criteria based on understandable data are important in this process (for instance, simple apple-to-apple comparison, majority votes are easy to understand). It contributes to the decision makers to smoothly explain about their decisions to stakeholders including occupants and minimize complaints.

5) Developing continuable activities: It is difficult to continue the meaningful activity even with the decision-making criteria and the periodical meetings. If each of the stakeholders only cares one's own situation, they don't have to formulate their opinions into one conclusion. Therefore, commissioning managers needs to create a mutually shared objective among the stakeholders.

3. Case Study I: Large-scale Leased Commercial Building

3.1 Building Profile and Targeted Commissioning Phase

The authors conducted commissioning process at a large-scale leased commercial building during the operation phase. The building has 193,000 square-meter of floor space, consisting of high-rise office complex (110,000 square-meter) and low-rise commercial complex including movie theaters. At this building, due to the highly conscious owners, substantial time and cost were spent for commissioning from the construction phase. After the completion in Fall 2006, the commissioning team established by the owners, the architects/engineers, the constructors, the facility managers, and the commissioning managers continues the proactive efforts for sustainable energy management.

3.2 Commissioning Management on Developing Facility Management Standards

The first action taken after the completion was to develop a facility management standard. At this building, the commissioning manager led the commissioning team to develop a highly satisfying management standard by focusing on the following aspects.

1) Promote occupants' understanding of building design intent: For instance, energy efficient designs such as automated blind control or daylighting control system don't work without occupants' understanding. The commissioning team made a thorough explanation of functions and effects, by arranging sessions for key personnel of tenants and delivering information though intranet.

2) Develop standards conscious of energy conservation: Illuminance and temperature setpoint are commonly leaved for tenants' decision. At this building, the owner was proactively involved in the standard development process with assistance of the commissioning team. The team performed space environment measurement, and defined the setpoint allowance range. The team promoted cooperation of the tenants.

3) Collaborative deployment with tenants: Along with asking cooperation from the owner, the commissioning team promotes proactive actions led by tenants to be spread to others.

Through the above activities, the commissioning manager converts the owners' needs into the action plan by summarizing the key points with understandable language and multidirectional information. Series of the activities supports the holistic decision making process.

3.3 Frameworking Retrofit Plan

In conventional practice, energy efficiency improvement and retrofit planning are initially started at the timing of periodical retrofit or when deterioration of equipment or system trouble occurs. At this building, even soon after the first year of the completion, budget for a retrofit project was reserved due to the proactive attitude toward improvement. The retrofit project consists of the following categories: 1) more detailed energy measurements, 2) more detailed system controls, and 3) more energy retrieval.

Table 1 shows the expected energy saving results achieved by the operational improvement and the retrofit project planned. To frame the plan for each item, the commissioning manager analyzed and visualized the existing circumstance, and provided multidirectional insights to lead conclusions. In this project, the commissioning manager acted an important role to guide clear decisions.

Table 1 Estimated Energy Saving of the Retrofit Project at the Large-scale Leased Building

	Category	Subject	Estimated Savings*
1	Energy Measurements	Power meter installation at each tenant	Unknown
2	System Controls	Programmable operation of exhaust fans	0.17%
		Automated valve installation at tenant chilled water supply	0.66%
		Economizer optimization at office and movie theater	0.48%
		Automation of hot/chilled water control	0.59%
		VAV control optimization	0.03%
		Schedulable switch installation at elevator air conditioning	0.01%
		Optimizing Partial load operation of Hot/chilled water pumps	0.24%
3	Outside Air Utilization	Increased use of ventilation cooling	0.12%
		Natural ventilation at atrium space and electrical room	0.43%
		Total	2.73%

* Percent of total annual energy consumption of the building

4. Case Study II: Research Laboratory

4.1 Building Profile and Targeted Commissioning Phase

The second case study is a 37,000 square-meter research facility, consisting of office space and laboratory space (approx. 17,500 square-meter each). The commissioning manager was involved in the 12th year of operation to conduct commissioning process mainly at the office space. Until then, the facility management has prioritized security, occupant satisfaction, and cost. Efficiency of the system was mostly ignored. The dramatic change of the facility managers' mind was led by the new mandatory regulation to submit the energy performance and management standards.

4.2 Formulating Requirement Items for Energy Conservation Activities

At first, the commissioning manager arranged a workshop gathering the owners, occupants, architects/engineers, and facility managers. In the workshop, the requirement items for operational improvements were formulated. The workshop was carefully organized so that every stakeholder can freely express one's opinion. The opinions were summarized into 10 project requirements through fair votes (Table 2). The more than a dozen of occupants participated in the workshop were selected as leaders of the whole occupants. They were requested to place a temperature and humidity sensor at each of their desks, and gather opinions from other occupants. In common practice, retrofit plans are usually developed only by engineers and owners. It is unique to involve every stakeholder including occupants and formulate project requirements prior to the engineers' retrofit plan.

Table 2 10 Project Requirements at the Research Laboratory

No.	Location	Requirement Items
1	1st floor atrium	Improve indoor thermal environment in heating seasons.
2	Rooms/spaces without constant occupants	Improve operational rules of air conditioning and lighting.
3	Meeting room 5	Retrofit HVAC system.
4	Meeting rooms	Optimize pre-cooling/heating operation.
5	Office	Improve office zoning of air conditioning and lighting.
6	Office, meeting rooms	Instruct facility manager on energy saving HVAC operation.
7	Common to all	Optimize operation and maintenance cost of HVAC system.
8		Improve operation and maintenance of lighting fixtures.
9		Utilize ventilation cooling in nighttime and intermediate seasons.
10		Report decision-making process to occupants.

The operational improvement activity was conducted to fulfill the 10 project requirements one by one. As the result, 18% of power saving and 40% of heating/cooling energy saving could be achieved at office areas over 5 years only by the operational changes. During this process, complaints were raised regarding thermal environment and change of user rules. However, the complaints were considerately solved through mutual understanding with the occupants. This accomplishment was significantly contributed by the owners, the facility managers, and the leaders of the occupants, who mutually understood the objectives.

4.3 Contribution of Commissioning Management in Retrofit Project

While the operational improvement came to stay, retrofit of the HVAC system was planned before the 15th year of operation. The workshop with all stakeholders was arranged again, and the project requirements for the retrofit project were itemized. The commissioning manager delivered the owners' needs which represent the project requirements to the architects/engineers. The architects/engineers could minimize the design options, and the owners could smoothly turn over the project to the architects/engineers without concerns.

5. Conclusion

The most important element of commissioning management is not delivery of documents and evaluation by experts. It is the process that all the stakeholders represented by owners formulate mutual understandings toward shared, clear objectives. The process is to think, construct, and activate buildings together. The benefit brought by commissioning is to amplify the satisfaction among people.

Towards the forthcoming low-carbon society, the role of commissioning activity should be expanded from the optimization within the existing functional requirements, to optimizing the use of buildings and even optimizing lifestyle. To accomplish this goal, it is essential that all stakeholders including owners and occupants undertake the activities with thorough understandings, throughout the building lifecycle. The commissioning procedures introduced in this paper will greatly contribute to the activities.

In Japan, the benefit of commissioning will be understood through the number of examples. The authors strongly feel that the commissioning will become a new role to guide the sustainable building lifecycle in future.
