Place attachments develop slowly but can be disrupted quickly and can create the need for a long-term phase of dealing with the loss and repairing or re-creating attachments to people and places. These three phases are interdependent, as qualities of the initial attachment or disruption can ease or exacerbate the stress of loss and difficulty of re-creating attachments. Much of the challenge facing those with disruptions of place attachment is to negotiate reconciliation between the past (what has been lost) and the future. Certain aspects of pre-disruption attachment may forecast the extent and severity of the disruption and the availability and effectiveness of coping mechanisms [18]. Therefore attachments are important for their long-term consequences. Place attachments are continuous and form a dynamic model of people-place bonds [16]. The most stabilised conditions contain the possibility of future change, and therefore embody varying states of readiness for the onset of a new transition cycle [32]..

There are two important studies that specifically address the process by which place attachment is formed. Fuhrer and Kaiser’s (1992) work entitled “Attachment to the home place: the emotional bases" is important as it explores the aspects necessary for the formation and maintenance of place attachment [19].

Fuhrer and Kaiser (1992) advanced the field of people–place relationships by thinking of place as a facilitator of emotional needs. They adapted Bischof's model of social motivation which suggests that "four emotions represent the core of social regulations: security, arousal, autonomy and libido. Thus, "places are experienced in terms of these emotions and represent the basis for regulating both identity and social interaction" [19]. They developed and tested a model involving three processes of place attachment. Place was described as a facilitator of emotional needs, based on the emotions of (1) security, (2) autonomy and (3) arousal. Significant relationships between social and physical qualities of the home place and of the emotional dimensions were found. The results revealed that these emotional meanings represent the bases of attachment to the home place.

Gerda Spellers' (1996) work has expanded Fuhrer and Kaiser's concepts on the aspects of place attachment, including external stimulation, emphasizing the importance of appropriation and place congruence [20]. These aspects not only seemed to lead place attachment but also play an important role in order to maintain it. However, she also argues that further research is needed to establish whether these five aspects of place attachment are apparent in other research contexts, such as work environments.

2.3 The Models of Place Attachment

Several models of people-place relationships have been put forth in an effort to provide framework for how people develop ties to places and some has received limited empirical tests.

Gerson et al. (1977) in his structural alternative model focused on attachment at the individual level [21]. They define attachment as "an individual's commitment to the neighbourhood and neighbours". This commitment takes the form of both social involvement and subjective feelings. According to this model, attachment develops as a result of an explicit cost/benefit analysis. The individual is believed to evaluate the neighbourhood based on what he or she is giving up or gaining by living there. As long as the benefits outweigh the costs, an individual feels some attachment to the area. Both people and place characteristics are considered within this comparison and contribute to attachment [22].

Stokols and Shumaker's (1981) in their model of place dependence relied heavily on Gerson et al.'s (1977) model of place attachment and extrapolating directly from Thibaut and Kelley's(1959) model of comparison level and comparison level for alternatives [23]. They hypothesized that persons may become dependent upon their current dwelling and neighbourhood through comparison process. The individual considers the number, range, and salience of needs being met by the current home, including the quality of resources available in the area, and this analysis yields a “comparison level”. The individual goes through a similar process in considering alternative places. If the current locale compared unfavourably with potential alternatives, the person was not considered to be dependent upon the current place, and was in fact more likely to move.

Stokols and Shumaker (1981) develop the concept of place dependence or an “occupant’s perceived strength of association between him or herself and specific places”. They proposed that the assessment of “strength of association” involves a two-component process, including an individual’s judgement of: the quality of current place; and the relative quality of comparable alternative places.

Stokols and Shumaker expanded their model of place dependence to include integration of satisfaction. Attachment derives from a positive evaluation of the quality of the place vis-à-vis one’s needs to what extent the environment allows certain functions to be carried out. Attachment will be all the stronger the greater the number and the more important the needs satisfied. But the basis of the model remained more cognitive than affective [24].

Stokols at al. (1983) reported empirical support for the place dependence model of person-place transactions. However dependence as described by Stokols and Shumaker (1981), can be affectively different from attachment Stokols et al. (1983), these researchers did not maintain this distinction in their empirical research. Instead they used a direct measure of attachment, as well as their measures of place dependence, to examine the effect of person-place bonds on outcomes of interest.

Prohansky (1978) took a totally different approach in his discussion of the relationship between people and places [25]. Whereas the other two models operate attachment in a functional sense with reference to places, symbolic attachment can also be found for places that have only symbolic value, which embody group identity, etc [17]. Prohansky defined place-identity as an individual’s awareness and perception of the world as represented by a collection of “memories, conceptions, interpretations, ideas, and related feelings about specific physical settings as well as types of settings”. And attachment derives from the meaning the place has for person’s identity [26]

The model does provide a useful theoretical explanation of why people may need to develop attachments or bonds to their socio-physical environments. There are problems however, with the breadth of the theory as there are very limited empirical studies to test the relationship of place to the development of self identity. In addition, Prohansky argues that place identity is both cognitive and affective; yet it is unclear how these separate systems operate in defining place identity.

The purpose of this review is to obtain an understanding of the vast volume of theoretical and empirical work on place attachment in order to clarify the relationship between and person and place and provide the background for the research design.

3. Research Design

Change is an experience which can be threatening in advance however very little is known about why change should be threatening. Personal meanings are important determinants of the impact of change [10]. A key to the meaning of place lies in the expressions that people use when they want to give it a sense carrying greater emotional charge than location or functional node.

The question which must always be raised is whether the new environment produces demands and situations which are different from the individual expects. What practices should organisations undertake to maximize the benefits and minimise the costs of the rising tide of transitions? The conceptual framework of the study aims to answer such questions.

The relocation projects provide the opportunity for a field experiment in which facilitators and inhibitors to the formation of place attachment can be identified during the whole process. As part of the British Facilities Management, Thames Valley Network, given the opportunity to study several work groups that will experience office renovation within the same facility in Nationwide Headquarter, Swindon.

The study involved a three phase-longitudinal approach conducted over an eighteen month period to monitor the process of place attachment (and detachment) starting two months before the relocation and ending sixteen months post relocation. Data was gathered primarily from in-depth interviews. However a survey instrument was also used to measure attitudes.

The case study relocation scheme was announced and accepted in July 2003 and the first interviews in phase 1 of the study, took place in March 2004, one month before relocation. The relocation followed in April 2004. The second set of interviews, I2 were undertaken in June 2004 as well as questionnaires.The timing for data collecting phases (periods) were determined by theoretical and practical considerations. After the move, the two month period was considered to be long enough for people to gain a sense of permanence and not be caught up in the frustration of practical tasks regarding the move. Seven month post-relocation was thought to allow enough time for people to evaluate the new situation about their attachments in the final phase of data collection.

A longitudinal approach was important to understand the dynamics of place attachment. It was intended to show the nature of the growth and trace patterns of change in an individual [27]. The rich data provided by repeated in-depth interviews with employees over a one year period provided an essential resource for exploring the process of change.

Several problem points can be derived from analytical approaches in previous place attachment studies:

- In place attachment studies a variety of approaches exist (either theory building or theory testing) which lack coherence
- Place attachment can be thought of as both a product and outcome (i.e. feeling attached) and a process (i.e. reasons for attachment) [24] [28]
- The existing theory on "place attachment" is incomplete and may not be applicable in all types of work environment.

The proposed model is adopted from Passini's (1992) model of cognitive mapping. Passini suggested that people cycle through a set of decisions using a process of 'matchmaking' to evaluate a decision and determine behaviour [29] [30]. As place attachment is a cognitive process, matched feedback process well explains how this mechanism works in a changing environment; people cycle through within move (before move, on the move and after move). Our expectation of a future setting is the product of our past experiences. In a familiar environment, a person recalls what should be sensed at a location and this is checked against what is actually sensed. If there is a match, then a planned behaviour is executed, as establishing new attachments. If the two do not match, it is problematic; he shows resistance to change. New approaches are needed to manage the expectations and attitudes. It is suggested that once precursors of his previous attachment are identified, they can be used as a mechanism to adapt to new situations and find the match to continue the process (Figure 3).

While defining the attachment, one should consider not only cognitive bonds which explain the operational aspect, but also the emotional and symbolic content of the bond which covers the precursor of attachments; individual characteristics influencing attachments; and characteristics of places which influence whether people attach to them. Place attachment is the pattern of reactions that a setting stimulates for a person. These reactions are a product of both cognitive and emotional/symbolic aspects of the bond (Figure 1).

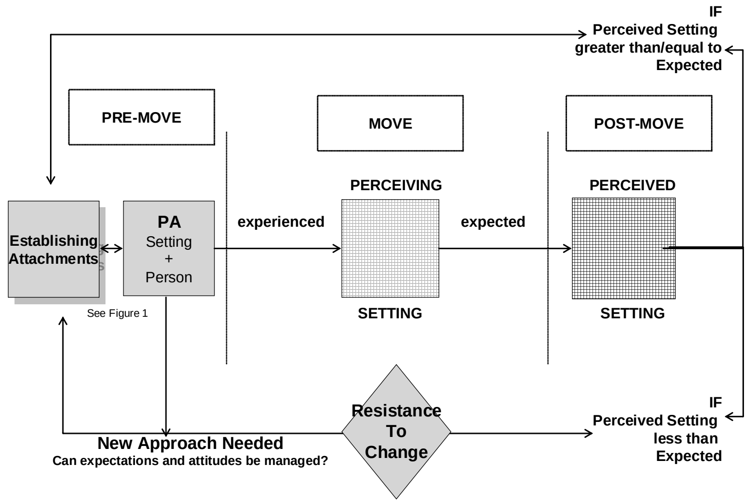

Figure 3: The proposed model-matchmaking process (adapted from Passini's (1992) model of cognitive mapping)

There have been many attempts to conceptualise the process of interacting with an environment and the role of place attachment in determining spatial behaviours. While the previous models reflect on the complexity of place attachment, they go no further in providing testable hypotheses that would stimulate research. The proposed model in this study, offers some integration of the processes, concepts, and relationships involved.

It would be wrong to suggest that previous models explaining place attachment are mutually exclusive. They place different emphasis on the importance of stability and, therefore, on the consequences of leaving a place. The proposed model takes account of this issue. While the emphasis of the research is on the emotional and symbolic bonds, a quantitative survey explaining the cognitive process of attachment would provide numerical support for the links.

4. Conclusions

The analysis confirms the presence of "place attachment" issues in the cases studied. Employees and themanagement of the department expressed concerns about this. The question raised is 'what conflicts arise between user expectations and the eventual characteristics of the new work environment?' Moreover, 'what practices should organisations undertake to minimise change resistance and to maximise the benefits of organisations connecting people through their beliefs and feelings?' The conceptual framework of the study aims to answer such questions.

It has been shown that place disruptions (move experiences) interrupt the processes that bind people to their socio-environments. In order to understand the impact of this disruption, one must examine: (1) pre-existing conditions that influence the experience of attachments, as well as (2) post disruption conditions that influence how individuals can cope with their losses and begin rebuilding ties to places and people [18]. The difficulty of coping with loss and re-constructing place attachment is that organisations rarely appreciate the depth and extent of these attachments and yet these emotional connections remain unmanaged.

Change is necessary. Without it, organisations and individuals become complacent and stale. However in managing change, the critical task is to understand how changing one element changes the rest; how sequencing and pace affect the whole structure. Achieving this critical balance means balancing new strategies whilst preserving the sense of continuity. This is achieved by managing the organisational context in which change occur and creating connections with employees. The question of place attachment has a role to play in managing the emotional connections with new workplaces. Facilities managers, designers and planners need to be aware that people become attached to place and that they are likely to encounter resistance from them. In the knowledge that place attachment is a significant part of human well-being and psycho-cultural adaptation to an environment, designers may be able to solve problems of work space design. Design elements can be introduced that nurture a sense of belonging in an organisation.

Living environment – relation between sociopsychological and real estate aspects

University of Ljubljana, Slovenia

Abstract

Real estate is one of the most important elements of the infrastructure, connected with place of living and its environment. Very important parts of the living environment are the public buildings and other infrastructure, above all traffic. There are different interrelated aspects, from which real estate could be elaborated: technical, functional - physical, economic, marketing, urban, normative (ownership), ecological–ergonomic.

The main problem generally refers to the relationship between sociopsychological and real estate aspects. We were interested in: the structure of perceptions connected with different aspects of real estate in the living place and in its environment, types of public buildings and sectors of traffic infrastructure which are perceived as most worthy of financial investments; and the difference between the groups of participants regarding perception of environment and real estate aspects and regarding the perceived needs of investments into different infrastructure areas. We verified hypotheses, that perceived needs for investment differ regarding area of investment and regarding group of respondents. We expected, that evaluations of proper living environment discriminate between different evaluation of its offer.

Four groups of participants were embraced in the research: students of psychology, employees or owners of real estate agencies, people, employed in important public institutions and people with academic education from the field of building construction.

The following variables were identified in the framework of the actual research: demographic characteristics; objective characteristics of living place and its environment, connected with real estate; subjective variables, connected with living place and its environment, like evaluation of living place, its environment, the people living in the environment, the different offers located in the environment, but also the evaluation of proper working place; perceived need for the financial investments into different areas of infrastructure.

Factor analysis reduced evaluative variables, measuring perceptions connected with living place and environment. Treating the evaluations as predictors we discovered significant discrimination between two groups of respondents who evaluated the offer in their living environment: evaluation of the people, together with some evaluations of environment have the highest correlation. Friedman's nonparametric test for the repeated measures revealed the perception of investment priority, connected with traffic infrastructure, into new apartments, geriatric buildings, hospitals and youth clubs. We discovered with the Kruskal – Wallis test that public groups more than others prefer investments in apartments and engineers more than others prefer investments in swimming pools.

Keywords: environment, infrastructure, perceptions of real estates, public buildings, investments

1. Sociopsychological aspects of real estate

Different responses on environment depending on climate, self-evaluation, values, lifestyle, culture, identity and efficiency of individual could be expected by particular target samples. That can be reflected in the relation toward real estate status of the family, living place, organisation, evaluation of inheritance and nation. The life cycle of real estate has not only the nature of technical, technological and economic aspects but also is the result of different perceptions of individuals between the real estate processing. The relation is detached through the functional, living, ecological and other qualities.

The real estate market is a process of social interaction and communication which is indicated in the process of offer and demand. Real estate market research is dealing with urban experts, investors, financial experts, agents, marketing researchers, sociologists, psychologists. It contains few phases: defining market sphere, analysing economic base (sources, employment, income, population, economic trends), analysing market condition (offer and demand), projections and conclusions (intensity of demands, sort, price, market share) and analysing potential profit (regarding legally, location, physical, market, social, psychosocial, financial facts). The multidiscipline is important for people concerned with real estate, in the sense of versatility, following the legal, economic, social, cultural, architectural trends and rules. Experts should be educated at the schools (Thompson, 2002) equally on the cultural and technical level because the importance of natural and humanistic sciences is on the same level for the integral personal growth.

The main questions in environmental research are connected with interaction between environment and social behaviour, and their assimilation to changes which are caused. The interaction models between individual and environment are gathering on analyses of social variables (individual and group, personality, culture, part, organisation, social-economic characteristics) considering the influence of physical facts and variable's analyses of nature and shaped environment (characteristics of architecture and landscape, characteristics of environmental processing, sphere and frequencies of the processes). From the marketing point of view real estate could be interesting on every level of the market network, and it can have ergonomic and its ecological part (Stockols&Altman, 1991).

Macro-environment is decided with two elements of space's comprehension (Kovič, 1992): A) Space is measured in four dimensions (co-ordinates of space and time), is objective real and present. It is conditioned by the combination of elementary climate and geo-morphological components of nature and built environment. B) Space is represented in un-measurable dimensions, is subjective real. It is conditioned by the perception and spiritual field of global space with interactive influence. The built environment is exactly defined and suited for the given or perceived circumstances at a particular moment. Components of global space, which define the quality of un-measurable space, are always changing and influencing the human perception of living environment.

The town is a place in which three basic components of spatial ingredients are connected: nature space – it gives the basic shape of land, it's structure and characteristics, with water, vegetation, fawn and clime; social setting – it includes individual and community, activities, institutions, culture with customs and manners; and material products – which form the culture of the society with buildings, installations and recourses. All together are expressing the entireness of occurring and collaborating nature, beings and things in dynamic process of changing and revitalising, from which neither past, nor in development focused future is not excluded.

One of the important questions of psychological research of the environment is the interaction between the individual and environment. This concept has significance in the sense of interaction of the individual with his immediate physical environment. The word interaction means reciprocal activity or influence: environment on individual and individual on environment. An individuals influence is possible on its immediate environment, especially if we talk about two-way influence. This interactive relation was shown by Piaget (1971) with processes of assimilation (adaptation of something to oneself) and accommodation (adaptation of somebody to environment). Assimilation and accommodation are basic processes of interaction with environment. Biological views of the mentioned processes, Piaget "transferred" on the level of psychological functioning. Assimilation and accommodation have become basic processes of interaction with physical and social environment. From the view of individual psychological processes are the base for the analysis of cognitive development of individual.

Cognitive models of interaction between human and environment are dealing with questions: about the relation between characteristics of the environment and individual characteristics; about the differences in cognitive perceptions and categorisations of the physical environment, from the point of view of various social and cultural groups and their social and spatial behaviour, standpoints and stereotypes toward physical environment; and about social representations of different macro-objects and macro-events (Rus, 1997).

The integration of global and local views is significant for urban analyses nowadays. The new urban concepts are related with social changes in line of globalisation, development of informative and communicative technology, democratisation of society, ecological consciousness, energy economising and changes of life style and patterns. Slovenian towns, where the consciousness about preserving the culture in the meaning of architectural heritage exists, are uniformed under the influence of investment capital and modern designing access. Some of the objects or complexes escape from the uniformity by changing the content, the open spaces are becoming scenes for social interactions and collective identity (Dimitrovska, 2001). Rem Koolhaas (1995) has the theses of fluid and an-rational space, in which particular objects are only artefacts or substrates of urban ingredients. The final result could be only autistic in dis-functionally space. Open interactive spaces are removed from the uncommunicative and aggressive environment of streets, squares and parks to the supervised world of internet, as well as the enclosed and safe space of market centres and terminals.

2. Research problem

The problem generally refers to the relation between sociopsychological and real estate aspects. More concretely, it could be explained as the following questions: Which is the structure of perceptions connected with different aspects of real estate in the living place and in its environment? How do these perceptions discriminate between two groups of respondents, who 1/ more positive or 2/ less positive evaluate different offers, connected with the quality of life of their living environment? Which types of public buildings and sectors of traffic infrastructure are perceived as most worthy of financial investments? Do the target groups of respondents differ regarding the perceived needs of investments into different infrastructure areas?

The following hypotheses are formulated:

- There are significant differences unperceived need for investment into different areas of real estate (for example: schools, hospitals, sport halls, etc.).
- There are significant differences between four groups of respondents in perceived need for investment into particular category of real estates (for example: schools, hospitals, sport halls, etc.).

- Evaluation of the living place, its environment and of people living there (as set of predictors) significantly discriminate between two levels of criteria (perceived offer in the place of living: above and under median level).
- Perceived investments into different areas are mutually dependent, forming also independent groups (criteria of perceptions).

The research comprised four groups of participants:

- students of psychology from the Ljubljana University, Slovenia (n=25, mean age=25.80, SD=5.8, 0,9 women, 0,10 men);
- owners or employees of real estate agencies in Slovenia (n=31, mean age=43.55, SD=12.66, 0,4 women, 0,6 men);
- employees in the public sector and state institutions from Slovenia (n=24, mean age=39.20, SD=14.00, 0,6 women, 0,4 men);
- employees in the field of construction business in Maribor, Slovenia (n=28, mean age=37.36, SD=10.82, 0,6 women, 0,4 men).

Applied instruments are only a part of a comprehensive questionnaire, connecting questions about objective characteristics of real estate and correspondent perceptions (evaluations). The following variables were identified in the framework of the actual research:

a/ particular demographic characteristics;

b/ particular objective characteristics of living place and its environment, connected with real estate;

c/ subjective variables, connected with living place and its environment. All evaluations were obtained as summative scores, using the semantic differential with seven point bipolar continuums (example of one bipolar continuum: warm 1 2 3 4 5 6 7 cold).

The following bipolar attributes for evaluation of the living place, place for leisure time and work place were embraced in differential: space enough/ not space enough, dark/ shine, satisfying/ not satisfying, dirty/ clean, settled/ not settled, poor/ rich, pleasant/ unpleasant, full/ empty, equipped/ not equipped, cold/ warm, dry/ wet.

The following bipolar attributes for evaluation of the environment 1 were embraced in differential: clean/ dirty, supplied/ not supplied, cultural interesting/ not interesting, quiet/ noisy, entertaining/ boring, peaceful/ violent, friendly/ hostile, pleasant/ unpleasant, social/ not social, open/ closed, lives with tourism/ doesn't live with tourism, expanding/ collapsing, with good management/ with bad management, with good offer/ with bad offer, dynamic/ rigid, cooperates with people/ doesn't cooperate with people.

The following bipolar attributes for evaluation of the environment 2 were embraced in differential: adapted to the people with different needs/ not adapted, with enough space for everyday living/ not enough space, with efficient traffic infrastructure/ not efficient, without traffic locks/ with traffic locks, with secure traffic/ without secure traffic, with regulated parking places/ without regulated parking places.

The following bipolar attributes for evaluation of the offer in the place of living were embraced in differential: enough kindergartens/ not enough, enough shops/ not enough, sports buildings/ not enough, enough health centres/ not enough, enough cultural institutes/ not enough, enough green parks/ not enough, enough open spaces/ not enough, enough children's playgrounds/ not enough, enough leisure activities/ not enough.

The following bipolar attributes for evaluation of the people were embraced in differential: optimistic/ pessimistic, active/ passive, independent of others/ dependent, worth imitating/ not worth, exciting/ not exciting, oriented on future/ oriented on past, interesting/ uniform, not oriented on commonness / oriented on commonness, in harmony with oneself/ not in harmony, successful/ not successful, opened/ reserved, considerate/ not considerate, convinced worth of own aims/ not convinced, oriented inside/ oriented outside.

d/ perceived need for the financial investments into different areas of infrastructure: educational institutes (primary schools, high schools, university buildings), health infrastructure (into health centres, hospitals, other, geriatric centres), sport (swimming pools, skating halls, athletic stadiums), traffic(highways, railways, local roads), apartments (new apartments), culture (opera halls, theatres, museums, youth centres). Perceived need was measured on the 5 point scale (1=not needed, …, 5=needed very much).

Internal consistency for the instrument was identified for each of the four compared groups. Cronbach's alpha for each summative instrument in each group was higher than 0.80.

3. Results and discussion

Table 1: Mean ranks of Friedman's nonparametric repeated measures test: perceived need of investment into particular objects for all subjects together

	Mean Rank		Mean Rank
primary schools	8.04	highways	10.98
high schools	8.85	railways	11.08
university buildings	8.86	local roads	11.13
into health centres	8.82	new apartments	12.08
hospitals	10.46	opera halls	5.95
geriatric centres	10.34	theatres	7.38
swimming pools	8.79	museums	6.86
skating halls	5.51	youth centres	10.49
athletic stadiums	7.38		

Note. N = 89; Chi-square (16) = 275.56, p = .000.

Friedman's nonparametric test for the repeated measures revealed the perception of investment priority. The highest priority is connected with new apartments, traffic infrastructure, youth centers, hospitals and geriatric buildings. The lowest preference was discovered in the case of all infrastructure connected with culture (opera, museums, theaters).

Dwelling problem is one of the most burning problems in our country. Prices for the new apartments are very high (these can be compared with the prices in highly developed countries in Europe), supporting the financial loan system is not attractive enough for young families, on the other hand there is not enough real estate for renting which causes very high rents. So, following analyses of development prospects offered by trends in supra-regional material and immaterial communication, recollection about issues in renewal of the Slovene housing stock is becoming a very dynamic dimension (Zupančič Strojan, 2004). Conscious balancing of extreme trends and respect for multiple, not necessarily economical or natural conservation dimensions of sustainability, but also wider cultural ones in any physical scale, can help in establishing dynamic balance.

It is very interesting that perceived need of investments in new apartments, railways and local roads have the highest values. The main problem in Slovenia is the lack of an efficient public transport system in spite of the fact that new residential building are built on the peripheries of towns. Polycentric strategy of decentralisation activities, besides connecting knowledge and business innovations, includes spatial integration in the mean of urban designing and improving traffic accessibility between the towns and other countries (Pogačnik, 2000). The investments intensity is oriented in highways corridors, for which the special state programs and legislation are accepted, meanwhile the view of connecting the suburbs and other settlements near big urban centres with the efficient, attractive public transport is neglected in spite of very strong dependency of personal transports, problems with park places and pollution.

Table 2: Kruskal-Wallis nonparametric test for four independent groups and perceived need for investments as independent

areas of investment	**Mean Ranks group1 group2 group3 group4**				**Chi square (df =3)**
primary schools	51.1	43.1	47.3	51.2	1.64
high schools	57.3	37.9	48.9	50.8	6.84 #
university buildings	55.5	39.5	51.3	48.7	4.71
into health centres	53.4	38.4	48.5	47.7	4.23
hospitals	50.6	45.8	51.7	44.1	1.45
geriatric centres	44.0	53.9	52.9	41.4	0.63
swimming pools	44.3	39.2	45.4	58.9	4.34 *
skating halls	48.1	37.9	47.3	54.5	8.40
athletic stadions	53.2	35.9	52.9	48.8	5.60 #
highways	42.2	48.7	44.5	52.3	2.22
railways	47.8	47.9	42.2	50.9	1.40
local roads	46.1	49.1	50.1	46.6	0.37
new apartments	48.8	48.1	57.1	37.2	8.15 *
opera halls	46.1	44.5	48.9	47.0	0.35
theatres	51.6	39.9	49.0	47.5	2.86
museums	49.1	41.0	48.7	50.2	2.16
youth centres:	55.6	43.8	42.7	47.2	3.14

Note. N1 (students) = 18, N2 (agencies) = 24, N3 (public)= 19, N4 (engineers)= 28.
** $p < .05$. # $.67 < p < .78$.*

Almost no significant differences were discovered with Kruskal – Wallis test between the groups of respondents, two variables were discovered as important (p<0.05): investment in swimming pools and new apartments. Public group more than students, real estate agents and engineers prefers investments in apartments and engineers more than others prefer investments into swimming pools. Slovenians like sports, so it is also a country of sports champions in team or individual competitions in spite of some bad real estate conditions for training: there is not a football stadium, olympic swimming pool, or athletic stadium in our capital Investments in sports objects are needed and would also be great challenges for engineers.

Table 3/1: Structure matrix: correlation between measured variables and canonical discriminant function

	Function 1
Evaluation of the people	.67
Evaluation of the environment1	.66
Evaluation of the environment2	.58
Evaluation of the working place	.45
Evaluation of the living place	.36
Evaluation of the leisure time	.13

Note: Measured variables are summative scores.
Wilks' lambda = 0.62, Chi – square (16) = 32.14, P = 0.00.

Table 3/2: Functions at group centroids

Perceived offer	Function 1
Under Mdn	-.67
Above Mdn	.89

Note: Perceived offer is dichotomised regarding Median value.

Table 3/3: Means and standard deviations for independents – predictors for criterion »higher - lower« evaluation of the offer in the living environment

	Under Mdn		Above Mdn	
	M	SD	M	SD
Evaluation of the **people**	**50.90**	**12.16**	**62.32**	**9.08**
Evaluation of the **environment1**	**64.88**	**15.35**	**78.00**	**12.87**
Evaluation of the **environment2**	**21.39**	**7.21**	**28.93**	**7.38**
Evaluation of the **working place**	**53.76**	**11.98**	**61.22**	**8.77**
Evaluation of the **living place**	**56.10**	**12.89**	**62.35**	**8.20**
Evaluation of the **leisure time**	**60.07**	**11.83**	**62.19**	**8.22**

Note. All evaluations are summative scores, measured with semantic differential.

Particular summative evaluations, measured with the questionnaire, were treated also as predictors in discriminative analyses with perceived offer as two level criterion. We discovered, that they significantly ($p < 0.05$; $p = 0.06$) discriminate between two groups of respondents, who represent criterion variable, dichotomized regarding the median value into those, who more (above median) or less (under the median) evaluate the offer in their living environment. Evaluations of proper living place, of leisure time place have the lowest discrimination, and evaluation of the people, together with some evaluations of environment have the highest mentioned correlation. It seems, that evaluation of the offers is closely connected with evaluation of people, which may mean that investments in environment's real estate must not "forget" aspects, which facilitate the satisfying of some other social–emotional needs. The environment is laying on one side of the field of physical perception (Trstenjak, 1987). On other side exists the subjective picture of it, arising in the interactive process between the observer and the environment as a product of different experiences and sensitive perceptions

Table 4.1: Statistics of Factor Analysis

Variable	Commu-nality	Factor	Eigen value	Percent of explained variance	Cumulative %
Living place	1	1	3.56	50.9	50.9
Leisure time place	1	2	1.19	17.0	67.9
Evaluation of the environ.1	1		0.78	11.2	79.0
Evaluation of the environ.2	1		0.50	7.1	86.1
Evaluation of the offer	1		0.45	6.4	92.5
Evaluation of the people	1		0.33	4.7	97.2
Working place	1		0.20	2.8	100.0

Note. There are two components with eigenvalue equal or > 1;

Table 4.2: Rotated component matrix (varimax) for studied variables: evaluations of the living place, its environment and of people living there

Variable	Factor 1	Factor 2
Living place (accommodation)	.27	**.80**
Leisure time place	.15	**.86**
Evaluation of the environment1	**.80**	.40
Evaluation of the environment2	**.84**	.07
Evaluation of the offer	**.75**	.10
Evaluation of the people	**.76**	.36
Working place	.13	**.69**

Note: Variables are represented as summative scores, measured with semantic differential

Factor analysis reduced evaluative variables, measuring perceptions connected with living place and environment (with evaluation of working place added) into two factors, both together explaining about 70 % of variance. The first factor of the varimax rotated matrices correlates exclusively with different evaluations of the environment, including the evaluation of the people, living there and the second factor correlates exclusively with the evaluation of the living place, of the place, where somebody spends his free (leisure) time and with the evaluation of the working place. This factor may be specific for tested group(s), whose social status is characterized with shared quality of living place and working conditions.

4. Conclusions

The intention of this research was to explore the relation between the individual and real estate, and vice versa, with the aim that an investor, financial expert, urban designer would know what kind of investment are perceived as most worthy or needed, all seen from the aspects of future invests, building companies and living environment.

We can stress on the results of the research, that in Slovenia:

- The highest priority for the perceived need of investment (table 1), which is good information for investors, financial experts and building companies, is connected with: new apartments, traffic infrastructure (local roads, railways, highways), youth centers, hospitals and geriatric buildings. Perceived need of investment in educational buildings (university buildings, high schools, primary schools), into health centers and investment connected with sport (swimming pools, athletic stadiums) is in the middle. The lowest one was discovered for cultural objects (theatres, museums, opera halls) and skating halls.

- Public group more than students, real estate agents and engineers prefers investments in new apartments and engineers more than others prefer investments into swimming pools (table 2), what could be seen as challenge for engineers and designers.
- The evaluation of the offers (table 3.3) is closely connected with evaluation of people. It means that investors, social experts and designers should consider aspects, which facilitate the satisfying of social-emotional needs, while accessing the investments in environment's real estate.
- Participants separated perceptions connected with living place and environment into two factors (table 4.2). The first factor correlates with different evaluations of the environment including the evaluation of the people living there and the second factor correlates with the evaluation of the place for living, leisure time and working.

Abstract

High-density high-rise building development is the most spectacular feature of Hong Kong's urban areas. However, fire safety and conditions of these buildings become major concern of occupants and the government as the majority of the territory's population live in high-rise apartment buildings. There is increasing pressure on maintaining the level of safety performance in buildings. The recent occasional accidents of falling concrete pieces and windows in Hong Kong have aroused public concern over the possible dire consequences of building neglect. In view of Hong Kong's growing problem of urban decay and building dilapidation, urban renewal has become a matter of great urgency.

In the current economic climate, however, budgets for urban renewal are unlikely to meet the ever-increasing needs. Although it is unlikely that this problem can be overcome completely within an injection of further resources, it is possible for the government to improve the situation by ensuring that the best solution in terms of 'value for money' is achieved in the urban renewal programme. The Building Safety and Conditions Index (BSCI), developed by the Faculty of Architecture of the University of Hong Kong, can indeed help to solve the contemporary building problems.

The BSCI is a benchmarking tool for classifying buildings in respect of safety and physical conditions of buildings. Objectiveness can be achieved in the formulation of the BSCI by adopting rigorous multi-attribute decision-making techniques such as the Analytical Hierarchy Process. Through the BSCI, occupants and the public will be informed of the safety risk associated with their living environments. In view of the monetary benefits, the building owners will upkeep their properties in serviceable conditions. For the government, the BSCI can serve as a priority setting tool to facilitate resource allocation to repair or upgrade buildings with the most urgent needs. Also, with reference to the results of the BSCI assessment, an alternative strategic solution can be achieved.

Keywords: Benchmarking; building labeling; building classification; poli; safety and conditions

1. Background

High-density high-rise building development is the most spectacular feature of Hong Kong's urban areas (Choy, 1998). In Hong Kong, there are now around 42,000 private buildings territory-wide (Housing, Planning and Lands Bureau, 2004). About one quarter of these buildings are 20 to 40 years old and are more susceptible to maintenance problems, particularly those without proper management. This accounts for about half of the residential building stock in Hong Kong. As a matter of fact, the problems of building disrepair and unauthorized building works (UBW) have long been the eyesores of the cityscape in Hong Kong, like many other developed cities. From 1990 to 2002, accidents related to UBW resulted in at least 21 deaths and 135 injuries (Leung and Yiu 2004). In addition, as the majority of population in the territory live in high-rise apartment buildings, the occupants are highly prone to hazards like fire and structural stability. Several tragic fires in recent years have illustrated the gravity of the situation. Requests for addressing the prolonged problems of inadequate building management and maintenance in Hong Kong have become more frequent than ever and any further delay to solve the problem of building neglect cannot be tolerated in any means.

In view of Hong Kong's growing problem of urban decay and building dilapidation, urban renewal has become a matter of great urgency. Urban renewal includes processes ranging from rehabilitation to comprehensive redevelopment. As advocated by Government of Hong Kong Special Administrative Region (2005), enhancing the distinctive characteristics of our territory through urban renewal, which is conducive to the development of local community economy, should be put at the top of agenda. However, upholding the public safety in respect of building conditions is costly. This can be exemplified by the recurrent expenditure of Buildings Department, which is the local authority controlling new development and existing building stocks. As shown in Figure 1, the expenditure has risen from HK$470 million in 1999/2000 to HK$743 million in 2003/2004 (Audit Commission, 2003).

In expectation, budgets for urban renewal cannot meet the ever-increasing societal needs. The problem of deferred actions for achieving better living environment which is common in many countries is resulted eventually. It is clear that increasing pressure is being brought to bear on the government resources available for urban renewal and the process of setting priorities has always been a problem for policy-makers. Although they are aware of the benefits of setting priorities, little effort has been put into the development of a systematic approach for prioritizing works.

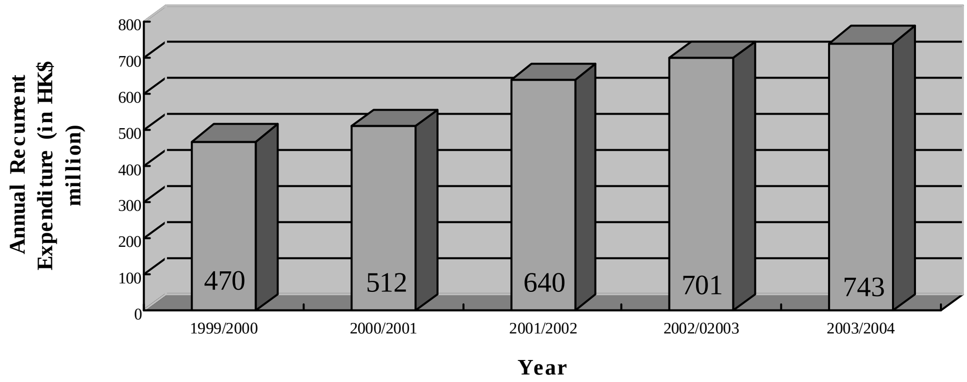

Figure 1: Annual recurrent expenditure by the Buildings Department in the past five years (Source: Audit Commission, 2003)

Therefore, there is an outcry for policy-making tool for better resource allocation for arresting the problems of building neglect in Hong Kong. Indeed, the Building introduced by Ho and Yau (2004) as a benchmarking tool for maintenance managers can help to bridge the gap. Not only can the BSCI assessment framework and the index itself promote private incentives in the upkeep of building conditions by market force, but also serves as a decision-making tool for the government. This paper studies the applicability of the BSCI for facilitation of urban renewal in Hong Kong.

2. The Building Safety and Conditions Index (BSCI)

The BSCI is a benchmarking tool, developed by the Faculty of Architecture of the University of Hong Kong, for classifying apartment buildings in respect of their safety and physical conditions in view of the need to enhance the living environment of our city. It serves to indicate the level of achievement of individual buildings in enhancing the safety of both occupants and the general public. The assessment scheme of the BSCI is backed up by rigorous and sound theoretical foundation so its creditability and practicality can be achieved. Besides, what makes the BSCI distinguishable is that its assessment framework is bespoke for the mass assessment of buildings.

2.1 Features of the BSCI

The BSCI assessment framework is intended for first-tier screening of building safety and physical conditions. Thus, a wide coverage of buildings within a short period of time at a reasonable low cost is a must. Accordingly, the assessment framework should be applicable to most apartment buildings, be they low-rise or high-rise. In addition, the factors to be considered should be directly related to building safety and conditions that pose hazards to occupants and the public. These factors should also be measurable and verifiable so objectiveness can be maintained. However, subjective judgments are unavoidable in most cases of condition assessment. In this regards, validation with documentary evidence such as record photos is necessary.

Moreover, the assessment methods should be practicable and simple, and only characteristics of buildings easily assessable by the public are acquired, measured, and assessed. Whenever possible, a building is assessed with reference to its basic configurations and conditions. On-site assessment is generally confined to common areas and the external environment only so no inspection to individual flats is required. Last but not least, the BSCI is the aggregation of the performance of individual building factors into a simple and user-friendly index for each building. For the easy consumption of ordinary people, the index can be presented in various forms such as numeric index or grades A, B, and C. Based on the index or grade, the general public can be better informed of the performance of buildings in respect of safety and physical conditions.

2.2 Construction of the BSCI

From above, the BSCI is defined and it is essentially an aggregate figure of ratings and weightings of all building factors directly related to safety and conditions of a particular building. Mathematically,

$$BSCI = g\ (w_1, w_2, \ldots, w_n; F_1, F_2, \ldots, F_n) \qquad (1)$$

where w_i (i=1, 2, …, n) denotes the relative importance (weighting) of the i^{th} building factor in affecting the safety and conditions of that building; F_i denotes the rating of the i^{th} building factor collected using the above assessment framework; n is the total number of building factors; and g is a function that combines all w_i's and F_i's. The simplest form is the weighted arithmetic mean, with all w_i's summed to unity:

$$BSCI = \sum_{i=1}^{n} w_i F_i \qquad (2)$$

2.3 Hierarchy of Building Factors

The building factors, F_i, in equations (2) have been identified through literature reviews and workshops with relevant professionals and experts. For the purposes of the BSCI, a number of safety attributes have been first made out. Fire hazard should take a place because it has long been regarded as one of the most threatening hazards to the building occupants (Chow et al., 1999 and Lo, 1999). The fire safety ranking system developed by Lo (1999) is apt for Hong Kong's situation and provides valuable guidance for identifying fire safety attributes. Yet, building safety embraces not only fire safety, but also many other factors such as structural integrity and falling objects (Buildings Department, 1997 and Choy, 1998).

Finally, eight key safety attributes, namely fire resistant construction, means of escape, means of access for fire-fighting, fire services installations, internal conditions, external conditions, density, and special hazards are identified. To come up with a practical assessment scheme for building classification, the safety attributes are decomposed into a list of building factors that can be, as far as possible, objectively measured. The building factors relevant to the safety attributes are shown in Table 1 for illustration.

Table 1: List of building factors that affect safety attributes

1. Fire Resisting Construction	5. Hazards
l compartment volume l staircase opening l fire-resisting doors	l incompatible uses l electrical installations gas installations
2. Means of Escape	6. Density
l travel distance l direct distance l discharge value l obstacles l exit and directional signs	l population per floor l number of flat per floor
3. Means of Access for Fire-fighting	7. External Conditions
l emergency vehicular access l fireman's lifts l distance between fire services access point and fireman's lift	l conditions of canopies l unauthorized building works protruding from the external walls l finishes l falling objects
4. Fire Services Installations	8. Internal Conditions
l fire extinguishers l hose reels and fire hydrants l emergency lighting	l debonded tiles l cracks l spalled concrete

The list is not exhaustive. Some strategic building management factors which apply to all safety attributes, namely management organization (e.g. deeds governing common areas, owner's corporations, and property management companies), documentation (e.g. the keeping of building records), emergency preparedness (e.g. plans for emergency situations, the provision of contingency funds), and post-occupancy evaluation systems (e.g. occupant survey), are not included. These factors should not be ignored because building safety is inseparable from building management (Choy, 1998).

For facilitating the determination of weightings of different building factors, the relationship between the safety attributes and various aspects of building factors is then mapped together to develop a hierarchy of building factors. Intuitively, poor conditions of building are attributed to misuse and the lack of maintenance. However, much literature (for example, Van Erdewijk, 1988; Heimplaetzer and Goossens, 1991 and Al-Homoud and Khan, 2004) pointed out poor design is one of the causes of building-related accidents. Therefore, building design should play an important role in building safety. In this regard, building factors are grouped into two main categories, namely *Design* and *Management* at the top level, as shown in Figure 2. Each of the building factors at the bottom level will be assessed in accordance with a scoring table, which was designed after a thorough consultation with experts in the relevant fields.

With reference to the hierarchy, *Design* factors include three categories, namely *Architecture*, *Building Services*, and *External Environment*). *Architecture* mainly deals with the provision of passive systems like means of escape and means of access for fire-fighting and rescue to protect the occupants in case of fire. Also, this category is assessed on the measures against falling objects such as the provision of utility platforms. Similar to *Architecture, Building Services*, such as fire services, electrical installations, and fuel supply, are included because their designs also have a direct influence on the safety of building occupants. As for the *External Environment*, hazards like the presence of a petrol filling station in the neighbourhood are considered. With regard to these design aspects, the safety issues of buildings can be addressed at the outset of a development project.

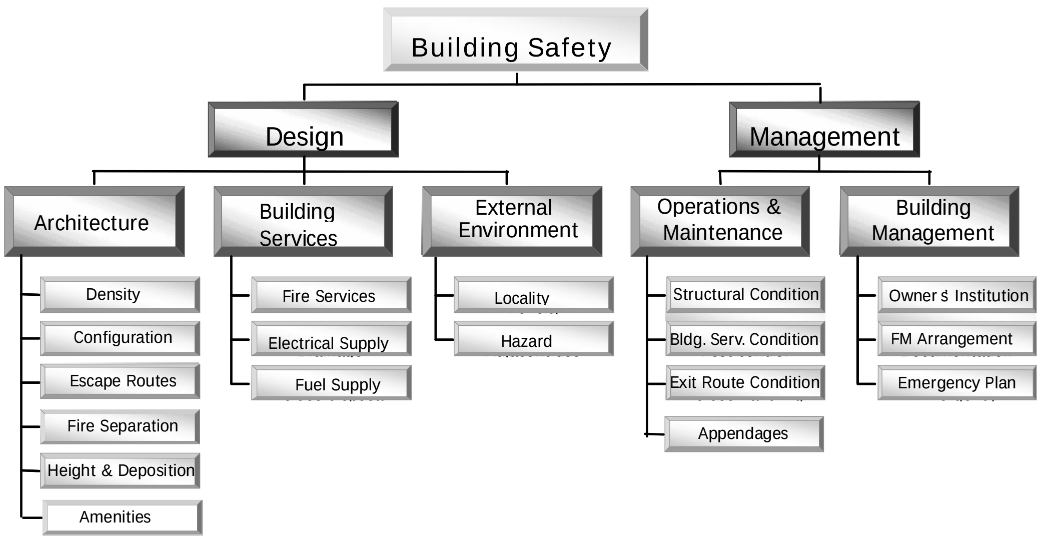

Figure 2: Hierarchy of building factors for safety and conditions assessment

Likewise, building factors under *Management* are grouped into two categories, namely *Operations & Maintenance* and *Building Management*. *Maintenance* is the inspection and upkeep of various building fabrics and services while *Operations* refers to the tidiness and integrity of the exit routes and presence of UBW in the building. *Building Management*, regarded as the software for improving the safety and condition of buildings, embraces strategic issues such as owner's institution, arrangements of facilities management, emergency preparedness, and post-occupancy evaluation.

2.4 Determination of Weightings

Step 1 — The interviewee completes the questionnaire in a laptop computer.

Step 2 — The ranking, weighting and internal consistency ratios are calculated using the computer package *Expert Choice 2000 2nd Edition*.

Step 3 — The analyzed results, i.e. the weighting and ranking of each building factor are reported to the interviewee.

Step 4 — If the internal consistency ratio in any category level is not lower than 0.1 which is the accepted level of internal consistency as suggested by Saaty (1982), the computer package will locate the likely source of inconsistency. Without influencing the interviewee's decision, the interviewee is allowed to revise their response either following the suggestion of the computer package or filling in the questionnaire again.

Step 5 — After the interviewee completes the revision in the laptop, an instantaneous feedback on the internal consistency ratio is shown to the interviewee on the computer.

Step 6 — If the internal consistency ratio is still not lower than 0.1, the interviewee can follow Steps 4 and 5 again for further revision. The process will continue until the interviewee does not wish to make any further changes.

Figure 3: Procedures of the AHP interview

Turning to the determination of the relative importance of the building factors in equation (2), multiple decision criteria systems, such as the Analytical Hierarchy Process (AHP) developed by Saaty (1982), will be adopted to calculate the weighting w_i. The hierarchal representation facilitates the assessment of the relative importance of the building factors using the AHP. Workshops are organized to interview representatives from relevant professional bodies and universities to determine the weightings of building factors perceived by these interviewees. Through a pairwise comparison of the relative importance of all factors at the same level of the hierarchy, the building factors can be prioritized. The detailed procedures of the interview are shown in Figure 3. With the use of AHP, more reliable weightings can be achieved, which is one of the most crucial aspects of the BSCI assessment framework. When all w_is and F_is are found, the overall index BSCI, which is a single measure of the performance of building safety, can be computed.

3. Applications of the BSCI

Ho and Yau (2004) stated that safety is an abstract concept which attracts diverse perceptions to different people. With the integration of people's perception with different background in a scientific manner, the BSCI provides a means of objective and widely accepted *inter*-building comparison for distinguishing the good from the bad. It serves as a benchmarking tool to measure and compare building performance in terms of safety and conditions. It is believed that a well-publicized and well-received BSCI can facilitate the urban renewal in Hong Kong. On one hand, it promotes the private sectors to voluntarily maintain the buildings by market force. On the other hand, the government can make use of the BSCI for its decision-making process.

3.1 Promotion of building care by market force

A safe home is a good one. Buildings with better safety performance should be valued higher. Other than the longevity of assets, it is because less risk premium will be paid by the potential buyers for the unforeseen problems brought about by the disrepair of the purchased properties. These buyers may risk paying a large amount of damages, ranging from approximately HK$60,000 to HK$350,000 per unit, as compensations for the victims in future building-related accidents (Leung, 2003). This amount constitutes quite a substantial portion of the average value of the units. Furthermore, well-maintained buildings may attract more favourable mortgage terms, insurance premium and rental income. However, there is asymmetric information regarding the building safety performance during property transactions. Therefore, the public places a high emphasis on the building age which is taken as a proxy for the safety performance of a building.

The BSCI now provides a useful tool for evaluating safety aspects of a building that are not easily observable. According to such previously hidden information provided by the index on how each building performs in terms of safety, the public can distinguish buildings of similar ages with different safety performances. The BSCI creates labelling effects on those better-performed buildings and these will be translated into higher property values. With a view to the prospective monetary benefits, most property owners would voluntarily exercise their management and maintenance responsibilities. With a reassessment mechanism, property owners of buildings with lower grades could implement improvement projects to their buildings in consideration of the potential monetary benefits. As empirically shown by Chau, *et al.* (2003 and 2004), improvement works brought about a substantial increase in property value which far exceeded the cost of upgrading.

At the same time, the BSCI can serve as a useful performance evaluation tool for the maintenance managers so that the continual maintenance performance can be evaluated by tracking the BSCI of the relevant buildings periodically. In other words, the BSCI can be used as a key performance indicator for maintenance services providers (Ho and Yau, 2004). The same is applicable to the developers and designers, with the incorporation of design factors in the BSCI assessment scheme. This is because higher grades obtained for their housing products or managed buildings can be a powerful marketing tool, especially when concerns over the quality of our living environment continue to surge. More importantly, the BSCI offers information on good design, maintenance and management practices. Designers and maintenance services providers can cross-check their practices with the criteria set for the scheme, and follow the practices to improve their services.

Eventually, positive recognition is awarded to well-designed, managed and maintained buildings through the BSCI. The desire of owners, developers, designers and maintenance services providers for more benefits, be in monetary terms or not, will bring market forces into play to foster a culture of building care. This would attract more resources from private sectors to be invested in the upkeep of private apartment buildings.

3.2 Decision-making tools for government

It is not uncommon for government budgets to hardly meet the ever-increasing societal needs of urban renewal. Hence, it is essential to ensure that the best solution in terms of ‘value for money’ is achieved in an urban renewal programme. The BSCI can be used as a priority setting tool for decision making and budget planning, providing a basis for allocating and directing funding to specific building-related problems. The value of the BSCI becomes more apparent when the number of problematic buildings in Hong Kong is so large and fiscal resources for urban renewal are limited and must be spread out over extended periods.

Needless to say, the grade or numeric figure of the BSCI can tell how a building performs on safety aspects. This priority setting function of the BSCI can help the government efficiently allocate resources to the areas where action is most needed. Apart from simply classifying buildings into grades A, B, and C, the government can make the full advantage of the assessment framework for decision making. Using the rates obtained from actual assessment and the hierarchy in Figure 2, scores can be for the *Operation and Maintenance* and the *Building Management*. The former reflects the existing conditions of buildings while the latter measures the potential for good safety performance to be achieved. The pair of scores of all buildings in Hong Kong can be mapped in a 2-dimensional matrix, as illustrated in Figure 4.

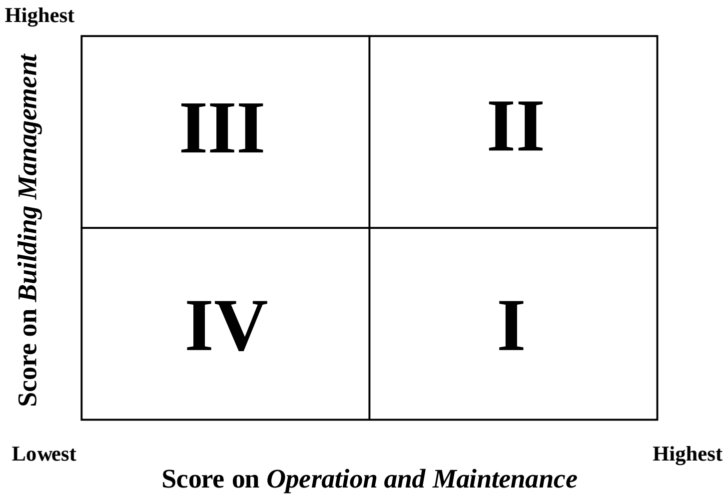

Figure 4: Connection between Operation and Maintenance and Building Management

Owners of apartment buildings with poor existing conditions but with high potential to achieve good safety performance (i.e. buildings in Quadrant III) will be encouraged to undertake improvement works to their buildings in return for higher rental or value of their properties. For buildings with good existing conditions but lacking potential for future safety performance (i.e. buildings in Quadrant I), the government should put more resources to educate the owners on the importance of building care. For instance, assistance should be given to these owners in forming owner's corporations.

Because of the lack of potential to achieve good safety performance, improvement to buildings with poor existing conditions (i.e. buildings in Quadrant IV) may not be practical. Resorts like government loan for improvement works and government-led improvement works should be opted for these buildings although the money will come from the public purse. Redevelopment may be also considered for buildings of this end. To the other extreme, the public resources to be allocated to well-conditioned buildings with potential for future safety performance (i.e. buildings in Quadrant II) should be minimal.

4. Concluding Remarks

The purpose of creating a building is to provide an improved environment for individuals, organizations, and communities (Halliday 1997). It is a common belief of ours. Paradoxically, the problems associated with building safety do not only affect property occupants or users, but also problematic results and their costs are spread across the society. Failure of the general public to undertake systematic and planed preventative maintenance to privately owned buildings has led to a substantial maintenance backlog and provided a contributing factor to the continued proliferation of unauthorized building works, incidence of canopy collapses and fatalities from fire (Choy, 1998).

Undoubtedly, these problems should be properly addressed without further delay but incremental remedies have been criticized for the lack of forethought. A long-term view and sustainable solutions should be taken. The BSCI developed by the Faculty of Architecture of the University of Hong Kong can serves these purposes. The implementation of the BSCI is beneficial to all parties. For the general public, the assessment scheme provides a useful tool for building performance evaluation. For developers, designers, building owners, and maintenance and management services providers, the information provided by the assessment scheme encourages better design, construction and maintenance of their buildings. As a result, the BSCI assessment scheme will serve to foster a culture of constructing and maintaining good quality buildings. Resources from private sectors are pumped into urban renewal. For the government, the results of the BSCI can be used as a policy tool. Such benefits become more noticeable especially during the time of government's financial stringency.

Client’s Tool For Leading Edge Construction And Design Briefing

Nina Ryd,
Facilities Management Consultants (email: nina.ryd@fmkonsulterna.com)
Inga Malmqvist,
Chalmers University of Technology - Facilities Management (email: imalm@arch.chalmers.se)

Abstract

This ongoing research and development project seeks an innovative and planned approach to capture requirements in construction projects, with the purpose of overcoming the restrictions of the conventional briefing process. It aims to develop practical tools that support and facilitate understanding and implementation of client’s requirements, effective collaboration between stakeholders and create an innovative, groundbreaking briefing process. Such tools help reducing uncertainties and future problems by early consideration of issues affecting the lifecycle of a facility. Comprehensive development trends in Sweden effecting the improvement of briefing tools are described. Emphasis is on strategic briefing. Processes that converts corporate strategy into property investment or corporate real estate decisions. Processes that capture the organisation's mission, vision and values, as well as guide the process of considering alternatives that satisfy the corporate strategic direction. The project will be based on a number of empirical investigations, case studies and interview surveys among client organizations as well as development of a prototype. The results provide insight contributing to the construction client’s as well as the facilities manager’s development of competence with regard to the consequences of their selected strategy for facilitating briefing and provision of facilities.

Keywords: briefing/programming*, client, facilities management, corporate real estate, end users, stakeholders, process.

*The British concept construction and design briefing is used as a synonym to the American concept architectural programming throughout this paper.

1. The Client Briefing Tools Project

1.1 Overview

This paper reports preliminary findings of an ongoing research and development project founded by FORMAS (www.formas.se), the Swedish Research Council for Environment, Agricultural

Sciences and Spatial Planning. The project seeks an innovative and planned approach to the founding of client requirements in design and construction projects. The overall aim is to develop practical tools that support and facilitate understanding and implementation of client requirements. Furthermore, the project considers the foundation for successful management of requirements throughout the construction process and the lifecycle of the facility. The development of this briefing tools are assumed of particular interest for client representatives, project managers, development managers, developers and design managers in the real estate and construction sector.

1.2 Industrial Relevance

This R&D project is forming an organised community of people belonging to the industry, real-estate companies, and the real estate division of the county council as well as from universities [1] where the new ideas can more easily reach industry's expectations and where client's needs can be better faced, and where business problems can be thoroughly discussed.

The practical value of the project is expected as following:

- It contributes to innovative development, satisfaction and support of the client's objectives, demands and requirements of the construction sector
- It contributes to the development of the client's knowledge about the character of innovative construction briefing processes.
- It provides insight for construction clients with regard to the consequences of their selected methodology for capturing requirements and provision of facilities.
- It provides insight contributing to the construction client's development of competence
- Implementation and use of the tools in selected client organisations will be one major long term value.

2. The Briefing Process

Rezgui et al. [2] defines the briefing process as "a process running throughout a construction project by which the requirements of the client and other relevant stakeholders are progressively captured, interpreted, confirmed, and then communicated to the design and construction "team". This definition broadens the customer perspective [3]; [4], emphasizes cyclic aspects [5] and clarifies the briefing activities [6]; [7]. However, there always needs to be an avenue for stakeholders to identify, clarify, analyze, formulate, and confirm their perspectives [8] - a process with the overall aim of continually co-coordinating the client's business and facility planning.

2.1 A Strategic, Tactical, and Operative Briefing Process

Strategic briefing is a concept that has still not been completely accepted in Sweden. This basically British concept was introduced at the beginning of the 1990s to reduce the limitations experienced in traditional specification development when both public and private operations were in a state of constant change [9]. The more conventional, needs-initiated briefing process was based on the assumption that the requirements a structure must meet can be described with the help of studies of existing work processes, interviews with employees, and management.

Strategic briefing springs from the current operational needs, but also takes a longer perspective and focuses on the operation's strategic development plans, its prospects, and the building's potential for adaptation for other uses. It is a matter of identifying the activity that is to be housed in the building, how it might change, and the factors that affect these changes. Bertelsen et al, for example, found that the identification of the strategic themes is of fundamental importance for the client's possibilities to manage the construction process [3].

The tactical briefing process helps define the course of action. An operative brief considers those aspects that can be adapted and changed as the operation changes. It includes operational and building-related performance specifications, guidelines for layout, and interior design concepts that together form the foundation for the individual organisation's use of the premises.

3. Comprehensive Development Trends in Sweden - Effecting the Improvement of Briefing Tools

In 2003, twenty three in-depth semi-structured interviews were carried out with representatives from the following organisations: Swedish Cabinet Office and Ministries, the Swedish Board of Civil Aviation, Akademiska Hus AB (2), The National Swedish Property Board, the National Fortifications Administration, Specialfastigheter, County Council Property in Uppsala, Locum AB (2), the Swedish Church, SAR competition office, property consultants Jones Lang LaSalle, White Strategi architects, BSK-architects, Forum for Health Care Building, Gotland's, Malmö's, and Härryda's municipal property offices, The Swedish Pharmacy, Denmark's Radio, Swedish Posten, The Directorate of Public Construction, and Property in Norway [10]. Those chosen for the interviews had good knowledge of and experience in the sector, regularly carry out briefings, and represent different types of organisations and operations.

Each interview was recorded on tape and transcribed. The respondents were sent transcripts, which gave them the opportunity to make corrections and additions or change the content if necessary. Some of the respondents reacted with annoyance to these transcripts as they exposed the interview dialogue as it actually was. Due to this, several respondents received applicable narrative summaries of the interviews instead of transcripts from tape. In addition, some respondents had a second opportunity to react on descriptions of their experience due to balance experience and reflections over the time of approximate one year. Relevant documents supplied by interviewees were also reviewed.

The semi-structured interviews centred on descriptions of how briefing is carried out today and on what the respondents wanted to improve. A number of specific areas were covered: methods, roles, responsibilities, decision-making processes, scope, formulation of needs, and suggestions for improvements. The results that are of importance when developing briefing tools are described in the following section.

3.1 Increased Client focus, Higher Pace of Change, and Sell-off of Properties

Several factors affecting the conditions for Swedish briefing have changed in the last decade. One of these is an increased customer focus resulting in discussions on how briefs are carried out in individual projects. This was discussed on a broader perspective in terms of which building and project planning policy companies and organisations in the consulting, building, and real estate industries should follow.

Project manager at a county council-owned property company: *"As a result of the introduction of market rents, we have been forced to become more client-oriented… We have begun working on a handbook on how we can carry out a more professional strategic facility planning process."*

Project manager for a state property company: *"Our operations have been streamlined since so many project manager functions are now being bought in the market, while our briefing work has grown and has been forced to become more customer-oriented."*

Project manager for a public property company: "*The problem with our earlier briefing is that we had too little contact with the customer. The people who developed the briefs did not really know very much about the actual needs of the organisation that would use the building."*

Development manager in a property business: "*In connection with extensive sell-offs of our properties, we have had an intense discussion on the actual needs of the organisation, which resulted in more interest in analyses of the connection between the organisation and its buildings"*.

Within the private sector, an increased focus on core activities means that it is more unusual for a company to own its own premises. The briefing process is now based on a more refined user perspective rather than the owner perspective, which was used previously. The pace of change within the organisations has also increased, which means more frequent moving and shorter planning horizons. At the same time, the client is being given more formal responsibility for the management of building projects. The Swedish Planning and Building Act [11] require that the clients ensure that the work is carried out according to the provisions indicated in the law and regulations. This responsibility applies to the function, design, technical solutions, and control of the work. At the same time, many state client functions were affected by cutbacks resulting from more and more services being bought from architectural and technical consultancies. Thus, a representative for the client carries out the briefing process.

On the other hand, the interviews demonstrated that some competencies in the briefing area are often judged to be far too strategic and difficult to purchase and are therefore kept within own organisation in private as well as public sector. In addition, some respondents have expanded the strategic briefing work within their organisations. In this way, the market has contributed to a refinement of the briefing process and caused its main focus to shift.

3.2 More Inexperienced Players in the Early Stages

Several respondents pointed out that the building market has been solid in recent years, something that has also meant more building orders for one-time buyers, primarily from business and industry. As these two groups do not have much experience in the building sector, they are glad to call on consulting services for their briefing needs, which helps explain the increased demand for these firms' services. This puts even more focus on how briefing is conducted.

Some of the respondents emphasised their belief that briefing should be viewed as a strategic assignment and, for this reason, it is not part of traditional, operative project management or design work. This has also contributed to the creation of new consulting services that focus on the briefing process.

Several contractors have invested in their project development programmes to increase their expertise in managing the early stages of the construction process directly with the user as a way to provide more value for the customer as well as to make better business. Since keeping the process under control is of importance for their profitability. When the contractor takes the initiative for a project and propels it from the idea stage to operations and management, the process changes all roles of those involved. This means that the contractor must be able to inspire confidence, be sensitive to the wishes of others, and be able to identify and analyse the clients' needs.

3.3 The Need for Clear and Precise Concepts in the Briefing Phase

The absence of concepts and an established language for the briefing phase was identified as a problem by the majority of respondents. Several apply designations that the KBS (The Swedish National Board of Public Building) formulated in its time during the 1970:ies and 1980:ies, although, in practice, the designations are individually interpreted and used in various ways, while others have developed their own concepts. When the concepts for and within the briefing process are vague, communicating with users and the organisation's representatives can be a significant problem.

Developer: *"There is no common language. During the design phase, we have a lot of technical terms. When we talk about detail design, everyone knows what that is. When we're in the design process, everyone knows what the various phases demand and when the deadlines are. But there is no common language for the briefing phase. It has not been defined?'*

Some of the property owners and their representatives who were interviewed solve the problem by doing much of the work that the client or tenant, who was intimately involved in the implementation, should have been responsible for, while others solve the problem by hiring special project secretaries within the property development company. They have knowledge of the industry and the technical terms that are used in the building project.

3.4 Different Types of Briefing Processes

The respondents work with different types of briefing processes to which they also assign different names. In addition to using designations from the National Board of Public Building, they also use the definitions that are sometimes found in urban planning, and company and operations-specific guidelines. At times, the same briefing data are used for other purposes in a reworked format. Several of the respondents voiced concern over the fact that there are no applicable guidelines or a concordant vocabulary for the different kinds of briefings and for what the different categories of briefings should include, even if most of them say that they know what the different types of briefings can be expected to include.

3.5 Unclear Areas of Responsibility for the Brief

A good number of the respondents would like to have a clear definition of roles and the division of responsibility in the building sector in general. Several respondents felt that it is more important than previously to clearly define the role of the different parties involved during the briefing phase.

Administrator: *"Off and on during the goal discussions, areas of responsibility are created that are supposed to determine who is responsible for what, but they can hardly cover all situations".*

There was consensus that an unclear, decentralized division of responsibility runs the risk that responsibility for the briefing process will fall between the cracks and that this ambiguity can diminish competency in the area in the long run.

The majority of the respondents have experienced difficulties when they ask their tenants for descriptions of the operations and needs and other information that serves as the foundation for the briefing process.

Briefing architect: *"One can hardly expect the people who represent buildings and furnish operational-compliant buildings to know everything about their tenants' businesses. Just as the business representatives cannot be expected to know the types of information required for a briefing process".*

Property owner: *"We try to make it clear that this is the tenants' facility planning programme. This information serves as input for our design work, our orders. The tenant is responsible for working out a plan for his facilities. We try to be a little 'overly' clear here. I think this is good and necessary, so we know who is responsible. Tenants have to understand that if what they say is wrong, then things wont turn out as they want".*

In those cases in which the information on the business was reported, some of the respondents expressed concern over uncertainty regarding the agreement between the various people who submit information. It was indicated that the consultants hired to carry out the briefing process were sometimes far too dependent on the view of the operations presented by those submitting the information.

Several respondents also expressed concern over a lack of understanding in user groups of the briefing process's requirements in general and the time required for its execution in particular. There was very little understanding regarding the fact that the briefing requirements must often be discussed for sometimes even several years before a satisfactory result is achieved.

All the respondents believe that a well-executed operations description is the basis for a successful briefing needed for an integrated business development and strategic facility planning process.

3.6 Applied Briefing Process Methods

Briefing processes have been part of the organisations used in this study for a long time, and several of those interviewed have had a good deal of experience with this type of work. Many also worked with similar assignments at the former National Board of Public Building. Work methods that were applied on the board are still used to a great extent within private consulting firms, tenant organisations, municipalities, county councils and governmental departments. Methods have been adapted to current operations and it was felt that they worked well during a period of transition.

However, trends and developments within the respondents' own organisations call for clarification and articulation of the briefing's function.

Reasons for change is the increased demand for briefing formulation, including a move to greater client focus with clearer responsibility for long-term profitability from investments. Other trends mentioned include new formats for the briefing process—with more influence from private sector clients and developers—that have already been tried in a number of municipalities. Other types of agreed-upon briefing plans, such as supplements to land use agreements, are also being used. In this manner, the interface between the municipal detail planning regulations and the individual client's briefing process is changing. Increased understanding of the briefing process's strategic importance, the need for an accountable quality system, an aging staff heading toward retirement, and the need to transfer knowledge before the older members of the staff retire were also given as factors on how and to what end briefing processes should be conducted in the future.

On the whole, the respondents believe this development is a positive one. Many feel that the previous routines were often undeveloped, poorly adapted to customers, and far too often based on personal experience. Other disadvantages include lack of comprehensive overview and difficulties in making use of positive experiences.

Project manager in the early stages: *"We knew that our colleagues were collecting a lot of useful briefing documents - good examples. On the other hand, there was no survey or knowledge of how the documents were related to one another, which explains why we have recently begun work aimed at describing the entire briefing process"*.

Some property owners also expressed a self-critical attitude and admitted that, as of now, they have not actually worked out any briefing process methods. However, other managers have already begun to renew their methods for the early stages in the building process from a business-like and client-focused strategic facility planning perspective.

3.7 The Need for New Ways of Working that Generate Constructive Thinking

Several respondents emphasised the importance of creative and constructive thinking as the basis for a successful briefing process. Some went so far as to maintain that it is absolutely decisive and that they are looking for ideas and suggestions on how to implement this mode of thinking.

Client: *"We are looking for good examples of how to get an early dialogue started, tricks of the trade and other methods for taking the initiative. We want to find out how to capture the good ideas, make contact in the right way, how to initiate a process so that, when time is of the essence, we are not forced to do something that everyone can see will be bad"*.

The interviews are replete with observations from those responsible for the briefing process on the difficulties of balancing a favourable work method with daring to critically examine the operations with the purpose of elucidating priorities and actual needs. This was viewed as a sensitive balancing act that is difficult to manage, both for those who manage the briefing process and those who are part of the business or organisation that will use the facilities.

Property owner: *"If the process is experienced as being wrong, then it stays in a tenant's memory for a long time. That is not good, either for us or for them, and particularly not on the threshold of a long-term rental relationship"*.

Several of the respondents imply that it is good for individual projects to have as thorough and detailed a briefing process as possible, but when the organisation is questioned in an attempt to attaining this detailed description, this can be experienced as a potential threat to social relationships and the desire for continued, open discussions. The more clarifications and questions with the intent of achieving a better brief, the more situations arise that can lead to disagreements that, in turn, lead to difficult decisions.

The formulation of goals and needs that arise in consensus are experienced as easier to carry out than those that arise because someone was forced to compromise. It was stressed that more general goal descriptions can act as the instruments that hold a briefing process together over time, even if the goals are difficult to objectify in the actual project.

Everyone agreed that trust is a prerequisite for a constructive specification development process. It is required in order to access the right specification information. There also has to be trust that the individuals conducting the briefing process are competent and have the experience and authority to carry out the assignment. In addition, trust is needed so that people are able to vent their disagreements and priorities in periods of uncertainty without running the risk of a deadlock.

Client: *"The briefing process should take place in a safe environment so that people can communicate, and this has to do with trust. People shouldn't be afraid of making fools or themselves or saying something that's wrong. Not drawing quick or drastic conclusions from something someone has said. These are a few of the personal qualities that are extremely important for making this process work. If there is no trust, then there will be 'attitude' and people 'taking stands'. People notice this kind of behaviour immediately"*.

According to the respondents, the need for a creative and constructive briefing process is both fundamental and complicated. Points of departure focus on relationships, balance between comprehensive and more detailed attitudes, management of insecurity, and different types of trust.

4. Discussion and Future outlook of the R&D project

The findings from the interview study regarding the standing of the construction client and the tools he/she utilises will be combined with the results of an ongoing questionnaire (mars - april 2005) in order to provide a deeper understanding of the mechanisms that are fundamental for the clients' innovative management of projects for the provision of facilities. A presumption is that methodologies and tools could be for example quality function development, problem structuring methods, group decision-making techniques or computer based tools such as database applications and spreadsheet packages. A basic assumption for this study is also that the client today is forced to utilise too production-oriented/process-oriented tools during a project involving the provision of facilities. To focus on the perspective and activity of the construction client, instead of the internal interests of the construction sector, means that attention is shifted from discussions about misinterpreted demand formulations and shortages regarding quality of the building as a project to the prerequisites for developing the clients' competence and management methods. This is in order to allow the client, in the best possible manner, to be able to influence that the outcome of a project is in agreement with its strategic intentions. A perspective that not only focuses on the design and content of specific demands or documents, but that also aims for deeper change with regard to the praxis of the construction industry.

A questionnaire based method will be applied with the purpose of accounting for the following:

- What the client's tools are, as well as the choice of established tools in relationship to new concepts.
- Verification of factors that a tool has to support or/and if there are other factors that are more relevant?
- The client's decisive choices before and during a project involving the provision of facilities.
- What administrative and organisational processes influence the construction client's possibilities regarding the management of a project involving the provision of facilities?

The gathering of information is primarily via a larger number of questionnaires (approx. 100) with a systematic choice of representatives from Swedish construction client organisations. The forum for cooperation between state-owned property boards and real estate management (Samverkansforum för statliga byggherrar och förvaltare), as well as the Swedish association of construction clients' (www.byggherreforum.se) network and membership register is utilised for the choice of respondents. In addition to this, the relevant documentation and other written sources will constitute the empirical basis for the following of this R&D project.

5. Conclusions

Even if one should be cautious about simplifying the results from the interviews, there are some basic points that are vital for support of the client's briefing:

Briefing tools should:

- facilitate communication and shared understanding of the client's targets with regard to a facility-provision project, but also act as an engine for capturing, preparing and identifying strategic, tactical and operative information and requirements.
- include systems for regularly following up agreed brief assignments and not just final targets. This creates a better possibility of early capture and rectification of things that are unclear.
- be user-friendly and contribute to more active and creative participation on the part of everyone – not least the client as well as less experienced players

- facilitate structuring and prioritisation of the client's requirements.
- support discussions about alternative conceptual and possible solutions.
- support a translation of the client's picture of requirements into measurable requirement formulations.
- simplify verification that the brief's (detailed design brief) requirements are satisfied in the planned solutions as well as deal whit responsibilities.
- deal whit change management
- support both solution-neutral functional descriptions and technical specifications of the client's wishes with the aim of establishing creative conditions for planners to generate physical conditions that best support the client's business targets.
- support different kinds of briefing processes, such as strategic, tactical and operative briefing.

It is advantageous if briefing tools contribute towards better understanding and integration of the client's requirements on the basis of a customer-oriented approach. The tools should contribute towards more explicit definitions and improved communication of the client's requirements and expectations with regard to a facility planning project, so that connections with overall business targets are strengthened.

Valuing Productivity Loss due to Thermal Discomfort

Abstract

Thermal discomfort may decrease productivities. This paper derives the economic principle of assessing the market value of such productivity loss based on standard economic principles of the Marginal Productivity Theory. These losses are expressed in terms of proportional losses in economic rents and profits. This paper aims to provide a basis for systematic market valuations of losses due to thermal discomfort, and hence varying strategies under varying circumstances.

Keywords: Productivity loss, thermal comfort, predicted mean vote (PMV), marginal productivity theory.

1. Introduction

Adbou and Lorch [1994] verified that the productivity of occupants is greatly affected by the thermal comfort. Wyon [1996] and Kosonen and Tan [2004] make significant contributions to human thermal comfort. Quantitative relationship between the productivity level and Predicted Mean Vote (PMV) is now defined for some activities. This finding has a great impact on air-conditioning control. Market data and Simulations of PMV changes under varying air-conditioning control systems of buildings at different locations will be investigated.

2. Marginal Productivity Theory

Thermal comfort affects the productivities of staff working in an office.

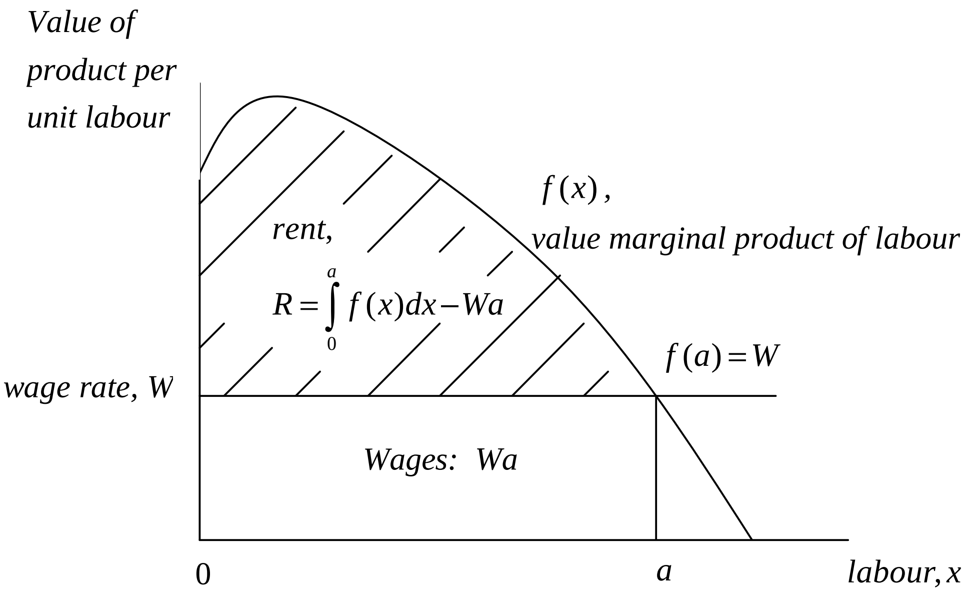
Suppose the value marginal product of labour is a function f of the quantity of labour input x. This function f is a decreasing function of x according to the Law of Diminishing Marginal

Productivity (see, for instance, Stigler [1966]). Standard economics would illustrate that maximum economic rent, *R*, could be receivable at *a* units of labour input into production, where *f(a)=W* , the competitive wage rate. And the maximum economic rent:

$$R = \int_0^a f(x)dx - Wa \qquad (1)$$

Graphically, rent is the area under *f(x)* from *x=o* to *x=a*, less wages *Wa* :

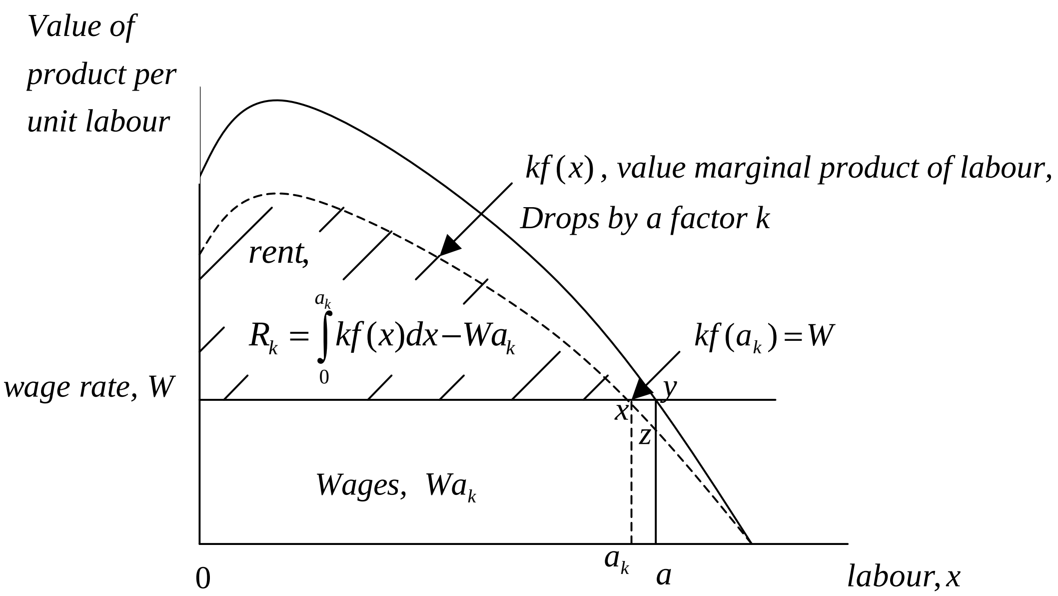
Graph 1: value marginal product and rent



3. Productivity Drop

Now suppose a change in temperature has resulted in a reduced productivity, say *k* times the original value marginal product *f(x)*. For instance, *k= 0.9* means a 10% drop in the output product *f(x),* at any quantity of the labour input, x. Then graphically, *f(x)* becomes a "10% lower" curve at every point labour input:

Graph 2: A drop in productivity



A smaller productivity would imply smaller profits, and therefore, economic rent: $R_k < R$, and

$$R_k = \int_0^{a_k} kf(x)dx - Wa_k \tag{2}$$

Since k and R are readily available data, we may estimate R_k *using* k and R.

Firstly, from Equation (1), we may re-write kR as:

$$\begin{aligned} kR &= k[\int_0^{a} f(x)dx - Wa] \\ &= \int_0^{a} kf(x)dx - kWa \\ &= \int_0^{a_k} kf(x)dx + \int_{a_k}^{a} kf(x)dx - kWa \end{aligned} \tag{3}$$

Comparing this to R_k in Equation (2), and adding terms $-Wa_k$ and $+Wa_k$ to this Equation (3), in order to allow sufficient components for R_k, we have:

$$kR = \int_0^{a_k} kf(x)dx - Wa_k + \int_{a_k}^{a} kf(x)dx + wa_k - kWa$$

$$= R_k + \int_{a_k}^{a} kf(x)dx + Wa_k - kWa \tag{4}$$

Graphically, the term $\int_{a_k}^{a} kf(x)dx$ is the area $a\ a_k\ x\ z$. Assuming the line segment $x\ z$ is reasonably close to a straight line, then this area is reasonably close to:

$$\int_{a_k}^{a} kf(x)dx \cong W(a-a_k) - \frac{1}{2}(a-a_k)(1-k)W$$
$$= W(a-a_k)(\frac{1+k}{2}) \tag{5}$$

Putting this into (4):

$$kR = R_k + W(a-a_k)(\frac{1+k}{2}) + Wa_k - kWa \tag{5}$$

After rearranging,

$$\frac{R_k}{R} = k - \frac{(1-k)(a+a_k)}{2} \cdot \frac{W}{R} \tag{6}$$

When the reduction of labour input due to a drop in productivity is negligible, i.e. $a \cong a_k$ (or, in other words, the employer finds that the drop in productivity does not justify a labour cutting exercise), then

$$\frac{R_k}{R} \cong k - \frac{Wa}{R}(1-k) \tag{7}$$

This means the ratio of reduced profits (or more accurately economic rent) to the original, R_k/R, could be approximated by the ratio of reduced productivity to the original, k, less the corresponding drop, by the factor (1-k), on the wages-to-rent ratio (Wa/R).

Equations (7) could therefore be used to estimate the loss in profits, given data of rent, wages, labour employed, and reduction of productivity loss due to thermal discomfort. If the loss in productivity is so significant that the employers have to cut staff, due to significant reduction in income, then Equation (6) should be used instead.

This implies that if wages is large compared to economic rent, i.e. Wa/R ratio, economic rent (profits) would reduce at a ratio greater than that in productivity loss: R_k/R much smaller than k. In simple words, the larger the labour costs, comparing to business profits, the greater the effects (of productivity drops) on profits.

4. A Numerical Example

Suppose there are two small offices, one a stocks broker at the Central Business District of Hong Kong; and the other, an engineering consultant in the sub-urban area. Both offices occupy 1,000 square meters of usable floor area. The CBD one costs \$12,000/m2 yearly to rent; and the sub-urban one, ten times less: at \$1,200 /m2. The stocks broker pays higher wages to its staff, around \$5 million a year; and the engineering consultant, \$3 million. Gross profits for the stocks broker, before wages and office rental, is \$7.5 million; and the engineering consultant, \$3.5.

Table 1. The stocks broker vs. The engineering consultant

	Symbol	Stocks broker in the CBD	Engineering consultant in the sub -urban area
Office size	s	100 m^2	100 m^2
Yearly rent /m^2	y	\$12,000/m^2	1,200/m^2
Yearly rent payable to the landlord	$y\ s$	\$1,200,000	\$120,000
Gross profits (before wages and office rental)	$G = \int_0^a f(x)dx$	\$7,500,000	\$3,500,000
Yearly wages	Wa	\$5,000,000	\$3,000,000
Economic rent (after wages but before office rental)	$R = G - Wa$	\$2,500,000	\$500,000
Net profit	$\Pi = R - ys$	\$1,300,000	\$380,000
Wages–to-Economic Rent Ratio	Wa/R	2	6
Ratio of reduced economic rent to original, if *k=0.9*	$\frac{R_k}{R} \cong k - \frac{Wa}{R}(1-k)$ from equation (7)	0.7	0.30
% Loss in economic rent	$l = (1 - \frac{R_k}{R}) \cdot 100\%$	30 %	70%
Reduced Economic Rent	R_k	\$1,750,000	\$150,000
Net profit after productivity drop	$\Pi_k = R_k - ys$	\$550,000	\$30,000
Loss in net profits	$\Pi - \Pi_k$	\$750,000	\$350,000
% Loss in net profit	$(\frac{\Pi - \Pi_k}{\Pi}) \cdot 100\%$	58%	92%

Table 1 shows that the net profits, after all wages and office rentals, are \$1.3 and \$0.38 million respectively. Now suppose that productivity drops by 10% due to thermal discomfort. Equation (7) allows us the estimate the profit loss due to such drop in productivity. The results in Table 1 show that the engineering consultant suffers from a much bigger % loss in net profit, 92% vs. 58%. The stocks broker's absolute loss in profit is, however, larger: $0.75 vs. $0.35 million.

Absolute loss in profit depends on the base, of the original profit, and the office rental due to location. Such conclusion cannot be easily generalized to all other examples. However, Equation (7) shows that the ratio of the reduced economic rent to the original, R_k/R, is always a negative function of *Wa/R*: the wages to economic rent ratio. Systematically plotting k, the proportion of the reduced productivity to the original, against *Wa/R*, we have the following Table 2.

Table 2. The Sensitivity of R_k/R to k and Wa/R. (the stocks broker; and # the engineering consultant)*

	k **: the proportion of reduced productivity to the original**									
***wa/R*: wages–to -economic rent ratio**	**0.95**	**0.90**	**0.85**	**0.80**	**0.75**	**0.70**	**0.65**	**0.60**	**0.55**	**0.50**
	Rk/R: **the proportion of reduced economic rent to the original**									
0.500	0.93	0.85	0.78	0.70	0.63	0.55	0.48	0.40	0.33	0.25
1.000	0.90	0.80	0.70	0.60	0.50	0.40	0.30	0.20	0.10	0.00
1.500	0.88	0.75	0.63	0.50	0.38	0.25	0.13	0.00	*(0.12)*	*(0.25)*
2.000	0.85	**0.70***	0.55	0.40	0.25	0.10	*(0.05)*	*(0.20)*	*(0.35)*	*(0.50)*
2.500	0.83	0.65	0.48	0.30	0.13	*(0.05)*	*(0.23)*	*(0.40)*	*(0.57)*	*(0.75)*
3.000	0.80	0.60	0.40	0.20	0.00	*(0.20)*	*(0.40)*	*(0.60)*	*(0.80)*	*(1.00)*
3.500	0.78	0.55	0.33	0.10	*(0.13)*	*(0.35)*	*(0.58)*	*(0.80)*	*(1.03)*	*(1.25)*
4.000	0.75	0.50	0.25	0.00	*(0.25)*	*(0.50)*	*(0.75)*	*(1.00)*	*(1.25)*	*(1.50)*
4.500	0.73	0.45	0.18	*(0.10)*	*(0.38)*	*(0.65)*	*(0.93)*	*(1.20)*	*(1.47)*	*(1.75)*
5.000	0.70	0.40	0.10	*(0.20)*	*(0.50)*	*(0.80)*	*(1.10)*	*(1.40)*	*(1.70)*	*(2.00)*
5.500	0.68	0.35	0.02	*(0.30)*	*(0.63)*	*(0.95)*	*(1.28)*	*(1.60)*	*(1.92)*	*(2.25)*
6.000	0.65	**0.30#**	*(0.05)*	*(0.40)*	*(0.75)*	*(1.10)*	*(1.45)*	*(1.80)*	*(2.15)*	*(2.50)*

Negative figures (in brackets and *italics*) in this table show cases of negative economic rents, due to substantial reduction in productivity. These are cases in which reduction of profits are so high that such profits could not even to cover operating costs and wages, not even before paying the landlords the office rentals.

We may also see from Table 2 that for any reduction of productivity due to thermal discomfort, *Rk/R* is monotonically decreasing for increasing values of *Wa/R*: the wages-to-economic rent ratio. *In other words, ignoring office rentals payable to the landlord, profits decrease more rapidly for offices where ratios of wages to profits are high*.

5. Conclusions

We started off by deducing the relationship between reduced economic rents to productivity drop due to thermal discomfort, based on the standard marginal productivity theory. We then deduced that the ratio of the reduced economic rent to the original, *Rk/R*, is a function of the proportion of reduced productivity, *k*, and the wages-to-economic rent ratio *Wa/R*: as stated in Equation (7).

This relationship allows us to estimate the reduction in profits due to productivity loss, using data of wages and gross operating profits, which are readily available in a normal office. Numerical and sensitivity analysis concludes that the profits before rental payments (i.e. economic rents) decrease sharply for cases where the ratios of wages to such profits are high.

Such rules of thumb allow the decision maker to (a) to estimate the potential profit loss when a drop of productivity due to thermal discomfort is causing alarm; and (b) whether or not to rectify the problem, given the costs of the rectification. This could be done by simply comparing the potential profit loss to the potential cost of installing sophisticated equipment to monitor and control the indoor environment. Further development along these lines, to develop practical tools of implementation, is expected of the next stage of this research.

Sustainability in facilities management

The Valuation and Appraisal of Sustainable Development

Abstract

The property market continues to be unsure about the benefits of environmentally sustainable development and accordingly it is not usually reflected in the property valuation and analysis process. Using the concepts of price and worth, an outline valuation process is developed to assist the valuer to take environmentally sustainable development into account through rent, capital growth and psychic income. Research has shown that lessees are prepared to pay a higher rent for improved comfort and control of the environment. Analysis of market evidence has shown that a psychic element of income can increase prices paid for properties by reducing the initial yield. Taking elements of return including higher rental rates payable by tenants and firmer capitalisation rates acceptable to landlords into account together, it is shown that a property exhibiting the highest environmental design and management principles can achieve a substantially improved property investment worth. These remain to be reflected in the general approach to estimates of market price.

Keywords: price and worth, psychic income, income approach, market sentiment, sustainable development

1. Introduction

The principle of environmental sustainability "implies using natural resources in a way which does not eliminate or degrade them or otherwise decrease their usefulness to future generations, and implies using non-renewable natural resources at a rate slow enough as to ensure a high probability of an orderly societal transition to new alternatives" [1]. The World Bank has used the phrase "development that lasts" in this context [2].

The process of sustainable built asset management is continuous throughout the life cycle of the property. The life cycle comprises "consecutive and interlinked stages of a product system, from raw material acquisition or generation of natural resources to the final disposal" [3]. In the context of property and construction, it is a time horizon which commences with the acquisition of land, includes the design and construction of buildings, and continues with the ongoing operation of the property and ceases with the ultimate demolition or deconstruction and recycling of the property.

In Australia, buildings are responsible for 30% of all raw materials used by society and they consume more than 40% of all energy produced causing more than 40% of all air emissions [4]. Development will not be sustainable if the economic constraints under which the property development process operates are not considered. There is a common perception that there is no demand or support for sustainable development. However, the impact of buildings on the environment requires that the property and construction industry contributes to the ESD culture.

The relationship between benefits and costs is commonly assumed to be an impediment to the uptake of sustainable development. The property and construction industry and its clients tend to focus on short-term gains rather than long-term savings or investment opportunities. Perceived higher initial construction costs and maintenance costs are major obstacles, as they reduce profitability. The anticipated additional cost of ESD features is a reason for the perceived indifference of clients to environmental issues.

In Australia, concern for initial costs is reinforced by the involvement of a number of actors in different phases of building delivery, from development, ownership to occupation of structure. Energy efficiency, for example, is not considered a high priority for potential tenants and the emphasis industry puts on initial costs versus life cycle costs militates against ESD considerations.

Inappropriate financing models or lack of access to capital discourages investment in sustainable buildings. There is also no incentive to act, when often the investor is not the ultimate user who is responsible for energy bills. In addition, energy, like other business related expenses, is tax deductible and the plant and equipment that uses energy is can be depreciated against taxable income. Lenders of capital neglect environmental costs in their assessment frameworks.

The property market continues to be unsure about the benefits of environmentally sustainable development (ESD) and accordingly ESD is not usually reflected in the property valuation and analysis process. Using the concepts of price and worth, an outline valuation process is developed to assist the valuer to take ESD into account through rent, capital growth and psychic income. Research has shown that lessees are prepared to pay 5% to 10% higher rent for improved comfort and control of the environment [5]. Analysis of market evidence has shown that a psychic element of income can increase prices paid for properties by reducing the initial yield [6]. Taking all of these elements of return together, a property exhibiting the highest environmental design and management principles can achieve a substantially improved property investment worth. These remain to be reflected in the general approach to estimates of market price.

It is common for investment valuations to be prepared in association with market valuations the former by DCF and the latter by capitalisation. It has been common to adjust the investment variables in the DCF so that both methodologies provide the same result. This tends to suggest that price and worth are identical (which would be so in a fully informed market in equilibrium and is certainly so for a buyer in that market). But reference to any of the financial markets dispels this notion; transactions occur as a result of differing opinions about price and worth and this is of significant relevance to property.

Sales evidence may be analysed and its results used to value a comparable property in the normal way. But this reflects what the market has been paying for comparable properties; it does not necessarily reflect the normative solution, i.e., what it should have been paying.

First, the paper briefly reviews the findings of a sample of the empirical research in which the costs and benefits of ESD are detailed. Second, the residual analysis methodology adopted for the purposes of this paper is briefly described. Third, the data used in this paper are recorded including current market data. Fourth, the calculations are illustrated using the conventional residual model. Finally, some concluding comments are offered together with some suggestions for further research.

2. Background

Conventional business case decision making tools can be used to evaluate ESD buildings, but they have generally not been used, or used inappropriately. ESD buildings by their nature must be considered over the entire life span of the development, not simply the design and construction stage. Therefore, a whole of life or life cycle cost approach to the evaluation of ESD buildings is appropriate. In simple terms, this is because increased investment in sustainability features of building design can be offset by reduced running costs and potential productivity gains during the occupation of the building. Concentration predominantly on increased capital costs of development for ESD buildings, and use of static business case analysis tools which support this view, leads to inappropriate or inadequate consideration of the total development.

The presumption that ESD buildings “cost more” needs to be considered further. The perception that sustainable design and construction inherently contains a substantial cost premium is considered one of the main barriers to ESD [7]. Due to the fact that the construction industry and its clients generally tend to concentrate on short-term gains rather than long-term savings or investment opportunities, this perception that ESD buildings require higher initial construction costs and maintenance costs, is a major obstacle as this reduces the profitability of the project. Indeed, six Californian property developers interviewed in 2001 estimated that green buildings cost 10 to 15% more than conventional buildings [8]. In terms of capital development cost, there is a dearth of published information as regards the cost premium of ESD buildings. Information currently available tends to support the contention that ESD buildings require additional capital expenditure. Exactly how much extra depends upon the level of sustainability measures introduced, although there are some broad guidelines that can be deduced from the little available information.

The International Netherlands Group (ING) Bank in Amsterdam completed in 1987 is perhaps a pioneer in this field, with passive solar heating and ventilation, cogeneration and waste heat capture, day lit office space and interior cores, rainwater usage etc. The additional cost of these features is estimated at approximately 2% of the development cost [9]. The more recently completed 60L building in Melbourne, touted as “the premier green building in Australia” [10], is believed to have carried a capital cost premium in the order of 5%. An analysis of 33 projects certified as “green” by the United States Green Building Council (USGBC) found on average the capital cost premium is about 2%, although this premium varied from 0.66% level 1 certified buildings, up to 6.5% for level 4 (highest) certified buildings [11]. A further study conducted in the United States by Davis Langdon compared the cost of 45 USGBC certified green buildings with 93 conventional buildings. This study found that that there was no significant difference in the construction costs between the two categories of buildings [12]. This is not to say that ESD buildings will not cost more. The Colorado Court energy and resource efficient affordable housing project in California, estimated that the projects special energy measures cost in the order of 12% of the total construction cost [13]. The proposed Council House 2 building in Melbourne includes $11.3million of ESD features in a total building cost of $51.045 million, a premium of around 20% [14].

Yet there is a large body of evidence which suggests that ESD buildings, whilst having an initial capital investment surcharge, will repay this investment many time over in terms of lower energy and operational costs. The ING bank cost premium payback period was just three months and the annual savings of US $2.9M continue. The building uses a tenth of the energy of it predecessor, and a fifth of that of a conventional new office building in Amsterdam. [9] The Four Times Square development in New York was completed in 2000 and considered “the first skyscraper to embrace standards of energy efficiency, indoor air quality, and sustainable materials use..” is expected to have operational costs of 10-15% lower than a comparable project. The energy efficiency measures are estimated to have a payback period of three years [15]. A report to California’s sustainable Building Task Force, touted as “the most definitive cost benefit analysis of green building ever conducted” concluded that that minimal increase of capital investment of approximately 2% to support green technologies in buildings would, on average over a 20 year period, result in life cycle savings of 20% of total construction costs. Of these savings, approximately 30% (6% of total saving) emanated from reduced energy and resource usage, and 70% (14%) from increased production productivity and health values [11].

The issue of productivity and ESD buildings is an interesting one. Whilst the original thrust of ESD buildings focused predominantly around greenhouse gas emission reduction and associated energy cost savings, more recently the relationship between the internal building environment and production productivity has commanded attention. Clearly there are difficulties in relation to measuring the value of productivity as a function of building environment, due to the complexity of the many factors which contribute to the way human beings function. Whilst energy efficiencies can be measured fairly precisely, productivity of building inhabitants tends to be less certain [11]. Nevertheless, there is a strong band of case-study evidence to suggest that improved building environments support increased productivity.

The renovation of the Reno Post Office in Nevada, undertaken with objective of reducing energy costs, also heralded a 6% increase in worker productivity [16]. The Pennsylvania Power and Light Company incorporated task lighting for their drafting staff. The effect was to reduce energy bills by 73% which in itself produced a return on investment of 24%. But quicker drawing production times, coupled with increased quality and accuracy of work, reduced sick leave and improved worker morale, combined to produce a return on investment of over 1000%. [16]. After PNC Realty Services operated from a new "green" certified building in Pittsburgh, one of the Directors described the benefit of the new facility in terms of productivity and staff – "people want to work here, even to the point of seeking employment just to work in our building. Absenteeism has decreased, productivity has increased, recruitment is better and turnover less" [17]. Closer to home, the new administration building for Melbourne City Council is expected to save $1.12 million pa (approximately $120 per m2 pa) as a result of an increase in staff effectiveness estimated at 4.9% [14]. These benefits are considerable. Unpublished research conducted by Advanced Environmental Concepts found that the cost of sick leave remuneration in Australia in 2000 (excluding cost of replacement staff, disruption of production etc) was estimated to be $1550 per employee, whilst the cost of replacing employees, or staff churn, is estimated to be anywhere from 29 to 130 percent on an employee's annual salary.

But these benefits do not necessarily end with increased productivity and a happier workforce. The ING Bank credits its rise from No.4 to No.2 bank in the Netherlands with the new image the building has presented to the public [9] thereby giving rise to an opportunity to include psychic income. This is an element of return brought about by the benefits of owning and operating a socially desirable asset. This is similar to the benefit of owning a "trophy" property, a sentiment that is recognised by the market usually by the medium of a firmer capitalisation rate. It follows that the benefits of ESD should be recognized by the market and reflected in appraisal methodologies as the ESD culture becomes more widely adopted.

So the issue of productivity and performance in ESD buildings can include many dimensions including reduced staff absenteeism and turnover, increased production output and quality through employee comfort and enthusiasm, to improved organizational branding and public perception. Whilst these clearly have a financial benefit which, although perhaps difficult to measure precisely, is nevertheless very significant, it is becoming clearer that these benefits represent a watershed for ESD buildings. Suddenly a building becomes an organizational benefit, and the people within them are considered to matter, rather than simply a way of housing an organization [18]. ESD buildings are no longer just about reduced emissions or increased productivity, but the people who live and work within them are identified and acknowledged as a fundamental and worthy resource in their own right. And this has another financial benefit – reduced risk to occupiers of the building due to the adverse affects of poor indoor air quality. Clearly this has beneficial implications for the insurance of occupants within ESD buildings and the designers of such buildings. In one notable example, designers of ESD buildings who undertook appropriate training were offered a 10% insurance premium rebate as a reflection of the relationship between design and physical ailments, predominantly due to poor indoor air quality [19].

And thus ESD buildings take on a social dimension, in addition to the financial and environmental perspectives. Such an approach is in line with current trends toward "triple bottom line" reporting procedures. Indeed, such a model serves as apt business case decision making model, and a project deemed feasible under such criteria would no doubt embody the ethos of environmentally sustainable development.

3. Methodology

Residual valuation is adopted to illustrate the effect of considering ESD components of return to establish their worth. Owner-occupiers should see immediate benefits provided by this methodology in promoting their accommodation requirements to shareholders and the community. It is obviously less apparent to investors for the reasons outlined above and market recognition is required in these circumstances. Residual analysis is dependent upon a rearrangement of the developer's equation. The developer's equation may be more fully stated as follows:

Value = (Gross Income – Outgoings) / Capitalisation Rate

Costs = Land + Building + Finance + Marketing + Profit

The developer's equation is often rearranged in order to calculate land value. This is known as residual analysis or residual valuation as the case may be. It ties in with the concept that the return to land, economic rent, is a surplus return. In practice, economic rent cannot be separated from the worth of the land in unimproved terms. Thus the residual value is found as follows:

$$L= V-(B+F+M+P).$$

A hypothetical study using residual analysis is used to compare a conventional office property with an ESD property (see below).

Income occurs in many forms, the major classifications in the property context being:

- rental income e.g. rents for offices, retail space in shopping centres and industrial buildings
- sales income e.g. sales of residential lots or units (flats, apartments, detached homes), subdivided floors in office buildings or units on industrial estates.
- business income where the building is the business e.g. hotels in which income is derived from 'room-nights', food and beverage, dining and conference facilities and so on.

In the context of this paper, value may also be generated by increased productivity and the improved well-being of building occupants.

The establishment of net income for evaluation purposes is stressed. All costs of owning and operating buildings must be deducted to achieve net income and this should include allowances for repairs, preventive and corrective maintenance and programmed replacement of building components. Given that building occupants make accommodation decisions based on total accommodation costs (gross rentals), reduced outgoings should lead to increased net operating income.

The price of land is very much a function of market supply and demand. The residual study also allows for land purchase expenses as well as legal fees for conveyancing and for other associated fees and charges. Land holding costs are also included such as State Land Tax and municipal and water rates.

Feasibility studies are usually prepared in the first instance prior to any building documentation being prepared and it is at this stage that decisions are made about whether or not to pursue particular proposals. Accordingly building cost estimates must be "right" early on despite the lack of detail. All building costs must be allocated here including professional fees (usually around 8% to 12% of building cost).

Whether debt or equity, capital required for building development is all treated as a factor input accruing interest for the time that it is involved in the project. In the early stages of feasibility analysis, capital is considered in two tranches:

- Capital expended on the development from the outset, e.g., land costs and expenses. Interest is charged on the amount for the full development period.
- Capital expended during the development process, e.g., progress payments for building. Here, interest is charged on the amount for half the development period (assuming constant expenditure). Thus the whole of the required capital is not set aside at the commencement of the development process.

Sundry allowances, for either or both sales and leasing, often referred to as ripening costs, are also usually included in feasibility studies. Allowances for agents' commissions will be required (10% to 15% of the first years' rent for a leasing commission and 1% to 2% of the sale price for a sale commission) in addition the costs of advertising and promotion.

An allowance may also be made under this heading for the letting up process. It is rare that a building is fully precommitted so that the full rental is paid from the date of completion. Usually an allowance is made for vacancies or the business starting up process. Any leasing inducement required could also be accounted for here.

The profit motive is of course the main driver to building project development. Profit constitutes the developers allowance for risk and return and it is treated as a development costs in residual analysis. Feasibility studies are often computed in order to establish potential profitability.

4. Data

A comparative study of two hypothetical properties, one a conventional office building and the other having ESD features, is provided to illustrate the point of this paper. It is accepted in this paper that the ESD building provides an improved internal environment leading to the benefits reviewed above. The data used in the study are described below.

Market rental values for office buildings are currently around $300 per m2 gross effective after allowing for lease incentives. Property economists currently predict a substantial rise in rents (50% or more) over the next year or two [20]. This will be brought about by the removal of the lease incentives to achieve the levels of current face rentals. A gross rental value of $400 per m2 has been adopted for the conventional building in this study. A 5% rental premium is allocated for the ESD building to reflect the improved internal environment.

An allowance is also made for improved productivity. Referring to the CH2 building in Melbourne, salary savings of $1.12 million pa are estimated and this amounts to $120 per m2. A saving of $100 per m2 is allowed for the hypothetical ESD building in this study.

The outgoings for the ESD building have been reduced from $80 per m2 to $70 per m2 in line with the findings discussed above.

The net operating income is capitalized at 8% for the conventional building. An indicative allowance for psychic income is made by firming the capitalisation rate to 7.75%. It is assumed that both buildings are fully precommitted.

The building costs are estimated at $30 million for the conventional building and $35 million for the ESD building to allow for the additional costs of ESD features as outlined above. The same development period is used for both buildings.

An interest rate of 8% is adopted for both buildings.

Developer's profit is included at 10% for the conventional building and 15% for the ESD building. This reflects an additional risk for the latter despite the improved returns listed above.

5. Results and Conclusions

The residual studies are illustrated in table 1. As can be seen, the land value for the conventional building is $2.2 million and that for the ESD building is $8.8 million. This hypothetical study indicates that the worth of the ESD building ($58 million) is substantially greater than its estimate of price ($40 million) as suggested by the conventional building.

The study shows that in the current market where ESD buildings are valued as though they are conventional buildings, the application of the concept of worth demonstrates that ESD buildings can generate higher values/benefits. As stated above, this concept can be readily accepted by owner-occupiers, but acceptance in the investment market requires further research and analysis including:

- Psychic income
- Improved rental values
- Better technical performance of ESD buildings
- Improvements in productivity and other building occupant advantages.

Construction Finance	interest		8.00%			8.00%		
	construction period		24		$2,400,000	24		$2,800,000
GROSS RESIDUAL LAND VALUE					$32,981,818			$46,346,564
Less rates and taxes					$100,000			$100,000
					$32,881,818			$46,246,564
Less holding costs	interest		8.00%			8.00%		
	preconstruction period		6			6		
					$5,480,303			$7,707,761
					$27,401,515			$38,538,803
Less land purchase expenses			6.00%		$1,551,029	6.00%		$2,181,442
NET RESIDUAL LAND VALUE					$25,850,486			$36,357,361

Parameters of accessibility for sustainable design

D.Eric Pollock,
architect SAFA, reg. arch. California USA no.27090
head, sustainable development, Helsinki Polytechnic, Finland (email: eric.pollock@stadia.fi)

Abstract

Sustainability in the built environment includes taking the basic questions of accessibility into account in the pre-planning stages. Accessibility in the built environment includes physical access, visual access and audio access. Well-planned, accessible buildings and urban environments require less retrofitting and modifications during the building life cycle, and are therefor more sustainable. Institutions that produce planning guidelines are essential tools for planning the built environment.

Keywords: sustainability, physical access, accessibility, design, programming

1. Overview

1.1 Background

In 1992 the United Nations assembled the UN Conference on Environment and Development in Rio de Janeiro, which was based on the Brundtland report (WCED World Commission on Environment and Development 1987. It adopted a number of documents, in particular the Rio Declaration and Agenda 21, the Climate and the Biodiversity Conventions (United Nations 1993) pointing out pathways towards sustainable development. This includes how to reconcile social development and environmental protection in a vibrant but resource-efficient economy. In 1995, the Commission on sustainable development CSD has included the institutional dimension of sustainability to the environmental, economic and social ones, resulting in a four-dimensional concept of sustainability.

The concept used is based upon a balanced approach, aiming to avoid irreversible damage in either dimension with equal emphasis. This is equivalent to not overburdening the carrying capacities of the subsystems underlying the different dimensions. Irreversible damage or exploitation must not take place concerning humans (i.e. secure health and self-realisation), the environment (i.e. safeguard viability), the economy (i.e. guaranty competitiveness and satisfaction of material needs) and the institutional system (i.e. make it reliable, trustworthy but open to evolve). The WSSD (World Summit for Sustainable Development in Johannesburg, 2000) further adopted policies for Participatory openness to major groups, gender and minority equality and the decentralisation of power as prominent examples from Agenda 21. [1]

The UN Decade of Education for Sustainable Development (DESD) was launched at UN Headquarters on 1st March 2005. The UN Secretary-General Kofi Annan noted that, in addition to the international launch, a series of regional and national launches of the Decade will take place during the course of 2005. See http://www.un-ngls.org/decade-education.htm for details.

1.2 Accessibility

Accessibility in the built environment includes physical access such as ramps and elevators, visual access such as comprehensible colours and shapes, and hearing access, such inductive amplifiers for meeting rooms and auditoriums.

When such requirements are understood in the programming stage of building projects, then their actualization through the bidding process into realization is clear. Building Information sheet requirements and standards exist, but their application in a later phase is virtually impossible, without forfeiting architectural quality or needless, costly changes in the working drawing stage. Enlightened owners and developers understand the attractivity of buildings that are accessible to all possible users. The concept of seniors living at home for as long as possible also supportws the idea of accessible housing on the general market.

1.3 Objectives

What steps must the designer take to ensure that a building project contains all necessary parameters for accessibility in the conceptual phase? The requirements of accessibility that are observed at the implementation stage are time consuming and costly. Awareness of standards, guidelines at the municipal, national and European level are absolutely necessary to serve the client with building solutions that have a long life cycle and low retrofit need.

2. Requirements

Existing standards for physical, visual and audial accessibility exist at the local, national (Finnish) levels and the EU level. The Finnish Building regulations RakMK section F1 barrier-free building, and the Dwelling design regulations G1 require that all persons are allowed access to all public, service and business buildings and sites. The RT Standard sheet Accessible mobility and environment RT 09-10692, Nov 2002 and (new version 2005) covers the requirements for access routes, parking spaces, ramps, stairs, lifts, entrances, doors, toilets, saunas, meeting rooms, hotels and dwelling spaces. [2]

EU building standards for accessibility are given as recommendations, such as The European Design for All **e-Accessibility** Network (EDeAN), established in July 2002, in accordance with one of the specific goals of the **eEurope 2002 Action Plan.** The Action Plan was agreed on and committed to by the European Commission and all the member states**.** One of the action points included in the plan was to "ensure the establishment and networking of national centers of excellence in design-for-all and create recommendations for a European curriculum for designers and engineers".

EDeAN was primarily created to provideinput for European Curricula in Design for All, a forum for Design for All issues, idea sharing through joint activities such as conferences, symposia and exchanges of students and scholars. EDeAN is also charged with fostering awareness and promoting changes of culture in the public and private sectors. It will also establish links with appropriate education channels to embed Design for All best practices in new curricula. Through a series of common activities and proposals, it is hoped that the network will become a cohesive group that can effectively work toward the advancement and excellence of Design for All.

The eEurope action Plan section 2c. states "Participation for all in the knowledge-based economy states that as the knowledge-based economy advances, the exclusion from ICT becomes more and more a barrier to economic, employment and social opportunities and to using public services. Disadvantaged areas and groups are at higher risk of lagging for various reasons including low-income and poverty, lack of ICT infrastructures, awareness and training opportunities, or difficulties of access because of disabilities. On the other hand, ICT can overcome barriers of distance, distribute more equally knowledge resources and generate new services for citizens with special needs. . . Thus, the risks of the digital divide need to be transformed to digital opportunities by actions focussed at disadvantaged groups and areas. Accessibility to ICT and on-line information and services, taking particularly into account the needs of people with disabilities, is a precondition for ensuring an Information Society open to all. In this respect, governments have to take a lead to ensure equal opportunities of access". [3]

3. Accessible projects

Two Projects which have observed the standards of accessibility in the pre-planning stages are Helsinki Polytechnic Art and Media building TAVI and the IIRIS center for the Visually impaired.

The Helsinki Polytechnic Art and Media building TAVI extension at Hämeentie 161 in Helsinki is a 1625 m2 three-storey extension to an existing building. The students are very creative, and can often be found on evenings and weekends studying. Both the owner and the architect understood the parameters of accessibility, which made the design process from schematics to working drawings without major changes for accessibility reasons. However, the building review board required that the floor levels of the building be lower than the existing ones, to avoid excess height. This caused the need for ramps, but were made at the maximum slope of 1:12.5. The building has an accessible lift and WC.

The Finnish Federation of the Visually Impaired (FFVI) service center IIRIS is a special service provider with a social element as well as an advocacy organization for the blind and the partially sighted. The aim of the Federation is to secure the blind and visually impaired an equal status with other Finnish citizens. To achieve this the Federation seeks to improve the capabilities and skills of the visually impaired, while also trying to influence the society at large. Particular attention for problems of glare, lack of contrast and orientation have been adapted into the building design. Other physical accessibility questions such as ramps, accessible toilets, and services for the blind are also an integral part of the building. [4]

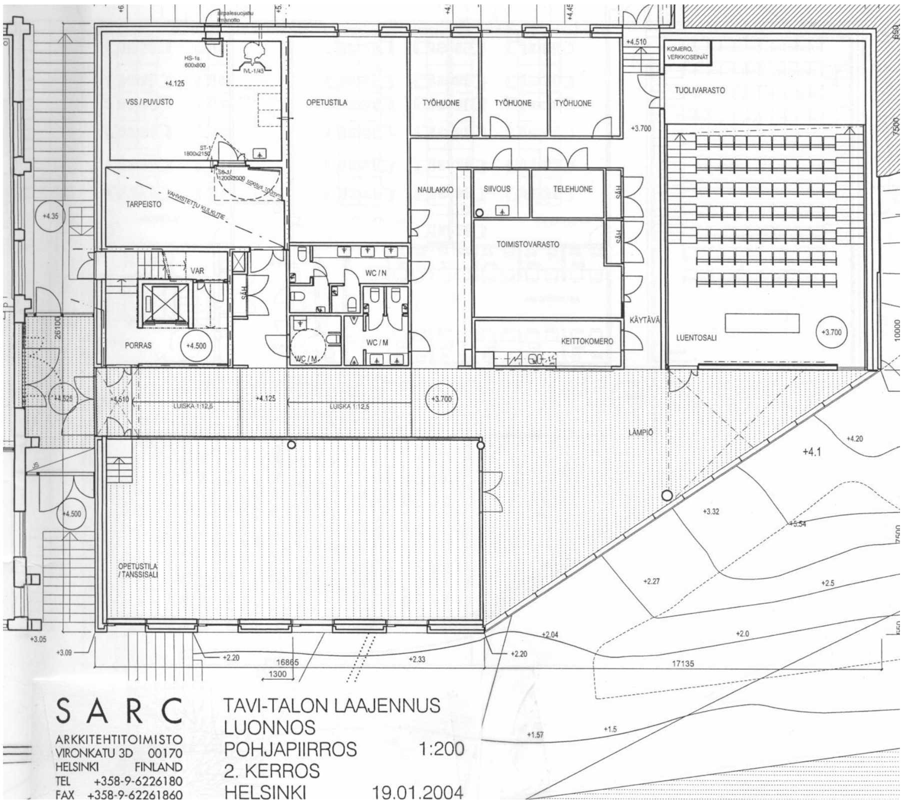

Figure 1: Floor plan of the Art and Media extension, Helsinki Polytechnic

Figure 2: Finnish Federation of the Visually Impaired, Iiris building

4. Results

In the two projects shown, the owners strategy and the designers professional ability to understand the needs of physical and digital (internet) accessibility were incorporated into the design project brief. Space requirements, budgets and services were designed with accessibility in mind as part of the design process, not as an extra permit phase hindrance. The finished buildings will have a longer life cycle with less costly retrofitting, because the design process included all needs of present and future users.

5. Conclusions

Owners and designers that understand both the law and the reality of accessibility in the workplace, schools and dwellings can include accessibility into their projects in the schematic phase, rather than repair buildings later for special users. Designers can refer to the accessibility parameters given, and refer to standards and recommendations to check their projects for their level of accessibility.

Life-Cycle Values

Sakari Pulakka,
VTT – Technical Research Centre of Finland (email: Sakari.Pulakka@vtt.fi)

Abstract

Life-cycle values are mainly caused by combination of location and most significant characteristics of the facility. Life-cycle economical, energy-saving, ecoefficient, healthy and social facilities are quite similar: durable enough and desirable with functional, change-flexible and unrestricted spaces as well as reliable, advantageous and undamaged systems and other products and materials.

Life-cycle value analysis will be utilized by different kind of organisations in building and facility trades when comparing concurrent technical solutions with each other and making cost-effectiviness, profit and cash flow analysises. The life-cycle economical comparisons should be focused on those characteristics and products with real importance.

Advicing shall be organized through many kind of channels and training programmes.

Keywords: Life-cycle cost, life-cycle economy, values

1. Introduction

The Life-Cycle Value model presented is based on results in networking projects (Table 1) most important of which LCC for building trade (www.LCC-bygg.com) and LIFETIME (www.ril.fi/Resource.phx/tietop/lifetime.htx) as well as working in ISO (15686-5) and CEN (TC348) - standardisation expert groups and developing so many kind of LC-tools.

Life-cycle valueing will be utilized by different kind of organisations in building and facility trades when comparing concurrent technical solutions with each other and making cost-effectiviness, profit and cash flow analysises.

2. Objects of Life-Cycle Valueing

Life-Cycle Valueing is a tool for value-managing of facility-based human terms, quality, culture and economy (Figure 1).

The figure 2 outline examples of objects for life-cycle based decision making within the area of facility maintenance. The life-cycle economical comparisons should be focused on those characteristics and products with real importance.

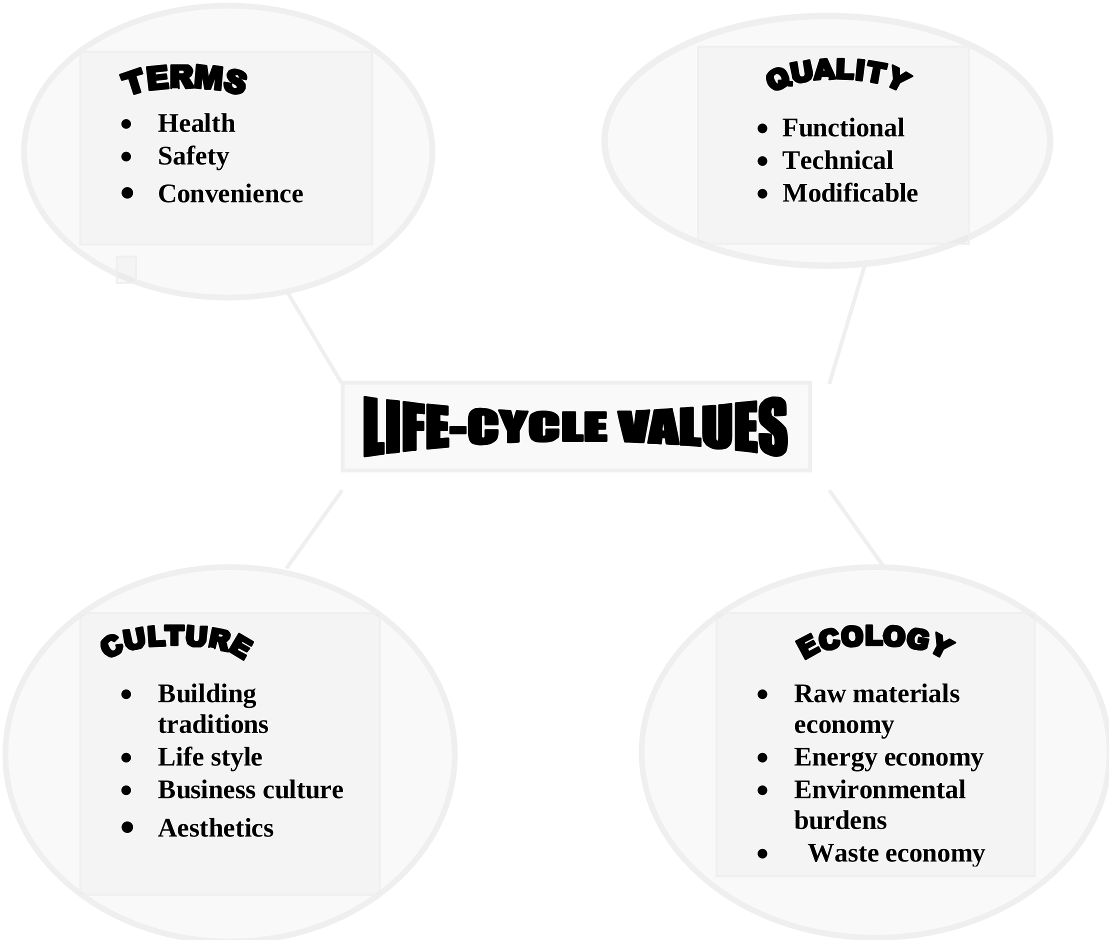

Figure 1: Value factors

In *facility investment* and space acquisition the main interest is concentrated on location, use of spaces and the most essential characteristics (Figure 3). The calculations will also be utilized by comparing possible life-cycle tenders.

Product selection shall be concentrated with facades and windows, base floors and roofs, separation walls, coatings, furniture, ventilation, heating and electrical systems and routings as well as information systems.

By *use and maintenance* the important life-cycle areas are planning, use directions of ventilation and information technology and applying right maintenance methods.

Facility development shall be based on *condition determination*, suitable new construction practises and definition of wanted functionality. The solutions are mainly based on original state of the building: appearance, space complexes, level of energy consumption, modification rate and other technical settings. The life-cycle advantageousness shall be compared with corresponding new house.

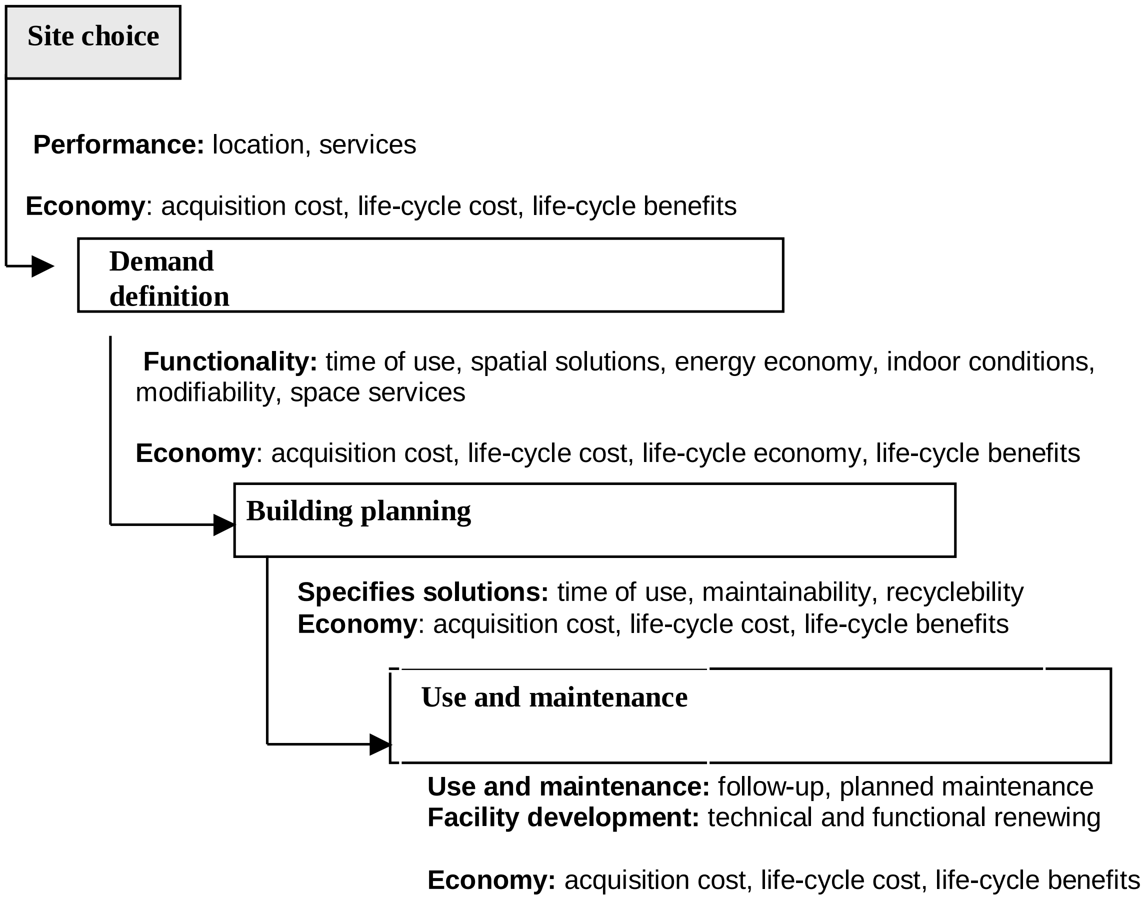

Figure 2: Focusing of life-cycle based decision making

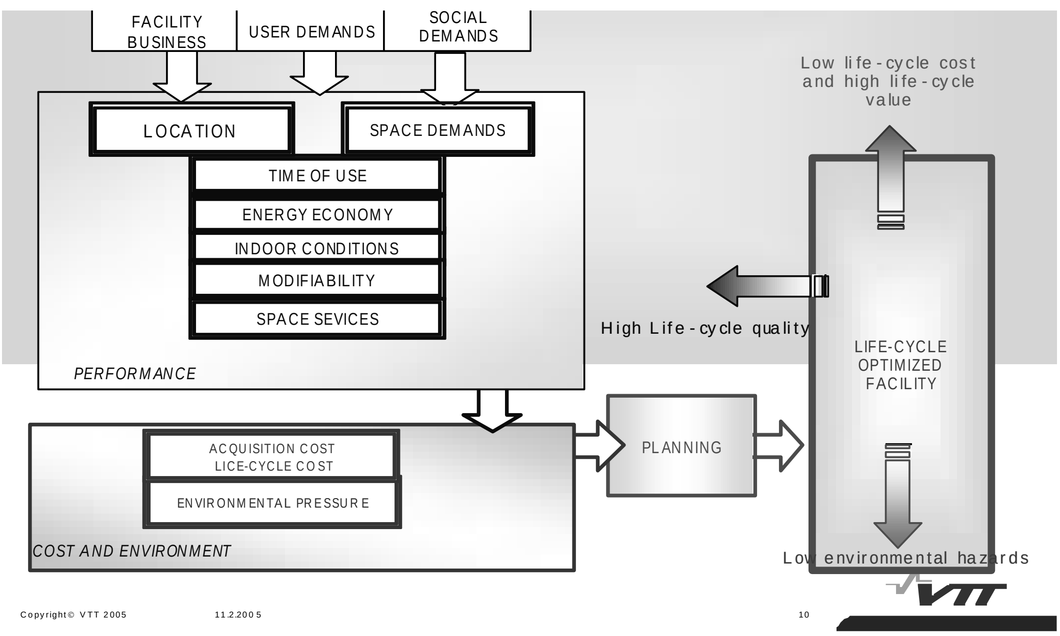

Figure 3: Methods of Life-Cycle Valueing

3. Methods of Life-Cycle Valueing

The LC- method is primary based on CEN/TC 348 (Facility Management) and ISO15686-5 (Whole Life Costing), other manysided international co'operation as well as numerous national development, networking and tooling activities. It includes following definitions:

- **Life-Cycle Costs** (total cost over a technical, economic or functional life-cycle) or Whole-Life Costs (total cost over the whole life of facility, building or component) are usually caused by acquisition, operation, maintenance, modification, renewals and environmental needs for building, system or product (Table 2) as well as possible disposal. The same classification may be applied also in case of facility development as well as individual acquisitions. Present value calculation (all costs accuring within a chosen period of time discounted to a current cost level using a relevant discount rate) is the primary method for life-cycle costing. And, annual costing is fair for cash flowing.

Table 2: Classification of life-cycle cost

Type of life-cycle cost	Description
Acquisition cost	Investment including all material, labour and sub costs caused by acquisition of facility, product or material. If the length of life cycle is lower than lifetime, the acquisition cost include only the repayd share.
Funding cost	Price of money within chosen life-cycle.
Facility management	Salaries, rents, taxes, insurances.
Operating cost	Continual cost caused by the use of building including energy, water, waste, cleaning, other space services etc.
Maintenance cost	Time-planned maintenance and renewing of components.
Modification cost	Cost of spatial modifications.
Development cost	Improvement of technical systems, building parts and/or environment through demand management and building condition charting.
Risk cost	Unexpected cost caused by moisture, fire, storms, breakings of systems etc.
Environmental costs.	Possible needs for soil refreshment and sheltering, use of raw material, cost of demolition and recycling etc.

- **The length of life-cycle** is typically 10 or 25 years. Functional life-cycle may be short, many social analysises mean very long life-cycles. The choice of life-cycle will be based on real needs of decision making: Budgeting time, Loan time, Permanence of actions, Period of facility development, Time for life-cycle planning,…. The life-cycle has a remarkable influence on cost distribution (Figure 4).

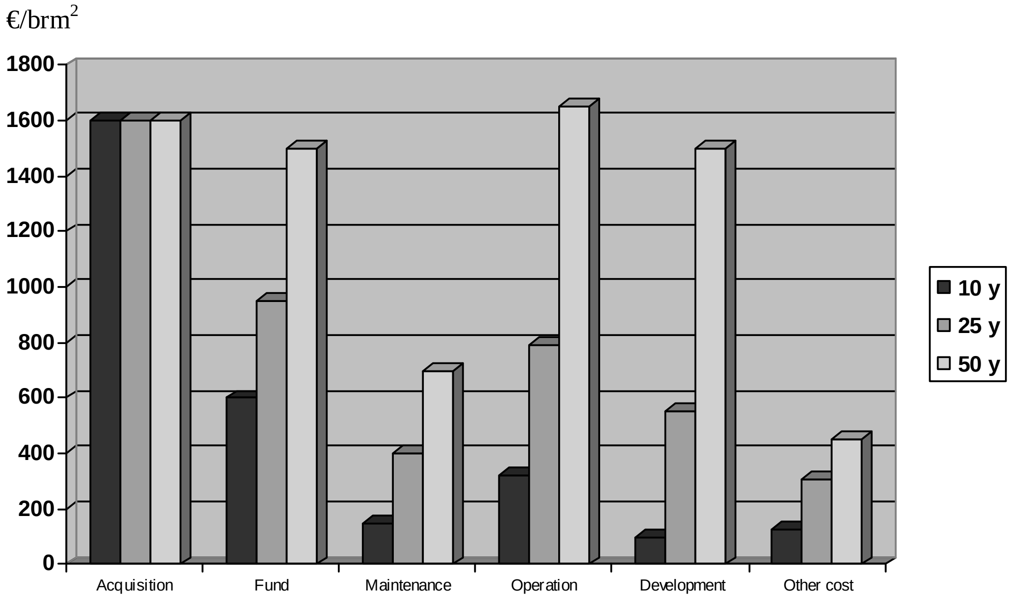

Figure 4: Division of life-cycle costs in different life-cycles

- **Real rate** (nominal rate – inflation) is based on real need and price of money**.**
- **Life-Cycle Economics (LCE)** may be calculated as difference between Life-Cycle Income (LCI) and Life-Cycle Cost or directly as difference in life-cycle costs

$$\mathbf{LCE = LCI - LCC} \text{ tai } \mathbf{LCE = LCC_{diff}}$$

- **If the Resale Value (RV)** is taken in account (for example based on differences in functionality characteristics, remaining life time and possible space service value), **Life-Cycle Profit (LCP)** is the sum of life-cycle economics and difference in resale value:

$$\mathbf{LCP = LCE + RV_{diff}}$$

- By means of profit calculation may be defined **Profit rate** and **Payback time**.
- **Life-Cycle Benefit** is the best relation between performance characteristics, acquisition and life cycle cost, possible life cycle incomes and effects on resale and Environmental Hazards (EH). It may be calculated by means of equation

$$\mathbf{(LCI_i \times RV_i)/(Aq_i \times LCC_i \times EH_i)}$$

- The **sensitivity analysis** may be based on: optimistic ***–probable–*** pessimistic

Possible economical **risks** on different levels

- Advancement of resale value, permanence of characteristics, maintainability and chances of valuation and combatibility of systems with further needs for facility management.
- Mistakes concerning building planning, accessibility of building products, operative experiences, damage riskability and way of use.
- In production process insufficiency of professionals, problems with acquisitions, actions and transfer of project start towards winter time.
- In use and maintainance underprizing in planning phase, defaults of use and maintenance directions, unexpected rises of prises, larger and careles use of systems, unexpected damages and problems with usability in case of user changes and faults and lacks of maintenance actions.
- In case of facility management a failed consolidation of actions, unexpected damages revealed by demolition and disturbances caused to users.

Life-cycle values are mainly a consequence of the combination of location and most significant performance characteristics of the facility (Table 3).

Table 3: The effects of alternative life-cycle characteristics to the costs compared with ordinary parameters (examples)

Location Southern Finland Life cycle 25 y Real rate 2 % Cost level 6/2005	Acquisition cost **€/m²**	Life-Cycle Cost **€/m²**
Choice of life-cycle characteristics		
*Heating energy economy		
- low-energy level	+20	-30
- minimum energy level	+50	-20
* Inner climate		
- quality class S3	-50	-75
- quality class S1	+80	-120
* Modification rate		
- spacially modifical	+90	-25
- very modificable	+150	+10
* Levels of inner quality		
- high class	+150	+250
- representational	+500	+750
Choise of products		
* Facades		
- highclass facades	+100	+ 130
* Windows		
- energy saving windows	+15	-20
* Effectiviness of heat recovery		
- effectivity 40 %	+5	-8

As an **application example** of life-cycle optimization (acquisition cost, price of money, life-cycle cost, life-cycle economy, profit rate) has been compared a typical office building to a house with better functionality (Table 4). That has been reached by means of life-cycle optimized technical solutions including effects on user activities. For example better inner climate and lower energy consumption is based on interactive ventilation system with excellent automatic control engineering, good insulation ofbase floor, walls, roof and windows as well as effective heatrecovery of ventilation. The inner temperatures are adjusted to stay stable. And longer time of use is based on sufficient structural durability, higher rate of modifications and low riskability of any kind of damages.

As *economical parameters* are calculated

- real and relative effects on acquisition cost and life-cycle cost
- relation to the multiplication of acquisition cost, environmental hazards and life-cycle cost

As conclusions may be generalized that a life-cycle optimized office building compared with a traditional office building

- is 10...40 % more expensive as acquisition
- means 0...20 % higher life-cycle cost
- makes it possible to have 10…30 % higher life-cycle incomes
- has 15...50 % higher resale value
- is very advantageous as investment
- is very cost-effective when observing also environmental hazards
- means as copied remarkable benefits to society

More over it has been noticed that the officeworkers have less symptons and a little better productivity because of better inner climate, high level of information technology, maynsided space services and better work satisfaction.

As an ordinary building falls into decay and goes out of date, a life-cycle optimized building ages worthly and and intelligently.

Table 4: Example of calculating life-cycle economy of life-cycle optimized office building compared with an ordinary

		Traditional building	Life-cycle optimized building
Location	Southern Finland (Vantaa)		
Building type	Office building with steel frame		
Area	2 000 brm²		
Life cycle	20 y		
Realrate	5 %		
Portion to be financed	70 %		
Cost level	6/2005		
FUNCTIONALITY			
Time of use		50 years	80 years
Modification		modular	free
Relational energy consumption		100 %	75 %
Inner climate		ordinary	excellent
Space services		ordinary	manysided
RELATIONAL ENVIRONMENTAL EFFECTS			
Emissions CO_2 eq.		0,60	0,45
Unrenewable energy resources		0,20	0,15
Wastes		0,10	0,07
Other use of natural resources		0,05	0,04
Environmental risks		0,05	0,03
Environmental **H**azard index (**EH$_i$**)		**1,00**	**0,74**
ECONOMICAL EFFECTS		€/a/m^2	€/a/m^2
Acquisition cost **Aq**		**85**	**110**
Funding cost		36	46
Facility administration cost		5	7
Maintenance cost		14	12
Operating cost			
Heating energy		5	3
Electrical energy		10	12
Other operation cost		8	10
Modification cost		25	3
Environment cots		3	2
Lif**e**-**C**ycle **C**ost	**LCC**	**191**	**205**
Life-**C**ycle **I**ncomes	**LCI**	208	240
Life-**C**ycle **E**conomy	**LCE = LCC$_{dif}$**	**+17**	**+35**
RELATIONAL DIFFERENCES			
Acquisition cost index	Aq_i	1,00	1,29
Life-Cycle Cost index	LCC_i	1,00	1,08
Life-Cycle Income index	LCI_i	1,00	1,16
Resale Value index	RV_i	1,00	1,45
Life-Cycle Benefits	**$(LCI_i \times RV_i)/(Aq_i \times LCC_i \times EH_i)$**	1,00	**1,63**

4. Conclusions and suggestions

There are different needs for life-cycle based decision-making on different levels of activities to be utilized in different kind of organisations. LC-systematics should be based on ISO15686-5 and CEN/TC 348 when applicable.

As the starting point of generalizing life-cycle based decision making is to specify concepts and calculation model as far as focusing the most essential life-cycle characteristics on different levels of facility business. They also cover the most important objects of technology development. Generalizing of life-cycle contracts shall happen at the same time both in producing companies and in client organisations.

Town planning and realistic population forecasting have the most remarkable importance on time of use of building stock. Also compact and complimental society structures are the way to save several thousand euros per habitant during 30...50 years. So areal life-cycle optimization is necessary next to individual building planning. For example the transfer towards ecoeffective society takes at least 25 years. Generalizing of life-cycle optimized facility concepts should mean

- Reduction of heating and electricity energy making it easier to optimize energy management and increase importance of renewable energy resources.
- Increase of both GNP and employment and transferring labour inputs from energyproducing countries to homelabd and from wasting to recycling services.
- New kind of business possibilities (for example building concepts, coating structures, recycling products).

Life-cycle economical, energy economical, ecoefficient, healthy and social facilities are quite similar: durable, energy-saving and desirable with functional, change-flexible and unrestricted spaces and reliable, advantageous, undamaged recyclable systems, other products and materials. There shall be combined the most economic and ecoefficient performance characteristics to the life-cycle optimized technical solutions in the bestpractise (or nextpractise) building concepts.

The public sector has a central role in promoting life cycle advantageous solutions through its own production and giving directions and building codes. This requires commonly approved technology foresight systematics. The private sectors are applying directions and codes in life-cycle optimized ways and seeking new areas of business which aim at high profits through intensive innovation processes. This means growing international value networking.

Advicing towards life-cycle valuable solutions shall advanced through multisided channels and training programmes. The role of innovation technology is also increasing:

- Product information databases (for example LifePlan)
- Web –based costing tools (for example BeCost)

- Product modelling (for example RYHTI –HVAC –Costing tool)
- Mapinfo based space-costing (for example TILASUKU –tool)
- Simulation tools (for example VTTHouse -tool)
- Client-Demand management (for example EcoProp -tool)

A review of sustainability in construction and its dimensions

Amr Sourani,
Research Scholar, Dept. of Civil and Building Engineering, Loughborough University, Leicestershire, LE11 3TU, UK (e-mail: A.I.Sourani@lboro.ac.uk)
Dr. M. Sohail,
Senior Research Manager, Dept. of Civil and Building Engineering, Loughborough University, Leicestershire, LE11 3TU, UK (e-mail: M.Sohail@lboro.ac.uk)

Abstract

Sustainability is becoming an increasingly important topic for construction research. It is a multi-dimensional topic involving social, economic, and environmental aspects. Sustainable construction generally refers to the application of the principles of sustainable development in the construction industry. Its definitions, interpretations and priorities will be largely dependent on the context of study. Despite the many claims to benefits that sustainable construction can bring, sustainability still seems not mainstreamed in the construction industry. Focusing on context of the UK construction industry, this paper provides an overview on the subject of sustainable construction and introduces some key knowledge gaps around the issues of conceptualisation, linkages to project life cycle, linkages to project management, implementation mechanisms and tools, and construction procurement. It is hoped that if the gaps are filled, there might be a better chance for sustainability to gain its due place in construction. Through a synthesis of the relevant literature, the paper reviews the criteria representing the social, the economic and the environmental dimensions of sustainable construction. Further research suggests the use of the Delphi Technique as a means of developing a common understanding and consensus among experts regarding sustainability criteria that public clients should address in developing a procurement strategy.

Keywords: sustainable construction, review, social, economic, environmental

1. Introduction

Sustainable development has gained an increasing importance in the construction industry. The application of its principles in this industry is generally described as sustainable construction. With the increasing recognition of the importance of the concept, huge number of definitions have emerged. One of the most common definitions of sustainable development is the one introduced by The World Commission on Environment and Development [1] "*Humanity has the ability to make development sustainable – to ensure that it meets the needs of the present* *without compromising the ability of future generations to meet their own needs"*. Focusing on the UK context, this paper provides an overview on the subject of sustainable construction, explores some of the knowledge gaps related to the subject, and presents the criteria underpinning the social, the economic and the environmental dimensions of sustainable construction. Further research is suggested to obtain a consensus regarding sustainability criteria that should be addressed by public clients in developing procurement strategy.

2. Sustainable construction – an overview

In general, sustainable construction is about the application of sustainable development in the construction industry. Raynsford provides a detailed definition for sustainable construction [2] *"Sustainable construction is the set of processes by which a profitable and competitive industry delivers built assets (buildings, structures, supporting infrastructure and their immediate surroundings) which*

§ *enhance quality of life and offer customer satisfaction*

§ *offer flexibility and the potential to cater for user changes in the future*

§ *provide and support desirable natural and social environments*

§ *maximize the efficient use of resources."*

The definition offered by Raynsford puts emphasis on both the process and the product and introduces some aspects of social, economic and environmental sustainability. However, the definition does not fully capture all the aspects implied by the term. A more comprehensive definition is offered by Constructing Excellence [3] which introduces sustainable construction as the application of sustainable development in the construction industry and suggests that sustainable development is *"all about ensuring a better quality of life for everyone, now and for generations to come, through:*

§ *social progress which recognises the needs of everyone*

§ *maintenance of high and stable levels of economic growth and employment, whilst*

§ *protecting, and if possible enhancing, the environment, and*

§ *using natural resources prudently*

Sustainable development embraces the three broad themes of environmental, social and economic accountability, often known as the 'triple bottom line'." [3]

Regardless of the context, sustainable construction always integrates different dimensions, including social, economic and environmental dimensions. However, the interpretation and the priorities of sustainable construction could be largely dependent on the context as the needs and the conditions of the developed countries are widely different from those of the developing world [4]. For example, the principles highlighted by Gibberd [5] have been developed to support sustainable construction in developing countries and in particular South Africa. Another example could be found in the comment offered by Ofori [6] on the paper of Hill and Bowen [7]. Ofori argued that the paper of Hill and Bowen was written to reflect, at large, the point of view of developed countries in spite of mentioning some issues that were relevant to the context of South Africa. Realizing the differences between developed and developing countries, CIB and other organizations published "Agenda 21 for Sustainable Construction in Developing Countries" [8]. According to this Agenda, such differences are related to the problems and their scale, development priorities, capacity of local industry and government, skill levels in addition to cultural and world view issues which influence the understanding and implementation of sustainable development and construction.

However, it seems that there is a lack of awareness about sustainable construction in both the developed and the developing worlds. In the Netherlands, for example, a survey which was carried out in 1998 showed that quarter of architects and half of the building contractors did not know what sustainable construction was [9]. In the US, Landman showed that lack of training and education in sustainable design/construction was one of the primary barriers to more widespread sustainable building practices [10]. Watuka and Aligula, in their study of sustainable construction practices in the Kenyan construction industry, reported that sixty four percent of the respondents on a questionnaire administered to Architects, Engineers, Quantity Surveyors and Contractors indicated lack of awareness about sustainable construction practices [11].

In the context of the UK, promoting awareness and understanding of sustainable construction was declared as one of the objectives of the UK strategy for more sustainable construction [12]. Although awareness within the construction professions and trades was increasing, it was not enough [13]. The need to raise awareness of sustainable development throughout the industry was also highlighted by the publication "Society, Sustainability and Civil Engineering" [14]. Lack of awareness might be attributed to lack of clear conceptualisation of sustainability, lack of clear case for sustainability benefits, lack of integration of sustainability issues in education and training programmes, the traditional perception that limits the understanding of sustainability within the environmental dimension, the dominance of economic drivers in the performance of businesses at the expense of social and economic issues, and lack of long term perspective.

But lack of awareness is not the only barrier to achieving sustainability, which still seems far from reach in an industry considered as "inherently defensive" for change [15]. There is evidence that the construction industry is falling behind other sectors in its attitude towards sustainability [16]. The progress in the field has been hindered by many barriers, such as the industry's fragmented nature, lack of long term perspective, clients' unwillingness to share burden, lack of clear concept definition of sustainable construction and its benefits, regulatory constraints and inconsistent government policy, and lack of fiscal incentives [16, 17, 18].

3. Some knowledge gaps

3.1 Conceptualisation

Some of the recently published material in the literature perceives sustainability as an environmental problem. Consequently, the balance that needs to be created between the environmental dimension and other sustainability dimensions is not adequately acknowledged. There is also a noticeable lack of consensus on the issues underpinning sustainability and its dimensions. Hill and Bowen and Ofori point out that sustainability principles are still poorly defined and argue that these principles are subject to much confusion and disagreement [6, 7]. Ofori [6] argue that this could even be extended to the frequently quoted definition of sustainable development offered by The World Commission on Environment and Development. Lack of understanding and fuzziness of the concept present one of the barriers to the implementation of sustainable construction [17]. Further work, therefore, is still needed to better conceptualise sustainable construction.

3.2 Linking to the project life cycle

Sustainable construction could be better understood if it is aligned to the different phases of the project life cycle. From an implementation point of view, it would be more appropriate to provide such alignment [19]. Among the efforts that addressed sustainability within phases of the project life cycle are: Kibert [20], where the different project phases were integrated within a model for sustainable construction; the publication "Sustainability Accounting in the Construction Industry" [21], where a sustainability accounting plan considered the different phases of the project; Ashworth and Langston [22], where whole of life assessment was linked to the measurement of sustainability. However, there still seems lack of understanding regarding how the principles underpinning the different dimensions of sustainability could fit within the different phases of the project life cycle and what impact this issue could have on the different activities carried out within these phases.

3.3 Linking to project management

Project management could provide a suitable framework to implement sustainable construction, and project managers, through their leading role in the project, could be in an ideal position to promote it [19]. However, there is little evidence that sufficient research has been carried out to establish clear linkages between sustainable construction and project management. An examination of a summary of the UK Association of Project Management's Body of Knowledge [23] would indicate that sustainability does not feature as one of the key topics in that body. It is important to mention here that some of the topics addressed there – such as safety, health and environment; and value management are closely related to sustainability. Yet, they do not provide sufficient coverage of all the issues underpinning it. One of the few attempts to link sustainability to project management was carried out by Uher who developed a project management model for achieving sustainable construction and presented the need to integrate sustainable construction into the traditional project delivery strategy, which is constrained by time, cost and quality objectives [19]. The model developed by Uher focused only on the conceptual stage of the project life cycle. Further work linking sustainability and project management and considering the different phases in the project life cycle is still needed.

3.4 Implementation Mechanisms and Tools

A significant part of the literature discussed the principles of sustainability without sufficient consideration of how they could be implemented, an issue that was also raised by Uher [19]. More work is needed to identify implementation mechanisms and tools and to identify how sustainability could be integrated in the decision making process.

Sustainability has different dimensions and criteria which might be in conflict sometimes. An assessment of sustainability needs to take into account the different criteria underpinning it. This could lead to the use of multi-criteria decision making techniques for assessment. Such techniques were used for solving problems in construction management [24] and selecting construction procurement strategy [25]. In some cases, multi-criteria decision making was used with sustainability provided the basis for choosing criteria for decision making, as in developing SWARD [26]. There is potential to use such techniques to make informed decisions that consider sustainability criteria in problems such as selection of contractor or choice of procurement system [4].

3.5 Sustainability and Procurement

The need for introducing sustainability principles to construction procurement has been increasingly acknowledged. Some publications have addressed many useful issues in the context of sustainability and procurement e.g. the Sustainability Action Plan [27] and Addis and Talbot [28]. However, there still seems a need for further research within that area. For example, the framework developed in the Sustainability Action Plan [27] is based on 10 themes for action. Although these themes provide many useful sustainability principles in general, they do not embrace other principles mentioned in the literature, such as those presented in Tables 1, 2, 3. A more comprehensive and up to date list of the criteria representing sustainable construction that should be addressed is therefore needed. In addition, there is a need to examine procurement systems and strategies in terms of the extent of addressing the objectives of sustainability dimensions. Further research regarding the actions through which sustainability can be better addressed in developing procurement strategies and the barriers facing such actions is still needed. The gap was further discussed in Sourani and Sohail [4].

4. Dimensions of sustainable construction

Despite the variance between the different definitions of sustainability, there is a wide acceptance that sustainable development integrates, at least, three dimensions: social, economic and environmental. Some publications in the literature have mentioned other dimensions of sustainability such as technical sustainability [7, 26], cultural sustainability [6, 15], community sustainability [6] and managerial sustainability [6]. However, in the context of the UK construction industry, the concept of the triple bottom line, which focuses on social, economic and environmental sustainability, remains dominant. Some of criteria underpinning such dimensions are presented below. However, they are rather general guidelines to explore the areas of focus within these dimensions. More effort is still needed to reach a common understanding of the issues representing these dimensions, highlighting the relevance of such issues to the different parties, linking them to the project life cycle and defining how they can be addressed within this cycle. Further research is suggested below to contribute to the effort needed to achieve these targets.

Table 1: Criteria representing the social dimension of sustainable construction

Social sustainability criteria	**Sources**
Protecting and promoting human health through a healthy and safe working environment	[7, 17, 26, 27, 29]
Participation of stakeholders – including community involvement	[15, 17, 26, 27, 28, 30]
Improving the quality of human life including poverty alleviation	[7, 15, 31]
Making provision for social self determination/enhancement	[7, 15]
Training and development – including implementing skills training and capacity enhancement of disadvantaged people	[7, 12, 29]
Seeking fair or equitable distribution of the social costs and benefits of construction – including equal opportunities among different ethnic and social groups	[7, 31]
Seeking intergenerational equity and reducing cost for future generations	[7, 31]
Diversity - including making provision for cultural diversity in development planning	[7, 17, 29, 31]
Social inclusion	[15, 26, 28]
Improving image/reputation	[12, 29]
Employment – including equal employment opportunities	[12, 17, 30]
Recruitment and retention	[27, 29]
Equality	[15, 27, 29, 31]
Accessibility	[12, 28, 30]
Work in occupied premises	[17, 29, 32]
Working environment	[18, 27, 29, 32]
Security – including minimising crime	[17, 28, 30]
Satisfaction – including workforce satisfaction and user satisfaction.	[17, 18, 27, 28, 29]

Table 2: Criteria representing the economic dimension of sustainable construction

Economic sustainability criteria	**Sources**
Financial affordability for intended beneficiaries	[7, 26]
Maintaining high and stable levels of economic growth	[3, 12]
Using life cycle costing	[18, 26, 30, 32]
Creating and maintaining high and stable levels of employment	[3, 7, 12, 28, 31]
Support of local economies	[15, 18]
Investment – including investing some of the proceeds of non-renewable resources to meet the needs of future generations. Investment in green products and in the use of renewable resources.	[7, 31]
Use of Key Performance Indicators (KPIs)	[18, 32]
DQI - Functionality and Flexibility	[18, 30]
Viability	[18, 28]
Profitability	[2, 12, 17]
Competitiveness	[2, 12, 7, 17]
Productivity	[17, 18]
Value for money	[17, 18, 30]

Table 3: Criteria representing the environmental dimension of sustainable construction

Environmental sustainability criteria	**Sources**
Conserve energy	[7, 12, 17, 18, 28, 30, 31]
Conserve water	[7, 12, 17, 18, 28, 30]
Conserve land	[7, 12, 17, 18, 28, 30]
Conserve materials – reuse and recycling	[7, 12, 17, 18, 28, 30, 31]
Resource utilisation	[7, 26, 28, 30]
Consider renewable energy	[7, 17, 18, 30]
Minimise pollution – water, land and air pollution (including noise) – at global and local levels	[7, 12, 17, 18, 28, 30]
Preserve and enhance bio-diversity	[7, 12, 17, 18, 30]
Creating a healthy, non-toxic environment – including high indoor air quality	[7, 18, 20, 30, 31]
Protect and enhance sensitive landscapes including scenic, cultural, historical and architectural	[7, 17, 18, 28, 30]
Re-use existing built assets	[12, 18, 30]
Waste minimisation and management	[7, 12, 17, 18, 28, 30, 31]
Environmental Impact (process and product)	[18, 26, 30, 32]
Transport – including provision of public transport	[18, 30]
Visual impact	[17, 28]

5. Further research

Further research will focus on developing a common understanding of the criteria representing the social, the economic and the environmental dimensions of sustainable construction that public clients should address in developing procurement strategy. This will contribute to overcoming some of the knowledge gaps outlined above in terms of consensus and conceptualisation, linking to procurement as one of the stages in the project life cycle, and linking the to public clients as one of the parties concerned. The Delphi Technique will be used to confirm and evaluate criteria obtained from the literature review and the experts' responses and to derive a consensus, among sustainability experts, regarding the most important criteria

6. Conclusion

Sustainable construction describes the application of sustainable development in the construction industry. As the needs and the conditions of the developed countries are widely different from those of the developing world, the interpretation and the priorities of sustainable construction could be largely dependent on the context. However, regardless of the context, sustainable construction always integrates different dimensions, including social, economic and environmental dimensions. The progress in the field has been hindered by many barriers such as the industry's fragmented nature, lack of long term perspective, clients' unwillingness to share burden and lack of awareness, which seems to be problematic in both the developed and the developing worlds. The paper explored some of the knowledge gaps related to the subject including conceptualisation, linkages to project life cycle, linkages to project management, implementation mechanisms and tools, and construction procurement. It reviewed the criteria underpinning the social, the economic and the environmental dimensions of sustainable construction through a synthesis of the relevant literature. More effort is still needed to reach a common understanding of the criteria, to highlight the relevance of the criteria to the different parties, to link them to the project life cycle, and to identify how they can be addressed within this cycle. Finally, to contribute to achieving such targets, the use of the Delphi technique is suggested to obtain a consensus among experts regarding sustainability criteria that should be addressed by public clients in developing a procurement strategy.

Abstract

In delivering value services to buildings' clients/users, it is vital to gauge building occupants' feed back through post occupancy evaluation studies and walk-through at completion of a project. Such studies are rarely taken in the building industry in the UK apparently for cost reason. On the other hand, there is inkling in the facilities management profession that their role is marginalised particularly during the design processes of buildings contrary to the emerging notion of integration of FM in the design processes of projects. Post-occupancy evaluation studies will help to understand the role of facilities managers not only in the running and maintenance of facilities but further harness their role from initial inception of a project as well as establishing new performance indicators. Post-occupancy evaluation studies were carried out for various buildings including building with innovative sustainability design measures such as the application of hybrid natural and mechanical ventilation technologies. Indoor air quality parameters (temperature, humidity and CO_2) and external wind conditions, temperature, humidity and solar radiation were monitored for the investigated buildings. Structured occupants' surveys and informal interviews with occupants, facility managers and building designers were conducted.

The monitoring results for a building employing hybrid natural ventilation and air-conditioning systems showed that the indoor air quality parameters were kept within the design target range. Due to the short-falls in the control strategy for the hybrid system implemented, it was found difficult to quantify and verify the contribution of the natural ventilation to the internal conditions and, hence, energy savings. It was concluded that the value service for client/users was compromised due to the lack of facilities managers and system and software engineers involvement at early stages of the design processes in the buildings studied. System and software engineers for the building services control were consulted to devise the systems after the completion of the project. It was evident there was a lack of communication between designers, facilities managers and system and software engineers. This has lead to the failure of the control strategies and under-achievement of the full potential of the innovative technologies employed in the design of the buildings. Which further calls for a more holistic life cycle design approach for projects with genuine involvement of FM and IT specialist at the early stage of the design processes.

Keywords: Post-occupancy evaluation, hybrid systems, facilities management, building management system, wind catchers and indoor air quality

1 Introduction

Designing for comfortable internal conditions in buildings is a necessary goal for occupants' good health, well-being and high productivity. The application of passive design principles can help to achieve this goal with less energy consumption and at no extra cost to the building. Such passive design principles include the employment of wind catchers for natural ventilation in buildings. Predictive design tools are commonly used during the early design stage for sizing of systems. These prediction tools, such as thermal models and CFD, are based on steady state conditions and cannot accurately establish the performance of ventilation components in building, particularly when the external and internal conditions are transient and occupants' pattern and activities are changing [1]. It is critically important to gauge building occupants' feed back through post occupancy evaluation studies. Such studies are, rarely taken in the building industry in the UK for cost reason. Government's initiative such as the Building Regulations future performance certification of buildings, air pressurisation and thermo-graphic testing promote such studies to develop energy performance indicators for new and existing buildings [2].

The wind catcher/tower system is a passive ventilation system which not only extracts air using passive stack principles but also utilises the concept of a wind tower to supply air to the spaces as well. Traditionally, wind catchers were employed in buildings in the Middle East for many centuries and they are known by different names in different parts of the region. They were constructed, traditionally, from wood-reinforced masonry with openings at height above the building roof ranging from 2 m to 20 m. With taller towers capturing winds at higher speeds and with less dust [3]. Their application in the hot arid region of the Middle East is to provide for natural ventilation/passive cooling and hence thermal comfort. Wind catchers are traditionally used in places of high urban densities where surrounding buildings obstruct free stream air flow. Traditional wind catchers can be beautiful objects, feasible architectural feature additions to buildings and are inherently durable [4, 5].

In modern design of wind catchers, the two ventilation principles of wind tower and passive stack are combined in one design around a stack that is divided into two halves or four quadrants with the division running the full length of the stack. As the wind direction changes so do the functions of each of the halves or the quadrants in the wind catcher. This renders the wind catcher as being operational whichever way the wind is blowing. As there are no free parts to the wind catchers, their maintenance is very small. It has the benefit of taking supply air at roof level, which is often cleaner than air supplied at ground level, particularly where the building is adjacent to a road in urban areas [5].

Post-occupancy performance evaluation of indoor environment in buildings where innovative technologies such as wind catchers are installed will assist in validating the systems and test their applicability in buildings for natural ventilation. The subjective assessment of occupants' satisfaction with indoor air quality and their ability to control the operation of wind catcher, hence controlling their environment, is an important criteria in validating the application of the hybrid air-conditioning and wind catchers. Furthermore, such studies will enable the understanding of the success/failures in the design and operation for such systems. This further will provide vital information and knowledge for designer and facilities managers. In this paper, sample quantative results of post-occupancy evaluation studies for two buildings are discussed. The two buildings are the Bluewater Shopping Malls, Kent, and the Seminar Room at the School of Construction Management and Engineering building.

2 Description of Buildings

2.1 Bluewater Shopping Malls

Bluewater Shopping Malls in Kent are newly constructed, out off town, shopping malls. The buildings incorporate wind catchers to ventilate the malls. The wind catcher cowl is inspired by the old form of a Kent oats houses as seen in Figure 1. These forms of oats houses were widely used in the area and became an architectural feature in modern buildings around Kent. The building is an innovative application for wind catchers in the UK and provides the opportunity for validating the application of wind catchers in a temperate climate, such as the UK. The building is managed via an Integrated Building Management System. The wind catchers are automatically controlled in conjunction with mechanical ventilation system.

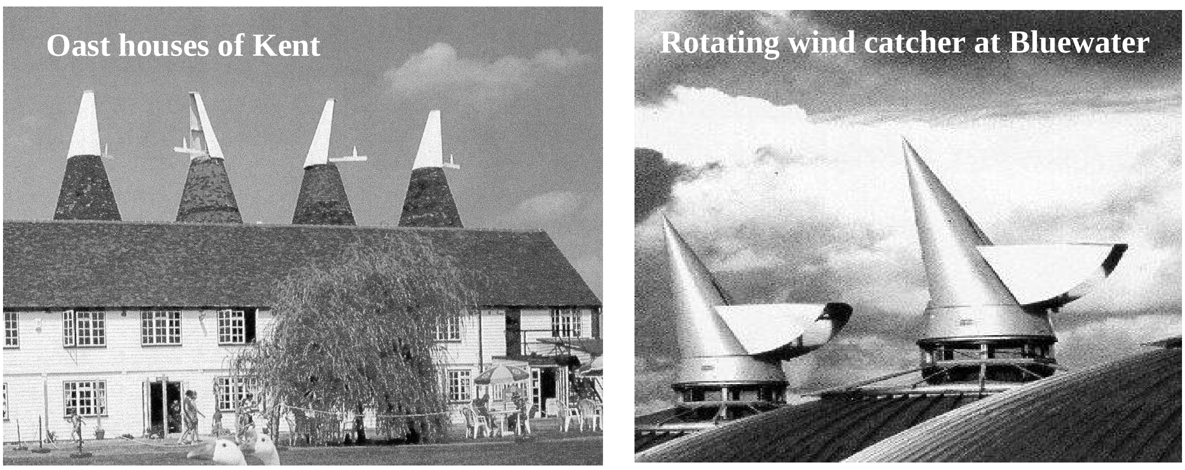

Figure 1: Traditional and modern rotating wind catcher at Bluewater shopping malls, Kent

The Bluewater building consists of three rectilinear form shopping malls with other reception halls and ancinary services (Figure 2). The three malls are forming a triangular shape with south, west and east facing malls and service courtyard in between. Shops were distributed around the three mall streets over two floors. The malls were ventilated using a mixed mode of natural ventilation applying wind catchers and air-conditioning system using the air handling units located on the roof of the buildings. There are 39 rotating wind catcher units distributed along the malls (13 units in each mall street). The performance investigation is carried out by taking the centre of each mall as a monitoring point. Indoor air quality parameters such as temperature, humidity and CO_2 level were controlled by the AHU units.

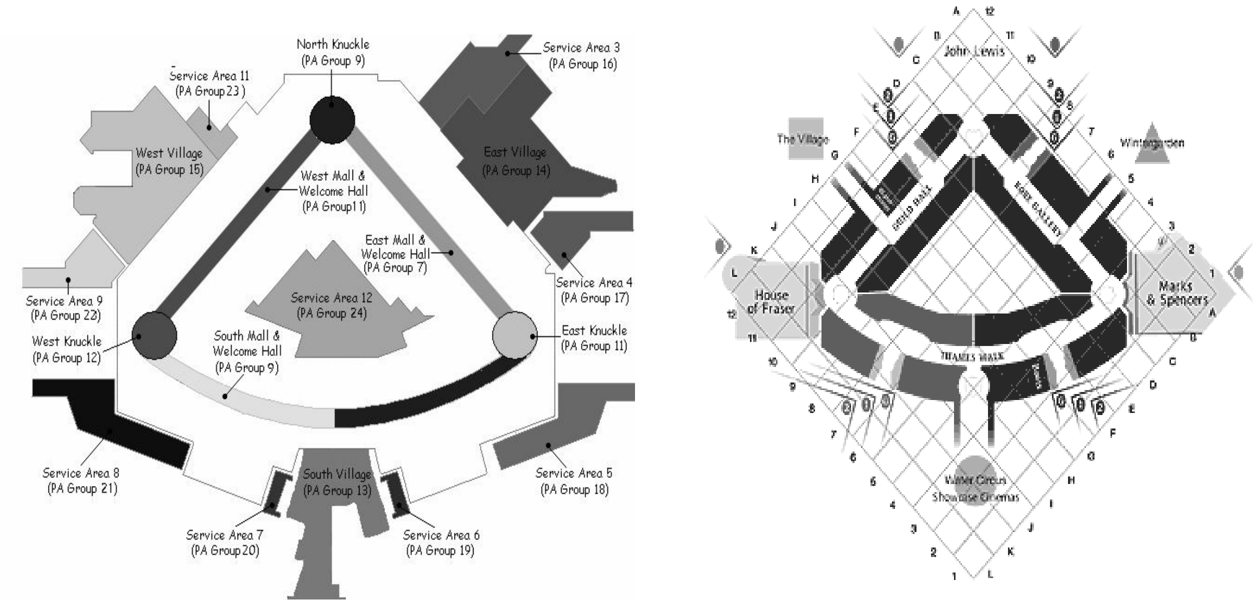

Figure 2: Plans of the shopping malls at Bluewater, Kent

2.2 The Seminar Room 2n09

A combined wind catcher and light pipe (Sun Catcher) was installed in a seminar room at the University of Reading, UK. The 3 storey building was constructed in 1973 and has a split level. It has a rectangular form with two offices running along two corridors, north and south, with atria, service cores and offices in between. The seminar room was newly refurbished and located in the second floor on the North side of the building with a floor area of approximately 61 m^2 and a volume of 211 m^3. The room's external and internal walls are light cream paint blockwork with a pitch roof of 2.5°. The room floor is composed of carpeted concrete with a false ceiling giving a floor to ceiling height of approximately 3.5 m. Two windows are located in the north wall of the seminar room and at adjacent bays each side of the concrete beam in the middle of the room. The windows extend from 1 m above floor level to ceiling providing a glazed area of 1.8x2.5 m. The room's IT area includes 5 computers with intermittent use. Figure 3 shows internal views of the seminar room with the wind catcher segments surrounding the internal light pipe diffuser (Figure 3 a1). The position of the wind catcher in relation to the windows is shown in Figure 3 a2. External view of the wind catcher terminal with the external light pipe translucent dome is shown in Figure 3b. The wind catcher system (1x1x1.5 m) is constructed from glass reinforced plastic with four segments, surrounding the 550 mm diameter light pipe, each with an area of 0.191 m^2 and a total duct area of 0.764 m^2. Each segment was fitted with manual dampers for air flow control operated at ceiling level.

Figure 3: Position of the wind catcher in the seminar room

Indoor air quality parameters were monitored inside the room at two different points. In the centre of the room, internal temperature, humidity and CO_2 concentration were measured using Automatikproducter (AP) and Onset HOBO H08-007-02 indoor air quality logging system. At monitoring point 2 (adjacent to the computer suite) internal temperature and humidity were measured using a complete Davis Vantage Pro weather station, which measure all external conditions including temperature, humidity, wind speed and direction, atmospheric pressure, rain and solar radiations. The weather station is located at the top of the building (2 m above building level, 15 m above ground level and 75 m above sea level). Both the Automatikproducter (AP) and Onset HOBO and the weather station were connected to a PC to facilitate data recording. The Solomat 4100 indoor air quality monitor and data from the weather station at the Metrology Department, the University of Reading, were also used as cross reference with the Davis Vantage Pro weather station data. The measurement of air change rate was carried out using the tracer gas decay method. SF_6 (Sulphur Hexaflouride) was used with CBISS 12 points Intelligent Sampling System (MK2) connected to Brüel and Kjaer (INNOVA) single gas analyser type 3425.

3 Results and Discussions

3.1 Bluewater Shopping Malls

The Integrated Building Management System (IBMS) provided the interface for operating all building equipment and their operations. The system is mainly used to check on the operation of the equipment. Alarms were sent to the IBMS console about any failure and malfunctioning of the equipment such as the air handling units and wind catchers. The IBMS log external weather conditions parameters, AHU status and operation data and internal air quality parameters at an interval of 15 minutes. The IBMS system has been operational for more than three years.

The recorded data is saved into MS Access software. The database is then interrogated via a program in MS Excel developed using MS Visual Basic programming tool. The Excel program provide the data required for any week in the year. The saved database for the year 2001 was interrogated and analysed to investigate the operation of the ventilation system and establish the performance of wind catchers at one central point in each malls street (south, west and east malls). Particularly, their contribution to the indoor air environment and energy savings achieved if any. For investigating the summer operation the database was interrogated for different weeks in the summer period. Figure 4 gives the results for one week in August in the south mall street. The indoor air quality monitors were kept within the design target providing acceptable indoor air environments for the shoppers. The CO_2 never exceeded 1000 ppm, which is an acceptable level according to ASHRAE recommendations [6].

To investigate the co-ordinated operation of the wind catchers with the AHU, fan pressures were plotted across the external wind speed, external temperature and humidity. The results show that the fan pressure was at its highest, approximately 130 Pa, while the recorded external wind speed at its peak with a recorded maximum measurement of 3.7 m/s (Figure 5). It was well established by observation that all the wind catchers units were facing the prevailing wind direction. The results show that in all the malls the fans were at their highest operations at the same time the external wind speed was in the range of 1-3 m/s for the full wind catchers' operation, hence not reducing fan pressure by operation of the wind catchers. This was due to the lack of co-ordination between wind catchers and the AU which is not considered in the IBMS system. This control system failure greatly emphasises the need for the inclusion of facilities managers, software and system engineers at the early stage of the design of the project, i.e. at day one in the inception of the project.

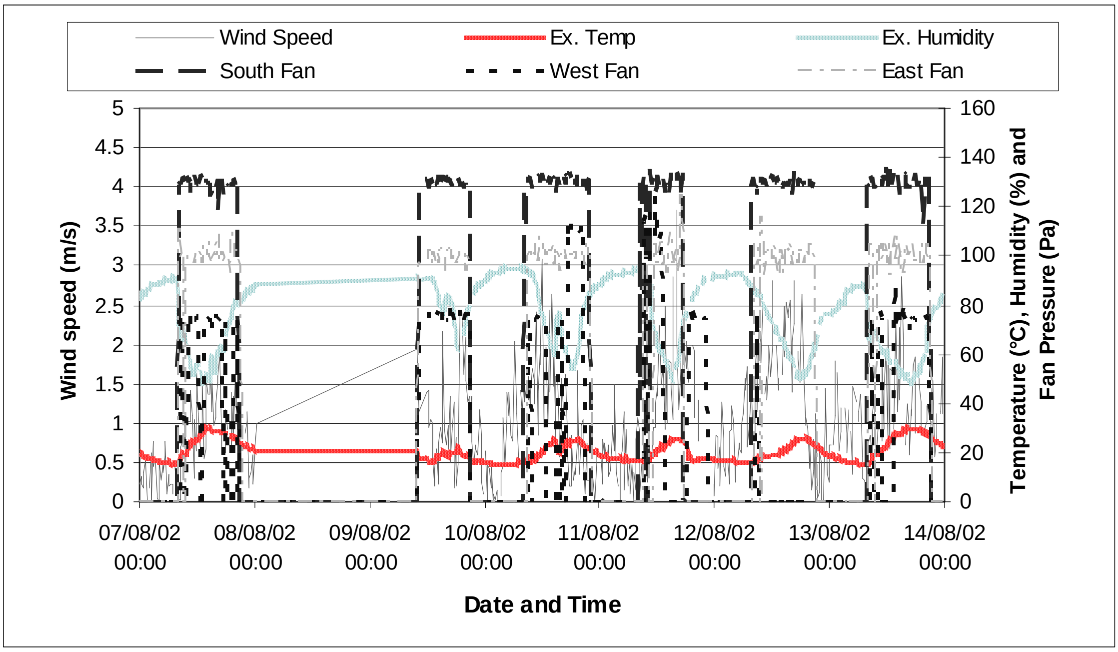

Figure 5: Plotted external wind speed against fan pressure and external temperature and humidity

3.2 The Seminar Room 2n09

3.2.1 Monitoring Results

The wind catcher was tested with dampers fully open and half open while the windows were closed. Tests were also carried out with windows open half the full size (1.8 x 0.212 m) and full size (1.8 x 0.424m) of the wind catcher duct area of 0.762 m^2. The results of two cases are presented in this paper. Case 1: wind catcher dampers fully open/ windows open half duct area during the month of August. Case 2: wind catcher dampers fully open/ windows open full duct area during the month of September.

The combined effect of wind catcher when fully open with open windows was investigated in Case 1 test during the month of August. The size of open windows area was half the size of the duct area of the wind catcher. Figure 6 shows the results for the test in Case 1. While internal humidity and CO_2 levels were maintained at an acceptable level, the internal temperature is higher was higher due to the high external temperature. The combined effect of window/wind catcher operation reduces the internal temperature adjacent to the window. The difference between internal and external temperature was at least 3 °C. The CO_2 level inside the room did not exceed 500 ppm. This is below the ASHRAE recommendations of CO_2 concentration of 1000 ppm [6]. Furthermore, in this case (Case 1), tests were conducted to evaluate the ventilation rate using tracer gas measurement. Further tests for ventilation rate in the afternoon were carried out to establish the validity of tracer decay method in analysing the ventilation rate. Generally speaking the ventilation rate increased during the night and the early hours of the morning and reduced during the warm afternoon as can be seen in Figure 6. This is due to higher temperature difference and relatively high wind speed in the night, thus confirming the suitability of applying wind catchers/towers for night time ventilation in buildings.

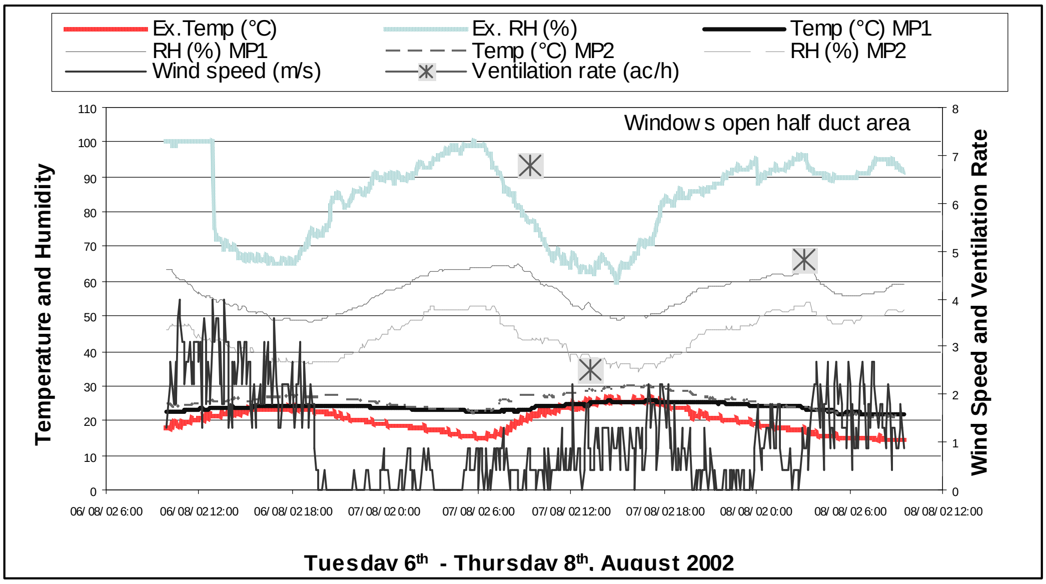

Figure 6: Variation of the measured ventilation rate, wind speed and indoor air quality parameters

The measured local ventilation rates in both conditions of window opening size in this Case show little or no variation when the windows were open the full wind catcher duct area. If the window open area is reduced to half the size of the wind catcher duct area some variation in the localised ventilation rate was observed particularly during the night. The ventilation rate was slightly lower by the window (SP4, 1.6 ac/h). Such a ventilation rate is considered to be insufficient when compared with the CIBSE recommendation of 6-10 ac/h.

Table 1 gives the measured ventilation rate, thermal and indoor air quality parameters in the repeated tests for Case 1. The results showed that the ventilation rate (hence, the performance of the wind catcher) depends on the wind speed and direction. The repeated tests for the ventilation rate in the afternoons gave similar results in a range of 2 – 2.5 ac/h as in the previous tests. The analysis of these results, (taking into consideration the variation of external conditions) showed no discrepancies in air change rate, thus establishing the applicability of tracer gas decay method in measuring air change rate for wind catchers. However, the overall building performance is more complex and depends on other variables, such as the thermal mass of the building, air infiltration through the fabric in addition to windows and the wind catcher opened areas.

Table 1: Averaged measured indoor air quality, thermal and ventilation parameters, repeated Case 1 (windows closed).

Date and time	**ventilation rate ac/h (average)**	**Temp diff**	**Wind speed m/s**	**Direction**	**Ex.Temp (°C)**	**Ex. RH (%)**	**Temp MP1 (°C)**	**RH MP1 (%)**	**CO_2 ppm**	**Solar Rad. (W/m^2**
Afternoon 23/07/2002 1 5:52- 18:40	**1.4 (82 l/s)**	**5.3**	**2.8**	**W**	**18.7**	**81.1**	**24.0**	**59.0**	**488.4**	**143.1**
Night 23/07/2002 20:30:- 23:29	**2.3 (135 l/s)**	**7.1**	**2.0**	**W**	**17.1**	**81.8**	**24.2**	**55.1**	**469.2**	**2.3**
Morning 24/07/2002 00:08 - 03:08	**3.5 (205 l/s)**	**8.0**	**1.0**	**NNE**	**16.2**	**82.1**	**24.2**	**53.0**	**411.6**	**0.0**

In Case 2, the size of the opened window area was increased from half to full duct area. Figure 7 shows the measured indoor air quality parameters in Case 2. The monitored indoor air quality parameters were kept within acceptable levels. The measured ventilation rate in the night was lower than in the afternoon despite the higher temperature difference and slightly higher wind speed. This can only be explained by the variation in wind direction. The ventilation rate is dependent on temperature difference, wind speed and wind direction and, hence, the established performance of wind catchers. However, in some cases the ventilation rate was found to be insufficient with values of 2-5 ac/h compare with the calculated ventilation requirement of 11 ac/h.

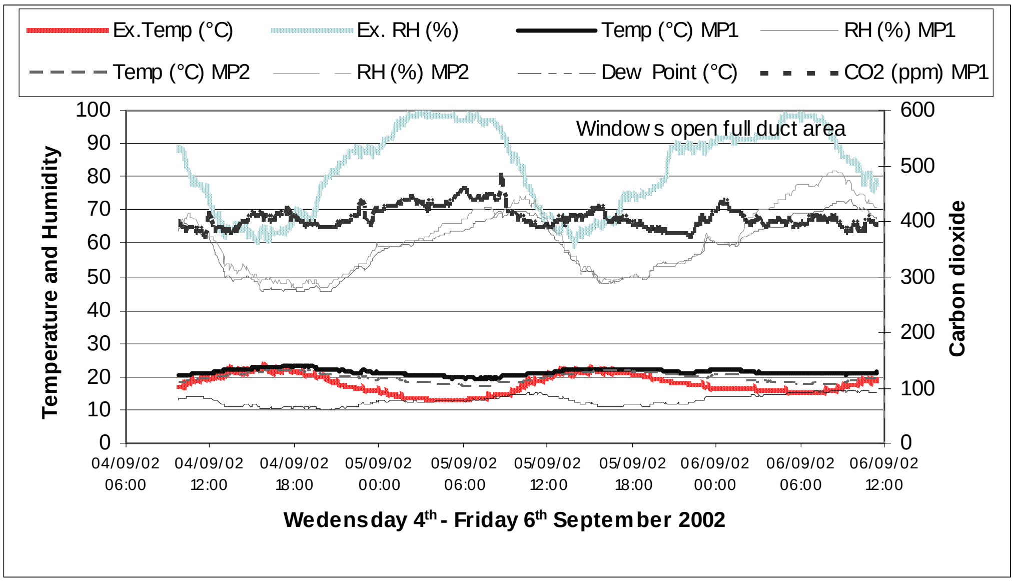

Figure 7: Measured indoor air quality parameters in with windows open full wind catcher duct area, Case 2

3.2.2 Occupants Survey

The study of subjective assessment of the indoor environment in the Seminar Room 2n09 was conducted using structured questionnaire. The questionnaire was structured around four main areas; personal details, thermal environment, visual environment and overall environment in the seminar room. For the data entry, data manipulation and statistical analysis, SPSS software for Windows was used. SPSS is a package developed originally for social scientists using large mainframe computers. Since then it has been refined and redeveloped for different types of computer architecture including Windows [7].

Table 2 gives the nationality versus overall thermal conditions cross tabulation. The majority of the occupants were neutral (41.7%), one third of the occupants felt significantly warm, and 16.7% of the occupants felt only slightly warm. The distribution of overall thermal comfort in conjunction with age is shown in Figure 8. It shows that the majority of occupants in the age range 20 – 40 felt neutral to slightly warm. With regard to the recommendations of the installation of the wind catcher and light pipes systems, 75% of the occupants surveyed welcomed the application of the system for natural ventilation and daylighting in buildings. The same percentage found the air movement inside the room to be acceptable. Interestingly, although 25% of the occupants found the air to be stagnant they still welcomed the installation of wind catchers. This could be due to the environmental awareness of the occupants and their desire to apply renewable energy and low energy architecture systems in buildings. Furthermore, through informal interviews many occupants of the seminar room expressed their satisfaction with the performance of the wind catcher and they changed their sitting area to be under and around the wind catcher in the summer months of 2002.

Table 2: Distribution of nationality with overall thermal conditions

Nationality * Overall thermal conditions Crosstabulation

			Overall thermal conditions				
			warm	slightly warm	neutral	slightly cool	Total

4 Conclusions

Post-occupancy evaluation studies enable the validation of building design processes and operation. Such studies will enable emerging concept of learning from use, which facilitate much needed integrative approach for building design and operation. Particularly, integration of FM and software and system engineers at early stage of the design processes. In this paper post-occupancy evaluation studies were carried out into two buildings; Bluewater Shopping Malls in Kent and the Seminar Room 2n09 at the School of Construction Management and Engineering. Monitoring of indoor environment in real weather conditions was conducted to evaluate the indoor air quality within the buildings together with an occupant survey.

The Bluewater Shopping Malls in Kent provided an innovative application of a wind catchers integrated with the mechanical ventilation system (hybrid). The integrated system is controlled via the Integrated Building Management System (IBMS) which recorded all external and internal parameters into a computer database. The summer month operation showed that the indoor air quality parameters were kept within the design target range. It showed that the fans came into operation whenever the CO_2 level was reaching a set-point of 1000 ppm. The operation of the fan increased the ventilation rate and hence reduced the CO_2 concentration to the recommended value. While the wind catchers were operational, no data was recorded regarding their operation, opening time and position. Though the control strategy implemented was working effectively in monitoring the operation of mechanical ventilation systems, i.e. AHU, it did not cover the integration of the natural ventilation system, i.e. wind catchers, with the mechanical ventilation. Controlling the operation of the wind catchers via the AHU led to isolation of these systems in the event of malfunctioning of the AHU, hence the wind catchers will remain shut. Due to the shortcoming of the control strategy implemented in this project, it was found difficult to quantify and verify the contribution of the natural ventilation systems (wind catchers) to the internal conditions and, hence, energy savings.

The monitoring results and occupant survey conducted in a University seminar room showed that indoor air quality parameters were found to be within acceptable level when the wind catcher was operating. The air change rate measured was in the range of 1.5 ac/h to 6.8 ac/h. These results were complemented with occupants' survey analysis where 75% of the occupants welcomed the installation of wind catchers systems.

The results of the monitored buildings emphasised the importance of harnessing the pivotal role of facilities managers and software engineers in the early stage of design. Looking beyond the figures, post-occupancy evaluation studies provide an ideal tool for processes improvements and understanding of behavioural changes through the various stages of the construction cycle of a project. The studies will provide indispensable knowledge and information to be incorporated into new project and thus achieving the goal of client/user centred integrative design and service delivery.

The Growth of Environmental Requirements in International Facility Management

Mikko Nousiainen,
Helsinki University of Technology (mikko.nousiainen@tkk.fi)

Jaakko Pöyry Infra Consulting (seppo.junnila@poyry.fi)

Abstract

In the service and light industry (SLI) companies have already realised that the use of facilities causes a large share of their environmental burden. This study presents typical environmental objectives within the largest companies operating in the SLI and investigates whether these companies have specified facilities (facility management) as a high priority issue when minimizing company's environmental impacts. In addition, the study aims to determine whether there has been any increase in environmental requirements for facilities management organizations in recent years. We found that the most typical environmental objectives in SLIs are reduction of electricity consumption, waste recycling/re-use, waste minimisation and reduction of climate change emissions, all of which are closely related to the use of the facilities. At present, one third of the companies studied emphasize the role of facilities in their environmental management. When comparing the results between the years 2003 and 2005, we see that the most typical environmental objectives have changed and that more companies have explicitly stated the environmentally important role of facilities or facility management.

Keywords: environmental management, environmental objective, comparison, facility management, service industry

1. Introduction

Corporate social responsibility (CSR) and sustainability are of growing importance for companies operating in the service and light industries (SLIs). For example, the number of organisations certified according to the ISO 14001 environmental management certificate increased thirty-four per cent in the year 2003 to over 66 000, the highest number ever [1]. Companies also publish significantly more CSR reports than they did some years ago [2] [3], and, for instance, over fifty per cent of companies listed in Fortune Global 500 publish environmental reports [4]. CSR includes several fundamental elements, of which the most important are a company's duty to openly report its environmental performance and to minimise its environmental impacts. Recent studies have disclosed that, in the SLI, a large part of the environmental burden of companies is most likely caused by the facilities themselves [5].

Furthermore, it has been suggested that facility management (FM) should have the key role of environmental management of SLI companies, since facilities represent less than ten per cent of company expenses but cause almost a half of the environmental impact of the SLI organisation [6].

Several studies have been conducted about companies' environmental reporting but on a more detailed level environmental management is less studied [7]. Only a few studies have analysed SLI companies' environmental management from the facilities or FM's point of view. In one such study, SLI companies were found not to explicitly state facilities in their environmental management, but yet their most common environmental objectives related closely to the use of facilities [8]. From society's standpoint, SLI companies, such as banks, are an important group of companies and the potential for reducing the environmental impacts of SLI companies has been found to be significant [5].

This study presents the most typical environmental objectives within the largest companies operating in the SLI and investigates whether these companies have specified facilities (FM) as a high priority issue when minimizing company's environmental impacts. In addition, the study aims to determine whether there has been any increase in environmental requirements for facilities management organizations in recent years.

2. Method, material and selection of companies

The study is based on the case study method and environmental information published by SLI companies. The study was carried out as a multiple-case study and by using a time series design. The study has an exploratory approach and embedded units of analysis. [10] Each company represents a case and each named objective an embedded unit of analysis. The data collected related to both qualitative environmental objectives (i.e. to reduce energy consumption, environmental risks) as well as quantitative ones (i.e. the use of energy [GWh], CO_2 emissions [tons]). The data was entered into a matrix and each environmental objective analysed. Quantitative environmental objectives were separated out from qualitative objectives and then the data was analysed by country and by industry sector, special attention being paid to the recognition of facilities FM. Finally, the results were compared with a similar study conducted in the year 2003 and published in 2004 [8].

Altogether, thirty-one SLI companies were included in the study. The companies were selected as being among the five largest, based on turnover, in their respective area, and as having published environmental information. The largest companies were selected because "they are highly visible to stakeholder groups and are often presented as examples of environmental behaviour of the industry as a whole" [11]. The selected companies were the same as those in a previous similar study to obtain better comparability. However, two companies have changed since 2003 because of corporate fusions, so new companies replaced the old ones (Sonera > TeliaSonera, SCC Scandiaconsult > Ramboll) [12][13].

The companies represent three different geographical and four industrial areas. Of these companies, eleven are Finnish, ten European and ten from the USA, and the industry sectors are represented as follows: banks and insurance (eight); trade (eight); ICT (nine); consulting (six). European and American companies were selected on the basis of the Fortune Global 500 list [14], and Finnish companies on the basis of the Talouselämä 500 list [15] (in Finland Talouselämä is equivalent to Fortune or Business Week). European and American consulting companies, however, were selected on the basis of one consulting company's peer group [16], because typically the turnover of consulting companies is too small to reach the Fortune 500 list. Selected companies are presented in Table 1. by country of origin and industry sector.

The study is based on publicly available environmental information on the Internet pages of the companies. Besides Internet pages, the data used also include other available documents on the Internet, like annual, sustainability or CSR reports. The data were mostly collected in the autumn 2004 and reviewed in February 2005.

3. Results

3.1 The most common environmental objectives

In this results section companies' environmental objectives are analyzed first in general and then by companies' geographical and industrial sector distribution. After that, the change in companies' environmental objectives, and the role of facilities and FM, are analyzed. Environmental objectives of each studied company are presented in Table 2.

Almost every company, about ninety per cent, uses environmental objectives, and, surprisingly, about sixty per cent of companies measure their environmental performance by using quantitative environmental objectives (Table 3.). The use of quantitative environmental objectives, in general, is considered as a sing of better capability to manage environmental

impacts, and therefore declare organisation's commitment to environmental management. Companies who have the most reported qualitative and quantitative environmental objectives are Kesko, AXA, Nokia and Deutsche Telekom.

Table 2: Environmental objectives recognized by a company. An empty box (□) indicates a qualitative objective and a full box (■) a quantitative one. A thin square ( ) around a box indicates a positive change and an X a negative change compared to year 2003.

Companies are emphasizing several environmental objectives as a part of their CSR, and the most typical environmental objective in SLI seems to be the reduction of electricity consumption. Almost every company has emphasized it in its environmental management, and over half of the companies also measure their electricity consumption. Other common environmental objectives are waste recycling/re-use and waste minimization. As well, reduction of climate change emissions, environmental requirements in purchasing and minimal water usage are often seen important.

When the results are analyzed in geographically, we see that European companies have recognized more environmental objectives than Finnish and US companies. The difference between European and Finnish companies is, however, quite small if compared with the difference between European and US companies. This is especially true in the use of quantitative environmental objectives. In addition to the most typical environmental objectives, each area also has its own characteristics. Most studied European companies focus on climate change, and in most cases company has a quantitative climate change indicator. In Finland attention is paid to waste recycling/re-use, environmental purchasing and heat energy whereas US companies find recycling/re-use and following the legislation important. The most common environmental objectives in studied geographical areas are presented in Table 4.

Table 4: The most common environmental objectives in Finland, Europe and in the United States.

Finland	Europe	USA
Electricity	Electricity	Electricity
Waste recycling / re-use	Climate Change	Waste recycling / re-use
Heat	Waste	Legislation
Water	Environmental purchasing	Climate Change
Waste	Water	Waste
	Paper	
	Commuting	

Differences exist also between the industry sectors. Banks and insurance companies, ICT companies and trade companies are all almost equally active in their environmental management. The consulting sector is a more passive industry sector, and three consulting companies have no environmental objectives. Excluding consulting, each industry sector has some typical objectives. For instance, banks and insurance companies are interested in commuting, paper use, and environmental requirements in purchasing, while trade companies focus on transportation/distribution and packaging. ICT companies communicate that they follow legislation and are especially interested in minimizing their climate change emissions. It should be noted that all studied ICT are measuring their climate change emissions. The most common environmental objectives in each industry sector are presented in Table 5.

3.2 The change in environmental objectives

Companies' environmental objectives presented in this paper are now compared with the results of similar study, which was published in the year 2004, and which is based on data collected in the year 2003 [8]. We see that SLI companies have now recognized more environmental objectives

Table 5: The most common environmental objectives in each industry sector. The following objectives were equally common in each sector. Banks and insurance: waste, recycling/re-use, water; Trade: transportation/distribution, packaging, recycling/re-use; ICT: climate change, legislation; Consulting: Electricity, recycling/re-use; ALL: climate change, purchasing.

Bank and insurance	**Trade**	**ICT**	**Consulting**	**ALL**
Electricity	Electricity	Electricity	Electricity	Electricity
Environmental Purchasing	Waste	Climate Change	Recycling / re-use	Recycling / re-use
Waste	Transportation / distribution	Legislation		Waste
Recycling / re-use	Packaging	Recycling / re-use		Climate Change
Water	Recycling/re-			Purchasing Water

than in the year earlier. This study evaluated 22 most common environmental objectives, from which fourteen are nowadays used more often than earlier. These are waste recycling/re-use, reduction of climate change emissions and facilities. Facilities is used as a qualitative objective, probably because quantitative measurement is challenging. Some objectives are used less than earlier (Figure 3.).

However, the number of companies, which have recognised environmental objectives, has not changed, so the development has taken place in previously active companies. Companies who have enhanced most the reporting of their environmental objectives are Motorola, Deutche Telekom and Pinault-Printemps Reroute. By contrast, some companies, i.e. TeliaSonera and SOK, share now less environmental information than earlier, mostly because of company fusions.

The total number of environmental objectives emphasized by a company has also risen. Geographically, both European and US companies seem to measure their environmental performance more today than earlier, whereas the studied Finnish companies appear to now use less quantitative environmental indicators (Figure 1.). The trend to use qualitative environmental objectives seems to be mounting in all geographical areas. This trend is also seen when industry sectors are compared; and further it holds true for quantitative environmental objectives. Banks and insurance companies have adapted most new qualitative indicators, and they also seem to measure their environmental performance more than other industry sectors. The consulting sector is an exception since no development can be seen in there. The most remarkable change in environmental objectives has occurred among ICT companies who are emphasizing reduction of climate change emissions and waste recycling/re-use more strongly then earlier (Figure 2.).

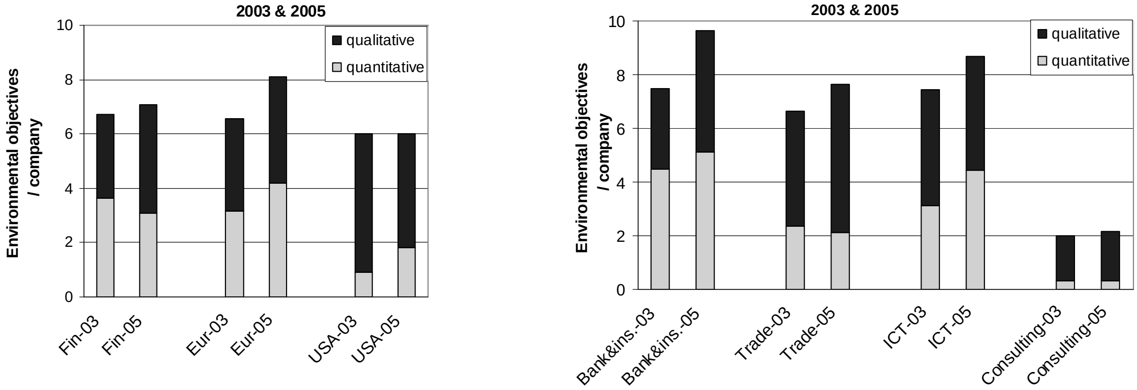

Figure 1. & 2: The number of environmental objectives in Finnish, European and US companies and in different industry sectors in the years 2003 and 2005.

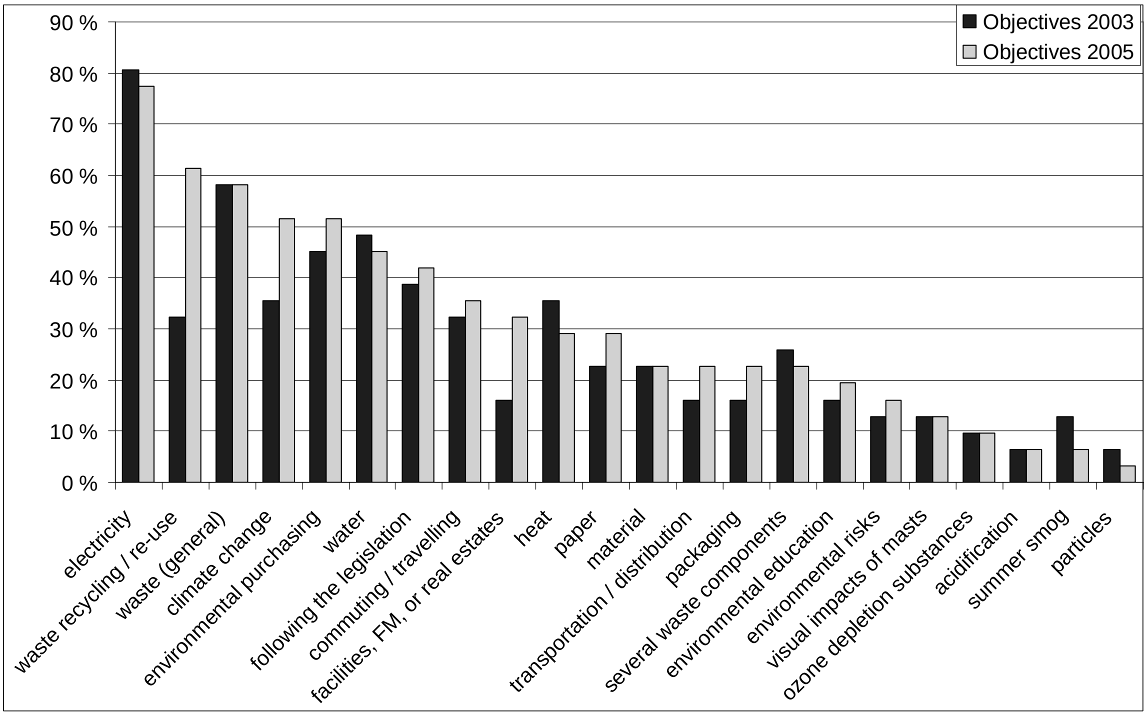

Figure 3: Environmental objectives used by the SLI companies in 2003 and 2005.

Generally speaking, companies have improved their environmental reporting. Most companies, 21 out of 31, have enhanced the available environmental information in their Internet sites. Typically, the companies have improved the availability of quantitative environmental information. Many companies have also activated in their CSR during the last two years, and they are now publishing CSR-reports, using the Global Reporting Initiative (GRI) Guidelines, and striving for a certified environmental management system.

3.3 The role of facilities and facility management

At present, ten out of thirty-one companies have explicitly stated performance of facilities/ facility management as an environmental objective. Four of these companies are Finnish, four

European and two American; five are banks and insurance companies, two are trade companies, and three are ICT companies.

Surprisingly, the greatest growth among all environmental objectives has taken place in facilities/FM. The number of companies who have explicitly stated facilities/FM as an environmental objective doubled since 2003. In contrast, environmental requirements in purchasing, for example, increased very modestly (Figure 4.). The increased focus on facilities, and also on waste management/re-use, indicates that companies aim to improve the environmental performance of concrete and ordinary matters.

Furthermore, some facilities recognized companies are very strongly accentuated facilities or FM in their environmental management. The companies have, for instance, environmental programs and life-cycle objectives especially for facilities, and companies, such as Microsoft and SOK, are using or exploiting building environmental certification systems. Moreover, some companies who have not explicitly stated facilities in their environmental management, are, for example, paying attention to energy usage, implementing building management applications, and even performing energy audits in their buildings. It seems that these companies have indirectly recognised the important role of facilities from the environmental management point of view.

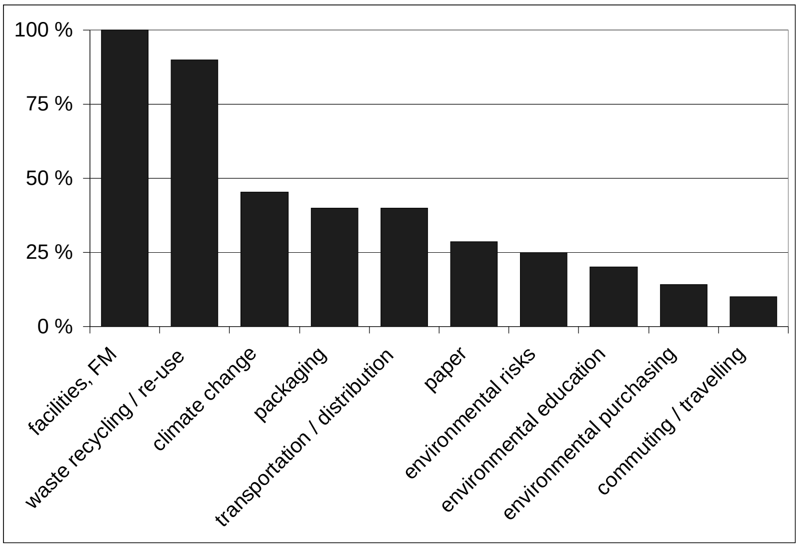

Figure 4: Increase in the use of environmental objectives between 2003 and 2005.

4. Discussion

This study presented the most typical environmental objectives within the largest companies operating in SLI, and investigated whether facilities or facility management have been specified as an environmentally high priority issue in these companies. In addition, the study aimed to determine whether there has been any growth in environmental requirements set for facilities management organization in recent years.

The role of facilities and FM in SLI companies' environmental management is clearly increasing. The number of companies who have explicitly stated facilities in their environmental objectives doubled during the last two years, being now roughly one third of companies. SLI companies are taking a more and more comprehensive viewpoint towards environmental issues, and their most typical environmental objectives are reduction of electricity consumption, recycling/re-use, waste minimization and reduction of climate change emissions. European companies have improved their environmental reporting more than US companies, which in general seem to be less active in their environmental management. However, companies with smaller turnover may not see CRS as important as large companies, and they might be less willing to invest in it. This may be the case also with studied consulting companies.

Buildings sustainability, or environmental performance, is universally becoming a more and more important issue. Interestingly, in the US, the use of the building environmental certification system (LEED) has grown over 30 per cent in 2003 [17], and green buildings are a hot topic in the construction and real estate sector. This study showed a notable increase in the status of facilities in companies' environmental management, which suggests that in the future the importance of facilities and FM will be even more widely accepted, when SLI companies aim to minimize their environmental impacts and emissions. It has already being stated, perhaps commercially, that "senior management will start to see the value of having facility managers who are skilled in green buildings" [17].

Some limitations can be recognised. First, the main limitation relates to the use of only one source of evidence. According to Yin [10], the quality of a case study is always improved when several sources of evidence are used. Second, the selection of companies from each industry sector may have caused distortions because different industrial sector classification is used in Fortune and Talouselämä magazines. The third limitation stems from the very diverse interpretations of the concept "environmental objective". In some companies, environmental objectives are understood as very practical and strict instructions, whereas in others, they are seen as wide-ranging, general statements. Also, companies don't communicate their environmental objectives clearly and unambiguously.

5. Conclusions

Companies' environmental responsibility is becoming an increasingly important issue, and companies are realising the importance of facilities and facility management from the environmental management point of view. This may result in significant changes in the needs and expectations the facility users (e.g. SLI companies) have for facility owners, facility managers and facility service providers.

The practical implications of the results are probably the most substantive for facility and real estate companies. These companies should take advantage of the results when improving their operational practices, planning their future strategies and developing their services.

Refuse Collection Facilities and Health Concerns in Dense Urban Residential Buildings

Dr. Edwin H W Chan,
Department of Building and Real Estate, The Hong Kong Polytechnic University, Hong Kong China (email: bsedchan@inet.polyu.edu.hk)
Miss Grace Lee,
Department of Building and Real Estate, The Hong Kong Polytechnic University, Hong Kong China (email: 04900969r@polyu.edu.hk)

Abstract

Refuse collection facilities and the related management are of particular importance to dense urban residential buildings because they are normally congested and high-rise with noted difficulties with vertical transportation. The issues in concern include property management, cooperation from and convenience of the residents, technology and cost benefit of the facilities. All the efforts in the refuse collection management aim to provide a pleasant and hygienic environment for the resident. However, there is little in-depth study carried out to examine the relationship between the refuse collection facilities and their impact of the health of the residents. This topic was brought to focus after the recent outbreak of the atypical pneumonia, known as SARS in Asia in 2003. Peoples in the region were more concern about their built environment and its impact of their health. This paper present the findings of a study carried out in Hong Kong which compared the popular traditional refuse collection systems and the more advanced automatic refuse collection system. The study was carried out with particular reference to the health issues of the residents. The study found that apart from the consideration of cost, technology and efficiency of the facilities, management of the facilities is the most critical for the success of a refuse collection system.

Keywords: Healthy Building, Refuse Collection, Management, Facilities, Residential

1. Background

After recent outbreak of the atypical pneumonia, known as SARS in Asia in 2003, the public concern about protecting human health and preserving the quality of their living environment had been aroused. As refuse collection facilities are widely recognized as hotbeds of bacteria cultivation, it is worth to examine the relationship between the refuse collection facilities and their impact of the health of the residents, and recommend some ways to improve the refuse collection management in order to provide a pleasant and hygienic environment for the residents. Nevertheless, little in-depth studies are carried out to investigate this issue. This paper present the findings of a study carried out in Hong Kong which compared the popular traditional refuse collection systems and the more advanced automatic refuse collection system, identified the social acceptability and financial viability of those systems, and developed guiding solutions for refuse collection management.

1.1 Overview

Everyday, thousand tonnes of refuse from residences (known as domestic wastes) are generated in Hong Kong [3]. Figure 1 has shown the disposal rates of domestic waste per capita in 1991-2003. Obviously, such huge amount of refuse not only affects the living environment of the citizens but also impose health risks on them and the cleansing workers. Numbers of previous researches indicated that health hazard would be generated from the process of refuse collection [6, 7, 10, 12]. Sigsgaard (1994) also reported that Danish refuse collectors were prone to suffer from allergies, infections and respiratory problems. In order to minimize nuisance and health risk to the cleansing workers, the residents and their living environment induced by huge amount of domestic wastes, refuse should be disposed of properly [8].

Figure 1: Per capita disposal rates of domestic waste in 1991-2003

2. Conventional Refuse Collection Systems VS Automated Refuse Collection System

2.1 Conventional Refuse Collection Systems

Conventional Refuse Collection Systems (CRCS) are traditional refuse collection methods commonly adopted in Hong Kong throughout the years. There are two types of CRCS: one with refuse chute and the other without. For the residential developments with the provision of refuse chutes, the occupants either dump their refuse directly to refuse chute or dispose the refuse at designated areas on each floor. The cleansing contractors then collect their refuse to refuse room on each floor and dumped the wastes to the refuse chute through indoor refuse disposal inlets. The refuse collection bin under the chute would store the refuse temporarily. The cleansing workers transport the refuse collection bins inside the refuse chambers located at G/F of different blocks manually to the central refuse collection point where Food and Environmental Hygiene Department (FEHD) collects refuse daily at predetermined time. For the buildings without refuse chute provision, the residents dispose their refuse at specified locations on each floor. The cleansing workers collect the refuse and package them into larger plastic bags or place them into the collection bins. Then, the bags or the bins will be conveyed to the ground floor by passenger or goods lifts.

2.2 Automated Refuse Collection System

Automated Refuse Collection System (ARCS) is a more advanced type of refuse collection system. It is controlled by centralized and computerized programs [5]. The refuse dumped through indoor refuse disposal inlets on different floors to the refuse chute or outdoor refuse disposal inlets is temporarily stored in refuse storage facilities. The sensors will be triggered once the storage facilities are full and refuse released from the refuse discharge valves will then be transported to the central plant room through underground ductworks by suction of air. The refuse enters into the cyclone type refuse separator which separates the air and refuse for further treatment. The exhaust air is discharged to ambient air after treatment by de-odorizing facilities like carbon filter or chemical scrubber while the refuse is compacted and stored in a refuse container ready for disposal (Figure 2).

ARCS is not a new device for refuse collection in Hong Kong property market. In mid-1990s, the Hong Kong Housing Authority (HKHA) had implemented two ARCS pilot schemes at Wah Sum Estate and King Shing Court and at Shek Yam East Estate respectively. As this system was subjected to positive comments and had enhanced the living environment at that time, HKHA had approved the adoption of ARCS as a standard provision for future public housing estates and Home Ownership Scheme (HOS) courts to enhance their sanitary and environmental conditions since 1998 [4]. Besides, this system was also adopted in several private commercial projects in Hong Kong. For examples, ARCS are installed in Hong Kong & Shanghai Bank Headquarters, Cathay Pacific and Lufthansa flight kitchens, and Hong Kong Science Park, etc.

Figure 2: Routing of refuse and air in ARCS

2.3 Comparison between Two Refuse Collection Methods

2.3.1 Characteristic of CRCS

(1) Low installation, operation and maintenance costs as it does not involve mechanical devices and construction of central plant and underground refuse conveying ductwork.

(2) Nuisances such as spills and odor would be generated probably during movement of refuse from each floor to the central collection point and loading of refuse from the refuse collection bins to the refuse collection vehicles that may pose health risk on the cleansing workers and the residents nearby.

(3) Bags containing refuse dumped into the refuse chute may break before reaching the refuse collection bin underneath or the refuse may throw everywhere in the refuse chamber when total amount of refuse is far beyond the holding capacity of the bin. Thus, the bin or the refuse chamber will be smeared with dirt and sanitary or hygienic problems are resulted.

2.3.2 Characteristic of ARCS

(1) ARCS is perceived as a more healthy operation for refuse treatment as the chances of emission of unpleasant smell and spill of refuse are significantly reduced when the refuse is transported in concealed ductworks and stored in containers for disposal.

(2) Total numbers of cleansing workers required under ARCS for conveying refuse from refuse chambers on G/F of each block to central collection point and loading the refuse to the refuse collection vehicle can be greatly reduced.

(3) Movement of noisy refuse collection vehicles and unpleasant odour generated from the refuse collection bins and vehicles can be eliminated. Hence, the overall image and appearance of our society can be improved.

(4) To connect all refuse chutes from different blocks to the central plant room, extensive underground conveying ductworks have to be provided, which pose difficulties in arrangement of the routings of various types of utility services.

(5) More underground spaces are required for accommodating refuse transportation piping.

(6) Provisions of underground refuse transportation pipe works and the central plant have increased the installation and maintenance costs. The Hong Kong Housing Authority revealed that the installation cost of ARCS is 10 times more than the initial cost of the conventional method.

(7) As the refuse is transported inside the ductworks by suction, and the refuse and exhaust air are treated by mechanical means, high running cost and energy consumption are expected.

(8) The chance of system breakdown due to mechanical failure is high that may affect normal refuse collection. Once the system fails, refuse should be handled manually and nuisance would be created.

Table 1: Results of comparison between characteristics of two systems

	CRCS	**ARCS**
Cost - ***Installation*** - ***Maintenance & Operation***	Low	High
Spatial Requirement	Moderate	Large (mainly U/G spaces)
Health Risk	High	Low
Nuisance Generated	Probably	Not probably
Labour Required	Intensive	Not intensive
Chance of System Breakdown	Low	High

3. Discussion

Although the comparison supports that ARCS prevails over the traditional method as it improves the living environment of the residents [11] and benefits the society as a whole, its popularity in Hong Kong residential development is still low comparative to CRCS. The major obstruction is due to high initial and running cost of ARCS (Table 2). As mentioned by the Hong Kong Housing Authority, the installation cost of ARCS is 10 times more than the initial cost of the conventional methods. Owing to the financial consideration, the Hong Kong Housing Authority has ceased to install ARCS in public estates recently.

Table 2: Installation, operation and maintenance costs for ARCS

	Installation Cost* **(per flat)**	**Operation & Maintenance Cost*** **(per flat per month)**
Hong Kong Housing Authority	$5,000	$30
ARCS Installer	--	$24
ARCS Supplier	$5,000	$25
Average Cost	**$5,000**	**$26**

* Costs obtained from projects of three parties with more than 3,000 flat units in a single development

Private sector also advised that it was not cost effective to install ARCS in private residential developments especially those in smaller scale after carrying out cost-benefit studies. The installation cost of ARCS could only be justified if there was sufficient numbers of flats in a development, and the operation and maintenance costs could also be reduced when there were certain amounts of residents to share the costs. However, most of the private residential developments nowadays are in small or middle scale; therefore, the installation cost per unit is much higher for private development. The developers have lower incentive to invest in ARCS and they give up this option for refuse management and adopt a cheaper acceptable alternative i.e. CRCS instead.

Apart from the installation cost, high operation and maintenance cost is also a reason making ARCS less attractive. ARCS is an automatic refuse collection device without heavily rely on people to dispose the refuse. It is supposed that the savings in labour cost can partially cover the additional operation and maintenance costs induced by ARCS. Nevertheless, the labour cost for handling refuse could not be reduced after using ARCS. The property management staff pointed out that self disposal was not preferable in Hong Kong especially in public housing estates because some residents would dispose substances that may damage the refuse chutes or cause fire accidents. Thus, cleansing workers were required to be employed to dump the refuse to the chutes for the occupants, and total running cost of ARCS including labour cost was still high.

4. Results of Questionnaire Survey

From late May to July 2004, questionnaire surveys to the residents living in public housing estate, sandwich class housing and private residential development were conducted and 651 numbers of questionnaires were returned. Nearly 80% of replies pinpointed that refuse collection methods would affect their health in large extent. Undoubtedly, many residents supported ARCS as they strongly believed that the system could improve their living environment. However, many of them were not willing to pay additional amounts for operating and maintaining the system. The results were summarized in Figure 3 and 4.

About 40% of respondents living in public housing estate believed that ARCS was the best refuse collection system; however, approx. 30% of them are happy to use CRCS (using refuse chutes) if additional amount of fee should be paid for ARCS. For the residents in sandwich class housing estate, 64% of respondents preferred ARCS and approx. 25% of respondent would like to adopt CRCS (using refuse chutes). About 63% of respondents in private residential development preferred ARCS and 32% of respondents preferred to use refuse chutes while 4% of them would like to use lifts to convey their refuse. The questionnaire survey perceived that the residents generally supported ARCS even though they were living in various types of housings. They believed that this system could minimize the nuisances generated by manual handling of refuse, eliminate negative health impacts on residents and cleansing workers, and enhance overall hygienic and sanitary conditions of their estates.

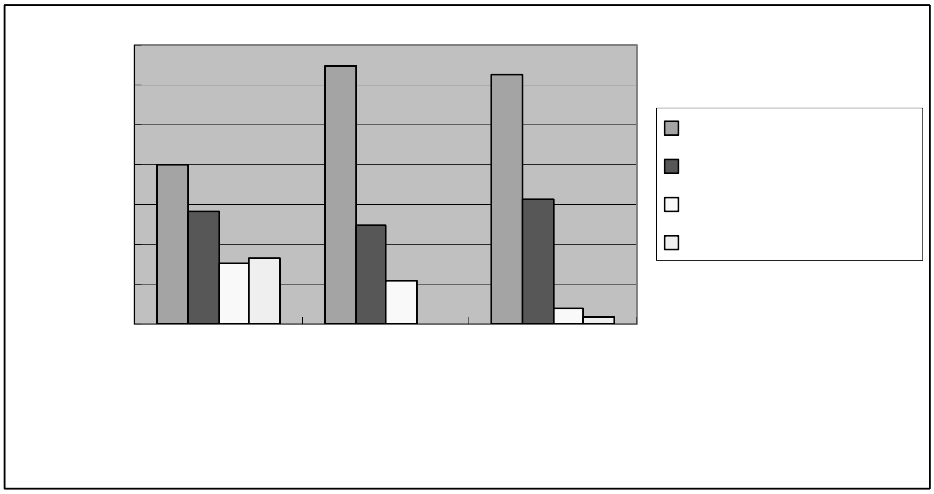

Figure 3: Residents' preference towards the refuse collection systems

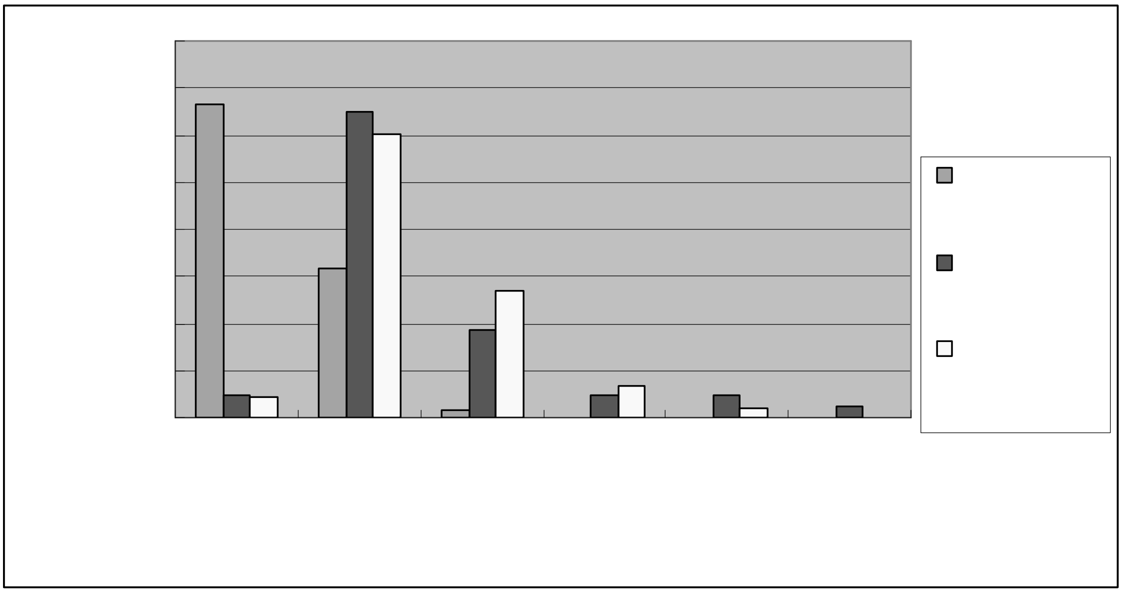

Figure 4: Willingness to pay for supporting ARCS

Nevertheless, majority of the respondents living in public housing estate would NOT like to pay additional amount to support the normal operation of ARCS. Some of them claimed that the Hong Kong Government was responsible to provide a healthy living environment for them and therefore, government should pay for installation, operation and maintenance of the system. If they had to share part of the cost of ARCS, they would prefer conventional system. That explained why there was significant amount (about 44%) of respondents selected conventional refuse collection system in the survey. For the respondents who were living in sandwich class housings and private residential buildings, most of them were willing to bear the cost for operating and maintaining ARCS; however, they only accepted a maximum increase of less than 5% in monthly management fee. With reference to the figure in Table.2, the average operation and maintenance cost per flat per month was about $26 only which could probably be covered by the maximum amount (i.e. 5% of existing amount of monthly management fee or rent) the residents were willing to pay. Hence, the developers have to justify the financial viability of the installation of ARCS solely before selection of the most suitable refuse collection method in their property development.

5. Recommendations

5.1 Importance of Proper Management

As afore said, the popularity of ARCS is low due to its high installation cost even though it is widely recognized that this system can enhance the environment when dealing with refuse. The developers cannot justify the cost to install this advanced refuse collection system and they prefer to adopt traditional system at this moment. To cope with the problems induced by the conventional refuse collection system, proper management of these facilities can help a lot. The nuisances can be minimized through proper building management by frequent cleaning of refuse rooms and chambers; replacement of refuse collection bin before reaching its holding capacity; using refuse collection bins with larger capacity; advance planning of the refuse transportation route in order to minimize the movement of bins and refuse collection vehicles in the estate, etc. In addition, self disposal can be promoted through property management to reduce the workload and health risk imposed on the cleansing workers as they are not required to expose to the refuse removing from the bin to the chute. In order to facilitate the owners or tenants to dispose the refuse through indoor refuse disposal inlets, contactless devices such as infra-red sensor and voice recognition device for opening them can also be installed to avoid disease transmission and possible contamination by direct contact.

Waste separation can also be promoted to reduce the total amount of household wastes generated in an estate. Through proper education by property management staff, most residents would discard general household rubbish directly into refuse chute and put recycled materials like paper, aluminum cans and plastic bottles in designated areas inside the refuse room. The cleansing contractors would collect the recycled materials and dispose other wastes at the bottom of the chutes for them. After implementation of the recycling scheme, it is believed that the cleansing contractors can earn more on top of their basic monthly salaries by selling recycled wastes. With incentives, the cleansing contractors are willing to take up the responsibility to collect those wastes. In this way, both cleansing workers and residents are benefited as the hygienic conditions are sustained and even improved when adopting conventional refuse collection system.

5.2 Other suggestions

(1) For those who would like to install ARCS in their developments, it is desirable to install it to serve several residential projects in the same district at the same time in order to spread the initial cost for installation of this system among estates. Each resident can also bear a smaller amount in operating and maintaining it.

(2) To minimize the risk of infection, refuse collectors should take injections regularly, such as tetanus shots and hepatitis B vaccine. They should wear protective gear like goggles, nose-and-mouth masks and heavy masks. They should also use clean water and towel to scrub themselves during breaks or after works [12]

(3) In-depth study on the impact of refuse collection methods on health and cost-benefit study should be carried out before drawing conclusion on promotion or adoption of ARCS. If it is scientifically proved that ARCS systems are the only way to solve the health problem imposed by the conventional refuse management system, ARCS systems should become essential installations even though their initial cost may be high.

6. Conclusions

The questionnaire survey pinpointed that many Hong Kong citizens concerned about their health and living conditions. As the residents believed that refuse treatment was one of the major factors affecting their health, they would support or prefer a refuse collection system that could treat the refuse in a more hygienic way i.e. ARCS. Nevertheless, they would not like to pay more money to support the operation of the system. Besides, there were other obstructions for promotion of this system. The developers found difficulties in determining break even point and could not justify the cost to install this system. Hence, the publicity of this system is low nowadays. It seems that the local practitioners and researchers still have a long way to go before having a technically feasible, economically viable and high efficiency proposal on refuse collection. This study provides an insight that good building management could address nuisance problems induced by refuse collection system. To enhance the living environment of the residents, more resources should be put on the management of existing refuse collection facilities.

Abstract

Despite the abundance of research on innovation in organisations, very little is known about service innovation as opposed to product innovation. Novel developments in customer care, front-of-house FM and new ways of working share parallels with service innovations in other sectors where a change of process has profound effects. More specifically, little is known about the FM environment most likely to stimulate service innovation. This paper attempts to describe the emerging concept of 'innovation climate' and proposes using a measurement instrument to measure this phenomenon. The approach will enable characterisation of FM organisations in terms of their predisposal to innovate within the prevailing climate.

Keywords: Innovation climate, service innovation, innovation process

1. Background

This paper describes an ongoing study funded by the ICRC (Innovative Construction Research Centre) involving the participation of organisations in the Thames Valley region of the UK. An innovation network (BIFM Thames Valley FM Innovation Network) of around fifteen companies has provided a practical vehicle for the comparison of how FM teams in organisations engage in innovation. The Thames Valley is often described as the 'silicon valley' of the UK with a high preponderance of hi-tech organisations, although the network itself involves other client organisations including building societies, banks and service providers. Rather than simply providing a place for exchanging good ideas, the network sought to ask more fundamental questions about innovation in their organisations. What are the characteristics of a good FM innovation? What are the influencing factors that enable innovation? To answer these questions required a fundamental look at how FM individuals and teams function. Many of the organisations in the network were involved in radical and challenging innovations that often pushed the boundaries of FM activities. What were the features of these organisations that enabled them to achieve this?

2. Innovation in services

A number of recent research papers examining the nature of *service innovation* have highlighted the feasibility of testing such innovations in a scientific and controlled manner. Innovation in services has “emerged from Cinderella status, from being neglected and marginal, to achieving wide recognition as being worthy of serious study” (Miles, 2000). The perception of services as non-innovative activities has progressed to a widespread view that innovation can play a major role. This has resulted in increasing attention being paid to service innovations (Evangelista, 2000; Miles, 2000; Drejer, 2004; Tether, 2004) . The “laggard” classification of the service sector as being solely subject to client “pull” (Howells, 2000) has given way to a much more positive view of the sector in which a huge variety of complex and innovative activities go on (Hertog, 2000; Uchupalanan, 2000; Tether, 2003; Thomke, 2003; Vermeulen, 2004). Some authors have even gone so far as to suggest a unifying of approaches to innovation between the manufacturing and the service sector.

In Thomke’s study, Bank of America has applied the discipline of formal R&D processes to services. They have been running a series of formal experiments seeking to create new service concepts for retail banking. The company has turned a set of their branches into “laboratories” where research teams conduct live experiments during regular business hours. The results of these experiments are compared to those in normal branches, pinpointing attractive innovations for broader rollout. In this case, innovation in services, and services innovation is understood in broader terms, being extended to non-technological innovation.(Hipp, *et al.*, 2000).

3. Process of Innovation

In order to analyse innovation in a meaningful way, it is necessary to distinguish between the numerous stages, each of which have their own time-spans, resource requirements and decision approaches. There are several models in the literature suggesting the sequences of events in the evolution of an innovation (Wilson, 1966; Hage, *et al.*, 1970; Harvey, *et al.*, 1970; Zaltman, *et al.*, 1973; Kimberly, 1981; Rogers, 1983; Tidd, *et al.*, 1997; Van-de-Ven, *et al.*, 1999). As Edison realized, ‘innovation is more than simply coming up with a good idea; it is the process of growing them into practical use’ (Tidd, *et al.*, 1997). Rogers (Rogers, 2003), a leading researcher in innovation processes, proposed a model that consisted of a sequence of five stages (Table 1); the first two of which are concerned with the *initiation* and the latter three with the *implementation*.

Table 1: Roger's (2003) Stages of Innovation

Stage 1. Agenda setting	Initiation (Information Gathering)
Stage 2. Matching	
Adopt or Reject Decision	
Stage 3. Redefining/restructuring	Implementation and diffusion of innovation
Stage 4. Clarifying	
Stage 5. Routinizing	

The first two stages, 'agenda setting' and 'matching' represent the entire information gathering, conceptualizing, and planning effort leading to the adoption of an innovation. The decision to adopt or reject the innovation marks the end of the initiation phase of the model. The last three stages, 'redefining/ restructuring', 'clarifying' and 'routinizing' constitute all of the events, actions, and decisions involved in putting the innovation into use. Rogers does not consider his model to be fixed; the process may occasionally back-track or skip one ore more stages although he suggests "Later stages … cannot be undertaken until earlier stages have been settled, either explicitly or implicitly" (Rogers, 1983).

Field studies demonstrate the difficulties in analysing the process as a linear succession of events. Research led by Van de Ven involved fourteen in-depth case studies of technological innovations in a variety of fields including: industry; education; agriculture; health; and defense (Van-de-Ven, *et al.*, 1999). This study pursued a common theoretical background for the data analysis in the innovation process. Their results showed that ideas develop in different ways, moving from inventions to reinventions. Some ideas are discarded and others are carried one step forwards. In many cases different people are involved in the different stages, adding different perspectives and time horizons to the development of the idea.

At a certain level of abstraction it is possible to see the same basic process common to all of these models. The common elements in the innovation process are: 1) Initiation Period, 2) Development Period, and 3) Implementation / Termination period.

One key and unanswered question that arises from these models is whether the necessary factors for success are the same or different at each stage. More specifically, when looking at the situational context, is it possible to identify an optimal environment for every stage. The study described in this paper will measure the climate of the contributors and stakeholders reflected through the different stages of an innovation. This will enable the comparison between them and analyse what makes some stages "push" for an innovative environment while others hinder this attitude. So, people are to be considered the main actors within "the innovation journey"; they will be responsible for the success and development of the idea. How can we nurture a climate for innovation and creativity in a sector where often good ideas are not recognised?

4. Climate for Creativity

Climate plays a vital role in determining the outlook or likelihood of innovation, creativity, or change taking place in a particular place. The study will focus on the psychological aspects of the work environment commonly referred to as "organisational climate". Organisational climate refers to the recurring patterns of behaviour, attitudes and feelings that characterise the day-to-day life in the organisation as experienced and understood by the individuals. The climate is observable at a surface level within the organisation and it changes in a dynamic way. In this way, it is important to distinguish between organisational climate and culture. The culture refers to a long term characteristic with deeper and enduring values, norms and beliefs of the organisation. The culture is long standing, deeply rooted and usually hard to change.

In the context of the innovation process, organisational climate plays the part of an intervening variable which can affect the results and development of an idea (Figure 1). From our research we wanted to know about the prevailing climates in our case study organizations. From this, it was hoped that we could establish an association between certain climate factors and innovation success in FM.

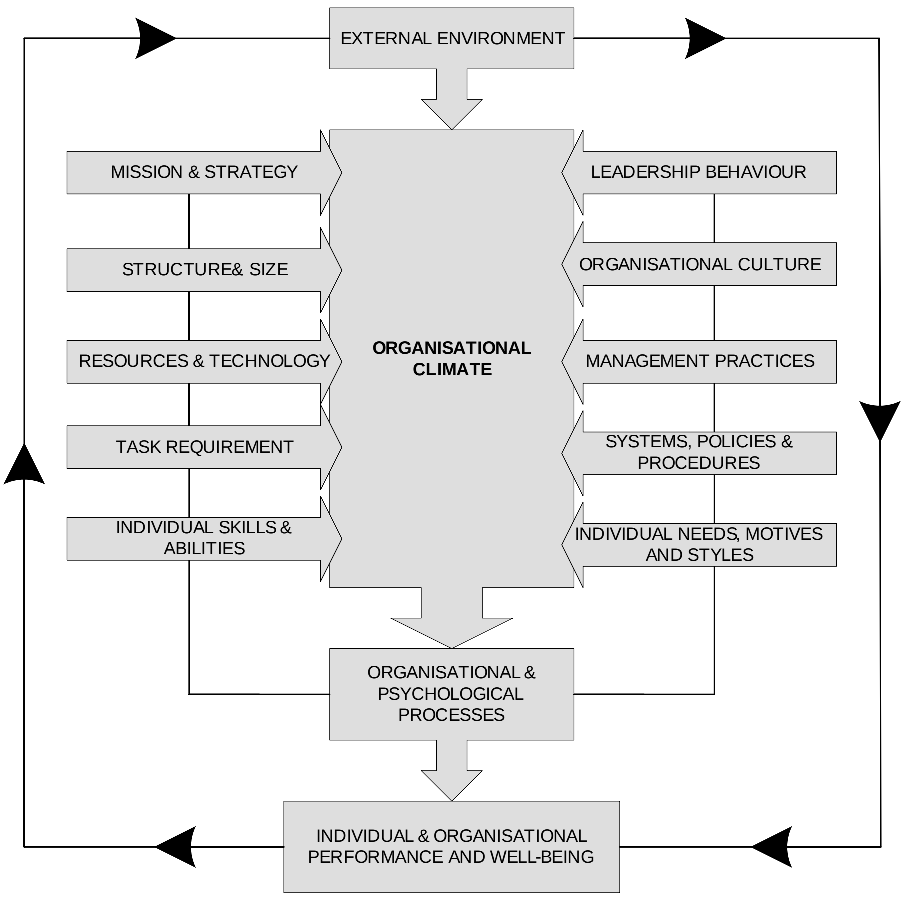

Figure 1 : A Model for Organisational Change (The Creative Problem Solving Group, 2002)

The organisational climate is influenced by many factors within and external to the organisation. The external factors refer to the markets changes, global financial conditions, and legislation that can affect the performance of the organisation. These factors cannot be controlled by the organisation; although it may demand new flexible behaviours within the organisation.

The transformational variables for organisational change are represented by the top four of the model shown above (Figure 1) – that is, ‘mission and strategy’; ‘leadership behaviour’; ‘structure and size’ and ‘organizational culture’. The mission and strategy define the basic purpose of the business and the way in which it is going to achieve it. Leadership behaviour includes any attitude seeking to transform the organisation. This has been found to have a profound influence on the perception people have of the climate for creativity and change (Ekvall, 1996). Organisational culture represents the roots that provide individuals with a sense of belonging to the organisation. It influences the way people respond to surprise, creativity and change. Structure refers to the way people and functions are arranged. Ekvall (Ekvall, 1996) has shown that the type of structure within departments of an organisation has an impact on employees perceptions of the climate in those departments.

The remaining elements of the model are referred to as transactional variables. They are used to preserve and implement changes taking place in the transformative level of the organisation. For the purposes of our research we applied this model using a standard measurement instrument known as the Situational Outlook Questionnaire.

5. The development of the Measure

The Situational Outlook Questionnaire has been developed looking at people’s perceptions of the character of life within a workplace. Its particular focus is on how attitudes, feelings and behaviours support creativity and change. This instrument grew from a research programme in Sweden during the 1980s concerning organisational conditions that stimulate or hamper creativity and innovation (Ekvall, 1996). The questionnaire tool was adopted by the University of Buffalo in the US from the earlier measure developed by Ekvall. As an Industrial psychologist working for Volvo in the 1950’s and other large Swedish companies in the 1960’s and 70’s Ekvall observed differences in how the working atmosphere of different companies affected the degree of participation in idea suggestions schemes.

The Situational Outlook Questionnaire (SOQ) will be used in this study to assess the climate for creativity, innovation and change within the FM sector. This tool enables a better understanding of the perception of the environment in which people work on a day-to-day basis and the impact on their predisposition for creativity and change.

The SOQ consists of fifty questions, with five questions for each of the ten dimensions. Each item is scored from zero to three; zero standing for "not at all applicable" and three for "applicable to a high degree." Thus, results will be reported in a 0 - 3.00 format.

The dimensions of the SOQ include:

- Challenge and Involvement: The emotional involvement of the members of the organisation in its operations and goals. A high challenge climate exists when the people are experiencing joy and meaningfulness in their job, and therefore, they invest much energy. Low challenge means feelings of alienation and indifference; the common sentiment and attitude are apathy and lack of interest for the job and the organization.
- Freedom: The independence in behaviour exerted by the people and tolerated within the organization. In a climate with much of this kind of freedom people are making contacts to give and receive information and discuss problems and alternatives; they plan and take initiatives of different kinds and make decisions. The opposite climate would include people who are passive, rule-fixed, and anxious to stay inside the frames and established boundaries.
- Trust/ Openness: The emotional safety in relationships. When there is a strong level of trust, everyone in the organization dares to put forward ideas and opinions. Initiatives can be taken without fear of reprisals and ridicule in the case of failure. The communication is open and straightforward. Where trust is missing, people are suspicious of each other and take initiative cautiously because of the high price mistakes bring.
- Idea Time: The amount of time people can use for elaborating new ideas. In the high idea time situation, the possibilities exist to discuss and test impulses and fresh suggestions that are not planned or included in the task assignment; and people tend to use these possibilities. In the reverse case, every minute is booked and specified. The time pressure makes thinking outside the instructions and planned routines impossible.
- Playfulness/ Humour: The spontaneity and ease that is displayed. A relaxed atmosphere with jokes and laughter characterizes the organisation that is high in this dimension. The opposite climate is characterized by gravity and seriousness.
- Conflict: The presence of personal and emotional tension in the organisation. When the level of conflict is high, groups and single individuals hate each other. There is gossip and slander present. In the opposite case, people behave in a more mature manner; they have psychological insight and control of their impulses.
- Idea Support: The ways in which new ideas are treated. In the supportive climate, ideas and suggestions are received in an attentive and kind way by managers and co-workers. People listen to each other and encourage initiatives. Possibilities for trying out new ideas are created. The atmosphere is constructive and positive. When idea support is low, the reflexive "no" is prevailing. Every suggestion is immediately refuted by counter-argument. Fault-finding and obstacle-raising are usual styles of responding to ideas.

- Debates: The occurrence of encounters and disagreements between viewpoints, ideas and differing experiences and knowledge. In the debating organisation, many voices are heard and people are keen on putting forward their ideas. Where debates are missing, people follow authoritarian patterns without question.
- Risk-taking: Tolerance of uncertainty and ambiguity evident in the workplace. In the high risk-taking case, decisions and actions are prompt and rapid opportunities are taken. In a risk-avoiding climate there is a cautious, hesitant mentality.

The nine dimensions and three supporting open questions in the questionnaire attempt to describe employee's perception of the atmosphere within the organisation, where higher scores on the nine positive dimensions with a lower score on the negative dimension (conflict) indicate a climate more conducive to creativity.

For FM professionals concerned with the design of the workplace, a surprising feature of the questionnaire is that there is no acknowledgement of the role of the physical environment on innovation. For example, an open plan design may encourage people to be more open about ideas. However, the tool has purposefully been designed with degrees of ambiguity to elicit a variety of views about what we mean regarding 'work environment'. Furthermore, the immediate goal of our research was to examine the broader concept of 'work environment'. However, we hope to develop our analysis in future studies to specifically address the role of the physical workplace in stimulating innovation.

The SOQ tool has been used for over 10 years in organizations around the world having studies (Ekvall, 1987; 1996; Ekvall *et al.*, 1983; Isaksen, *et al.*, 1999) supporting the validity and reliability of the SOQ. It is hoped that the results from the study can be used in a cross-comparison with other professions and other types of organizations drawn from this databank.

6. Methodology

The methodology used in this study measures individuals' perception of the climate dimensions for the three stages in the process of innovation: 1) Initiation Period, 2) Development Period, and 3) Implementation / Termination period. Respondents will complete the SOQ for each of the stages. As an accurate measure of the psychological climate for creativity the SOQ will be sensitive enough to show distinct differences between the three situations.

In this study the SOQ data will enable us to categorise organizations as being creatively innovative, average or stagnated. Since our study will also consider the stages of innovation, it is likely that organizations may exhibit different levels of innovativeness at different stages. In other words, the climate may be more supportive of innovation at the information gathering or implementation stages.

The SOQ is, however, not a direct measure of organizational stagnation or progressiveness. Rather, they act as a barometer gauging the general perception of how these dimensions are perceived within a given climate. The scores on the SOQ are best used as a profile and can help to identify strengths and potential weaknesses within any specific working situation.

The scores in the 'spider diagram' below give an example of the variation along the nine climates dimensions for a given organisation (Table 2). People in innovative companies exhibit higher scores for each dimension except for conflict.

Table 2: Comparison of Mean Scores for Three Types of Organisations

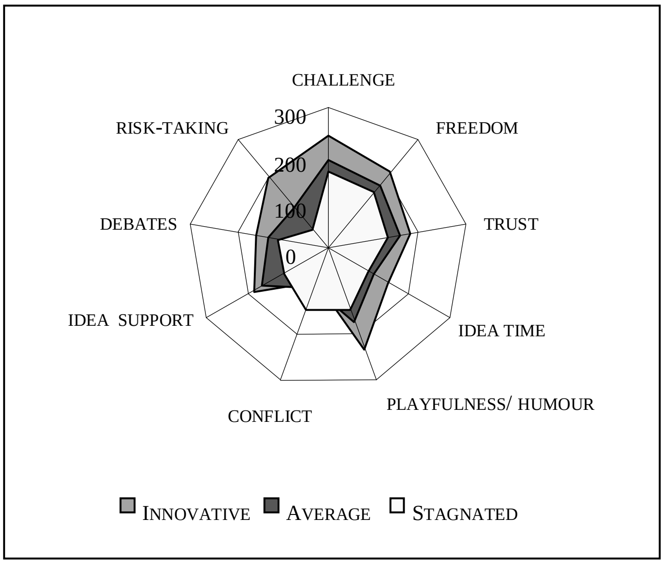

Table 3 Creativity in Stages of Innovation

	INITIATION	**DEVELOPMENT**	**IMPLEMENTATION**
Creatively Productive			
Creatively Average			
Creatively Stagnated			

From these results a comparison between the different stages of the innovation process will be undertaken (Table 3). This will help understand the psychological perception of individuals within an organisation (in this case the FM sector) during the "Innovation Journey", enabling the development of structures and systems to support organisational innovation in every stage of the process.

Being able to classify the stages of the process (creatively productive, average and stagnated), will benefit the organisation in various levels. On an individual level, the understanding of the climate will make the invisible more visible, prompting individuals to modify the climate within which they work. On a team level, an understanding of the climate will help promote honest communication among the team members. Suitable modification of the innovation climate will promote effective problem solving, enabling a productive group functioning and will shed light on unnoticed strengths upon which the team can build on. This analysis will allow organisations to better structure themselves to enable a more productive workplace; building upon those structures that seem to be working well whilst modifying others (Isaksen *et al.*, 1990).

7. Conclusions

This paper has provided an outline of the proposed study, identifying key unanswered questions for the facilities management community. The fact that FM is a service based industry has tended to marginalize the issue of innovation: a concept which has typically been exclusively associated with manufacture. However, the recent emergence of convincing research on *service innovation* is providing the imperative and analytical tools to further understand this process. The existence of an innovation network provides a unique opportunity to undertake longitudinal studies in innovation. The results from this research will enable the network not just to provide an exchange for good ideas but to acquire a more long-lasting understanding of how to 'do innovation'. From existing research, the evidence points to the fact that good ideas within a bad climate are inclined to fail and seemingly marginal innovations can have a big impact in supportive climates.

Abstract

The developing market of building management services (e.g. property management or facility management) is now a day characterized by different complexity factors regarding both demand and offer operators. From this situation of complexity some problems arise in managing the services processes and in controlling and assuring quality. At the same time, till now it has not really been developed a specific culture for buildings services, made both of a methodological approach for organizational and operational functions, and of an appropriate system of tools.

On the basis of these considerations, the paper – after a synthetic investigation of complexity factors and their influences and problems on services organization – has the aim to point up a working hypothesis: innovations and improvements for building services can be developed through a process of transfer of methods and tools from different industrial and management fields with an appropriate adaptation to the specific context of building industry. The paper selects and analyses some approaches and their possible applications in buildings management services: first of all it deals with Supply Chain Management, defining different modalities of treatment of this approach inside different building services organization models (aggregation, integration, homogeneous system of services). Besides, about the supply chain management in building services, the paper deals with different actions inside services phases (design, planning, programming, monitoring and verification) and related process supports (procedures, resources and information management systems, tools, check-lists, key performance indicators, audit, etc.). Finally the paper analyses possible applications to building services of customer value approach and knowledge management systems.

Keywords: Buildings services, quality management, supply chain management, knowledge management.

1. The buildings services scenario

1.1 Growing market and complexity factors

In Italy the market of buildings services is constantly growing, as shown by some market analysis and statistical investigations (Table 1). This developing market is now a day characterized by different complexity factors regarding both demand and offer operators, such as:

- the increasing number of specific services regarding different operational areas that should be really integrated in order to pursue effectiveness and efficiency of processes;
- the multiplicity of interacting operators different for skills, know-how and methods due to their origin from different contexts and disciplines (industry, construction, logistic sectors, safety and health, security, economical and financial studies, etc.);
- the difference in organization and contractual models, with problems in defining roles, authorities and responsibilities;
- the large range of functions of buildings and real estate (e.g. residential, health care, industry, etc.), each one dealing with specific requirements for needed services;
- the large number of information regarding the buildings, coming from a multiplicity of sources, that have to be spread between different operators.

Table 1: Scenario of Facility management market in Italy (milions of Euro 2003). From Cresme, Facility management 2003, III Report Market in Italy, Proseg, 2003.

		Real demand					
	Potential demand	**2003**		**2008**		**2012**	
		Min.	**Max**	**Min.**	**Max**	**Min.**	**Max**

1.2 Organization models and services operators

Now a day the scenario of services offer is represented by a large variety of operators - different for dimensions, organizational structures and approaches, origins, financial resources, etc – all active in national – and often also international – market, both in competition and in association, in many possible configurations and in very dynamic manners.

It is possible to summarize as follows the more significant categories of offer operators:

- "great operators", for instance, operators coming from the industrial Global Service field, firms engaged in utilities management (production and distribution of gas, water, fuel, etc.), firms rising from industrial groups through "spin off", international firms operating in industrial maintenance and energy areas, real estate consultants, and so on. They are operators very skilled in organizational themes, with significant financial resources and with an easy access to banking establishment, that only now are beginning to deal with buildings characteristics and behaviours;
- construction firms that, inside a general scenario of transformations in construction market (fragmentation of organizations, increase of maintenance and refurbishment demand, new types of contracts, new regulations in public works, etc.), are looking for new business opportunities inside fields in which they can apply their technical knowledge about buildings, their capabilities of relationship with public administrations, their expertises in construction supplier management;
- specialized suppliers of services (such as energy management, cleaning, security, etc ,) that try to profit by their consolidated relationships with their Clients and by their capabilities in designing and managing services, in order to extend their business areas by adding new services;
- very small firms, traditionally occupied in technical works with operational expertises in buildings and equipments maintenance, that now are gathering together in networks in order to collaborate and to act as a "single entity" in service supplying. The aim is to answer in a very flexible and dynamic way to various market requests with different temporary aggregations of services, trying to be more and more adherent to clients requirements. The network may offer activities of design, coordination and control of the assemble of services.

In general the tendency is towards the assembly of many and different services, variable in its configuration, with a single interface for Clients. Clients are changing their tasks: in the past the main tasks were selection and coordination of all the different service suppliers, today the main tasks are the definition of global service requirements, the selection of an unique service provider, the control of service results. Notwithstanding such an evolution, at moment it seems that demand operators, even if quantitatively important, have difficulties in defining the services results in terms of quality requirements (WHAT), and are not still able to drive the ways in which the offer could better organize the services (WHO and HOW).

1.3 A working hypothesis: innovations and improvements through a process of transfer

Considering the actual, complex scenario, it appears that - even if many contributions, expertises, know-how are presents - the real potentialities of this field are not yet completely expressed, since it has not yet be developed a specific culture for buildings services, made both of a methodological approach for organizational and operational functions, and of an appropriate system of tools.

Following this reflection, a working hypothesis can be assumed: innovations and improvements for building services can be developed through a process of transfer of methods and tools from different industrial and management fields with a specific adaptation to the particular context of buildings industry. In particular, considering the above mentioned factors of complexity and the problems of coordination, the attention can be put on some basic aspects and approaches as, for instance: supply chain management, knowledge management, interactions between demand and offer operators.

2. Supply chain management in buildings management services

2.1 Supply chain management approach

"*Supply chain management is a set of approaches utilized to efficiently integrate suppliers, manufactures, warehouse, and stores, so that merchandise is produced and distributed at the right quantities, to the right locations, and at the right time, in order to minimize system wide costs while satisfying service level requirements*" (Simchi-Levi, Kaminski, Simchi-Levi , 2000).

Considering this field of applications, through a process of transfer and adaptation from industry to buildings services, supply chain management can provide interesting contributions in terms of philosophy of approach, network management strategies, coordination modalities, methodologies and tools in the cases of many suppliers working together sharing some basic aims:

- to increase efficiency and effectiveness in complex services processes, where a high level of interactions exists between many decisions makers and operational teams belonging to different organizations, working with different modalities – sometimes synchronically, other times diachronically - on the same object (the building);
- to perform continuity and unique modalities in quality planning and control;
- to deliver a service constantly conform to customer requirements, reducing the period for response to not planned requests and to demand varying over time;
- to recognize and to solve, as soon as possible, possible conflicts between suppliers;
- to share common resources, information and knowledge with the aim of service optimisation.

2.2 Buildings services strategies according to supply chain management approach

Supply chain approach provides some keys useful to interpret actual and potential buildings services strategies. On this basis, at present it is possible to recognize different strategies in the processes and in the procedures that regulate the interaction between services suppliers. In particular, it is possible to identify at least three main strategies that represent different behaviours in supply chain management and that, at the same time, can be considered the steps of a progressive maturation of buildings services organizations, from a "simple addition" of services towards the creation of an organized system:

- *aggregation*. This strategy leads to some essential activities, such as selection of suppliers and control on results. Aggregation is typically the first step in multi-services organization and represent a very simple model of behaviour. It is based upon the definition of requirements for suppliers – and eventually of service delivery guide-lines - on the basis of the criterion coming from the objectives of the service, leaving full organizational and operational autonomy to the different suppliers;
- *integration*. This strategy has the aim to optimise the effectiveness of the processes and the quality of results through the coordination of the different suppliers, that preserve their internal own organization, but share with the supply chain interaction aspects concerning planning and development of activities, information, communication, logistic, etc. This strategy presupposes the individuation of an interface area inside the supply chain; from this area indications of coordination come and are spread to the suppliers that have to adapt their behaviours to needs "of superior order";
- *homogenizing*. This strategy represents the highest level in suppliers organization and the supply chain can be considered as an original entity. During the service period, the suppliers share not only coordination aspects connected with organizational and operational issues, but also: policies, strategies and goals expressed by the supply chain, collective service such as call centre, sophisticated management methodologies, information systems, purchasing

offices, legal and administrative supports, quality systems and procedures, safety and health management systems, statistical elaborations, data-bases, training and empowerment policies, and so on. Each supplier has to adapt the *modus operandi* to the supply chain directives, taking profit by using high quality services, that couldn't afford if standing alone, and by learning by high level experiences.

The acquisition of one of the different strategies implies that the activities of the supply chain management can cover a wide range of level (from the strategic through the tactical to the operational level), as synthesized in figure 1.

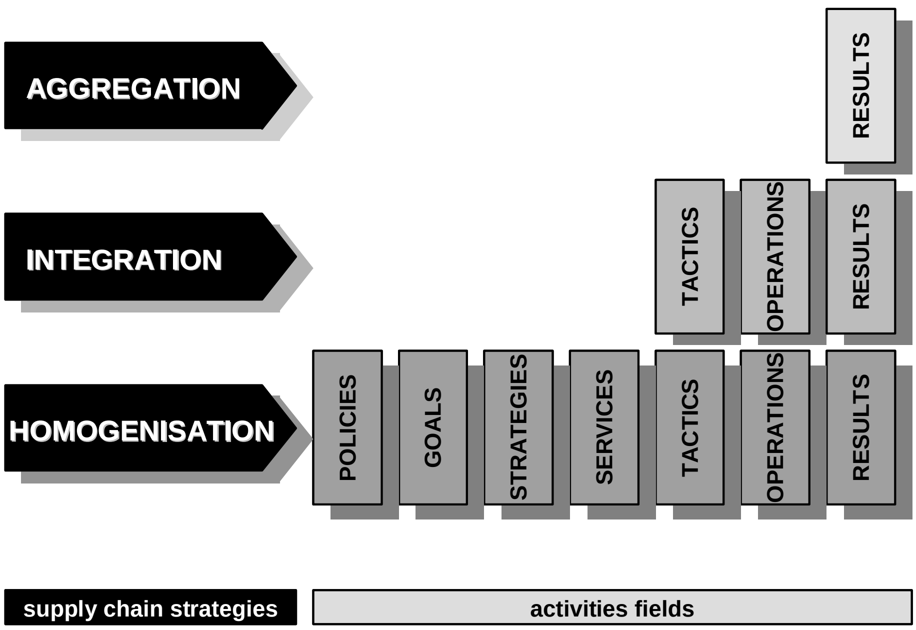

Figure 2: Supply chain strategies and activities fields shared by the services suppliers

2.3 Buildings services models according to supply chain management strategies

According to the above described supply chain strategies, it is possible to define several buildings services models (table 2), representatives of actual behaviours, of relationship with Clients and of modalities of interaction between suppliers.

Table 2: Schemes of the possible models concerning relationships between components of the supply chain

	Models	Description
MODEL 1		*Traditional model of one or several services in which the supplier is the only interlocutor of client. The supplier can select and aggregate sub contractors, that are chosen on the basis of prefixed requirements and controlled on the basis of the results that must be compliant to specifications and contracts.*
MODEL 2		*Evolution on model 1. In this case some aspects regarding coordination between sub-contractors are introduced. These aspects can initially concern operational actions and successively planning activities. It is possible to execute controls not only on final results, but also in process. Sub-contractors operate in autonomy, and may have to modify their plans only in the cases of necessary coordination with other sub-contractors.*
MODEL 3		*Evolution in the relationship Client-single supplier. Here it is the beginning of principles of supply chain management approach. The relationship between supplier and sub-contractors concerns not only the selection, coordination and control, but also involves goals, strategies, tactics. Inside the specific service contract, sub-contractors have to adapt some of their procedures and management methods (Quality systems, safety and health management, information systems, etc.). The links, that can rise, create the conditions for permanent relationships, also for other services contracts, toward the development of more advanced management styles.*
MODEL 4		*Model based on a relationship of the Client with a group of supplier, selected and gathered together in order to satisfy specific service requirements and to be more competitive due to the integration of many expertises and resources. Each supplier, for its competences, can interact with specific sub-contractors, according to the modalities of the previous models.*
MODEL 5		*Evolution of model 4. In this case there is a growing and a consolidation of relationships between suppliers, that are engaged in a permanent action of coordination in order to increase efficiency and effectiveness. This coordination can regard aspects related to planning, communication, information, logistic and criterion for selection and monitoring of sub-contractors.*

<table>
<tr><td>MODEL 6</td><td></td><td>The evolution of model 5 can lead to actions of extension of general coordination activities to the sub-contractors with effects of increasing efficiency of processes, better quality control actions, general sharing of knowledge and expertises to all the components of supply chain.</td></tr>
<tr><td>MODEL 7</td><td></td><td> Further level of growing of the supply chain management is the realization of an upper structure (the supply chain itself) that represents an entity that can be considered as a single decisional, informative and operational system, where all the suppliers share common policies, strategies, goals, procedure and services. The sharing of these aspect implies for all the supplier the acquisition of innovative management methodologies and tools. The expression of a common policy and goals allows to be much more competitive in the market and to better intercept and satisfy Client needs; besides it gives to the Client the guarantees of coherence and stability, very useful for fidelity and collaborations in relationships. Inside this model we can consider that the supply chain can be able to express an “intelligence of system” coming from the interaction between different shared expertises and knowledge of the suppliers, and that processes of auto-learning of the system are possible, amplifying, at level of supply chain, improvements realized at level of single suppliers. </td></tr>
<tr><td>MODEL 8</td><td></td><td>When the model 7 purses in maturation, it is possible to go to further improvements of the global system by involving in the sharing actions also some sub-contractors (for instance, the most significant for dimensions, for characteristics of their mission, for critic functions, for continuity in relationship, and so on).The homogeneous character of the supply chain is extended to lower levels, in order to increase knowledge and circulation of information and expertises, particularly those coming from operative fields. At the same time the sharing of management practices towards sub-contractors improves their competences and their capabilities of interaction with other component of the supply chain.</td></tr>
<tr><td>Key</td><td colspan="2">C Client   S Supplier   SC Sub-contractors   Supply chain
Selection   Coordination   Sharing</td></tr>
</table>

3. Supply chain management activities and supports

According to the eight proposed models for the supply chain management and on the basis of the key strategies of organization for buildings services (aggregation, integration and homogenisation), it is possible to analyse the different phases of service process (design, planning, delivery, monitoring and control), to underline the characterizing actions (selection, coordination, sharing), and to define main activities and related supports (table 3). In this paper only the most complete situation regarding homogenisation strategy is analysed.

Table 3: Key strategies of organization for buildings services according to supply chain management approach and, for each one, main actions characterising the different stages of a service process

		SERVICE PROCESS STAGES			
STRATEGIES	**ACTIONS**	**DESIGN**	**PLANNING**	**DELIVERY**	**MONITORING AND CONTROL**
aggregation	*selection*				
integration	*selection and coordination*				
homogenizing	*selection, coordination and sharing*				

3.1 Main activities and supports in service design stage according to homogenizing strategy

The main activities and related supports that characterize the design of service performances operating according to a homogenisation strategy regard:

- *design and implementation of the organizational structures*. The supports for this activity can be: organization chart (hierarchical and functional) of the structure; operational structures (call center, purchasing and legal and administrative offices, technical departments, EDP, etc); job description for main roles of the structure; information system;
- *definition of goals, policies, strategies and guide-lines for the management of the service.* The supports for this activity can be: management manuals (technical, administrative, logistic, health and safety, etc.); tools for Customer Relationship Management (CRM); management manual for quality; organizational and operational procedures (for coordination,

communication; interaction with Client, processes control; results control; management of environment, health and safety); procedures for purchasing (sub-contractors selection, structures of the orders, terms of payment, etc.);

- *statement of a knowledge management*. The necessary tools are knowledge management systems;
- *statement of benchmarking processes inside the supply chain.* The supports must be indexes for processes, results and client/customer satisfaction measurement;
- *human resources policies.* It is necessary to adopt training and empowerment procedures and programs;
- *definition of requirement for sub*-contractors selection. It is essential to rely on lists of organizational, economic, technical, logistic requirements. Typically: tools as vendor lists of sub-contractors of previous services and works, and procedures for the quality management of sub-contractors;
- *definition of strategies of customer value.* It ca be useful to collect and analyse previous clients relationships and to operate with case-based knowledge systems.

3.2 Main activities and supports in service planning stage according to homogenizing strategy

The main activities and supports that characterize the planning of service deal with:

- *briefing between suppliers*. The supports for this activity can be: general scheme of constrains, goals and service standards;
- *coordination of activities of documents and data collection and of physical survey*. It is necessary to adopt a common system of classification and coding for buildings and their parts;
- *implementation of the information system for the service*. It is necessary the assumption of an information system and the related procedures for implementation and use;
- *definition of the general plan for the service.* Supports can be: general scheme of the plan; guide-lines and criterion for the definition of priorities in the execution of interventions; guide-lines and criterion for logistic optimisations;
- *definition of the operational program for the service.* It can be useful to adopt methodologies such as linear and reticular programming techniques; besides it is necessary to point out target start and target completion (constraints in beginning and end of activities);
- *assumption of a common logistic support.* The main supports are: centralized purchasing office, a common warehouse management, a general qualified sub-contractors register;
- *implementation of common scheduling*. It is essential to get a centralized system of management (emission, allocation, closing, report) of the work orders;

- *training of workers.* Training activities ca be sustained by actions of tutoring (learning on the job), by procedures and instruction for the specific tasks and by teaching sessions based on themes closely connected with services jobs.

3.3 Main activities and supports in service delivery stage according to homogenizing strategy

If design and planning phases have been well conducted, if all coordination actions have been stated, and the flow of information, decisions and resources is adequately supported, in the development phase the main activities are merely:

- *management of resources*. The required supports can be: procedures and instructions for procurement and management of materials and services; information system with ERP functions (enterprise resources planning); procedures and instructions for warehouse management;
- *global vision and monitoring of current activities inside different suppliers services, with particular attention for safety aspects.* Useful supports can be coordination procedures for activities at high risk OHS (for instance Lock-out/tag-out, work permit, etc.);
- *work orders emission*. It is necessary to use an information system with functions for management of programmed and not programmed interventions;
- *report of completed works*. It is fundamental an information system with functions for implementation of clinical data sheets (feedback data);
- *continuous upgrading of information about building conditions*. It is necessary the presence of a system of technical, diagnostic and clinical data sheets.

3.4 Main activities and supports in service monitoring and control stage according to homogenizing strategy

It is very important to carry out activities regarding both monitoring and controls during services processes and at the moment of completion of works. The results of the services, the performances of suppliers and of sub-contractors that have been checked, fundamental interactions and communications with Client and between suppliers, and eventual problems, non conformity and corrective actions executed must be registered, analysed, elaborated, collected inside knowledge management systems in order to spread between the supply chain components new experiences and to increase the expertises of the chain.

The principal activities regarding monitoring and control functions are:

- *monitoring of sub-contractors performances*. It is useful to adopt: benchmarking indicators; *work-sheets* and *time-sheets;* procedures for supervision on works advancement and for account control; evaluation sheets for sub-contractors. It is important to record results of monitoring review inside information system;

- *monitoring of suppliers performances*. Possible supports are: process monitoring procedures; recurring audit sessions based on effectiveness indicators and in general on benchmarking indicators; *work-sheets* and *time-sheets;* procedures for supervision on works advancement and for cost accounting. It is important to record results of monitoring review inside information system;
- *monitoring of critical activities advancement* though specific work-sheets and time-sheets and specific monitoring procedures;
- *claim prevention on sub-contractors activities*. It can be useful to adopt special indicators, such as indexes regarding ratio between programmed and not programmed activities.
- *final control of suppliers services*. It is opportune to perform audit sessions based on client's satisfaction objectives. It is important to record results of audit review inside information system.

4. Conclusions

The evolution in building services market is now facing the need for an evolution of the traditional service delivery models. Both on demand side and on offer side the transition is towards the complete integration of different services; consequently the traditional model of service suppliers (mainly coming from the construction industry) needs new approaches in order manage the various complexity factors. The SCM "Supply Chain Management" approach seems to be particularly suitable and appropriate to give contributions for organizational and operational improvements in suppliers behaviours and, in general, for the maturation of an original culture in services field. It is therefore important that researchers and operators could join their efforts and interests about these themes also in order to smooth the progress of transfer and adaptation of principles, methods and tools from the industrial to the building sector.

Centre for Facilities Management, University of Salford (k.alexander@salford.ac.uk)

Abstract

FM organisations have long been argued for their being unique entities, like fingerprints... And when relating these organisations to each other, analysts and researchers use market sector based classification systems as the only criteria to group them. This paper is the first series of two papers, and demonstrates that current practice of relating FM organisations to each other in comparative studies has led to unintended results since it overlooks many significant characteristics of the Facilities Management organisations. This paper examines methods used in classification of organisations in general and then suggests a classification system for facilities management organisations.

We suggest in this paper that classification as an end product enables to relate FM organisations to each other in order to understand the similarities and dissimilarities between them. The outcome aims to be useful for those involved in comparative studies in FM organisations.

Keywords: Classification, FM Organisations, Market Sector based Classification

Introduction

In organisational studies, authors [1,2,3,4] argue that unless there is an adequate classification system, there is little guide for both practitioners and academics in understanding the organisations. It is therefore inappropriate to explore if what works in one organisation will work in another, and relate them to each other since there is no basis for knowing if the organisations are of the same type [4].

Yet, there is no classification system for FM organisations. And if we give Bailey the benefit of the doubt, without a classification system and rationale, we risk developing advanced concepts, reasoning, discourse and data analysis for FM organisations.

Bev Nutt [5] stresses the lack of relevancy and relativity in FM field, and estimates that: *"Only 40% of good FM practice can really be relevant to everyone in the world."* Academic colleagues recognise the diversity and fragmentation in practice [6,7,8,9,10] and they attribute this diversity and fragmentation to the nature of ‘client organisation’ (henceforth referred as: context organisation) [11,12]. Operated within the context organisation [13], FM responds to specific problems [14,15] and fails to form universal or common conceptualisations. The response of FM to its clients therefore become contextual [16,17,18]. And relating FM organisations to each other hence is merely based on the definition and classification of context organisations, assuming that FM organisations operating in similar contexts behave similarly.

The fundamental of classification is to ascertain the key characteristics on which the classification is based. So the research question we adopted here is: *what are the fundamental characteristics (patterns) of Facilities Management organisations that make them similar or dissimilar*? This paper represents the characteristic variables of FM organisations, and suggest that when measured, they are enough to distinguish one from another.

This paper, at the onset, starts with the negative side effects of the current classification system in the UK, and compares it with both FM literature specifically and then organisational literature in general. It then proposes a framework of a system for classification of the FM organisation.

1.1 Current practice in classification of FM organisations

Relating one organisation to another is mostly practiced in comparative studies, where consultants or academics attempt to compare like with like to deliver to an objective. However, these studies have been heavily criticised because of them being shallow and dysfunctional for organisational needs [19,20].

To better analyse the rationale for the current practice in comparative studies, we conducted a series of ‘focused interviews’ with both consultants and clients who have previously involved in comparative research studies. We focused our query on the current classification rationale in FM, and asked respondents about the negative side effects of practice, and also their suggestions for developing better classification systems.

All of the interviewees agreed that the current classification rationale rooted in market sector based classification is pragmatic and cost efficient in nature e.g. Standard Industrial Classification (SIC).

The main advantage of classifying according to SIC is: one can explain organisations’ response to similar operating environment—such as market sector and its pressures; regulatory influences — and organisations’ exposure to those market pressures. However interviews also showed that taken SIC as *the only* matter of classification causes misinterpretation in analysing FM organisations. Interviewees highlighted the following negative side effects of this practice:

a) The current classification rationale only helps the weakest practice to become a standard practice.

b) If not go in-depth, can lead into wrong business decisions.

1.2 Classification in FM Literature

Becker [21] and Davis et al. [22]; Price [23] and Brochner [24]; and Williams [25 and Varcoe [26] have introduced three different sets of classification rationale for Facilities and FM organisations. The pioneers of the idea of classifying FM organisations were G. Davis and F. Becker [21, 22].

First, Davis and his team classified 18 context organisations according to nature of change (low change/high change) and the nature of work (routine/non-routine). To them, FM operates differently in different contexts because of the attempt to fit into the organisational change. Similarly Becker advocated that FM can be categorised according to the context organisation, and his FM typology is based on FM's response to its context.

Relations between FM and the organisational change, and FM organisation's response and responsibility to change became an area of research especially in the 1990s. Several authors [14, 15,21,27,28] emphasised the Facility or FM as a change mechanism to adapt the organisational resources like buildings, systems, processes for the changing conditions.

Secondly, Price [23] proposed a generic classification system that incorporates the relationships between the context organisation and its customers. He sustains Bitner's [29] servicescape[1] idea from her classical work and concludes that there are two dimensions in classifying facilities: complexity of the service provision and the speed of customer feedback. The speed of customer feedback is related to the visibility and the proximity of service delivery to the customers of the context organisation. Brochner [24] further suggests that the duration of service relationship as an indicator for classifying the 'settings'. He exemplifies the difference between a restaurant and a hotel setting, former being a short term interaction and latter a long term.

Thirdly, Williams [25] and Varcoe [26] took a procurement and service provider relations perspective in defining and characterising the patterns in FM organisations and the industry. Williams models Facilities Management organisations in the following categories:

I. Total in-house facilities management
II. Outsourcing as 'Single', 'Bundled' or 'Packaged' Contracts
III. Total facilities outsourcing: management contract
IV. Total facilities outsourcing: managing agent

In addition to these three sets of classification rationale, we added the fourth: personnel's expectations. The influence of personnel on the FM policies and practice are mentioned extensively

---

[1] In 1992, Bitner defines servicescape as the built environment surrounding the service. However at a later publication in 2000 she feels the need to expand this definition to include social environment. Her recent definition of servicescape is: "immediate physical and social environments surrounding a service experience, transaction or event" (Bitner, M.J. (2000) The Servicescape in (eds) Teresa A. Swartz and Dawn Iacobucci, Handbook of Services Marketing and Management, Sage Publications, Inc., Thousand Oaks, p.37)

in the context of workplace making [30], staff involvement to workplace and FM decisions [27,31,15,21,32,33], usability. The involvement and the positive experience are usually to highlight the importance of managing the personnel's expectations. The better the expectations are managed, the better an FM organisation performs [24,35]. User involvement is primarily considered as means to manage their expectations.

However, these different approaches for managing personnel expectations have not been classified in FM literature. Although authors (those mentioned above) have attempted to classify FM organisations or their practices in their own area of study, there is still no holistic research encompassing these suggested characteristics variables in FM.

These different points of views in FM literature show also the diversity in FM perspectives. Notwithstanding Grimshaw's [10] criticism about the diversity of FM practice, it is also clear that: so does the theory...

1.3 Classification in Organisational Studies

Classification of organisations is not new to the academic fields of organisational behaviour. One could look at the use of Standard Industrial Category (SIC) Codes to see the utility of such classification systems. However, researchers over thirty years developed typologies based on a wider variety of criteria including: size, use of technology, strategies employed, systems utilized, degree of environmental stability, and who benefits. However none of these studies purposively addressed classification of organisations as the main topic. Instead, authors built up their research on these classes and prove or disprove their assumptions as the outcome of their research. It is therefore, of little use for the purposes of this research. However, authors agree on the scrutiny of *organisational structures* as the first step to describe organisations.

Organisational structure, as formal representation of an organisation, gives clues about people, influencing lines [36], decision makers, terminologies, duplicated work orders and tasks and integration and synergies [37,38,39], and even political conflicts [40,41].

2. External Patterns—Out: Relations between FM and its Environment

From both FM and organisational studies literature and the conducted interviews, we concluded that the relations an FM organisation creates are through (a) FM and its environment, and (b) FM and its formal and positional structure in an organisation. Attributes of different objects can be categorised in two groups: External patterns and internal patterns [42]. In other words, one of the relationships is related to internal structure of FM and another to its external environment.

External environment is where the transactions take place. This may include suppliers, clients or customers, and competitors. In addition, there will be more general aspects of the environment which will have important effects, such as legal, technological, cultural and ethical developments. The FM organisation and its external environment are explained here by four patterns: customers, personnel, organisational change and sourcing options.

In describing the significance of the transaction between an organisation and its environment, Pugh [43] states that (p.97):

“All organisations are situated in an environment, be that business, governmental, educational or voluntary service. In this environment are other organisations and peoples with whom transactions take place. These will include suppliers, clients or customers, and competitors. In addition, there will be more general aspects of the environment which will have important effects, such as legal, technological, cultural and ethical developments”.

Duncan [44] explains that characteristics of organisational environments are defined by the complexity and the dynamism. To compare, he illustrates that while banking industry operates in dynamic and complex, cardboard box industry operates in static and simple environment.

The external and internal patterns, or characterising variables used in this study are explained further below.

The context organisation is drawn like an amoeboid shape, representing the environment [45] in which FM organisation operates. The environment is defined as the source of inputs for the organisations and is the recipient of organisational outcomes [46.47]. We accepted context organisation as “the environment” for FM organisation.

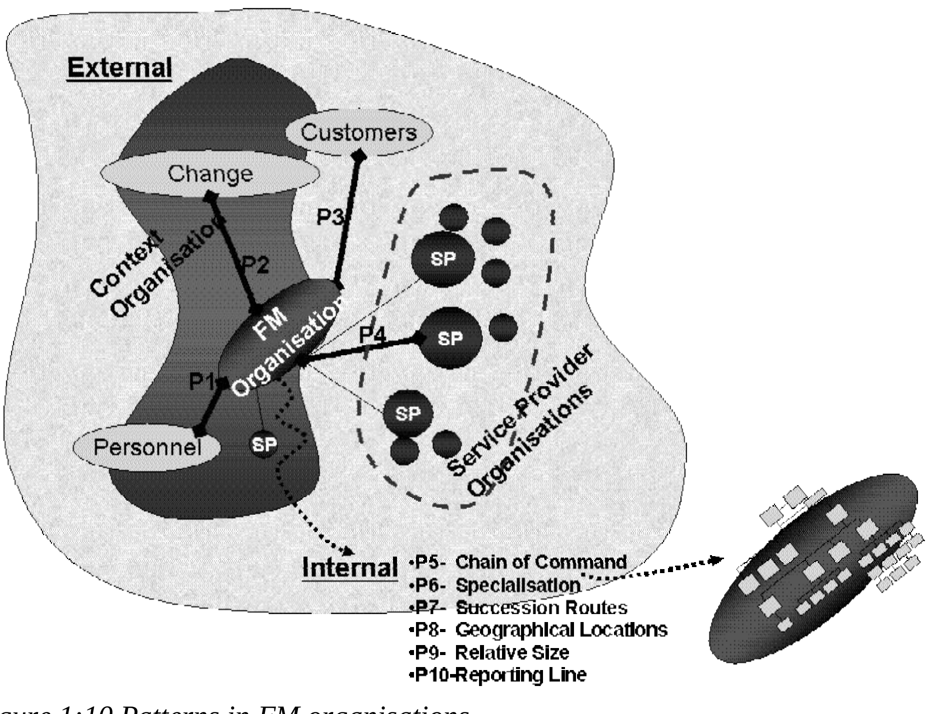

Figure 1:10 Patterns in FM organisations

<u>Proposition 1:</u> The external characteristics of FM organisations depend on its relations to the environment, more specifically to expectations of personnel, organisational change, visibility to customers and procurement options incorporating the service provider organisations.

Pattern 1 (P1): Occupancy profile

The quality of service delivery is driven by the personnel's expectations. Boyer [48] and Felder's [49] studies showed that there is a positive correlation between the occupational status and personnel's expectations from the company. However, this did not become apparent before Lee and Mitchell's study by the end of 1994. Their study discovered that professional background is the most critical parameter for managing the personnel's expectations in pursuit of employee retention [50,51,52].

In classifying the relationships between individuals and the employer organisation, Blau [53] and later Prandy [54] suggested nominal measures such as professional background (referred here as occupational profile) or occupational status as central to any sociological class scheme in organisations. They argue that "employee expectations change according to the professional background, which implies specific formal training and thus substantial homogeneity of background" [55].

This point was also stressed during the interviews. The interviewees stated that the level of quality in service delivery varies significantly according to the 'occupancy profile'. Some business departments are provided with better and higher quality services than the others. For example the building that accommodates CEO's office, is provided with a higher quality service than company's other buildings in its property portfolio.

This summarises the fact that unless the personnel's expectations are met, they might voluntarily leave the organisation, and therefore risk the company's performance [52,53,54].

More recent surveys by Office of Population Censuses and Surveys [55] classified employment and labour characteristics using the 'Standard Occupational Classification' (SOC), which consists of the following major groups:

I. Managers and Senior Officials
II. Professional Occupations
III. Associate Professional and Technical Occupations
IV. Administrative and Secretarial Occupations
V. Skilled Trades Occupations
VI. Personal Service Occupations
VII. Sales and Customer Service Occupations
VIII. Process, Plant and Machine Operatives
IX. Elementary Occupations

We used the SOC to identify the level of personnel expectations; i.e. the higher the rank in SOC, the higher the expectation. The distinction in rank also identifies the different patterns of expectations. To illustrate, out of the nine classes of SOC, the No.1, managers, executives are the professions with the highest expectations, and the occupations like elementary construction, agricultural, process plant occupations, come with the lowest expectations.

Pattern 2 (P2): Organisational change

Organisational change refers to forms of adapting the context organisation to its external environment and its requirements. Kaya and Williams' [57] previous study shows that there is a direct correlation between a company's churn rate and the speed of organisational change. Their findings substantiated Gladwin [58], Eley and Marmot [59] and FMA's [60] suggestions that the churn rate is an important indicator of change and dynamism in organisations.

However the churn rate should be monitored continuously. Gilleard and Yat-lung [19] criticise that comparative studies fail to address dynamic change by the use of static imperatives like churn rate. A snapshot assessment may give misleading results if the company goes to a business change during the period of evaluation. Kaya and Alexander [61] suggested some three to five years record of churn rate in referring to organisational change and its impact on the workplaces.

Pattern 3 (P3): Visibility to Customers[2]

Pattern 3 follows Price [23] and Brochner's [24] emphasis on the impact of physical setting and services (serviscapes) to customers' purchase intentions. We therefore suggest speed of customer feedback and duration of service relationship as two parameters for classifying facilities with respect to their visibility to customers.

The closer facilities services to the customers, the more visible they are, and therefore the faster the customer feedback. The longer the duration of service relationship, the more visible the services. In our analysis, we scored both the speed of feedback and the duration of services for the 22 surveyed organisations.

Pattern 4 (P4): Procurement Options

Pattern 4 follows Williams' [25] four types of procurement options as the indicator of structural relationships between FM and the service providers. We have earlier discussed that sourcing model and procurement options are the characteristics of the relationship between supply and demand.

The four external patterns dissolving relationships between FM and its environment, and the associated variables and attributes are summarised in the following table:

---

[2] Customers are those the organisation is getting the benefit from. They are the raison d'etre for the organisation. The reader should be acknowledged that Drucker's (1954, p. 37), statement that the purpose of a firm was to create and keep customers – for "it is the customer who determines what a business is"

	Patterns	Variable	Independent Variables (IV)	Attributes
R1	Relations between FM and personnel Expectations of personnel from FM	Occupational status (Occupational profile)	See 9 categories above	Expectation score
R2	Relations between FM and organisational change	Workplace change	Churn Rate	% Percentage of the last 3 years
R3	Relations between FM and customers of context organisation	Visibility of FM services	Speed of customer feedback Duration of service relationship in the servicescape	Visibility Score
R4	Relations between FM and service providers	Procurement options	See 4 categories above	1-2-3-4

3. Internal Patterns—In: Formal Analysis of FM Organisations

FM organisations are no different than any other organisations. They have organisational structures, internal relationships and an organisational architecture. The formal representation of an organisation often takes the form of an organisational structure, where the relationships are represented.

Proposition 2: If FM organisations are not different than any other organisations, then organisational variables, such as hierarchy, specialisation, succession routes, geographical dispersion, size and reporting line should be the six internal patterns that define the formal analysis of an organisation.

These six dimensions are considered as the six patterns of an FM organisation with respect to its internal structure.

	Pattern	Variable	Independent Variables (IV)	Attribute
R5	Chain of Command	Organisational Structures	Hierarchy	# of levels between Head of FM and the Board member
R6	Specialisation	Organisational Structures	Span of Control	Max number of subordinates FM managers have management responsibilities
R7	Succession Routes	Organisational Structures	Reporting Director's span of control	# of positions represented for promotion to reporting director of FM. The higher the positions, the less succession opportunity
R8	Geographical Dispersion	Organisational Structures	Regions, states of countries FM has responsibilities	# of regions / states / countries
R9	Size	Size of FM Size of Context Organisation	Relative Size of FM	In-house FM staff per personnel
P10	Reporting Line	Organisational structures	The position or function to where FM is reporting to	1- Board 2- Property 3- HR 4- Operational Director 5- Finance Director

Pattern 5 (P5): Chain of Command

This refers to the unbroken line of authority that extends from the top of the organisation to the bottom. It can be measured by counting the number of levels in a typical organisational structure. It is one of the key characteristics to define and organisation. When people are talking about the hierarchy, tall structure, flat organisation they usually refer to gain of command in organisational structures.

In FM organisations the hierarchy can be measured by counting the number of lines that extends from the bottom of the FM up to the Board member.

Pattern 6 (P6): Specialisation

Child [62] emphasises that specialisation deals with the number of jobs broken down into narrow areas of work and responsibility so as to secure the benefits of specialisation. Specialisation is widely used in organisational analysis to refer to the dissemination of responsibilities according to the specific areas of expertise.

For the FM organisations surveyed in this Thesis, the focus is on the degree of specialisation; i.e how specialised are the FM organisations. This can be understood from the organisational charts by reading the maximum number of subordinates reporting to a direct line.

Pattern 7 (P7): Succession Routes under Reporting Line

It is a structural issue if the jobs and tasks should be grouped according to functions or product or service type. Succession route shows the ways of promoting vertically.

In FM organisations, the succession route is the flow in the organisational structure that leads into the reporting line. It is therefore if the Reporting Director's span of control is limited to three, then succession route is limited to three too because an FM emploee progressing his carreer in FM can be pushed upwards in the organisational ladder up to the reporting line.

Pattern 8 (P8): Geographical Dispersion

Organisations operating in different regions, countries locations also represent this geographical diversity in their management concerns. For example they represent regional managers dedicated for a specific region and structure the regional organisation accordingly. While in some cases this might give some autonomy, in some cases this is nothing but unnecessary fragmentation of business.

FM is no different to any other organisation, and in a diverse property portfolio it might structure itself in respect to the number of geographical locations that business operates.

Pattern 9 (P9): Relative Size

Size of the organisation [53,63,64,65] is one of the most important aspects of an organisation [66]. Blau [53] incorporated this relationship as one of the two major basic generalisations in his formal theory of organisations.

However, rather than referring to size of the FM organisation only, in this research we suggested to use 'relative size', since it reflects the weight of FM in the organisation. Relative size refers to size of FM and the context organisation. For instance, an FM organisation with 15 FM full time employees (FTE) responsible for 10,000 occupants is different than an FM organisation responsible for the same number of occupants with lesser FTE's. This is formulated as:

$$No = \frac{\textbf{Normalised} \left[\sum \textbf{personnel}\right]}{\textbf{Normalised} \left[\sum \textbf{FM employees}\right]}$$

This fraction is another attribute to understand what proportion of the population FM represents in the organisation (FM's catchment population).

These nine patterns suggested here are the characterising variables for FM organisations, each of which is associated with independent variables. When these patterns merge and come together, they can classify the organisations at a multi-dimensional space. This is explained further down.

Pattern 10 (P10): Reporting Line

Positional power in organisations plays a vital role in decision making. Although there are other kinds of power, the reporting line best represents the positional power amongst them. Relating the organisational literature to FM, authority and reporting line are both related to positional power; such that one step higher level of management to Head of FM is an indicator of decision authority in terms of positional power. This Thesis has only analysed the positional power as means to the reporting line of FM organisations.

To identify the patterns in reporting lines the author has asked the UK's six national service providers to list the variety in their client's reporting lines [67]. Five common reporting lines are identified in the UK, these are: Board, Property Director, HR Director, Operational Director and Finance Director

Depending on the reporting line, the policies, strategies and processes of FM organisation can change. It is therefore considered in this Thesis as another dimension that characterises the FM Organisations.

4. Conclusions

This paper demonstrated the characteristic variables, called here as patterns of FM organisations that make one client side FM organisation dissimilar or similar to another. These patterns differentiate the way in which the FM organisations are formed for their goal attainment.

Four of these patterns are related to the external environment of an FM organisation. These are expectations of personnel, organisational change, visibility to customers and procurement options. And six of them are related to the internal structure of an FM organisation. These are: chain of command, specialisation, succession routes, geographical dispersion, size and reporting line.

This paper prepares the background for further studies in classifying FM organisations to relate and understand them in relation to their similarities and dissimilarities. When the measures of these 10 patterns are close, it means that they are similar to each other. The successor for this paper is the illustration of this empirical study in an application to define and identify the FM organisations.

Mapping distributed knowledge to assess quality of complex urban environments

Luiz Bautzer,
CSTB Centre Scientifique et Technique du Bâtiment – France (luiz.bautzer@cstb.fr)

Abstract

Municipal institutions and social housing corporations struggle to establish a efficient joint facilities management processes within economically and socially fragile urban areas. The key problem is establishing common understandings of constrained social situations. Through a concrete example, we explain the role of representation devices in bringing together knowledge about, on the one hand, day-to-day, facilities management and on the other hand, public management stakes concerning social housing. We finally present a dashboard that facilitates organisations in their efforts to measure their collaborative capabilities in achieving facilities management excellence in constrained urban areas.

Keywords: quality assessment, cross-boundary collaboration, urban regeneration, New Public Management

1. Purpose of the paper

Optimizing Facilities Management (FM) in public housing estates depends on the capability to articulate two apparently contradictory trends.

- ***minimizing coordination costs*** *:* on the one hand, the search for leaner and more cost-effective asset management processes favour governance principles designed to instil more (explicit) knowledge into better-aligned processes. Sophisticated asset management devices are developed to standardize coordination routines between specialized activities and manage cross-boundary collaboration. These devices are focused on control through rules, procedures and asset measurement techniques such as dashboards, planning devices and budgeting tools.

- ***managing unstable organisational interdependencies between facilities management contributors:*** on the other hand, as facilities management and maintenance performance is more and more the result of the capability to react adaptively to new and unforeseen circumstances due to citizens' practices, political agenda shifts, facilities managers need to *work and learn together* to cope with uncertainties.

Our paper is about the way FM teams build capabilities enabling them to cope with these two trends. We point out the impact of *quality definition devices* (FM standards, classification systems about unexpected events, data-processing tools, information repositories...) on building capabilities to manage the way *different* and nevertheless *interdependent* FM contributors *work and learn together* in poor urban housing environments.

Through qualitative case studies about seven cities of a French Region, [1] we highlight two main aspects about the way these quality assessment devices contribute to ***create and share knowledge*** through mutual adjustments between public housing institutions, municipal service providers and local political authorities:

- In a first part or this paper, we describe how key stakeholders (State administration, local authorities, urban services providers, public housing institutions) develop new *capabilities to represent collectively* "hybrid" FM processes bundling together technical and social knowledge about low-income families practices in their housing and urban environment.

- In a second part, we outline a "dashboard" measuring the organizational capabilities required to control and facilitate collaboration between *different* and nevertheless *interdependent* facilities management contributors; the "dashboard" allow FM teams to position themselves with regard to key capabilities in managing functional interdependences while preserving their own requirements according to the each phase of the facilities management process.

2. The context: coping with uncertainty

We have focused our research on the way Facilities Managers set up organizational routines to handle every day problems resulting from the lack of coordination between different institutions accountable for urban services of social housing estates situated in deprived urban areas. [2]

Our approach is based on qualitative case studies about a public program aimed at developing "arms length management" initiatives ("*Gestion Urbaine de Proximité*"). We highlight recent transformations initiated by New Public Management aimed at achieving affordable housing for economically and socially fragile populations. French administration [3] deployed since the early 2000' a contractual framework in order to formalise "service level agreements" between key service providers within housing estates. Latest transformations initiated by this contractual approach are designed to optimize public aid allocation to poor urban areas.[4]

The contractual framework is supposed to both develop business-like quality standards and assess FM teams' capabilities to solve complex urban problems resulting from social practices

---

[1] Région des Pays de la Loire : Nantes, Angers, Le Mans, Allonnes, Laval, La Roche sur Yon, Saint Nazaire, Chollet.

[2] ZUS :Zones Urbaines Sensibles.

[3] An initiative called *« Gestion Urbaine de Proximité »* focused on developing social cohesion through a larger program called *« Politique de la ville »*

[4] A major move in this direction was the allocation of 4 billion euros to a new government agency (*ANRU - Agence Nationale pour le Renouvellement Urbain*) in order to create a new offer of 250 000 social rental residences envisages, the rehabilitation of 400 000 social rental residences and the demolition of 250 000 residences before 2011.

of vulnerable households. These problems are frequently linked to the fact that decision making processes depend on collecting dispersed information about the quality of services delivered within large-scale housing estates.

Facilities management teams need to develop capabilities enabling a combination of on the one hand, technical *standards* optimization and on the other hand, social awareness of the *specific* problems related to the fragile situation of the population living in these neighbourhoods. Our first diagnosis revealed that FM Key Performance Indicators of social housing institutions are still specialized, sector specific and poorly interoperable

Social housing corporations are predominantly focused on economic data expressing the return on investment of their housing park (turn-over, rent collection and arrears, vacancy rates). [5] Local authorities have developed throughout the past thirty years, large amounts of studies and informal knowledge about urban social practices. Their data is focused on inequalities in housing: mix of population, unemployment rates, special needs of minority groups and safety & security issues.

2.1. "Aligning processes" does not necessarily mean "instilling co-responsibility"

Facilities management teams in large scale housing face two main uncertainties:

- design and manage a *programme* to progressively and systematically up-grade the rapidly aging multi-storey dwellings characterized by mass housing construction techniques of the 70' and 80' ;
- Cope with *unexpected* events (vandalism, incivilities, etc...) that rapidly jeopardize quality of services delivered and generate heated discussions and (potentially) violent interactions with tenants.

There are at least two ways to deal with with the lack of coherence between planning FM activities and integrating disruptive events resulting from social practices.

The first way is to focus on "alignment" and minimising co-ordination costs. The search for leaner and more cost-effective organisations favoured initiatives designed to develop a business-like culture in traditional facilities management processes. Managers set-up quality standards that should be deployed by FM teams through "compulsory" and "unavoidable" processes. Market-oriented measurement techniques such as benchmarking and budgeting tools are supposed to achieve considerable cost reduction.

---

[5] Corporations are more and more aware about the need to manage more effectively data about tenants' complaints; a nationwide effort is being deployed in 2005 to systematically use "customer satisfaction surveys" in day to day management.

But, we observe that in complex urban environments, process alignment doesn't necessarily generate higher levels of satisfaction of poor households and security living in aging housing park.

Approaches focused mostly on "control" reduces FM Team's capacity to cope with *unforeseen* events observed in the urban environment: *doing things by the book* within unquestionable and clearly defined structures diminished the more flexible forms of adjustments between social stakes and technical requirements.

An alternative way is to enable facilities managers to be able to deal with unforeseen events by enhancing the representation of every day (but nevertheless complex) problems.

Quality of services delivered within deprived urban areas, is considered as being a result of well-organized collaboration between different institutions. FM performance is based on the capability to work and learn *together*. Hereafter we describe an example of a simple device developed by local authorities of the city of Allonnes (France) to enhance their capabilities of dealing with numerous neighbourhood uncertainties encountered. The initial concern of the city council was the need to create a common means of representing problems faced by facilities managers and social workers during the summer months. During these holiday months, managers had less people at the "hot spots" of the neighbourhood where teenagers and young adults tended to carry out multiple forms of incivilities and degradation of urban equipment. The lack of resources acted as a spur to imagining alternative knowledge sharing, creation and re-use routines. To do this, municipal facilities management teams looked for a simple way to map unexpected events and improve follow-up procedures within the district. The resulting device was a two-fold representation characterised by two main components:

- a first page, sum up information about unexpected events,
- a second page, seize possible follow-up on curative measures and expected improvements.

The document was widely diffused in order to benefit from information supplied by "third parties".

2/2 DSU/02/04/2004

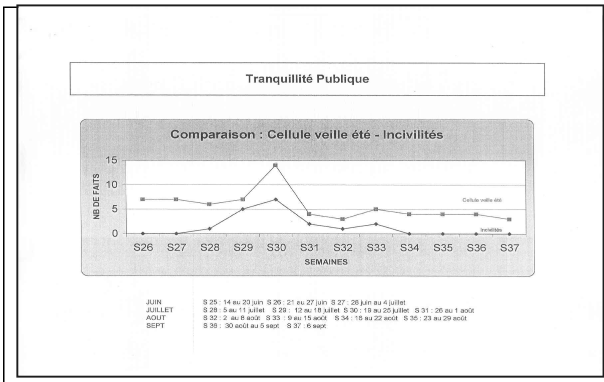
The second page, establish a link between factual information and the context where the event occurred by qualifying more precisely:

- *where ?* : dwelling and/or urban surroundings localization :
- *who* ? is accountable for curative actions? and *how ?* will follow-up be organized
- *how much* ? : costs and impact of curative actions undertaken; costs evaluation of repairs and follow-up on billing and insurances;
- *"and so what ?"* : traceability about potential legal pursuits (dates & qualitative observations).

This is an interesting example of an effort to "bundle" together information about non-programmed curative actions in order to produce a de-contextualized representation of the specific social practices of a district.

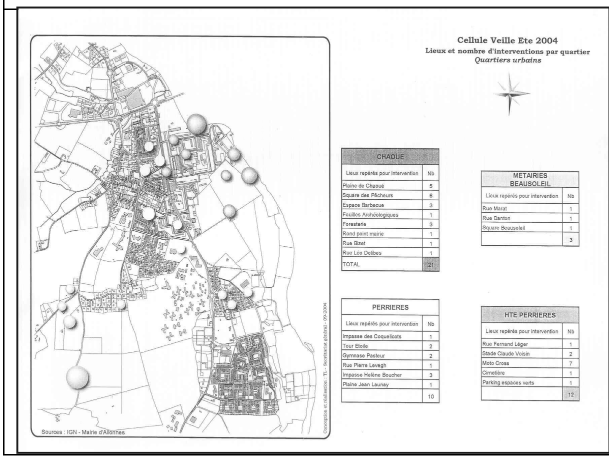
The detailed representation of the curatives actions in a district allows social housing managers and local government authorities to initiate the elaboration of a legitimate deliberation process incorporating both business-like criteria (optimization of facilities management processes) and welfare state ethical imperatives (improvements to obtain “affordable” quality of life in a poor district).

This approach enhances local team’s capabilities to represent coherently and publicly display *variations* of (unexpected) “vicinity problems”. We draw attention to this second step in the “*rhetorical”* [6] process which leads to a more legitimate representation of the “quality of life” in the district: formalising quality ***ratio variations*** is the basis of the rhetorical process leading to managerial ***accountability definition***. A simple data gathering device about day to day incivilities in the neighbourhood is the opportunity for qualifying responsibilities related to “exceptional” events in business-like facilities management processes.



Events are identified week by week. Seasonal peaks are identified so as that controversies [7] about accountability and resource allocation for proactive initiatives may be organized.

Therefore possible proactive initiatives may be organized in the following year to avoid this kind of disturbance.



Problems are also positioned in the urban space.

Simple software enables a clear identification of the frequency and the nature of the problems encountered by technical and social teams.

Priorities may be more *coherently* defined with regard to resource allocation.

[6] See also Laufer (2001) for a detailed explanation about the role of *rhetoric* and marketing techniques in legitimacy building processes of modern public management.

A basis for a simple *benefits case* can be drawn from a spreadsheet adding up all costs related to a series of events in the neighbourhood.

Up-dating of budget programmes can be made and trade-offs may be discussed with local authorities.

In this case, more than just “aligning technical processes” and “coordinating team interventions”, local authorities designed a representation of the district practices that involved:

- articulating formal and informal knowledge sharing processes;
- combining individual skills to bundle together technical and social issues;
- capitalizing on unforeseen events to create knowledge enabling preventive actions in order to tackle constantly evolving social problems within these urban fringes of the city.

This representation of problems encountered during a specific period of time in the neighbourhood, creates pragmatic opportunities to establish “paths” between different forms of knowledge (individual-collective, tacit-explicit) where “exceptional” events are integrated into de-contextualised management procedures.

What seemed at first glance “exceptional” and unforeseen events (incivilities, destruction of urban equipment, etc.) caused by “deviant” youngsters gradually become an dimension of a “normal” facilities management process.

More *consistent programming* enables better co-ordination of curative actions which involve centralized municipal technical teams, local facilitators and social workers. Further detailed analysis of the data about apparently unsystematic events enabled pro-active initiatives to be implemented the following summer in the identified “hot spots” in the district.

Information transfer enabled by information repositories (light databases about recurrent incidents, technical documents about quality standards, Excell spreadsheets on curative actions costs, etc.) and light information and communication technology (e.mails, Intranet forums) counterbalance difficulties in frequently mobilising *all* the local teams involved in managing the district. Distributed co-ordination reduces the number of time-consuming face-to-face meetings.

3. A dashboard to assess FM capabilities building process

We highlighted the fact that mutual adjustments between public and private corporations, between technical experts, social workers and local authorities and – finally between the various institutional teams and citizens, are a key capability in deploying facilities management in constantly evolving neighbourhoods and unpredictable urban environments.

FM performance is a matter of building *capabilities to cope with uncertainty* rather then just setting an identified performance targets or service level agreements. The combination of different forms of knowledge creates a representation of FM processes that allows social housing managers and local government authorities to collaborate more effectively and securely share information about both the dwelling (internally) and the urban environment (externally).

FM teams are confronted to at least three key questions:

- *Firstly,* how to transfer information between different organisations, different sites, different teams?
- *Secondly,* how to integrate information about unexpected events into programmed facilities management processes?
- *Thirdly,* how to create the appropriate context that enables and encourages knowledge sharing and creation about potential facilities management improvements?

Our analysis shows that FM teams – in both public councils and private housing organizations - have difficulties in bringing together these three sets of questions. Working with a small team of FM project managers working in the seven cities involved in our research, we established a "road map" on which teams are able to situate themselves and rank their capabilities to address these key questions.

We describe hereafter these three domains of potential improvements in more detail and outline the progressive development levels of the corresponding capabilities.

3.1. Understand why unexpected events occur

Let us turn to the first set of questions. The introduction of a contractual definition of "service level agreements" of the service provided by different organisations [8] cause a lot of problems concerning the way *informal knowledge* is framed.

Teams need to develop their capabilities in prompting a new framing of unexpected events. This means being able to choose the right *questions* that trigger existing FM routines. It is more than just defining the content and the associated processes to codify and transfer "facilities management" data. It is rather choosing the right *problems* to be addressed in order to develop

[8] Public, semi-public and private organisations.

shared perspective about "doing" things together in the district. This requires a new approach and management skills focused on emergent information about the districts life, tenants' practices and their cultural specificities. The stages of evolution of capabilities related to representing functional interdependence are characterised in Table 1 below:

Table 1 – Framing functional interdependences

CONTROL	Top down approach focused on aligning FM "solutions" Functional interdependence as a "moral" injunction*: "teams must work together!"* No shared perspectives of the practical outcomes of the proposed enhancement of functional interdependence
FACILITATE	Identify knowledge "brokers" in charge of developing methodologies for identifying FM "problems" Quality assessment of user's needs done by technical experts
LISTEN	Aware of the need to involve users' communities Involve citizens to boost local initiatives and capture informal knowledge Develop FM skills to manage knowledge networking to analyse local populations practices in the neighbourhood
ASSESS	Development of a facilities management KPIs integrating informal "third parties" knowledge Link formal (budgetary) facilities management indicators and day to day quality of urban services (periodical surveys, …)
INTEGRATE	Assessment devices and survey results are integrated into the facilities management strategy Integration of short term facilities management indicators into budgets Communication on proactive FM initiatives to key stake holders (local authorities, elected officials)

3.2 Representing collectively functional interdependences through quality standards

A second type of capability concerns the way teams use the *As-is* diagnosis: how they create a shared view about current problems to enhance accountability definition. The importance of this type of capability is usually underestimated. When confronted to unexpected problems, FM managers jump immediately into curative actions guided by abstract *To-be* targets. These are usually defined by central experts and engineering oriented departments. In this case controversies are focused on FM "solutions". Each contributor to the FM process seeks to justify its variations of performance by pointing to problems caused by inconsistencies in services delivered by their counterparts. Creating a thorough diagnostic about the "problems" encountered facilitate teams to avoid controversies about conflicting "solutions." [9] Progress within this area is signalled by different stages shown in Table 2 below:

[9] An efficient way to establish this kind of organizational diagnostics is to walk around the neighbourhood to build collectively a shared picture of the situation. See. Allen and Bonetti (2004).

Table 2 – Representing functional interdependence

PASSIVE	Waiting to be confronted to unexpected events Random knowledge gathering about disruption in FM processes No systematic traceability about crises, incivilities, tags, etc.
AWARE	Aware of the need to involve key knowledge providers about potential problems in the neighbourhood Growing awareness of the importance of knowledge *re-use* for operational effectiveness (sharing lists of problems already solved)
ACTIVE	Involve "third parties" in "on the spot" diagnostics (local teams dealing day to day with neighbourhoods problems, technical experts) to clarify functional interdependence
OPTIMISE	Organise knowledge sources & implement a knowledge re-use strategy of existing dispersed k-bases Selecting best knowledge sources about unforeseen events based on various FM contributors
VALUE	Audit of knowledge re-use practice Measurement of "costs vs. benefits" of acquisition of new FM knowledge Action plan to map and manage overlaps in knowledge utilisation

3.3. Capabilities to communicate about FM performance

In order to diffuse efficiently ***To-be*** performance targets, FM teams need to go beyond the usual strategy consisting in defining a formal "quality charter" and communicating it through "top-down" initiatives. FM teams need therefore to address simultaneously two different initiatives:

- create more or less informal routines to share knowledge through day-to-day encounters to refine their ***As-is*** diagnosis about how unpredictable events disturb FM processes.
- establish stable ***To-be*** references and facilitate re-use of known information about current dysfunctions;

Confrontation about As-is "problems" and To-be "standards" creates the capabilities in going beyond the definition of de-contextualised "quality charters". The confrontations enable a more reliable *representation of performance variations*. As communication about expected performance targets becomes more en more effective teams are able to define and deploy pro-active initiatives. We have identified below a number of intermediate stages towards "best practices" in this area.

Table 3 – Capabilities to communicate about quality standards

PUSH	Use a push strategy for sharing knowledge through diffusion of "FM charters"
SELECT	Being aware of re-usability of documents produced to up-grade FM charter
INDEX	Define standardised guidelines for enhancing charters on quality standards Indexing documents for easy retrieval
CLIENT-FOCUS	Segmentation of user's needs Explain "how to use" the charter and/or related documents (tutorials) Add links to the document to point to the context (knowledge and people) / Best practices market (reward asset contributors)
DEMAND-DRIVEN	Diffuse charters and related documents only in response to an identified need Follow-up the re-use of diffused documents Put a value on key knowledge (metrics of use)

3.4. Organizing the representation of performance variations to secure information sharing

The third key area of action concerns the creation of the *context* to enable and encourage knowledge sharing and creation about FM performances. Designing such a context means developing a dialogue that can articulate both informal collaboration and formalized coordination. Here, organisational structures and physical conditions are important but not decisive.

What really "makes the difference" is the capability to set up links between day-to-day informal problem-solving and formalised co-ordination processes, "road-maps" between creative and fuzzy approaches to FM problems and practical outcomes with clear rules and formalised KPIs. These links can be established through a common set of diagnostics about the limits of current facilities management practices. [10] Organising "conversations" about key events [11], creating meaningful stories, building common languages and vocabularies are different ways to create a context that enables shared perspectives about "managing" knowledge. They also facilitate involvement of key actors in knowledge management initiatives.

Again, it is worth tracking the progress along the *formalisation* and *networking* paths separately, as the indications (shown in the Tables 4 and 5 below) are different:

[10] See Bonetti (2001)
[11] Carlile (2002)

Table 4 – Formalizing hybrid representations

NON-COORDINATED	Looking for FM tools to support formalised knowledge exchange Growing awareness of a limit of the informal management of knowledge
K-BASE	Attempt to gather the knowledge into knowledge bases Managing knowledge cycle through knowledge bases
K-BRICKS	"LEGO" approach to FM knowledge formalisation (best practices, references, methodologies…) Define categories of "LEGO" blocks to improve FM performance variations visibility
LINKS	Take into account the fuzziness of organizational knowledge Try to integrate experience and districts context with knowledge bricks
COMBINE	Organising "conversations" combining FM knowledge objects with face to face relationships & invest in organisational context

Table 5 - Networking

LOCAL	Informal knowledge is not structured in the neighbourhood Awareness of FM networks' fragility
BUILD	Awareness of manageability of FM networks Identify key collaborations around FM processes in the neighbourhood Managing organised links between informal networks
CONNECT	Enable knowledge re-use by communities of practices Organise face to face events about exemplary *"unexpected* problems solving *routines*"
WEB-BASED	Improving efficiency of knowledge transfer / re-use with ICTs Assessing FM contributors re-use practices Multiply connections through IT tools
INTERNALISE	Leadership's appropriation of FM management and involvement of local elected authorities in steering teams Hybrid representation of FM processes diffuse through all the layers of the accountable organisations

4. Conclusion: re-instilling uncertainties of "real life" through "hybrid" representations of FM processes

Our analysis of current practices within seven French cities of the Pays de la Loire region shows that FM teams working within social housing in deprived urban areas are facing the following paradox:

- the more public administration develop quality control devices to better manage technical and organizational risks due to constantly evolving poor neighbourhoods;
- the less local facilities managers are capable to deal with cross-organisational stakes and be involved in more unpredictable urban participatory policies.

To manage this paradox, teams are developing "hybrid" management tools to facilitate the articulations of different forms of knowledge about delivering urban services and taking into account the specific expectations of vulnerable households. Our findings show that the lack of shared quality assessment devices erodes the ability of facilities management teams to undertake FM initiatives in more "deliberative" agendas of urban planning and facilities management.

Research results highlight facilities managers' efforts to *introduce more flexible workflows* for until now relatively low coordinated practices based on shared diagnostics about problems. Most managers, especially elected local authorities, tend to underestimate that agreeing on the "problem" is frequently more effective than having the optimum solution. The key difficulty is to bring all institutions accountable for the quality of services delivered throughout the neighbourhood to establish and share a new balance between technical solution and social problems. Quality assessment infrastructures play a key role – they bring together apparently different types of knowledge (social & technical). They help to design the "facilities management lifecycle" ***across*** organizational boundaries. The *"hybrid"* [12] and *"abbreviated"* [13] representations of quality of services would consequently facilitate collaboration across public and private institutions. Through these representations they *publicly display* their complementarities within new deliberative forums.

Finally, the capabilities building "dashboard" is a simple – "work in progress" type - device to bring FM teams to assess their present position in building governance capabilities to enhance facilities management of social housing estates exposed to unpredictable events within vulnerable urban environments.

Abstract

Construction project management is a new and effective activity in Lithuania. The demand for construction project managers is constantly increasing due to the higher amount of constructions that increased in our country within the last years by 20-30 per cent per year. Contracting authorities of construction projects give necessary investments for the implementation of their ideas; they wish an optimal achievement of the goal with no deeper consideration of the implementation process of the whole project. This concerns all the stages of construction project management. Facilities management is one of the least investigated stages of construction project management in Lithuania.

In Lithuania, the term *facilities management (FM)* originated in the scientific and practical activity not long ago. Each country has different level and scope of the development of facilities management activities. Therefore currently, the determination of the efficiency of FM activities under the conditions of Lithuania is a topical issue that requires the proper evaluation of current situation, determination of the best practical models and scientific tasks as well as consideration of the recommendations that would contribute to the development process of FM activities in Lithuania. The preparation of different specialists of this field in universities and other education institutions is particularly of great importance.

Keywords: construction project management, facilities management

1. Introduction

Under the conditions of market economy, all contracting authorities of constructions are to follow strict requirements assessing the costs, quality and duration of construction works. To satisfy the requirements becomes more and more complicated, because all the processes of work have a tendency to become more complex and the scope of specialization is constantly expanding. Contracting authorities of construction projects wish the optimal implementation of their ideas with no deeper consideration of the implementation of the whole process. They are ready to give all necessary investments for this. Such conditions determined the origin of a new field of activities – construction project management. This activity originated in Western Europe more than 30 years ago and currently is becoming more and more important.

Project management is the integration of management functions, management methodology and management technique in order to achieve the desirable final results of project implementation. In special literature resources the term construction project management appeared not long ago therefore there is no exact and standardized definition of this concept yet [5].

On the basis of the experience of foreign countries, in Lithuania the process of construction project implementation is divided into several stages (Fig. 1). In the stage of the determination of expedience of a construction project the goals, tasks, restrictions and possible implementation variants of the project are considered. According the common standards or analogs, the financial analysis evaluates the costs of a construction project depending on the variants of selected construction sites. The goal of such calculations is to evaluate investment demand and financing possibilities.

In the pre-design stage the legal issues of project implementation are analyzed (i.e., whether it is purposeful to purchase the land or better to lease it) and the conditions to obtain the construction permit are discussed. In this stage principal technical solutions are analyzed, optimal project variants are selected, estimation for construction costs according to common indices is presented and the duration of construction works is determined [5, 6, 7, 8].

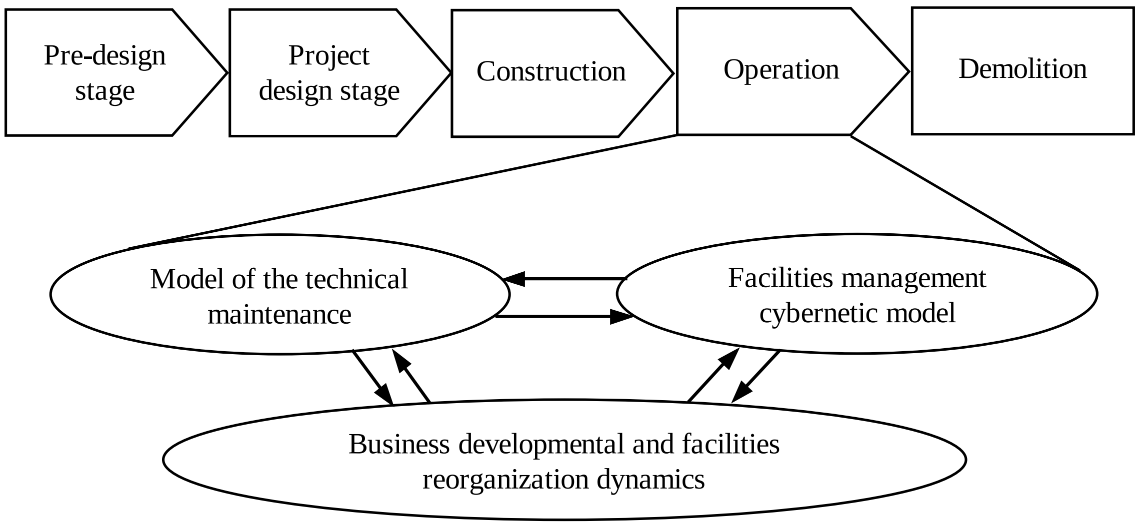

Figure 1: Constructions lifetime cycle and FM structural elements

During the project design stage the technical project of a construction is prepared. This part of the project includes a more detailed estimate. Having prepared the technical project and the estimate, a competition for the implementation of construction works is organized. The contractor-the winner is responsible for the engineering preparation of construction works, preparation of the implementation project of construction works and the implementation of construction works.

Before the operation of a building possible construction defects are eliminated. Then the building is ready to be used.

During the operation period of buildings different changes might occur that affect their operation qualities. Some changes may adversely affect comfort, domestic, work or industrial conditions; others may induce the disintegration of separate constructions or the whole building. This is due to the physical and moral depreciations of buildings. Physically depreciated buildings are often repaired: different elements are renovated, reinforced or replaced. Morally old buildings and the buildings with changed functions are reconstructed [15].

The maintenance and improvement of the functions of constructions within their lifetime require a purposeful implementation of strategic long-term organizational and economical tasks. Such activity is called facilities management [2].

Constructions used for different purposes have different constructional scheme, engineering equipment, main business technology, work regime and conditions (e.g., the activities of hospitals, gas stations, schools, etc.). Therefore the facilities management of different buildings has its individual peculiarities [14]. However, from the methodological point of view, common principles of FM activity are available [9, 10].

2. Problems and Tasks of Facilities Management in Lithuania

The term construction project management appeared in scientific and practical terminology in Lithuania about 10 years ago. The term facilities management started to be used about 5 years ago, because since then the construction project was understood and analyzed only until the onset of the operation period of a building.

The term facilities management comprises the object, its structure, operation functions and the whole operation system [11, 13]. Scientists of Lithuania and other countries give the following suggestion for the analysis of the facilities management: the problem is to be analyzed in administrative, technical, spatial (accommodation) and other services management aspects [16].

The effective activity of facilities management allows creating optimal conditions for the implementation of the main activities, the rational maintenance, repairing and modernization works of buildings; it also allows reducing operational costs of buildings as well as using efficiently the investments to ensure the modernization and necessary functionality of buildings [1, 4, 13].

In Lithuania, the maintenance of constructions is carried out in two ways: 1) the enterprise or owners of the building carry out all works by their potency or 2) facilities management services are provided by another enterprise according to the contract. Most enterprises and organizations in Lithuania carry out the maintenance of constructions by their own potential. Common industrial or added costs are used for this purpose, which makes up the greatest part of total expenses and adversely affect the competitiveness of the main activity of the enterprise. Construction maintenance departments are functioning inefficiently in the enterprise therefore this leads to higher expenses, compared to the costs needed for specialized construction maintenance enterprises.

Moreover, the quality of services is often insufficient as all works are usually done in the method of "fire fight". This means that defects are eliminated too late, i.e. only when they appear, and this requires much higher expenses.

To summarize the scientific researches and practice of constructions maintenance in Lithuania, facilities management problems and tasks might be divided into several groups (Fig. 2).

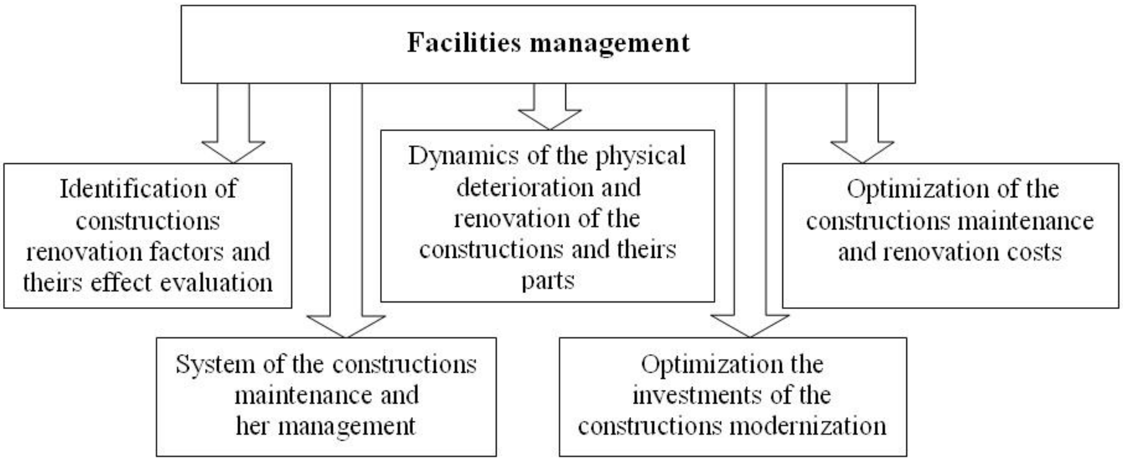

Figure 2: Tasks of facilities management scientific researches in Lithuania

In each group of tasks some studies have already been conducted. Lithuanian scientists have proposed the new multi-criteria evaluation method of the renovation of constructions and their separate elements. This method is based on the calculation of the effectiveness of a project or its components on common complex criterion evaluating the most important indices of the studied object. Moreover, the application of special software enables to create alternative solutions and to estimate them [16, 17, 18].

Scientific literature gives different reasons that determine the renovation of constructions. The reasons for the renovation of constructions in Lithuania are shown in Fig. 3.

Fig. 3 presents the results of scientific researches carried out on the determination of constructions renovation reasons in Lithuania. The results of those studies are needed for the prognosis of economy indices of constructions. The data of such kind of studies is different in each country. This is mainly influenced by the economical situation, traditions, legal environment, construction type and other conditions in every separate country.

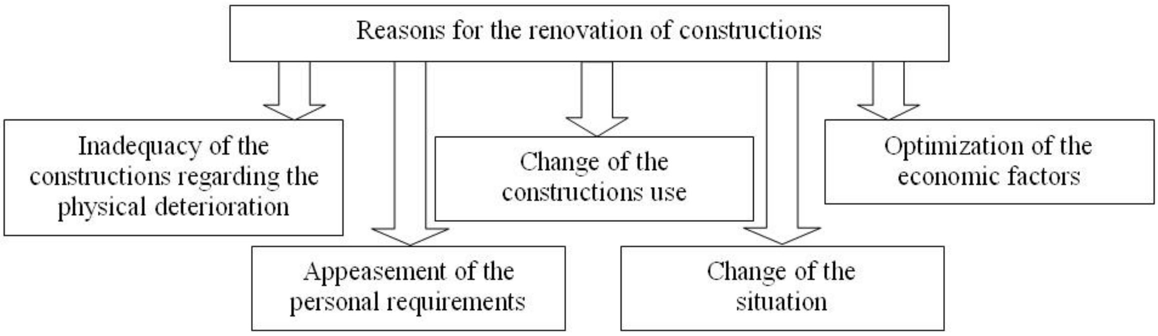

Figure 3: Possible reasons for the renovation of constructions in Lithuania

The dynamics of physical deterioration and reparation of constructions and their components makes the strongest impact on facilities management work structure the amount of necessary costs. During the construction operation period those costs and investments make up to 75% of total expenses during the construction lifetime period [3]. The amount of the costs depends on the solutions of a construction project and the effectiveness of facilities management activity during the construction operation time (Fig. 3). Having analyzed the dynamics of physical deterioration and reparation of constructions and their components, an optimal facilities management functioning model can be created.

The model of construction maintenance and reconstruction allows optimizing the amount of necessary costs and demand of investments during the construction operation period.

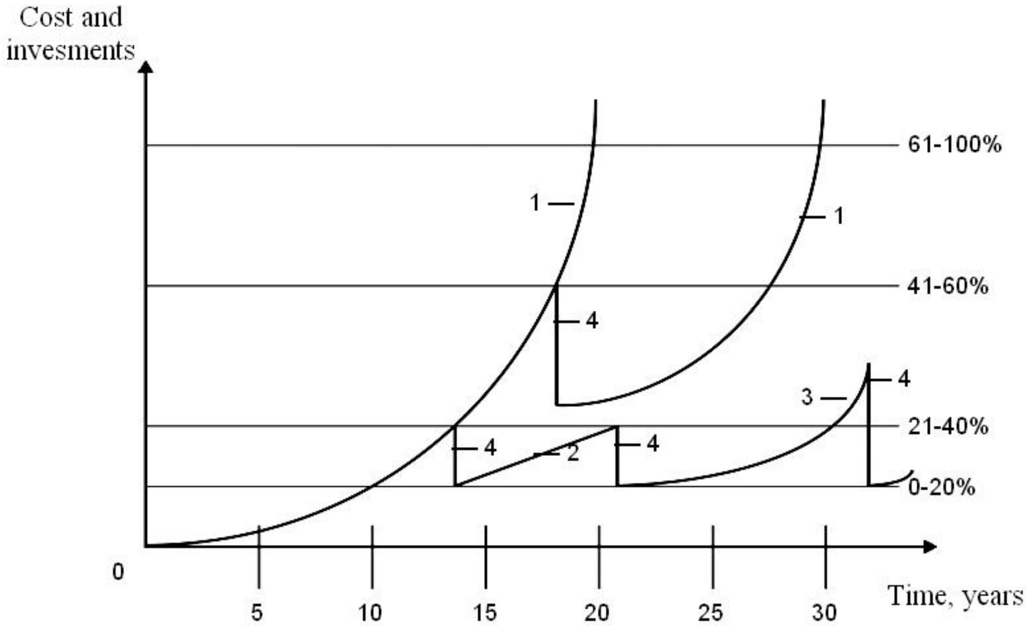

Figure 4: Changes in costs and investments during the construction operation period

Fig. 4 shows possible changes in costs and investments depending on the maintenance and reconstruction model of a building. Here: 1 – curve of natural deterioration of the construction; 2 – curve of construction deterioration when effective maintenance is performed; 3 – curve of construction deterioration when maintenance is performed; 4 – repair works of the construction.

Construction maintenance system and its management make a strong impact on the efficiency of construction operation. Therefore the creation and practical implementation of the management model of this activity has a strong practical and educational significance.

The transformation of management systems is strongly affected by the development of different studies and the practical application of their results. Facilities management cybernetics model might be created on the basis of the achievements in theory, applied mathematics, informatics and economics studies. Practical application of the facilities management cybernetics model determines the purposeful, reliable and effective functioning of an enterprise [12]. However, in practice this management model of an enterprise might be implemented only with sufficient normative, methodological, informational and legal resources of the management system [5].

Fig. 5 presents the scheme of a construction management cybernetic model. Such cybernetic interpretation of construction management allows to understand better the essence of construction management as well as to apply the main principles of such management for the achievement of the goal.

Fig. 5 gives systematical elements of the management model: resources, facilities management process, management apparatus, results, control information, regulation, inner and outer environment of the system.

Resources describe the totality of all means and devices necessary for the implementation of constructions management process. The structure of the resources and their provision intensity depend on the peculiarities of implemented constructions management solutions.

Facilities management process is described as a purposeful and effective performance of interrelated logically based activities when implementing rational (optimal) project solutions.

Results are systematical elements describing the final or transitional constructions management result expressed in the system of indices. This might include indices expressed in physical (material) or economical (efficient) indices, e.g. parameters characterizing technical state of a construction, amount of works performed, amount of costs, etc. The system of such indices is used for the control, analysis and correction of solutions. The creation and practical application of the index system determine the efficiency of construction management.

Control information is used to detect the variations of constructions management processes.

Regulation. Two principal systematic elements are regulated: resources and constructions management processes. On the basis of the regulations the variations of constructions management processes are eliminated and further rational (optimal) development is ensured.

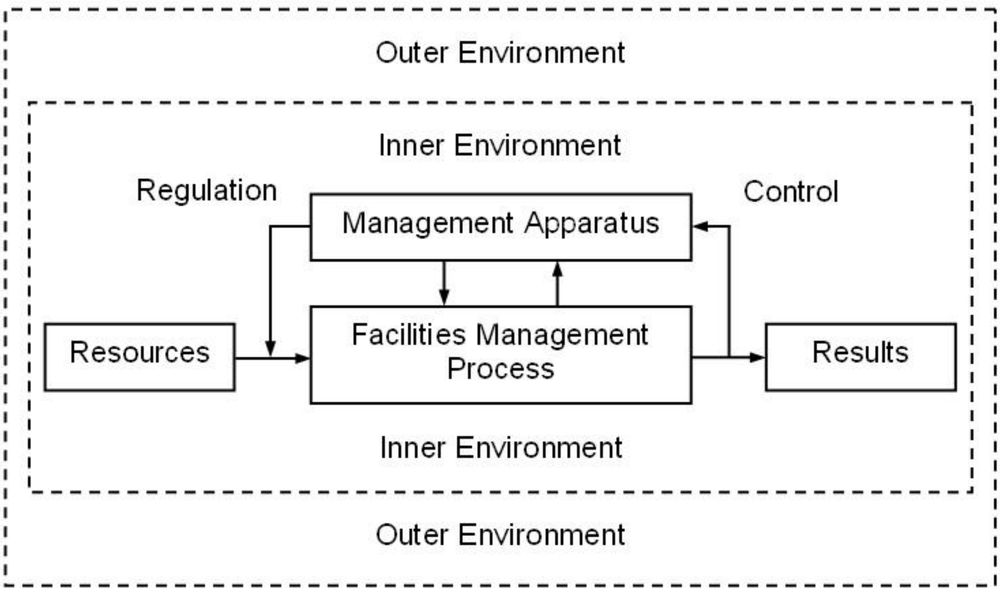

Figure 5: Scheme of the facilities management cybernetic model

Facilities management cybernetic model is a universal instrument that may be effectively applied in practice [10].

3. Preparation of Facilities Management Specialists in Lithuania

After Lithuania restored its independence in 1991, the transformation processes occurred in all spheres of activities. During this period the system of education and specialists training changed, too. The top priority was given to the transformation of the training system of different specialists as in the future the education, qualifications and learning of Lithuanian citizens will strongly influence national competitiveness and welfare of inhabitants of the state. The education and study system of Lithuania is affected by the development of market economy, the internationalization of all processes as well as the traditions of national culture [5, 6, 9].

The changes in functions and structure of Lithuanian economy determine the demand for certain specialists. As the experience of certain European countries shows, good economical results and high living standards may be achieved even without any material resources. In such case topical issues become education system and preparation of different specialists.

Internationalization processes gives more freedom for capital exchange and people movement as well as creates better possibilities for the development of economics and other fields of activities. On the other hand, it also sets new requirements for the professional training level of specialists and the application of scientific achievements in practice. This will be a top issue when determining the competitiveness of national economical systems in the international market [5, 6].

There is a three-stage study system in Lithuanian universities: background studies (bachelor's degree), master studies and scientific doctor studies.

Kaunas Technological University prepares specialists of different fields. All study programs were formed and implemented gradually, on demand, under suitable conditions and possibilities. Currently, a new master program suitable for Lithuania's economy – "Properties management" - is under implementation. This program comprises complex studies of construction project management, however most attention in this program is paid to the studies of facilities management activities.

Facilities management might be studied by bachelor graduates of construction engineering. The demand for such kind of specialists is constantly increasing in Lithuania. Objects of the activity of facilities management specialists might include various enterprises and organizations: industrial or commercial enterprises, offices, hotels, gas stations, hospitals, living complexes, educational institutions, etc. This might be functioning or temporally non-functioning objects [13].

4. Conclusions

The term construction project management appeared in scientific and practical terminology in Lithuania about 10 years ago. The term facilities management started to be used about 5 years ago. Currently, those interrelated activities have become particularly important in Lithuania. This might be explained by two reasons: 1) the amount of construction works is rapidly expanding and makes up 20-30% per year; 2) 70% of all investments are used for renovation, modernization and reconstruction of old buildings.

Thus, the demand for construction project managers is constantly increasing, and more attention is paid for the maintenanc3e, modernization and reconstruction of existing buildings. Moreover, enterprises of different business activities are trying to develop their competitiveness by reducing the functional costs of their activities. Such cost reducing possibilities might be detected in the construction maintenance and management system. As the tendencies of the development of enterprises show, those functions are often transmitted to certain specialized companies, which results in cost reduction by 30%. The effective functioning of construction maintenance enterprises is mainly determined by the selection of an optimal construction technical maintenance model as well as efficient application of investments for the modernization of buildings. To solve those problems, scientific studies need to be performed and best practical recommendations are needed.

PUBLIC PRIVATE PARTNERSHIP: A SERVICE INNOVATION The Treasury Building case

Jean Carassus,
Centre Scientifique et Technique du Bâtiment (CSTB).Paris, France. carassus@cstb.fr

Abstract

A Public Private Partnership (PPP) contract combines the competences of a client, a bank, a designer, a construction company and a facilities manager, to finance, design, build and manage a building or an infrastructure.

It is a service innovation analysed through a case study: the PPP/PFI Treasury Building refurbishment and operation project in London. The analysis method is the Barcet and Tannery one [1], specifying the service as an aim, as a concept, as a process and using specific means and resources. PPP is a process service innovation, following a "methodological trajectory", which is the result of a change of competences and technical (material and immaterial) characteristics [2].

The main innovation through PPP is the combining of usually separated competences: client, architect, construction firm, facilities managers and users. This combining of competences is revolutionary in an industry where design and build have been for a long time separated from facilities management and use. This combining competences innovation is just beginning through a quite long learning by doing process.

Keywords: Public Private Partnership, service innovation, service key performance indicators, competences, facilities management.

1. Introduction

Most of the time, government or local authorities fund public buildings and infrastructures, and the building of the facility and its operation after completing are separated. On the one hand, the construction of the facility is provided by designers and construction firms through public procurement (design bid build, design and build, construction management)1, on the other hand,

---

- [1]for a comparison between the different procurement procedures, see for example Konchar and Sanvido [3] for the US and UK procurement processes and the special issue of *Building Research and Information*, edited by Graham Winch, on procurement procedures in the European Union [4].

the public authority manages the operation and maintenance of the facility itself and with sub contractors (for heating, lifts, cleaning…).

Public private partnership (PPP) is a new way to finance, build and manage public buildings and infrastructures. Usually, in a PPP process, the public authority negotiates, through a competitive procurement process, a single contract with a private consortium specifying the funding, the design, the construction and the operation, for ten to forty years, of the facility. The public authority pays the investment and the operation through annual rents after the completion of the building. When the contract is achieved after ten to forty years, the facility is owned by the public authority. PPP is a feature of ongoing change of the construction sector, from the structures to the service [5] [6].

2. A service innovation

Even if the facility may be different on technical aspects through PPP, in comparison with a usual public procurement, this new way is obviously not a technological innovation. It is a service innovation

Gallouj [2] has highlighted five kinds of services, namely: « quasi products » (whenever the service is highly standardized), operational or manual services, informational or relational services, intellectual or professional services, and finally the packages of products and services.

The final service of a PPP process is the package of a product (the building) and a service (the management of the building),

Sundbo's typology [7] inspired by Schumpeter's one [8] specifies four service innovation categories:

- Service innovations: new service,
- Process innovations: change in the service elaboration procedures,
- Organizational innovations: change in the management modes,
- Marketing innovations: marketing, sales, and so forth.

PPP practice is a change in the package (building plus services) elaboration procedures; it is fundamentally a process innovation.

Gallouj [2] defines a service as a "set of characteristics and competences", the final characteristics of the service Ym resulting from the simultaneous mobilization of competences (coming from the service provider -Cp- and the client -C'q-) and technical characteristics Tn (material and immaterial). Innovations are particular movements of those competences and characteristics.

According to him, service innovations evolve according to different possible “innovation trajectories”, namely:

- the material transformation trajectory ê M (Y), which corresponds in the alteration of the material basis of the service,
- the information processing trajectory ê I (Y), corresponding to new data, new uses of data, network sharing of information, etc,
- the methodological trajectory ê K (Y), dealing with the implementation of formalized methods for knowledge processing,
- the « pure » service trajectory ê C (Y) corresponds to the direct mobilization of competences, regardless of any material, informational or methodological support.

PPP is a service innovation evolving essentially according to a methodological trajectory through formalized methods, even if it normally makes necessary the use of new data and if alters the material basis (the building) through life cycle cost design. We will highlight the weight of the implementation of new formalized methods used to specify and to control the PPP process.

We have already analysed service innovations in the construction sector [9] [10]. How to analyse PPP as a service innovation? To study and set up a service innovation, Barcet and Tannery [1] suggest a method in four analysis levels summed up in the following table.

Table 1. The service innovation analysis method

Analysis level	Question	Topic	Meaning
1. The client system	What for? Whom for?	The functionalities	The service as an aim
2. The result of the performance	What?	The service product	The service as a concept
3. The supply system	How?	The performance	The service as a process
4. The means and resources	What with?	The tools, methods, information, technical means, skills, competences	To implement, or to obtain, means and competencies

From Barcet and Tannery (1998)

To be more specific, a PPP case will be analysed: the refurbishment and the operation of the Treasury Building in London. This project is one of the ten PPP cases studied in the UK, Italy, Denmark and France, by a French team, assisted by European experts [11] 2. The project is one of the notable British "Project Finance Initiative" (PFI) investments, in the political frame specified by the Conservative government in 1992, amended by the Labour government in 19973.

3. The service as an aim

The first analysis level is the service as an aim, the client system. Her Majesty Treasury (HMT) had three main goals through this PPP/PFI refurbishment project of its head offices:

- To spread the payment of a significant investment, in a context of low level of financial public means,
- To design a building to back a new business process in the ministry, focused on a team and network way of working more than a hierarchical one,
- To provide a high level of day to day service to the employees.

Usual public procurement systems do not allow differed payment of a public investment. Conversely, to design a building to back a new business process and to provide a high quality service to the end users are normally possible through usual public procurement procedures.

[2] Then this team made the framework of a French Public Sector Comparator (PSC), available at www.fondation-igd.org/ [12] and the PSC dedicated to the French hospitals. This PSC is included in the French PPP guide for hospitals, available at www.mainh.sante.gouv.fr/ppp.aspx [13]
[3] On recent evolution of British PFI, see Allen et alii [14], Weill and Biau [15], and the following websites: www.partnershipsUK.org.uk [16] , www.4ps.co.uk [17], www.nao.org.uk [18].

4. The service as a concept

The second analysis level is the service as a concept, the service product. The concept offered by the PPP/PFI process has two main characteristics:

- The private partner pays the investment, the public authority spreads the reimbursement through rents paid during a long period, the first rent being paid after the completion of the building,
- A single team, dealing with the funding, the design, the construction and the facilities management is responsible for the package, refurbished building plus the services provided for a long period.

This concept, in comparison with the usual public processes, is a very innovative one: commonly public procurement plans a payment of the investment by the public authority during the design and construction time, and separated processes for construction and facilities management.

5. The service as a process

The third analysis level is the service as a process, the supply system. The PPP/PFI process has four main characteristics:

- A new procurement system with, in the case of the Treasury Building, two tenders: one for the package building and services, one for the funding,
- A transfer of risks from the public authority to the private consortium,
- The valuation of the transferred risks in the amount of the rent,
- A long term partnership between the two parties.

In 1995, an invitation to tender was issued for the refurbishment and operation of the HM Treasury’s offices in London. Exchequer Partnership was selected in September 1996 as preferred bidder after a competitive procurement process, but Labour Government elected in 1997 considered it inappropriate to proceed at that time. Following a review of the project a contract was signed in August 1999. HMT had also to set up a new tender on funding which was concluded in January 2000 [19]. The facility was successfully delivered one month early in July 2002, when payment of the unitary annual charge for 35 years commenced.

The two parties negotiated a complex contract specifying the package design, refurbishment, hard and soft facilities management by Exchequer Partnership (EP), a Special Purpose Vehicle Company, created by a construction company (Bovis Lend Lease), a developer (Stanhope) and a facilities manager (Chesterton), and the funding through index-linked bonds insured by Ambac (monoline insurer). Johnson Workplace then controlled Chesterton. The facilities manager was no longer EP's shareholder. Forster and Partners are the architects of the project. Figure 1 sums up the present construction and property business system.

We have studied the first half of the refurbishment, the second one, specified by another PFI contract with the same partners, is in progress.

The risks allocated to the private consortium are:

- Obtaining Planning permission and listed building consents,
- Design and construction compliance to achieve the occupier brief and deliver output brief performance,

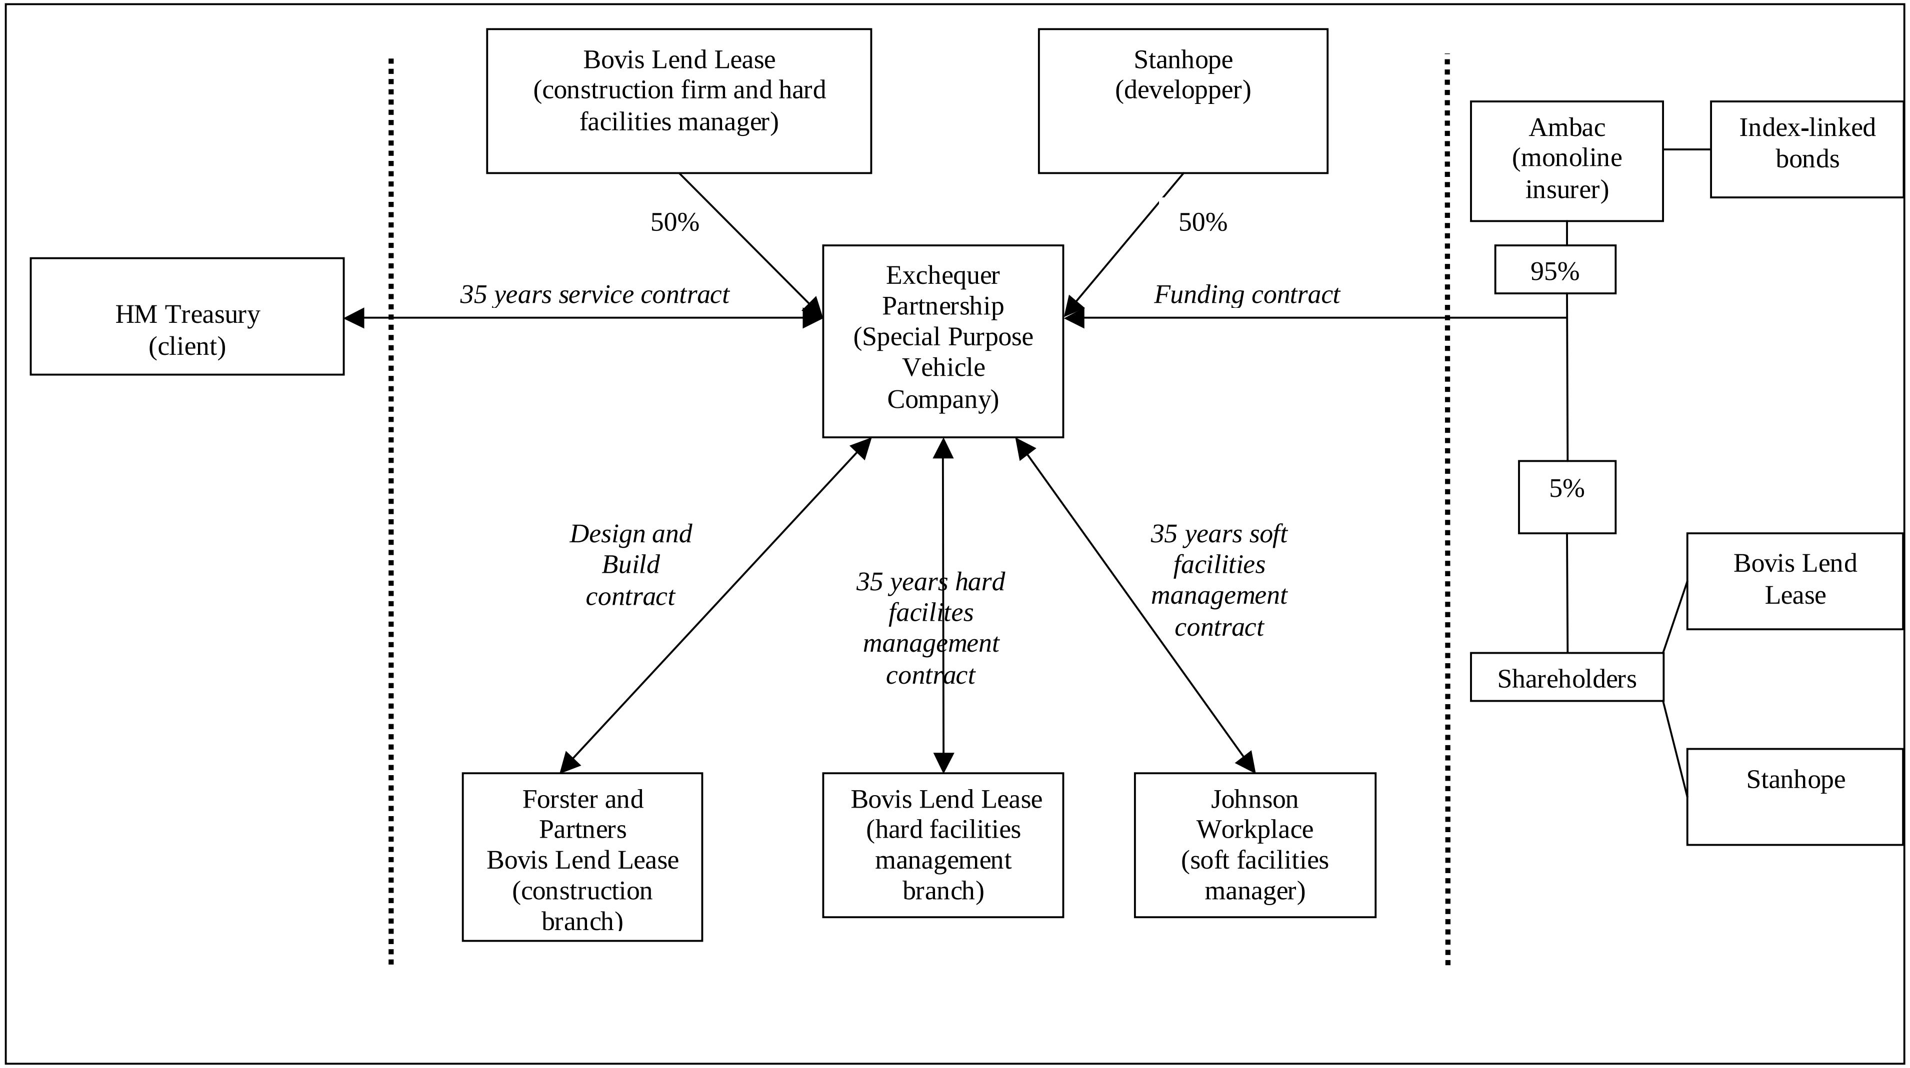

Figure 1. Treasury Building PPP/PFI project : the construction and property business system

- Construction and latent defects risk, which was significant in a poorly maintained 100 year old building,
- Service delivery risk, which lasts through the life-cycle of the facility. Many of these risks were then re-allocated to the FM sub-contractors by Exchequer Partnership (EP), although these risks were capped and above a threshold are retained by EP,
- Bankruptcy risk. Should EP fail, Ambac are obliged to step in to assure service delivery,
- Regulatory changes requiring changes in the output or occupier briefs,
- Letting risk i.e finding a tenant for other half of the building.

The risks shared include inflation, in that the unitary charge is index-linked. The risks retained by the Treasury include changes in user requirements implying changes in the output or occupational briefs other than those required due to changes in national regulations.

The valuation of the project and the transferred risks is embodied in an annual unitary charge of £14M during 35 years. The cost of the project was £141M, of which £112M represents design and refurbishment. The amount of £29M corresponds to the negotiation costs and the funding costs, among them, preparation and negotiation costs were about £7M for Exchequer Partnership.

The PPP/PFI process involves a long term partnership between the parties. According to the interviewees, this partnership works very well. In our opinion, success factors for such a partnership are:

- The willingness of the parties for the success of the HMT head offices refurbishment in a PFI process,
- The high level competences of the partners,
- The quality of the tools and methods (see infra)
- The profitability of the contract for the private partner.

No specific information is available on the profitability, but we think that it is very difficult to manage a serene partnership, when the contract has been under priced by the private partner and is not profitable4.

6. The methods and the competences

We are dealing now with the fourth analysis level suggested by Barcet and Tannery (1998), the means and resources one: tools, methods, information, technical means, skills, competences.

Our analysis highlights five aspects dealing with the means and resources:

- The competitive procurement process,
- The funding method,
- The occupier brief and associated tools,

[4] See for instance the problems of the under priced STEPS deal between Inland Revenue and Mapeley [20].

- The output brief and tied tools,
- The combining of usually separated competencies.

We will also underline some lacks, especially the need of operating costs data bases.

We did not get into details to analyse the competitive procurement process because we chose to study the Treasury Building case more than one year after completion of the refurbishment. In opposition to the usual procurement one, the PPP competitive procurement process is a performance-based one. The occupier brief and the output brief specify the results to be obtained but do not define the solutions to meet them. The private partner elaborates the practical means to reach the objectives and to measure the output.

The counterpart of this very productive process is the time and the cost. The negotiation between the public authority and the preferred bidder is long and pricey. The complexity of the long-term contract explains a part of the cost, but solutions have to be fund to moderate the cost of PPP/PFI contracts5.

The Labour government asked HMT to set up a separate tender for funding. An opportunity to innovate was created. Bank financing and bond financing competed. One solution was funds provided by one or several banks, through a negotiation between the project company and the bank. The other solution was funds provided by bond investors, through an agreement via an intermediary, a bond arranger.

Bond financing was chosen for three reasons (NAO 2001):

- The project length, at 37 years, including design and construction, is 4 years longer than the longest period for which banks would have been willing to lend,
- Index-linked finance can be cheaper than fixed rate finance and favours bonds,
- Monoline insurance of a bond reduces the interest rate bonds investors will require and increases the attraction of a wrapped, or insured, bond finance relative to bank borrowing.

Although bond financing was more competitive than bank financing at the time of Treasury funding competition this may not be always the case.

The occupier brief described the required functionality of the facility in technical terms. As we noticed one objective of HMT was a design to back a new business process in the ministry, focused on a team and network way of working more than a hierarchical one. This involved an occupier brief focused on a shift from wholly cellular to partially open plan offices. This activity included a pilot open-plan office. This choice and technical aspects were discussed in many meetings between the design team and Treasury staff, dealing with space design, access control and security, health and safety, information technologies, lift, signage and way…

[5] Public task forces promoting the best practices, technical expertises put in common, free practical PPP guides, standardised contracts or parts of contracts, control of the cost of the advisers are some solutions; but the problem is complex. We just notice that PPP can also concern, like in Italy, small and non complex projects involving local authorities and regional construction firms, without many advisers.

According to the architects, the quality of the occupier brief is one of the success factors of the project. After completion of the refurbishment, the Post Occupation Evaluation is the tool in relation to the occupier brief. This survey, made six months after moving in, dealt with:

- Place: aesthetics, temperature, lighting, cleanliness, workplace, space for concentrated work, space for collaborative work,
- Technology and services: telephones, filing, printing, shredders, information technologies, catering, reception,
- People and processes: feelings, communication, openness and transparency, flexibility in working practices, productivity and innovation.

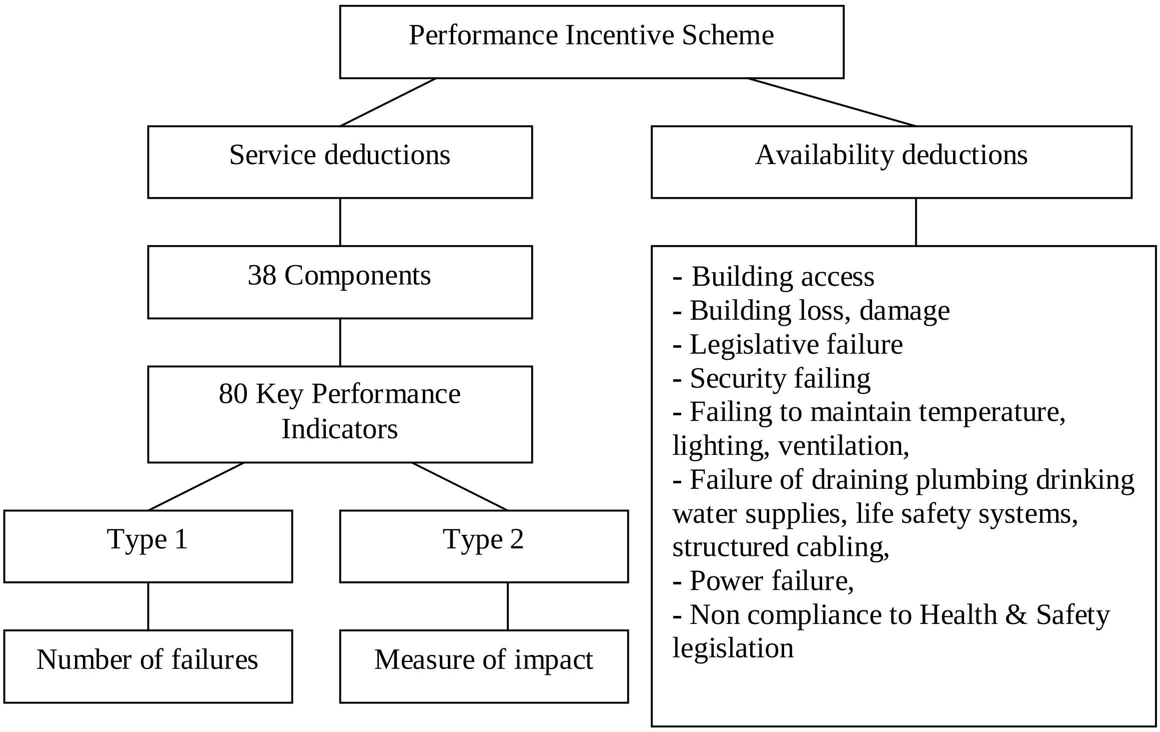
The level of satisfaction was high: 83 % of respondents said that their working environment had improved in terms of functionality and afforded more opportunities for collaboration. Some critics concerned temperature monitoring, noise and privacy. To change attitudes regarding the suitability of open areas for "private" conversations was wished.

The output brief and tied tools sound very innovative. The output brief deals with the facilities management issues in terms of the service delivered to the users. Facilities management deals with eleven topics:

- Hard services: Mechanical, Electrical, Plumbing (MEP), lifts, building fabric, pest control, furniture,
- Soft services: security, cleaning, catering, waste management,

help desk and general facilities management being used for hard and soft FM.

A Performance Incentive Scheme specifies service and availability deductions. Service deductions concern 38 hard and soft facilities management components and are measured by 80 Key Performance Indicators (KPI). The 67 type one indicators involve financial penalties, the 13 type two indicators do not involve financial penalties.



Source: Exchequer Partner

Figure 2. The Performance Incentive Scheme

Audits of FM made four times per year by the monocline insurer and permanent control by HMT facilities managers fill up this rather sophisticated service control system.

The last topic dealing with methods and competences concerns maybe the most potentially innovative aspect of PPP: the combining of usually separated competences. Figure 3 sums up the separation of the different mobilized competences in separate contracts in a Design Bid Build process. Figure 4 illustrates the combining of the mobilized competences through a PPP long term contract.

The client as investor and as facilities manager, the architect, the construction firms, the facilities management subcontractors work usually in a separate way.

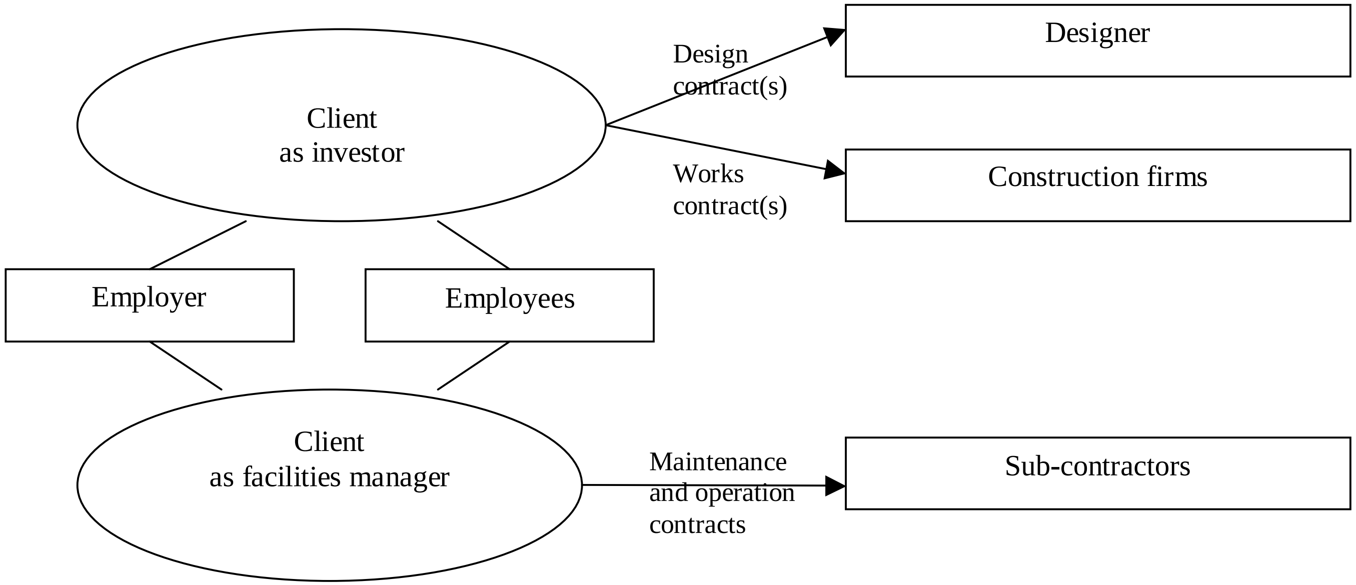


Figure 3. The separated competences in a Design Bid Build process

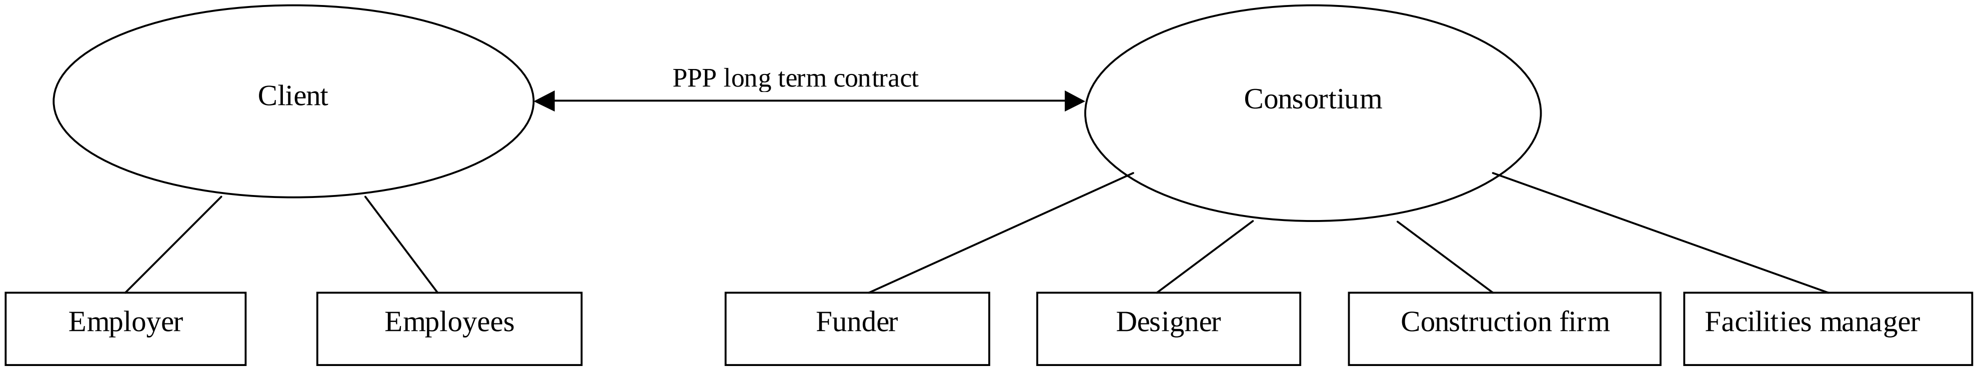

Figure 4. The combined competences in a PPP process

The PPP process obliges them to work together, the result of this combined work being written down in a long term contract. For the first time, the architects designed a building by working with the users and the facilities managers. They told us that this process forced them to look at the project in a new way. The combined competences of the architects and the facilities managers allowed to improve many aspects of the project: heat summer, ventilation, lighting, windows curtains, wall paint, carpet quality etc. The sophisticated service control system is also the result of combined competences of the client and the facilities managers.

The players are not used to do so. PPP is a “learning by doing” process which requires time to learn how to combine the competences. This implies a cultural revolution in the construction industry. For ages, construction and facilities management have been separated. New ways to work together as client, architect, construction firm, facilities managers have to be invented.

This also makes new tools necessary. For example, operation costs data bases are needed. Such data bases, giving the maintenance and operation costs and the link between them and the investment costs, are necessary. There must be practical life cycle costs data bases for each kind of building (offices, hospitals, schools, prisons…), based on real costs, not theoretical ones.

Those data bases and contract contents could be designed in a sustainable way, with new incentives, for example the gains of energy consumption being shared between the public and the private partners. Long term PPP contracts are a very good opportunity to design, build and manage buildings in an environmental friendly way.

7. Conclusion

The Barcet and Tannery (1998) method offers a comprehensive view of a service innovation. Success factors concern each of the four analysis levels. The players have to answer very clearly the strategic questions dealing with the service innovation: What for? What whom? What? How? What with?

The high level quality of the tools and the combined mobilized competences are key success factors of the innovation. We agree with Gallouj (2002) when he specifies a service innovation as the result of a change of the service provider’s and client’s competences, and technical (material and immaterial) characteristics of a process. The analysis of a PPP/PFI project, such as the Treasury Building one, a process service innovation following a methodological “trajectory”, confirms this definition.

The potential of innovation through PPP sounds high. The main innovation is the combining of usually separated competences. This combining of competences is revolutionary in an industry where construction has been for a long time separated from facilities management and use. The efficiency of the PPP process is that the players are obliged to write down in a long term contract the result of their innovative cooperation.

Innovation is just beginning. Practices will change progressively. Some innovations are still potential, such as practical life cycle costs data bases and long term sustainable facilities management.

Actually many PPP innovations could be used to improve the usual Design Bid Build and facilities management processes. Accurate occupier and output briefs, cooperation with the facilities managers and the users, financial incentives to make the works time shorter, multi service contracts, performance indicators, financial incentives for efficient operation are examples of PPP best practices which could be employed to improve usual procurement and facilities management processes.

8. Acknowledgements

I would like to thank, for all the information given through interviews:

- Mr Nick Gray, Faithful & Gould,
- Mr Thomas Huw and Philipp Eichstadt, Forster and Partners,
- Mr Barry Kearton, Chesterton,
- Mr Paul Lewis, Stanhope, Exchequer Partnership,
- Mr Richard Lewis, Bovis Lend Lease, FM branch,
- Mr Karen Mangroo, Exchequer Partnership,
- Mr Paul Pegler, HM Treasury.

I would like to express them all my deep gratitude. Nevertheless, I alone am responsible for the text and any errors in this paper.

Towards the New Criteria of Elderly Housing by the Model of Independent Mobility

M. Himanen,
VTT Building and Transport, Helsinki University of Technology (mervi.himanen@vtt.fi)

Abstract

The approach of the new criteria starts from the existing knowledge, looks the needs and wishes of the seniors and uses the Models of Independent Living and Mobility as means of organising the design knowledge. The approach of the models is qualitative. The outcome of these concepts is shows in so called the activity cards, while the activity was chosen as a dominant factor from the four angles studied in this project of the elderly habitation: activities, abilities, resources and qualities. Another main variable of the Models is resources, which represents more the housing providers approach to the independent living of elderly. The end-user oriented housing design is looking the habitation from the residents perspective, and even in housing provision the activity based approach to habitation will increase while both market pull and technology push domain the design. The Models emphasise the idea that a starting point can be anywhere in the ball: activities, resources, qualities or abilities − depending on the situation and what kind of point of view is taken.

Keywords: housing, design criteria, senior citizens, independent living, end-user requirements, design criteria, Design-for-all, housing surroundings, Model of Independent Mobility

1.Background

This paper is drawing much from the EU Fifth Framework project Elderathome, The Prerequisites of the Elderly for living at home: Criteria for Dwellings, Surroundings and Facilities (QLK6-CT-2000-00405). The focus of the EU-project Elderathom is to develop criteria for dwellings, equipment, surroundings and services so that elderly people can live longer independently at home. Despite the fact, that large amount of general and detailed information is available about the expert knowledge on housing, surroundings and services of the elderly, this information is non-uniform and in a different level in each European country. Summaries and in depth focus on the basic criteria have been identified necessary. Improving the independent living conditions of the existing housing stock has been targeted. The idea has been to improve functioning, in order to obtain better convenience and usability by the elderly. The project will make an inventory of the state-of-the-art of criteria of products and facilities necessary for independent living, identify the wishes and needs of the elderly, identify the criteria for the manageability of housing and suggest new developments in order to contribute future independent living.

If comparison for finding wrights or wrongs, good or bad is not fertile, the identification of similarities and differences internationally in recommendations, regulations and design guidelines make it possible to understand national features and to learn from others when respecting the facts of universal human existence and housing phenomena due to various climatic conditions and rich housing traditions in Europe.

There are three forms of preventing the difficulties due to the impropriate housing condition for the aged residents: renovation and repair of present housing, moving or relying on assistive services, which substitute the difficulties due to the impropriate housing condition for the aged residents. Housing should in the first place satisfy the basic housing needs for shelter and the surroundings are designed accordingly. Apart from the technical aspects of the surroundings of the building, also the quality of the wider living environment is considered. In many cases, it is difficult to make difference between these two approaches to design. The expected better standard of living of elderly sets new questions. What are the modern targets of the good living and what is known about the physical and mental health promotion of elderly? How they have to be taken into account in design of housing, housing surroundings and facilities. Furthermore, how the housing and service providers as well as facilities management can promote new lifestyles of elderly?

The willingness of the elderly to renovate and repair their homes counts. The possibilities of renovating or repair existing housing stock are crucial, while elderly are not very willing to move although that alternative is not totally excluded either [1]. It is questionable if the use of assistive services is a good solution although in many cases a necessity. Renovation or repair is a one-off investment, but services cost repeatedly. The expectation of too high cost effects due creation of too many recommendations and regulations is a reason for deliberation in actions of authorities. It is an interested starting point for the project, while both authorities and voluntary work can benefit from accomplished new knowledge. On the other hand, also such businesses in this area as housing and service providers and facilities management can use this opportunity to reach knowledge of if the end-users or the customers are ready to bye their products.

It is very important to understand and to remember that the new criteria have no intentions to form any kind of minimum or maximum standard not to mention to aim to become a regulation. It is a checklist covering issues related to elderly housing for understanding and checking the situation in each case of elderly habitation.

Housing challenges many fields of sciences. It is a combination of social sciences, cultural history and ethics, economics and housing technology: transport design, town planning or zoning, landscaping, civil engineering, architecture, interior design, structural engineering, and HVAC, electricity and smart house technology. This challenging holistic approach includes also ecological and environmental psychological aspects. The knowledge of economics can be found out rather seldom from national economics, except from municipal economics and economies of households, but the more often from geographical economics, building economics, life-cycle-cost analyses, and from properties and facilities management.

The United Nations General Assembly adopted the UN Principles for Older People, in the year 1991. These call for action in many areas, among them:

− Independence: Older persons should have access to food, water, shelter, clothing, health care, work and other income-generating opportunities, education, training, and a life in safe environments.

− Participation: Older persons should remain integrated into community life and participate actively in the formulation of policies affecting their well-being.

− Care: Older persons should have access to social and legal services and to health care so that they can maintain an optimum level of physical, mental and emotional well-being. This should include full respect for dignity, beliefs, needs and privacy.

− Self-fulfilment: Older persons should have access to educational, cultural, spiritual and recreational resources and be able to develop their full potential.

− Dignity: Older persons should be able to live in dignity and security, be free of exploitation and physical or mental abuse and be treated fairly regardless of age, gender and racial or ethnic background.

Besides the regulations the Finnish housing designers and planners mainly have used the recommendations of the RT direction cards published by The Building Information Foundation (RTS, http://www.rts.fi/english.htm) and occasionally more detailed directions and recommendations including in the TTS Institute‘s Home Economic bulletins. VTT has established a product called VTT Building and Transport ProP® (Requirement Management System). It is a classification, which takes into consideration Finnish and international standards, norms and classifications. It includes all kind of housing and surroundings and is not specified in elderly. Similar classification is: PAYCO in Spain which automatically translates the clients' (with little or no previous experience) requirements into design specifications.

An electronic database called ARVI[1] (arvi.projekti.com) is under the way to become an addition source of valuable information of housing design criteria concentrating on the criteria which is taking into consideration the housing needs of the elderly and disabled. Also new experimental

[1]A method for design of housing for people with limited abilities in mobility and activity.

databases have been created such as VIRAPS[2] (http://viraps.uiah.fi/), which aims to an automatic system suggesting housing designs for the end-users who enter information of their housing needs into database.

There are two certificates for elderly housing in the Netherlands the Woon Keur Certificate (www.woonkeur.nl) and Seniorenlabel. The Europa House Group is constantly working together with the rules for housing in general, not particularly for elderly, but also taking the needs of special groups carefully into consideration.

A large group of people - people with disabilities, older people, children, tall and short people, people with prams, travellers carrying heavy luggage - can all encounter barriers and obstacles in the built environment. The "European concept for accessibility" states (1996):

> *"To ensure equal chances of participation in social and economic activities, everyone of any age, with or without any disability must be able to enter and use any part of the built environment as independently as possible."*

European Manual for Accessible Built Environment was formulated at the end of 1980's and the firs version of the manual was printed in 1990. The idea to write such a manual was initiated by the Central Co-ordinating Committee for the Promotion of Accessibility (CCPT) and the same organisation produced the manual. The objective was to bring about new initiatives to improve the accessibility of the built environment in the European Community. The manual is also hoped to help in standardisation work.

According to the European Manual for Accessible Built Environment all buildings open to the public must be fully accessible, while working places and dwellings can have a standard of accessibility in accordance with the rules of the individual country. Such buildings can be houses, shops, theatres, restaurants, public telephones, banking services, information kiosks, self-service systems, public transport facilities and places of work. In order to use an information and communication technology terminal or other ICT system, the built environment around it must be accessible.

---

[2] The Internet-based VIRAPS service brings user-orientation into the housing industry by connecting the databases of the various companies involved in the building process. The VIRAPS service allows customers to search the database for suitable apartments in their preferred areas. Customers planning their apartments with the VIRAPS service can customize them according to their wishes and make changes in their interior design. These decisions are divided into environment, construction and infill levels. The integrated cost-calculator keeps customers informed about how their choices affect the final cost of the apartment. User-orientation of the VIRAPS service benefits both customers and companies: customers can balance their needs and desires with the right price, while the companies can increase their turnover and adapt to the markets faster and more accurately.

2. Models of Independent Living and Mobility

The Models of Independent Living and Mobility of Elderly include four main elements or variables: activities, abilities, resources and qualities (Figure 1., Figure 2.). Models describe the idea of different variables needed to be taken into consideration when promoting wellbeing and supporting independent living at home. The Models represent the holistic approach in which different relevant factors are integrated. The variables ensure for example that making reparations meets the requirements of users.

Figure 1: The variables of models of Independent Living and Mobility

The normative mode (the form) of criteria shown in the activity cards (Table 1. to be published at www.vtt.fi) is telling both of the qualities of phenomenon and the reasons why one should have criteria of that kind formulated in easily opening manner. The expressions are focusing on rather needs and wishes than on solutions.

The Models of Independent Living and Mobility are means of organising the knowledge. The approach of the models is qualitative. The outcomes of these concepts are shown in the activity cards, while the activity was chosen as a dominant factor from the four angles of the Models. Another main variable of the Models is resources, which represents more the housing providers approach to the independent living of elderly. The end-user oriented housing design is looking the habitation from the residents perspective, and even in housing provision the activity based approach to habitation will increase while both market pull and technology push domain the design.

The approach of domestication is starting from the facilitation of activities of everyday living and the approach of the housing provision starts from the general principles of quality requirements of housing, which can be realised by certain business activities. The Models emphasise the idea that a starting point can be anywhere in the Model: activities, resources, qualities or abilities − depending on the situation and what kind of point of view is taken.

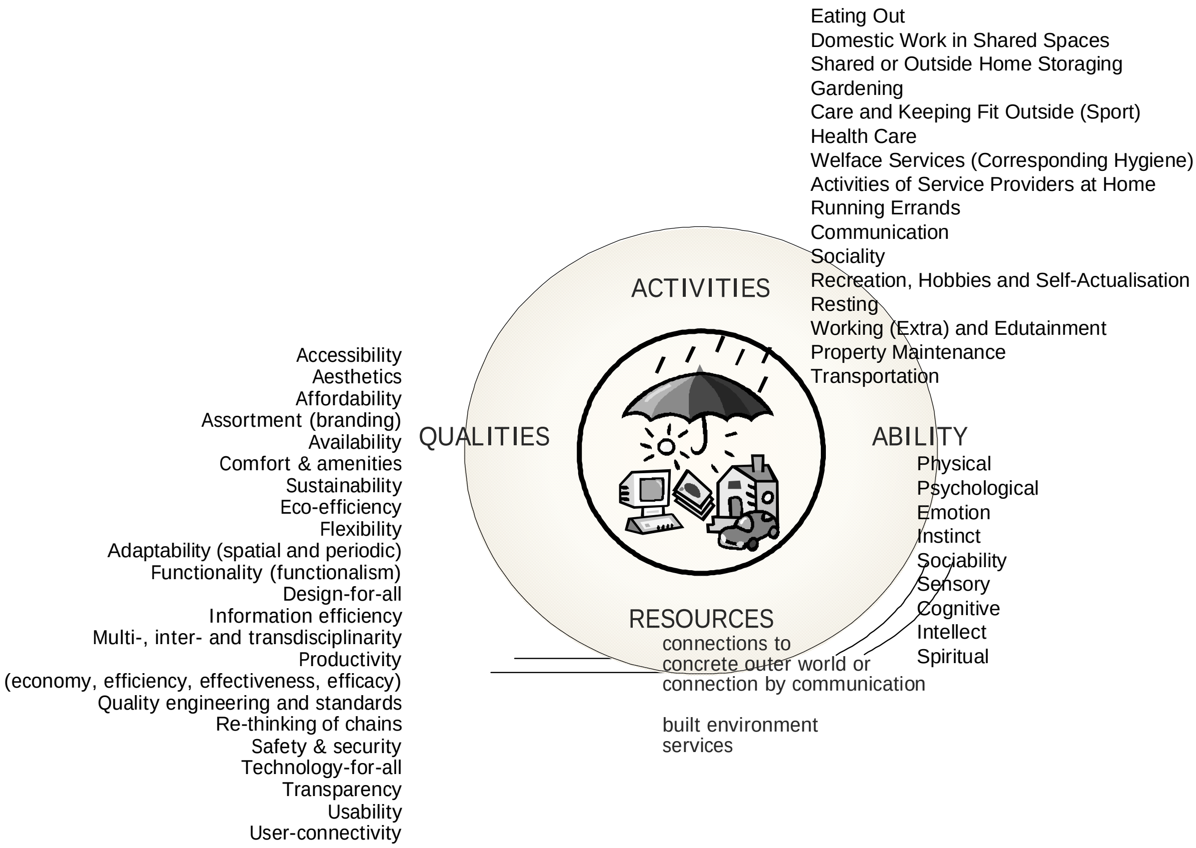

Figure 2: The Model of Independent Mobility of Elderly.

2.1 Activities

Common housing activities are care and keeping fit, eating, personal hygiene and dressing, moving, recreation, communication and self-actualization, sleeping and resting, gardening and maintenance, housework and storage. They were used in the Model of Independent Living. The Model of Independent Mobility is covering the same activities but looks at activities taking place outside home or activities, which connect home outside surroundings and services (Figure 2.). They can be compared with the Activities of Daily Living (ADL)-indicators, which are often used in the geriatric of a functional capacity of elderly. The activities are divided into the Physical Activities of Daily Living (PADL) and the Instrumental Activities of Daily Living (IADL). However, the new criteria look the activities also from the point of view of abilities when the ADL-indicators look them rather from the point of view of disabilities and limitations in everyday living. The criteria of surroundings can be tailored by the needs of accessing services, the activity level of the senior tenants and not only the current physical and psychological health condition but rather the promotion of health and function − even disease prevention in old age.

Mobility is a basic activity of all activities, which are related to surroundings of homes, the near neighbourhood and connections by information and communication technology and media from home.

2.2 Resources

The surroundings are defined as the area connecting the inhabitants to the outer world, services, activities and social life. The connections and access to services, transport and relatives, friends and other people are needed. This connection can be a concrete one as a corridor, a courtyard, a path. It can be a more abstract one as a link via communication technology or even as an access by virtual reality. These are the resources.

Apart from the technical aspects of the surroundings of the building, the quality of the wider living environment or neighbourhood has also been considered. From the geographical approach can be found that the housing surroundings does not mean the housing unit scale, but the building site condition and in certain extent the neighbourhood, which during a standard house building processes means the street in front of house(s) and the connections to the public municipal services: electricity, water and sewage pipelines if needed, and possible gas or district heating pipeline, and connections to telephone and other communication networks. Within the Elderathome project the neighbourhood was the space within the walking distance from home and surroundings is the area next to the houses. The walking distance is dependent on the ability to walk, but often it means the distance within around 15 minutes' walk. This is for a healthy person roughly 1 km (or a few hundred meters more).

The area in focus is the connecting channel like staircases, lobbies, terraces, courtyard and possible garden, walkways, parking, back lanes and connections to information and transport systems: private vehicles: (airplanes), cars, boats, motorcycles, cycles, public transport and pedestrian and cycling pathways. Examples of resources can be given as:

- Operable building elements (fence, ports, doors, stairs, ramps, lift, locking with doorbells, door telephones and video monitoring)
- Active structures (automated doors, windows, thresholds, curtains, shadings, etc.)
- Storage rooms near entrance for walkers, bikes, skies, other sport equipment, etc.
- Entrance halls or other space for to move or bring in and out goods (groceries, deliveries, repair equipment or furniture)
- Telecottages (and satellite offices), meeting and banqueting rooms, extra quest rooms, space for welfare service or maintenance providers
- Technical and maintenance spaces
- Shelter (shelter for entrance, terraces, barbeques, separate storage buildings, etc.)

− Yards and gardens

− Seats and rest areas on housing surroundings and in the neighbourhood

− Hobby and recreation areas and facilities (plays, shared equipment, etc.)

− Possible domestic appliances outdoors

− Paths (walking paths, sideways, shortcuts)

− Back lanes and streets

− Neighbouring housing, nature and public buildings

− Personal transportation: access to vehicles and parking places or storages

− Public transport: stations, stops and platforms, information (signs, signals, labels and timetables)

− Surfaces, coverings and pavements

− Location of personal business, services or public transport

− Telecommunication – media connections (e.g. gable television, satellite dishes), telephone and data lines, gables and antennas, personal devices of home health care e.g. wearable devices – pendant alarms, vital signs monitors, alarms for safety and security systems (burglar, fire).

2.3 Qualities

There are a good number of qualities, which belong to the general concept of good housing practice or building and maintaining housing. Any of them cannot be left without attention when designing and facilitating built environment. Still, certain ideas of them can be named more important to the criteria of surroundings than those of the dwelling or services (Figure 2,). For mobility, the accessible design (accessibility) is one of the main considerations. Other important qualities for mobility, physical surroundings and connections are availability, Design-for-All, sustainability, re-thinking of chains, safety and security, user-connectivity, usability, Technology-for-All and transparency. Such qualities as availability, affordability, Design-for-All, user-connectivity, productivity, quality engineering and standards, usability concern all activities and are not mentioned in the activity cards separately. However, some of them are not very well developed in the context of built environment: user-connectivity, usability, Technology-for-All and transparency.

The quality of multi-, inter- and transdisciplinarity is not mentioned in the list while it is everywhere present. For the need of easy access to the activity cards, a hierarchy of the qualities is helpful.

Qualities are essential for good design in any case, and cannot be excluded in criteria, which aim rather to a general checklist than to detailed instructions. In a complex modern world the basis of the design principles can be even forgotten during the sophisticated design work and there are almost never too many checklists. Most of these qualities are well known in the context of housing and building. Some of them might need some specification in the context of elderly housing.

2.4 Abilities

The Elderathome project is focusing on those, who are in old ages:

- Able to live independently in an improved environment,
- Able to live independently in an improved environment and with services provided at home or
- Willing to live in an environment designed specially for health promotion.

The Elderathome project is not especially interested in those who:

- Are able to live independently in any environment or
- Have health problems needing specialised care permanently.

Not all elderly have severe disabilities, but the prevalence of disability or limitations is the highest amongst this demographic group. In the old ages the physical abilities, senses and cognition tend to weaken. The impaired abilities often lead to a need of outside help or arrangements in the dwelling and they are especially significant when considering independent living at home. The abilities, however, not the disabilities make the independent living possible. However, many elderly can trust their long life experiences and their good psychological and social skills as well as their mentality in the independent living conditions, if something unexpected will happen or despite the impairments of old ages [3], [9]. On the other hand, also these previously mentioned abilities might fail and cause problems. Some elderly are for example too lonely or too scared in order to live alone or independently, although their physical condition would allow them to do so.

The abilities for the Model of Independent Mobility were determined together with Veli Himanen on the basis of the work we have done on human and technological intelligence [4], on CEN/CENELEC Guide 6 [1] and the latest literature on psychology, e.g.[1]. They are as follows:

- Physical (dexterity, movement, manipulation, reach, seizures, strength, voice)
- Psychological (temperament, feelings, behaviour patterns; habits, addiction, motivation)
- Emotion (the consequence of bodily reactions and mental modes due to stimulus, or sensing and feeling)
- Instinct (genetically programmed behaviour)
- Sociability (social relationships, group behaviour, social life and norms)

- Sensory (hearing, sight, taste, smell, touch, balance)
- Cognitive (understanding, integrating and processing of information)
- Intellect (know, comprehend and reason; knowledge management, memory, learning)
- Spiritual (intelligence for creativity or for satisfaction of needs, intuition to reach tacit knowledge and handle instincts with intelligence, mental growth and transcendency).

3.Implementation

New criteria is suggesting concepts for lacking existing design criteria and formulating criteria out of them shown by activity cards (Table 1.). A starting for organising the existing design criteria was found from the accessibility strategy of the Ministry of Transport and Communications Finland [10] covering equally all people, feasible for independent living of elderly housing and surroundings especially after the problem of noise and lack of light and awareness were added, classifying problems of environment:

- Differences between levels
- Need of space
- Reaching distance especially when carrying items
- Orientation especially in finding ones way if sight is not good
- Balance in stairs, ramps and vehicles
- Reach of small people and wheel chair users
- Lack of strength in opening doors
- Complexity in use of technology and in understanding information contents
- Safety of infrastructure and maintenance
- Allergy; respiratory in particular
- Inequality caused by environment
- Noise
- Lack of light
- Lack of awareness.

Table 1: An example of an activity card.

Criteria	Variable		
	QUALITY	**ABILITY**	**RESOURCE**
Reaching distance It is important to reach certain basic services and being active on daily basis in the surrounding neighbourhood or in local village, while the visits to rural centres and cities are done more occasionally. It is easy and appealing to move, walk or run and reach the needed destination for running errands, reaching services, meetings and visits, promoting physical and mental health. There is possibility and adequate easiness to use private car. The uses of vehicles for reaching cf. Transport.	Accessibility Re-thinking of chains Sustainability Eco-efficiency Flexibility Adaptability Assortment Safety & security Functionality Comfort & amenities Aesthetics	Physical Psychological Sociability Intellect	The routes are short. The ramps are not too steep and long. There are enough and comfortable resting places available in the housing surroundings and neighbourhood, in the paths and especially on the way to stops and stations. Parking places near dwellings are safe and conveniently arranged. Parking garages are social secure and are good to manage. The sitting areas; seats and other public furniture are attractive. There are shelters in the mobility area. Because it is difficult to carry items such as groceries and equipment for activities, there can be lockers for temporary storing along the routes. For chaining of various transport modes there are locked shelters for vehicles or moving aids for periodic storing also in the near neighbourhood (e.g. parking of a walker) or in the stations are available walkers and rollers for use during walks. The housing complexes are in attractive scale and the opening up is conveniently arranged and recognisable. Town planning is based on the human scale as well as the use of car (cf. Transport).
Need of space It is easy to use a walker and cycle or bike (or use a preferred means). When running errands in offices etc. it is possible to have enough space provided for to operate and put and have things in a safe place.	Accessibility Flexibility Adaptability Safety & security Functionality Comfort & amenities Aesthetics	Physical Psychological Sociability Spiritual	Sufficient dimensions, finish, design and layout of: o Shared spaces and spaces for entering and exiting o Courtyard and garden o Paths, ramps o Parking places, pathway form the parking area to the home entrance o Streets, walkways and alleys o Stops and stations o Plazas

The end-user interview revealed that senior citizens are not necessarily aware of the possibilities how the housing can aid independent living [1]. The aim of the criteria is to raise awareness of how built environment can help the elderly and other parties involved to plan the possible changes for provision of independent living in their present homes. The new criteria form, in the first place, a framework and a checklist for the occupants, designers and service providers for common understanding of needed changes of individual senior citizen's habitation. The new model can be used in two ways:

− As a tool for analysing the existing knowledge and as a tool for formulating the comprehension of the habitation of the elderly and formulating a criterion out of them

− It can serve as a planning tool for empirical cases and be a generator of new ideas for implementation and criteria.

The thinking behind the existing criteria seems to be based rather on common habitation in cities and in suburban areas than that in the rural areas or surroundings of private housing. Living in block of flats or in other types of common housing arrangements are in focus. The new criteria of surroundings are not − at least purposefully − making this type of discrimination between the habitation and living styles of elderly. The existing criteria are numerous rather of limitations than of alternative advices and solutions when facilitating the independent living. The human disabilities and impairment lead the thinking. The new criteria of surroundings tend to suggest some advancement of this respect by looking also the abilities of elderly due to e.g. long and rich life experience and the freedom of selecting alternative living styles and surroundings. Not always, but in some cases the long life experience stand for better awareness of ones abilities and their relation to the possibilities in life in general and also of what is possible due to the surrounding conditions including built environment. The better understanding of life makes the social relationships and social skills valuable.

4.Conclusions

There are two tasks for the criteria of surroundings. They shall be designed to avoid obstacles such as:

− Insecurity

− Costly economics of facilities management (high housing costs - affordability)

− Distance

− Uncomfortable design

− Unattractiveness

− Bad weather

− Arguments against bad sociality and too small privacy

− Physical obstacles

− Lack of connections: parking places, public transport, etc.

− Attitudes of housing mangers and other tenants,

− Interim obstacles

− Lack of binding regulations that specify preciously the interpretation of the concept of housing and surroundings of independent living of elderly,

− Lack of European wide harmonised advisory guidelines

− Ignorance and lack of awareness of the effect of built environment for independent living of elderly

− Elderly housing has not been regarded as big business

− Laws and building norms are too weak to facilitate independent living of elderly

− .

Such examples of the obstacles can be mentioned as public transportation may be inaccessible and unavailable; attendant care services may be inadequate and dehumanizing; income maintenance programs and health care assistance can be inadequate informed; or community facilities and programs may be unresponsive and inaccessible. In addition, individuals may not be able to get out of their homes or get around inside because of architectural barriers. Even in the housing environment there are numerous issues which people confront. Landlords may discriminate against elderly people. Landlords and tenants can be patronizing and create problems for visiting home care attendants. Housing can be unaffordable, especially for people with low to moderate incomes. Large housing projects are often unsafe and may not have adequate accessible neighborhood facilities. Also, many communities do not have emergency housing hostels and facilities which are physically accessible.

On the other hand, they can promote the quality of life and make the every-day life not only easy but also enjoyable. This part is not very fully covered in the existing knowledge of independent living and housing surroundings and neighbourhood.

Some suggestions for bettering the situation can be made:

− Inform the market

− Coordination between countries in creation of housing norms and specifications (EU Directives)

− Close collaboration between politicians, technicians and citizens

− The will to co-ordinate all the agents involved and programme the interventions

− Including the knowledge of special housing and surroundings concepts as the independent living of elderly in the education of architects and building engineers

− Making fully clear who is responsible for applying new concepts

− A more accurate analysis of the effects of adaptations of built environment for independent living of elderly

− Identifying the areas where common requirements are most important

− Facilitating the change in built environment for the independent living of elderly by supporting financing systems (loans, allowances).

Kose [7] has stated good questions about the design criteria of built environment of elderly:

"Safety: To what extent should safety be pursued?

Health: How healthy[3] an environment can be?
Function: How convenient should a house be? (How does one distinguish convenience from laziness?)
Comfort: How would a stimulus-free environment affect a human being?
Economy: Who will eventually bear the cost?"

The criteria of surroundings is highlighting not only the problems with built environment but the criteria cover also the way of having fun, pleasure, environmentally comfortable. Resources include possible solutions without any prejudice to what is suitable to offer to elderly; it is their own choice and a right of all to choose from what or from the best engineers and architects can offer.

5.Acknowledgements

The results from the EU 5FP Elderathome are carried out by the partners who contributed to the project with material: TTS Intitute in Finland (coordinator, Kasanen, Pirkko, Humala, Iris, Pehkonen, Irmeli, Kivilehto, Sari, Väisänen, Kirsi) and VTT in Finland (Jantunen, Jutta, Karjalainen, Sami, Rauhala, Riitta, Sjögren, Ann-Marie) , ProASolutions in Spain (Masides, Alba, Llimargas, Joan, Aragall, Francis, Codina, J.), By og Bygg in Danmark (Gottshalk, Georg), Wagningen University in the Netherlands (Steenbekkers, Bea, van der Linden, Marlin, Wittebrood, Illegems, Hoogendoorn, Floriska).

Facilities Business and its Management

The changes and recent developments in built facilities knowledge and solutions are the main areas to be covered in this book. Businesses demand highly serviced workspaces and total flexibility. Present needs cannot be extrapolated over decades. How are sustainability concepts, sustainable buildings and infrastructure affecting built facilities business, its management and the underlying understanding, methods and solutions?

Those who can successfully interpret changes happening in the construction and facilities businesses can achieve significant gains through improved company or business models. Business environments are constantly changing thereby providing new opportunities for innovative firms.

Emerging solutions for defining end products, relying heavily on the preferences of users to guide design decision-making are clearly providing a mind shift from supply-driven to end-user-driven attitude. The book addresses also new concepts, methods and solutions for explaining built environment quality and functionality.

This book is part of a series of scholarly books on *Combining Forces – Advancing Facilities Management & Construction through Innovation*.

Other books in this series include:
-Understanding the Construction Business and Companies in the New Millennium
-Global Perspectives on Management and Economics in the AEC Sector
-Systemic Innovation in the Management of Construction Projects and Processes
-Performance Based Building
-ICT in Construction and Facilities Management
-Learning from Experience – New Challenges, Theories, and Practices in Construction

Table of contents

Preface

This book highlights Performance Based Building (PBB) experiences from four continents as they were presented in the international CIB Symposium COMBINING FORCES in Helsinki in June 2005. Eighteen papers describing different PBB perspectives are classified into four sections. Fifteen presentations in the first three sections report the main outcomes of the EC funded PeBBu Thematic Network.

The first section starts by describing the structure and impacts of the PeBBu network followed by presentations of the main technical PeBBu Domains: life performance on construction materials and components, application of PBB to healthy buildings, innovation and design. The last paper in the first section extends the European networking to Australia and Asia.

The second section deals with the PBB framework and tools. The first paper makes a pan-European comparison of international classifications for performance requirements and building performance categories used in various evaluation methods. It is followed by a presentation of a decision support toolkit, which can be seen as a step towards an integrated platform for performance based building. After that a compendium of statements of requirements is reported. The last paper in this section bridges the PBB framework to the nD models in building and construction.

The third PeBBu section deals with performance based building standards and practices. It starts by giving an overview to regulations and finishes by discussing the construction product directive. In between, the procurement issue is described from the Danish perspective followed by sharing the Mediterranean and NAS (newly associated states) views on performance based building.

The last section in this book is not part of the PeBBu Thematic network. It discusses the energetic-environmental certification issue of urban lighting installations and contemplates partnering as an answer to procurement in performance based building. Finally, an analysis is given on the factors affecting the effectiveness of performance based standards in Singapore.

We hope this book finds interest among practitioners and researchers willing to implement and develop further the concept of performance based building.

The PeBBu Network

The Performance Based Building Network: Impacts and Perspectives

Mansi Jasuja,
CIBdf, International Council of Research & Innovation in Building and Construction
(email: mansi.jasuja@cibworld.nl)

Abstract

This paper provides the background on the establishment and operation of the EU funded and CIBdf managed Performance Based Building (PeBBu) network. It gives an overview of the program, components, activities of the network so far. CIB has traditionally played a crucial role in the development of the performance concept and in its practical applications in the development of standards and regulatory requirements. With the establishment of the PeBBu project, the development of the performance concept has taken on a new dimension of practical approach and involvement of a large variety of stakeholders internationally.

Since its conception, the project has grown to include aligned activities such as two compendia projects and involvement with several CIB commissions. Extension into the Newly Associated States (NAS) countries and recent launch of the Australian network of PeBBu are examples of the fast spreading phenomenon of the performance approach. The PeBBu programme of work includes 6 scientific domains and several other tasks including PBB and CPD, PBB Decision making toolkits and CRISP Sustainability indicators.

The paper provides key lessons learnt from the experience of running the network programme. This is very useful for similar future endeavours that can learn from the PeBBu experience to succeed in hastening and widening the adoption of the performance approach in the building industry. These lessons include the dynamics of the various stakeholders in the building and construction sector for adoption of performance based principle. The lessons learnt are based on first hand experience of coordinating and managing the network and feedback from network participants.

The major accomplishments of this network such as expansion of the network and establishment of several aligned activities and strategic relations are also part of the paper. Activities and outputs that engage and benefit various stakeholders are described. There are still many hurdles to face and many challenges to encounter. This paper concludes with a perspective on the future of Performance Based Building in the times to come.

Keywords: Performance Based Building, Thematic Networks, performance approach/concept

1. Performance Based Building: an Overview

Performance Based Building is not a new concept! It has been practiced in some measure since ages even though it was not formally known as the performance approach. The earliest example of this can be found in the Hammurabi Code (c. 1950 to 1910 BC), which gave a dictum that a house should not collapse and kill anybody. This concept was also reflected in the early architectural philosophy of the Romans, as described in Vitruvius's De architectura libri decem (1^{st} century BC). Let us try to understand how we in the current times define the performance concept.

1.1 The Performance Concept

The process of designing, planning, coordinating and constructing a building involves an entire spectrum of building professionals who work cohesively together to address the needs of the client. However, this process is not so straightforward. Construction professionals, often new to each other, have to operate within unclear and dynamic processes and procedures. The way in which the building fulfils the expectations of all the stakeholders, including the providers, managers or occupants of the building, is increasingly becoming the measure of its success.

The design not only has to be buildable (in terms of cost and time), but stakeholders are increasingly enquiring about its maintainability, sustainability, accessibility, fire deterrent features, and its functional acoustic, energy and the performance. Each of these parameters has to satisfy a whole host of social, economic and legislative conditions. Traditionally, these conditions are governed by prescriptive codes and standards. Prescriptive standards are easy to understand and follow and the results are easy to monitor. However, their inherent inflexibility stifles innovation, leading to a poor match between true user requirements and the building, and poor value for money. By changing the focus from the input material's specifications (traditional, prescriptive approach) to the output user requirements (performance based) we will increase both the quality and the long-term value for money of our buildings. [1]

The performance based building (PBB) concept provides a flexible and technically non-prescriptive framework for building design and construction. The PBB approach enables greater innovation, aids international trade and cost reduction. Its application consists of translating human needs (functionality, comfort, etc) first into functional and then into technical performance requirements, implementing them within a regulatory framework and enabling the construction of buildings that provide long-term satisfactory performances. The Performance Based Building (PBB) concept applies itself to the constructed asset planning, programming, design, procurement and construction, life cycle management and operation, and to building regulation control. Although its definition is acutely debated, it is considered in broad terms as "*the practice of thinking and working in terms of **ends** rather than **means***". [2]

2. Establishment of the PeBBu Network

Recognising the relevance of the performance based building concepts for the building and construction sector of Europe, the PeBBu Thematic Network was established in 2001 and runs until September 2005 to further the knowledge, dissemination and application of the PBB concept worldwide. It is funded under the European Commission's (EU) 5th framework – Competitive and Sustainable Growth. Organisations from both EU and non-EU countries involved in PeBBu are research institutes; research funding organisations; universities; architectural and engineering offices; contractors; manufacturers; regulatory bodies, building and construction consultants, industry associations and governmental agencies.

2.1 Objectives of the PeBBu network

The main objective of the PeBBu Network is ***"Stimulation and pro-active facilitation of international dissemination and implementation of Performance Based Building in building and construction practice",*** and in that context to maximisation of the contribution to this by the international R&D community. [3]

The Network aims at combining fragmented knowledge in the area of Performance Based Building in order to build a systematic approach towards innovation of the building industry and applying user requirements throughout the building process. From this, white spots and a coherent future research agenda can be derived. End-users, policy makers, building industry and regulatory communities are closely involved in this development in order to facilitate dissemination and implementation of research results.

2.2 Components of the PeBBu Network

The PeBBu programme[1] includes the following "core" components (refer to Figure 1)

- International programming / coordination of research within 6 Scientific Domains.
- Involvement of target groups / stakeholders through three User Platforms for respectively a) Buildings Owners, Users and Managers, b) Building and Construction Industry and c) International Standardisation and Conformity Community.

---

[1] More detailed information on the PeBBu Network, its program of activities and its organisation can be found in the designated PeBBu website at www.pebbu.nl. This website contains an online database with information on current PeBBu member organisations, all ±250 persons active in the various tasks, task description, meetings and publication; More information on the established Scientific Domains with downloadable PDF versions of recent Domain Reports; 1st International State of the Art Report on PBB; Newsletters; International Research Mapping Database.

- Four Regional Platforms in Europe to act as the bridge to and the initiator of aligned national activities (Northern, West/Central, East and Mediterranean).
- Network Management - Establishment of a Network Steering Committee, a Technical Committee and a Network Secretariat.
- Mapping of national and international research related to various aspects of Performance Based Building.

At the onset of PeBBu, the project began with 9 scientific domains[2]. These spanned across the various themes and aspects of performance based building. In the middle of the project, it was decided to terminate 3 of these domains (the domains on Built Environment, Organisation and Management, Information and Documentation) due to the vast scope of these domains, the lack of ongoing research and/or overlap with other domain work.

In addition to these core components, there are various aligned activities in support of PeBBu (Figure 1). These however, are not funded from the EU PeBBu budget. These aligned activities have been contributing to major achievements of the PeBBu Network. Meanwhile, in the first 2 years of PeBBu Programme, some other topics of interest relevant to PBB arose. These have now being developed as new tasks and are incorporated within the PeBBu workplan. The 3 new tasks are:

1. PBB & Construction Products Directive (CPD)
2. PBB Decision Making Tool-Kit
3. (CRISP) Sustainability Indicators for PBB.

---

[2] Domain 1: **Life Performance of Construction Materials and Components,** investigates the performance of a material/component over its design life and predicts the service life, given the variables.
Domain 2: **Indoor Environments,** deals which the performance criteria and evaluation methods for healthy buildings.
Domain 3: **Design of Buildings** defines the user requirements in performance terms, implementation of knowledge and training needs for professionals.
Domain 4: **Built Environment** provides an interface between building and urban design.
Domain 5: **Organisation and Management** manages the design, construction, operation and maintenance of a building using the performance concept.
Domain 6: **Legal and Procurement Practices,** deals with legal issues of defining building quality in performance terms.
Domain 7: **Building Regulations** involves implementation of PBB regulatory systems & the role of national/international standards
Domain 8: **Innovation,** establishes connections between innovation building life cycle phases using comparisons with other more innovative industries.
Domain 9: **Information and Documentation** emphasises the new information requirements needed to support the performance based approach.

2.3 Key Achievements to Date

The PeBBu Network has made considerable progress in its first two years of operation. Some of the main achievements of the 1st two years of the existence of the Network are:

2.3.1 Successful operation as a Network

The foremost aim of the PeBBu project is to be operational as a Thematic Network. In that aspect, the network is a big success with the network in place and regular meetings held to strengthen this network.

2.3.2 Expansion of the Network

This entails the expansion of the Network to include several new countries from the Newly Associated States (NAS Countries). This ensures a complete European perspective for the stimulation and establishment of PBB practices. 13 new organisations from the NAS countries are now members of the PeBBu Network. Apart from this, several observer-members have become a part of the Network.

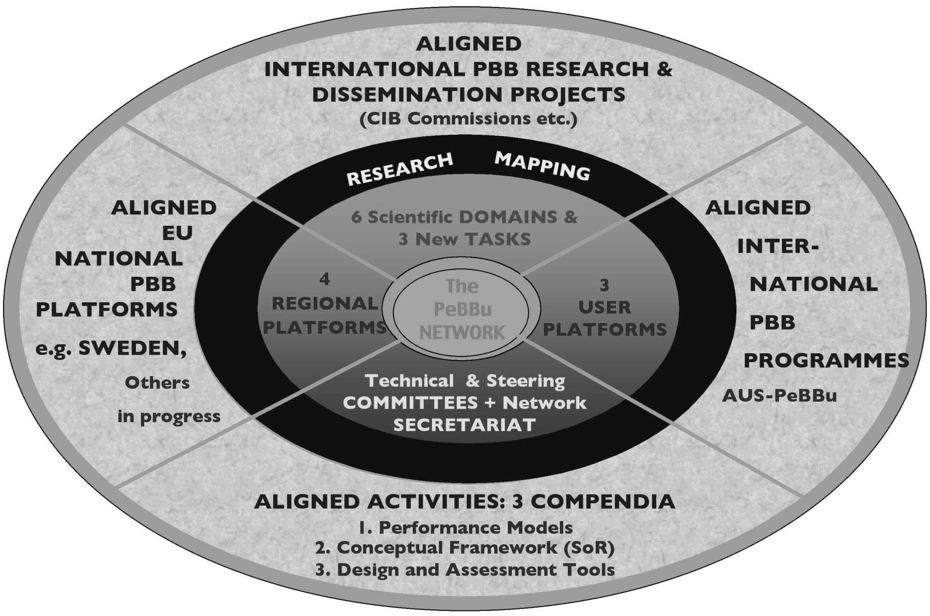

Figure 1: PeBBu Structure

2.3.3 Launch of Aus-PeBBu

An Australian version of the PeBBu Network has been launched in October 2003 in Australia. The Australian programme, referred to as Aus-PeBBu[3], is similar in structure to (EU)PeBBu.

[3] More information on Aus-PeBBu can be found on: www.auspebbu.org

With the launch of Aus-PeBBu, Australia is now able to participate in the global move towards the performance approach, which has occurred through regulatory changes from a prescriptive to a performance based building code. It is expected that Aus-PeBBu will expand to include countries in the Pacific Rim and South East Asia with which Australia and cooperation agreements in place (including New Zealand, China, Malaysia, Vietnam, Hong Kong, Singapore, Indonesia and India).

2.3.4 Establishment of aligned activities such as the PeBBu Compendia

The Compendium of PBB models developed a database that at present includes 30 such PBB models. PBB Compendium of Statements of Requirements aims for the development of a consensus based PBB conceptual framework and key-terminology. This has ultimately led to a consensus on PBB language, concepts and issues.

2.3.5 Production of the 1st International State of the Art Report

This gives an overview of the status off PBB in an international context. The International SotA analysis the spread of PBB principles through many National SotAs from the European context and a secondary research about proliferation of PBB principles in other parts of the world. [4] The International SotA has being published as a CIB publication and this is a good tool to disseminate vital information on PBB.

2.3.6 Establishment of many strategic relationships

Examples of these are:

1. Co-operation with ISO TAG8 (the ISO Technical Advisory Group that is responsible for building related standards) on a multi-year programme within ISO that aims for the production of performance based standards that are to replace or to be added to the current prescriptive ones.
2. Between PeBBu Domain 1: Life Performance of Construction Materials, Components and ISO. This relationship has influenced writing of standards related to durability of construction materials and components.
3. PeBBu has also established relationship with the E-CORE projects where PBB will be one of the main building blocks in a future European RTD strategy.
4. Co-operation with the Liaison Committee's of International Associations of Structural Engineering aiming for the establishment of a joint committee on PBB related pre-standardisation issues in the area of structural engineering.

2.3.7 Involvement with / and support of several CIB Commissions

Several CIB (Task Groups and Working) Commissions have been established to facilitate international exchange and co-operation in areas that cover aspects of PBB on a voluntary basis. As an average each such commission incorporates 50 appointed representatives of organisations worldwide who meet on a regular basis and aim for joint, voluntary, international R&D projects in their area.

3. Status of PBB

Over the last 50 years, there has been considerable development in the performance based approach. These developments have led to a clearer description of what the performance approach means in both concept and practice as well as its potential benefits and challenges [5]. These developments can be traced through the reports from the US Nationanl Bureau of Standards (1925, 1977), the proceedings of many conferences, and various CIB publications. [6]. Despite several leading programmes, implementation of the performance concept has been somewhat sporadic.

3.1 Status of PBB Domains

Although PBB is whole encompassing of the design, operation and maintenance of a building's lifecycle, under the PeBBu Network it has been divided into 9 (6 continuing) scientific domains to aid the investigation process. These domains span the complete lifecycle of a constructed facility - from the conceptual/ brief stage through to operation and maintenance (Figure 2). Moreover, they encroach on both soft and hard issues facing the design and construction process. The potential new activities of FM (facilities management) and education occupy definable "gaps" in the current PeBBu programme. This section summarises the state-of-the-art of the performance based approach in each of the 6 remaining domains of PeBBu and provides a brief future research agenda. [7]

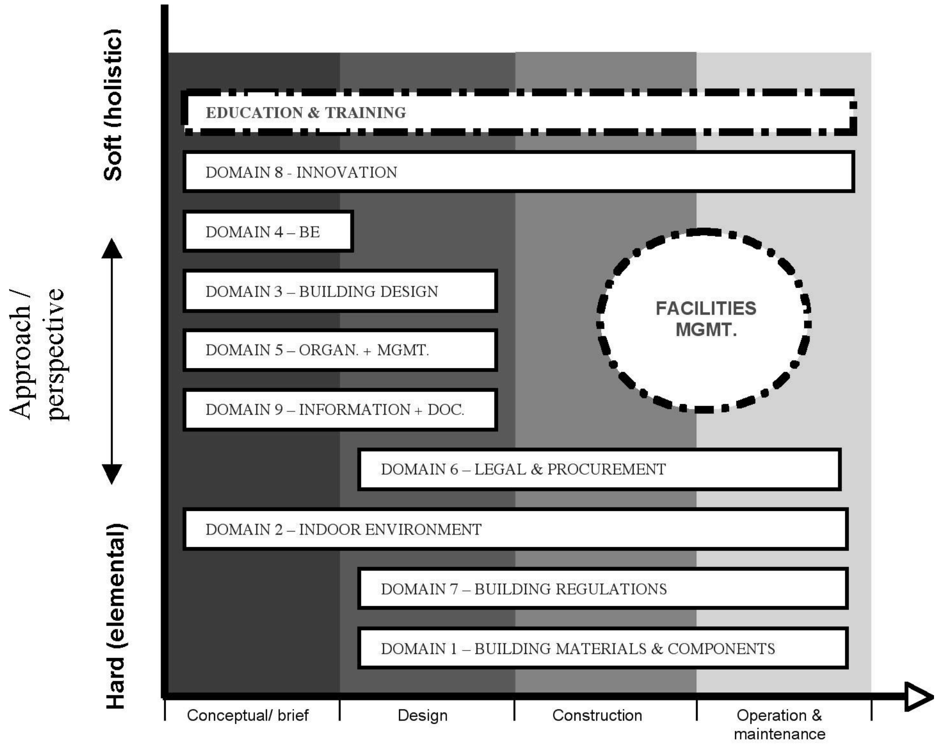

Figure 2: Domain Lifecycle Stages

3.1.1 Domain 1: Life Performance of Construction Materials and Components

The overall performance of a building relies on the performance of its materials and components. Therefore, how can the performance of materials and components be assessed in advanced to ensure the building performs as required? PeBBu domain 1 aims to address methods for predicting service life, particularly for novel building materials and components. Under PeBBu programme, this domain will further develop the Factor Method (system to estimate the service life when there is limited knowledge of long-term performance of components), develop an international suite of standards, and to design and prepare training sessions for both industrialists and academics.

3.1.2 Domain 2: Indoor Climate

This domain maintains that healthy buildings can be pursued by designers, constructors, building owners and building occupants, through the application of a number of qualitative and quantitative health-based criteria (methods, guidelines, protocols and tools to design, evaluate and measure the health status of buildings/ designs). The health of buildings in this context relates to air quality, ventilation, thermal comfort, noise and visual comfort. Although there is rich scientific literature and several experiences on the quality of the indoor environment, a uniform set of criteria across Europe or the world has not been defined. The majority of PBB implementation is isolated to different components and not in terms of the building as a whole. A general translation from subjective criteria to objective design parameters, and reverse when dealing with the evaluation, to a large part is still lacking. Research initiatives into the health and comfort of the building environment are ongoing. However, a lot of work is still required before PBB can completely replace current prescriptive buildings methods.

3.1.3 Domain 3: Design of Buildings

It has now become an economic necessity for the building industry to pay more attention to meeting user requirements. Therefore, there should be a focus on both the (technical) performance specifications for building parts, and on the management of (functional) user requirements and involvement during the building process. Thus, the problem of 'meeting with performance specifications' in the design stage of the building process should be addressed: -

5. The translation of client and user requirements into objective, measurable performance specifications.
6. Classifications and formats for performance specifications.
7. The testing of (preliminary) design results against agreed performance specifications.

PBB in the design of buildings has mainly been undertaken in research and education rather than practice. In several countries there are programmes aimed at structural changes in the building industry. Examples are ‘Rethinking Construction’ in the UK and the ‘Process and Systems Innovation Programme for the Building Industry’ (PSIB) in the Netherlands. The primary barrier for performance based design of buildings rests with the culture and existing fragmentation of the construction industry. In retrospect, linking performance based design with IT (product modelling systems), demonstrating its value in educational programmes and developing a universal language of specifications, could speed its adoption.

3.1.4 Domain 6: Legal and Procurement Practices

This domain focuses on the problems encountered towards PBB specifications via procurement and the legal issues that subsequently arise. There is currently no state-of-the-art that could be applied across the EU, rather a collection of national practices. There are two significant factors driving towards PBB, international and government influences. International influences have arisen from experiences of multi-national companies around the world and a desire to replicate best practice in other countries. Government influences have been founded on their responsibility for construction output, and that they need to maintain or increase output whilst at the same time reducing public sector expenditure. In order to reconcile these two forces, governments have increasingly turned to methods that involve private finance in projects. These methods include: Design and Build (D&B); Design Build Fund Operate (DBFO); Build Operate Transfer (BOT); Build Operate Own Transfer (BOOT); Private Finance Initiatives (PFIs); Public Private Partnership (PPP). Currently it is reported that in excess of 100 countries are procuring construction and engineering works under the generic heading of PFI. The majority of uncertainty lies with risk and liability, not least the issue of duty of care v duty of result. Both private and government influences have resulted in moves towards PBB since performance specification lies at the heart of both D&B and PFI philosophy.

3.1.5 Domain 7: Building Regulations

Innovation in construction is heavily dependant on the building regulatory system. In many countries, the system is based on what is termed a ‘prescriptive’ approach, where a single, or very few solutions are provided as ways to comply with building regulations. This has the effect of creating a design and construction industry that is restricted to designs that fit those specific solutions. Performance regulations, which focus on intended outcomes, are intended to encourage innovation and trade by expressing what regulations are intended to achieve. Many countries are moving in this direction or have already implemented PBB building regulations. However, there is very little research in the area of performance based regulatory system issues on a policy level. Research, in most cases, focuses on the technical solutions to the regulations. On a national level the Australian Building Codes Board has been fairly active in conducting research that relates to the building regulations. More specifically, Australia formed what is called the ‘Fire Code Reform Centre’ in 1994 to look at various issues relating to fire safety in an effort to improve the building code. Countries such as France and Canada also conduct similar research in various areas. In the United States, there has been some research in the area of risk and public policy as it relates to building regulations.

3.2 Domain 8: Innovation

The principal focus of PeBBu Domain 8 is to examine innovation through the ‘performance of buildings in use.’ Innovation is taken to concern the multifaceted value creating, capture and delivery role of buildings. This includes the building appropriately meeting the needs of the client system and of whole life cycle performance. Currently, there is a mass of technical, product-related criteria (principally from a top-down regulatory direction) that helps maintain a base-line standard of construction for health and safety purposes. This does not cover all areas of construction, such as the process of construction, or many aspects of the use of buildings and their impact on society. Both the EU Innovation Scorecard and the UK’s ‘Key performance indicators’ do not reflect any indicators in the area of innovation and learning. Nor do they focus on the client’s/ user’s needs. Performance metrics for innovation in PBB thus need to appropriately integrate building and business considerations. For the industry to succeed it needs to maintain a minimum level of innovation as a norm and this should be reflected in explicit innovation performance objectives for the various parts of the industry. The challenge for the domain will be to identify clear and realistic innovation objectives and measures, differentiated as appropriate by industry sector, which can make a real impact in practice. Part of this aspect will include consideration of the interactive roles of the various stakeholders running from materials suppliers, through builders merchants, designers, specialists and builders, to users and owners of the built facility.

4. Key Lessons from the PeBBu Network

The PeBBu project has provided the opportunity to engage a wide variety of stakeholders in moving towards the widespread application of the performance concept in building and construction. Some of the lessons learnt from running this project have been presented in this section. These are based on first hand observation and knowledge, and informal feedback from some network participants. The key lessons learnt are presented below:

1. **Importance of funding**: The benefits of the PBB concept are not always recognised by the industry to be of real and significant value and therefore, many critical stakeholders are hesitant to participate. The funding by the European Union of the project has proved to be a key push to the concept whereby several opportunities towards global and lasting promotion of the performance concept have emerged.

   The worldwide development and promotion of Performance Based Building has a much wider scope than the current scope of the PeBBu network. Much additional effort and in-kind contributions of time have been made by PeBBu participants to cover work that is not funded. Further funding of priority areas, which are not yet funded is therefore required. [8]

2. **Addressing fragmentation of the industry**: Fragmentation in the building exists at both the differing levels of expertise as well as working in different phases of a project (e.g. design phase vs. installing services phase). A rigid programme structuring is also likely to have similar fragmented effects. A more flexible programme of domains and tasks, which promotes maximum interaction and participation in various themes should be encouraged to remove barriers. An understanding of this prompted the movement from stand-alone meetings to organising series of meetings that promote greater interaction in the PeBBu project.

3. **Stress on value and benefits**: It is very important for a project like PeBBu with a strong research focus to identify and communicate the benefits and value of the application of PBB to the stakeholders. Producing such a statement of value and benefits should become a priority for the project.

4. **Necessity to engage the right stakeholders at a right time**: This implies that it is not necessary to involve all the stakeholders in all the phases of the project. Critical people who can easily become the stakeholders champions in the project need to be engaged at the outset.

5. **Effective communication and collaboration**: This is a practical lesson from the PeBBu network that brings forth the need to facilitate collaboration through effective communication. Despite the developments in the IT sector where electronic communications have taken over the majority of meetings, it was realised in the course of the project that face-to-face meetings were essential to the operation of the network. Similarly there is a need to communicate the right message in the best possible way to the right stakeholders!

5. FUTURE CHALLENGES & MAIN PRIORITIES

Performance based regulations and practices are currently both mandatory and voluntary. Culture and a lack of resources have somewhat prohibited the regulation bodies to fully ‘prescribe’ PBB practices. PBB must be contextualised to suit a particular country and lessons learnt from other PBB applications must be reviewed and adapted to differences in government, culture, and economy. Successful application of PBB requires the development of new knowledge, understanding and PBB tools.

Prescriptive-based building sometimes works well in simple deemed-to-satisfy buildings, thus, the application of PBB principles is not always necessary. Therefore, the two approaches should work in harmony: the performance approach should be available to those who require more complex innovative developments or design concepts driven by stakeholder requirements.

In order to obtain the maximum benefits of PBB, the following needs to be delivered: -

1. Actions to progressively align organisations business processes to PBB
2. Education and training regarding the appropriate circumstances for using PBB
3. The steady increase of the performance criteria captured within PBB

Other framework issues that need to be addressed to support the PBB concept include public policy, regulations, innovation (in various fields such as materials, building technology, design and construction process etc.). In particular, developing assessment methods that verify the approach to support the regulators, methods that allow the client to ensure that their performance requirement is actually delivered, and guidance of how to include PBB in an organisation’s business strategy are crucial for the assurance of both the client and construction professionals.

The PeBBu project expects a further increase in stakeholder involvement in various aspects of PBB. However, specific methods need to be explored to engage effectively the critical stakeholders that can help hasten and broaden the adoption of the performance concept. One of the main challenges lying ahead of the project is to identify clear value and benefits of the Performance approach for various stakeholder groups, substantiated with real case studies, and to package them for a compelling presentation. This will ultimately facilitate client- or demand-driven innovation, made possible by the performance approach.

Abstract

PeBBu domain 1 on life performance of construction materials and components is part of the EU financed thematic network on Performance based Building. Domain 1 addresses issues in a thematic field, where performance based building, service life, life performance and environmental declaration of products draw attention to each other. As can be seen in the recent development of international standards, service life and performance requirements gain a significant position as part of sustainability assertions of buildings and building products. Domain 1 aims to identify aspects of practical application of the ISO standards series 15686 on service life planning, as these standards provide the methodological basis to identify service life, and to provide the market with service life information. As service life per se relates to performance requirements and performance over time, and as sustainability in building construction related to fitness for purpose, performance based building fulfils a central hot-spot of concern in relation to building sustainability.

D1 addresses stakeholders' concerns when involving service life – both concerning the provision of information as the adaptation of information to a specific building design. Hence, concerns of manufacturers as well as designers and other relevant stakeholders are dealt with. Issues of concern for further R&D as well as feedback and input to ongoing international standardisation, are identified by D1. With the direct link to the durability and service life research community and the involved standardisation bodies, the thematic network can play an important role in promoting performance based building.

Keywords: Virtual enterprise, information exchange, information systems, distributed engineering

1. Introduction

PeBBu is a thematic network, funded under the European Commission's 5th framework addressing competitive and sustainable growth. The Performance-based building network was initiated in October 2001 and will be running through to September 2005. One of the main reasons to establish the network was to facilitate and enhance the existing performance-based building research and activities by networking with the main European and international stakeholders. The creation of a network that is supposed to utilize synergy-effects well beyond the termination of EU funding is the main aim. Involved are currently more than 60 organisations worldwide.

Currently ongoing international standardisation projects, both on ISO (ISO/TC59/SC17) and CEN (CEN BT/WG174) level set environmental declaration of building products into the context of sustainability assertions ("sustainable building" in ISO and "integrated environmental performance of buildings in CEN"). In that context, it is of outmost importance to address the entire life cycle of the product, per se or as part of a larger functional component or ultimately the building. This in turn requires information about all relevant stages of the life cycle, including predictions or estimations of service life aspects. First based on a reasonable understanding of the post production life cycle stages, an identification of processes occurring during the life cycle can be made, and hence first then, such scenarios and their associated environmental impacts or sustainability aspects can be identified and included in declarations. Where these developing international standards are relating to service life, they may take benefit from the establishment of standards or standardised routines for the declaration of service life of products. Meanwhile, it must be obviously clear, that for a manifold of products used in building construction, an expression of service life appears meaningless to establish. Examples for this are ancillary products as well as generic products that are produced and supplied without any knowledge about their application. Examples are cement / concrete, construction wood, etc. For other mass products, such as screws and nails, the link between exposure environment and product choice may be so obvious, that a service life declaration is not needed in practice. A declaration of service life information for products is intended to enable stakeholders, like e.g. the designer or the investor, to take decisions among product options, and to enable the methodology of service life planning to be operational, with all its potential applications and benefits.

Assessment of service life, and declaration of service life, may follow a three-step sequence, along:

- A description of product properties
- An analysis of the durability of a product under certain conditions
- A testing-based or estimation-based expression of service life of a product under given conditions

In order to identify the current status of service life consideration in the construction sector, and in order to inform about the ongoing work, PeBBu D1 has established enquiries among material producers and building consultancies. The goal is to identify to what extent the ISO standards are known and applied throughout industries, or whether and on what basis claims relating to service life of products are being made. Preliminary findings from the enquiries directed to manufacturers allow the conclusion that the industries in general are aware of the market relevance of service life information, and that many manufacturers are ready to provide information, or have started consideration of service life aspects of their products. In general, service life information is not yet systematically provided to the market, as well as it is not yet demanded either, but the actors appear to be able to provide and handle such information within reasonable time frames. A rising demand for service life declaration formats can therefore be foreseen. Ultimately, the demand for service life information will raise due to the attention the issue receives in international standards related to sustainability. In order to allow the industries to supply the market with service life information, a clear demand for harmonized rules on how to declare service life can already be detected.

2. Introduction

The international council for research and innovation in building and construction (CIB) began work on the subject of building performance in the 1970es. The "performance approach" was described as "first and foremost, the practice of thinking and working in terms of ends rather than means. It is concerned with what a building is required to do, and not with prescribing how is it to be constructed" [4]. Over the years, CIB has started numerous working groups addressing performance-based building; among these the thematic network PeBBu, being a thematic network addressing performance-based building in 6 scientific domains, 4 regional platforms and 3 user platforms.

The six scientific domains are:

1. Life Performance of Construction Materials and Components
2. Indoor Environment
3. Design of Buildings
4. *(Built Environment) cancelled*
5. *(Organisation and Management) cancelled*
6. Legal and Procurement Practices
7. Regulations
8. Innovation
9. *(Information and Documentation) cancelled*

Even though domains 4, 5 and 9 have been cancelled, domain reports as well as an international R&D agenda will be produced.

Domain 1 on life performance of construction materials and components draws its rationale from the fact that the overall performance of a building relies on the performance of its materials and components. While performance aspects of materials, components, and systems cannot sufficiently and entirely describe building performance, evidently the assessment of material and component performance is a necessity to ensure the building performs as required. Domain 1 has been established to focus on methods for predicting the service life of construction materials and components.

As service life and life performance information may be based on experience and with that may be available for materials that long since have been applied and / or tested, for new and innovative materials, such information is not available for obvious reasons, but ever so needed for application in performance based building. Hence, a method for *estimation* of service life is needed. The ISO standard series 15686 addresses service life planning of buildings and constructed assets. This standard series also provides a method for estimation of service life, and the PeBBU domain 1, with its focus on life performance of construction materials, components and systems specifically relates to these standards. Domain 1 intends to exemplify these standards with the goal to enable wider provision of information needed for the process, as well as enabling a wider application of service life information in project planning and building design.

While focussing building materials and components, the context of functional application of materials and components deserves consideration. Consequently, D1 also addresses systems. An example for the reporting of D1 is given in the French state of the art report on the performance approach [7].

3. Performance approach as key element in sustainable construction

Application of the performance approach has recently led to the establishment of performance based building regulation, see for instance [8] and the New Zealand Building Codes [9]. Another driver for the application of a performance approach in building construction are “Public-Private-Procurement” (PPP) contracts, which are a growing trend in numerous countries. While earlier public institutions generally became the owner of works as delivered by industry, they automatically assumed the induced costs of a bad prediction of the service life. With PPP, they are now contracting with companies which will build and manage a works for a beforehand agreed number of years: for their own interest, these companies will then try to get better control on the service life of the works, and ask commitments from the product manufacturers. [10].

Additionally, there also is an obvious role of performance based building in the context of sustainable construction. As the performance approach starts off with an expression of what is expected from a building, in terms of functionality, the identification of performance requirements can perform as an anchor in other elements of sustainable construction. Based on durability assertions, service life planning can assist in the identification of reasonable scenarios for the service life and for the development of performance over time. As the service life is defined as ending when the building or parts thereof no longer meet or exceed established performance requirements, these requirements turn significant for the description of the building or product life cycle. Additionally, the performance requirements help to identify processes employed during the use phase. These in turn are needed in order to establish environmental declarations and to enable life cycle cost calculations that do consider the entire life cycle. As the identification of scenarios and processes is depending on the current application context and user requirements as well as to the development of performance over time, this means that the declarations and life cycle calculations depart from default scenarios and consequently reflect a building specific situation. While a building specific consideration enables decision takers to tailor the information underlying decision making to the developing design, it must be noted that due to this adaptation, the generated declarations and assessment results may loose their validity for generic interpretation [11][12].

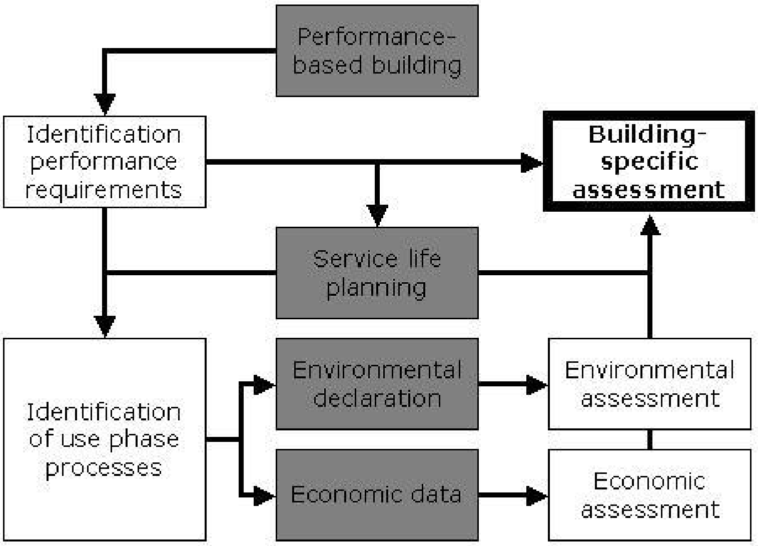

Figure 1: Performance based building and service life planning as central elements of sustainable building [13].

4. Link to Environmental Assessment / Sustainability Assertions

Where the topic of sustainable construction on one hand provides the contextual frame and the philosophical reason for acting on the topic of service life, the methodologies developed to identify reference service lives and estimated service lives, also in terms of service life declarations, provide input to in especially environmental product declarations of building materials and components, and equally evident, to the assessment of environmental performance of buildings, both items addressed in ISO/TC59/SC17 and in CEN/BT WG 174.

These international standardisation projects also identified, similar to the content of figure 2 below, that the assessment of environmental performance of a building goes well beyond the aggregation of product level information. The performance of products throughout their use phase as part of the assessed building becomes a key point of interest.

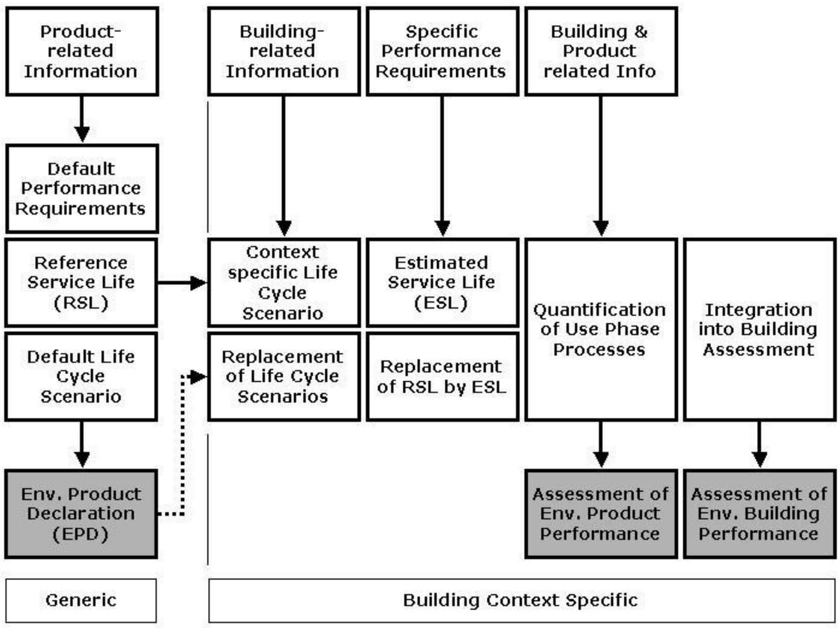

Fig 2 – the route from product information to assessment of building performance [14].

The consideration of product performance as an element of building performance, and the recognition that a correct description of a product life cycle often is not possible isolated from an inclusion of the building in which the product actually is performing, leads to the necessity to identify the functional context of a product, component or system. This context on the one hand requires performance from its parts, while each part may provide preconditions of functionality and performance to other parts, or the entity. At the same time, performance requirements as expressed by users and other stakeholders, may concern the entire building, or may be directed to specific elements of performance. This inter-dependency of performance in a building context can be illustrated as in figure 3 below.

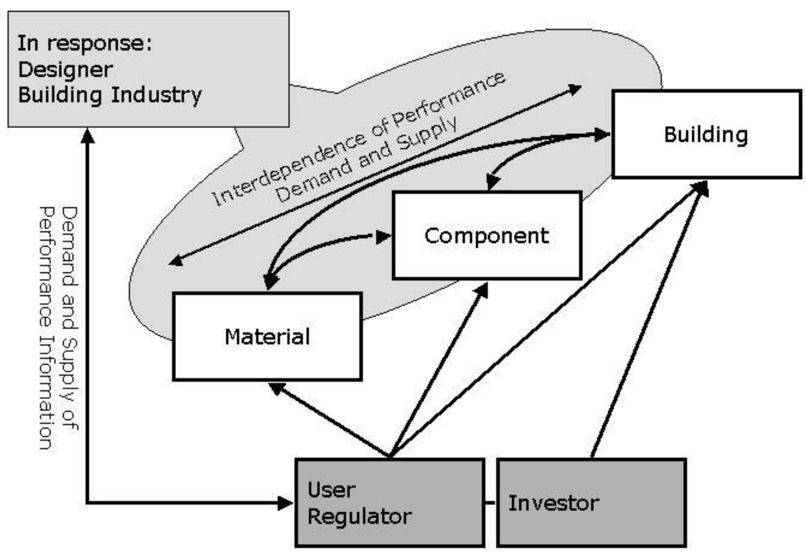

Fig 3 – Dependence of performance of products, components and buildings [15].

5. Modelling Durability and Life Performance – PeBBu D1

PeBBu domain 1 ‘life performance of materials and components’ has as one of its main objectives to further develop the methodologies contained in the ISO 15686 standards series in order to bring the concepts closer to practical application. The demand for this objective stems from the situation, where product manufacturers are willing to provide environmental declarations about their products, and where they also are generally willing to provide information about durability and long time performance of their products. They can however not be made responsible to provide the market with information on durability and performance for situations that are highly specific. In other words, manufacturers can only provide information valid for a small selection of situations that correspond to the main purpose of their products, and that reflect a small selection of conditions in which their products are applied. These restrictions refer both to the application of the product, the integration into a building, the product wear due to use, the exposure to environmental degradation, climatic situation etc.

For situations, where the actual product application, or the specific use conditions do not coincide with the expectations the manufacturer had in mind when providing information, this information may not be valid. In cases of extreme deviation, the information may even be considered as irrelevant. Ultimately, the manufacturer can neither be held responsible for provided information.

Still, designers and other stakeholders have to make decisions related to the integration of products into a building design, or related to the expression of performance requirements, be it in the clients brief or in performance based regulation. The expression of reasonable performance requirements relies on competent and well informed bodies establishing these requirements. “Classification of stakeholders as demand and supply sides is a convenient simplification. However, in reality the industry cannot be so easily categorized as consisting of these two sides. In some instances, some stakeholders can be on both sides (e.g. a developer), and in other instances can be on either side. Since the performance approach is mostly about fulfilling the desired “ends” of the demand side, any project that involves educated and innovative stakeholders on the demand side and well-equipped stakeholders on the supply side has a much higher possibility of success.” [16]

D1 strives to identify the knowledge-demand of relevant stakeholders and to equip them with information so that they each can adopt their behaviour on the product- and building-related “information market” to the demands arising from an application of the performance approach. Concerning life performance of materials and components, this means that the suppliers of information must deliver information that reflects well established “main stream” scenarios for the life cycles of their products, rather than the most beneficial case, while providing information in transparent means, that enable the user of information to identify, analyse, and where necessary adapt and replace parts of the information provided.

For this, the user of information must be equipped with sufficient knowledge about scenarios and their validity as well as their significance for provided information. Further, they must be enabled to identify when scenarios need adaptation of replacement in combination with information about other scenarios and associated data.

When a designer of a building, or another relevant stakeholder, detects that the basis on which declarations have been provided does not sufficiently coincide with the application in the planned building, the designer appears to be the only reasonable initiator of the adaptation process. This does not mean that he has to perform the process, but it will have to be performed as part of his initiative and responsibility. The process to adapt declarations from a generic to a case specific context is illustrated in figure 4 below, where additionally, the spheres of responsibility are indicated. Even where the information is modified, the starting point has still been the information contained in the RSL, meaning also the adapted declaration / assessment is based on manufacturer information.

As product manufacturers are the primary source for product information, they may provide the market with life cycle and service life information based on the reference service life, as established in ISO 15686-1 [17]. Based on enquiries cast to manufacturers, it can be said, that a large share of manufacturers is addressing the issue of durability and service life of their products. Not all are aware of the ISO standards, however. The procedures of addressing service life and durability are different between companies, likewise the communication of such information to the market. Where some manufacturers provide information, others appear to rather use information for internal purposes in product development. Currently, the variety of approaches to the issue of service life appears to create some doubts as to the value of provided information. While different approaches all may have their justifiable fields of application, there is an evident demand arising for guidance and harmonization, especially in a situation, where forthcoming standards are relying on information about service life, [6] For these standards to succeed, there is an evident demand for the establishment of a common basis for identification and communication of service life information.

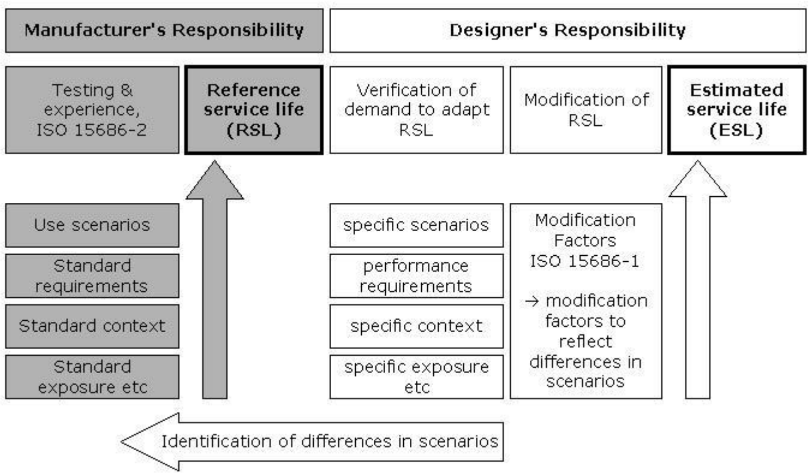

Fig 4 – The role of manufacturers and designers concerning determination of RSL and ESL [14].

Manufacturers appear to a certain extent reluctant to provide data on reference service life of their products, claiming that the service life of a product depends not only on the quality of the product itself, but as well on the way it is installed in the building, the conditions of use and the care with which it is maintained. Therefore, it may be realistic to think about a more open way to communicate information and data on service life. Two tools have been developed in CSTB for addressing that point: data fusion and Failure Mode and Effect Analysis (FMEA), where data fusion [18] can be applied for an exhaustive compilation of various heterogeneous data available on the service life of a product (test results, expert advices, field data, manufacturer assumptions), and FMEA [19] for anticipating the different ways a product may fail, and for drawing event graphs to illustrate it.

Such a set of data, more explicit and transparent than only a number for service life expectation, may cause less resistance for manufacturers to provide, and may be more open for designers to adapt to their actual project.

6. Conclusions

Innovation in the building sector may be described as either supply-driven or demand-driven. In the first case, the provider of innovative solutions will seek to convince key market actors to recognize and apply the innovative products, in the latter case, the suppliers of products are to develop solutions that meet the requirements originating from the innovation demand. In both cases the communication of life performance, or service life, aspects is an essential element of information. For innovative solutions, which in many cases are new developments rather than adaptations of existing solutions, no information on long-term performance and service life will be available. Such information hence must be estimated, e.g. in accordance to the EOTA guidelines and the ISO 15686 standards.

Where service life information is communicated between various stakeholders of he building sector, it has to be assured, that a common understanding, also of the underlying scenarios for which information has been provided, as well is communicated and understood by all parties participating in the communication. A harmonized approach to service life declaration may be very helpful.

PeBBu D1 aims to investigate to what extent actors in building construction already today are informed about the ISO standards, to what extend they make use of service life information and apply the performance based building concept. A general conclusion is that the concepts appear to be well known, but there still is a significant lack of experience and feedback form examples, where the concepts have been applied systematically and successfully. However, the availability of information and the number of examples of application is rising, all while the development of tools for the application of service life planning has taken up momentum. From this, in combination with the general awareness of the usefulness of the concepts of performance based building and service life planning, it can be assumed that the development of tools, and the integration into standards relating to building sustainability, will spur the application of the concepts.

The communication of service life information within the construction sector sets high requirements concerning transparency of the information. A declaration of service life can only reflect one or a few scenarios for product application. Therefore, designers for instance, may need to perform or initiate a process of modification of declared information, all in order to obtain information that is relevant to the situation in a specific building context. The primary source of information will still be the manufacturers, while recognizing that information provided by them only can be based on reference scenarios. Such scenarios must be available for scrutiny by those applying the provided information.

Abstract

The European funded Project PeBBu, Performance Based Building, is a Thematic network under the Competitive and Sustainable Growth program, which started September 1st, 2001 and will run for 4 years. In one of the domains of PeBBu, the domain Indoor Environment, a state-of-the-art on the Performance Based Building (PBB) approach with respect to healthy buildings is prepared.

The state-of-the-art on performance criteria for healthy buildings deals with current available methods, guidelines, protocols and tools to design, evaluate and measure the health status of buildings or designs for buildings. The health of buildings in this context relates to: air quality, ventilation, thermal comfort, noise and visual comfort. The work furthermore presents a framework in which the state-of-the-art and future research in this area can be positioned.

After a short introduction into PBB and its definition, this paper will summarize the state-of-the-art with respect to performance and healthy buildings, i.e. the results from the work of this domain within the PeBBu Network. With the developed framework as a base, different points of departure are chosen to indicate the status of performance based building: the building point-of-view and the environmental attributes point-of-view.

The main conclusion is that the PBB-approach already has a basis in the building process, but that some specific topics are lacking that currently impede the further integration of PBB. Indoor environmental attributes appear specifically suited for the PBB-approach and some interesting initiatives of performance based approaches for healthy building are ongoing or have been developed in recent years. Nevertheless, a lot of work still is required before PBB can completely replace the current prescriptive building methods, if possible at all.

Keywords: performance based building, indoor environment, healthy building, thematic network

1. Introduction

1.1 Performance Based Building

Performance is a concept that has gained increasing attention over the last couple of decades. In 1982 CIB [1] already presented statements that define performance for the building industry:

- The performance approach is thinking and working in terms of ends rather than means.
- Performance is concerned with what a building or building product is required to do and not with prescribing how it is to be constructed.
- A design solution, traditional or novel, will always need a quantitative base for testing and evaluation of its performance.

Initiated by CIB, PeBBu is a Thematic Network under the EU-Competitive and Sustainable Growth program. It started in 2001 and runs for 4 years. The overall objective is to stimulate and pro-actively facilitate the international dissemination and implementation of performance based building (PBB) in the building and construction practice. It is not intended to present the ultimate solution for PBB, but to allow for a more fundamentally motivated and integrated continuation of the further development of PBB.

The PeBBu-project has been divided in nine domains for which the PBB approach should be investigated. The here described work deals with the 2nd Domain: Indoor Environment. The intention of this domain is based on the believe that the achievement of healthy buildings can be pursued by designers, constructors, building owners and building occupants, through the application of qualitative and quantitative health-based criteria. From the occupant point-of-view, the ideal situation is an indoor environment that satisfies all occupants (i.e. they have no complaints) and does not unnecessarily increase the risk or severity of illness or injury. This environment is directly related to attributes as:

- *air quality*: health and comfort related to sensory, chemical and toxicological effects of compounds in the air,…
- *ventilation*: fresh air rate, re-circulation, efficiency,…
- *thermal comfort*: temperature, air velocity, humidity,…
- *noise*: noise from outside, indoors, vibrations,...
- *visual comfort*: view, illuminance, luminance ratios, reflection,…

Although there is a rich scientific literature and several national experiences on this subject, a uniform set of criteria across the European countries has not yet been defined. In PeBBu one of the objectives for the Indoor Environment domain is to deliver a state-of-the-art report on existing performance criteria for healthy buildings.

1.2 Definition

The concept of PBB and its methodology have been described in CIB-Report 64 in 1982 [1]. In the report of Foliente et al. [2] the state-of-the-art on PBB is updated. These two documents form the line of thinking that has been aimed for within the domain. In literature one can find a large amount of information on PBB and on performance criteria, but also a lot of different definitions. Foliente et al. [2] already noted that "first and foremost, a clear definition of the performance-based concept is needed and agreed on".

A definition of performance is context based. With respect to buildings, examples of contexts are the stakeholder, the building phase or a building object. E.g., with respect to the stakeholder, the user will have very different performance requirements than the contractor. The user wants to live comfortably in the building, whereas the contractor is interested in the performance of individual building objects to obey to the design plan. In the end of course everyone is interested in the total performance, in the building process this is not necessarily the case. This also means that PBB does not end with the completion of the building. Performance during the building life is considered just as important. Performance therefore is also a function of time.

With PBB the initiator does not have to deal with the indoor air temperature or the insulation thickness. He just can identify that he would like it to be comfortable under given specific conditions and/or that he wants the building to be energy efficient and healthy. In the design process then however translation rules are required to convert this subjective information into objective design rules and to define evaluation procedures. Translation and evaluation procedures are found in, e.g. legislation, rules of thumb and more sophisticated tools as modeling and case/knowledge based reasoning.

The above described definition of performance in the building process has been visualized in Figure 1. It has been compared to the non-performance approach. The performance approach part of the figure was adapted from Huovila and Leinonen [3] and originates from illustrations by the Dutch Government Building Agency. The total figure was developed and agreed on during the 1st PeBBu Domain 2 Workshop and the NAS Workshop [4].

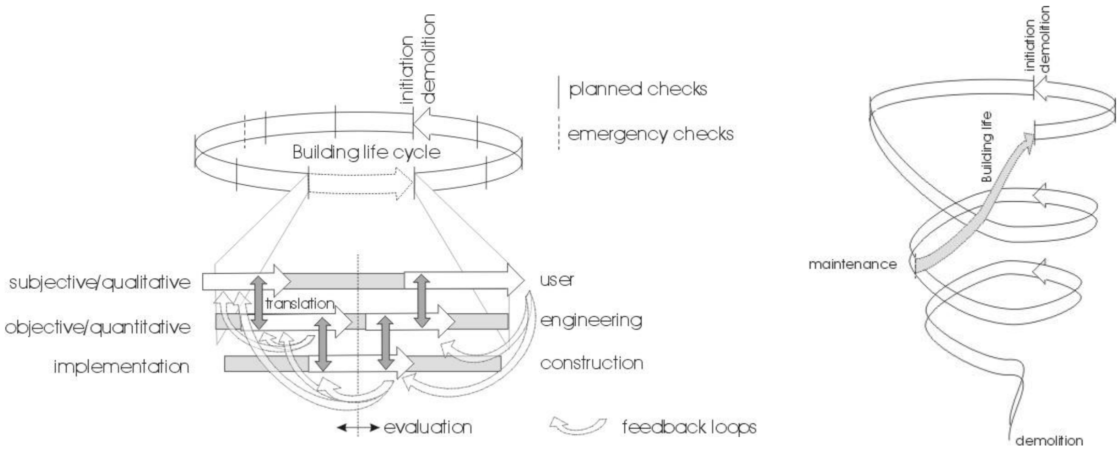

Figure 1: Performance based [left]versus a non-performance [right] approach.

The idea for the non-PBB approach is that maintenance is performed at a point of time of the building life when problems already have arisen and extra costs are required to correct the situation. With the PBB-approach the performance of the building should stay at its desired performance level throughout the building lifetime, and this is checked regularly. The zoomed out process for a specific change in the user requirements is similar for other required (performance) changes during the building life and is also the same for the initiation, design and construction of the building. Feedback loops are introduced to indicate the evaluation process that is an important part of the performance based approach.

1.3 Framework

Given the number of performance definitions and the different contexts that can be found, it is difficult to keep track on all the building performance information that is available. This also accounts for all the translation rules that can be derived. Therefore a system should be developed that allows a logical structuring of all the information related to performance based building, but also may improve the applicability of the PBB-approach. Obviously we are looking for a framework in which we can fit the PBB-approach and the available information in a logical and unambiguous way.

Several parameters should be incorporated in the framework. The most important parameter is the performance requirements that are set by the stakeholders. Furthermore, the point of time in the building process will determine the type of requirements that are set. This will be closely related to the building phases that can be identified. Finally, the actual building performance is of interest. This parameter has a close relation with the building objects.

Interrelations between the building phase and the type of stakeholder are obvious, as is the case for building objects and building phase. Each specific performance criterion therefore can be related to the individual contexts. By presenting these contexts on axes in a three-dimensional format a matrix is developed that facilitates the performance-based matrix. This approach has been derived from the work of Mallory-Hill [5] and can also be found, though in a different context, in Foliente et al. [2].

The framework is visualized in Figure 2. The matrix approach presents a database that allows filtering to come up with the specific performance requirements that relate to a specific building phase or stakeholder. It may also relate to a specific environmental attribute X or Y that is addressed differently (i.e. different target values and evaluation methods) at different points in the building process.

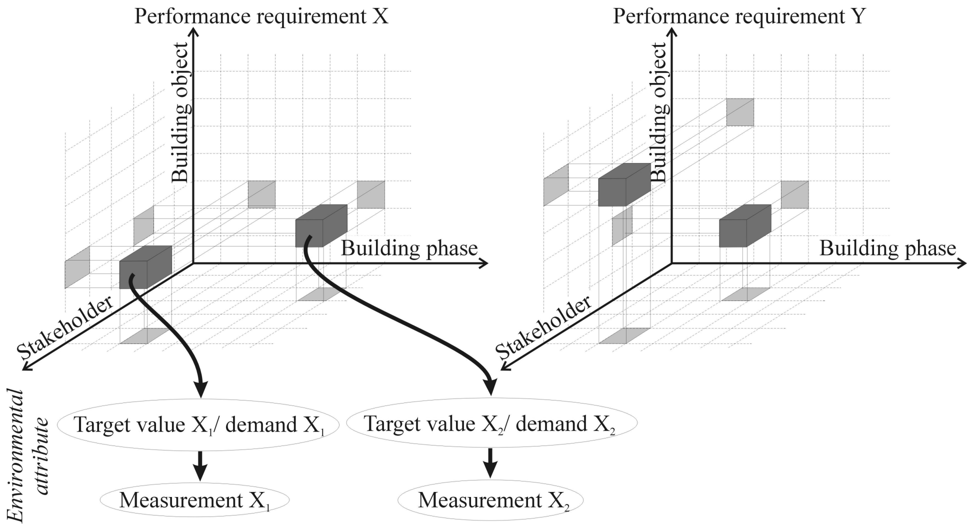

Figure 2: The Performance-Based Matrix.

2. State-of-the-Art

The above presented definition of PBB and the developed framework were required to come up with a state-of-the-art on PBB, and PBB and the Indoor Environment in particular. This state-of-the-art in the PeBBu project is derived through a literature study and a study of ongoing research in combination with input from the participants in the network. This is an ongoing process given the enormous amount of work that already has been devoted to PBB.

The intention also was to organize and categorize this information, in order to identify gaps in the PBB-information. That is why the state-of-the-art has been summarized according to the different axis of the framework in Figure 2. A database structure has been developed for this. For a categorization to the indoor environment the attributes as Air quality, Ventilation, Indoor climate, Acoustics and Lighting have been used. Assuming that the framework/database can be filled with information derived from literature and ongoing research, it eventually should be possible to identify the gaps in the matrix. These gaps should be valued and commented on and it should be determined whether they require additional research. This presents the goal of the PeBBu-project. Of course, available references may fit well in the eventual future PBB framework, e.g., as a reference to a target value or an evaluation procedure, or as a translation technique.

Summarizing the information that has been gathered from the literature research thus far, and assuming the above described context based performance approach, one can conclude that a lot of information on PBB is already available. However, most of this information deals with isolated topics and lacks the connection to the larger point-of-view. For example, with respect to materials (e.g., material emission) and some individual building objects (e.g., energy performance) the performance thinking is well established. Though differences between EU-countries are obvious, with at a first stage focus on the energy performance and in a second phase on, e.g., material emission. Furthermore, focus has mainly been put on the separate (building) phases and not on the translation between higher level performance requirements and lower level implications (see Figure 1 [left]). A general translation, beyond the traditional solutions, from subjective criteria to objective design parameters, and reverse when dealing with the evaluation, to a large part is still lacking. This hampers innovative developments, which forms one of the important drivers for the application of the performance based approach. Individual initiatives on several aspects however can be found. The coupling of these initiatives and the generalization appear to be important research areas for PBB. The Indoor Environment domain is one of the domains within PeBBu for which the translation from subjective to objective information is a key-item.

Some interesting examples of PBB and the Indoor Environment already can be found. For example, the Government Building Agency in the Netherlands presents a progressive approach with respect to the application of PBB. It builds on developments in the Dutch Building Decree [6]. The integral quality of buildings that are designed by the Agency is captured through the use of performance specifications. Indoor environmental attributes form an important part of these requirements. The performance specifications for building environmental attributes are presented in a subjective manner that fits in with the brief phase. Translation into the next phases, as visualized in Figure 1, is partly made by referring to, e.g., rules of thumb and guidelines. On the other hand for some attributes values are prescribed that restrict the freedom of design. So the trade-off between performance and prescriptive based values is still under discussion. Regulations currently restrict the unprecedented use of the performance approach in the design phase. On the other hand, the equivalence principle that is introduced in the Dutch Building Decree allows for new developments. From the literature study it appears that the Government Building Agency presents the state-of-the-art with respect to PBB as currently implemented in the actual building process. Note that this only applies to the first phases of the building process.

A different approach with regard to PBB has been developed by the Finnish Society of Indoor Air Quality and Climate (FiSIAQ). They have combined specific performance criteria in order to come up with a classification of the indoor climate [7]. The classification deals amongst others with target and design values for thermal conditions and the indoor air quality, with criteria for construction cleanliness and moisture control and criteria for material emissions and clean HVAC components. For these topics a categorization is proposed from which target values and material use are derived including general verification procedures. The classification affects the design as well as the construction phase. For the latter, categories are determined that rank the construction cleanliness. For building materials classification labels have been developed that objectively qualify a building product. In general, the highest classification for construction and building materials is required to obtain the highest classification for the indoor climate. This classification is in action in Finland since 1995 and has been developed further since then. The FiSIAQ-classification is voluntary, but currently it is a code of practice to apply this classification of the indoor climate, especially when it is used for marketing purposes. Developments in the building industry, e.g. labeling of materials and cleanliness of HVAC systems, are adapted to this procedure. The significant reduction in material emission that has been achieved through the introduction of the material label indicates the possibilities of the PB-approach.

The above two examples relate performance thinking mainly to the design and construction phase. The user phase nevertheless is just as important. This is where the ASTM Standards on whole building functionality and serviceability may be applied [8]. This evaluation procedure captures the quality, i.e. the performance, of a building by comparing the present-day requirements set by the occupant with a rating of the facility. To a large part relative objective descriptions are given to perform this comparison. This is one of the several examples of serviceability rating, as a part of the post occupancy evaluation, that are available and applied in practice.

In [4] approximately 30 other approaches that are performance-based have been categorized to the building phase(s) in which they can be applied. Such a categorization has also been made for the other axis of the framework, i.e. stakeholders and the building objects. From this categorization one can conclude that the (limited) translation between building phases as found in the approach by the Dutch Government Building Agency and FiSIAQ are relatively scarce. An important question of course is how this translation should be determined. In this respect interesting initiatives on PBB, that specifically deal with indoor environmental attributes, present possible solutions. These initiatives try, e.g., to translate complex material properties in low-level user friendly performance characteristics [9] or present design decision support in the early design phase to adhere the design to desired performance requirements [10].

With respect to health and comfort we can find several initiatives on defining performance criteria and translating them into design solutions. In the EU 5th FW Project HOPE (Health Optimisation Protocol for Energy-Efficient Buildings) a procedure has been develop to determine the health and energy performance of existing office and apartment buildings [11]. Recently also the ISIAQ-CIB TG42 Guideline on Performance Criteria of Buildings for Health and Comfort has been published [12]. In this guideline performance criteria and design information has been gathered to design healthy buildings. The guideline has been developed from the information that has become available from, amongst others, the HOPE-project and from the FiSIAQ approach as described above. These references present the state-of-the-art with respect to performance and healthy buildings.

3. Practical application

Performance-Based Building over the last two decades has found itself a basis in the building design, construction and use. The main difficulty with the term performance is that its scope has become so broad that different definitions are used. In principle the difference in definition is not problematic as they often refer to different parts of the building process. This means that the definitions for performance to a large part are context-based.

An important step in the development of PBB must be the unambiguous definition of performance in the different phases of a building life. Figure 1 visualizes the possible steps in the building life that can be distinguished (initiation-brief, design, construction, use, renovation-demolition). As indicated in the figure and in the text, in between these steps it often will be necessary to perform some kind of translation in order to deal with the performance criteria in the next step. In Table 1 the different performance definitions in the different steps are summarized. The Indoor Environment Domain of the PeBBu-project can be found in all steps (phases) of the building life and adheres to the performance context described in Table 1. This makes the indoor environment one of the more important topics in relation to performance-based building.

Table 1. Short description of the different context in which performance is used throughout the building life.

Steps	Performance context
Initiation-Brief	Functional and (qualitative) performance requirements as defined by the investor/owner.
Translation	Link qualitative requirements to quantitative (performance) criteria and define evaluation methods (e.g. conditions for evaluation) or otherwise determine other objective evaluation methods.
Design	Quantify the requirements/performance criteria either through the evaluation of the design via tools or by applying expert/knowledge-based or other objective information that enables the evaluation as agreed on.
Translation	From the design process the importance of performance requirements for the construction process and material use should be indicated, including evaluation procedures.
Construction	Evaluation of the quality of the applied materials and the built constructions during the building process as agreed on.
Translation	Evaluation procedures for whole building systems in principle should be described in the design phase.
Use	Evaluation of the quantitative performance criteria of the new building, that were derived in the design phase. They may be linked directly to the functional/qualitative performance requirements in the brief.
Translation	If the user requirements change, the building performance should be weighted to the new requirements.
Renovation – Demolition	The building performance should be checked on a regular base to identify whether the building meets the performance requirements set. Deviation may lead to a renovation plan or a new building (> Initiation-Brief).

To validate the developed framework principle (Figure 2), in relation to Table 1, the ISIAQ-CIB TG42 Guideline on Performance Criteria of Buildings for Health and Comfort [12][12][12] has been applied to fill the framework. The result of this is a database where the separate paragraphs of the report are organized towards the three axes of the framework and to the environmental attributes that are dealt with. A search on, e.g., a specific stakeholder or building phase results in the specific paragraphs that relate to those criteria. This example has been made accessible through the PeBBu Domain 2 homepage (http://www.bouw.tno.nl/pebbu).

The idea of the framework is that such a database is extended with similar information (reference or fully included) for all building phases, stakeholders and building objects, preventing overlapping and contradictory information. It should also include translation guidelines, amongst others evaluation procedures. In a further development the database may also function as a digital blueprint of the building (from initiation to demolition).

The example has shown that the principle of the framework functions. However, it is regarded crucial to apply a useful (not too large) division of the Stakeholders and Building Phases. For the

Building Object such a feasible subdivision was not established. It will require more effort to develop a general well applicable division that can be used for the framework. The search facilities as available through internet allow a quick scan of the available information.

4. Research agenda

Following the state-of-the-art the next step in the process of PeBBu is the development of a research agenda that lists developments that are regarded required to enhance the performance-based approach with respect to the indoor environment and in particular healthy building. The developed methodology and framework have been applied to set up this research agenda. Figure 3 summarizes the important topics.

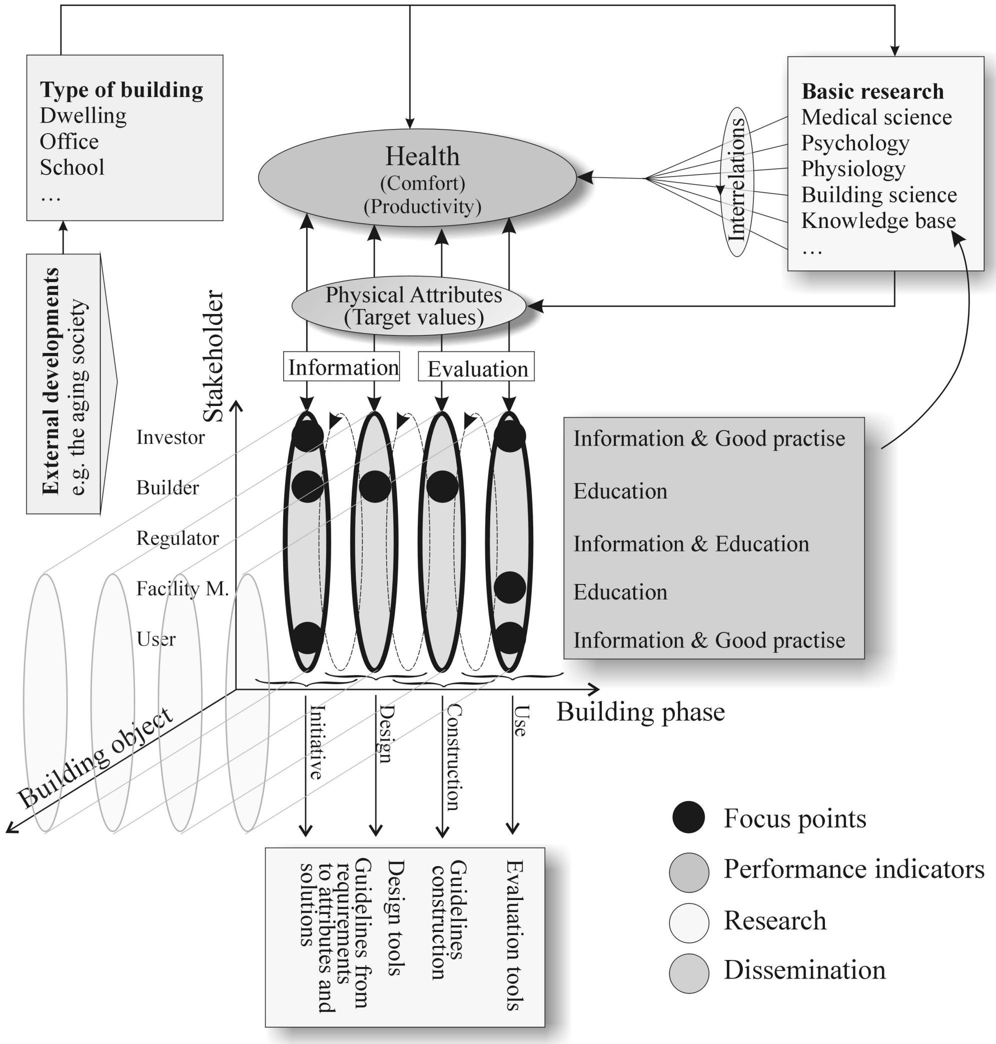

Figure 3: Research agenda for the PB approach in relation to the indoor environment.

Figure 3 has the developed framework as a base. On the axes the Stakeholder, Building phase and Building object are positioned. In the figure the focus is on the Stakeholder and Building phase. The literature study has indicated a lot of research on individual building objects and components, but it has proven to be difficult to subdivide the building in a sensible listing of building objects and components. Furthermore, developments described in the state-of-the-art at first instance are focused at whole building level or its major components. In the yellow box above the framework major research areas at basic level are shown to come to further definitions for performance indicators as health (and comfort and productivity) and to target values for (physical) attributes that relate to that. Developments are ongoing in this area, but it is noted that especially from a medical point of view a sound basis to a large part still is lacking (e.g., dose-response relations and causality). Psychology and physiology are topics that have had little attention thus far in relation to indoor environment and health. Furthermore, it is obvious that interrelations are present between psychology, physiology and exposure to the indoor environment with respect to the appreciation of that indoor environment. Building science and the knowledge base have formed the major part in developments relating to indoor environment and health. Based on the envisaged developments, the latter two will remain important research items in order to come to healthy buildings.

For the stakeholders and building phases the subdivision in overall terms is in included in the framework. The gray ellipses indicate that in every stage of the building phase all stakeholders in principle are present. However, focus points indicate the important stakeholders in each phase. The dotted (ellipse) arrows between these ellipses indicate the translation between the separate phases. The relation with the performance indicators is acknowledged in each phase, be it informative or through evaluation.

For the different building phases several research items can be identified. Most of these research items relate to the translation of information (higher level subjective to lower level objective and reverse) and to support tools for the evaluation (in the design, construction and user phase). Ongoing research at material and component level are not explicitly mentioned in the figure but can find their way via the framework.

Dissemination, an important aspect in the understanding and appreciation of the PBB approach, should take place at stakeholder level. The three most important topics for dissemination are Information, Education and Good Practise. The manner how this is presented to the respective stakeholders however will have to differ significantly. E.g., the communication to new users of a building to prevent misuse, or displaying the current health status of a building.

Finally, the gray boxes indicate that the research agenda should have the type of building as a reference and of course should adhere to developments that arise outside of the framework scope.

5. Conclusions

The results from the Thematic Network PeBBu indicate that PBB, in the Indoor Environment domain, already is being applied to some degree in the different phases of the building process. Furthermore, attention on this topic has increased significantly in recent years. However, mostly application is restricted to a single building phase or building object and little information is yet available on the translation of qualitative performance requirements to quantitative implications to the building. This hampers the further introduction of PBB in the building process.

The presented state-of-the-art includes more than a summary of existing information. The topic required more preparation as little consensus on the topic was available in literature. The PeBBu network presented a good platform to generate this consensus. Nevertheless, the topic remains complex and very extensive.

For performance requirements on health and comfort several interesting initiatives are ongoing or have recently been completed. The work in HOPE and ISIAQ-CIB TG42 are good and practical examples of that. However, a lot of work still is required before PBB can completely replace the current prescriptive building methods, if possible at all.

Acknowledgements

PeBBu is partly sponsored by the European Union in the GROWTH program. Coordinator is CIB in The Netherlands. Other main contractors are: TNO Environment and Geosciences and EGM Architects (The Netherlands),: WTCB (Belgium), CSTB (France), VTT (Finland), University of Manchester, University of Salford and BRE (United Kingdom).

Research Institute for the Built and Human Environment, University of Salford, UK

Abstract

There is growing consensus within research and industry communities that appropriate performance-based building approaches yield better performing buildings than prescriptive approaches. However, there are two schools of thought on the relationship between performance-based building approaches and innovation which are often in debilitating opposition. The 'content' school champions that performance-based building is the innovation in itself. In contrast, the 'contextual' school advocates that performance-based building provides the enabling environment to stimulate a raft of innovation activity which may include prescriptive, as well as performance-based, elements.

This paper argues that these two schools are not in conflict; indeed, there is significant value in recognizing and integrating them to form an evolutionary approach which promotes continuous development and use. A framework is offered which conceptualizes the performance-based approach as an evolutionary cycle of innovation across industry and project contexts, and between social and technical systems.

Key words: Performance-based building, innovation, evolutionary model

1. Introduction

Performance-based building (PBB) is intertwined with the present interest in, and momentum towards, performance-based building codes and standards (for example, see [6], [10], [12], [13], [17]). The key driver for this trend is the view that traditional prescriptive approaches act as a barrier to innovation. Within this context, discussion within the PeBBu Domain 8 community (http://www.pebbu.nl/maincomponents/scientificdomains/domain8/) has produced two schools of thought regarding the relationship between performance-based building and innovation. The 'content' school of thought has advocated that PBB is the innovation in itself, and that PBB approaches replace traditional prescriptive approaches with a new paradigm. In contrast, the 'context' school of thought has argued that performance-based building provides the enabling environment to stimulate a raft of innovation activity which may include prescriptive, as well as performance-based, elements. This paper argues that these two schools are not in conflict; indeed, there is significant value in recognizing and integrating them to form an evolutionary approach which promotes continuous development and use. A framework is offered which conceptualizes the performance-based approach as an evolutionary cycle of innovation across industry and project contexts, and between social and technical systems.

2. Key issues from the literature

2.1 The 'content' school: PBB as the innovation

The 'content' school advocates that PBB is *the* innovation which progresses "the practice of thinking and working in terms of ends"[14, page 4] through the creation of performance-based codes and regulations which are implemented at a project, technical system level. Averill [2, page 18], for example, emphasises the key challenge of PBB as the "quantification of the level of performance which a building material, assembly, system, component, design factor, or construction method must satisfy." The 'content' school posits PBB as a direct replacement for traditional prescriptive approaches which are viewed as acting as a barrier to innovation in that "improved and/or cheaper products may be developed, yet their use might not be allowed if construction is governed by prescriptive codes and regulations" [11, page 12].

The underpinning assumption is that this body of technical regulations and codes will stimulate a 'technical system push,' linear process of innovation, i.e. the development of PBB regulations and codes lead to a flow of new materials, components, systems and processes at a project level. Policy makers and researchers involved in the development of PBB regulations and standards commonly (if implicitly) draw upon this model to champion the need to move away from procedural, rule-centred regulation, which they view as being synonymous with prescriptive regulations which encourage minimum compliance, to a more flexible approach that allows relevant actors to move beyond compliance to sustainable innovation. Bowen and Thomas [5, page 3], for example, stress that PBB codes enable designers and contractors "the freedom to choose one of several possible means to achieve the required performance and therefore provide for flexibility and innovation."

Commentators, however, are cautioning against the unreflecting displacement of traditional, prescriptive approaches with PBB codes and regulations, and are emphasising the need for the *appropriate* use of PBB which fit the particular needs of the context in which it is being used (for example, [7], [16]). Baark [3, page 13] notes, for example, the high cost of managing risk intrinsic to novel solutions with the argument that, "considerable obstacles in pushing forward innovations related to construction projects arise from the existence and interpretation of [performance-based] building codes and regulations. When a new technology is proposed for a construction project, getting government approval turns out to be decisive …[and that] …many engineering consultants regard the efforts required to provide justifications for innovative solutions as excessive. The money and time involved in such endeavours can certainly be a discouraging factor for the engineers during their thinking process." This argument has been paired with the note that "prescriptive codes provide a simple 'cook-book' approach and, for the majority of construction projects … they provide the least costly method of ensuring an acceptable level of [performance]" [5, page 3]. The need for a more contingent approach to PBB which appreciates differing contexts and, thus, different requirements, has fuelled the claims of the 'context' school of thought detailed in the next section.

2.2 The 'context' school: PBB as an enabler of innovation

The 'context' school of thought view PBB as a guiding framework which provides a stimulating, supportive environment which encourages innovation, be it traditional, prescriptive or PBB codes and regulations, or a combination of the two, to provide buildings which "meet all the goals established by society and the client [2, page 18]. The 'context' school of thought is grounded on two key assumptions. First, it adopts a contingency premise that the PBB approach is not universally applicable to all projects in all circumstances. Rather, a contingent view of PBB is promoted which appreciates projects with different characteristics and circumstances require different mixes of PBB and / or prescriptive elements. This argument is captured in Figure 1 which suggests, on the left hand side of the diagram, that where the client system requirements are known from the start, a 'product' view of innovation is appropriate and that this is best supported by a prescriptive approach. Indicative scenarios of this position would be repeat projects with a sophisticated client and / or simple, standard performance requirements. In contrast, where there is a need for a co-evolution of requirements between the client system and the project team, as depicted on the right hand side of the diagram, a 'process' view of innovation is appropriate and best sustained through a PBB approach. Indicative scenarios would be a one-off project with an unsophisticated client and / or complex, novel performance requirements.

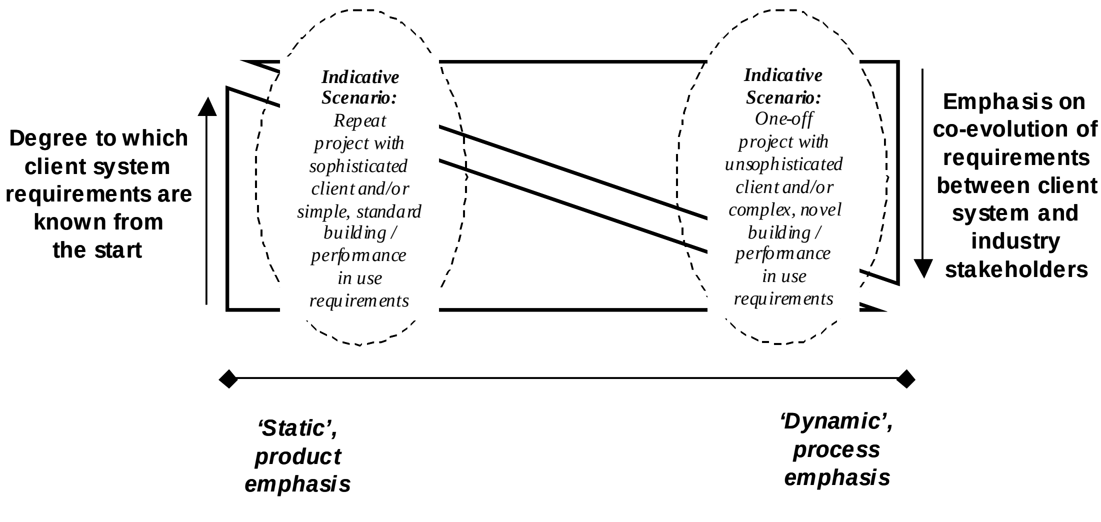

Figure 1: Product / process innovation continuum

Second, the 'context' school emphasises a social systems perspective which argues that innovation is determined by the nature and intensity of interactions, interconnectedness and synergies from a wide spectrum of agents which gravitate around a project setting. Inter-organisational networks promote and facilitate the development and exchange of knowledge and resources that are needed to encourage learning and innovation in participating companies (for example, see [4], [8], [15]). Indeed, it has been argued that the greater the number of inter-organisational networks a company is involved in, the greater the likelihood of generating and supporting successful innovation (for example, see [1]). PBB is seen as providing a discourse to shape beliefs and expectations of social system actors, and, in so doing, enable, facilitate and align activities of actors to forge a pluralist technical system made of performance-based and prescriptive elements. Adapting Edquist [9], the 'context' view of PBB has social system learning and innovation at its core through the accommodation of various ambiguities and the promotion of the diffusion of different, contingent, conceptualisations of PBB; and, as a consequence, provides a broad framework rather than formal theories of action.

3. A synthesis of the 'context' and 'content' perspectives of PBB: An evolutionary approach

The 'context' view offers the insight that PBB is a driver of innovation by providing a guiding framework which envisions and supports social interaction that stimulates context-specific configurations of prescriptive and / or performance-based elements. In apparent contrast, the 'content' perspective presents PBB as the innovation, in that it provides the technical tools and methodologies to implement performance-based approaches, and which replaces prescriptive approaches. These two views are, we argue, not contradictory, but complementary. An evolutionary model is advocated (see Figure 2) which dynamically links, consolidates and further develops the social system ('context' school) and technical system ('content' school) dimensions of PBB across industry and organisation / project contexts. The model operates as follows. First, it is accepted that PBB does not function independently, but that in order for it to be adopted and used, PBB must be part of a larger configuration of mutually attuned elements such as infrastructure, knowledge, skills, organisation, regulatory standards and cultural norms, through which the PBB approach can be handled productively by a range of actors. PBB, therefore, must be embedded within the industry context at a social system level to a degree where there is sufficient *confidence* in PBB as an approach to be considered as one of a portfolio of viable options which can be *adopted* by organisations in project contexts, and which the industry wide knowledge (in the form of 'good practice', codes and regulations) can be *developed* at a technical system level.

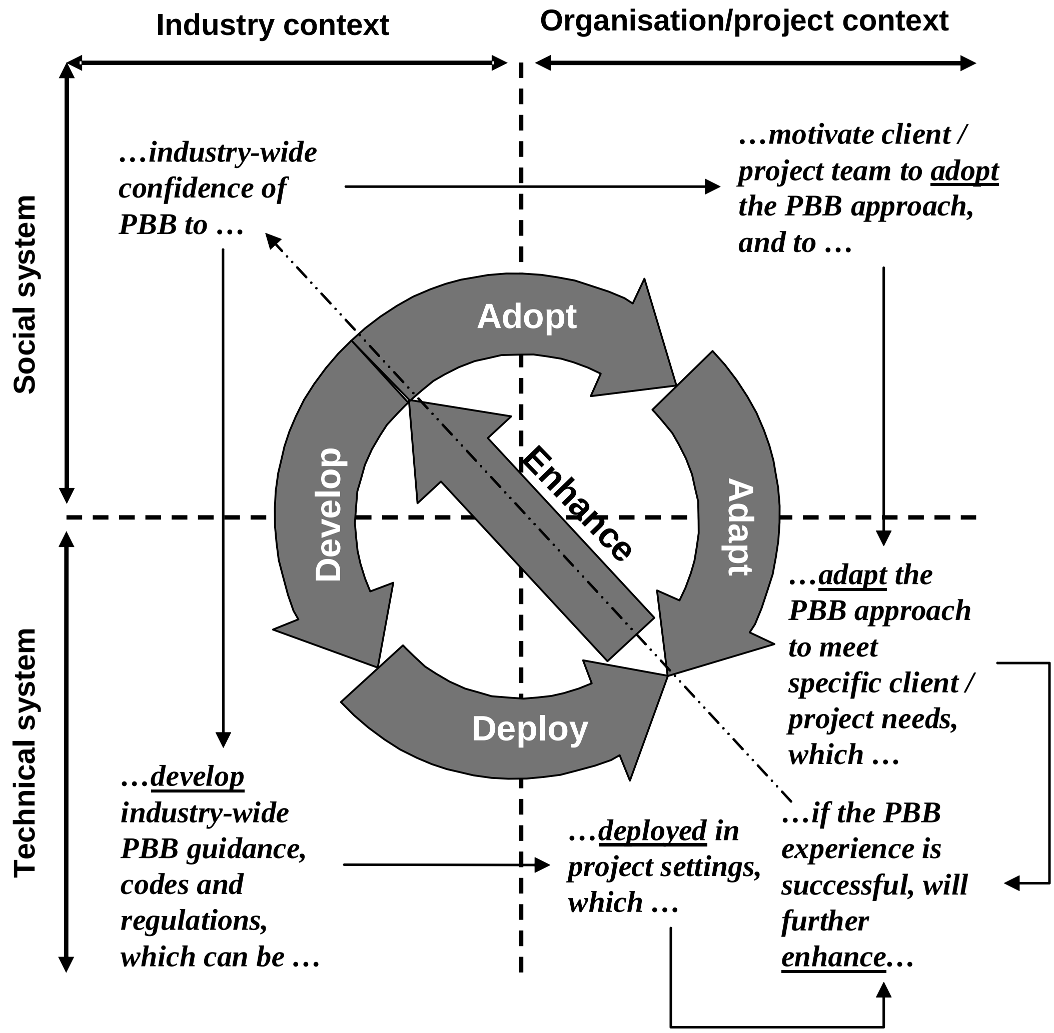

Figure 2: An evolutionary model of performance-based building

The network of organisations within a project context, having the confidence and *motivation* to adopt the PBB approach within a project context, then *adapt* it to meet the particular characteristics and needs of the project. The adoption and adaptation process is a sense making and negotiation process between the project participants at a social system level, before the resultant PBB approach is implemented at a technical system level. This process will involve the *deployment* of appropriate knowledge from the industry context, technical system repository. Finally, if the PBB experience is fruitful at a project level, the confidence and learning will feed back to the industry context social level to further *enhance* the motivation to consider PBB as a viable option in future projects, and to further development the industry context technical system. The cycle above is depicted as a positive one; however, the cycle might be negative, in that if the experience of PBB within a project setting is negative, the feedback to the industry system social context will undermine the motivation to further consolidate and develop PBB as a viable option.

4. Conclusions

The focus of this paper is to delineate two schools of thought on the relationship between performance-based building and innovation. The 'content' school which champions that performance-based building is the innovation in itself. In contrast, the 'contextual' school advocates that performance-based building provides the enabling environment to stimulate a raft of innovation activity which may include prescriptive, as well as performance-based elements.

This paper has argued that these two schools are not in conflict; and there is significant value in recognising and integrating them to form an evolutionary approach which promotes continuous development and use. A framework has been offered which conceptualises the performance-based approach as an evolutionary cycle of innovation across industry and project contexts, and between social and technical systems.

Performance-based Design: bringing Vitruvius up to date

Dik Spekkink
EGM architecten / Spekkink C&R (e-mail: d.spekkink@spekkink.nl)
Dordrecht / Woudrichem, the Netherlands

Abstract

A performance-based design (PBD) is a building design that is based on a set of dedicated performance requirements and that can be evaluated on the basis of solution independent performance indicators. The performance-based design approach is a means to enhance the professionalism and the client orientation of the building design sector. It is aimed at satisfying the real client needs ('answering the question behind the question') and leaves the design process open for creative and innovative solutions. The performance-based approach makes 'integral design', with parallel, interrelated contributions from all design disciplines imperative. Although PBD has been put to practice in many countries to some extend, design practitioners appear to be hardly aware of it. Actions need to be undertaken to enhance the awareness of PBD. Performance based building regulations have proven to be a key success factor in the implementation of PBD and governmental clients should take the lead in further implementation.

Keywords: Performance-based design, client orientation, performance requirements, design process, design assessment

1. Performance-based Design

1.1 Backgrounds: scope and objectives

'Design of Buildings' is one of the scientific domains (Domain 3) of the Thematic Network Programme 'Performance-based Building' (PeBBu), that is funded by the European Union. Since the start of the PeBBu Programme in 2001 some 40 experts from 18 countries participated in the domain work.

The scope that has been chosen for PeBBu Domain 3 is strongly related to the notion that the 'end user' of built facilities becomes more and more important in the building process. A strong incentive for performance-based design derives from this 'emancipation of the end user'. 'The' end user demands quality from his own perspective. During the last few years it has become more and more clear that it is an economic necessity for the building industry to act more consumer oriented and to pay more attention to meeting with user requirements. As a result and in the field of performance-based building, a certain shift from a primary focus on performance specifications for building parts to a mix of this 'hard' perspective and a more 'soft', holistic perspective of performance-based building can be seen. In the latter perspective the focus is e.g. on the management of functional user requirements and user involvement during the design process and beyond. Which is basically a shift from solving an internal problem of the building industry to solving the end users' problem.

Performance-based Design (PBD) is considered to be of strategic importance for achieving the overall PeBBu objectives, especially because a building design determines to a large extend, intended or unintended, what the performance of the building in use will be. In this respect two aspects are of crucial importance in the design stage:

- making sure that the right users' performance requirements are considered;
- the prediction of the building performance on the basis of (preliminary) design results, in other words the assessment of the design.

This leads to the following issues that are addressed in the Domain's work:

- the translation of client and user needs into assessable performance specifications (or: the matching of user requirements and performance specifications of built assets);
- classifications and formats for performance requirements and specifications;
- the management of client and user involvement in the design process;
- assessment methods for design results.

The objective of the Domain 3 work is to clearly define these issues, give a comprehensive state-of-the-art overview and, from that, give recommendations for future research in these fields. A second objective is to develop modules for programmes that aim for the education and training of design professionals. These modules will be aimed primarily on enlarging the awareness of Performance-based design.

The essential role of Domain 3 within PeBBu is about the integration of knowledge and systems from other PeBBu domains in the context of real building designs. The building design is where it all comes together. More information can be found in the Third Domain 3 State of the Art report "Bringing Vitruvius up to date", that is published on the PeBBu website (www.pebbu.nl) [1].

1.2 Performance-based Design defined

Performance-based building is concerned with orientating activities around the performance in-use of built environment products and services and extending this approach as far back along the supply chain as is appropriate. PBB is about what a building should do for the client, the users and other stakeholders, rather than about how the building should be constructed. Thus, stakeholder requirements, together with legislative building regulations, are very important in the context of Performance Based Design. Performance requirements should express the real user needs behind the question for a built product. Following this principle a Performance-based design can be defined as follows:

– A Performance-based design is a building design that is based on a set of dedicated performance requirements and that can be evaluated on the basis of performance indicators.

However, Domain 3 'Design of Buildings' is not only about the result of a design process, but also and primarily with that process itself. A Performance-based design process can be defined as follows:

– A Performance-based design process is a process in which performance requirements are translated and integrated into a building design.

2. State of the art of Performance-based Design

2.1 PBD in general

The Domain 3 inventory of the state of the art shows that PDB is mainly an issue in research and education as yet. Design professionals (architects and engineers) are generally not very aware of PBD. In this respect a distinction should be made between two different approaches to PDB*:*

– designers and engineers have to meet with performance based client briefs and building regulations;

– designers define their work in a functional design plus a set of performance criteria, rather than work out the design traditionally in technical drawings and specifications.

The first approach can be recognised in most building projects in countries that apply performance based building regulations, mostly countries in the northern part of Europe. Applicants for building permits have to prove that the designs comply with the regulations, so every design professional is involved in PDB to some extend, consciously or unconsciously. Performance based building regulations and codes often include performance requirements for safety (structural safety, fire safety, earth quake resistance and so on), health, serviceability, energy efficiency and environmental impact.

The second approach is closely related to performance based procurement. Up to now, this approach has only been put to practice on a relatively small scale, mainly in the same northern countries. Mostly government building agencies take the lead; they organize pilot projects and/or experiments to set an example for innovation of the building process. The general idea is that the 'demand side' of the building process defines a functional design and a set or performance requirements, allowing the supply side to choose the most suitable technical solutions matching these requirements, availability and cost. This second approach to PBD has hardly been put into practice in non governmental projects as yet. One of the barriers is that clients, apart from a few very professional clients, do not trust this kind of procurement, that they experience as rather abstract and intangible and therefore too unsure and risky. They often prefer to be able to control the whole design and building process.

In general engineers and technical designers are more used to working with performance requirements than architects. The main design areas where performance based design and procurement is applied, are service engineering (acoustics, lighting conditions, indoor climate, air quality, and so on), energy consumption and maintenance.

2.2 Translation of client and user needs into assessable performance specifications

Interesting methods for the matching of client and user needs and performance specifications can be found in e.g. the Netherlands and Canada. The Dutch Government Building Agency (GBA) e.g. is developing a computer aided interview technique for (future) users of office buildings. Dependent on the combination of answers that are given to predefined questions ('question tree'), the computer generates a set of specialist performance requirements. The system is based on fifteen years of experience with the performance based briefing and procurement.

In Canada the International Centre for Facilities (ICF) developed the 'ST&M-approach' ('Serviceability Tools & Methods') [2]. The method comprises a set of standard tools for measuring in broad terms what is needed and what is provided; it compares what functionality the occupant groups require and how well assets support those needs. Scales are used, giving a range of standard levels, so that stakeholders can choose how much of each topic is needed. For every topic there are two scales. The first is a functionality requirement scale giving levels of functionality from 0 to 9 (demand). The second is a serviceability scale for assets, also ranging from 0 to 9 (supply). Each couple of scales is calibrated. There are scales for some 200 topics. This is probably the most elaborated and easy to use example of how performances specifications can be matched with user requirements (and the other way around).

In many countries client briefs are usually solution oriented. They often contain technical and space solutions, that belong to the domain of the building industry. These are hard for clients and end users to understand, because they are not involved in that domain. Research by VTT in Finland shows that performance based briefs turn out to be easier for the end users to understand, because they appeal more to the end users' own domains and processes. Moreover, performance based requirements in briefs give designers possibilities to fully exploit their knowledge accomplishing creative and flexible solutions.

2.3 Classifications and formats for performance specifications

A survey of material from only a few countries already shows a wide variety of 'classifications' that are used for arranging performance specifications in briefing methods. Even on a national level several different classification methods are encountered. There is a clear need for a generic conceptual framework for performance based design and building and a common set of basic definitions.

2.4 The management of client and user involvement throughout the design process

As this is quite a new topic, there is little information available about the state of the art in this field. The best examples probably come from project developers who open project websites, allowing future users to follow the process online. Several developers offer future users the opportunity to give input and choose from options in the course of the process. These project developers experience that, when they offer these opportunities, the processes have to be very transparent; it has to be very clear for all parties involved until which moments which decisions may be postponed, in order to prevent frustration of the process and extra costs. Several market parties in Western European countries struggle with this. In general we may conclude that the building industry is not a very user oriented industry.

In several countries we see large scale programmes aimed at structural changes in the building industry. Examples are ‘Rethinking Construction’ in the UK and the ‘Process and Systems Innovation Programme for the Building Industry’ (PSIB) in the Netherlands. One of the common goals is to change construction into a more consumer oriented industry. Further development of the performance concept may contribute to that, as this concept is user oriented by nature.

2.5 Assessing design results

Too often the requirements are not met in the final product. There are various reasons for this: cutting costs in some phase of the project, inability to find suitable design solutions to fulfil the requirements, forgetting the original requirements, and so on. To avoid this, an early and continuous verification has to take place in the design process (Ang et. al, 2001 [3], Becker 1999). The user has to be sure that the desired performance targets will be fulfilled. And if this is not possible, the user has to know this on beforehand.

Assessment methods may vary from simple measuring (e.g. the amount of net square meters offered) via standardized calculating (e.g. the strength and stability of building structures or the energy loss) to simulating certain aspects of the behaviour of the building in-use (e.g. daylight penetration in different seasons and under different weather conditions). In some EU member states national building regulations are more and more performance-based. Also European regulations, that have to be implemented in the national building regulations of all EU member states, are as a rule performance-based. Very well known of course is the Construction Products Directive (CPD). Performance-based regulations often refer to national standards, where not only performance levels for building parts and properties, but also the corresponding assessment methods are defined.

Assessment methods in European and national standards are mostly aimed at the testing of actual buildings or building products. However, one of the main problems in PBD is how to predict the performance of a building on the basis of a design. For many quality aspects the 'total building performance' depends on a complex interaction of many influences. On the one hand there are no validated, standardized assessment methods available to predict the total building performance, but on the other hand this performance will determine the client's perception of the quality delivered to a great extend. The only way to do it is by simulation of the building behaviour, using integrated data models. All over the world institutes and universities are in the process of developing simulation applications to facilitate this, using modern information and communication technology (ICT).

2.6 Barriers

According to the members of Domain 3 the main barriers for further development and implementation of PBD are the traditional culture of the building process, the suspicion of design and engineering professionals that PBD will further undermine the design profession and the conviction of design professionals that the responsibility for the technical design cannot be separated from the responsibility for the functional and architectural design (which is the case in performance based procurement). Also many architects believe that the most important quality aspects of buildings cannot possibly be translated into performance specifications.

Other drawbacks that have been mentioned are the segregation and fragmentation of design, engineering and construction, the uncertainty about risk and liability, the (lack of) professionalism of clients, lack of experience. Moreover, during the economical boost of the last ten years, there was little incentive to change. Maybe today, while the whole European building industry suffers from an economic crisis, there is more readiness for innovation.

3. Ten reasons for Performance-based Design

PBD is not a goal in itself, it is a means to reach the 'higher' goal of creating more added value for the client, the end user and other stakeholders. The performance-based approach requires a different attitude, a different way of thinking about designing buildings than in the traditional design process. Implementing the performance-based approach in the design process requires a change of culture. Experience teaches that cultural changes do not occur overnight; it takes a lot of effort and a lot of time. Design professionals will have to be convinced. Many of them seem to consider PDB as a (further) degradation of their positions and interests in the building process. The Domain 3 members thought of ten reasons that make it worthwhile for design professionals to put effort into the performance-based approach.

1 PBD provides for a more client oriented way of thinking and working in the design process. The performance-based approach is basically a client orientated way of thinking and working, especially in the design process.

2 Performance-based thinking helps clients and designers to gain better knowledge about how a building operates or should operate. As performance-based building primarily has to do with what a building should do for the owners and users, it enhances the awareness of how a building-in-use operates or should operate.

3 PBD leads to cost effectiveness, better quality and better client and user satisfaction. Quality, in client oriented way of working, can be defined as the extend to which a product or service meets with the client's and end users' needs, wishes and expectations. Performance requirements intend to express clients' and users' needs explicitly. A performance-based approach in design offers better conditions for meeting with those needs and – as a result - for better quality and better client and user satisfaction.

4 European and national building regulations are more and more performance-based (as opposed to prescriptive codes). Designers will have to prove that their design solutions meet with the legislative requirements. Therefore it is imperative that design professionals adopt the performance-based way of thinking and working.

5 PBD prevents designers from tumbling into solutions from the very beginning without proper understanding of the real client and user needs. In practice designers often start to develop solutions immediately. Also owner and user requirements in briefs often seem to be recipes for solutions, rather than descriptions of the performance of the building in-use. This may obscure the real needs behind the owner and user requirements. Moreover it may rule out unexpected creative, innovative and/or cost effective solutions on beforehand. PBD stimulates thinking about 'the question behind the question' before jumping to conclusions.

6 PBD provides architects with the tools to be the integrator in the design process. Vitruvius already stated ten centuries ago, that architecture is the fusion of functionality, solidity and beauty. With this definition, Vitruvius made a strong plea for integral design. PBD is also all about integral design. Someone has to do the integration of contributions of all parties involved and the architect is best positioned for that. In many countries the architect lost his integrating role in the building process, because he was not able to cope with all the technical systems. The PBD concept provides him with the tools to be the integrator again. It's like bringing Vitruvius up to date in a modern setting.

7 PBD offers better conditions for creativity and for generating added value. As performance-based building codes and requirements allow designers to come up with a variety of solutions, the performance-based approach will enhance creativity and innovation in the design and building process, with more added value for clients and end users as a result.

8 PBD offers the opportunity to make better use of knowledge and expertise of contractors and suppliers, allowing them to come up with innovative, cost effective solutions. Multitudes of building concepts, techniques and products are available for the building industry and more are added every day. It is impossible for designers to have knowledge of all available concepts, techniques, products and new developments. Contractors (and suppliers) often have better knowledge of the market, but also they cannot possibly have mastery of all available concepts and techniques. They have to specialize. But when they are confronted with building designs that are specified in detail, they will often not be able to use their own specializations. When architects and other designers refrain from giving detailed prescriptive specifications

for every building part and complete the functional and aesthetic design with a set of performance specifications for building parts instead, allowing contractors to use their own techniques and market knowledge, that might lead to cost effective solutions, better quality and more value for money for the owners and users.

9 PBD helps to fill in the building industry's responsibility for the environment. Future generations have the right to live in a healthy and sound environment. Legislation in this field is mainly performance-based, leaving the responsibility for how to meet with the legal requirements to the designers to a great extend.

10 PBD is common practice to some extend already. In practice most designers already are involved in PBD to some extend, consciously or unconsciously, e.g. in relation to meeting with energy consumption and other environmental requirements. So to most designers PBD is not a completely new concept. Besides that it's important to understand that total systems of performance-based building or design do not exist. PBD can be applied in a more or less extensive form, depending on the circumstances of a project. This means that designers do not need to change their 'normal' way of working from one day to another in order to implement PBD.

4. Performance approach in the design process

The performance of a building or a building part is always the result of the interaction between different solutions for different subsystems, like the architectural system, the structural system, the climate system and so on. This is depicted in diagram 1.

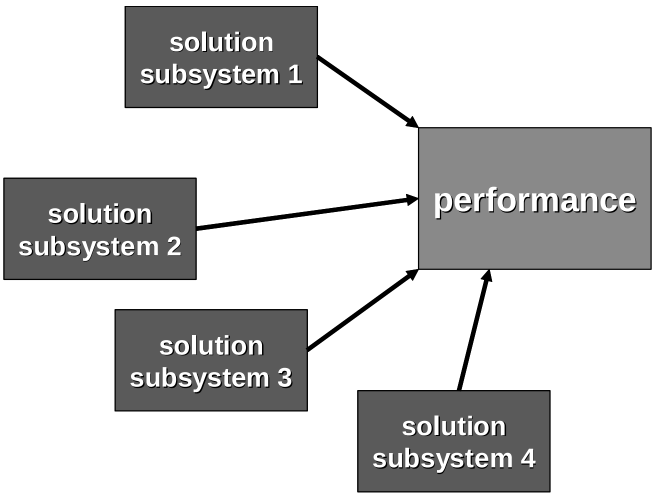

Figure 1: 'Performance' as the result of different solutions for different subsystems.

Designers have to deal with systematic interrelations between different performance specifications, which often relate to different fields of expertise. Thus, the performance-based approach calls for integral design, with parallel, interrelated contributions from all design disciplines involved. The end user is probably not really interested in the performances of different subsystems; he experiences the performance of a built facility as a whole. The design disciplines will have to co-operate closely to create an integrated facility design. In some aspects also the expertise of the contractor and specialized subcontractors is needed to get optimal performance.

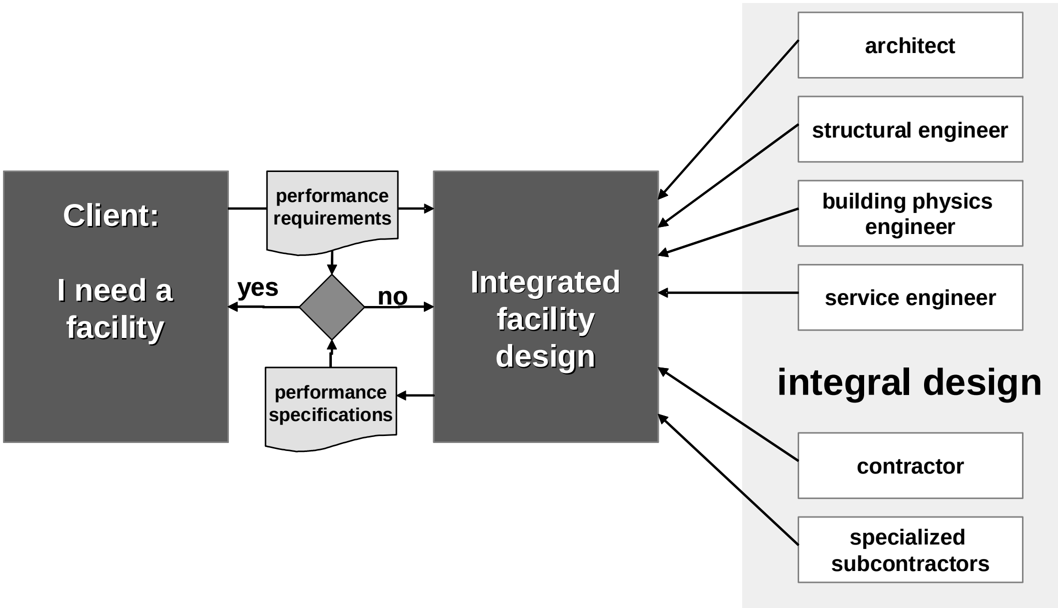

Figure 2: Performance-based Design calls for an integral design approach

As the Performance-based approach is the practice of thinking and working in terms of ends rather than means, it provides for openness to the infill of the design process. It provides suppliers (both designers and contractors) with the opportunity to come up with creative solutions. Therefore, in principle as many requirements as possible should be performance-based and measurable. Requirements and solutions (prescriptive specifications) should be mixed up as little as possible, as solutions will essentially always be compromises.

However, some essential aspects of design, such as architectural and cultural value, cannot be expressed in ‘hard’ measurable performance requirements. Nevertheless these aspects may be quite an important component in a stakeholder’s general appreciation of a built asset. This means that also in a performance-based design process, these aspects should be fully taken into account. Also a client should be free to choose a specific solution or product, if he really wants that. In other words: in practice it will be unwise to be too fundamental in following a performance-based design approach; a design process will always be hybrid to some extend.

It appears to be a world wide trend that clients and future users demand more involvement and influence in the building process as a whole and in the design process in particular. E.g. modern ICT provides them with the tools, like internet and virtual reality, that enable them to participate actively in the process. Moreover, it becomes more and more clear that it is an illusion to think that the design process can start with a complete and unchangeable client's brief. Also for the clients and users the design process is a voyage of discovery and they expect the designers to facilitate that voyage. The question is how to do that and at the same time improve the efficiency and manageability of the design process.

Already in 1992 the Dutch Building Research Institute (SBR) issued a report about a new system of briefing that allows clients to develop the brief in interaction with the design [4]. This should be done in a controlled process, in which briefing and designing are, though parallel, separate processes. According to this system, after each formally concluded design stage the brief should be updated and further completed with the information that is necessary for decision making in the next design stage. This process is depicted in figure 3 (‘ass.’ means assessment).

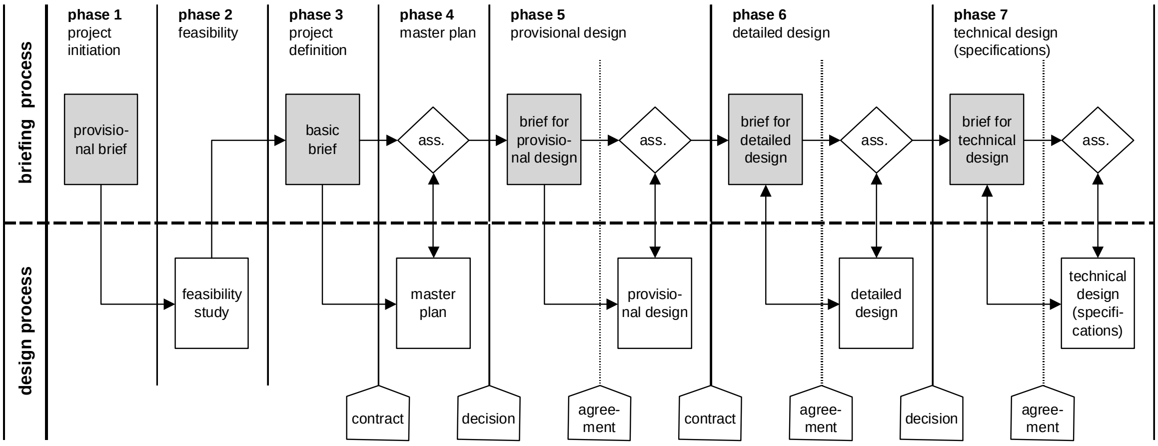

Figure 3: overlapping of the briefing process and the design process (source: SBR publication nr. 258, Rotterdam, 1992)

The principle is taken over by the Royal Institute of Dutch Architects (BNA) and the Dutch Association of consulting Engineers (ONRI), who recently issued a common ‘Standard Task Description’ (STD) for designing buildings in 2004 [1]. This STD [5] is basically a breakdown of the design process into interrelated tasks per phase for all disciplines involved (commissioning, architecture, building physics, interior design, structural engineering, service engineering, landscape design, project management). In this system, that will be the basis in the Netherlands for contracts between clients on the one side and architects and consulting engineers on the other, each new design phase starts with an evaluation, update and further elaboration of the brief. The STD has also been developed to facilitate integral design. Members of BNA and ONRI sensed that there is a growing demand for this among their clients.

5. Conclusions

Design practitioners are hardly aware of Performance-based Design (PBD) as yet, although many of them are involved in PBD to some extend already. The performance-based design

[1] Similar developments can be found in e.g. Norway, Sweden, Germany and New Zealand

approach has already been applied in different cases and countries, but not necessarily under that name. PBD is a means to enhance the professionalism and the client orientation of the building design sector. The time seems ripe for it, as there is a growing demand for integral design. In some countries tools for integral design are developed by associations of architects and consulting engineers. PBD calls for integral design.

It seems appropriate that actions should be started to enlarge the awareness of Performance-based design. In this respect the participant in PeBBu Domain 3 came up with the following suggestions:

- make existing projects or designs, in which the performance-based approach has already been implemented to some extend, more explicit (‘best practices’);
- government leadership in the implementation of PBD can be a powerful stimulus;
- incorporate the performance approach in design education;
- enhancement of “total building performance” in a life cycle environment (long term performance);
- performance based building regulations have proven to be a key success factor in the implementation of a performance-based way of thinking in building design;
- mutual recognition of performance assessment methods through standardization.

CSIRO – Manufacturing & Infrastructure Technology, Melbourne, Australia

Abstract

This paper presents background development, an overview of programs, activities and accomplishments to date, and possible opportunities/challenges for further development of the Performance Based Building (PeBBu) Networks in Australia and East Asia. The primary goal in these efforts/activities is to effectively engage the key stakeholders that can help hasten and broaden the adoption of the performance concept in practice.

Keywords: Performance approach, performance based building, innovation, trade, stakeholder engagement

1. Performance Based Building

Performance Based Building is an approach to building-related processes, products and services that is concerned predominantly with the required outcomes (the 'end') and not with how these outcomes are achieved (the 'means'). This is in contrast to the traditional prescriptive approach, which tends to focus on specifying the method or solution for achieving the required outcomes.

Process requirements would include time, cost, profits, health and safety, and other process outcome indicators. The attribute requirements for product – which can be the whole building or any of its individual components – would include safety, health and amenity, maintainability, sustainability, etc. Service requirements involve requirements to support the users or businesses of the built facility during the occupancy stage (i.e. includes all facility management functions).

Performance based building:

- encourages better understanding and communication of client/user requirements, thereby reducing opportunities for disputes and producing delighted customers;

- allows the building practitioner considerable flexibility with regard to design solutions – encouraging innovation and providing the opportunity for cost-optimised solutions;
- facilitates international trade.

2. The PeBBu Networks

In order to progress the technical developments in, and the practical implementation of, performance based building, the CIB Board and Program Committee initiated the Proactive Program on Performance Based Building in the 1998-2001 triennium (Foliente 2000). Then with funding from the European Union (EU) Fifth Framework Programme, this was followed by the establishment of the Performance Based Building (PeBBu) Thematic Network, running from October 2001 to September 2005 (see www.pebbu.nl).

In 2003, the Australian Performance Based Building (Aus-PeBBu) Network was established to promote the performance approach in Australia (see www.auspebbu.org) and to facilitate linkages and exchange of information with the EU-PeBBu Network.

In 2005, an informal network of agencies or organisations in countries in the Asia-Pacific region formed Asia-Pacific PeBBu.

3. Aus-PeBBu

The network of Australian researchers and industry representatives who constitute Aus-PeBBu are not only participating in the meetings and activities of the European Union-funded (EU) PeBBu network, but also running activities (working groups, industry seminar/workshops and a project web-site) aimed at promoting performance based building in Australia.

The main developmental activity in the Aus-PeBBu network is incorporated into seven technical domains or working groups:

1. Building Materials and Components
2. Indoor Environment
3. Building Design and Engineering
4. Sustainable Built Environment
5. Innovation

6. Legal and Procurement Matters
7. Building Regulations and Standards

With one exception, these scientific domains match those in EU-PeBBu, to provide one-to-one correspondence of efforts and to maximise opportunity for participants in both networks to discuss similar topics and issues and to cooperate on matters of mutual interest.

The main difference in the program is the inclusion in Aus-PeBBu of a domain “Sustainable Built Environment”. With significant national and international interest, initiatives and investments in sustainable development, this is a timely topic.

With less funding and much smaller scope than the EU programme, Aus-PeBBu has a relatively stronger focus on facilitating the proactive application of the performance approach through best practice project delivery processes, instead of building regulation. The Building Code of Australia (BCA) had adopted the performance concept in the mid-1990’s (see www.abcb.gov.au). Australia’s experience in performance-based code development and implementation is very extensive, and shared with the members of the Inter-jurisdictional Regulatory Collaboration Committee (IRCC); IRCC is an unaffiliated committee of ten of the leading building regulatory agencies from eight countries (see www.ircc.gov.au/).

4. Asia-Pacific Network

Aus-PeBBu has now extended its informal network to East Asia, with counterparts in Japan, Singapore, Hong Kong, China, Thailand, Vietnam, Philippines and Indonesia at this time. The participation of the developing countries in the region is partially funded by the Australian Government under its Asia Pacific Economic Cooperation (APEC) Support Program.

The informal Asia Pacific network has as its primary goal the sharing of information, experience, expertise and efforts to promote the practical and effective implementation of the performance approach in building and construction in the Asia-Pacific region and in individual participating countries. Like Aus-PeBBu, there is strong focus on stakeholder engagement. Unlike Aus-PeBBu, we anticipate a greater focus on applications of the performance concept on building code and regulations and in product assessment, appraisal and evaluation (e.g. for trade purposes).

5. Common Issues & Objectives

The main factors that hinder widespread adoption and implementation of the performance concept can be grouped into technical and non-technical issues. Some of the lessons learned in running the

EU-PeBBu and the Aus-PeBBu Networks have been discussed by Bakens et al. (2005). An innovative technology diffusion strategy based on the “tipping point” principle, as applied in the construction industry by Foliente and Boxhall (2002).

Technical challenges have been identified by Becker (1999) and Foliente (2000). In this regard, the two Networks aim to contribute to the following areas of long-term technical development:

- Establishment of a whole-of-life performance framework (including performance indicators and criteria);
- Development of a guide on methods of establishing/setting performance;
- Expansion and maintenance of the database compendium of performance tools or methods that can be used to achieve targets (e.g. during design), and to assess/verify/evaluate performance in-service; and
- Establishment or development of a best-practice compendium of benefits of the performance approach based on actual/real projects (collected from each country).

In the Asia-Pacific Network, this will be facilitated by network members coming together for a series of annual seminar/workshops in different member countries over an initial 4-year period. It is anticipated that the network will be self-sustaining after this time.

6. Conclusion

From the CIB international membership and Europe, the performance based building networks continue to expand – first in Australia and now in Asia-Pacific. Mechanisms for a 2-way information flow from one network to another are implicitly in place. If managed properly – e.g. critical information and lessons from one network are passed on to another, people from one network get involved in another, etc – there is a potential for: (a) wider adoption of the performance concept in building regulations, procurement, delivery and management, and (b) greater opportunities for innovation and enhanced trade.

PeBBu has now extended its informal network to East Asia, with counterparts in Japan, Singapore, Hong Kong, China, Thailand, Vietnam, Philippines and Indonesia at this time. The participation of the developing countries in the region is partially funded by the Australian Government under its Asia Pacific Economic Cooperation (APEC) Support Program.

Performance Based Building Framework and Tools

A comparison of international classifications for performance requirements and building performance categories used in evaluation methods

Abstract

User requirements, building performance, performance indicators and building performance evaluation (BPE) methods are being discussed, developed and applied in various countries. There seems to be little consensus however, as to which building performance evaluation criteria and methodologies might best apply in which situations. By a comparative analysis of the methodological similarities and differences between the aspects and topics addressed in the "ASTM Standards on Whole Building Functionality and Serviceability", the NOPA (New Office Promotion association of Japan) Minimum Standard in Japan, the BPE tools and methods applied in Europe, this paper illustrates the various approaches to user requirements and building performance evaluation, as well as how user requirements are defined, which performance criteria are described, which indicators of capability are included, which measurement tools are used, and how the requirements of the stakeholders and the performance of the facility are compared. The paper concludes with a comment that in a global market, there is a growing need to build on these different approaches to create a more comprehensive standardized and universal methodology to state requirements, describe and choose performance indicators, and compare the two in order to verify that the building product or service performs as required.

Keywords: assessment; building information model: evaluation criteria; functionality; performance approach; performance indicators; quality; serviceability; suitability; sustainability; tools; user requirements

1. Initial positions and objective

The main drivers that are leading to the development of a Performance approach in building have already been often described. Knowledge of the current discussions about the performance concept as applied to building (PBB) will be assumed here ([1],[2],[3],[4]). How the

Performance approach applies both to the regulatory and non-regulatory context has been discussed through the contributions of both individual scientists and work groups (including CIB TG 11[1], W060[2] and PeBBu[3]) ([5],[6],[7],[8],[9]). There is agreement meanwhile that the use of a Performance-based approach in the building industry encourages innovations, allows for more open competition, promotes transparent procurement, and supports cost-effective building. As a result, several countries (e.g. Australia, Canada, Great Britain, New Zealand, Spain, The Netherlands, etc.) have decided to integrate Performance-based regulations in their building codes and to modify codes towards a Performance or Objective-based approach.

The Performance approach has originally been primarily concerned with improving the project delivery process for new construction. Early on, the focus was on how requirements of both occupying and non-occupying users in respect to “technical, physiological, psychological and sociological aspects”, as Gibson [10] puts it, could be achieved as might be “discussed and agreed between a client and a design team” based on a functional brief (program). Furthermore, until the early 1980s, performance standards considered primarily parts of buildings, building products, materials and components [10]. As such, until then, only marginal attention within the performance approach was given to requirements beyond the functionality during use of the physical elements of a building, suggesting that the performance approach was focused and applied *in a narrow sense* with an emphasis on the technical functions of the parts rather than the whole. In 1982, ASTM set up a different kind of sub-committee focused on the performance of whole buildings and facilities[4]. By 1995, ASTM approved the first set of standards that addressed the functionality and serviceability of whole buildings from the end user perspective.[11][12] This set of standards is based on a method and tools created by a team led by contributing authors Davis and Szigeti. Davis and Szigeti developed a method [13] for describing the functionality requirements of the users (demand), evaluating the serviceability of whole buildings and facilities (supply), and comparing the two using calibrated scales[5]. These scales include a combination of functional elements on the demand side, and a combination of physical features on the supply side. This method is currently being standardized internationally (ISO TC 59/SC14/WG10) and adapted to the needs of other countries such as France [14].

In continuing and increasingly intense scientific discussions, in part in the context of the EU funded PeBBu project [5], the Inter-jurisdictional Regulatory Collaboration Committee (IRCC), the International Council for Research and Innovation in Building and Construction (CIB) W60 and TG37, and the International Building Performance Evaluation (IBPE) Network [15], it is possible to identify a trend that is moving toward a clearly broader way of looking at building performance over the “Whole Facility Management Cycle” [10]. Other terms heard in discussions such as *total building performance, whole life performance, overall performance* or *integrated building performance* demonstrate that an expansion of the contents of the application area is currently taking place, similarly to an understanding that the project delivery phase is only a small part of the whole life cycle of a facility. These types of developments indicate that the concept of building performance is being applied more broadly which is defined by the authors as the *performance approach in a broader sense*. In addition to many other scientists and work groups, Luetzkendorf and Speer have also been concerned with the broader application of a performance approach. They build on the work of Davis and Szigeti

[13] and Balck [16] and suggest that a performance approach needs to also be used by the supplier / contractor to signal product quality, to consider the perspective and specific realm of interest of other actors (in addition to the end user), as well as in subdividing the contents of overall performance into individual aspects with relative independence [3].

The Performance approach in a broader sense is receiving increased attention. There are on-going discussions – including those involving international standardization – on how the description and evaluation of buildings should take place and how these can be harmonized (such as “Service Life Planning” (ISO TC 59/SC 14) and ”Sustainable Construction” (ISO TC 59/SC 17)). For instance, the approach is also being used as the basis for developing a system to evaluate the contribution of single buildings towards sustainable development. Functional, design, technical, economic, environmental and social aspects need to be considered simultaneously. A number of “multicriteria” decision support tools are currently being proposed, including a sustainability index for the measurement of sustainable performance. [40] The relative weight of different aspects to be considered will depend on the requirements of the client and other stakeholders for each project and the importance of the facility in support of the mission, goals, and purpose of the organization, or in support of the objectives of an individual or family. In addition, the use of a performance approach in determining the average useful life of buildings and building components is being discussed [17]. However, the methodologies developed, or considered by various authors and research groups, vary greatly. This paper discusses the general criteria and system which can be used to structure building performance in such a way that performance requirements, criteria and results can be more easily aggregated and dis-aggregated. In addition, the various ways of viewing the concept and developments surrounding the performance approach in North America, Europe and Japan are presented, examined and compared based on selected examples.

2. Suggestion for major performance categories

Expanding the performance approach with regards to its task, its interpretation and its area of application by including additional actors, concerns and supplementary functions requires developing major categories where user requirements are grouped in a coherent fashion.

2.1 Performance Categories

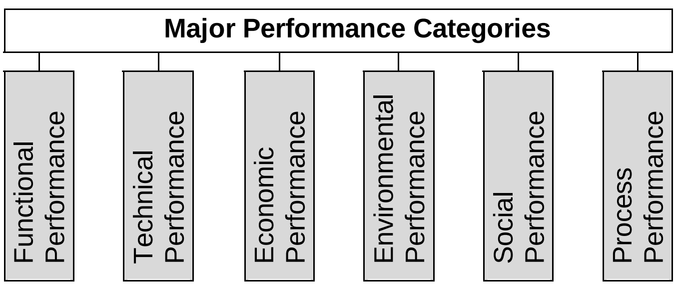

Figure 1: Performance categories

Figure 1 contains the authors' suggested performance categories and Table 1 details the categories by way of short descriptions and examples.

Table 1: Description of performance categories

Functional Performance Functional performance of a building describes and assesses how well use-specific activities and processes can be performed in the building. Criteria include suitability of the surface and space program for planned use, accessibility and barrier-free design, adaptability to changing user requirements and uses, etc. Functional performance is closely related to the needs of the building users and others such as visitors, and the public community.
Technical Performance Technical performance describes structural, physical and other technical features and characteristics. Criteria included suitability for the planned service life, load capacity, maintenance and revitalization capability, structural resistance to fire, control of noise transmission, heat insulation of building shell, etc.
Economic Performance **a) Real Estate Performance** Real estate performance is the earnings trend and value of a real estate property. It is especially useful for the decision-making processes of investors and property owners. A performance requirement is likely to be increased revenue and value. **b) Cost Performance** Cost and financial performance describes financial expenditures involved in planning, construction, operation, maintenance, demolition or waste disposal at a particular time or within the life cycle of a facility. The current criteria have moved towards LCC (Life Cycle Costing) methods. Cost performance is used by managers, planers, building users and facility managers to monitor and control costs. Investors and property owners especially consider non-allocatable costs.
Environmental Performance Environmental performance describes and assesses the building's features and characteristics relevant to its impact on the environment. The effects on both the local and global environment are considered. Energy and material flows and resulting effects on the environment are recorded. The use and conversion of areas are also considered in part. Low resource utilization and/or reducing effects on the environment contribute to improving environmental performance.
Social Performance The description and assessment of social performance is based on criteria that indicate the health, comfort and safety of users, visitors, residents and neighbors of the building. In addition, the building's cultural value is also usually assessed. Codes, regulations and standards provide a base for these performance requirements, but clients often choose to demand more.
Process Performance in Strategic Planning, Design, Construction, Operation, Maintenance, Management and Use The overall building performance is influenced by the quality of processes involving planning, construction, use and facility management. It is thus suggested that quality of planning, construction on site, management and building related services be described and assessed separately as process performance.

Taken together, the major performance aspects divided into individual categories form an information pool within which individual criteria (i.e. essential features relevant for assessment and decision-making) can be classified. The criteria in turn can be matched and measured with individual performance indicators. Classifying criteria within the system of categories depends on interpretation. Criteria can be meaningfully allocated to more than one category. For instance, the criterium 'health & comfort' can be allocated to both functional performance and social and compliance performance. In the authors' view, it is important that essential criteria are listed as fully and completely as possible. Performance results for individual criteria within each category can be obtained by means of testing, calculations or factoring based on scientifical methods. The performance requirements or results for criteria within one category can be combined into a single index representing the partially aggregated performance of the building. Similarly, the overall performance is deduced by full aggregation of the categories when required by the user or organization, on the basis of some calculation or algorythm. If weighting among individual categories is included, it should always be transparent and explicit. For instance, one category of requirements may be more important to the organization with regard to its mission(s) [18].

2.2 Interests and information requirements of stakeholder groups

The parties involved in the entire building process each have a specific scope of interests with various resulting information requirements. Each of the actors involved view and assess performance differently. For instance, the investor is primarily interested in the economic performance, particularly the property's earnings trend. The user and facility manager have a distinct interest in operating cost performance. Authorities and regulators are interested in environmental performance because of an interest in protecting the environment, and also in health, safety, security, fire, blast and seismic performance, and compliance with current codes and regulations. The actors seen as relevant are listed in Table 2. The number of actors involved, however, is larger. As a result, the interrelationships among all actors are more complex. The list represents merely a selection of the actors involved. Bakens *et. al.* [5] provides a more detailed look. Classifying actors to a supply or demand side is not fruitful because many actors can be on either side of the demand-supply dialog. A demand actor for a particular performance can also be a third party supplier further along the value-added chain.

2.3 Life cycle phases and events within the life cycle

A performance approach can be used in every phase of a building's life cycle. The authors refer here to the 6 phases set forth by Preiser [15] which are directly adopted and carried over in Table 2 (3a). The building delivery cycle begins with strategic planning. Individuals, groups or organizations determine their medium or long-term needs based on the mission of the organization, or individual objectives, and goals and targets for the project, as well as feasibility studies in organizational contexts. For example, which rate of return, which market group, which image and external perception, and which budget and time plan should be achieved, are formulated during this phase. During programming, the goals and targets laid down within strategic planning are discussed between the client and programmer and systematically documented. Within the design phase, the requirements of the programming phase are translated into concrete and feasible technical specifications for construction. During this phase, planners, designers and engineers have the complex task of translating the goals set by investors, clients and/or developers into a more detailed set of performance targets. During construction it is important that the builders and contractors understand the performance requirements and targets and know how to turn them into a set performance requirements and targets for their suppliers. Throughout occupancy, the degree of performance-in-use attained by the project can be determined by building performance evaluations. These evaluations include assessing the level of user satisfaction by way of a number of different methods, including surveys, interviews, walk-throughs, participant observation, etc. Performance testing at the site (e.g. energy performance) can be conducted as part of facilities management, e.g. through monitoring energy use, water use, etc. As part of the building adaptive reuse or recycling, new performance goals are often established that are oriented to new standards and technical innovations and/or changing user demands because of changes in the way of working of the occupants, or because there is a change in tenant or occupant group altogether. The building might not be adaptable to new uses and hence will be deconstructed and recycled. This marks the end point of the cycle and also the beginning point of a subsequent building delivery and use cycle. Within these phases, there is a need for information specific to certain events in the life cycle of single buildings as also indicated in Table 2.

2.4 Functional classification of buildings

Performance demands can either be generally applicable or specific to use in a given situation. Use-specific requirements can be derived from the required or necessary functionalities of use. As a result, it is recommended to have a building classification system based on use or function. Most countries have a national system to classify types of building use or function. After having compared and contrasted three classifications, one from Germany[6] one from the United States[7] and one from ISO 6241-1984[8], the authors put forth the following suggestion of classification as listed in Table 2.

2.5 Levels of hierarchy and application

Performance can be required and measured for various levels of decomposition of the building and its system. Extending on [10] levels of hierarchy include property, built environment and environment, and society (see Table 2). Building performance relates not only inwardly but also to the outside world. This could be either considered within the neighbourhood i.e. the built environment, or society at large. In particular, buildings play a significant role in a sustainable development. [40] Discussions include whether buildings are to be accounted for within emissions trading. The performance concept can be applied at different regulatory levels, for example as agreements between states or on international level, included in national building regulations, applied or enforced by public authorities, used and applied by business or privately, all the way to the level of products and materials.

2.6 Work phases of performance approach and types of instruments

The essence of the Performance approach is to make the requirements for the project explicit “demand” so that the suppliers can respond with appropriate solutions “supply”. In each transaction, there is a demand-side and a supply-side.

The work for the Performance approach can be divided into the following sequence:

1. Make the Mission(s) / Objective(s) explicit. Formulate individual, organizational, and/or societal project goals
2. Translate goals into performance requirements, criteria, indicators of performance, targets and levels
3. Plan / realize (for new buildings as well as renovations)

4. Test the Performance results or evaluate based on criteria and indicators
5. Match Performance-in-use to requirements, i.e. compare performance requirements (targets and levels) and level of capability to perform of relevant features and characteristics of the property (during programming, design and construction, commissioning and occupancy).

Instruments - or tools – are used in several work phases including 2, 4, 5 and 6. Differences need to be made explicit between tools that: (a) support the formulation of performance requirements (including checklists, standards), (b) offer help in describing, calculating or assessing a building’s essential features and characteristics (i.e. during planning: planning and assessment tools; for existing buildings: questionnaires, test methods, use evaluations), (c) compare requirements and features of the design or the building with what is required, or with other buildings, and (d) translate the results of the performance assessment into a form of communication that is suitable for the various actors involved (e.g. a label, an energy pass/certification for buildings). Complex tools are capable of making the cited functions (a-c or a-d) available as a self-contained “tool-kit”. Some tools of b) and c) can also be used the other way around for a supply-oriented approach. In this case (c) would involve investigating which customers or target group would be suitable for an existing building. This concern is also relevant for planning and construction when it is intended that an existing building may serve several sets of users either at the same time or sequentially. The procedure necessitates that in the case of (a) above, several requirement profiles for various target and user groups (e.g. singles, couples, families, seniors, communes, disabled etc.) exist and are available. For instance within housing, a particular user group maintaining an individual lifestyles most probably will have other requirements regarding the living space than the next group. These very particular requirements have to be accounted for. Instruments or tools within (a) need to be developed so that actors on the supply and demand sides can communicate better with one another.

2.7 Summary

Table 2: Categories, stakeholders, life cycle stages and milestones, levels of hierarchy and levels of application for Performance Concept considerations

1. Major Performance Categories (authors' suggestion)	**2. Stakeholders** (authors' suggestion expanding on [6], [10])
• Functional Performance	• Investor / Owner
• Technical Performance	• Bank / Insurance Company
• Economic Performance (Real Estate and Cost)	• Designer / Planner / Engineer
• Environmental Performance	• Contractor / Builder / Product, Material, Service supplier
• Social Performance	• User / Occupant / Visitor / Public
• Process Performance	• Facility Manager / Property Manager
	• Regulators / Authorities / Society
3a. Life Cycle Phases (quoted from [15])	**3b. Specific events within whole life cycle** (authors' sugg.)
• Strategic Planning	• Investment
• Programming	• Financing
• Design	• Appraisal
• Construction	• Leasing / Letting
• Occupancy	• Purchase / Sale
• Adaptive reuse / recycling	
4. Types of occupancy (authors' suggestion expanding [6],[7],[8])	**5. Levels of hierarchy** (authors' suggestion expanding on [10])
• Commercial	• Society
• Cultural	• Environment
• Education & Research	• Built Environment
• Governmental & Public	• Property
• Health	• Building
• Industrial	• Sub-systems (e.g. Interior Spaces and building sections)
• Leisure & Entertainment	• Elements and Building Components
• Religious	• Products and Materials
• Residential	**6. Levels of Application** (authors' suggestion)
• Sports & Recreation	• International
• Technical infrastructure & Transport	• National
• Other Buildings	• Communal / Public
	• Business
	• Private

Table 2 provides a summary of the different areas of Building Performance under consideration - as briefly discussed in the above section. There are interrelationships between all areas. Such a system of categories can serve as a basis for reviewing existing methods and tools which will be introduced in the following sections.

3. Description of situation and development in selected global areas

3.1 North America – Canada and the USA

3.1.1 Canada

a. Canadian National Building Code: Canadian Objective-based Building Codes

Canada is one of the countries furthest advanced in adopting a new set of National Building Codes. Since the mid-1990s, Canada proceeded with a major consultation program and analysis of the current National Building Codes. Work is based at the National Research Council Canada – Institute for Research in Construction (NRCC-IRC)[9]. [19],[20],[21],[22],[23]

b. Functionality and Serviceability of Whole Buildings and Facilities: Methodology created to match Requirements and Performance / Serviceability (ST&M)[10]

This work was started in the late 1980s, at the request of the Federal Government of Canada. The methodology and an application to the "Office Building Type" were published by 1993[11] [13]. They became ASTM [12] standard in 1996 and ANSI standard in 1997. [12] The methodology is currently an ISO Committee Draft, CD 21933-1.

ASTM Technical Committee E06 on Performance of Buildings, formed in 1946, with current membership of approximately 850, has jurisdiction of over 170 standards at this time. One of several technical subcommittees within E06 is subcommittee E06.25 on Whole Buildings and Facilities, started in 1981 as a Task Group and officially designated as a Subcommittee in 1983, to develop and promote standards for the description, measurement, prediction, improvement and management of the overall performance and serviceability of buildings and building-related facilities. A major part of the work in support of this subcommittee is based in Ottawa, Canada, at the International Centre for Facilities – Centre International d'Etudes de la Gestion des Bâtiments et Installations[13]. The related standards are under the jurisdiction of ASTM E06.25, and the newly formed ISO TC59 / SC14 / WG10. [24],[25],[26]

c. Performance Based Information and Documentation

Based at the University of Montreal, Professor Colin H. Davidson has been working on a design-manufacture-build decision process model that traces the Performance-related steps and the information required at each step. His interest in quality and performance started in the early 1970s, and he, and his work, can certainly be noted as pioneering in this subject matter. Work is based at University of Montréal[14] – IF Research Group. [27]

d. Performance Based Information for the Management and Maintenance of Built Assets

The Institute for Research in Construction (IRC) of the National Research Council Canada (NRCC) is Canada's construction technology centre. Established in 1947, IRC provides research, building code development, and materials evaluation services. Working with partners, IRC addresses issues that have a large economic impact, assisting industry to innovate and develop technologies that are safe, durable and cost-effective.

In particular, IRC has created the following:

- An object model for maintenance management of roofing systems as a case study to demonstrate the applicability of a proposed generic framework for integrating the maintenance management of built assets. The framework consists of five sequential management processes: (1) Identify Asset, (2) Identify Performance Requirements, (3) Assess Performance, (4) Plan Maintenance, (5) Manage Maintenance Operations. The model builds upon the Industry Foundation Classes (IFCs) (Releases 2.0 and 2X) to define object requirements and relationships for the exchange and sharing of maintenance information between applications. Maintenance Management is one of the defined projects within the Facilities Management (FM) domain committee of the International Alliance for

Interoperability (IAI). Several extensions are proposed to the IFCs including the representation of functional requirements, assessed condition of objects, inspection and maintenance tasks, and libraries of non-specific information. Usage scenarios are provided to illustrate the use of the model to carry out selected processes.

- The Building Envelope Life Cycle Asset Management project has identified enabling technologies critical to attaining its objectives of optimizing the service life of building envelope components and systems. The preliminary investigation concentrated on the need for close links between user requirement modelling and those of service life prediction, life cycle economics, maintenance management, and risk analysis. The integrating tool is product modelling. Although there is a rich history in the field of user requirement (performance concept) modelling; however to date, there is no conceptual model and little vocabulary to represent the concepts described in much of this research and related standards. In addition, the language in the applicable ISO standards needs refinement and more structure. Work is based at National Research Council Canada – Institute for Research in Construction (NRCC-IRC)[15] [28], [29].

3.1.2 The United State of America

At the time that this paper is being written, the government of the United State of America (USA) includes probably the largest set of organizations that are implementing a comprehensive Performance based approach program from the very top. In 1993, Congress passed a law titled "The Performance and Results Act, 1993". It requires all government agencies to prepare Strategic Plans that also include a Performance Plan [30]. In 2004, the Executive Branch of the US government issued an Executive Order detailing how government assets will need to be managed, including reporting on key performance indicators on a quarterly basis [31].To implement this Executive Order, US government agencies are assembling the current measures of performance that are used to assess the performance of their constructed assets. A report has just been published by the Federal Facilities Council [32] detailing those Key Performance Indicators (KPIs).

In the US government, performance-based contracting is mandatory. The USA Federal Acquisition Regulations [33] state that: "Performance-based contracting means structuring all aspects of an acquisition around the purpose of the work to be performed, with the contract requirements set forth in clear, specific, and objective terms with measurable outcomes as opposed to either the manner by which the work is to be performed or broad and imprecise statements of work."

In order to comply with the Act of 1993 and the Executive Order of 2004, agencies of the US Government are starting to apply the same "performance" approach to the logistics that support their operations, including all capital assets. As an example, in a recent paper, Hammond et al report on how "The US Coast Guard is fundamentally changing the way it manages its resources in response to a policy shift with a focus on performance results." [34]. In order to respond to this shift, the US Coast Guard is applying the ASTM standard methodology described earlier [11] [12] [13] [25] [26] for defining demand, assessing supply, and analysing the gap between requirements and capability to perform to its logistic support functions [35]. This methodology and the new sets of scales created for the US Coast Guard, together with the results from a Facility Condition Index, a Mission Criticality Index, and other sets of criteria, are used to prepare a gap analysis for each asset considered and to set priorities for project funding.

The US General Services Administration (GSA) is moving in a similar direction, and also requesting that, as of 2006-01, the software applications that it will use should be IAI – IFC compliant (International Alliance for Interoperability – Industry Foundation Class). This again will have a major impact on how building information and data will be classified and organized.

3.2 Europe / Germany

At the European level, two directives have been passed that are close in content to the performance approach: the Construction Products Directive (93/68/EEC) and the Energy Performance of buildings directive (2002/91/EC). Currently, it is suggested that the term 'integrated building performance' be used for an overall system to describe and assess buildings as part of CEN standardization activities. This would include the categories technical performance, environmental performance, cost performance and comfort and health performance. At the national level, some individual countries have already included the performance approach in their building codes, including Great Britain, the Netherlands, Sweden and Norway [1]. Spain has been following these developments for some time and is looking into the possibilities of introducing it. [4]. France was initially very active in the performance approach development and applied it for civil works but rarely for buildings. Up to now it has not been legislated within the country. [4]. Currently, research institutions (CIB, CSTB, VTT, BRE, TNO, etc.), professional institutions (RICS, RIBA, BNA, etc.) and universities in Europe (Karlsruhe, Salford, Delft, etc.) are working with the performance approach and already have developed performance tools and instruments. Selected examples of existing tools and instruments are listed in section 4 and are classified into a proposed typology.

In Germany, the term performance is not widespread. As described in detail in [3], the term quality, as used in Germany, can be applied in the same sense as the performance approach. This is congruent with the principles of ISO 9000. Standards that regulate the tendering of construction services (anchored in VOB/A, Section 9 since 1973) [36] offer the possibility that investors/owners and contractors/builders agree by contract on construction services based on performance-based contracting and tendering. This is an alternative to the present detailed description of construction services to be performed. In Germany, there is an intensive discussion underway on the possibilities of implementing the principles of sustainable development in the building industry. A series of instruments are available such as guidelines, checklists, data processing tools and building passports[16] for buildings. There is furthermore an ongoing debate in the field of functionality for housing, residential buildings and surrounding living environments concerning the question of how differentiated lifestyles and living aspirations can be translated into requirement profiles for specific user groups. Instruments in this regard are being developed at the University Karlsruhe.

3.3 Japan

In Japan, the New Office Promotion Association of Japan (NOPA) was established in June 1987 as a core organization for the promotion of new offices. In this regard, the most important contribution by NOPA is that of a survey that was undertaken to formulate *recommended minimum standards* for the planning and design of new offices in Japan. This set of standards is collectively referred to as the NOPA New Office Minimum Standard, and has as its objectives, to improve and enhance both workplace environmental quality and workplace impact on productivity. It must be emphasized that the focus area of NOPA, together with the NOPA New Office Minimum is specifically *office environments* and not general building performance as might be suggested by other approaches discussed in this paper.

Since its inception in May 1995, the NOPA New Office Minimum has become the primary means of evaluating and improving office environments in Japan in terms of both workplace environmental quality and impact on productivity. During this time the Standard has been used extensively to evaluate, acknowledge, and reward innovation in office environments by giving awards to new offices that have achieved high standards. The achievements of the NOPA New Office Minimum Standard can be better understood and appreciated when considering the fact that the NOPA New Office Minimum is not legally enforced, but adopted and adhered to voluntarily by organizations based on their commitment to ensure employees' health, comfort, general well-being, and safety. As such, the NOPA New Office Minimum Standard has become known as an objective indicator of the state of new office environments in Japan [37].

The NOPA New Office Minimum [38] consists of a total of 22 standards in 10 categories. The standards are formulated on a minimum-requirement basis and where possible, expressed numerically. The Standard focuses on the general work area, but where necessary, also includes ancillary spaces, which contribute to the performance and accomplishment of work in the office environment. Topics covered by the NOPA standards range from the general characteristics of the office environment, to recommendations pertaining to the provision, use, and optimization of resources such as office automation (OA) equipment, desks, chairs, and filing, and finally, criteria regarding Facility Management (FM), managerial aspects, considerations regarding environmental awareness and employees' health, comfort, well-being, and safety [37]. In order to determine the evaluative capability and comprehensiveness of the NOPA Minimum Standard, research by Le Roux et al. [39] subjected the NOPA standards to a comparative analysis with the IBPE tools. Results of the comparative evaluation indicated that both evaluation tools include similar criteria that focus on evaluating the performance of basic environmental aspects such as lighting, acoustics, and indoor temperature. Since the standards included in the NOPA New Office Minimum are formulated according to minimum-requirements as apposed to optimum performance, the ability of the standards to identify specific problem areas and evaluate aspects of good design, is regarded as low. Compared to the IBPE tools, the New Office Minimum includes additional evaluation topics which are related to managerial and operational aspects, quality of office furniture, and employee health, comfort, well-being, and safety. Although topics related to managerial and operational aspects are generally not considered as impacting directly on a facility's environmental performance achievement level, an assessment of these topics provide an indication of how employees perceive the environmental quality of the office, as well as their level of job satisfaction.

An important difference between the two evaluation tools was the absence of occupant questionnaires from the NOPA New Office Minimum. This necessitated on-site investigative-level surveys by surveyors in order to determine aspects pertaining to the performance of the specific office environment. As illustrated by the performance evaluative approach of the IBPE tools, feedback from occupants provides additional information regarding the specific environment's performance achievement. As such, the NOPA New Office Minimum focuses specifically on assessing an office environment's performance (serviceability), rather than actual user-requirements. In this regard, the approach taken by the ASTM Standards on Whole Building Functionality and Serviceability is exemplary in terms of evaluating both user-requirements (functionality profile as per the ASTM Standards) and facility performance (serviceability profile as per the ASTM Standards). The evaluation methodology of the NOPA New Office Minimum therefore allow for only bottom-line evaluations to be undertaken. Recommendations based on these evaluations subsequently are generic in nature and would suit the majority of organizations and facilities.

4. Survey of selected instruments (tools, standards, checklists, set of indicators)

Selected instruments and tools were examined according to areas of application and type (as discussed in section 2.6.) and are depicted in Table 3. Table 3 shows that the instruments can be applied within one or more areas but not in all. The reason is that they often were developed for a specific application at first, with more functions and applications pursued later.

Table 3: Typology of selected performance instruments and tools

Application / Instruments / Tools	A: Performance Requirements[A]	B: Performance Measurement[B]		C: Performance Assessment[C]	D: Performance Communication[D]	
		New Build.	Existing Build.		Non-rated	Rated
1a. Codes and Regulations[a]	Building Decree[1]					
	CPD (93/68/EEC)[2]					
1b. Standards[b]	ASTM standards[3]					
		NOPA M/S[4]				
2. Checklists / guide lines	Healthy Office[5]					
	SIA 112/1[6]					
	Guideline SusCon.[7]					
3. Calculations / algorithms[c]		LCA-Tools[8]				
		LCC-Tools[9]				
			SAP 2001[10]			
4. Measurements[d]			Accounts[11]			
5. Questionnaires[e]			CBE (IEQ)[12]			
	DQI[13]					
6. Building descript./passport[f]					Build. File[14]	
7. Labels / Certificates				ECOHomes[15]		
8. Integrated Tools[g]		EcoProP[16]				
		LEGEP[17]				

Index: fully applicable | partly applicable | not applicable

A Formulation of stakeholders' requirements
B Description, measurement and evaluation of newly planned or existing buildings
C Matching stakeholders' requirements with building delivery
D Communication of non-rated or rated results

a National building codes and regulations (mandatory)
b International or national standards (non-mandatory)
c e.g. LCA, LCC or energy rating tools etc.
d e.g. reading of meter, energy consumption reports, charts
e e.g. expert walkthrough, occupancy and use analysis
f e.g. plans, specifications of materials, technical components
g e.g. software based complex tools

n	Site (size, location, condition, landscaping)	X	X					X
n	Site accessibility + safety (transportation)	X	X	X	X			X
n	Site amenities (parking, recreational spaces)	X	X					X
n	Space clarity (separation, demarcation, zoning)	X	X	X			X	
n	Space efficiency, capability and capacity (e.g. internal circulation)	X	X		X	X	X	
n	Space suitability and usability (size, mix, layout, location)	X	X		X	X	X	
n	Thermal conditions (temperature, movement, humidity)	X	X					X
n	Thermal protection of envelope (in winter and summer)	X	X	X	X			X
o	Unit costs (power, fuel, space, services personnel)	X						X
n	Users-controllability of building systems (temperature, air, lighting)	X	X			X		X
n	Vibration	X		X				X
n	Views to outside, Daylight	X	X	X	X			X
o	Waste management	X		X	X	X		X

5. Proposed criteria within a framework

There are two major scientific groups developing and working on approaches for describing and assessing overall building performance. On the one hand are those who have applied the approach to the project delivery process. More recently, there has been a whole new movement focused on overall sustainable development. The latter group recently adopted the concept of environmental performance of buildings. The authors appreciate that the performance concept applies to any set of requirement topics. Therefore they suggest that a possible combination of major categories may have the following structure:

Table 5: Performance Categories and Criteria - Overview

1. Functional Performance	
• Space suitability and usability (size, mix, layout, location) • Space clarity (separation, demarcation, zoning) • Space efficiency, capability and capacity (e.g. internal circulation) • Service life (building components and technical systems) • Noise protection / Acoustic performance	• Flexibility / Adaptability / Variability • Site (size, location, condition, landscaping) • Site amenities (parking, recreational spaces, etc.) • Availability, support and potential of technical systems and installations for processes (power & water supply, lighting, alarms, IT, HVAC)
2. Technical Performance	
• Load bearing capacity (*structure* / floors) • *Stability* • Maintainability, condition of components, finishes + fixtures	• Durability • Reliability • Thermal protection of envelope / Heat loss and solar gain
3. Economic Performance	
a) Cost Performance • Investment costs • Design & Planning costs • Building and Construction costs • Operation and Maintenance costs • Demolition and disposal costs • Unit costs (power, fuel, space, services personnel) • *Total cost of ownership* • External costs	**b) Real Estate Performance** • *Value* • *Income stream* • *Return on investment*
4. Environmental Performance	
• *Energy performance class* (Energy rating) • Resource consumption (power, water, fuel, materials) • Impacts on environment (emissions, effluents, hazardous waste) • Land use intensity	• Biodiversity • Reuse-/ recycle-/ deconstruct-ability • Replenish- and availability of raw materials Energy intensity for production and construction • Renewable energy
5. Social Performance	
Comfort and health • Thermal comfort (temperature, movement, humidity) • Air quality (freshness, contaminants, smoke, exhausts) • Views to outside, Daylight • Lighting and glare • Acoustics • Vibration • Signage, way finding and orientation • Privacy • Cleanliness (site, building, interior spaces, fittings, fixtures) • Interaction and rest spaces • Controllability of building systems (temperature, air, lighting) • Duration of usability/operation of building services and amenities • Availability of services and amenities near site	**Security and safety** • Accessibility (users incl. disabled) service/maintenance personnel) • Access control and security (staff, personnel, public) • Fire safety • Precautions for safety in use (slipping, tripping) • Provisions for natural catastrophes **Identity** • Integration of building within site and surroundings • Cultural, historical, recreational value of site • Involvement, participation and identification • Aesthetics, spaciousness, image, appearance
6. Process Performance	
• *Effectiveness and efficiency of design, planning and construction process* • Management of building service • Monitoring of technical systems / installations	• Availability of data/information for building servicing • Failure response and efficiency of building servicing • Waste management

Index:	carried over from Table 5	*added by authors*	~~regarded as inappropriate~~

Table 5 represents how the criteria carried over from Table 4 can be sorted into the major categories from Figure 1. Some criteria can be allocated to more than one category, depending on how they are viewed and interpreted. It remains important, however, that the criteria, as recorded within the system, should be cross-referenced, if they are included in more than one category. The criteria can be used to describe requirements at an early stage within the decision-making process (i.e. during strategic planning and feasibility studies) for new buildings and are then mostly of qualitative nature, as well as at the different phases of the Life Cycle of the facilities. The criteria can also be applied to measure and evaluate the decisions taken through measurements on existing buildings.

6. Conclusions

The authors note that buildings are increasingly traded in an open and global market place e.g. within open-end and closed-end real estate investment funds. When looking from the stock market investors' perspective, highly aggregated information, which makes a building's performance in one part of the world comparable to another, would be useful to better assess the worth of an organization and of the real property it uses. In particular, measuring its rental space would be a first step in consistently reporting the value of a real estate portfolio. [41] Such information is also useful for portfolio management by organizations operating in many markets and by organizations with a need to allocate funds to building projects according to priorities that are clear, transparent, traceable and auditable. Next to highly condensed information, there is the need for transparent information. Especially financial institutions, following the guidelines of Basel Capital Accord II[17], will scrutinize building performance (termed property rating) carefully and evaluate financial risks connected with the property investment. This development makes building performance evaluation more important than before. There seems a greater need to measure, evaluate and communicate a building's performance in a standardized manner, requiring collaboration between all involved in the entire building process.

P.O. Box 1800, FIN-02044 VTT
Emails: Janne.Porkka@vtt.fi , Pekka.Huovila@vtt.fi

Abstract

The additional Performance Based Building (PeBBu) Thematic Network task on decision support toolkit (DST) has reached its final stage. PeBBu aims at combining fragmented knowledge in the area of Performance Based Building in order to build a systematic approach towards innovation of the building industry and applying user requirements throughout the building process. End-users, policy makers, building industry and regulatory communities are closely involved in this development in order to facilitate dissemination and implementation of research results.

The objective of PeBBu DST task was to collect promising decision support tools into a toolkit and to test the most promising ones in selected PeBBu Domains. This paper represents the DST content, sums up the testing results from and summarises key findings from passionate discussions amongst different performance based building experts.

The task included successful test sessions in October at Delft and in November at Porto facilitated by VTT Building and Transport (Finland) and University of Reading (U.K.). They outlined future PBB development needs in the industry and in different customer segments. The problems of the construction and real estate cluster have been pointed out to be insufficient customer orientation and on this matter PBB offers extremely promising foundation.

The most challenging part of the task, outlining the future development directions for PeBBu, is finally introduced as a PBB Framework describing present stage, next steps and future challenges.

Keywords: Decision support tools, decision support toolkit, performance based building, post occupancy evaluation, check lists, requirements management, quality function deployment, multi criteria decision making, design structure matrix, iBUILD, interoperability, PBB framework

1. Introduction

1.1 Performance Based Building

Performance Based Building (PBB) is defined as ‘the practice of thinking and working in terms of ends rather than means’, as applied to building and construction [1]. Concept provides a flexible and technically non-prescriptive framework for building design and construction. Its application consists of translating human needs (functionality, comfort, etc) first into functional and then into technical performance requirements, implementing them within a regulatory framework through codes/ standards/ specifications and enable the construction of buildings that provide long-term satisfactory performances. Application of the performance concept is gaining worldwide interest and acceptance. It is becoming increasingly recognised as a possible basis for globalisation and synchronisation of the trade of building materials. [2]

The PBB concept applies itself to the constructed asset planning, programming, design, procurement and construction, life cycle management and operation, and to building regulation control. The application will provide substantial benefits to both the end-user and to the participants in the building process. Performance Based Building [2].

1.2 PeBBu Thematic Network

PeBBu thematic network aims at combining fragmented knowledge in the area of PBB in order to build a systematic approach towards innovation of the building industry and applying user requirements throughout the building process. From this, white spots and a coherent future research agenda can be derived. End-users, policy makers, building industry and regulatory communities are closely involved in this development in order to facilitate dissemination and implementation of research results. The Network especially stimulates investments in research that may be expected to produce practical recommendations for the adoption and application PBB throughout the building industry and in all phases of the building process [2].

1.3 DST Objective

The additional Performance Based Building (PeBBu) task on decision support toolkit (DST) has reached its final stage. The objective was to collect promising decision support tools into a toolkit and to test the most promising ones in selected PeBBu Domains. This paper represents the selected tool, sums up the testing results from and summarises key findings from passionate discussions amongst different performance based building experts.

The task included successful test sessions in October at Delft and in November at Porto facilitated by VTT Building and Transport (Finland) and University of Reading (U.K.). They outlined future PBB development needs in the industry and in different customer segments. The problems of the construction and real estate cluster have been pointed out to be insufficient customer orientation (The European Construction Technology Platform, ECTP, Vision 2030 Report [3]) and on this matter PBB offers extremely promising foundation. The most challenging part of the DST task, outlining the future development directions for PeBBu, is finally introduced as a PBB Framework describing present stage, next steps and future challenges. Task produced two final reports [4].

2. DST - Selected Tools

Seven promising decision support tools supporting owners’ and clients’ decision making are structured under value management, value engineering and process management. Selection based on applicability and interoperability covering building life cycle phases. Toolkit contains Post Occupancy Evaluation (POE), Check Lists (CL), Requirements Management (RM), Quality Function Deployment (QFD), Multi Criteria Decision Making (MCDM), Design Structure Matrix (DSM) and iBUILD tool (Figure 1). Colours and numbers indicate applicability priorities.

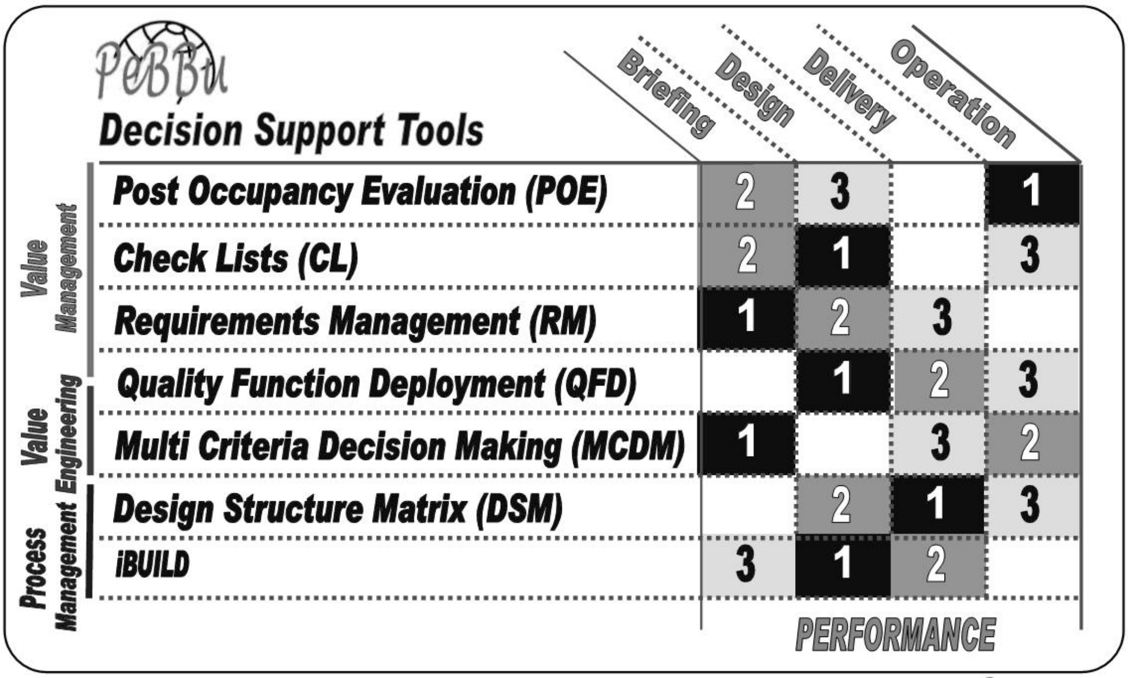

Figure 1: Selected PeBBu Decision Support Tools and their primary applicability.

2.1 Tool Introductions

POE process evaluates buildings in a systematic and precise way after few year of usage. Valuable input to the early project stages can be drawn from use and operation. Method is formal and comprehensive examination and evaluation of a building using methods aiming to study the effectiveness of designed environments from human user perspective. The results are presented traditionally as building strengths and weaknesses and method is often repeatable because of systematic and adaptive nature. Nowadays many of the studies in occupied buildings exploit POE. It's also clear that the operation phase should have more attention than earlier phases due to its financial importance. [5, 6, 7, 8, 9]

Complex nature of buildings is understood better through **Check Lists.** Those have been exploited in other tools but unfortunately performance based approach is still lacking universal classification. There are various CLs existing such as CIB Master Lists (supports performance) [10], ASTM (functionality and serviceability) [11], GBC (sustainability) [12], LEED (sustainability) [13] and VTT ProP® (conformity and performance) [14]. Main objective of Check Lists is their two-way connectivity to other tools, especially in setting performance objectives and making design decisions.

Requirements management ensures that we know what the customer really wants and also verifies that these objectives are met. Purpose is establishing a complete, consistent and unambiguous requirements specification [15]. Performance of the building should be defined comprehensively before the actual technical solutions get defined [16, 17]. Requirements and design are strongly linked; changing nature should be remarked also in tools. EcoProP software for systematic requirements management (see Figure 2) from VTT Building and Transport was introduced [14]. Software helps to set systematically performance objectives, to view requirement profiles, to estimate LCC and LCA impacts and finally to form an appendix to design brief on performance objectives. A data base tool includes pre-set requirement levels paving the way for applying by various users in different building types.

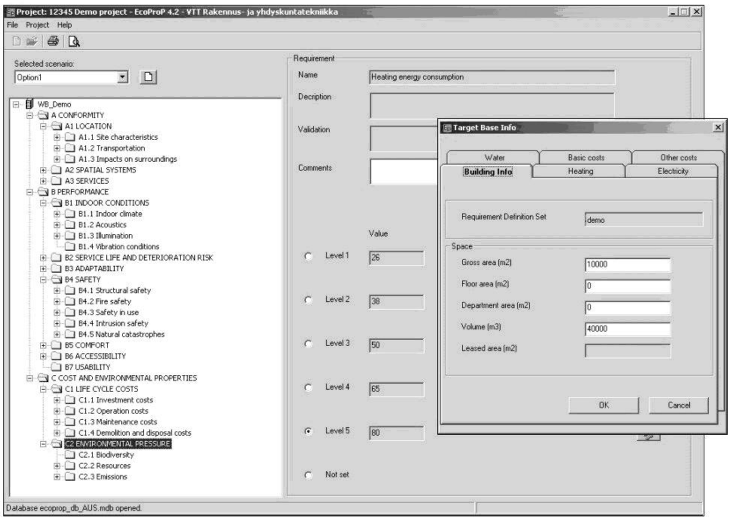

Figure 2: EcoProP software for systematic requirements management.

Quality Function Deployment (QFD) helps to represent performance objectives and priorities and then increases transparency on evaluate how and whether these objectives can be met [18, 19, 20]. Both of the contributors, Reading and VTT, introduced own solutions. ***Reading QFD tool*** is targeted to managing large amount of data, includes systematic priorities setting and assessment against benchmarks. ***VTT's QFD ProP*** is lighter combination and therefore exploited also in PeBBu DST Domain testing with integration to EcoProP.

Multi criteria decision making helps to structure discussion on objectives, relations and alternatives and synthesize those to model. Theoretical approach bases on value tree analysis. Widely recognised Analytical Hierarchy Process (AHP) uses the pairwise comparisons to solve multiple attribute problems, but when number of variables increases procedure becomes time consuming [21, 22]. Web-HIPRE comprises different MCDM tools (including AHP) used for prioritisation and analysis [23].

Design Structure Matrix (DSM) is a compact and clear representation of complex system and capturing method for the interactions/interdependencies/interfaces between system elements [24, 25]. Visual relationship matrix reveals key information flows and sets simultaneously targets to process analysis and re-engineering. It used for finding the optimal order of tasks and defining product architecture (modularity and interfaces) and forming teams in large organisations. In case the problem exists it helps also to solve inconsistencies. There is many commercial applications available for DSM.

Last tool, **iBUILD** from TNO Netherlands enables market driven product development in housing by modular intelligent parametric designs for houses [26]. It highlights client possibility to make changes and still exploit lower process of mass-production. Computer applications help the non-professional client in decisions and visualise consequences. The system streamlines the building process through the generation of drawings, support in selection of building products from suppliers, to derive plans and schedules, to prepare procurement and production orders.

3. DST Test Results

Leading theme in testing was interoperability; work is started with one tool and continued with other, as Figure 3 illustrates. Requirements management tool EcoProP and QFDProP exploiting house of quality matrices formed the interoperable platform for testing.

The first trial was conducted in Delft for Domain 2 (Indoor environment) led by Mr. Marcel Loomans (TNO) in October 2004 using a single family house that has been built in Kotka in Finland (case: Loiste). It highlighted innovative energy efficient steel frame solutions of high comfort. The test focused on managing the indoor conditions. The first DST workshop validated the test approach with a relatively simple housing case. The second test was arranged in Porto for all scientific PeBBu Domains in November 2004 using an industrial, adaptable and durable office building designed in the Netherlands (case: IDF Building). Slightly different approach was maintained in each domain. The leader of Domain 3 (Design), Mr. Dik Spekkink (Spekkink C&R), exploited the opportunity most effectively.

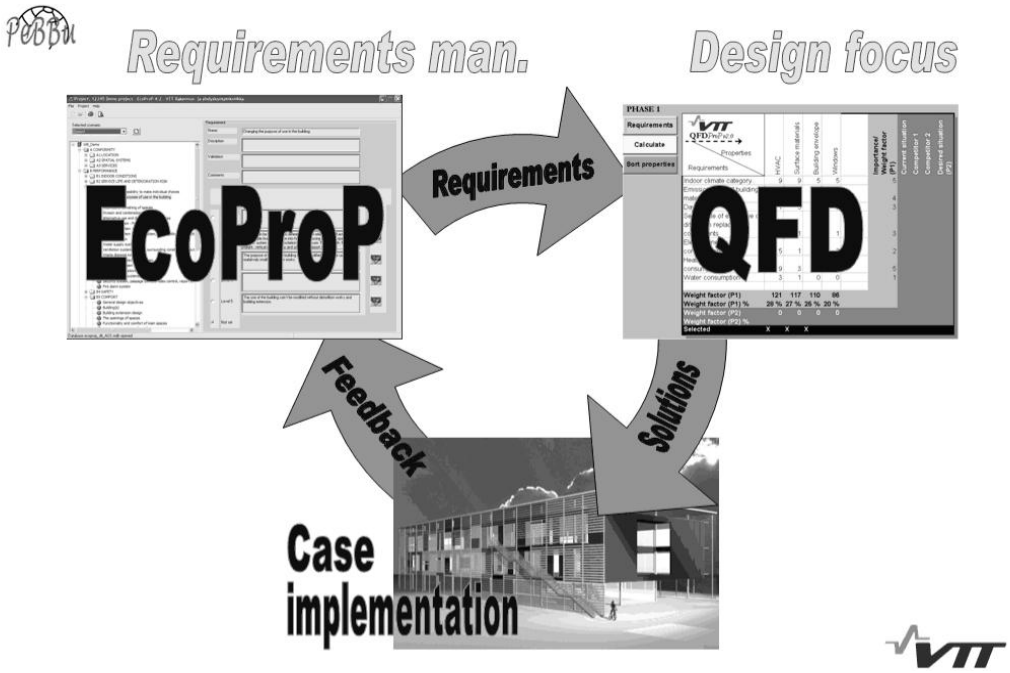

Figure 3: An example of integrated value management tools.

3.1 Case Introduction

Leading ideas of IFD building (Figure 4) development are: High adaptability, good indoor conditions, low environmental pressure, optimised running costs and value, representing corporate brand: serving image and innovative design and technical solutions [27]. It supports multiple layout solution inside the office floors, offering fixed solutions combined to flexibility in others.

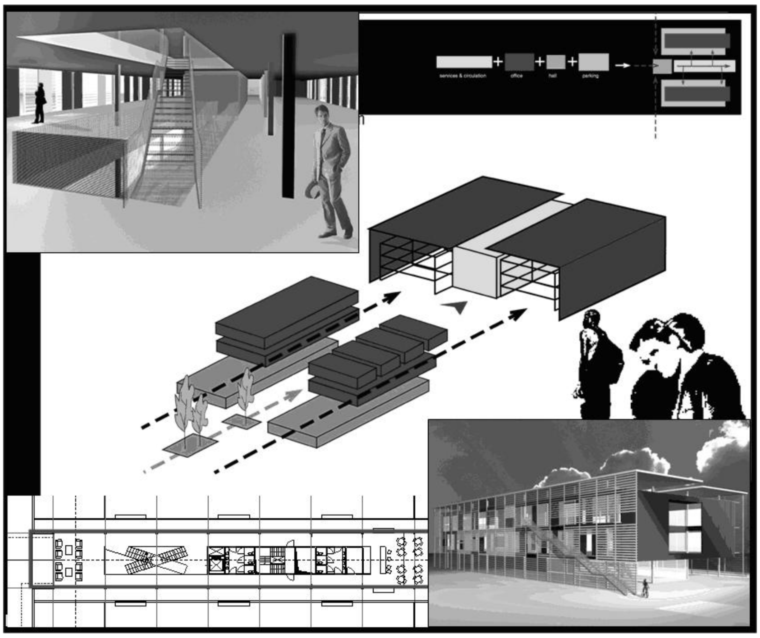

Figure 4: IFD Building.

3.2 Test Results

Performance objectives were captured with EcoProP that was remarked valuable aid in implementation the performance approach because the users are 'forced' to think their objectives before technical solutions. Experiences of implementations revealed that it increased discussion, commitment and teamwork. It also verified that the original needs were documented and ensured that essential requirements are not eliminated. Software was exploited in team session characterized by Domain members challenging each other. VTT ProP® classification was used to collection of performance requirements, following characteristics were remarked:

- Conformity
    - Location, spatial systems
- Performance
    - Indoor conditions (Indoor climate (FISIAQ), acoustics, illumination, vibration)
    - Service life and deterioration risk, safety
    - Adaptability, comfort, usability, accessibility
- Cost and environmental properties
    - Energy consumption (LCC, LCA calculations), water consumption
- Process
    - Process issues (Briefing, construction, quality assurance)

Lack of common performance classifications was remarked as an overall bottleneck for PBB. One possible baseline for this development is to study the content of VTT ProP® or other potential classifications. Certain inconsistencies were remarked but overall structure is performance based. One should also notice that different spaces need different requirements. Spaces have varied needs and defining their characteristics independently would offer better usability. It's vital for implementation to consider also requirement interrelations. This analogy isn't included at present EcoProP software, because of its complexity.

Decision support tools need also well documented manuals and supporting system. This means more reference information and exploitation of expert consultation. Systems shouldn't base on web-based information because URL addresses are considered to have their own service life and limited availability. Predefined lists pave way for rating objectives at a project level. Lists help to improve quality and simultaneously speed up process. They might also lead to incomplete solutions and in certain phases empty cells offer possibility to customisable solutions.

QFD was used to judging how well the original design criteria and technical solutions meet customer needs. Most of the attention was paid to following: indoor climate, material emissions, daylight, service life etc. Requirements were rated against properties (such as building envelope, windows) and these sorted properties were further considered in second phase finally describing characteristics of technical solutions. Results indicated that HVAC system was considered as critical part. Impact is stronger in offices than one family houses but Finnish building domain uses widely FiSIAQ indoor air quality classification; setting detailed recommendations for target values, design guidance and product requirements. It was clearly noticed that systematic procedures are needed to project meetings. Somebody has stated it clearly: "Client don't optimize the process, they hire a contractor to do that".

DSM can be used to organise tasks or workers and supported by Last Planner to help in validating execution possibilities. Potential use of DSM is in process analysis and risk assessment. DS tools enable proving of procurement practices benefits. Integration of tools is possible to by product model technology - requirements attached seamlessly to processes.

4. Conclusions

Observation 1: Traditionally the emphasis has been very much on design and construction. Experts from various countries and fields portrayed that yesterday's situation has been far too greatly production driven instead of being customer orientated. Situation in ICT tools was remarked to slightly better.

Observation 2: The emphasis is shifting from construction of facilities to operations. Discussions led to analysis that revealed emphasis is shifting to operation phase. Although the importance of design and construction is clearly understood the emphasis is predicted to shift towards operation model. The operation model is a starting point for new projects. According to ICT tools the change is intended to be stronger, because next generation tools are moving towards automation and use of standardized solutions.

Conclusion 1: ICT Tool development needs flow from Operation model to Requirements model. Value of facilities for user culminates to quality of requirements model. Therefore is strong need to develop the interface between operation model and requirements model; supported by seamless life cycle data management further to design and production.

Conclusion 2: Verification tools for proposed performance entities are needed. There is a need for verifying materialising of proposed performance entities by validation tools and appropriate applications are needed especially to design assessment.

5. Recommendations for the Future

The recommendations leading to better image amongst the audience and growing markets are structured to four main categories in Figure 5.

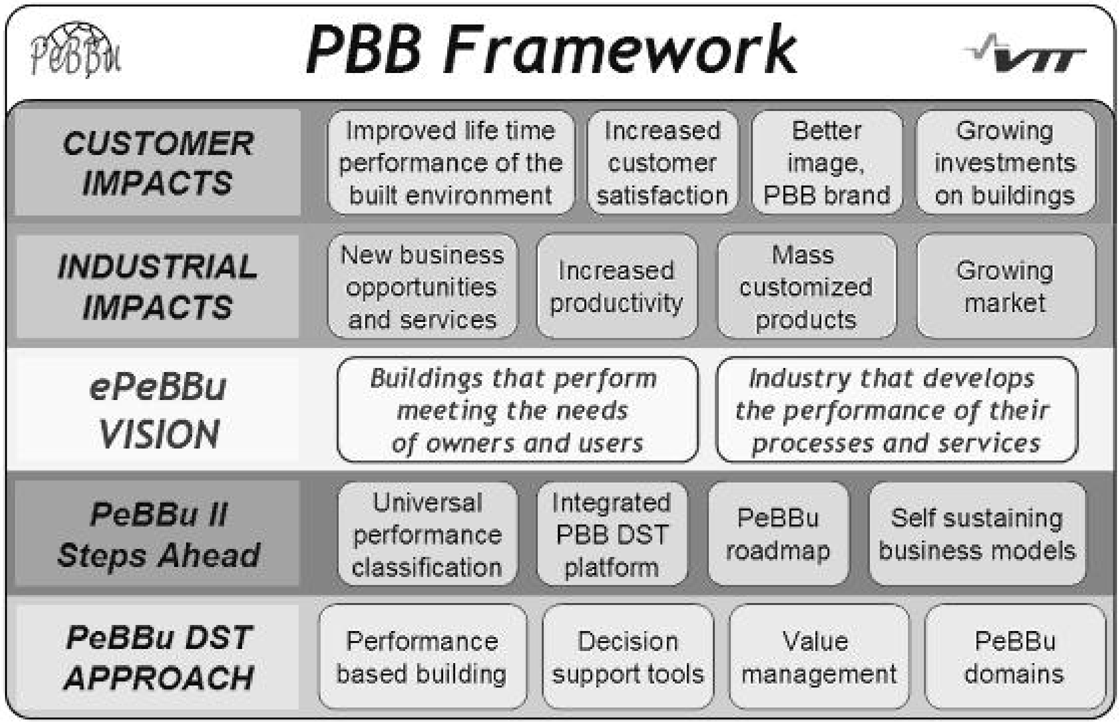

Figure 5: PBB Framework.

5.1 International Framework and universal Performance classification

***Problem**: No common means of true communication on performance properties exist.*

PBB needs a common vocabulary and a logical framework where different performance criteria can be referred to. A millennium version of a new CIB Master list could structure the high level criteria like the work was started in the CIB Compendium. The low level characteristics that may be material or technical solution dependent should be left open. A widely accepted generic performance framework would increase interoperability of tools and accelerate the diffusion of implementation.

Recommendation 1: Internationally accepted performance based building classification: a "PBB Master list 2006" (succeeding CIB Master list 1964, 1972, 1983 and 1993 editions).

5.2 Integrated platform with interoperable tools

Problem*: The support of performance management is scattered and number of isolated applications are unsystematically applied for sub-optimising individual solutions.*

It is evident that product model technology has developed to a level where it can enable the attachment of data from various phases to it, such as requirements management. This shift is intended to motivate developers towards consumer driven process.

Recommendation 2: a "PeBBu II" should be activated focusing on "ePeBBu Platform" and "PeBBu compatible applications" with pan-European true experts on board.

5.3 Value models, incentives and constraints

Problem*: Despite of the potential considerable benefits of PBB widely shared by researchers over the past decades very little, if any, change can still be observed in everyday practice.*

The reasons preventing the change must be identified and a credible path of progress with risk assessment is needed. A Roadmap describing the vision (or future scenarios) and needed action plan with relevant steps would show the way forward. Relevant landing points and indicators measuring the state together with listed incentives and barriers would complete the picture. Success stories (from outside or inside) or good practices could facilitate the implementation.

Recommendation 3: A cross-disciplinary study a "PBB Roadmap" objectively assessing various future scenarios could provide a discussion basis bridging various professions and disciplines.

5.4 Value adding whole life services

Problem*: It is still a mystery "current supply" could be transformed to meet "future demand".*

The industrial implementation of the PBB Roadmap needs methodological competence of forming value networks, establishing win-win-win rules and adopting customer oriented life cycle services. If the business models remain questionable no progress can be achieved.

Recommendation 4: Self sustaining profitable business models are needed to breed customer oriented networked life cycle services.

5.5 Information dissemination, regulations and education

***Problem**: People are lacking information and knowledge – it is a challenge to encourage innovation and development through regulations.*

Accessibility of information must be ensured. Value forming in the process enabling learning must be supported.

Recommendation 5: The development needs to be encouraged and assured at all levels.

The PeBBuCo study[1]: Compendium of Performance Based (PB) Statements of Requirements (SoR)[2]

Françoise Szigeti
International Center for Facilities (ICF) Ottawa, Canada (email: fs-gd@icf-cebe.com)

Abstract

This paper presents the results from a study to develop a *Compendium of Performance based Statements of Requirements (SoR) for Constructed Assets*. The Compendium provides a source of information about SoR to those applying the approach to the procurement, delivery and Whole Life Cycle Management of buildings, facilities and other constructed assets. It is posted at the CIB PeBBu website. This website will be a place for gathering Performance Based (PB) Statements of Requirements (SoR). The Compendium is intended to provide examples of implementation of the "*Conceptual Framework for Performance Based Building (PBB)*". The Compendium and the PBB Conceptual Framework complement each other. Together, they provide the following: (a) what is the Performance concept and how it applies in the building and construction industry sector, why it is an important concept, how it helps customers and suppliers to better understand each other, and how it helps the suppliers to respond more appropriately to the requirements of their customers, (b) a template for data gathering about projects and sample case studies of building projects that have used a Performance based approach, in at least one major stage of the project cycle, (c) essential terms and definitions from both the "demand" and "supply" side, and (d) key bibliographic references. Successful application of a Performance based approach depends on closely matching user requirements (demand) with the performance of assets (supply). The Compendium is concerned primarily with how to communicate requirements, in the form of Statements of Requirements (SoR), which are prepared by customers, and Functional Statements, which appear in Objectives and Performance based codes. Key to the approach is that the requirements for a project define clearly and explicitly; what the building, the building product, or the related service is required to do, and not prescribe how it is to be constructed, manufactured or provided. The Compendium was developed in the context of a PBB Conceptual Framework for the whole life cycle management of facilities and constructed assets. The Conceptual Framework shows how links and matches can be made between user requirements (demand) and the performance of assets (supply). To illustrate how this works in practice, case studies are included based on real life applications of a Performance based approach in projects developed by RGD (Netherlands), and Defence Estates (U.K.).

Keywords: evaluation; evaluation criteria; client; compare, demand; functionality; match; performance concept; performance-based approach; performance based building; performance

indicators; serviceability; statement of requirements; suitability; supplier; supply; tools; user requirements

1. Introduction

The Compendium of Performance Based Statements of Requirements is intended to provide examples, based on case studies, and information that will help those applying the Performance Based Building (PBB) approach to the procurement, delivery and the whole life cycle management of buildings, facilities and other constructed assets [1] [2]. It builds on a previous study[3]. [3]

The PeBBuCo project has been developing documents in support of the main PeBBu project to confirm what is understood by a "Performance Based (PB)" approach as it applies to Building. The PeBBuCo team has prepared a "consensus based conceptual framework" for this project. This consensus has been significantly accomplished by presentations, papers and other communications with members of PeBBu. [4] [5] [6] [7]

2. Results from the PeBBuCo Study

The Compendium and the PBB Conceptual Framework complement each other. Together, they provide the following: (a) what is the Performance concept and how it applies in the building and construction industry sector, why it is an important concept, how it helps customers and suppliers to better understand each other, and how it helps the suppliers to respond more appropriately to the requirements of their customers, (b) a template for data gathering about projects and sample case studies of building projects that have used a Performance based approach, in at least one major stage of the project cycle, (c) essential terms and definitions from both the "demand" and "supply" side, and (d) key bibliographic references.

3. Compendium of PB Statements of Requirements (SoR)

Successful application of a Performance based approach depends on closely matching user requirements (demand) with the performance of assets (supply). The Compendium is concerned primarily with how to communicate requirements, in the form of Statements of Requirements (SoR), which are prepared by customers, and Functional Statements, which appear in Objectives and Performance based codes. Both the regulatory and the non-regulatory documents and process should include methods for validating, verifying and testing or assessing results. Key to the Performance based approach is that the requirements for a project define clearly and explicitly what the building, building product, or related service is required to do, and not prescribe how it is to be constructed, manufactured or provided.

The Compendium has been developed in the context of a PBB Conceptual Framework for the whole life cycle management of facilities and constructed assets. The Conceptual Framework show how links and matches can be made between user requirements (demand) and the performance of assets (supply). To illustrate how this works in practice, case studies are included based on real life applications of a Performance based approach in projects developed by RGD (Netherlands), and Defence Estates (U.K.).

4. What is PBB: A Conceptual Framework

4.1 The Performance Concept is simple

The clearest definition is contained in the CIB report #64. Gibson states that: "The Performance approach is [..] the practice of thinking and working in terms of ends rather than means. It is concerned with what a building or a building product is required to do, and not with prescribing how it is to be constructed." Gibson explains further that "In some parts of the building materials industry, performance specifications are known as "end result" specifications, while prescriptive specifications are known as "recipe" specifications. [8]

The prescriptive approach differs in the following way: "It describes means as opposed to ends, and [is] concerned with type and quality of materials, method of construction, workmanship, etc". [8]

4.2 Two Key Characteristics of the Performance Concept

4.2.1 Two languages: WHY&WHAT <---> HOW

The Performance concept requires two languages. On the one hand, there is a requirement (demand) and, on the other hand, there is a capability to meet that demand and perform as required (supply). The language of the client is needed on the demand side and the language of the provider is needed on the supply side. These are different and it is important to recognize this fundamental difference. (Figure 1)

4.2.2 Match and compare

Clients say, "At the end of the day, we need to be able to verify that what we get, at move in and over the life cycle of the facility, is what we asked for and paid for". [9] Evaluations and reviews as part of design, construction, commissioning, POEs, and benchmarking, need to refer back to explicit statements of requirements, otherwise they are based on perceptions, intuitions and guesswork. So, whether or not a "pure" performance approach is used, there is a need for making requirements more explicit and linking those requirements to the objectives for the project. Altogether, an evaluative stance is therefore useful throughout the Life Cycle of constructed assets.

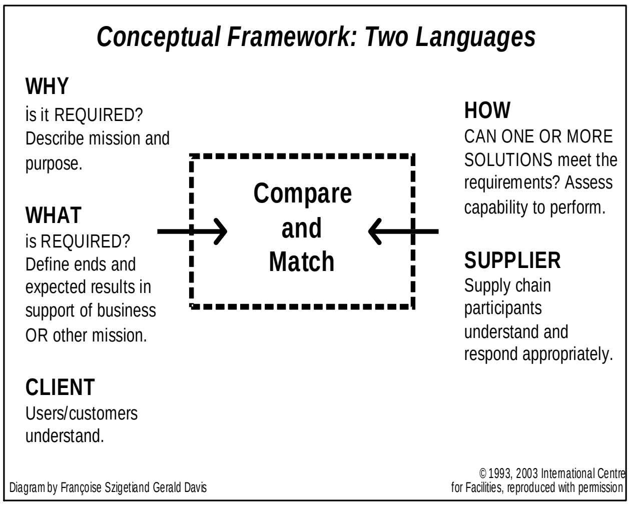

Figure 1: Conceptual Framework: WHY + WHAT and HOW – Two languages

4.2.3 It is not one or the other

Using a Performance based approach does not preclude the use of prescriptive specifications when the use of such specifications is more effective, efficient, faster, or less costly. When that is the case, it is useful to remember that prescription, whether in codes, standards, or specifications is implicitly based on past performance, and on prior experience, observation, tests or study. It is not likely that a facility will be planned, procured, delivered, maintained, renovated and used using solely a Performance based approach and documents at each step of the way, down to the procurement of products and materials.

5. Statements of Requirements (SoR)

Over the last decades, there has been a growing recognition of the need to consider buildings and constructed assets in the context of business, from the perspective of end users and as “means of production”, not only as overheads and cost centres. They are a useful support to business ends. Concepts such as Demand, Supply, Production, and Use, help us understand the relationships between building occupants and users (demand) and those who provide, maintain and operate the constructed assets (supply). Statements of Requirements (SoR) are, or should be, dynamic, not static, documents that include further details as projects proceed. They are part of a continuous process of communication between clients (demand) and project teams (supply).

SoRs, as understood in ISO 9000, include not only what the client requires and is prepared to pay for, but also the process and indicators that will provide the means to verify that the product or service delivered meets those stated requirements. They provide the information that anchors a Performance based approach. They are at the core of the whole life cycle management of facilities and provide the main basis for evaluations and other verifications when facilities are in use. They are the reference point for the commissioning process. Similar documents should be part of any procurement, as appropriate for the item being procured and the level of detail needed. SoRs are part of the audit trail. (Figure 2) [10] SoRs provide the documentation for overall projects, the link to the context and between demand and supply. (Table 1)

Asking questions to prepare a comprehensive SoR, and to support and document decisions, gives the provider team a clearer understanding of the project at hand. This can be a green field project or a renovation project of an existing asset. Assembling such a document usually leads to a more appropriate match between constructed assets and the needs of clients. Herewith is a sample of questions that the SoR might answer with regard to a building project as a whole.

- What is the building or constructed asset for? Why is it needed, and by whom?
- What mission(s) or objective(s) does it respond to and support? What task(s) does it need to facilitate? What kind of financing, ownership, and procurement route are most appropriate?
- What levels of performance are appropriate in this situation on specific criteria, and within what budget? What are the possibilities for trade-offs?
- What is the expected service life of the whole, and of components, parts, etc.? Are there some critical functions that require special support?
- What will it cost to run per year? What is the total cost of ownership?
- What are the milestones and deadlines? Are there any penalties for late completion?
- Does the client require that the building be designed to return energy to the grid? What level of labeling (e.g. BREEAM, LEED) is the client targeting?
- Will the activities housed produce hazardous waste, or other kinds of pollution? If so, what is required to deal with this situation? What impact will this have on the environment?
- What about the use of water and other resources, etc.
- What kinds of accessibility does this property require? Etc.

Table 1: WHY AND WHAT <compare> HOW: Context for Statements of Requirements

Hierarchy	WHY + WHAT	COMPLIANCE	APPLICATIONS Characteristics: Aspects Topics - Attributes
Society levels •global •international •national •regional •municipal •local	**Requirements levels** •Objectives / Goals / Targets •Functional Statements and other Requirements in user language •Performance Requirements in technical language •Operational Requirements	**CODES** •**Mandatory** --have legal authority •Minimum required (e.g. for fire, health, safety, etc.) **STANDARDS (external) / NORMS** •**Not mandatory** -- have legal authority ONLY if included in regulations •Either higher level of performance than Codes or additional attributes not covered by Codes and Regulations + Indicators of capability	**Building regulations and other applicable regulations** (e.g. environmental/green topics, clean air, accessibility, hazardous waste, water, etc.)
•Customers & stakeholders, •Groups of 'users' (inclusive of visitors and surrounding community)	Same as above	STANDARDS (internal) •**Voluntary** – internal to the organization or group •Either higher level of performance than Codes or additional attributes not covered by Codes and Regulations + Indicators of capability	**Statements of Requirements (SoR) (Project brief / Program)** **•Description of "user group/individual" / Mission(s) / Operations / Logistics support / resources, etc.** **•Environmental context** **•Time / Project milestones** **•Cost / Financial /Economics** **•Procurement route** **•Quantity** **•Functionality** **•Serviceability (Equivalent indicators of capability)** **•Service Life / Required condition** **•Security / Protection** **•Accessibility, Sustainability** **•Other attributes, etc.**
Individual/specific users (e.g. home owners, shopkeepers, hotel managers, etc.)	Same as above		
Evaluation, validation, verification / auditing	**Compare / Match Gap Analysis**	**Performance Test Methods (PTM), calculations, measurements, etc.**	**Key Performance Indicators Customer Satisfaction surveys, assessments, metrics, etc.**
•Infrastructure of Countries, Municipalities, Whole sites •Whole Buildings and Constructed Assets •Buildings, Building Systems, and Sub-systems •Components and Elements •Products, Services and Materials	**HOW** •---->From project and design analysis to constituent parts--->• •<---To whole constructed asset from constituent parts<-----•	•Prescriptive & PB Technical Specifications used on projects •Occupants' manual, O&M manuals, Building Systems Commissioning documentation, testing and controls software applications, etc.	•Acceptable solutions / Deemed to satisfy solutions •Specific solutions in given situations

Szigeti, F. & Davis, G., International Centre for Facilities (ICF) © 2001rev 2005. Based on a sketch by Foliente, G., CSIRO

Figure 2 [10] illustrates the Life Cycle Management of Facilities, and other constructed assets. It shows the Life Cycle from the perspective of those who manage, operate, maintain and use them, whether as owner-occupier or landlord. It also shows the key role of SoRs as the documents of reference throughout. User and stakeholder requirements define the objectives for the conditions and assets to be provided for a specific purpose, but independent of what solution might be chosen. They can be expressed in qualitative or quantitative terms. Performance requirements translate user requirements in more precise quantitative and technical terms, usually for a specific purpose. [8]

User and performance requirements need to be stated so that they can be measured and compared. Donna Duerk explains how a performance requirement should be written:

- address the outcome of an objective;
- be precise and unambiguous;
- be measurable
- be operational – be capable of being met;
- be positive and not negative;
- be capable of being used as a yardstick. [11]

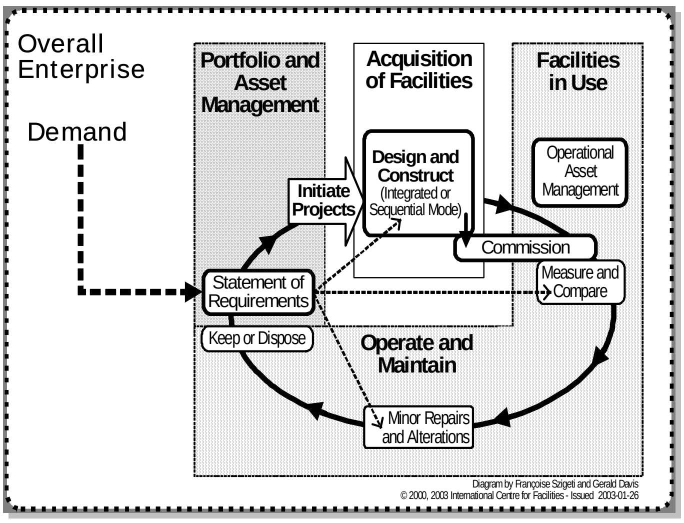

Figure 2: Statement of Requirements and the Whole Life Management Cycle of Facilities

6. Bringing non-regulatory and regulatory models together

The "Performance System Models" diagram [12] maps the flow of decision making from society and business objectives to construction solutions (Figure 3). This diagram brings together Non-Regulatory and Regulatory models. [6]

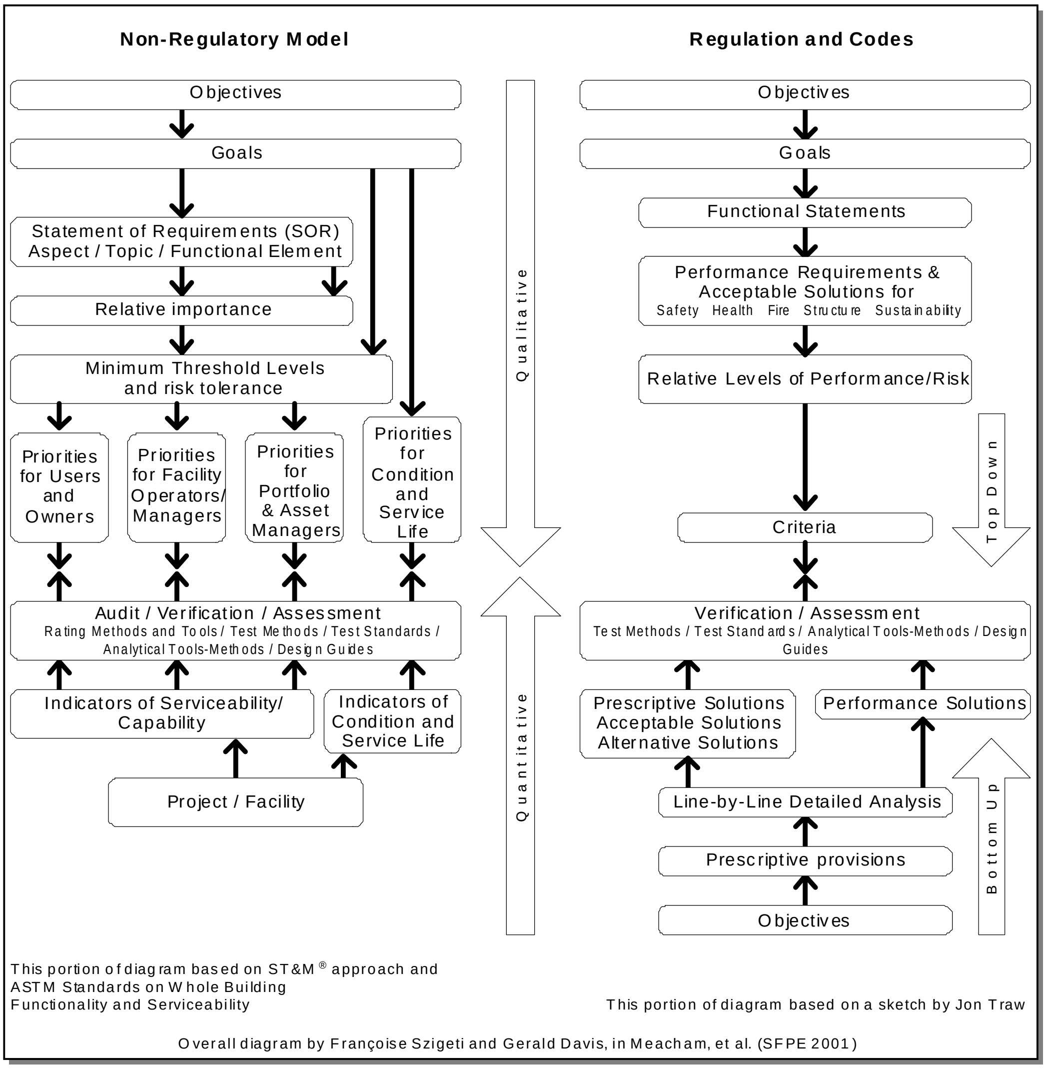

Figure 3: Total Performance System Models:A Framework for Describing the Totality of Building Performance (Source: Meacham et al. 2002)

The right-hand side of Figure 3 shows the requirements mandated by Codes and Regulations with the force of law. These are expressed in Functional Statements, and include for example, all design and construction issues that have a bearing on health and safety. The left-hand side illustrates what the client is willing to pay for. These requirements have no basis in regulation or law. The upper half of the diagram on the left shows client expectations, and the lower half shows the tools, measurement techniques and indicators which can be used to assess how well client expectations are met.

At the top of Figure 3 client expectations are expressed at their highest level first, then translated into Statements of Requirement, then sorted into priorities, then considered according to the priorities of the various interest groups. Starting at the bottom of the diagram the quantifiable and measurable performance indicators of the Project, Facility, or Asset, are mapped. The indicators begin with test methods, standards and tools, and move through indicators of serviceability, condition and service life that will be understood, measured and acted upon. Other aspects or attributes of the project can be defined and assessed in a similar manner.

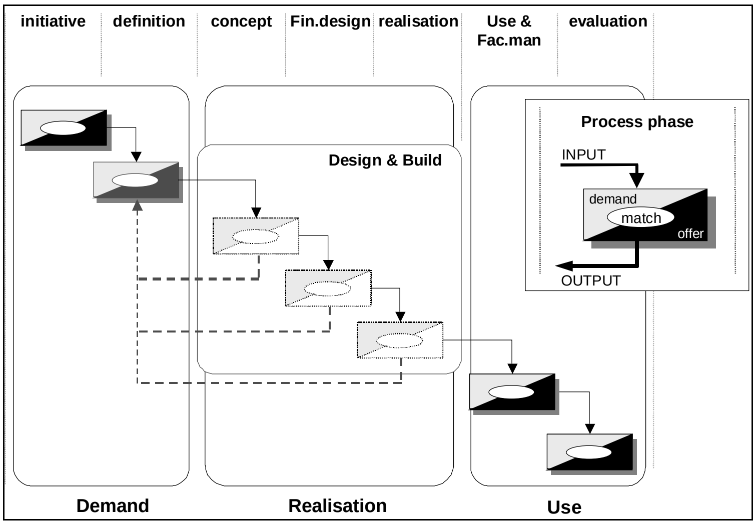
7. Summary of the Case Studies

The case studies assembled to-date and included in the Compendium cover major projects in the UK (the Building Research Establishment - BRE case study) and in the Netherlands (the Rijksgebouwendienst / Dutch Government Buildings Agency - RGD case studies). [13] [14] They were prepared separately, by individuals who are familiar with the evolving conceptual framework for SoR.

The BRE case study concerns two projects undertaken by the Ministry of Defence (UK), as part of their ongoing Prime Contracting Initiative. The first project dealt with is the “Building down Barriers” test project of the concept. The second is the pilot (Scotland) phase of the Regional Prime Contracting project. Prime Contracting is an example of an integrated project, where the design and construction phases of procurement are not rigidly separated, either chronologically or in terms of which party is responsible for each phase – in practice there is an integrated team comprising clients, designers, constructors and facilities managers within an integrated supply chain. Prime Contracting aims to deliver both capital improvements (new and refurbishment projects termed Core Works) and facilities management services (termed Core Services) across the full range of Defence property, including offices, barracks, training grounds, aircraft runways etc. The ultimate aim of the project is to provide an estate suitable to support the delivery of Defence services.

The Rgd case studies concern 4 projects where Rgd were involved on the client side. They range from a museum to a tax department. They are also examples of integrated projects, where both public sector and private sector performance requirements are involved. Three of the four projects are part of two major programs, one to build new Law Courts and the other to build new Tax Department Offices. [15]

As stated above, SoRs are a key link between demand and supply. Figure 4 illustrates the relationship of the Statement of Requirements to each of the transition points during the Design-Build delivery Process



Source: Oostinga, D., Compendium of PB Statements of Requirements, CIB 2005

Figure 4: Project & Life cycle TRANSITION points

Project 1. Summary: The Rotterdam "Wilhelminahof

The Rotterdam "Wilhelminahof" consists of a complex including: a Palace of Justice, the Regional Headquarters Tax Office, and a commercial office building. The overall goal for the project was to give the urban development within the area a boost for further investment. The urban revitalization was to be initiated by the "Wilhelminahof" building.

Procurement and tendering were based on functional requirements on the desired serviceability of the buildings. A DBFM-O (Design - Build - Finance - Manage – Operate) contract was signed in the transition from definition to design stage in public private contract with the Rgd. The bridge nearby over the river Maas and a subway station were part of a Public Private Partnership initiative. Within the building process, Performance Based Building focused on contracting at an early phase of the project and on performance specifications. The project documentation consists of a spatial statement of requirements, performance requirements, technical descriptions, prescriptive solutions, and functional requirements including organizational descriptions, general requirements and guidelines. The project was a mixture of innovative Performance Based Building and traditional aspects.

Project 2. Summary: Naturalis, National Museum of Natural History, Leiden

Naturalis is the newly build housing for the National Museum of Natural History in Leiden. By refitting the railway station site and by renewing and refurbishing the monumental "Pesthuis" (seventeenth century building, Plague house) a historical part of the city has been revitalized. The development of Naturalis is the result from a Public Private Partnership between the Municipality of Leiden, the Rgd and developer HBG Real Estate (formally known as Mabon). The project was owned by a private party at first and rented by the Rgd. Today the building is owned by the Rgd.

Projects 3 and 4. Summary: Central Building for Tax Department, Roosendaal and Heerlen

These two project are based on New build – Integrated contracts (development contract). Performance Based Building focused on contracting at an early phase of the project and integrating design and build capabilities through a development contract. Procurement and tendering were based on demand performance specifications which were the tender documents. Based on performance offer specifications, the projects were awarded to the developer. The basic contract between the Rgd and HEVO consisted entirely of performance specifications as they were formulated by the Rgd and the Tax Department.

8. Similarities and differences

8.1 Similarities between the UK and Netherlands examples

In each of the examples, there are a combination of performance based requirements and input / prescriptive requirements within the Statement of Requirements part of the contract documentation.

- Each includes an expectation that involving a wider representative group in developing the requirements for the project and the design concepts will improve the output / building.
- Each project has included some documentation which was standard / existing before the project, and which tends to be based on prescriptive requirements.
- Each project includes some element on maintaining / running / financing the project through a relatively long part of the life cycle post occupancy.
- Each has focused primarily on the earlier phases of the procurement process, and most emphasis and innovation appears to have been placed on how to communicate an SoR, rather than on checking responses.
- Each is expected to lead to efficiency and/or cost savings.
- Each is anticipated to support greater innovation.
- Each requires the parties to work with a high level of cooperation.
- Each challenged the skills on the client side in articulating their requirements in a performance based SoR.
- Each involved considerable cultural and process changes from typical procurement routes.
- Each involved a high level of collaborative checking of developing requirements and continual monitoring in the early stages of the project (the Cluster technique in the UK, the “pressure cooker” meetings in the Netherlands).
- Each involved some element of flexibility on the ultimate price to be paid for delivery of the project.

8.2 Differences between the UK and Netherlands examples

The key difference appears to be the role of the Architect – in the UK case study the term does not even appear, whereas it would appear that in the Netherlands the Architect expects to lead delivery of projects and determine key aspects of "good" design. An example would be in the case study on the Tax Department, where the Architect determined that glazing should cover the exterior of the elevator shafts despite the technical objections and consequent ongoing problem with cleaning (Section – Tax Department, item 4 - Lessons Learned).

The objective of capturing the expertise of facilities managers and gaining the cost and user satisfaction benefits associated may be difficult to achieve without a significant re-education process for Architects in the Netherlands. On the other hand, in the UK it is fairly apparent that very similar problems will occur. Future demand is often difficult to foresee. Unforeseen performance requirements for particular uses will be faced as within the Netherlands projects. In the UK Case Study, there seems to be a relatively weak Architectural contribution, which would appear to be the most appropriate skill set to resolve such issues.

From the Case Study reports, there appears to be more formal and developed techniques of risk management, value management and function analysis used with the wide project group in the UK, whereas these appear mainly to fall within the specialist knowledge of the Architect in the Netherlands. On the other hand, with the exception of the Building down Barriers project in the UK, the social and cultural challenges inherent in such procurement changes appear to be better addressed and understood within the Netherlands.

9. Concluding comments

This CIB PeBBuCo project was completed during the spring of 2005. Although the Compendium contains only a few case studies, some comments can be made, based on the findings of the case studies reported above.

Statements of Requirements have to be very carefully stated so that it is easy to verify that a proposed solution can explicitly meet those requirements.

High level statements of requirements need to be paired with indicators of capability so that design solutions can be evaluated before they are built in order to avoid misfits. In particular, the need for change has to be taken into account, since constructed assets have a long life, while uses and activities can change very rapidly.

When checking a design solution against the "explicit and implicit" requirements for a project, it is essential to test different ways that the spaces might be used in order to anticipate changes, otherwise a building, in whole or in part, can become very quickly unfit for the occupants.

Endnotes

[1] The study was commissioned by CIB (The International Council for Research and Innovation in Building and Construction) and completed during spring 2005. It was co-funded by the Rijksgebouwendienst (RGD, Government Building Agency, The Netherlands) and the United States General Services Administration (GSA), with in-kind contributions by the International Centre for Facilities (ICF, Canada) and the Building Research Establishment (BRE, U.K.). Team members were: Kathryn Bourke, Dr. Josephine Prior and Francoise Szigeti.

[2] Based on papers, documents and presentations prepared as part of the PeBBuCo study in support of the PeBBu project.

[3] This prior study was also commissioned and funded by CIB and co-funded by RGD.

Performance-Based Framework & Applications for nD Models in Building and Construction

Greg Foliente,
CSIRO – Manufacturing & Infrastructure Technology, Melbourne (greg.foliente@csiro.au)
Selwyn Tucker,
CSIRO – Manufacturing & Infrastructure Technology, Melbourne, Australia
Pekka Huovila,
VTT – Technical Research Centre of Finland (email: pekka.huovila@vtt.fi)

Abstract

This paper presents a conceptual framework for the systematic application of the performance approach in the planning, delivery and management of built facilities. The full benefits of the performance approach are not always realised because of a lack of facilitating tools and platform that allow data interoperability and ease of practical and comprehensive application of the concept. Thus, this paper also describes the application of multi-dimensional (nD) models for performance modelling and analysis before construction (as virtual design & construction tools) and during the life of the facility.

Keywords: Performance approach, nD models, interoperability, virtual building, performance evaluation

1. Performance Based Building

The proactive and comprehensive application of the performance concept in the whole, or parts of the, process of procurement, delivery and management of built assets leads to: (a) better understanding and communication of client/user requirements; (b) better fit of client/user requirements & supplied facility; and (c) considerable flexibility in design solutions for building practitioners, which encourages innovation and cost-optimised solutions.

The performance approach works when desired outcomes of the process (e.g. time, quality & cost, return on investment, etc), product (e.g. in functional terms such as safety, health, amenity & sustainability) and/or services (e.g. maintenance and other facility management functions) are clearly described (as in a project brief), and achieved in the design, construction and management of the facility. But these benefits are not always realised because of a lack of facilitating tools and platform that allow data interoperability and ease of practical application of the concept [1,2].

This paper presents a conceptual framework for the systematic application of the performance approach in the planning, delivery and management of built facilities. It also describes the place and application of multi-dimensional (nD) models for performance modelling and analysis before construction (as virtual design & construction tools) and during the life of the facility.

2. IT-Based PBB Platform

A monolithic tool for a systematic and comprehensive application of the performance approach is impractical. There already is a preponderance of specialist tools available for aiding decision-making [2], and for performance analysis, design and assessment (some of these have been collected in a web-based compendium: www.auspebbu.org/page.cfm?cid=3).

A more acceptable approach is towards interoperable PBB decision-support tools. Figure 1 shows an IT-based framework for the systematic application of the performance approach in the whole life cycle of built facilities that allows different decision support tools and performance models to interoperate. As discussed in Ref [2], many of these tools have different uses and advantages.

In setting the performance requirements, there could be three sets of tools. The first is a performance requirements management tool (second from top in Fig. 1), such as EcoProp, which is used to set the performance targets for a project (either new or refurbishment) based on client/stakeholder goals and requirements. Ideally, this kind of tool should access a comprehensive database of performance indicators (top in Fig. 1). Depending on the type and nature of the project – identified early in the process – sets of indicators will either be made available or hidden from the performance requirements tool. Then, to set the priority ranking of performance targets for each project, a tool for performance requirements prioritisation (third from top in Fig. 1, e.g. a Quality Function Deployment tool for PBB) would be needed. This is important because finding solutions to meet required/specified performance attributes very often require performance trade-offs; a proper design/product solution to meet one set of attributes usually conflicts with another attribute.

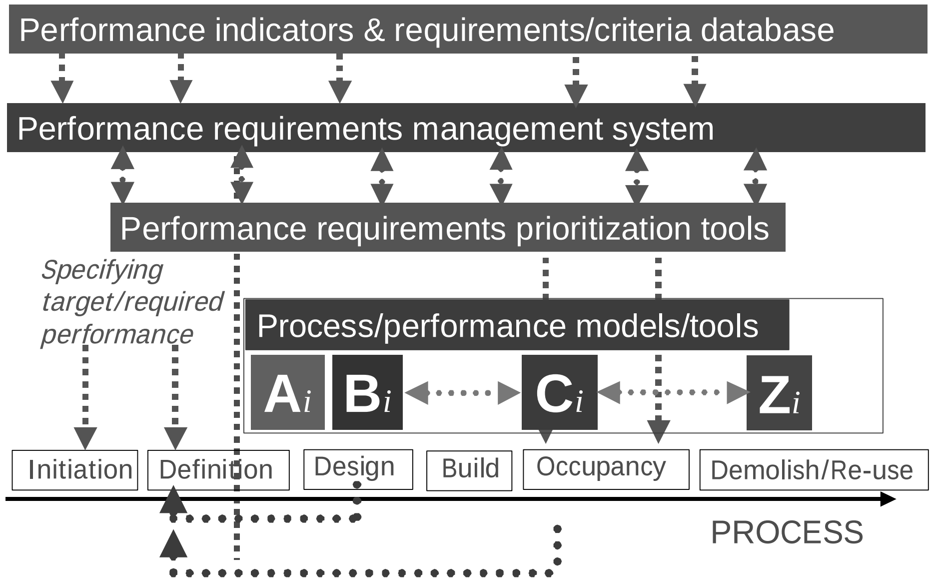

Figure 1: An IT-based framework for the systematic application of the performance approach in the whole life cycle

Then, to find solutions (in any stage from design, to construction or occupancy) to meet target requirements, various types of process and performance models are required (Fig.1). When used before construction, these tools are often called 'virtual building/construction' tools. Some of these can be integrated – via interoperability standards – into what is often called 'nD models'.

3. About nD Models

The terminology on n dimensions in describing construction systems seems to have first appeared around 2000 (e.g. [3]). The principle of extending the normal three spatial dimensions (called x, y and z) to the fourth dimension of time (i.e. x, y, z and t) follows the twentieth century physics approach. Suggested further dimensions included management attributes such as cost, schedule, procurement, materials, and accounting to allow project participants to visualize and manage the objects information [3]. Further dimensions such as colour and acoustics had since been added to the list. The concept of nD modelling in building and construction has culminated in an nD modelling roadmap [4].

But just what constitutes an additional dimension does not appear to have been made clear. Mathematical definitions focus on independent dimensions particularly linear independence, where the minimum number of dimensions required is most important in describing a system. In a mathematical sense, cost should not be an independent dimension because it is a function of all other attributes including time, i.e. cost can be calculated from the values of the attributes describing the constructed facility, e.g. size, type of frame, finish, how long it takes to build it and a series of constants representing cost per lineal or square metre. Many of the other suggested dimensions could similarly be derived from a smaller set of attributes, e.g. energy requirements, life cycle costs, acoustics and maintenance.

A proposed definition of nD modelling is that [5]:

'…nD is the parallel utilisation of building information for different analyses and evaluations …that will enable all stakeholders to experience the building, not just in a visual environment but in an information rich interactive system of all senses including acoustic (for ambient sound etc) and smell (to stimulate polluted environments)' etc. nD modelling '… is a new approach orientated to integrate existing and non-existing modelling approaches into a new way to deal with the different dimensions of a project from a predictive perspective.'

Such an approach to n-dimensionality focuses more on outcomes rather than the smallest set of independent inputs which enable a model to produce the performance measures required by different participants for each to quantitatively assess a design and understand the implications. In this usage, most "dimensions" cannot be compared to the basic spatial and time dimensions x, y, z, t and it can be misleading to do so. Thus, careful consideration of the characteristics which enable an attribute to be classed a dimension is required.

4. Conclusions

An IT-based framework for the systematic application of the performance approach in the whole life cycle of a built facility has been proposed. The place and use of decision support tools and nD models in such a framework were discussed.

Section III

Performance Based Building Standards and Practices

Performance Based Building Regulations

David Pilzer
Ministry of the Interior, Jerusalem, Israel
And other members of the Performance Based Building Network, Domain 7 "Building Regulations"

Abstract

The Building Regulations Domain of the Performance Based Building Network has collected relevant information about progress and difficulties in implementing performance regulations in participating countries. This paper discusses the experiences of the various countries as an amalgam. It then presents the leading research priorities in this field as they emerged from the domain discussions

Keywords: performance based building, construction regulation, code enforcement. .

1. Background

Domain 7 of the Performance Based Building Network has promoted international discussion and exchange of ideas and experience regarding the development, implementation, enforcement and support of performance based regulatory systems.

Building regulations typically seek to ensure the health, safety and well being of people in buildings. Toward this purpose they set minimum design and construction requirements. Building regulations may also promote other objectives, such as energy efficiency, serviceability, quality or value and facilitating the built environment to persons with disabilities.

Historically, building regulations were based on a prescriptive approach which severely limited the available solutions for compliance. Creativity and innovation were stymied or slowed as efforts were undertaken to adapt to or change the prescriptive regulations. These regulations also served to restrict and inhibit international trade.

Performance based regulations are predicated on the intended outcome and seek to encourage a variety of solutions for compliance. This promotes diversity and innovation in an industry that has traditionally been conservative. The performance approach also facilitates international trade. This applies to building products, processes and methodologies in the building design professions.

2. Objectives

Domain 7 of the Performance Based Building Network has collected relevant information about progress in implementing performance regulations in the participating countries. While discussion in the various domains tends to provide a favorable picture regarding performance based building, it may be a case of preaching to the convinced. The status reports in Domain 7 reflect an uneven picture of successes and frustrations in attempts to change the regulatory framework in the participating countries. While almost all of the countries are moving in the direction of performance regulations, most do not yet have a complete or fully integrated performance based regulatory system. In the absence of such a system, it is difficult, if not impossible, to implement fully the various aspects of performance based building.

The first objective of the paper is to provide a summary of those experiences. It includes:

1. Description of the regulatory system.
2. Scope of the regulations.
3. Enforcement and compliance.
4. Satisfaction level of the various practitioners.
5. What is perceived to be lacking or in need of enhancement (eg. gaps and barriers).

The second objective of the paper is to present research priorities as they emerged from the Domain discussions. Obviously there is a strong link to the gaps and barriers discussion of the status report surveys. However, in order for a subject to emerge as a research priority it had to result from the experience and needs of at least several countries.

The leading research priorities were as follows:

1. Verification methods to demonstrate that the required performance was achieved.
2. Risk informed regulations.
3. Methods for addressing acceptable or desirable levels of performance in existing buildings.
4. Creating a systems approach to performance requirements with quantifiable levels of performance.
5. Methods for evaluating the economic impact or feasibility.
6. Development of certification models and other means of approving designs and products.

3. Participation

Task members of the building regulation Domain hailed from the following countries: Belgium, Denmark, Greece, Hungary, Ireland, Israel, Lithuania, Netherlands, Poland, Slovakia and United Kingdom.

In addition, guests or observers from Australia, Canada, New Zealand and the United States participated in one or more of the Domain meetings. The participation and contribution of Australia was particularly significant as Australia operates a parallel network to the European Performance Based Building Network and several members were present at the various domain meetings.

Furthermore representatives from Australia discussed the findings of a productivity commission authorized by the Australian government to examine the contribution that reform of building regulation has made to the construction industry and to economic efficiency in that country. The Australian experience was particularly important as they have been pioneers in performance- based regulation.

Meetings, task members and guest represented a variety of organizations, academia, industry and government. They brought with them a range of professional backgrounds: architecture, code enforcement, engineering, legal, research and public administration.

4. Context

The Performance Based Building Domain is part of a thematic network funded under the European Commission's 5 th Framework – Competitive and Sustainable Growth. The program commenced in October 2001 and runs until September 2005. It involves networking various European and international stake holders to promote performance- based building, research and implementation.

Performance based building regulations need to be viewed within the larger general discussion of performance- based building. The concept put forth by the thematic network is that thinking about building and construction should be oriented to ends rather than means. "The basis of all building activity should be the performance of the building in use rather than the prescription of how the building is to be constructed". The other scientific domains of the network are life performance of construction materials and components, indoor environment, design of buildings, legal and procurement, innovation.

It should also be noted that there have been other international and regional cooperative efforts aimed at promoting performance based regulations. The most prominent of these is the Inter- jurisdictional Regulatory Collaboration Committee (IRCC). Furthermore, CIB has been active in this realm and sponsored a Task Group known as TG 37 which presented several papers at the CIB World Building Congress in Wellington, New Zealand in April 2001. This Task Group issued its final report in December 2004.

5. Scope of the Regulations

There are however distinctions between regulations and other aspects of performance based building. Performance based building is an encompassing approach related to the design, operation and maintenance of a building during its entire life cycle; essentially its general performance. The purpose of regulations is far more limited. Regulations seek to establish minimum standards of compliance. The generally stated purpose of most building codes is to ensure public safety, health and welfare insofar as they are affected by building construction. They typically regulate structural strength, adequate means of egress facilities, sanitary equipment, light and ventilation, and fire safety.

Just what else they regulate may vary in different jurisdictions. There is often confusion around consumer driven requirements that may or may not be authorized in the enabling legislation for a building code. In recent years the purview of many building codes has broadened, to include issues such as energy conservation and the needs of special population groups, particularly persons with disabilities. The extent to which, building regulations protect property or limit its potential damage is also a fuzzy issue. Their purpose is first and foremost life safety.

6. Description of the Regulatory Systems

As noted, all of the participating countries have some level of involvement with performance based building regulations. Obviously, there is a level of self selection as participation in the building regulatory domain was voluntary.

Members decided to undertake two surveys of the participating countries, both in order to understand the subtleties and differences between the regulatory systems, and to gauge and compare progress in implementing performance based regulations. The first survey was undertaken early in the network and domain activities, the second approximately four years later towards the conclusion of the project. The first survey had a limited response and the second is yet incomplete. An effort will be made to complete the survey and present its results at the CIB Congress in Helsinki in June and in the final report of the domain.

Nevertheless, various trends, conclusions and insights can be drawn from the incomplete survey results which are supplemented by country reports and discussions at the domain meetings.

6.1 An International Performance Based Building Code

Discussion was undertaken as to the possibility of a common shared international or pan- European performance based building code. The idea was resoundingly rejected for the foreseeable future.

Discussants noted the widely variable social, political, economic, administrative and legal contexts among different countries that make a common code impractical. Certainly there are also differences related to climatic conditions, building materials and building traditions. However, the intensity of the negative response may indicate additional underlying, less transparent, factors such as national, regional or even local pride and concerns about a loss of autonomy. All of this is not to say that the domain members did not see a broad basis for international cooperation. In fact there was full consensus on the benefits of cooperation and the opportunity to learn from the experience of other countries.

6.2 Prototypes for Performance Based Building Code Development

The Domain developed three prototypes for performance- based building code development that are described in the flow chart and survey form that follow. They constitute the second survey. Essentially for purposes of simplification and comparison, the pathways for performance based building code development were channeled into three prototypes that were designated cases A, B and C.

A represents those countries with the political will, the economic resources and the technical capacity to develop their own national model code.

B represents those countries at the opposite end of the spectrum in terms of very limited resources, internal technical capabilities, and perhaps lesser committment to performance based regulations. These countries are generally prepared to phase in various performance based building requirements into an existing regulatory system at a gradual and graduated pace.

C represents those countries that are prepared to revamp their building regulatory system to one that is performance based but from existing work carried out in other countries that can be adopted with minor adaptations or alterations.

All of the cases A, B and C involve some simplification and generalization and make various assumptions that obviously vary in the extent of their accuracy in the different countries. Probaby the most important assumption is that in all the cases key stakeholders in the building regulatory process have been engaged performance based regulations and are supportive. The point is that changing a building regulatory system requires a broad base of support. It can not be imposed top down as it will encounter resistance in the field. Neither will it evolve bottom up, as the field levels are unlikely to invest the time and resources or enlist the political clout to effecuate the change.

6.3 Country Updates

This section is based on reports at the domain meeting in Porto, Portugal in November 2004. Its content will be supplemented when the results of the second survey become available.

Table 1: Performance Based Building - Regulations Domain survey

1.	Preliminary Details:
1.1	Country Name: ______________________________
1.2	Other reference for building code:______________________
1.3	Last published edition (year): __________________________
1.4	Report submitted by: _____________ (name and e-mail)____________
1.5	Job title/Affiliation: ____
2.	Backround/Contextual Information:
2.1.	Brief description of code context in terms of 1.development 2 implementation. (please, attach a separate diagram as per the draft flow chart).
2.2	Brief description of social, political and legal context as related to above diagram (2.1).
2.3	Information regarding relevant administrative framework (who is doing what).
2.4	Information regarding future directions (adoptions, revisions, changes).
3.	Key Terms and Definitions (please include only keywords used in this from that need clarification` i.e. this is not for terms in the code itself).
4.	Code Structure and Contents
4.1	Structure of the code (diagram and/or tables).
4.2	Contents (outline as in table of contents, but with a short description of the main heading` e.g. 1-3 sentences).
4.3	Other technical notes.
5.	Key Lessons/Comments on Development and Implementation of the Code.
6.	Contacts and References
6.1	Contacts persons for further information and explanations.
6.2	Web sites for relevant information.
6.3	Other printed information that is available.

The Australian model will be discussed separately based on their extensive experience and a productivity commission study recently completed.

Belgium has a building regulatory system that is partially performance based. Local authorities continue to use prescriptive requirements. Performance based regulations are viewed as a means and not an end. Representatives see a combined system of prescriptive and performance based regulations evolving over time.

Hungary`s building regulatory system is primarily prescriptive. There is an energy survey requirement in place. That is performance based but not widely used. Representatives see a trend toward withdrawal from mandatory requirements.

Israel currently has primarily prescriptive requirements. However a government commission appointed after a social hall collapse recommended a substantial overhaul of the regulatory system including a comprehensive performance based code, and a process for evaluating new building technologies. Preparation of the performance based code is well underway. Fire safety requirements will remain mostly prescriptive.

The Netherlands also has a mixed building regulatory system that has been evolving over the past decade.

Poland has mandatory norms and standards, some prescriptive and others performance based that now constitute a building code of approximately 70 pages. Ordinances increase from year to year and the code grows.

Slovakia has a performance based code for the energy performance of building and is focusing regulatory efforts on CPD implementation.

The United Kingdom has an regulatory system based on 15 "approved documents" that are essentially performance based. "Deemed to satisfy" provisions are prescriptive but allow for equivalents. Experience shows private enforcers have resisted and complicated the use of performance based documents.

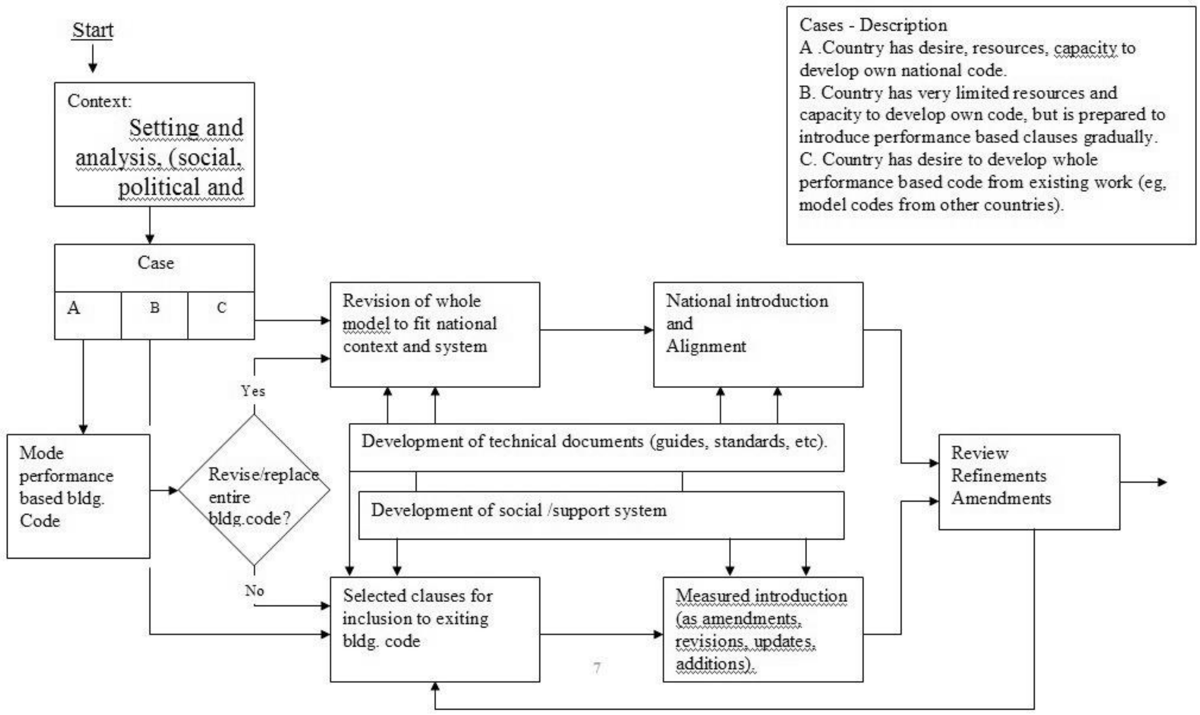

Figure 1: Possible performance based building code development prototypes for different countries

6.4 Reform of Building Regulation in Australia

In 1994 the Australian government established the Australian Building Code Board that vigorously pursued a performance based code. While the Board had no regulatory powers in and of itself, the code was adopted and used by the states and territories. This past year, 2004, the government of Australia undertook an extensive examination of the contribution of building regulation reform to economic efficiency and the construction industry.

The report found that the reform was successful in encouraging skill acquisition, reducing costs and encouraging and enabling innovation. It constitutes a strong endorsement of performance based building requirements.

However the report found that regulatory reform is far from complete. The report recommended:

1. further reducing, jurisdictional variations and reducing the, erosion of the codes uniform application by local planning decisions.
2. better articulation of the performance based requirements.
3. seeking ways to enhance local administration and enforcements.
4. reexamining the approach to property protection from fire.
5. better incorporating environmental requirements in the code.

As described in a PeBBu news article from February 2005 the report further found that:

The majority of the performance: requirements contained in the Code do not provide readily measurable outcomes nor specify verification methods. The standards are more accurately described as "principle" based, specifying broad, but not measurable, targets or objectives for building. For instance, for structural provisions, the Code does not specify precisely the loads that must be withstood by any building (such as wide-speed loads or dead loads)–rather it requires that the building must withstand "actions to which it may reasonably be subjected". This means it is not possible to judge whether objectives have been met and gives little guidance to building practitioners.

The report advocated resolving this issue and several other weaknesses in performance aspects of the code as part of the future work program. Overall the examination endorsed the performance based approach as "having the capacity to deliver significant benefits to the building industry and consumers".

7. Enforcement and Compliance

Enforcement and compliance are essential to the efficacy of any building regulatory system be it prescriptive or performance based. Generally, enforcement and compliance are based on the requirement for a building permit for any construction activity. It is the request for a permit, from the authority having jurisdiction, usually the municipality. That sets the system in motion. Plans are submitted usually as part of the permit request. Plans are reviewed and approved before a permit is issued. This is most often where the public and various building practitioners interact with the regulatory officials regarding the code and its requirements.

Once a permit is issued and construction begins there are likely periodic inspections in the course of the work. Once completed the construction is again inspected for full compliance of the work with the code before a certificate of occupancy or completion is issued. If work is not in accord with the code it must be corrected or done again. There are of course numerous possible variations on the process, but these are its essentials for almost all building work. Without a system of enforcement and compliance. The code is of little or no significance. Having said that, there are never the less wide differences in the extent and degree of enforcement in different countries and in some instances in different areas of the same country. In remote, rural and agricultural regions and areas where people tend to build

themselves rather than employ an architect, engineer and building contractor, municipalities are less likely to have effective code enforcement and compliance. Even in these areas public buildings, schools, large commercial buildings and factories are more likely to employ building professionals and will try to conform with some level of code compliance even if there is no enforcement system.

Other significant differences in enforcement and compliance revolve around the type or extent of work that is enforced. Wherever there is any enforcement it addresses first and foremost new construction. Here too there is the greatest relevance to the type of code requirements. The building regulation system likely also addresses additions, alterations and repairs to existing buildings. Generally maintenance work is not regulated but any other work involving change to exterior facades structural alterations or change to the electrical, plumbing, mechanical or fire protection systems of the building is likely to be officially regulated. The way in which minor work is defined and the extent to which it is regulated varies widely. Occasionally a functional distinction is whether the work is carried out by the owner/occupant or a building professional. Electricians, plumbers and heating ventilation and air conditioning contractors in places where these occupations are licensed are more likely to comply with permit requirement even though it is the owner occupants who are more in need of the supervision of their work and its code compliance.

Historic buildings are likely to be exempted from compliance with portions of the building code Performance based regulations are more likely to provide the flexibility that will enable compliance.

8. Satisfaction Level of the Various Practitioners

The issue of performance based versus prescriptive regulations pertains primarily to architects and engineers and to a lesser extent to building contractors. It also pertains more to large, unusual and sophisticated buildings than to residential, low rise, standardized building and construction.

Manufacturers of building materials and products are also relevant clients of the performance based code.

The satisfaction level of these practitioners with performance based regulations tends to vary. All desire fast building review approvals. The extent to which they themselves and the local regulatory officials are familiar and comfortable with the performance aspects of the codes is a function of time and willingness to learn and innovate.

In general there will be a segment of the building community that is resistant to change and will constantly pose the question:

"What do they really want?" Accordingly it is helpful that a new, performance based requirement be accompanied by deemed to satisfy provisions that are also prescriptive.

9. Gaps and Barriers

Given that the introduction of performance based regulations is often a gradual process, the new regulations may not address what some building professionals regard as the most important issues or those that most interest them, Similarly when they are partial or fragmented they can not comprehensively address all code requirement issues. There may be a need to merge performance requirements with prescriptive ones for various building systems or materials. Performance requirements by their nature often require greater effort by the practitioner to demonstrate compliance, In addition because they are new the performance requirements are less familiar and have not yet stood the tests of time and use by the various building professionals. Most of all it is difficult to verify compliance with performance based regulations, This last issue will be discussed more extensively in another section.

10. Leading Research Priorities

Each of the performance based building network domains was requested to recommend research priorities in their field. For the building regulations domain this proved not to be a difficult task. The experience of the various countries at various stages and with different degrees of success in implementing performance based regulations provided a convenient platform for the discussion of research priorities.

There was wide agreement on the importance and benefits of network and the potential for sharing the results of research in a number of areas. The subjects that emerged as research priorities were agreed upon based on the needs and wants of at least several of the participating countries:

These were as follows:

1. Verification methods to demonstrate that the required performance was achieved.
2. Risk-informed regulations.
3. Methods for addressing acceptable or desirable levels of performance in existing buildings.
4. Creating a systems approach to performance requirements with quantifiable levels of performance.
5. Methods for evaluating the economic impact or feasibility.
6. Development of certification models and other means of approving designs and products.

10.1 Verification Methods

The leading research priorities are heavily weighted toward verification. In order to verify compliance we need to be able to measure performance.

In this list of research priorities verification repeats itself with different, emphasis in four of the six priorities. Only risk informed regulations and methods for addressing performance in existing buildings address the objectives part of performance. Verification methods reflect a level of involvement and understanding of the performance approach that go beyond the declaratory stages about the advantages of the performance approach. Performance requirements, as noted, are usually stated as objectives. Objectives are generally qualitative.

However enforcement and compliance obligate verification that is quantitative. Herein perhaps lies the Achilles heel of performance based regulations; i.e. the difficulty in evaluating and ascertaining compliance. Qualitative matters, by their nature involve a large degree of subjectivity. Requirements as stated in building regulations can not tolerate fuzziness or lack of clarity. Ultimately the code official or building inspector needs to be able to make compliance determinations that are cleat cut, consistent and defensible under administrative review and legal challenge.

Quantitative requirement can be matched to qualitative objectives of performance based building regulation but it is difficult if the advantages of the performance approach are not to be lost in the process. Key performance indicators are a promising approach that may be able to bridge the gap. They need to provide simple yet coherent criteria that set the acceptable level or range of performance in ways that can be verified by tools at the disposal of the regulatory community. Generally key performance indicators involve benchmarking a given situation so that targeted performance can be assessed and compliance determined.

While technical performance criteria and verification methods have been proposed in a number performance based regulatory areas, particularly energy conservation, domain members demonstrated their keen interest in the expansion of verification methods as research priorities, the results of which can be shared internationally.

This is a significant challenge that will impact the future success of the approach.

11. Conclusions

Performance Based building regulations have broad support in the international arena. Different countries are proceeding according to separate prototypes and at varying paces in incorporating performance based regulations into their building codes. Most are not doctrinaire in their approach and are prepared to mix performance based regulations with prescriptive ones according to their understanding and experience as to which will best serve them.

While the idea of an international performance based building code was resoundingly rejected, there was full agreement regarding the advantages of international cooperation and shared research. The strongest future research priorities revolved around verification methods that provide quantitative indicators for qualitative objectives. International cooperation should continue and these and other research priorities should be aggressively pursued.

Acknowledgements

This paper was developed from discussions of the building regulations domain of the performance based building network and is based on the cumulative experience of the participants.

Special thanks are due to Dr. Greg Foliente, CSIRO, Australia who suggested and formatted the survey, Dr. Aleksander Panek, Warsaw University, Poland who co-chaired with me the Porto Portugal meeting and Mr. John Carson, CSIRO, Australia who presented the Reform of Building Regulation report by the Productivity Commission of the Australian Government at that meeting.

Performance-based procurement in Denmark

Kim Haugbølle
SBi – Danish Building Research Institute (email: khh@sbi.dk)
Hørsholm, Denmark

Abstract

Although researchers, practitioners and authorities have for decades discussed the performance approach as a means of improving productivity, quality and innovation in building, the expectations have not been fully met. First, this paper will scrutinise the Danish model for performance-based building. This paper will stress that the Danish building legislation is by and large performance-based. Second, the paper will identify new trends and challenges to traditional procurement. It will be pointed out that especially integrated teams are challenging traditional procurement. Third, the paper will point out that strong elements of the prescriptive approach are present in professional practice. The paper will suggest that the relationship between prescriptive building and performance-based building is not a dichotomy but rather a continuum.

Keywords: Building Regulations, clients, legislation, procurement methods, contracting

1. Introduction

The issue of performance based building is not new in Denmark or internationally. Encouraged by the directors of the four Nordic building research institutes, the CIB Working Commission W60 was established in 1970. W60 defined the performance approach as follows [1]:

> *"The performance approach is, first and foremost, the practice of thinking and working in terms of ends rather than means. It is concerned with what a building or building product is required to do, and not with prescribing how it is to be constructed." (p. 4).*

In the following years, a number of articles on the performance concept was published. In 1974, the Danish Building Research Institute issued SBI Directions 94 on the why's and how's of the performance concept including the first performance-based specifications of requirements for non load-bearing internal walls and windows [2]. Under the leadership of E. J. Gibson, W60 published a number of reports on the performance concept and its terminology see e.g. [3, 4]. It was expected that prescriptive specifications would largely be replaced by performance-based specifications when the necessary fund of scientific knowledge was available. In reality, the picture has become rather blurry.

2. Setting the context

The Danish building and housing cluster is generally characterised by many small firms and a few large companies, but the industrial structure has been changing considerably in recent years [5]. Despite the current changes taking place, the building process is still dominated by the professionals, notably the architects and consulting engineers. Thus, the Danish building process has more in common with the British building process with its emphasis on consultants and cost-control than the French building process with its emphasis on contractors and cost-reduction. To echo Winch & Campagnac [6] and Winch [7], the Danish building and housing cluster can be characterised more as a professional system than as an industrialised system.

A number of policy studies have analysed the challenges facing the Danish building/housing cluster, see e.g. [8]. Most of these studies have been shaped more or less directly by the pioneering work of Michael E. Porter on the competitive advantage of nations and regions, see e.g. [9]. Although Porter's original diamond model of determinants of competitive advantage has been partly abandoned, the focus on clusters has prevailed. Instead, the Danish analyses of the building/housing cluster has turned towards more actor-oriented analyses focusing on the value chain. Figure 1 synthesises the framework deployed in a number of Danish studies of the building/housing cluster.

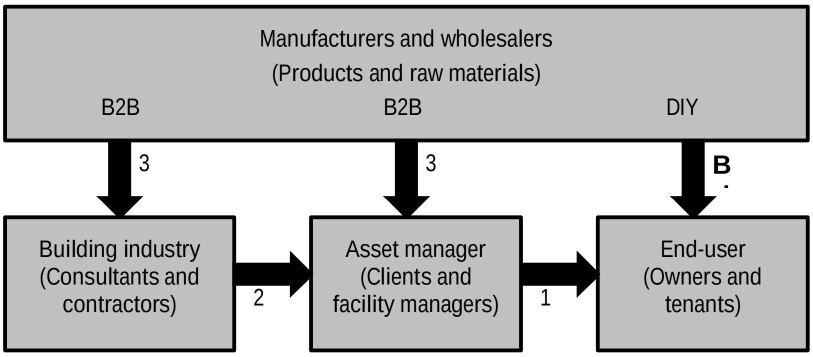

Figure 1: Markets and actors in the Danish building/housing cluster

The framework provides us with an overview of the *context* in which the actors of the building process have to operate. Framed by governmental regulation and the knowledge system, the building/housing cluster can be divided into four subcategories of actors linked through three separate markets. The four groups of actors are:

- The end-users consisting of e.g. owners of single-family houses, tenants, and employees.
- The asset managers of private, public and semi-public organisations running existing facilities and acting as clients of new buildings and refurbishment.
- The building industry consisting of planners, engineers, architects, contractors etc.
- The manufacturers including wholesalers of construction products and raw materials.

Each of the subcategories of actors is in principle linked through three separate markets of services and products. The three markets are:

- 1. A property market between end-users and asset managers.
- 2. A building market between asset managers and the building industry.
- 3. A product market between manufacturers and the building industry, asset managers and end-users.

On each of the three markets, different actors will procure and produce various products and services. A proper interpretation and translation of one set of performance requirements (e.g. from users to clients) to another set of requirements (e.g. from clients to the building industry) is crucial for creating best value.

3. The regulatory framework

The cornerstone in the Danish regulatory framework of building is a performance-based building legislation divided into three levels. The first level is a fully performance-based Building Act [10]. It should be noted that several other types of legislation are relevant when building in Denmark e.g. the Planning Act, the Act on the Preservation of Ancient Buildings, and the Working Environment Act. The Building Act covers new buildings, extensions to buildings, conversion of buildings and other alterations, any changes in the use of buildings that are significant, and demolition. The purpose of the Building Act is to:

- Ensure that a building is built and furnished in such a way that it provides sufficient security with respect to fire, safety and health.
- Ensure that buildings and surroundings are given a reasonable quality with respect to the intended use and proper maintenance.
- Promote actions to increase productivity.
- Promote actions to avoid unnecessary resource consumption in buildings.
- Promote actions to prevent unnecessary use of raw materials in buildings.

The Building Act defines when a building permit, a notification or no action is needed in order to commence and take a building into use. The Building Act describes the obligations of a client, delegates responsibilities to the local authority, describes sanctions in case of violations etc.

The second level of the regulatory framework is the Building Regulations, which are divided into BR-S 98 [11] for small buildings or dwellings and BR 95 [12] for all other types of buildings. In general, the Building Regulations are performance-based. Each chapter in the Building Regulations will begin by stating the targets to be met, for example [12]:

> *"4.1.(1) Buildings shall be designed and arranged so that, having regard to their use, satisfactory conditions are achieved for everyone with respect to safety, health, accessibility and use, and for cleaning and maintenance." (p. 41).*

In many cases, the commentary will point to various sources of information for recommendations of approved ways to comply with the building regulation. The commentary will for example refer to the SBi Directions, standards issued by Danish Standard or circulars and Orders from ministries and agencies, especially the Ministry of Labour.

In general, the Building Regulations do not stipulate solutions. However, you can find a few examples of provisions that directly stipulate specific solutions. One example is a provision that directly stipulates the use of lifts in multi-storey buildings. In the Building Regulations, you may also find a few examples of solutions not to be used. For example no pipes are allowed through the floor in the wet part of wet rooms due to poor performance of known practices.

The third level of the performance concept in Denmark is the SBi Directions issued by the Danish Building Research Institute. The SBi Directions describe various ways to comply with the Building Regulations. They are not mandatory, but usually clients, consultants, contractors etc. will follow the directions. The SBi Directions can be grouped in three main groupings:

- The first group of SBi Directions describes specifications and solutions that are recognised to comply with the requirements stipulated in the Building Regulations.
- The second group of SBi Directions describes methods and instruments for verifying if buildings satisfy the requirements stipulated in the Building Regulations.
- The third group of SBi Directions includes handbooks or guidelines to be used for planning and executing building works or investigating and assessing specific problems for example related to the indoor climate.

4. Procurement

Procurement can take place along different paths and include different forms of contractual and functional relations (for more details see e.g. [13]):

- Traditional/separate trades contracting.
- Main/general contracting.
- Design-build contracting.

Although practice differs, tendering will normally include five types of documents. The documents will be held together by a general document referring to all the relevant documents. The documents will be referred to in prioritised order in case documents are in conflict:

- General conditions describing the legal conditions for the work. Usually the general conditions will refer to the agreed documents described below.
- Special conditions describe various exemptions from the agreed documents, but may also hold certain special technical specifications.
- Technical descriptions and specifications of the end result and work to be done.
- Drawings.

- Appendices like time plans etc.

In Denmark, contracts and agreements are generally drafted according to general conditions described in ABR 89 for consulting services [14], AB 92 for provision of works and supplies [15], and ABT 93 for turnkey contracting [16]. ABR 89, AB 92 and ABT 93 are agreed documents acceded to by the government, local authorities, counties and all relevant parties of the building process. As opposed to private clients, public clients are obliged to follow the agreed documents and may only diverge from the agreed documents in extraordinary circumstances.

The agreed documents define the liabilities of consultants and contractors with respect to delays and defects. If the consultant is exceeding time limits without a justifiable claim for extension of the time limit, the contract can stipulate a penalty that the consultant shall pay to the client [14].

The liability of the consultant ceases 5 years after handing-over of the building or the works in which the error or the negligence occurs. Unless otherwise stated in the contract, the liability of the consultant is limited to DKK 2.5 million. The consultant is liable for damage when such damage is the result of not showing due skill and care. Thus, the consultant is not liable for damage arising from conditions which cannot be considered generally known in professional circles, for accidental damages or for errors committed by the client or by others engaged by the client. The exact interpretation of the provisions on liabilities is left to arbitration tribunals and the law courts [14].

The contractor's liability in case of delays are stated in AB 92 [15]:

> *"**§ 25.** Delays which do not entitle the contractor to an extension of time limits shall be considered the liability of the contractor.*
>
> *Subs. 2. Where provisions have been made for liquidated damages or other special penalties, no additional claims arising out of delays can be made in excess thereof.*
>
> *Subs. 3. Where no provisions have been made for liquidated damages or other special penalties, the loss suffered by the employer shall be assessed in accordance with the general provisions of Danish legislation on compensation." (p. 7).*

Cessation of the liability for defects takes place 5 years after the handing-over of building works and attendant engineering works. The contractor is liable for defects if the work has not been performed in accordance with the contract, with due professional care and skill or in accordance with any instructions given by the employer. The same shall apply whenever the contractor has failed to provide other services agreed on in relation to the work [15].

The provisions on turnkey contracts or design-build contracts set out in ABT 93 [16] largely follows the general conditions for the provision of works and supplies within building and engineering (AB 92), but differences do exist for example regarding securities.

5. Trends and challenges: Integrated teams

Looking at the building process in a longer time perspective may illuminate some of the changes that have occurred in the past decades and the challenges facing the procurement of buildings. The building process has undergone changes along four lines:

- Process: The conventional picture of the building process as a sequence of distinct phases (brief, design and construction) is being challenged. Increasingly, a value chain perspective is being followed thereby introducing new ways of organising building projects.
- Actors: New actors like facilities managers and users have entered the building process. Others have had their roles redefined for example contractors or manufacturers who often carry out part of the detailed design.
- Issues: A number of new issues like accessibility and sustainability have emerged or are emerging as new requirements.
- Products: Manufacturers have constantly introduced a long range of new products. Furthermore the Construction Products Directive is likely to stimulate a more open European internal market for building products.

Since the beginning of the 1990s, a number of development initiatives have aimed at improving productivity and quality in building through process development. The shortcomings of the conventional methods for procurement had highlighted the need for an integrated approach towards design and construction of buildings. In the past 10 years, a number of different partnering schemes have appeared along the conventional methods of procurement. Although the term partnering did not enter the vocabulary until the late 1990s, it was especially the public development programme Process and Product Development in Building (PPB) running in 1994-2002 that spurred on an increased focus on process development and functional integration of design and construction. The programme along with other experiments during the 1990s included a wide range of new production concepts and forms of co-operation like lean construction, partnering, value management and workshop design. Despite their differences in scope, the experiments shared an ambition of integrating the value chain across professional boundaries including closer and more substantial collaboration with the client.

These experiments and initiatives marked the start of a hybrid practice of design and build contracting. However, a number of architects and engineers e.g. from the PPB consortia complained that the vertical/horizontal integration is just design-build contracting in disguise and favours the large contractors. Thus, the Danish one-liner ”partnering eller partering” (translates into something like “partnering or cannibalism”) became a widespread slogan for the early discussions on integrated teams. Despite the obvious clashes of interest, the trade associations of consulting engineers, architects, small contractors, large contractors and clients managed to issue a common guideline on partnering in 2001 [17].

On January 1 2004, the guideline was followed by a new amendment making it mandatory for governmental building agencies to systematically assess if partnering is an appropriate way to procure a building project [18]. The amendment was followed by a guideline differentiating between two forms of partnering: “early partnering” or “late partnering” [19]. In early partnering, contractors will be involved before the client and his consultants have drafted a proposal. In late partnering, the client and his consultants have drafted a preliminary project. It is worth noting that in both cases the conventional methods of procurement are used, but contracts following the agreed documents on general conditions ABR 89, AB 92 and ABT 93 may need some adjustments. Thus, partnering is not a new procurement method but rather a new way of co-operating in a building project based on existing procurement methods.

6. An example from practice: Axel Heides Gård

As the Øresund Bridge between Copenhagen in Denmark and Malmö in Sweden was opened, an important precondition for an increased integration of the Øresund Region was put in place. On behalf of the Danish and Swedish governments two parallel and similar building projects in Copenhagen and Malmö were studied by a joint Danish/Swedish research team in order to identify differences and similarities of building in the two countries. Here only the Danish case Axel Heides Gård in the planning and design phases will be treated (for more details see [20]).

Axel Heides Gård has a unique location in Havnestaden in the heart of Copenhagen and with immediate proximity to both the harbour and the conservation area of Amager Fælled – a huge recreational area. Havnestaden used to be a heavy industrial facility, but the facility closed down and Havnestaden is now under complete restructuring and rebuilding as a new uptown area of mixed use for light services and dwellings.

The building project Axel Heides Gård was developed by Kuben, which is one of the largest and most experienced private developers in Denmark. Kuben employs around 160 people and its services include development of building projects, client services and facility management. The company has more than 30 years of experience of building homes for people. Kuben is a non-profit organisation owned by two non-profit foundations, but it is not a social housing association.

The ambitions of Kuben for Axel Heides Gård was to develop dwellings for young newly established families and senior citizens at an affordable rent. The dwellings are publicly supported tenants-owned dwellings meaning that there is a fixed maximum price for the dwellings. The project includes 84 dwellings with an average size of 98 m2 distributed on 16 different types of dwellings of varying size. Axel Heides Gård is a genuine and undemonstrative residential area. In this respect Axel Heides Gård is a clear representative of good Danish building practice.

After Kuben acquired the site, a team of consultants was assembled. Kuben employed a small architectural practice and a medium-sized consulting engineering company to develop a project proposal. Both companies including the specific employees involved had been working together with Kuben time and again. Thus, mutual trust had been built up over time and an informal partnership had been formed. Consequently, the consultants had developed a rather good sense of the usual requirements of the developer and good working relations with Kuben.

The contract with the consultants followed the agreed document on consulting services ABR 89 with two notable differences. First, the building project was going to be tendered as a design-build contract but the winning contractor was obliged to take over the consultants hired by Kuben without opportunity to change the contract with the consultants unless sanctioned by Kuben. This way Kuben could avoid the typical problem of design-build contracting where the consultants are squeezed and the project "massaged" by the contractor to cut costs but on the expense of the quality of the project. Thus, Kuben as client could maintain its right – and if necessary exercise that right – to decide in every detail the concrete solutions in order to ensure best value and at the same time include the experience of the contractor on buildability. Second, the contract sum was lower than usual as a consequence, because part of the typical services of the consulting engineer was to be delivered by the contractor.

During a three-months period, Kuben and the consultants developed the project proposal. As is common practice, the project proposal was rather detailed. Geotechnical surveys had been carried out, the overall design of the residential area was in place, floor plans were ready, facades including choice of materials and glazing were decided on etc. Since the proposal called for exemptions from the urban planning, negotiations with the municipality had to be undertaken and a hearing among the neighbours carried out. Eventually, Kuben could send in the so-called Scheme A – an application for public financial support for the project.

When the application was granted, Kuben started to market the dwellings. In order to start building this type of project, at least 75 % of the dwellings needs to be sold and a tenants-owners association has to be established. Due to the inherent lack of affordable accommodation in the metropolitan area, the dwellings were quickly sold out. When the tenants-owners association was established, the association took over the role as client and thus the risk of the project. Bringing the future tenants-owners into the building process also brings in new requirements to be dealt with. Since Danish customers are very demanding regarding their homes, a number of options for individual choices in the dwellings have to be available. Thus, in accordance with usual practice (at least outside the social housing sector) the design-build contractor offered a fixed and prescriptive catalogue of possible individual choices on kitchen interior, bathroom equipment, surfaces, floors etc.

Meanwhile, Kuben tendered the project and commenced the detailed design of the project together with the design-build contractor. In another six-months period, the detailed design was carried out in close collaboration between the developer, the consultants and the contractor. During this period, a number of detailed requirements were fixed regarding for example windows so that the contractor could order these windows from the manufacturer. Bringing in the expertise of the contractor on constructability, other more complicated issues like the exact design of the terraces of the penthouse dwellings being part of the roof of the building were resolved as well. In this problem-solving activity, more or less explicitly formulated performance requirements were debated against perceived problems and specific solutions in a continuous search-and-learn process.

As a paradigmatic example of the professional practice within Danish building, Axel Heides Gård illustrates two notable observations. First, although Danish building projects are procured within a largely performance-based legislation, there are strong elements of the prescriptive approach present in Danish building projects too. This is due to the wish of clients to exercise control of the end product, the administrative practices of municipalities, the dominant position of consultants in the Danish building process, and the elaborate involvement of the end-users.

Second, in many Danish building projects the consultant will set out relatively detailed descriptions of the end product, while the contractor will often be responsible for some of the detailed design, construction methods, choice of products etc. But even a largely performance-based design will have to be turned into a prescriptive design at some point in the project. If not before, then at least when the building worker has to decide what materials, colours etc. he is going to use to produce a kitchen, bathroom etc. Thus, the issue of prescriptive versus performance-based building is not an either-or issue, but rather a continuum stretching from performance-based to prescriptive building. Within this continuum, a negotiation space exists which can be exploited by the actors of the building process to be more or less performance-based. As the project proceeds more and more options will eventually be cut off by a prescriptive decision (see Figure 2).

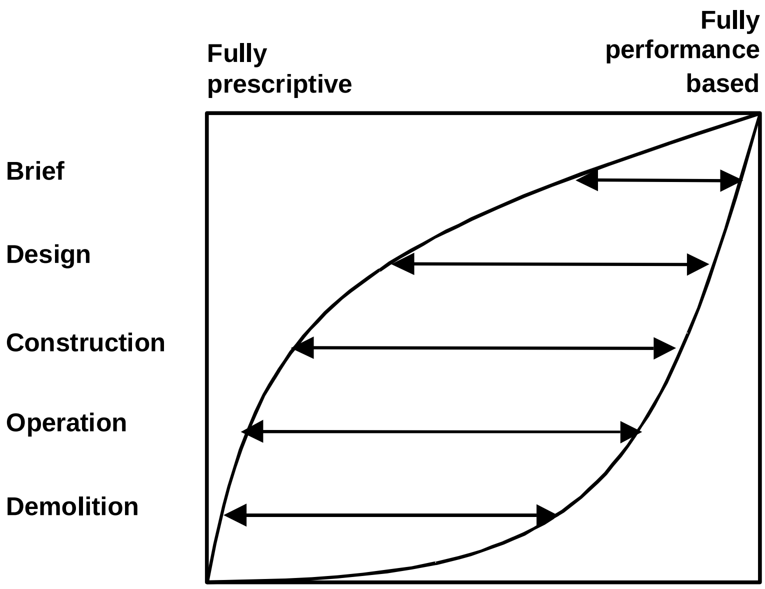

Figure 2: Negotiation space

7. Conclusion

First, this paper has scrutinised the Danish model for performance-based building. The cornerstone in the Danish regulatory framework of building is a largely performance-based building legislation divided into three levels:

- The Building Act.
- Building Regulations (BR 95) and Building Regulations for Small Dwellings (BR-S 98).
- SBi Directions describing various ways of complying with these regulation.

Although the Danish building legislation is largely performance-based, a few examples of direct prescriptions of solutions as well as examples of non-solutions can be found in the Building Regulations.

Second, this paper has identified a number of new trends and challenges to traditional procurement. A value chain perspective is challenging conventional pictures of the building process, the role of the actors is being redefined, new issues are emerging, and still more new products are being introduced. In the past 10 years, traditional procurement has come under pressure from especially partnering or integrated teams.

Third, this paper has examined the professional practice in Danish building. Although Danish building projects are procured within a largely performance-based legislation, strong elements of the prescriptive approach are present in Danish building projects too. This is due to the wish of clients to exercise control of the end product, the administrative practices of municipalities, the dominant position of consultants in the Danish building process, and the elaborate involvement of the end-users. Furthermore, the issue of prescriptive versus performance-based building is not an either-or issue, but rather a continuum stretching from performance-based to prescriptive building. Within this continuum, a negotiation space exists which can be exploited by the actors of the building process to be more or less performance-based. In conclusion: You can keep the performance-based door open for as long as you like, but you can't keep it open forever!

Performance-based building from a Mediterranean perspective

Abstract

One of the strongest points of PeBBu is having identified within the network four platforms for discussions which correspond to four similar geographic areas (North, South, Centre, East) to support the studies carried out in the framework of the project's scientific domains.

As regards the Mediterranean Platform (including Italy, Portugal, Spain, Greece, Israel and Slovenia) the two workshops held in Milan, Italy, in September 2003 and September 2004, highlighted some common regional factors that affect the concept of performance as perceived in this Region more than elsewhere as well as the barriers to the full implementation of this concept, which can also be found to different extents in other Countries.

Very briefly, some of the factors that most affect the performance concept, are:

- the influence of hot climate on materials and components behaviour and on design itself;
- living habits related to climate, as a factor affecting urban and architectural design;
- seismic risks;
- the need to establish a greater consistency between the most recent regulations based on the performance philosophy and more restrictive regulations concerning the protection and preservation of the cultural heritage.

As to barriers, in many South-European Countries the adoption of performance-based regulations is being seriously delayed and it is evident that the concept itself does not have the same meaning everywhere.

There also exist barriers of an economic nature and barriers linked to the specific culture of customers who are not able to clearly express their needs and, last, there is the problem of responsibility. In fact, whenever the designer is the sole responsible, it is evident that, whenever he can choose, the prescriptive approach proves to be safer than the performance-based one.

Keywords: construction, performance, materials, design, regulation

1. Overview

The Performance-Based Building (PeBBu) Network is funded through a Network subsidy within the Growth Programme that is part of the 5th Framework Research Programme of the Commission of the European Communities.

The main objective of the PeBBu Network is the “Stimulation and pro-active facilitation of international dissemination and implementation of Performance-Based Building in building and construction practice”, and in that context to maximisation of the contribution to this by the international R&D community.

The main components of this program infrastructure are, first of all, the international programming and coordination of research projects in nine scientific domains:

Domain 1: Building Materials and Components

Domain 2: Indoor Environment (former Building Physics)

Domain 3: Building Design

Domain 4: Built Environment

Domain 5: Organisation and Management

Domain 6: Legal and Procurement Matters

Domain 7: Building Regulations

Domain 8: Innovation

Domain 9: Information and Documentation

Late in 2003, the domains were brought down to six. In fact, it was decided to terminate three out of these nine domains (Domain 4, 5 and 9) due to various reasons such as an overlap of information in other domains, insufficient past or ongoing international research on the interface between domain themes and PBB.

- Involvement of target groups/stakeholders from the start of the programme through three User Platforms;
- Mapping of national and international research as far as related to – aspects of – Performance-Based Building;
- Four Regional Platforms in Europe to act as the bridge to and the initiator of aligned national activities;
- Network Management, including the establishment of a Network Steering Committee, a Technical Committee and a Network Secretariat.

2. Four Regional Platforms in Europe

In order to stimulate and facilitate national activities, to facilitate the input of typical national and regional characteristics into the international programming of projects and to prepare for the necessary future national implementation activities, four Regional PeBBu Platforms were established in the participating EU and EU Associate countries:

Region 1 (North Europe): Sweden, Finland and Denmark
Additional countries to attract: Norway, Iceland, Latvia, Lithuania and Estonia

Region 2 (West/Central Europe): UK, Ireland, Netherlands/Belgium, France, Germany
Additional countries to attract: Switzerland and Austria

Region 3 (East Europe): Hungary
Additional countries to attract: Poland, Czech Republic, Slovakia, Romania, Bulgaria and Slovenia

Region 4 (Mediterranean Europe): Spain, Portugal, Italy, Greece, Israel
Additional countries to attract: Cyprus and Croatia.

After applying to become a member in PeBBu Task 16, Slovenia has now definitely been relocated into the Mediterranean Platform. The reasons behind this relocation are the issues and topics dealt with in the Platform that are very close to the Slovenian reality.

At the end of the second year of the project, nearly all the objectives established in advance for the four Platforms were attained in the mid-term.

In particular, as regards the Mediterranean Platform, the most interesting results came out from the two Platform Workshop meetings, held in Milan in September 2003 and in September 2004.

The meetings focused on the discussion about the first State-of-the-art report as produced by the national partners of the Platform, centred around the topics dealt with by the nine scientific domains.

By comparing the different national scenarios, it is possible to outline common needs which are presented as specific recommendations in a Mediterranean perspective, in order to integrate the already accomplished scientific studies.

3. The Mediterranean Platform: the context of PBB

The state-of-the-art of performance-based building in the Mediterranean Platform, which includes Italy, Spain, Israel, Portugal and Greece outlines a very interesting and diversified scenario.

Historically, the performance-based approach originates everywhere at the beginning of the 70s, through different studies and researches and thanks the first voluntary standards. Over the following years, due to political and social issues, in some countries this process went through a setback, while in some other countries the performance concept has slowly but constantly got a footing.

In particular, starting from the great energy crisis which occurred in the late seventies, and over the next decade, nearly all Mediterranean countries provided themselves with laws dealing with energy-saving aspects.

In most cases, these laws were of a restrictive and prescriptive nature, due to the actual urgency of the situation and the culture of the time.

On the contrary, in Portugal, thanks to the favourable climatic conditions demanding for lower energy consumptions with respect to other countries, RCCTE (Regulations on the Characteristics of the Thermal Behaviour of Buildings) was at the same time focused on energy saving and thermal comfort of buildings.

Over the following years, environmental and sanitary emergencies and the strong cultural thrust of the CPD allowed to integrate the concept of mere energy saving with the specific needs of environmental sustainability and efficiency. Therefore, today the greatest efforts are concentrated on the revision of old legislations and the implementation of European Directives, among which Directive 2002/91/EC.

Over the time, in Spain many measures have been taken to optimise energy costs, to preserve the environment and to ensure the security and healthiness of living and working places.

The Plan for Public Housing (1998 – 2001) envisaged pilot schemes to promote sustainable homes where economical objectives met the need to preserve the environment. This policy was meant to develop suitable technologies in order to reduce the use of those materials whose production implied a risk to the environment, to reduce energy and water consumptions and to draw attention towards the specific bio-climatic conditions of the design site.

Also the development of photo-voltaic energy in the residential sector has been regulated with specific laws.

In Portugal, the E4 Programme contains a sub-programme for the building sector, the "National Energy Efficiency in Buildings Programme".

One of the activities within this programme consists in reviewing the "Regulation on the Characteristics of the Thermal Behaviour of Buildings"(RCCTE) of 1990 and the "Regulation on the Energy Systems for Air Conditioning of Buildings" (RSECE) of 1998. Other activities include the promotion of energy efficiency measures in public buildings and the promotion of the use of renewable energies in buildings.

Portugal is also considering introducing building energy certification.

In Israel, the amount of energy consumption in buildings is on the rise, due to a steady improvement in the standard of living and to the influx of immigrants in recent years.

To face this situation, the Ministries in charge are currently promoting a series of research projects with the aim of providing appropriate guidelines on the subject.

One of the topics that are being developed concerns the optimization of the use of sunlight in order to provide maximum comfort with a low energy consumption.

Another topic is about energy design tuned to particular hot-moist climatic conditions: the Israeli experience might be very useful to many other countries sharing the same conditions.

As far as Greece is concerned, the main framework of reference for energy-efficiency measures in buildings is the action plan called “Energy 2001”; a key action of this plan was the elaboration of a new national building energy code, aimed at replacing the existing thermal insulation regulation. According to other actions of "Energy 2001", including the reorganisation of energy management procedures in the public building sector, all public buildings needed to have an energy officer specifically appointed to deal with the energy management. This Plan has been supported by legislative initiatives, a draft Presidential Decree was prepared to establish financial incentives for energy-saving measures in buildings.

Ministerial Decision 21475/4707/98 was passed to improve energy efficiency in buildings in order to limit their contribution to CO_2 emissions. It introduced a variety of new measures in the building sector, including energy certification and energy audits of buildings, energy billing based on actual consumption, regular inspection of boilers, and third-party financing of energy conservation and renewable projects in public buildings. As of 2000, new public buildings – and as of 2004, all public buildings, including existing ones – are required to have an energy certificate, i.e. an energy identity card, stating the energy performance of the building based on an energy audit. Several measures have been introduced also outside the “Energy 2001” framework.

As far as energy-related topics are concerned, the Slovenian experience was quite different from the other countries.

First as part of former Yugoslavia, then as a country involved in the big conflict which broke out in the early nineties, Slovenia gained its “energy identity” in 1999 with the adoption of the new law known as “Energetski zakon”

Through appropriate measures, the Slovenian energy policy is giving priority to the use of renewable types of energy and energy resources that contribute to a lesser extent to environmental pollution.

The energy policy shall be focused on eliminating the consequences and replacing environmentally unfavourable technologies of using energy resources, whose combustion products accelerate the greenhouse effect (CO_2) and emit nitric oxide (NO) to the atmosphere.

This policy shall encourage the use of alternative resources at national level, and the use of smaller units at local level.

4. Main results from the Platform

The most interesting information emerged from the critical interpretation, from a Mediterranean perspective, of some of the results produced within the former nine scientific domains of PeBBu.

4.1 Materials and Components

The climatic difference between Mediterranean European countries and Northern European countries deserves to be further developed with a focus on the way it may possibly affect the behaviour and durability of materials and components.

Traditionally, laboratory tests are focused on the assessment of materials based on the influence of cold climates, while, for example, the effect of high temperatures on durability is not sufficiently investigated.

This aspect is particularly important also in the light of the climatic changes that are taking place at present that, according to meteorology experts, are accountable for the progressive tropicalization of large areas of the Mediterranean region.

4.2 Indoor Environment

Culturally and technologically advanced countries are nowadays paying a big attention to the healthiness of the indoor environment.

Over the last years the scientific production witnessed a great boost, first of all centred on the solution of the issues related to what the Americans called the “sick building”. Today, the culture of “biology” is directing studies towards the realization of a bio-building, that is to say, a building conceived and realized with technologies, materials and performances, that are not harmful to man and the environment over the time.

These last-generation studies are based on a performance approach.

The main difficulty today is represented by the overcoming of the prototype extent in order to turn the results of research into means and tools to be made available to designers and contractors.

Safety and healthiness requirements, such as fire-safety, acoustics, lighting, energy, hygro-thermal/moisture, should be reconsidered in the light of the specific aspects characterizing the Mediterranean area. Climate, traditions, culture are all factors affecting human habits and behaviour.

4.3 Building Design - Design of Buildings

There are at least two subjects that are quite relevant from a Mediterranean perspective.

First, the aspect related to safety during the construction phase. The building sector in Mediterranean countries is characterized by the presence of many small enterprises which are, in most cases, not well fitted out. There are in fact few barriers to penetrate this market segment, due to the extent and obsolescence of the building heritage that often calls for small maintenance and renovation interventions. To be more competitive, in many cases contractors make use of shadow and unskilled manpower and every year, for example in Italy, the price paid in terms of human lives is definitely too high.

In this connection, the recommendation is for the domain to include the Council Directive 92/57/EEC of 24 June 1992 on the implementation of minimum safety and health requirements at temporary or mobile constructions sites.

Another very important aspect is related to the seismic risk that, for the Mediterranean area is classified as extremely high. Israel is located in an area which is extremely subject to earthquake events and nearly all the Italian territory is characterized by such a phenomenon with different risk levels.

Another particularly interesting aspect regards accessibility. Since many years, in Italy attention has been increasingly drawn to frail users (the elderly and the disabled) to the point that the Italian legislation on the subject is deemed to be one of the most comprehensive and advanced today. The most recent provisions are also a good example of application of the performance philosophy to Italian laws.

4.4 Built Environment

A typically Mediterranean aspect is related to acoustic pollution. Southern Europe cities are traditionally more chaotic and noisy than Northern Europe ones. This is due to many factors (town-planning, density of population, traffic, etc.), among which the most relevant is climate. Where low temperatures force people inside, a more favourable climate encourages social relations and outdoor entertainment that imply a higher polluting load on the environment, especially from the acoustic point of view. In the light of these reflections, insulation products, systems and components, such as, for instance, façade elements, would deserve a differentiation by homogeneous climatic areas.

4.5 Organization and Management

The building process is, by its own nature, a melting pot of different competences and professionals. The main problem has always been the communication between all the actors involved in it.

No considerable differences exist, on this subject, among the Mediterranean countries according to their geographical position. This subject contains many pending issues that clearly nobody is still able to respond to in an effective way.

The Project Manager role has been more or less recently introduced in many countries and it represents a good opportunity to better manage the building process but it must be remarked that, at least in Italy, the training of such a professional role is still at dawn.

Two types of tools are proposed to assist owners, designers, contractors and supervisors, irrespective of regional boundaries :

- A list of requirements for each type of building, to identify the aspects to be taken into account;
- A software to support the management and to guarantee the performance of buildings.

4.6 Legal and Procurement

A contract with a performance value must describe what customers wish to obtain and then, at the end of the works, it must check whether the objectives have been achieved.

The domain report describes a universally valid model to support the achievement of final objectives.

The only objection to this point concerns the definition of satisfaction parameters that might vary from country to country and, in this connection, it would be interesting to identify the most suitable model to encompass the needs of Mediterranean countries.

4.7 Regulation

To complete the survey carried out among various European countries, it would be interesting to gather information about regulations in Mediterranean countries as well as in Turkey, Egypt, Cyprus, Malta and East-European Countries in general and to establish National Platforms to take into account national traditions, economies, climatic conditions and special factors which influence the Regulatory systems.

Thanks to the CPD, the first harmonized standards on products (the harmonised European Standards, and European Technical Approval Guidelines) are now spreading throughout Europe. These standards concern the performance of construction products. On the contrary, the European regulation still doesn’t guarantee the performance-based approach for what concerns the installation of products in the building, because the CPD does not cover all the performance aspects.

The performance-based approach remains limited to the regulation sector but still clashes with a scant culture outside the standardization sector; there should be a wide action to increase the awareness of users and stakeholders about the effectiveness of the performance-based approach.

The future review of the CPD may be an excellent occasion to draw more attention to the installation of products in the building (in other words, the recommendation is that the CPD should be more focused on the installation, which is already envisaged in the Directive).

A good question is whether the time is ripe to adopt a merely performance-based method in construction. Some projects are better carried out without a PBB approach.

As far as the Mediterranean Region is concerned, the PB-concept culture is slowly changing and it may be backed up by a good dissemination of results about cases proving the validity of such an approach.

4.8 Innovation

There is no great difference for what concerns the relation between innovation and construction industry in the different countries represented in the Performance-Based Building project.

Some aspects on this subject would deserve further investigations as to the performance concept applied to innovation.

A first remark concerns the fact that those who produce innovation can not take into account the performance of the building system or component where the innovative product is to be integrated. Safety aspects will therefore be tested by third bodies through the tools available today: the Agrément/Avis Technique, ETA (European Technical Approval). From this point of view, it is extremely important that within the domain, attention be drawn also to assessment systems, taking into account that the high costs involved are an obstacle to innovation for SMEs.

The importance of developing technologies that are more relevant to the construction process in Mediterranean countries should be more stressed for further elaboration within the Platform.

4.9 Information and Documentation

The scope of this domain was focused on the information infrastructure needed to support the adoption of performance-based building, with a particular care to the required development and introduction of user-friendly methods for gathering, making available and processing both general and project-specific information. To properly address this matter it is very important to know the information flow process, therefore a conceptual model of the flow was prepared.

5. Major barriers towards a more comprehensive adoption

The main barriers for strict adoption of solely performance-based regulations were precisely identified by the Israeli partners in the Platform.

The main barrier is the reluctance of designers and builders to accept responsibility for explicitly defined consequences. In general, many of them prefer regulations that define accepted solutions (Descriptive Approach), as compliance can easily be proven by the presentation of detailed drawings and construction brief. To prove compliance with performance-based regulations, calculations and/or laboratory certificates must be added, which usually imposes a larger workload on the engineers of the design team. In addition to that, checking compliance requires more skilled personnel. The shift from solely descriptive regulations to the adoption of mandatory Performance Requirements Standards thus encounters some difficulties at the design stage (mainly due to a lack of knowledge amongst professionals in some areas of building physics), as well as at the enforcement stage (mainly due to a lack of skilled personnel at local municipalities).

6. Conclusions

- There is a need to pay a greater attention to the specific issues of the Mediterranean areas, both at Community level and in terms of research and standardization;
- the seismic risk is very high in nearly all South-European countries and new provisions and rules are faced with a number of difficulties when they are to be enforced, even if they are inspired by a performance-based approach;
- a crucial aspect is represented by the climatic factor and the need to address such a topic in a more specific way, both at design and town-planning level, and for what concerns legislative and standardisation aspects, including laboratory testing;
- there is a need to define in a more precise way the concept of “performance-based approach” which still does not have the same meaning in all countries.

The Status of PBB in the NAS countries

PhD. Gábor Tiderenczl,
Npc for Quality Control and Innovation in Building, Budapest, Hungary
Dr. Károly Matolcsy,
Npc for Quality Control and Innovation in Building, Budapest, Hungary
Dr.Ing. Peter Matiasovsky (SAS, SK)
Institute of Construction and Architecture, Slovak Academy of Sciences, Bratislava, Slovakia

Abstract

This paper addresses the actual situation, background and the strategies of future implementation of PBB – Performance Based Building in the respective NAS (newly associated/associating states of Europe) countries: Bulgaria, Czech Republic, Hungary, Lithuania, Slovakia, Slovenia and Poland. The NAS countries are those belonging to the former Soviet block.

The objective of this paper is to describe why the situation of the NAS countries is so unique related to other platforms of the PeBBu thematic network. It will highlight the main barriers of PBB application in the NAS countries. This paper aims to enlighten, why the NAS countries show plenty of common features even if they are belonging to different regions, different language families, they have different historical backgrounds, different sizes and economical situations.

On the bases of the State of the art analysis, the paper describes the opportunities and potential strategies of spreading the PBB concept in the NAS countries. On this aspect, the accession to the European Union gives also a special situation and opportunities for these countries.

This paper is based on the NAS State-of-the-Art Report of the PeBBu network. The report was prepared by the task leaders and assisted by all members of the task and debated at the related PeBBu workshops.

Keywords: Performance based building (PBB; PeBBu); Newly associated states (NAS)

Introduction

The **scope** of the paper is to give an analysis of all aspects of future implementation and actual application of PBB – Performance Based Building in the respective NAS (newly associated states of Europe) countries on the bases of the PeBBu NAS State-of-the-Art Report. Task members are representatives from Bulgaria, Czech Republic, Hungary, Lithuania, Slovakia, Slovenia and Poland.

The **objective** of the paper is to present the background and the Status of PBB in the NAS countries with special focus on the ongoing PeBBu scientific domains and other PeBBu domain areas. Further **aim** is to provide a future vision and strategies for the implementation of PBB in the NAS countries in general and in the PeBBu domain areas.

At first this paper describes the background, why the situation of these countries is so unique related to other PeBBu platforms. It will describe the historical background of these countries that determined the possibilities of PBB and still influence the development of the construction sector.

The common features of the **construction sector** in the NAS countries will be pointed out. The paper will highlight the **main barriers of PBB** application in the NAS countries and on the bases of the background and the barriers it will discuss the **opportunities and potential strategies** of spreading the PBB concept in these countries. On this aspect, the **accession to the European Union** gives also a special situation and opportunities for these countries.

This paper will investigate the situation and the potential strategies of PBB in the NAS countries in the following ongoing **PeBBu scientific domain areas**:

Domain 1: Life performance of construction materials and components
Domain 2: Indoor environment
Domain 3: Design of buildings
Domain 6: Legal and procurement practices
Domain 7: Regulations
Domain 8: Innovation

The situation and the potential strategies will be analyzed also in the following **other domain areas**:

Built Environment
Organization & Management
Information and documentation
Fire safety & engineering
Accessibility
Facilities management
Energy & water management
Environmental sustainability
Education & training
Intelligent buildings
Structural design & engineering
Construction products directive (CPD)

As regards the **methodology**, the paper was prepared on the bases of the lessons learned from: PeBBu workshop; special PeBBu NAS workshops; PeBBu documents; contribution of the PeBBu NAS members; relevant literature and the scientific background of the task leaders.

1. Historical background, the construction sector and the status of PBB in the NAS countries

After the WW II all of the NAS countries were occupied by the Soviet army, and within some years became **soviet satellite states** with a very similar structure. An artificial socio-economical system was developed that determined the development of he construction sector and the possibilities of implementing the concept of PBB. There were special barriers of PBB due to this artificial system. In 1989/1990, the soviet systems collapsed, and new, democratic states were established. A **transition period** started from a planned economy to a market oriented economy in the 1990s with consequences and changes in every sphere of life. New barriers raised and the PBB thinking became even weaker than it was before the changes. In 1995 the NAS countries applied for EU membership and in the 1st of May 2004 ten of these European nations became **member states of the EU**. This situation gives new challenges and also new opportunities for these countries. These challenges and opportunities determine the development of the construction sector and the possibilities and strategies of further implementation of the PBB concept

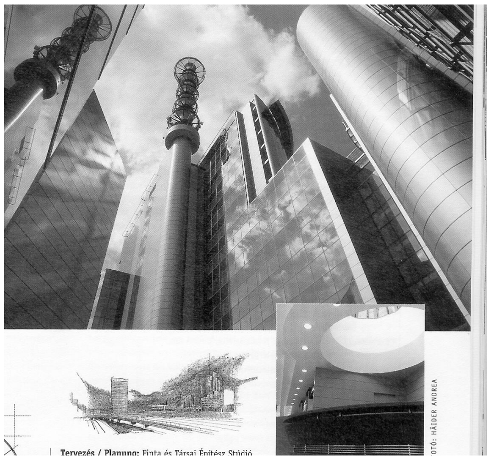
The **former socialist system** determined the development of the **construction sector** with the dominant role of the state and the practice of industrialization and mass production, that resulted a significant construction boom but with low quality buildings. Opportunities of getting proper building materials were very low, the lack was the most general feature and generally the performance criteria was adjusted to the only available solution. The low wages of architects and professionals and the ad hoc improvisation character and low quality of execution, all worked against the Performance Based approach. The standardization process was based on the opportunities of East-European cooperation, user requirements were not considered. The strong barriers of the artificial social, political and economical system before 1990 had a consequence of overall poorness comparing to the western countries.

The changes in the sector during the **transition period** occurred as a consequence of the former building practice. The strong role of the public sector stopped and the **privatisation** of the domestic building industry started. **International big companies** became new owners and realized large investments. These International companies basically make their research and development at the home countries, and rarely invest in research in the new countries. SMEs became dominant in the design and engineering practice. Ministries responsible for the building sector were ceased and the responsibility for the sector spread to several other ministries with the consequence of inefficient problem solving. With the **state withdrawal from the building market**, housing subsidies were dramatically cut, state investments became rare and low budgeted and inflation became dramatically high (over 30 %). As a consequence, **building industry has been declined**. The market type building demand became dominant and the investor began to be a dominant partner that often resulted in the lack of acceptable architectural quality. The segregation and fragmentation in building construction industry and the traditional approach to build as cheap as possible makes a rather great **increase in building failures**, basically in the residential sector, where the builders are mostly not professionals. Housing promotion is very low in all countries, the majority of the new dwellings are still built via a do it yourself practice or by black workmanship. **Black market** is very high in the building products field as well, partly due to the relatively high VAT. The transition period had also its difficulties as low skilled workers, low workmanship, low onsite safety, lack of quality inspection, instable financial background and high corruption rate. Also the problem of housing affordability emerged. On the other hand all up-to date products are available and also there are several prominent investments in the NAS countries.

Figure 1: Prominent investments in Budapest

a.) Siemens offices (architect: Lázár & Reimholcz)

b.) Police station (architect: Finta)



The special situation of the construction sector results also a **special status of PBB** in the NAS countries. Building activities in the NAS countries are the least performance-based among the PeBBu regions. Although CPD is entirely implemented in the NAS countries, the standardisation process is still rather weak and perspective in character. In the NAS countries in the construction practice the successful PBB usually depends explicitly on the responsibility and possibilities of all decisive partners and on their quality, but mainly on architect - client cooperation. The construction participants ordinary do not work in interdisciplinary teams and do not approach the construction in a wider context. The most important field, where the performance concept has been introduced is the technical approval of innovative products and related testing work. The most important fields, where further actions are needed are the design, procurement, budding and the control of the execution work in the platform’s countries.

Entering the EU in 2004 May, the **harmonization processes** in the NAS countries become more and more intensive. **CPD** determines the codes and decrees in all countries. The base would be the nominated Institutes of the countries for notification, which can act as a bridgehead of PBB. As a result of the NAS countries’ accession to the EU, it is expected that also the introduction of the performance concept will accelerate. There is a general agreement among professionals of its wider introduction.

2. Main barriers and opportunities of PBB in the NAS countries

A more general application of PBB would have several **advantages and opportunities** in the NAS countries, like the stimulation of new materials, techniques and competition, better performance of buildings, reduction of cost and risk and failures, more freedom and less barrier in design, more correlation with users' requirements, etc. However, **strong barriers** are still against PBB.

Barriers and opportunities of PBB can be classified according to different historic periods of their origin in the NAS countries, namely before the political changes, in the transition period and after the EU extension.

In the **time of socialism**, special barriers obstructed the implementation of PBB in the artificially isolated NAS countries, as the mass production, the COCOM list, the PLAN driven economy, etc. Most of these features are already over but some of them are still living or have influence.

As regards the implementation of PBB, after the political changes in the **transition period** new barriers and opportunities raised. There are still remnants of socialist mentality and short-term thinking. Lack of holistic approach, lack of cooperation, lack of finance, the weak credit systems and the low level of responsibility are all strong barriers. It is hard to achieve a breakthrough in habits joint to prescriptive regulations. There is a significant need for education and training and it takes a lot of time to become familiar with the performance-based approach. Other barriers are the lack of relevant indicators and testing methods, the lack of holistic life-cycle approach, the interest of producers, the segregation and fragmentation of design, engineering and construction or the attachment to traditionalism and routine. The conservatism of the construction sector doesn't promote innovation and change. Best Practice examples are not directly related to performance, and as investment in building is risky, lot of investors want to rely rather on proved and safe solutions. There is a low demand for the construction work in the domestic market. Smaller enterprises have no financial reserves and neither bank credits are available for them, which causes a high risk in surviving. The consequence is the decrease in the competitiveness in the construction market. Another special barrier is that older generation suffers from lacking speaking ability in foreign languages. English is very rarely spoken by the generation older than 40 years. That makes a strong barrier in implementing PBB materials, which are not in domestic language. On the other side the transition period resulted also in new opportunities, as the CPD implementation, the availability of new products and high quality buildings.

The **EU extension** can strongly influence many fields and so the construction sector in the NAS countries, most of them already member of the EU. N**ew opportunities and support of PBB** can be related to the free transfer of goods, services, information and people, more possibilities for innovations, more competitiveness, duty free prizes, more open society, European standardization, education and research support, decrease of regional and social differences, etc.

On the other hand, also some **new barriers** can emerge with the EU extension, like market deformations (temporary), the influence of strong interest groups, cartel agreements among producers, State budget deficit restriction, new tax policies, etc. **Obligations** are another aspect that comes with the EU extension and these should be considered rather as opportunities.

3. Status and strategies of PBB in the NAS countries in the ongoing PeBBu scientific areas and in other domain areas

The **6 ongoing PeBBu domains** are the followings: Life performance of construction materials and components; Indoor environment; Design of buildings; Legal and procurement practices; Regulations; Innovation. On the bases of the current situation this paper will draft some strategies that can serve the future implementation of PBB in the discussed domain areas.

In **Domain 1 "Life performance of construction materials and components"** we can see a development of quality and plenty of new up-to-date products, a product evaluation system and developing standards on one hand, however still plenty of low quality items on the market on the other hand. There are several researches related to durability issues, however few reference service life data are available and the factor method is not used in the NAS countries. Improving durability of constructions, developing new materials and techniques and increasing the use of local materials are priority aims. Well defined performance criteria, indicators, measurement and simulation tools are needed for further development. The works in ISO will impact and will direct the national efforts towards life performance of construction materials and components.

Issues related to **Domain 2 „Indoor Environment"** has not been really considered in the design process in the region, in spite of the increasing problems of indoor air quality due to more airtight buildings, open-burning heating equipments, moulds due to cold bridges, increasing level of indoor pollutants and emissions together with the lack of proper ventilation. Conditions for indoor environment in almost all countries are determined by legal and technical regulations but it is not controlled and buildings are typically designed for minimum permissible level. In practical design generally only aspects of comfort are considered, a more holistic approach to indoor climate and healthy building is seldom realized and this would be needed. Strategies should also address simulation, modelling and testing tools in order to predict complex indoor environment performances and also training special designers for indoor climate. A best practice example for careful indoor environment design on PBB bases in new construction is a commercial office building, the *"Tulipan House"* in Warsaw. Light, space, care for the natural environment, flexibility and comfort are the main features of the building. Special features will be sustainability and energy efficiency. The goal is to achieve 30% energy saving compared to a standard building and to use renewable energy sources to 50% of the total energy-use for indoor climate.

Figure 2: Best practice example for PBB: the "Tulipan House" in Warsaw, Poland

As regards **Domain 3 "Design of buildings"**, the former large state building design companies operated in the NAS countries have been divided into small design offices and the new situation caused new problems as well. Use of CAD systems became widespread, however the lack of control, the application of routine solutions, precipitation, the need of low construction cost are against performance-based design. In practice the successful PBD usually depends explicitly on the responsibility and possibilities of all decisive partners and their quality, but mainly on architect - client cooperation. Unfortunately, architects generally have a narrow orientation. Often "Ideal catalogue construction solutions" are applied and no explicit criteria and methodologies of the whole building performance monitoring and testing are used. Although several prominent buildings have been realized in the latest years, the former practice of do-it-yourselves still determine attitudes and austere buildings are constructed simply in possession of building permit without specification and implementation plans. A main barrier of PBD is that particular design participants do not consider the construction and its results as a complex system. Explicit performance criteria, less empirical approaches, a stronger control of technical and environmental performance, more complex tools & databases, whole life education & training are needed as a strategy. It is up to the architects and engineers to educate their clients in terms of PBB. It is important to increase the level of cooperation, communication and tenant/user participation in decision-making during the whole design and construction process on performance bases. Further aims are to develop and apply efficient Decision Support Systems, to improve the transparency of tendering and to apply Post-Occupancy Evaluations.

Figure 3: Examples of new construction activities in Bratislava, Slovakia a) Roman Catholic centre b) furniture department store Atrium c) housing complex in Kramare.

Concerning **Domain 6 "Legal and Procurement practices",** building affairs belong to the public administrational proceedings in the NAS countries. As former Ministries responsible for construction were ceased, responsibility for sector was distributed among 3-8 ministries. An inefficient operation was the consequence and especially housing policy became critical. The development of the institutional background, a construction policy and strategies are strongly needed. Regarding the procurement process, the building manager is responsible for it. The level of the application of performance criteria depends in particular cases on the building manager - his cooperation with architect, designer, contractor and his communication with the client. External influence will become important as a result of the implementation of new EU Directives and international obligations and this may require perhaps radical changes in the legislation documents. Consequently, it will be necessary to find a common framework for these provisions. In strategies it is important to develop construction process coordination and optimization, facility management and the tendering process. Also more information and databases are needed. It is important to work out efficient and more responsible construction and housing policies, to increase the quantity and quality of residential buildings and to develop complex programs for building renovation and urban renewal.

According to the main points in **Domain 7 "Regulations"**, the regulatory framework in NAS is composed of the Act on Construction and the Act on Construction products; National Technical Standards, European Standards (EN) and International Standards (ISO). Most of the EN and ISO are implemented in the region. The competent governmental institutions develop laws and decrees, while the Standards Institutions develop standards. The local authorities issue building permissions. Standards (mandatory / advisory) are related to special issues of the building regulations. CPD is the base document in all NAS countries and its implementation is almost completed. Although performance based concept has been integrated in the NAS Building Regulation in many areas, the national standardization process is still rather weak. Harmonization process with EU standards goes fast. The main strategies are to develop the institutional background of regulating the construction process and to develop performance based regulations and national standards on the bases of complex performance criteria and whole life cycle approach.

As regards **Domain 9 "Innovation",** after 1989 a

s large construction companies and central programs, also large research institutes were ceased and financial funds radically decreased. Mainly the Academic Research Workshops, Higher Educational Institutions, Innovation Parks, and Institutions for quality control exercise research activities today. Although there were several research programs related to PBB during decades, the application of innovation has several barriers as the common attitude of builders, the lack of R&D capacities of construction companies and the strong financial barriers. Great part of the innovative products comes out of the international research but there are excellent results also in the NAS countries. Several strategies could be defined, but first of all it is necessary to identify long-term values and make a balance between values and interests. Governments should promote innovation, education and training.

Further on this section a summary of the situation and the potential strategies in the following **other PeBBu domain areas** will be described: Built Environment; Organization & Management; Information and documentation; Fire safety & engineering; Accessibility; Facilities management; Energy & water management; Environmental sustainability; Education & training; Intelligent buildings; Structural design & engineering; Construction products directive (CPD).

As regards the domain of **built environment** more than 50% of the European population is living in cities, where two adverse processes can be observed. The symptom of sub-urbanization and deterioration of inner city areas are on one side and the increasing demand for good quality urban living is on the other side. The majority of the housing stock in the NAS countries cannot meet today’s needs, especially the run down and functionally obsolete inner-city blocks, the old mud houses and the large panel housing estates. Regulation of the development of the built environment and also regional planning has plenty of problems to solve. The process of sub-urbanization and urbanization should be balanced. New development plans are needed. There is a strong need for renewing, maintaining and operating existing buildings and for conducting complex urban renewal programs and large-scale panel reconstruction. Information channels should be also developed in order to inform all partners of the construction process and in authorities about problems and complex solutions concerning the built environment and its sustainability.

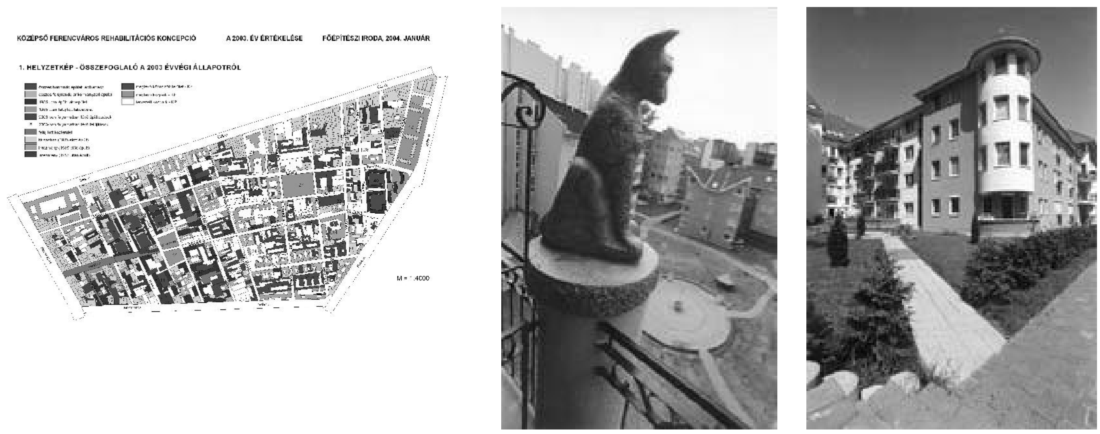


Figure 4: Best practice example of urban renewal program in Ferencváros, Budapest, Hungary.

Considering the issues of **organization and management**, the enterprises in the NAS countries have consistently began to build and should further develop the quality management systems and environmental management system, as next competitive advantage. There is lack of another certificate in safety systems that should be also created.

Documentation is related to the procurement process. In NAS the trends of traditional procurement model are dominant. Developing performance-oriented model is an issue of strategy and several barriers should be surmounted. As regards **information**, several professional journals and periodicals are issued and information materials available related to building and construction. Complex information on a performance bases should be created to stakeholders.

As regards the domain of **fire safety**, this issue gains a high recognition in the NAS countries. Testing laboratories are issuing certificates and approvals of materials and building elements from fire safety point of view. To develop fire regulations on performance bases and to provide more complex information on the subject would be necessary.

Regarding the domain of **accessibility**, the criteria are specified in the Building Regulations in most NAS countries, however only for public buildings are mandatory items to keep. More information and awareness and also proposals of accessibility in residential buildings are needed.

The group of the owners of the buildings applies **facilities management**. Since 1990 the tenure structure changed considerably in he NAS countries where the strong process of privatization has had serious consequences in maintenance and facilities management. Associations of the flat owners, special companies or housing corporations were established for facilities management. New acts are regulating their operation and organization, that should be further developed and the role of facilities management should be continuously increasing in the NAS countries.

As regards the domain of **energy and water management**, in the NAS countries the majority of houses are poorly insulated and strong energy conservation measures are needed. Reconstruction activities should be combined with additional thermal insulation. Also the practice of EU countries should be studied and the assessment tools developed. It is important to improve the energy-efficiency of buildings, to implement Energy Performance Directive, BEM and Building Energy Pass.

In the issue of **environmental sustainability**, all NAS countries are engaged for development, but in real term the national programs generally are rather week. Financial and political barriers are characteristic. To raise the public's awareness, to identify indicators for evaluation and to make proper practical measures for increasing environmental sustainability are strong challenges.

As regards ***education and training****, in the transition period the opportunities of the universities changed in the NAS countries. Neither education nor research got the necessary support. On the other hand international programs became open to NAS countries. PBB concept should be integrated in education, the general level of which is also necessary to improve.*

Concerning the domain **of intelligent buildings,** mainly the owners of new administrative and industrial buildings in the NAS countries apply the concept. As a realization of the user's expectations, intelligent buildings could be one of the platform to adapt the performance base approach. However, it is currently more a technologically oriented issue. It is needed to raise the awareness of the advantages of intelligent building systems regarding safety, security, indoor comfort and also to apply them in case of residential buildings.

As regards **structural design and engineering**, safety of construction is a performance based essential requirement in every NAS country. The performance of load bearing structures of buildings is addressed very strictly in the NAS countries. Internationally recognized researches should be continued in this field.

CPD was known from the time of its origin in the NAS countries and some principle like Essential Requirements came in law in the middle of the 90's. However, there is a lack of information of the control. CPD is an obligation and a good possibility in breakthrough in the NAS countries related to PBB. CPD should be also assessment based and clients' needs should have priority.

4. General strategies and the future of PBB in the NAS countries

The main **vision to the future** concerning the implementation of PBB is that after 10 years the differences between the NAS countries and the former EU countries will be decreased to a minimum level and most of the barriers will be ceased. Regional cooperation will be increased.

Several **strategies** are needed to realize this vision. Authorities should have an increasing role in developing construction policies, housing policies and strategies and in realizing these strategies. The institutional background of the construction sector should be developed in the NAS countries. The development of the national standardization processes is a key issue of strategy in implementing the PBB concept. It is important to raise the awareness of the professionals of the importance in thinking in performance terms. In order to spread the PBB concept in practice, clear performance criteria should be defined. In order to measure the performance in practice, indicators, measurement, testing and simulation tools should be developed. In order to increase the level and quality of regional and international cooperation, learning foreign languages should be promoted. These needs suppose the systematic institutional stimulation of research and the development of educational and construction activities at regional/national levels.

Concerning the envisaged **future implementation of PBB** in the NAS countries, in general only some participants of the construction design process are aware of PBB importance in practice. The construction companies formulate the need of PBB as the need of the complex quality of construction, which should be provided by the quality management. The barriers of wider PBB application in practice are seen in the cases when the particular construction participants do not consider the construction and its results as one complex system. The liability and responsibility is supposed to be a dominant factor enhancing the PBB. The increase of the education and knowledge level and the level of a systemic approach in the construction process are also fundamental conditions. The role and the quality of an architect is fundamental in the environment where the main criteria of a client's decision-making has economical character.

The necessity to **improve legislative framework** in the construction arise an excellent opportunity to implement the PBB approach. This opportunity could be very well detected in the widespread implementation and success of CPD in these countries. Experts believe that the increasing competition in the market will lead to a better understanding of performance based approach for the building industry.

5. Conclusion

In conclusion, relatively small number of best practice examples of PBB can be seen in the region and still plenty of barriers are against PBB. The complex solution how to support the PBB in NAS must issue from the promotion and propagation of cooperative approach of all partners to the construction based on complex building performance knowledge. The possibility of equal opportunities and the minimum threshold degree of economical freedom and stability are the fundamental conditions for this.

The accession to the European Union provides new opportunities, partly as obligations for implementing PBB in the NAS countries. Dissemination of the PBB concept and raising the awareness of it is important in all countries. National PeBBu Platforms would be important to develop in order to raise the awareness of PBB and overcome the barriers of languages in the participating countries.

If the key strategies will be conducted, the vision to the future related to PBB in eliminating the differences between the NAS countries and the former EU countries has good chances to be realized.

Performance Based Building and the Construction Products Directive

Abstract

The aim of this activity in the Thematic Network (PeBBu) Performance Based Building is to provide basic information on the Construction Products Directive (89/106/EEC) to the PeBBu domains and members and to receive and incorporate feedback in a final report that aims at linking PeBBU with the CPD. In additions, although the CPD starts from the 6 essential requirements for works, it leads to product conformity attestation only. It does not provide the link between the performance based approach used in product specifications and a performance based approach for works. Together with the members of the PeBBu domains, this relationship has been examined.

1. Introduction

The objectives of the PeBBu Network are stimulation and pro-active facilitation of international dissemination and implementation of Performance Based Building in building and construction practice.

It has been acknowledged that the Construction Products Directive (CPD, 89/106/EEC) should be a basic element in PeBBu work and therefore, the introduction of the CPD is considered to be a horizontal task in PeBBu.

The Steering Committee of the PeBBu Thematic Network decided on 4th August 2003 to develop a new cross-cutting activity on the integration of the knowledge of the Construction Products Directive into the work of the various domains and tasks of PeBBu.

2. The Construction Products Directive

The Construction Products Directive (CPD - 89/106/CEE) defines six essential requirements for construction works, which are detailed in interpretative documents. Starting from those essential requirements for works, the European Commission, after consultation of the Member States of the European Economic Area (EEA), specifies the regulated characteristics for construction products and kits in mandates to the European Standardisation Committee (CEN) and the European Organisation for Technical Approval (EOTA) to develop harmonised technical product specifications, i.e. harmonised European standards or European Technical Approvals, for the performance assessment of the building products.

The EC New Approach directives in general and the CPD specifically introduce a mandatory system of conformity attestation throughout the construction products sector. For some parts of the industry, CE Marking is not really new, due to other existing EU Directives, but the CPD has important particularities compared with other New Approach Directives.

Thanks to the CPD, the way technical product specifications are being written has changed. It is expected that the CPD technical specifications will be a driving tool towards performance based works specifications and regulations in a very large part of Europe.

3. Objectives and accomplishments of this task within PeBBu

3.1 Objective I

The first objective of this activity is to provide basic information on the CPD to the PeBBu domains and tasks and to receive and incorporate feedback in a final report that aims at linking PeBBU with the CPD.

3.2 Accomplishments (objective I)

At the start of 2004, an extensive “CPD supporting document” has been made available to all PeBBu members, meeting the main part of objective I.

The document presents the legal framework, the new and global approach, within which the CPD has been established. However, the Construction Products Directive can be considered as a special Directive under the New Approach, because it diverts with regard to some of its fundamental aspects, such as

- the essential requirements, are not related to the products, but to the works into which they are to be incorporated;
- manufacturers are obliged to comply with harmonised technical specifications, i.e. harmonised European standards or European Technical Approvals;
- the conformity assessment modules, applicable for all other new approach Directives; the CPD has its own “attestation of conformity (AoC) systems”;
- putting into service is not considered in the CPD; only placing on the market is addressed;

- The CE Marking is accompanied by all the harmonised product performances;
- The Directive becomes applicable for products at the start of the co-existence period for the relevant harmonised product specification and becomes mandatory at the end of that period.

The CPD supporting document also presents detail to the Directive itself, explaining its scope and the essential requirements, which required “Interpretative Documents”. These were published by the European Commission, before CEN, the European Standardisation Committee, and EOTA, the European Organisation for Technical Approvals, could be requested to start developing the harmonised technical specifications.

The European Commission (EC) issues Guidance papers to support Member States, specification writers, Notified Bodies and manufacturers in performing their tasks under the CPD. These documents contain much of the EC’s interpretation of the CPD, which is under permanent development. This will be reflected in the CPD supporting document as it is being revised during the PeBBu project.

Since 2001, when the first harmonised standard was cited in the Official Journal of the European Union (OJEU), CEN has published close to 300 harmonised standards, about 150 of those having been cited in the OJEU, while EOTA issued 19 ETA-Guidelines and, more importantly, close to 200 European Technical Approvals. The CPD supporting document presents the CEN and EOTA organisations and procedures, which also develop over time.

One of the main changes that the CPD has brought to the Construction Sector is that all manufacturers will have to establish and maintain a factory production control system that meets the requirements described in the harmonised technical specifications. In some cases, independent third parties, Notified Bodies, will verify whether manufacturers (continue to) meet those requirements.

3.3 Objective II

Although the CPD starts from the 6 essential requirements for works, it leads to product conformity attestation only. It does not provide the link between the performance based approach used in product specifications and a performance based approach for works. Therefore, in Objective II, this project will examine how such a link is being or could be established.

3.4 Accomplishments (objective II)

Based on the extensive explanation about the Directive itself, the CPD supporting document also provides information on how the CPD has initiated or supported the development of tools to use the CPD deliverables beyond the legal framework.

Voluntary initiatives to increase users’ confidence in construction products, such as technical approvals and third party conformity assessment, which existed long before the CPD, have and continue to be developed and transformed to cover issues that are not covered by the CPD and because the CPD is performance based, these voluntary initiatives develop in the same direction.

Works' specifications will also benefit from recent activities of the European Commission, CEN and EOTA. The development of the Eurocodes as European Standards and the EC's recommendation on their use throughout the European Union is fundamental in the harmonisation of structural calculations and a link with harmonised product specifications ensures a future uniform approach. Similarly, though less publicized, activities are being prepared in the field of fire (fire safety engineering) and acoustics. For public procurement, the CEN and EOTA technical specifications are mandatory, if available, linking the CPD technical specifications to the works once more.

The **Energy Performance of Buildings Directive** leads to a new increased activity in CEN and EOTA in preparing performance based solutions to determine the energy performance of whole buildings, linking to the CPD deliverables.

The CPD supporting document has been presented to the PeBBu Members during the PeBBu Work Shops in January 2004 (Manchester) and November 2004 and was made available electronically.

4. Relation with PeBBu domains

4.1 General

An enquiry among the existing PeBBu domains took place, linking the CPD with the area of performance based building that the domains cover. This enquiry aimed at facilitating interaction with the PeBBu domains.

4.2 Domain 1 "Building materials and components"

The CPD foresees the development of technical specifications on a performance based approach and therefore, input from this domain was likely to be important. The domain concentrates on durability assessment and the parameters that influence durability. EC Guidance paper F covers durability under the CPD and the most important aspects have been presented in the CPD report.

The International Standards Organisation (ISO) has published some parts and is working on a whole set of the Buildings and Constructed Assets - Service Life Planning standards (subparts of ISO 15686) guiding the life design of buildings. The concept of the factor-based evaluation of the service life has been introduced in the International Standard for service life planning of buildings, ISO 15686 Part 1. The method allows an estimate of the service life to be made for a particular component or assembly in specific conditions.

It is obvious that the majority of the factors necessary to determine the service life are not envisaged in the framework of the CPD and that the CPD’s contribution is limited to providing supporting information regarding the products as they are being placed on the market.

The construction products can only be CE Marked when they are fit for use and influences of the (internal or external) environment on products are addressed in harmonised specifications, as well as maintenance. Design and workmanship are however not covered under the CPD.

Under the CPD, all products are assessed for general intended uses (e.g. fire protective coating or thermal insulation for buildings) and the durability assessment is not linked to specific intended end uses. The end result of the assessment is a manufacturer’s product specific durability claim when placing it on the market. Moreover, the CPD is particularly aimed at manufacturers, i.e. they take responsibility for CE Marking, but cannot intervene in design, use and maintenance of their products.

The usefulness of the service life planning methodology being widely accepted, but the practical implementation in product standards not consolidated, CEN examines how the concept can be introduced in European product standards, as a voluntary provision.

4.3 Domain 2 "Indoor environment"

When considering air quality, ventilation, thermal, sound and visual comfort, the CPD does not directly lead to ready-for-use deliverables. It provides product performances such as release of regulated substances, water vapour diffusion coefficient, thermal conductivity/resistance, airborne and impact sound insulation and sound absorption.

The CPD's third essential requirement "Hygiene, health and environment" will lead to technical product specifications that deliver the means for a performance based approach for the indoor environment and release to soil, surface and ground water, as far as these are influenced by the construction products.

Regulated dangerous substances requirements are not harmonised at present. National regulations continue to apply, but a new CEN Technical Committee will develop horizontal assessment standards for future generations of harmonised standards.

In the framework of the European Commission's Integrated Product Policy, another CEN Technical Committee will examine how existing draft international standards can be used as a basis for environmental product declarations over time. In the meantime, CEN Technical Committees developing product specifications are using an "environmental checklist" to introduce environmental provisions in their standards.

4.4 Domain 3 "Design of buildings"

In the framework of the CPD, the 6 essential requirements relate to the works, not the products. Therefore, although the CPD leads to product specifications, there is a direct relationship to the design of the works and many of the CPD deliverables, or related specifications, allow activities related to the overall design of the works.

Having produced product standards, some CEN Technical Committees are now developing installation standards. Since all CEN Member Bodies are obliged to publish CEN standards nationally, these new installation standards will lead to a de facto harmonisation of installation practices, since standards are the "state-of-the-art" and because these standards may be referred to from national legislation.

European Technical Approvals (ETA) always contain provisions regarding the installation of construction products and therefore, the link between the product specification and the works is very clear in these cases.

4.5 Domain 6 "Legal and procurement practices"

The existing European Procurement Directives, respectively addressing products, services and works, lay a direct link to the (mandatory) use of European standards and European Technical Approvals.

By contrast, the new, coordinated, Pubic Procurement Directive, specifies that technical specifications drawn up by public purchasers need to allow public procurement to be opened up to competition and therefore, it must be possible to submit tenders which reflect the diversity of technical solutions. Works' technical specifications should therefore be drawn up in terms of functional performance and requirements, and, where reference is made to European standards or European Technical Approvals, tenders based on equivalent arrangements must also be considered by contracting authorities. Tenderers are permitted to use any form of evidence to demonstrate equivalence.

4.6 Domain 7: "Regulations"

The CPD, due to its national implementation in all EEA Member States, sets a legal framework for placing construction products on the market.

Member States are required to take all necessary measures to ensure that construction products, covered by a harmonized technical specification, may be placed on the market only if they are fit for the intended use, i.e. that they comply with the harmonized standard or ETA, that the applicable conformity assessment procedures are being performed and that the products have been duly CE Marked. This implies an obligation for Member States to organize and carry out market surveillance, in a way that is effective and sufficiently extensive to discover non-compliant products.

The Council Resolution of 10 November 2003 requests the Commission to examine the possibilities of better cooperation between the Member States.

The enforcement of the Directive (market surveillance) has however received little attention so far. It is not certain whether Member States use a reactive or proactive enforcement regime, but most seem to opt for a reactive system.

CEN considers whether harmonised product standards are suitable for market surveillance purposes, i.e. do they permit Member State to verify compliance of products placed on the market.

4.7 Domain 8: "Innovation"

As far as innovation is concerned, at first sight, the CPD does not provide the means to encourage innovation. CEN standards usually cover products for which experience exists and even EOTA does not have all the answers for the integration of innovative products in the system, although the Common Understanding of Assessment Procedure (CUAP) was intended in particular for innovative products.

The manufacturers' desire to demonstrate that innovative products meet the requirements for CE Marking can be easily understood. If conformity with the essential requirements of the CPD cannot be determined in the early stage of development, it will be difficult to convince users to purchase the product, and illegal to sell it. Before CE Marking is possible, manufacturers have to perform ITT and need to have an operational FPC system for the product in place. Both might take a long time to perform and establish.

Without economical solutions for CE Marking of innovative solutions, innovation in the construction sector might decrease, which is obviously not the intention of the CPD. On the other hand, solutions may not compromise health and safety.

5. Recent developments

The Construction Products Directive has been around for more than 15 years and is producing its first results. Nevertheless, interpretation continues to be necessary, as stakeholders are faced with new practical challenges when CE Marking their products.

5.1 Different production methods

During the development of the recently adopted EC Guidance paper M on initial type testing (ITT) and factory production control (FPC), the European Commission acknowledged the different production methods in the construction sector and requested CEN and EOTA to adapt their technical specifications, allowing manufacturers, using any production method, to continue placing products on the market.

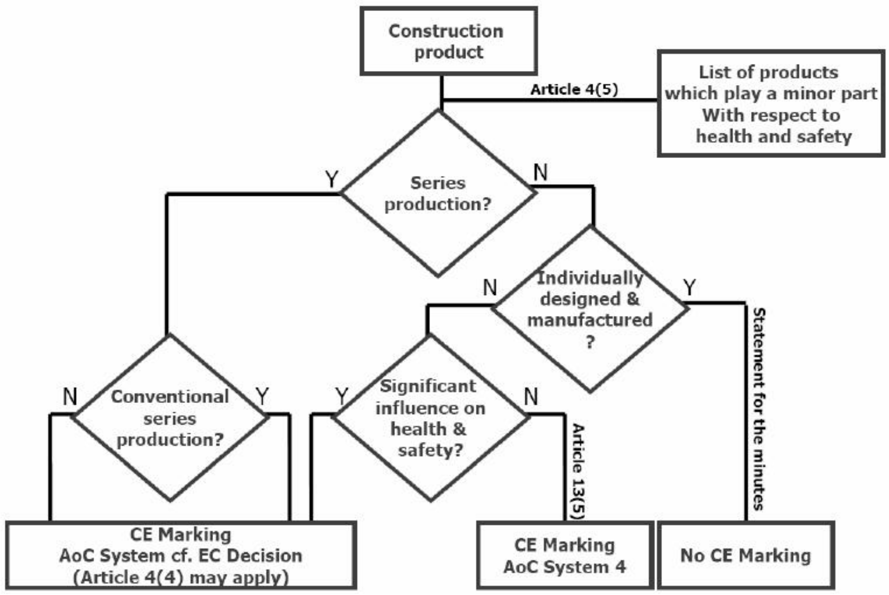

Figure 1: CPD Provisions regarding production methods

EC Guidance paper M distinguishes:

- Conventional series production: CE Marking obligation applies, conformity assessment in accordance with relevant EC Decisions
- Series production of products with varying properties (e.g. windows with an identical design, but different dimensions): CE Marking obligation applies, conformity assessment in accordance with relevant EC Decisions
- Individual (and non-series) production is divided into:
  - individually designed and manufactured products (e.g. restoration of cultural heritage); in this case, Statement N° 2 for entry in the minutes of the Council meeting that adopted the Directive in 1988 applies. Even if the product does not meet the (essential requirements of the) CPD, it can be placed on the EEA market, but without CE Marking, if Member States agree.
  - Individual (and non-series) production where the above does not apply, or in cases where the above does apply, but where Member States do not authorise the use thereof, the following options apply:
    - The products have no significant implications for health and safety: In this case, CPD article 13(5) is used, meaning that ITT and FPC are to be performed by the manufacturer, i.e. AoC system 4 applies, which may be contrary to the relevant EC Decision.
    - The products have significant implications for health and safety: In this case the EC Decision on AoC applies.

This differentiation, together with the European Commission's demand to CEN and EOTA to adopt proportionate conformity assessment requirements, should permit manufacturers of all sizes, using any of the above production methods to continue placing products on the market.

Although requirements need to be proportionate, they should also ensure that only safe products are placed on the market and requirements need to be equivalent, preventing market distortion, favouring one manufacturer over another. Performance based requirements, based on a statistical confidence levels are most likely important tools in this new development.

5.2 Placing on the market of products

Where there is a single manufacturer producing a construction product using an established standard manufacturing process from basic raw materials to placing the product on the market, then the responsibilities of the manufacturer and the Notified Body, if involved, are straight forward. However, in the construction sector, there are a significant number of situations where the supply chain includes other ‘actors’, e.g. sub-contractors of components and complete products, importers, distributors, merchants, where the responsibilities of the ‘actors’ and of the Notified Bodies are not clear and are not addressed in harmonised standards.

The CPD itself only considers the role of the manufacturer and his authorised representative. The ‘Blue Book’, which considers all New Approach Directives, and the EC Directive 2001/95/EC, the General Product Safety Directive, define the manufacturer's and distributor's roles.

In the framework of the New Approach, the **manufacturer** is:

- The manufacturer of the product, when he is established in the Community, and any other person presenting himself as the manufacturer by affixing to the product his name, trade mark or other distinctive mark, or the person who reconditions the product;
- The manufacturer's representative, when the manufacturer is not established in the Community or, if there is no representative established in the Community, the importer of the product;
- Other professionals in the supply chain, insofar as their activities may affect the safety properties of a product;

By contrast, a d**istributor is a**ny professional in the supply chain whose activity does not affect the safety properties of a product, while a s**upplier is a**n entity that supplies materials or products without placing them on the market, i.e. an entity that supplies goods to the manufacturer, responsible for designing and manufacturing a product with a view to placing it on the EU market

An a**uthorised representative is a**n EU established entity, appointed by the manufacturer to act on his behalf and recognised as such. The manufacturer remains responsible for the actions of the authorized representative under the CPD.

An **importer** *(who places a product on the market) is a* distributor who takes a product from a third country and places it on the EU market.

These definitions clarify the responsibilities as far as CE marking construction products is concerned.

Distributing a CE marked product, but not affecting the essential characteristics. A distributor buys in a packaged product, e.g. on a pallet, in a box, etc, and sells it to others without affecting its essential characteristics. The CE Marking is that of the manufacturer. The distributor is responsible for taking care that the packaging is not damaged and that the storage conditions defined by the manufacturer are respected (temperature, humidity, ...), i.e. the responsibility of the 'distributor' is limited to maintaining the integrity of the product and producing associated documentation as necessary for local use.

Repackaging and CE marking without affecting the essential characteristics. When a CE Marked product is repackaged, without its essential characteristics being modified (e.g. by transferring from a vat of 200 litres to 1 litre bottles, or by affixing a new label with his own brand name to the product and not referencing the original manufacturer who CE-marked the product), the entity responsible for repackaging is a manufacturer under the CPD. If the manufacturer does not want to refer to the original CE Marking, he has to apply a new CE Marking to his products making use of the original manufacturer's declared values, and to use a Notified Body, if required. In this case, the key element for CE marking is traceability. The Notified Body should consider that the product complies with the CPD, based on the original manufacturer's CE Marking, and check primarily that the repackaging manufacturer has taken all necessary measures and procedures to ensure that the properties of the product were not altered by repackaging. The repackaging manufacturer must always be able to prove the product he repackaged was CE Marked by the original manufacturer by showing a correspondence between the branded product he places on the EU market with his CE Marking and the CE Marked batches from the original manufacturer. The traceability has to be fully guaranteed.

Changing the properties of a CE marked product. If a manufacturer buys in a product and changes its properties before selling the product, he becomes a manufacturer under the CPD and must CE Mark the product as he places the product on the market.

5.3 CPD Performance based specifications

Chapter II, Article 7(2) of the CPD says "The resulting standards shall be expressed as far as practicable in product performance terms, having regard to the interpretative documents". Consequently, all EC Mandates to CEN and EOTA foresee that provisions in technical specifications should be expressed, as far as practicable, in product performance terms.

However, manufacturers being confronted with the legal requirement of CE marking all construction products find that testing may be expensive and CEN and EOTA are continuously being requested to simplify requirements. In addition, the technical state-of-the-art may not (yet) permit replacing existing design knowledge by test methods (e.g. durability requirements), preventing CEN and EOTA to introduce performance based requirements. Calculation, which may replace expensive testing, may also be burdensome and/or expensive.

Therefore, the European Commission concluded alternative solutions are necessary to remove some of the burden on manufacturers. The first solution used was the publication of deemed-to-satisfy provisions in the case of reaction to fire class A1 products in an EC Decision, permitting manufacturers to claim class A1, without testing. This principle is now also being used for other reaction to fire classes, through classified without the need for further testing (CWFT) in the case of (other) reaction to fire classes. These CWFT cases are also published in EC Decisions.

The solutions above are published in EC Decisions, since reaction to fire classes are regulatory classes. For non-regulatory classes, CEN and EOTA can introduce technical solutions in specifications, preventing testing and/or calculation through conventionally accepted performances (e.g. tabulated values, « typical » solutions).

However, specifications should always permit manufacturers to claim superior performances than those specified in deemed-to-satisfy provisions, CWFT-cases and conventionally accepted performances through testing (or calculation), encouraging innovation and preventing new barriers to trade.

Therefore, recent CPD technical specifications incorporate the principles of the performance approach by specifying:

- Requirements (objectives to be achieved)
- Verification methods, i.e. testing or calculation, which can be used to demonstrate whether or not products meet the requirements
- Performance expression methods (threshold performances, characteristic value, classes, levels, …)

And in addition, they specify products, materials, design and construction methods considered to meet threshold performances, levels or classes, without the need for testing.

Most CPD technical specifications will include both prescriptive and performance elements, but should in all cases be primarily performance based. The EC seems to adopt the idea that the performance approach is a means to develop technical specifications, promoting innovation and preventing barriers to trade, but not an end in itself.

Ing. Lisa Di Bartolomeo,
Department of Architecture and urban planning-Faculty of Engineering-University of L'Aquila, Italy (email: lisadiba@tin.it)

Abstract

Today the urban lighting at last performs a significant role in the field of the issues concerning the regeneration, the organisation and the urban promotion. During the years the progressive awareness about the necessity to determine a specific luminous night landscape has led to a definition of new objectives of intervention. In past times, the role of the urban lighting had a merely functional nature; just afterwards it acquired a figurative value, connected to the rereading and promotion of the urban landscape during night-time. However, in both cases the planning process was basically connected to the definition of a prevalent level of priority, responsible for the clear separation – visible for years – between the functional lighting and the architectural one. The will to define a night landscape for the urban environment entailed an increase of the level of complexity of the lighting processes, due to the increase in variables involved. In fact, the result – product of a holistic vision – is obtained only through the synergetic action of different levels of objectives. The urban lighting changes into a control of the relationship between the plant and the urban environment during the whole life-cycle, so considered in the totality of its functions:

- as an instrument of fruition and upgrading of the built environment. Function of the different destinations of use, of the specific spatial typologies, of the urban structure and morphology;
- as a service of public utility. Function of the efficiency, efficacy, economic character of construction and of consumption, of the easiness of maintenance and management;
- as an instrument for the sustainable development. Function of the reduction of the environmental loads and of the applicability of specific eco-compatible solutions.

The insertion of this latter function within the levels of objectives of an installation of urban lighting is definitely one of the most innovative aspects within the process of planning. The most suitable technical normative instrument to use is the need-performance based approach which emerges as an open system which can also be updated. Acting on the specifications of performance within the energetic field, the technological-innovative field, the field of quality of urban environment and of environmental and economic impact, it is possible to define procedures

for the achievement of different levels of quality within the intervention of urban lighting. The final goal is to classify the whole light installation according to its own performance and ascribing to the installation a score equal to the level reached by the same performance. This objective is operatively reached trough a separation into homogeneous parts of the problem organised in working phases. The operating model is developed through the phases of: analysis, definition of the objectives, individuation of the solutions, verification and assessment of the performance level. The conformity of the work performance to the requirements which have managed the planning, the construction and the management of it, sets its level of quality. This means to assert that the process of analysis-verification-assessment makes use of the comparison with benchmarks, properly located (identified), through which it will be possible to give an assessment of the light installation for areas of evaluation. The concept of ‘area of evaluation’ turns out to be a methodological instrument able to consider the different levels of requirement and the connected levels of objective (coming from the assignation of a weight, in terms of importance, to the hierarchy given to the different requirements to satisfy). In this perspective it is also possible to insert the lighting in the process for the sustainable urban development, as a component for the reaching of the parameters established by Kyoto’s protocol. This methodology involves in its own realisation all the actors of the process: from the utilities to the contractors, from the local authorities to the designers bound by a unique synergetic aim for the reaching of specific energetic and environmental performance.

Keywords: score rating system, need-performance based approach, requirement classes, levels of performance, areas of evaluation.

1. The process of environmental urban – lighting system

The urban renewal and the sustainable development of the landscape are themes of great interest, at the centre of the present debate about the reassessment of the town and of the urban policy. In particular, the urban renewal – apart from considering all the aspects connected to the identification of the values to preserve in historical-architectonic and landscape terms – can’t leave out of consideration the identification of strategies suited to the energetic-environmental management, able to improve the use of the areas, without causing disturbance to the present ecosystems. In this specific case, the reduction of the field of investigation to the system of empties constituting the connective of the urban fabric, and the restriction of the field of investigation to the process of urban lighting, define the environmental urban – lighting system. It is aimed to the satisfaction of the following requirements: improvement of the life quality, upgrading of the urban image, efficiency and energy conservation, sustainable development. It’s obvious that these requirements put the process of urban lighting in the field of the issues concerning the urban renewal, organisation and promotion, because it is able to produce economic, social, cultural and tourist implications. Moreover, the delineation of a complexity of contents, like this, implies the involvement of intervention politics characterised by more and more complex solutions, able to have important repercussions on the night landscape, on the activities carried out in it and, at the same time, on the sustainable development (through solutions of control of energy consummations and use, coming from renewable resources). Anyway, the promotion of the improvement of the quality of urban lighting has to consider the local conditions and the fact that the system consumption, management and maintenance is today a considerable charge for the local government; moreover, it has to consider the opportunities caused from the definition of an identity of the luminous night landscape in the process of renewal of the urban image. The progressive awareness of the role of the urban night landscapes has brought during the years to the definition of new aims of intervention. So, the aim to preserve and upgrade the identity of the places merges with the transformation processes; these latter are generated by the changed social requirements and by the need of development centred in the perspective of efficiency, efficacy, sustainability and low costs. The aim to pursue the improvement of the quality of the urban landscape – lighting system implies the setting-up of multidisciplinary and specialist tools to manage the complexity for the identification of qualitative, quantitative and procedural solutions. Practically it performs through a whole of actions – promoted by the local government – able to start a path of careful revision of the normative tools of guide and control of the whole process. As a consequence, the local government becomes the main actor of the possible transformation of the process of urban lighting and of the promotion of a new development model which respects the historical-architectonic heritage, the environmental values, the social requirements and the technical-economic practicability.

2. Aims

The task to guarantee specific qualitative levels of the luminous installations becomes the main purpose in the improvement process of the quality of the urban environment – lighting system. The qualitative levels are measurable in terms of performance (night and day urban environment performance, energetic-environmental performance, technological performance, economic performance and procedural performance). So this approach implies the definition and the classification of different reading levels about different and correlated disciplinary fields. The achievement of the result – product of a holistic perspective – can be reached through the synergetic action of several levels of combinable aims, organised and pursued through rules which define a technical normative of performance inside the process. This normative is aimed to the achievement of performance levels of intervention corresponding to the satisfaction of the purposes coming from the analysis of a basic requirement framework. The achievement of the aims requires:

- a strategy of intervention;
- a practical methodology.

3. The strategy

In this field, the satisfaction of the requirements revealed can be articulated through two different levels of action:

- the definition and the examination of a complex framework of requirements, which takes shape as an open system that can be updated. It is structured through the need performance based approach thanks to: the levels of aims, the classes of requisites, the compulsory and voluntary requirements and the performance specifications (indicators) for the achievement of the expected qualitative levels;
- the indication of procedures for the co-ordination of the activities which make up the phases in which the process is disassembled.

So, the promotion of a new development model of urban lighting implies the definition of an intervention tool which, acting on the performance specifications in a technological, energetic, economic field and in a quality range of urban environment, can define some procedures through which it can take into consideration the different levels of performance. They are practicable in the strategies of project, construction, management and the divestment system, or during the various phases of the process.

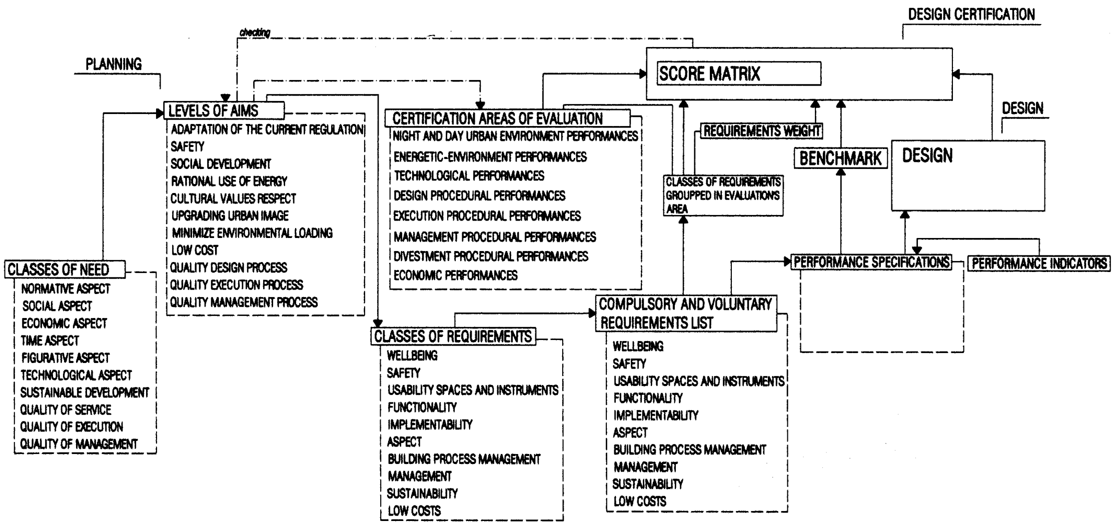

Figure 1: Need-performance based approach flow

4. The methodological approach

The innovation of the approach consists in the definition of a development model of the urban lighting process based on the fulfilment of a framework of requirements a priori defined. The translation of the requirement classes to satisfy in levels of objectives to pursue (health, security, satisfaction of social expectations, environment safeguard, rational use of energy, upgrading of the day and night urban environment, adaptation to the current regulations, etc.) is the methodological assumption of the process and enables the development of a *management system for the quality of urban lighting.*

This system is a way to conceive and represent a non-repetitive process, which can be greatly differentiated for aims and environmental context. Practically it is applicable through a division structured in components organised in levels and through supporting procedures to the macro-phases: productive out work, decision-making and productive in work.

It's organised by means of an inner technical normative instrument which has the task to guide and check the process (as a support of rational behaviour). It is capable to order in hierarchy the goals of each phase making up the process (planning, designing, execution, management and divestment). It is also able to connect them finding the relationships between the fact-finding areas in which the system is divided (usable spaces system, technological system, figurative system and procedural system). The development of a management system for quality provides for the definition of a practical methodology based on the structured division of the process in systemic connected components and on the classification of different sectors in which they can be articulated. This tool, using the individuation of goals and acting on the performance specifications, rather than on established solutions, is adaptable to each local reality. So, it is possible to do a first division in:

- urban lighting product-service system;
- urban lighting process system.

The system concerning the urban lighting product-service is a tool able to define and check the minimum levels of acceptability. These is the minimum requirements acceptable, which the system in its globally has to satisfy. The content of the system regarding the urban lighting product-service is functional to the need to structure the urban-lighting environment system in the following parts:

- spatial and environmental condition system;
- technological system.

It's useful to classify the following subsystems:

USABLE SPACES SYSTEM

- functional-dimensional system: concerning the use destination, it deals with the geometrical, dimensional, distributive, space-relationship aspects to the different levels of complexity, with specific reference to the requirements of wellbeing, usability, safety, integrability, aspect and management; its object is the spatial category, the settling complex.
- physical-environmental system: concerning the artificial microclimate, it deals with the aspects defining the environmental conditions of the spaces, with specific reference to the requirements of wellbeing, usability, safety and sustainability; its object is the environmental unity, the spatial category, the setting complex.

TECHNOLOGICAL SYSTEM ascribed to the requirements of the usable technology, it defines and checks the behaviour of the technological parts that make up the spaces in connection with the above-mentioned requirements; its object is the technological unity, the technical elements, the equipment and the material.

The system concerning the urban lighting process is developed during the temporal phases of the planning, realisation, management, maintenance and divestment. It requires the realisation of operational models and suitable actions to check the development of a management system for quality. So, it becomes the tool to use and to structure the procedures to manage and check the phases of the process. It’s made of a range of phases (sub-processes) interacting in parallel or in sequence, in which the management system for quality becomes a strategic factor to identify the aims to pursue, to programme the activities, to plan the test and the controls to carry out.

PROCEDURAL SYSTEM regarding the activities which characterise the process. It concerns the programmatic, organisational and managerial aspects connected to the execution of this activity. It also concurs the roles of the operators involved in the process.

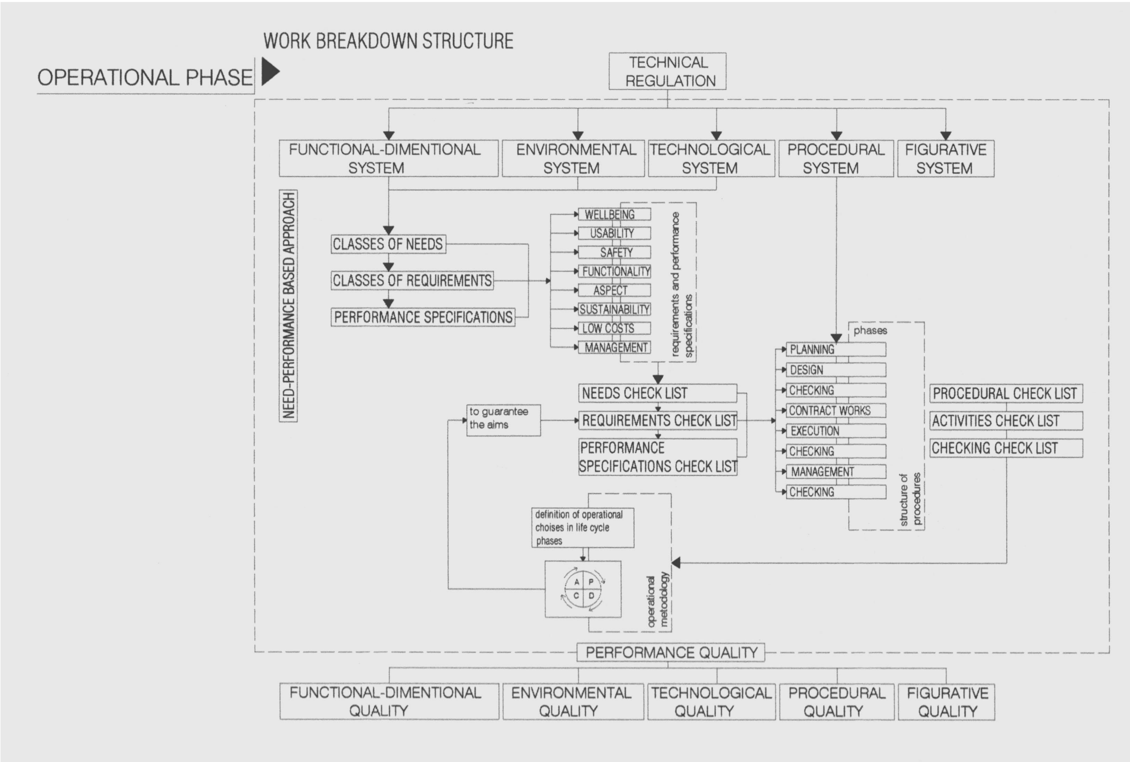

Figure 2: W ork breakdown structure of operational phase

This merely methodological approach is used to reread and systematise the characters which structure the luminous process of the historic centre. In other terms, it is necessary to apply different levels of reading of the disciplinary fields, interacting in a system of connections between the urban landscape and the technological system. The classification of the relationship spaces in spatial typologies and categories, with the following definition of the characteristics to upgrade or to ignore (through a value judgement), will intervene as a basic fact-finding structure. Then, it will be a support – as above-mentioned – of the procedural structure for the development of the temporal phases of the process: planning, design, execution, management and maintenance, divestment, in addition to the checking phase. This latter acts at the end of each previous phase. A division of the process according the need performance based approach and the following reassembling of the parts, assure the chance to define a guide-check tool of the urban luminous process able to allow, at the same time, a plurality of solutions.

5. Operational tools

The operational methodology based on a framework of requirements and on a procedural system uses a series of supporting tools through which the management system for the quality of the urban lighting process is practically accepted. In the following scheme it is possible to pick out:

- the urban lighting masterplan, guide and planning tool for the interventions, is calibrated for the middle-long term and identifies all the interventions to realise. Even if it doesn't have its own economic resources it has the task to define guide lines to choose the technologies and the techniques to use.
- The urban lighting programme, calibrated for the short-term, only includes those actions on which the agreement between the public and private parts took shape. It has the financial resources to carry out these actions.
- The energetic-environmental certification of the phases of the urban lighting process, instrument used to check and measure the reached performance levels.

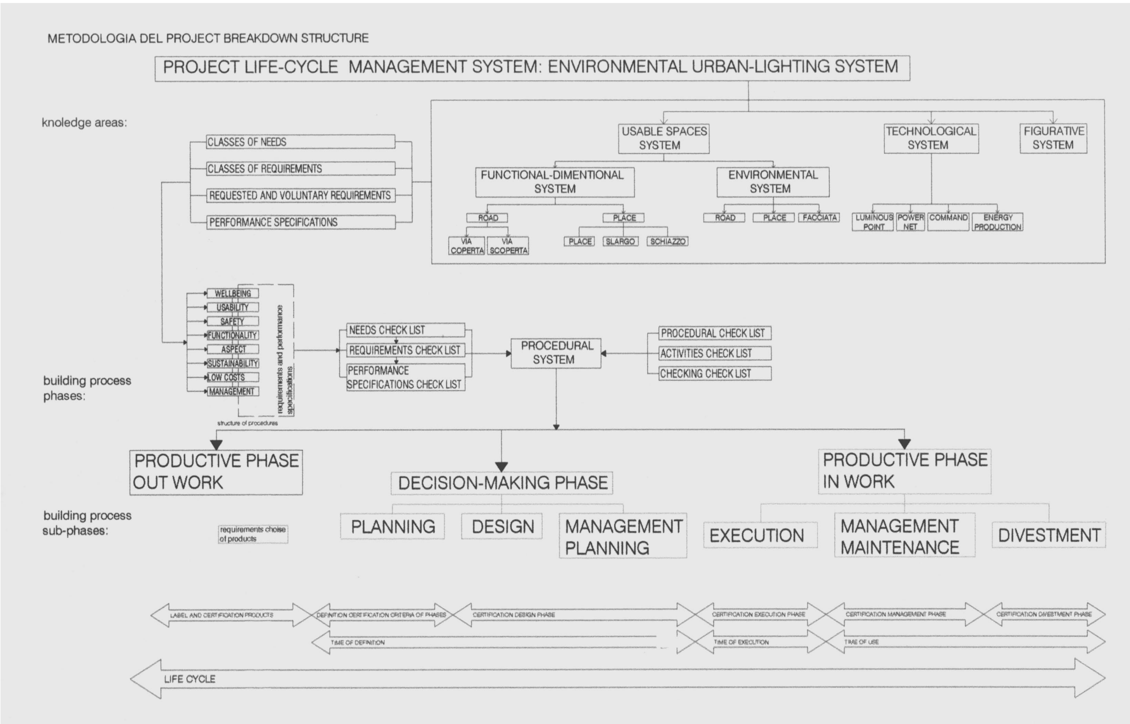

Figure 3: Work breakdown structure of operational phase methodology

The need to define an urban lighting masterplan comes from the will to give an organic development to the interventions of the municipal area. It intervenes as a planning tool and it has as purpose the definition of: the criteria of intervention for a luminous night landscape, the priorities of intervention and the technological, energetic-environmental and technical-administrative principles. It allows to define an operational methodology and supporting tools (abacus of conformed solutions and solution models) aimed to the pursuit of specific qualitative levels. Consequently, it is an instrument which can define the contents of the energetic-environmental certification process of each intervention (requirements of the evaluation's areas and assignation of weights in the score matrix, indicators and criteria of score assignation, chart of synergetic awards, assignation chart of certification levels, correspondence of awards).

The other two instruments intervene during the following phases of the process and require a deep revision of the relationships between public and private subjects. In fact, they are suitable to operate in the complexity delineated in the energetic sector, in which the urban lighting systems take their place. Exactly, the foreseen model goes toward a negotiated planning of the development of the urban lighting. It is necessary to pursue the realisation of objectives of economic development, connected to actions of social, environmental, formal and technological upgrading. The liberalisation of energetic markets, the acknowledgement of the European directives about the energy conservation and about the development of the renewable sources, the resolutions of the AEEG, the white certificates or titles of energetic efficiency, the role taken from the different actors involved (distributing societies, selling societies, ESCO, etc.), all that require a complex structure of procedures. Therefore, the programmes – projects require the definition of concrete interventions to follow, coming from the different technical-economic alternatives. In this perspective the quality component becomes a strategic factor for a correct management of the processes of urban upgrading and of sustainable development of the area. Moreover, the instrument energetic-environmental certification answers to the principles which structure the conception of a new model of development and upgrading of urban lighting:

- the objectives satisfaction principle
- the compensation principle

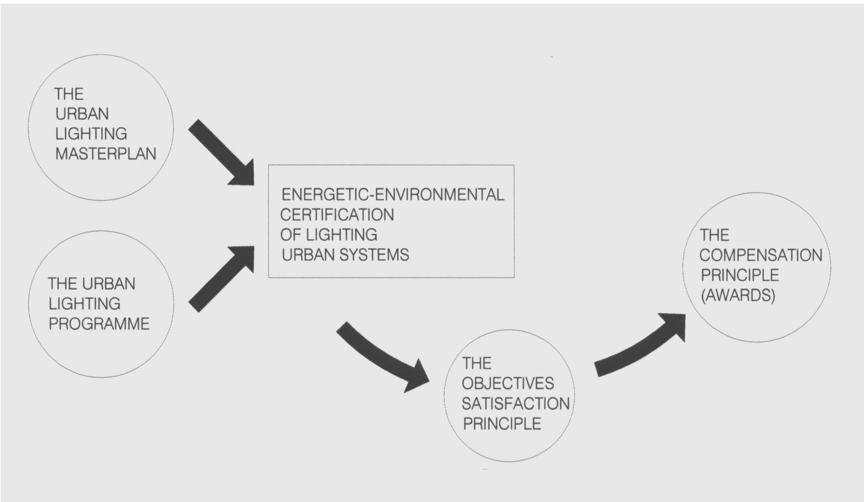

Figure 4: The principles

6. The principles

6.1 The objectives satisfaction principle

The development of the management system for quality is aimed to guarantee the fulfilment of the foreseen objectives. In this field the check phase has a determinant role. In fact, the use of :

- the need performance based approach: with the definition of the requirements to satisfy to reach the performance levels;
- the processes approach: with the definition of the procedures and of the check lists,

implies the necessity to have an evaluation system of the requirements fulfilment degree and of the efficacy of the system. This can be obtained through a "measurement process", thanks to the following consideration: without measuring it's not possible to compare, therefore to estimate the trend of any activity. Consequently, to be able to measure it is necessary to define some indicators. So it is possible to check the intermediate steps of the activity progress in each phase, as well as to measure, check and validate the phases of the process.

Therefore the definition of a specific checking and evaluation tool of the reached performance levels is, at the same time, the check of the fulfilment level of the foreseen objectives. It is expressed clearly with the process of energetic-environmental certification of the lighting systems, put at the end of each phase as indicated: certification of the planning phase, certification of the realisation phase, certification of the management and maintenance phase and certification of the divestment phase.

6.2 The compensation principle

The measure of the fulfilment level of the objectives is the basis of the compensation principle. It is the performance level of the urban lighting system. The nature and the aim of this principle can be understood after considering: the role of lighting in the process of urban upgrading and the role of lighting in the energetic sector. Moreover it is useful to reassert that, as above-mentioned, the programme of urban lighting concerns short-term actions, arranged between the public-private parts. This is expressed by the chance to leave to the private subject the total or partial realisation of the urban lighting system. These considerations also express the possible situations that could occur in the urban field.

1. Inside the upgrading programmes of the fabric of the city, the system of empties, or rather of the public space, can become an intervention object of the private. This activity can be applied compensating for the expense through the award tool. This principle requires two instruments. One of guide, typical of the planning phase, and made explicit by the lighting programme. The other, of check, is carried out at the end of the process phases involved in the operation. This system is necessary to guarantee the fulfilment of

the public objectives, formerly defined. At the same time, the concept of award implies a measuring of the fulfilment level of the objectives. On this point the energetic-environmental certification, assuming the estimation of the performance fulfilment level from A to G, can be a useful instrument to measure the award. The bigger the certification class, the bigger the advantages for the local government, in terms of quality of lighting system and, consequently, the bigger the advantages for the private subject involved. During the planning phase the local government has to define the certification criteria, as well as the awards ones.

2. Inside the upgrading programmes of the lighting systems, carried out thanks to loans from third party (FTT), the same practical procedure above-mentioned can be applied. Actually, even if the aims of the public part remain the same in both cases, the private ones significantly change. In fact, the private engaged in a urban upgrading process, after the decision to intervene on the public space, finds the chance to reach a system of reductions to keep on the real estate. Moreover, it has a pay back return of investment even in terms of general image of the urban environment which, therefore, will give more value to the operation. The private engaged to finance the total or partial upgrading and/or realisation of the urban lighting systems, finds profitability in the investment, if characterised by a very moderate risk and by a substantially constant cash flow originated by the energetic saving achieved. This allows this subject to be rewarded against the costs of the system planning, installation and management met in a reasonable time. It’s clear that this latter subject considers the energy conservation the fundamental requisite of the intervention. The tools above stressed become assumption for arrangement between the parts.

6.3 Certification systems of the energetic-environmental quality of the lighting systems in the phases

The check method of the performance level fulfilment has been found in a score rating system. In this system to each satisfied requirement a score is given which contributes to fix a general score, exemplifying the reached performance level. The system is structured on a list of requirements, grouped in areas of evaluation, and to each of them an evaluation judgement in numerical scale (score) is assigned, related to the conformity degree to the benchmark. In fact, the assignation of the score to each requisite occurs through the definition of the corresponding performance indicators and, consequently, of the criteria necessary to the check of the fulfilment level of these performances. The evaluation scale is structured through a corresponding chart between a value scale that goes from –2 to +5 and the criteria of score assignation, where the zero is the value or the benchmark concerning what can be considered as the current realising practice, with observance of the current laws and regulations. The score rating system adopted also considers synergetic awards if the requisites regarding a specific family, are satisfied all or, in significant percentage. The synergy award is a clear signal that shows that the best results are not given by the addition of single actions, but by a global and organic strategy. Moreover, the single requisites had importance in the belonging evaluation areas, according to a preventive assignation of the importance that each has. It emerges a sort of energetic-environmental report card and, through a pondered summation of the reached score for each considered requisite, it's possible to obtain an exemplifying global score of the performance level of the installation in exam. This evaluation is carried out for each phase of the process (planning, execution, management and divestment) and it defines a series of single or summable certificates, making a sort of quality label. The total score contributes to give a certification level according to the classes: A,B,C,D,E,F,G.

ENERGETIC - ENVIRONMENTAL CERTIFICATION IN DESIGN PHASE

7. Conclusions

The bottom strategy top down uses a operational model represented according to a reiterated process, which requires phases of closer examination alternate to check cycles to the different scales and phases of intervention. It requires a division in activities for each phase: analysis, definition of the objectives (requisites, performance specification), individuation of the solutions, check and evaluation of the performance level. The definition of given procedures, able to systematise the activities and the criteria of acceptance of each phase is a support able to assure a correct application of the same. These latter become application of the criteria fixed by the light masterplan (planning instrument of the interventions and of the certification criteria, that is of the minimum acceptable performance levels and of the possible ones). Finally they become as assumption for the evaluation and check of the application performance levels.

Sustainable Procurement: Is Partnering the key?

Kate Carter,

Abstract

Partnering has been cited as a means to deliver sustainability through the procurement system. This idea builds on the notion that sustainability and partnering have the same ethos of long term goals and mutual benefit. Sustainability is often seen as intangible and difficult to deliver at project level. There is often agreement at policy level as to the meaning of sustainability. However there is a common concern that sustainability is difficult to identify and therefore deliver through a construction project. By adopting a more appropriate procurement route sustainable development may become more achievable.

Research had been conducted in the context of the UK social housing sector, with its requirement for a move towards partnered procurement. The research sought to establish how frequently partnered procurement is taking place and how appropriate it is considered for the delivery of sustainability. The research focuses on the procurement selection and how this impacts on the sustainability of a project. Significant features of a partnering framework are identified to create a profile of partnering at project level.

A national survey of social housing providers investigates the attitudes towards partnered procurement. The results of these surveys are analysed to demonstrate the approach to procurement selection and the attitudes that are most commonly linked to the choice of partnering as a procurement route. This research provides a comprehensive snapshot of procurement selection practice and the relationship this has with the delivery of sustainable housing projects. There is a general consensus that partnering can deliver sustainability and that partnering is a more suitable form of procurement to achieve this rather than more traditional procurement routes. This research suggests that further longitudinal studies are undertaken to measure the long term performance of projects that are undertaken using partnered procurement.

Keywords: Sustainability, Procurement, Partnering

1. Sustainable Procurement

1.1 Overview

The research presented in this paper is part of a larger piece of research involved in the concept of sustainability and procurement of social housing. The social housing sector in the UK is obliged to consider sustainability when procuring new housing project. Partnering is often suggested as the most appropriate procurement approach to achieve improvement through the construction of building projects. This research considers the procurement of social housing and reports on research conducted with development managers of Registered Social Landlords (RSLs). Attitudes towards various procurement approaches was established to explore the link between partnering and the delivery of sustainability.

1.2 The Context of Partnering

A recurrent theme from the Rethinking Construction agenda is partnering and integrated teams. According to the Construction Best Practice Programme (CBPP), the two principles that embody best practice in construction are the abandonment of lowest capital cost as the value comparator and involving specialist contractors and suppliers in design from the outset. Partnering lies at the heart of the 'Rethinking Construction' agenda. Partnering is being advocated by the Housing Forum and the UK housing agencies as a means to deliver improvement through the procurement of social housing. Partnering is heralded as a means to achieve this supply chain integration.

The interpretation of partnering takes two forms. One, of a philosophical position or framework, and another a form of contracting. There is a difficulty in finding absolute agreement at a detailed level as to what partnering is and hence it may be applied to various forms of alliancing (Liu and Fellows 2001). Masterman (2002) defines partnering as a “discretionary system” of procurement. It is described as:

> *a means of administering and establishing an environment within which a project is implemented using any of the available procurement systems to carry out the funding, design, construction etc. of the project, although some systems work better with partnering than others.*
>
> (Masterman 2002:135)

This implies that it is not a form of procurement but a framework within which procurement takes place. This view is supported by the numerous definitions of partnering found throughout the literature. The CIB (1998) definition refers to a *management approach*. The CII (1991) talks about *long term commitment*. Culture change is a common theme, having significant importance to organisations planning to embark on a partnered approach to procurement. This change is necessary to move away from the entrenched exploitive and adversarial ways found throughout the construction sector to a more collaborative way of operating (Fisher and Stuart 2001).

There are two types of partnering. Project partnering where the relationship is put in place for one specific project and strategic partnering where there is a long term/ multi project arrangement. It tends to be stated that there is more benefit to be gained from strategic partnering although an acceptance that project partnering is most likely to be embarked upon by those new to the concept. There is consensus in the literature on the attributes of successful partnering. They include trust, mutual objectives, collaboration, equality, continuous improvement and agreed problem resolution. It is interesting to note that in a survey of construction professionals "failure to build a trusting relationship" was muted by a third of respondents as a barrier to partnering (Murray *et al.* 1999).

There is much less agreement on the processes of partnering. Partnering emerged in the UK construction industry at the beginning of the 1990s, and because of the relatively young nature of the concept there is not a large body of empirical research. A survey of contracting practices carried out on behalf of the RICS in 1998 revealed that only 1.7% of projects was carried out under partnering agreements. Partnering and collaborative working are not sufficiently evolved and researched to be able to draw lessons from past experience. Much of the evidence presented in research papers is anecdotal or based on a small sample.

Partnering in the social housing sector (ECI 2000) presents a prescriptive approach to partnering that can be used as a checklist of actions. The key objectives of partnering in the social housing sector are identified as *cutting out waste, increased predictability, secure life-cycle cost benefits and increase innovation.* There is little mention of culture change and philosophical position. Culture is identified as the main barrier to implementing partnering. There is recognition in most of the literature that both philosophical and process definitions are relevant and constitute an important aspect of partnering.

Partnering has been said to be capable of delivering up to 30 % cost savings (Bennett and Jayes 1995) over traditional sequential procurement. This figure relates to a programme of strategic partnering and is somewhat ambitious having not been supported by sufficient evidence to draw any firm conclusions. There is a growing body of anecdotal case study material that presents positive feedback from a partnered procurement route.

The CIB (1997) state that the benefits are significantly greater if partnering is applied throughout the supply chain. Integrated teams and supply chains although often written about separately are in fact a manifestation of partnering and one could argue partnering applied in the most comprehensive way possible. If clients really intend to unlock the potential of the supply side they will have to start projects entirely differently. This means assembling alliances of consultants, specialists and key manufacturers into integrated teams. Martin Davis of the Integrated Team Working Group states that if this is achieved **“**The supply side should be expected to drive and deliver on challenging performance targets”. He also emphasised the importance of research and development. "The supply side should welcome researchers working within integrated teams to help it monitor and improve its performance. Those universities and institutions supporting continuous improvement in the industry's key success areas should be given priority financially."

The Rethinking Construction report, *Accelerating Change* (Strategic Forum for Construction 2002) proposes that 20% of all construction projects have an integrated team and supply chain by 2004. It is not known if this figure has been achieved. It further states that *every link of the supply chain has a critical contribution to make towards sustainable construction and development.*

1.3 Sustainable Development

The construction industry has been identified as one of the most important areas for implementing sustainable development. The built environment is seen to have a significant impact on sustainability issues. In 1999, 50% of the UK’s CO_2 emissions were produced by energy use in buildings (M4I 2000). *Building a Better Quality of Life* (DETR 2000) places construction at the heart of the UK government sustainable development agenda. It claims that the construction industry has a huge impact on the quality of life in the UK and that considerable economic, social and environmental benefits can be drawn from a more sustainable construction industry.

The CBPP states that the client has a key role to play in the delivery of sustainable construction owing to their position within the construction supply chain (CBPP 2002). They are able to influence decision-making on how the construction process impacts the broad themes of environmental, social and economic sustainability. The client can demand forms of and encourage actions towards sustainable development with a clear value statement that guides all procurement activity. Quality, whole life costing, best value and people issues all make their contribution to the overall sustainability of a development.

Scottish Homes *Sustainable Development Policy* (2000) focuses on four key actions:

- Improving the thermal performance of housing
- Reducing the need for physical resources
- Influencing the location and mix of housing
- Raising and improving consumers awareness

Improving the thermal performance of housing has three chief benefits: To reduce CO_2 emissions, condensation and fuel poverty. Housing that is designed and constructed to minimise energy use in occupation has the ability to improve the occupant’s health and well being and reduce the devastating effects of fuel poverty. Housing Associations may consider the benefits accrued in terms of lower maintenance attributed to condensation and higher levels of tenant satisfaction.

The clients influence on the procurement process has the potential to address many of the failings of the construction in relation to long term sustainability. It is estimated that 30% of construction is re-work and only 40-60% of labour time is used efficiently. This incorporates substantial waste into the construction process. Eliminating this waste will have impacts not only in terms of environmental sustainability but also in terms of direct cost and time reduction and increased motivation and satisfaction across the team. Collaborative working is seen as an essential means to addressing this problem.

Brownfield site regeneration and redevelopment of existing buildings are both seen as sustainable options. The choice of site is one of the first steps in the procurement process and has far reaching implications in terms of community sustainability. At a micro level adaptability and mix of tenure in a housing development have a significant impact. Strategic planning and development, a product of collaborative working will have a significant role to play.

2. Linking Partnering and Sustainability

The Housing Forum sought to encourage partnering through the procurement process. Partnering is now central to the housing agencies' strategies for improving procurement of social housing. It has been suggested that the attributes of partnering are essential pre-conditions of achieving sustainable construction (Addis and Talbot 2001). HAs and their consultants and contractors will have to reach a mutual consensus on the definition of sustainability at project level if it is to be achieved within the overall procurement process. There is a need to link the policy, regulation and guidance to respond to the individual project circumstance.

In theory the difficulty in meeting the holistic goals of sustainable development policies is evident at project level. The ability of short term project objectives to address the long term altruistic goals of sustainability is limited. In practice evidence of creating buildings with one sustainable feature demonstrates a myopic rather than holistic approach to sustainability. Social housing projects have a requirement to demonstrate sustainability, yet the people involved in their procurement have a varied understanding of the term.

2.1 Methodology

A study of Registered Social Landlords (RSLs) was carried out to establish an understanding of sustainability and partnering within the social housing sector. The research tool selected was the questionnaire. This was chosen due to the size of the survey population. There are over 2300 housing associations within the United Kingdom. One of the main aims of the survey was to establish trends across the whole social housing sector.

The survey was conducted amongst the UK population of RSLs. 990 housing associations involved in development of social housing were selected for inclusion in the survey. Those that owned less than 20 properties were immediately eliminated from the survey population. This left a sample of 1090. One third of these organisations was contacted and invited to complete the survey. The questionnaire was supported by a letter addressed to the 'Development Manager'. A low response rate of 25% was achieved which was considered inadequate. A second round of questionnaire was sent out which raised the response rate to 37%.

The raw data were compiled within a Microsoft Excel spreadsheet and then imported into Statistical Package for Social Scientist (SPSS) to conduct the analysis. The questionnaire was concerned with the collection of perception in the subjective areas of sustainability and partnering. Attitudinal measuring scales were used to provide a number of options for the respondent to select. Composite measurement of an issue or ranges of issues is suggested (Wilson 1996). This involves asking more than one question on a similar area in order to develop a theoretical construct. It is used to gauge the link between sustainability and approaches to procurement. Two questions are strongly correlated and the responses can be used to construct a more accurate view on the issue.

2.2 Results

The results of the questionnaire provide a snapshot of the partnering activity that is taking place in the social housing sector. It also provides the general perception of the way in which procurement approaches are related to the concept of sustainability. The results provide the contextual background against which procurement decisions are being made.

It was found that a higher proportion of RSLs were engaged in partnering than not. The most common form of partnering was 'Project' partnering with consultants and contractors. Almost forty percent of RSLs were in partnerships with other RSLs (housing associations). The least common partnering was with sub-contractors or suppliers.

Strategic partnering was less common than project partnering. The only incidence of strategic partnering exceeding project partnering was the Large RSLs partnering with other RSLs.

Table 1: Incidence of Partnering in Social Housing Procurement (% of respondents)

	Split into small med large	**Strategic Partnering**	**Project Partnering**
Consultants	**Small HAs**	2	6
	Medium HAs	19	20
	Large HAs	22	36

	Total	43	62
Contractors	**Small HAs**	2	4
	Medium HAs	13	24
	Large HAs	24	42
	Total	39	70
Subcontractors	**Small HAs**	2	2
	Medium HAs	9	12
	Large HAs	11	13
	Total	22	27
Suppliers	**Small HAs**	2	2
	Medium HAs	9	11
	Large HAs	15	19
	Total	26	32
Other RSLs	**Small HAs**	4	6
	Medium HAs	15	20
	Large HAs	24	21
	Total	43	47

Traditional contracting, Design and build and Partnering were presented to the respondents as three procurement approaches. The respondents were asked to judge the strength of agreement with the statement in terms of the link held with sustainable development. The question was designed to gauge if the concept of sustainable development was perceived to relate more closely to any of the proposed procurement approaches. This allowed the respondent to provide a response based on 'gut-feeling' rather than in relation to specific experience. The data was collected with the use of a five-fold Likert scale. The scale ranged from *strongly agree* to *strongly disagree*. A central or neutral position was described as *uncertain*. Although this allowed the question to remain in effect unanswered it allowed a respondent to demonstrate lack of knowledge or experience in this area.

Table 2: Correlation of partnering experience and perception of procurement approaches

		Partnering		Design and Build		Traditional	
Project Partnering – Link with Sustainability	Consultant	.368	.002	.242	.083	.231	.103
	Contractor	.369	.001	.254	.054	.281	.030
	Sub-contractor	.611	.000	.306	.079	.288	.092
	Suppliers	.420	.002	.296	.058	.323	.188
	Other RSLs	.362	.009	308	.024	.235	.124
Project Partnering – Ability to deliver Sustainability	Consultant	.405	.002	.311	.015	.317	.022
	Contractor	.415	.001	.328	.008	.325	.000
	Sub-contractor	.556	.000	.385	.021	.373	.027
	Suppliers	.422	.004	.354	.021	.306	.074
	Other RSLs	.419	.004	.374	.006	.299	.043
Strategic Partnering – Link with sustainability	Consultant	.404	.001	.270	.065	.188	.249
	Contractor	.429	.001	.257	.077	.179	.264
	Sub-contractor	.633	.000	.373	.030	.239	.195
	Suppliers	.574	.000	.356	.023	.273	.106
	Other RSLs	.404	.002	.294	.043	.221	.162
Strategic Partnering – Ability to deliver sustainability	Consultant	.448	.001	.369	.010	.343	.018
	Contractor	.465	.000	.311	.025	.330	.021
	Sub-contractor	.584	.000	.530	.000	.397	.019
	Suppliers	.619	.000	.514	.000	.412	.007
	Other RSLs	.436	.001	.323	.027	.295	.049
Note: shaded cells indicate no statistical significance							

It was assumed that partnering practice would have an influence on the perception of the approaches to procurement and their link to sustainability and whether they are able to deliver sustainability. Each form of procurement was correlated with the types of partnering that had been undertaken by a respondent RSL. Strong correlation coefficients indicate that experience of partnering practice has provided a more positive view of a procurement approach and its link or ability to deliver sustainability. The coefficients and statistical significance are presented in table 2.

Without exception, all those that had experience of partnering agreed that partnering had a link to sustainability and it could deliver sustainability. Although this result is an expected result, it does confirm that the perceptions of partnering are borne out in practice. The strongest correlations were found in respondents that had partnering experience with sub-contractors and suppliers.

The correlation between traditional contracting and partnering experience generated the highest number of correlations that were not statistically significant. Those with either project or strategic partnering experience generally rejected the link between traditional contracting and partnering.

There was a moderate increase in respondents agreeing the link between design and build and partnering, although most of the agreement came from respondents with strategic partnering experience.

Experience of partnering appears to provide greater confidence in its ability to deliver sustainability as opposed to design and build or traditional contracting. The greatest confidence correlations were evident in RSLs that had partnered with sub-contractors or suppliers. This seems to support the view that the supply chain is critical to the delivery of sustainability conceptualised.

3. Conclusions

This study is part of a larger piece of research investigating the way in which sustainability is understood at policy and practice level in the social housing sector. Selection of procurement approach is a fundamental decision within the construction of a social housing sector. The requirement to deliver projects that demonstrate sustainability has changed the focus of decision making. The ultimate choice depends on a great number of factors including past experience. The RSLs with experience of partnering have far greater confidence in a partnered approach to procurement than a design and build or traditional route. This leads to the conclusion that where sustainability is a strong factor, there is going to be a greater liklehood of partnering being selected. This research is not able to confirm this view, but suggests that further research is required to establish the effect sustainability has on the ultimate choice of procurement approach.

Abstract

The objectives of this research are: (1) To identify the factors limiting the effectiveness of performance based (PB) standards; (2) To compare the views' of the industry and the Building Construction Authority (BCA) on performance based standards; and (3) To recommend the most significant factors for consideration in understanding and assessing the factors' effectiveness on performance based standards. The research methodology employed in the study consisted of a questionnaire survey. Data were collected from developers, contractors, consultants and suppliers. Results showed that the awareness level of the construction industry was poor and seven factors have been identified which are significant in limiting the effectiveness of at least one type of benefit accrued to PB standards. Findings from this study will enable the regulatory body to focus on the impact of these seven limiting factors in formulating implementation polices for performance based standards in the construction industry. Furthermore, this study will help to create greater awareness among the key parties in the construction value chain on the issues of performance based standards. Effectively, knowledge acquired by the industry will then maximize the potential of the performance approach.

Keywords: Performance based standards, effectiveness, awareness, regulatory body

1. Introduction

The performance based approach is a radical departure from the conventional procurement system in Singapore. The government's push for a performance based concept is exemplified by repealing the previous prescriptive regulatory system with a performance based regulatory system in January 2004. Although, it has been established extensively in studies by overseas researchers that there are more advantages to be derived from adopting a performance based approach than a prescriptive approach, researchers also found that there are factors that would limit its effectiveness.

One of the key reasons for the growing importance of the performance based approach is its ability to transcend barriers to trade within the international construction market. The performance concept has been implemented in developed countries like the United Kingdom in 1987, New Zealand in 1992 and Australia in 1994 but with varying levels of success [1]. The limited success of the performance based regulatory system can be attributed to the fact that the overall system has not been addressed and deficiencies in key areas like education and infrastructural support [2]. Therefore, it is imperative that knowledge of such issues is shared with the local industry so as to maximize the potential of the performance approach. Hence, it is the intention of this study to explore and determine the factors limiting the effect of performance based standards. In addition, the findings and generated models of this study will provide the parties involved in making strategic standardization decisions to make better decisions with respect to their requirements.

The objectives of this research are: (1) To identify the factors limiting the effectiveness of performance based standards; (2) To compare the views' of the industry and the Building Construction Authority (BCA) on performance based standards; and (3) To recommend the most significant factors for consideration in understanding and assessing the factors' effectiveness on performance based standards.

2. Research Method

A sample survey was used to gather the necessary information required for this study. In order to obtain an overall view of the effect of performance based standards on construction industry, four groups of target respondents were selected for the study. They included the developers, contractors, consultants and suppliers.

The source of contacts for contractors and suppliers were from the Building Construction Authority (BCA), Directory of Registered Contractors, 2004 edition. In the case of developers and consultants, they were selected from the Real Estate Developers' Association of Singapore (REDAS) website and the Singapore Institute of Surveyors and Valuers (SISV) website respectively.

A total of 250 electronic copies of the questionnaire were sent out to the various participants to gather the required data for analysis. These comprised 30 developer firms, 120 contractor firms, 30 consultant firms and 50 suppliers. The distribution pattern of the sample ensured that equal attention was paid to both the contractors and non-contractors. Questionnaires were emailed to the firms, and returned via the same routes. The survey was conducted from October 2004 to December 2004, and respondents were given three month to complete the questionnaires.

The questionnaire design consisted of four sections to facilitate data collection. Section A asked general questions to determine the characteristics of the respondents. Section B asked respondents about the factors affecting the implementation of performance based standards. On a scale of 1 (which represents strongly disagree) to 5 (which represents strongly agree), the respondents were requested to indicate the impact level of the factors during implementation in

Singapore. Section C, provided a list of benefits of using the performance based standards which the respondents have to rate on a scale of 1 (which represents strongly disagree) to 5 (which represents strongly agree). Lastly in Section D, the respondents had to rate a list of recommended measures implemented in construction industry to encourage the use of performance based standards on a 5-point scale where 1= strongly ineffective and 5= very effective.

3. Data Sample Characteristics

230 survey questionnaires were emailed to the various participants in the construction industry. A total of 30 forms were returned, giving an overall response rate of 12%. Among these, 15 responses were not usable as respondents were not aware of the performance based regulatory system that was already in placed. The profile of respondents is shown in Table 1. Construction firms formed the majority of respondents.

The respondents' profiles indicated that they were suitable and qualified to participate in this study. Furthermore, the wide spectra of designation of respondents which range from directors to student interns, is a good indicator of the level of awareness of the Performance Based Regulatory System (PBRS) within the industry.

Table 1: Characteristics of respondents

Respondents' characteristics	Total surveys sent	Total surveys received	Unusable surveys	Usable surveys
Nature of firm (predominant)				
Developers	30	3	-	3
Construction firms	120	14	9	5
Consultants	30	8	3	5
Suppliers	50	5	3	2
Total	230	30	15	15

4. Results and Discussion

The one-sample t test was first used to test the three areas in concerned: whether the limiting factors, benefits of performance based standards and measures to encourage usage of performance based standards are significant. Multiple linear regression (stepwise) is then used to generate six models – one of each benefit of performance based standards.

4.1 Factors Limiting the Effectiveness of Performance Based (PB) Standards

The one-sample t test is first conducted on the factors limiting the effectiveness of performance based standards (Table 2). All the factors except for the F8.10 (greater competition from foreign companies) have $p > 0.05$ and therefore it is concluded that these ten factors have an impact on the effectiveness of PB standards based on $\alpha = 0.05$.

The survey questionnaire was also emailed to the Building Construction Authority (BCA). A ranking on the level of agreement on the factors that limits the effectiveness of PB standards was carried out to compare the differences between BCA and the industry's views. It was found that both parties (BCA and the respondents) generally agreed that F8.1 (lack of performance indicators), F8.6 (lack of research and development in the field of PBRS) and F8.7 (liability issues of using PB standards) have an impact on the effectiveness of PB standards. These results were not uncommon and had been well established by past studies [3, 4, 5]. Hence, it is pertinent that Singapore should attempt to address such issues on an international basis, thereby tapping onto the expertise of other countries which are more advance in the use of PB standards which requires more technical knowledge to develop and apply than prescriptive standards.

However, there were differences in views for the regulatory body (BCA) and the respondents from the industry for F8.2, F8.4, F8.5, F8.9 and F8.11. This could stem from the fact that companies in the industry are ill informed of the developments of PB standards. There should be more promotion and seminars for the newly enacted regulations especially to the smaller firms in the industry which makes up the bulk of the industry. In 2000, BCA conducted a survey to gather the industry's feedback on the proposed change from a prescriptive environment to a PB environment and the survey results indicated a positive response from the industry. However, the survey results obtained in this study (as highlighted by the views of respondents for F8.4 and F8.9) seemed to suggest otherwise. In addition to a re-evaluation of the perception of the industry on PB standards, this survey also attempts to determine the possible factors limiting the effectiveness of PB standards (see Table 2). The findings of this study would enable BCA to be more aware of the impact of these factors during the formulation of implementation policies for the industry.

Table 2: Summary of One Sample t-Test results to identify significant factors

Label	Factor	Test Value = 3		Ranking (Mean)	
		Sig (1-tailed)	t*	Industry	BCA
F8.1	Lack of performance indicators	0.000	4.525	3 (3.93)	10 (1.00)
F8.2	Uncertainty involved in the use of PB standards	0.001	4.090	3 (3.93)	5 (2.00)
F8.3	Lack of knowledge to use PB standards	0.000	6.959	1 (4.07)	1 (4.00)
F8.4	Lack of support from parties within the construction chain	0.001	4.026	5 (3.87)	5 (2.00)
F8.5	Higher cost implications in using PB standards	0.006	2.870	6 (3.67)	10 (1.00)
F8.6	Lack of research and development in the field of PBRS	0.002	3.568	6 (3.67)	1 (4.00)
F8.7	Liability issues of using PB standards	0.000	5.292	6 (3.67)	1 (4.00)
F8.8	Lack of incentives to be innovative	0.041	1.871	11 (3.27)	4 (3.00)
F8.9	Hard to change the mindset of clients and other parties in the construction	0.000	4.583	2 (4.00)	5 (2.00)

	industry				
F8.10	Greater competition from foreign companies	0.119	1.234	9 (3.33)	5 (2.00)
F8.11	Inability of PB tests to relate to actual performance	0.002	3.568	10 (3.53)	5 (2.00)

* The one sample t-Test excludes the survey results from BCA.

4.2 Benefits of Using of Performance Based Standards

Respondents were requested to rate the benefits of using performance based standards (see Table 3). All the benefits except for the B9.2, B9.3 and B9.4 have $p > 0.05$, therefore it is concluded that these three benefits (B9.1, B9.5 and B9.6) that are accrued from the use of PB standards are significant based on $\alpha = 0.05$.

A comparison of views between BCA and the respondents was conducted and the results are largely similar except for B9.3 and B9.4. The main reason for this difference could be due to the nature of the local industry. The Construction 21 report has identified the intense competitive bidding environment of the industry as a potential obstacle to the progress of the industry. Clients' preference for the lowest bid has resulted in an unhealthy focus on price and inevitably, quality of works decreased which would result in greater number of defects.

Table 3: Summary of One Sample t-Test results to identify significant benefits

Label	Factor	Test Value = 3		Ranking (Mean)	
		Sig (1-tailed)	t*	Industry	BCA
B9.1	Higher quality of workmanship.	0.034	1.974	3 (3.47)	2 (4.00)
B9.2	Reduce cost of construction.	0.151	1.075	6 (3.27)	6 (3.00)
B9.3	Greater client satisfaction.	0.056	1.702	4 (3.40)	1 (5.00)
B9.4	Reduce defects problems of buildings.	0.068	1.581	5 (3.33)	2 (4.00)
B9.5	Greater flexibility to promote innovation.	0.000	6.089	1 (3.93)	2 (4.00)
B9.6	Increasing the global competitiveness of the company.	0.002	3.568	2 (3.67)	2 (4.00)

* The one sample t-Test excludes the survey results from BCA.

4.3 Measures to Encourage Usage of Performance Based Standards

Respondents were asked to rate the effectiveness of the measures to encourage the use of performance based standards in construction industry (Table 4). All the measures except for the **M10.3** have significant levels that are less than 0.05 and therefore it is concluded that these measures are significant. It is not surprising that M10.3 is not significant as most companies are expected to be unwilling to pay an additional levy on projects when the industry outlook is bleak and profit margins of companies in the industry are already very low.

A comparison of views between BCA and the respondents was conducted and it was found that both parties have differing views for M10.2. BCA is neutral on the idea of establishing a government sponsored body to lead and co-ordinate the construction industry's R&D efforts in PB standards. The possible rationale for this could be that BCA recognize the need for research and development into performance standards but the industry should reduce its reliance on the government and be allowed to mature to start its own initiatives. This view was shared by Dulaimi and Tan [6] who felt that local companies were over dependent on the government to lead the development of the industry.

Table 4: Summary of One Sample t-Test results to identify significant measures

Label	Factor	Test Value = 3		Ranking (Mean)	
		Sig (1-tailed)	df*	Industry	BCA
M10.1	Major players in the industry should take the lead in using PB standards to encourage other firms to use it.	0.000	14	1 (3.93)	1 (5.00)
M10.2	Establish a government sponsored body (Central Standardization Agency, CSA) to lead and co-ordinate the construction industry's R&D efforts in PB standards.	0.000	14	1 (3.93)	3 (3.00)
M10.3	Introduce a levy on all construction projects to fund the Central Standardization Agency.	0.151	14	5 (2.73)	4 (2.00)
M10.4	Subsidies to be given for companies to attend PB standards seminars.	0.001	14	3 (3.73)	4 (2.00)
M10.5	Greater clarity in enforcement issues in a PBRS framework.	0.000	14	3 (3.73)	2 (4.00)

* The one sample t-Test excludes the survey results from BCA.

4.4 Multiple Linear Regression to Determine Industry's Perception on the Factors' Effect on Performance Based (PB) Standards

Using SPSS, stepwise multiple linear regression technique is used to construct six models to determine the extent of respondents' agreement on each benefit accrued due to performance based standards, based on the 11 limiting factors. The Stepwise method will remove insignificant variables and thus only consider the factors that are of significant.

Of the six models generated, the most robust model is for B9.3; it has an adjusted R^2 value of 0.73. In general, the lack of robustness of the other models to determine the extent of agreement for B9.1, B9.2, B9.4, B9.5 and B9.6 could be due to the limited sample size of the survey (see Table 5). Therefore, results in this survey may not be conclusive. Despite this limitation, the survey results nevertheless gave an important insight of the awareness and knowledge of performance based standards amongst the respondents. This would enable the relevant authority like BCA to better understand the current situation in the industry and formulate policies to avoid the pitfalls of implementing the PBRS in the industry.

Table 5: Six Models Generated by Multiple Linear Regression Technique

No	Regression Models	Adjusted R^2
1	B9.1 = -1.462 + 0.867(F8.11) + 0.514(F8.8)	0.457
2	B9.2 = 1.218 + 0.559(F8.5)	0.218
3	B9.3 = -3.339 + 0.828(F8.8) + 0.965(F8.3)	0.730
4	B9.4 = 1.082 + 0.582(F8.4)	0.304
5	B9.5 = 2.159 + 0.451(F8.2)	0.409
6	B9.6 = 7.700 – 1.100(F8.7)	0.515

4.5 Discussion for Regression Model for B9.1

Higher quality of workmanship (B9.1) is expected from PB buildings as meeting performance requirements are a critical aspect of the PB approach. The PB approach allows for innovative means through the use of new technologies and techniques to increase the level of workmanship. But there are insufficient incentives (F8.8) for companies to go beyond compliance despite adopting a PB approach [7]. The more essential factor in affecting the quality of workmanship is the inability of PB tests to relate to actual performance (F8.11); due to its higher coefficient in the regression model. In addition, Cary et al. [7] indicated that PB standards can be imprecise and difficult to measure when they are qualitatively based. Currently, most performance indexes are lab based or results are simulated, they do not reflect actual building performance. One of the ways to overcome this is to have the major players like the Housing Development Board (HDB), Jurong Town Corporation (JTC) or Land Transport Authority (LTA) which have a large pool of buildings, to conduct a research. That is to look into the past records of materials used, testing methods and try to link it to building performance. Furthermore, there should be greater monitoring of such test and results for on going projects; this will facilitate the development of test indexes for actual building performance.

4.6 Discussion for Regression Model for B9.2

The benefit of reducing cost of construction (B9.2) due to usage of PB approach is ranked the lowest by the respondents in this study. The main reason could be that majority of the companies in the industry are small to medium sized companies which are driven by profits for the short run. Based on the survey conducted by BCA in 1999, 70% of the companies have a paid up capital of less than \$0.25 million and annual turnover of less than \$0.50 million [8]. Therefore, the initial increased in time and cost of adopting the PB approach (F8.5) is more than a deterrent for them despite the fact that a PB approach will result in more functional buildings at lower construction costs [9]. Hence, other than creating greater awareness of the PB approach, the local companies should consider formulating business strategies that ensures the survival of the company in the long run.

4.7 Discussion for Regression Model for B9.3

In the PB approach, the clients have the option to choose the balance of performance and cost they are willing to pay. Greater client satisfaction (B9.3) could stem from higher quality and greater value for money in the long run because meeting the performance requirements is paramount in the PB approach [10]. However, the lack of knowledge (F8.3) and lack of incentives to be innovative (F8.8) for using PB standards is impeding progress into this area. Therefore, the requisite infrastructure for the PBRS to thrive must be in place. In particular, for F8.3 which is ranked the highest by the respondents as well as having the higher coefficient in the regression model. Hence, the authority should focus heavily on establishing a local knowledge base for issues relating to PB approach.

4.8 Discussion for Regression Model for B9.4

A PB standard focuses much more attention on defining success and developing measures of success than on identifying failure modes [11], as a result it is capable of reduce defects of buildings (B9.4). However, the benefit of reducing defects is ranked 2nd lowest by the respondents (see Table 3). This could be attributed to the excess capacity of the industry which results in serious price undercutting that would lead to a subsequent loss of quality as contractors are forced to cut corners [8]. As a result, defects would be more likely to surface and disputes between parties would arise. In addition, symptoms of the ‘suicidal’ tender bidding of contractors have also resulted in delays in numerous construction projects as well as collapse of some established construction firms. Thus, the conflicts ensuing from the intense price competition has further segmented the industry, and resulted in a lack of support from parties within the value chain itself (F8.4). Therefore, it is suggested that the major players in the industry like the LTA and HDB take the lead in adopting the PB approach so as to influence the parties down the construction value chain.

4.9 Discussion for Regression Model for B9.5

One of the main reasons the performance based regulatory system was adopted in Singapore was because of the fact that it allows greater flexibility to promote innovation (B9.5). However, Lee and Barret [4] cautioned that it also increases the possibility of generating new or even greater risks compared to using prescriptive standards due to the uncertainty associated with it (F8.2). This uncertainty is mainly due to the nature of the PB approach as well as a lack of infrastructure to support the PB approach [3]. In addition, Theodore [5] pointed out that building clients, contractors and government regulatory bodies lack the basic competence required for expressing, interpreting and monitoring requirements in terms of performance. Hence, in order to encourage mass adoption of the PB approach, the authority must overcome the uncertainties through conducting of seminars to increase the knowledge base on the PB approach and developing adequate infrastructure for the PBRS to thrive.

4.10 Discussion for Regression Model for B9.6

The industry is made up of mainly small to medium sized companies, and as such few of these companies have the neither the capacity nor expertise to export their services [8]. Hence, although the change of regulatory system to a PBRS may increase the global competitiveness of a firm (B9.6), it is unlikely to have any impact on the operations of these small local based companies. In addition, such companies tend to be profit driven, and as the PBRS does not clearly spell out the obligations of parties (F8.7), it would further deter these companies from adopting the PB approach.

5. Overview of Results

Inter-jurisdictional Regulatory Collaboration Committee (IRCC) and CIB Task Group 37 members found out that a PBRS framework that works in one country may not work in another because of the differences in government, politics and culture. Hence, lessons can be learned from other countries but must be adapted to meet the individual countries needs. In retrospect, Ofori [12] noted that the government actions alone are insufficient to achieve the effectiveness of the implementations made to address the problems of the industry. It is clear that there are many measures to be adopted to remedy the issues but the problem is how to implement them successfully. Therefore, this study has determined the impact of the different factors on the six types of benefits accrued to PB standards. Knowledge gained from this study would then be beneficial to the regulating bodies during the formulation of polices to implement the PBRS.

In addition, the findings of this study also revealed that 50% of the respondents are not aware of the new PB regulatory system that is in placed. The industry is made up of mainly small firms therefore efforts must be made to reach out to these firms in order for the new PB regulations to have any positive effect. This new approach requires a radical new mindset of working as it involves greater professional judgment and responsibility from personnel at all different levels. Hence, the relevant authority should step up their efforts in generating greater awareness and creating a knowledge base for the PB approach.

As for the key parties in the industry, this study serves to generate greater awareness of PB standards among the companies within the industry. With a greater understanding of the issue, key players in the industry could then collaborate with the authority to formulate win-win strategies for all parties. Most of the benefits will only occur if the industry is used to working with the performance based concept and benefits will be maximized if the PB approach is applied throughout the building process [13]. Therefore, companies within the industry should be well informed of the developments in the performance approach as it would have an impact on their operations. The local market is shrinking and competition is intensifying hence the PB approach would increase the global competitiveness of the company.

6. Summary

Extensive research has been conducted on the advantages and disadvantages PB standards. In general, a successful implementation of the performance approach will increase companies' global competitiveness as well as raised clients' satisfaction through higher quality of buildings. However, there is a dearth of local research being done on the factors that limits the effectiveness of PB standards in spite of its growing importance. In view of this, this study was conducted to examine the factors' that contribute to the effectiveness of PB standards in the local industry. To fulfil this, the following issues were investigated.

Firstly, a review of past literature was conducted to provide the background framework of the PBRS that is implemented in Singapore and also to establish and identify pertinent factors having an impact on the effectiveness of the PBRS. Consequently, 11 factors were adopted for use in this study as potential limiting factors. The list of limiting factors and the benefits accrued to PBRS provided the foundation for a retrospective questionnaire.

Secondly, surveys were emailed to key parties in the construction value chain which include developers, contractors, consultants and suppliers. The companies were randomly selected from the REDAS website, SISV website and the BCA, Directory of Registered Contractors, 2004 edition.

Thirdly, the effects of the 11 factors on the effectiveness of PB standards were studied. The one-sample t test was conducted to determine the significant factors. A comparative ranking analysis was also conducted to determine any major differences in opinions between the regulating body (BCA) and firms in the industry based on the same questionnaire.

The findings of the one-sample t test indicate that all the factors except for F8.10 (Greater competition from foreign companies) are significant based on $\alpha = 0.05$ on a 1 tailed test. The result allows us to concentrate on the significant factors for this study. Similarly, the one sample t-test identified three significant benefits that can be derived from the use of PB standards. The use of Stepwise Multiple Linear Regression technique enables the automatic removal of insignificant variables therefore, despite the results obtained from the one sample t-tests; all the variables are included in the regression analysis.

Lastly, six models were generated using the stepwise regression method; one for each benefit accrued to the use of PB standards. This is to identify the factors having the most significant bearing on the effectiveness of PB standards. Attention can be given to the most important factors as identified by the model in order to maximize the effectiveness of PB standards. The stepwise procedure identified seven significant factors (F8.2, F8.3, F8.4, F8.5, F8.7, F8.8 and F8.11; refer to Table 2) that were associated with at least one of the six benefits of using performance based standards.

7. Conclusion

This study is useful in two main aspects. Firstly, it establishes those seven factors that are significant in limiting the effectiveness of PB standards in Singapore. In addition, it attempts to clarify the differences in viewpoints between the regulatory authority (BCA) and the parties in the industries. This serves to provide a greater appreciation of the limiting factors of the PB approach and its associated benefits. Secondly, it established a framework for determining the extent of respondents' agreement on the benefits accrued due to PB standards, based on the 11 limiting factors.

The findings of this study have provided the regulating authority with a greater understanding of the potential obstacles of the performance approach and the likely benefits that can be reaped. It can be said that there is no one model that fits all systems; therefore, careful planning must be carried out in the implementation of policies. More essentially, the authority should obtain feedback from the industry in order to create a win-win situation for all parties.

The importance on PB approach is best exemplified by the increasing attention that has been placed on sustainability and efficiency in the 21st century; the PB approach offers an alternative solution to attaining these two goals. The PB approach also enables the vertical and horizontal integration of the industry which allows for greater communication and integration of the industry. There will be a radical change in the method of procurement and consequently, the PB approach will enable the industry to mature and improves the current level of productivity which is one of the Construction 21 objectives.

Performance Based Building

Prescriptive building practice is still predominant in many countries. There is evidence that such practice inhibits innovation during the development and the use of built environments. By contrast, Performance Based Building (PBB) fosters innovation through the setting of performance requirements. At their best, these requirements provide challenging fitness for purpose parameters for the whole life span of built environments. Thus, the focus of PBB is on potential ends rather than definite means.

The European Commission funded Performance Based Building (PeBBu) Thematic Network has been a four year programme. It has been a multi-national venture involving many research scientists and industry practitioners. The PeBBu network has aimed at international dissemination and implementation of PBB throughout the development and use of built environments. The main results of this ground-breaking pan-European endeavour are presented in this book.

Section III: Use of Product Models in Construction

Section IV: Development and Evaluation of ICT Systems

Preface

The use of ICT in project based industries such as construction is maturing fast. It is seen as a catalyst for change and an enabler for better planning, monitoring and control of construction and facilities management activities. Nevertheless, there is much that remains to be done as the construction sector exhibits a set of key characteristics that differentiate it from other sectors as reported by Hannus et al. [1] and Kazi and Charoenngam [2]:

- The sector is heterogeneous and highly fragmented, depending on a large number of very different professions and firms, which are mostly small in size, tend to respond to local market needs and control only one element of the overall building process.

- Construction is one of the most geographically dispersed sectors with marked regional differences.

- Construction is highly project oriented. Any ICT used within a project must be deployable and profitable to all / several partners.

- Each construction project, whether to create a new facility or a renovation/repair project is typically unique. The final product tends to be very durable, lasting 25-50 years and longer, and represents one of the few non-transportable industrial products.

- When construction facilities become obsolete they are most often repaired, modernised and sometimes radically transformed to suit new requirements rather than disposed of and replaced with new, which is more typical for manufactured products.

- The sector is highly regulated. Regulations and standards are more rigorous in construction than in most other sectors of economy, with the involvement of several levels of governments (local, provincial, national).

- The sector is very labour intensive, with high mobility of the workforce and growing skills needs as construction technology becomes more sophisticated. The duration of contracts is often linked to the length of the site construction phase.

- Business relationships are temporary and often short-term, bringing together partners who may never work together again.

In fact, ICT usage in the construction sector is limited when compared with other industries such as manufacturing. While in part this may be due to the unique characteristics of the construction industry, there is a tendency for late take-up of ICT solutions, or when no appropriate solution exits, construction organisations develop closed proprietary solutions. Based on a wide industrial analysis and set of consultations, a set of current ICT usage trends were identified by Hannus et al. [1] as shown in figure 1.

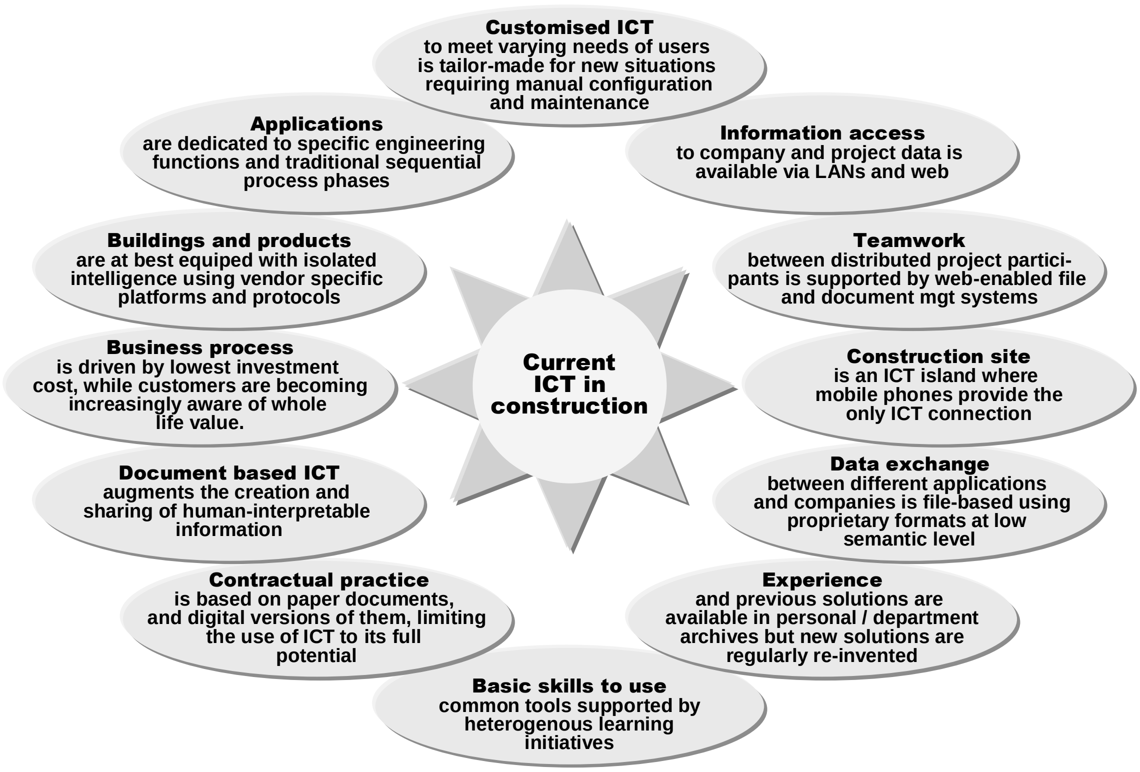

Figure 1: Current ICT Usage Trends [1]

Using the above trends (figure 1), as a baseline, a vision ICT in construction was defined as: *Construction sector is driven by total product life cycle performance and supported by knowledge-intensive and model based ICT enabling holistic support and decision making throughout the process by all stakeholders*. When compared with the current state (figure 1), it in essence promotes a paradigm shift from customised ICT to adaptive systems, from information access to ambient access, from teamwork to collaborative virtual teams, from construction site to digital site, from data exchange to flexible interoperability, from experience to knowledge sharing, from basic skills to ICT skills and awareness, from contractual practice to legal/contractual governance, from document based ICT to model based ICT, from business processes to performance driven processes, from buildings and products to smart buildings and products, and from applications to total life cycle support (figure 2).

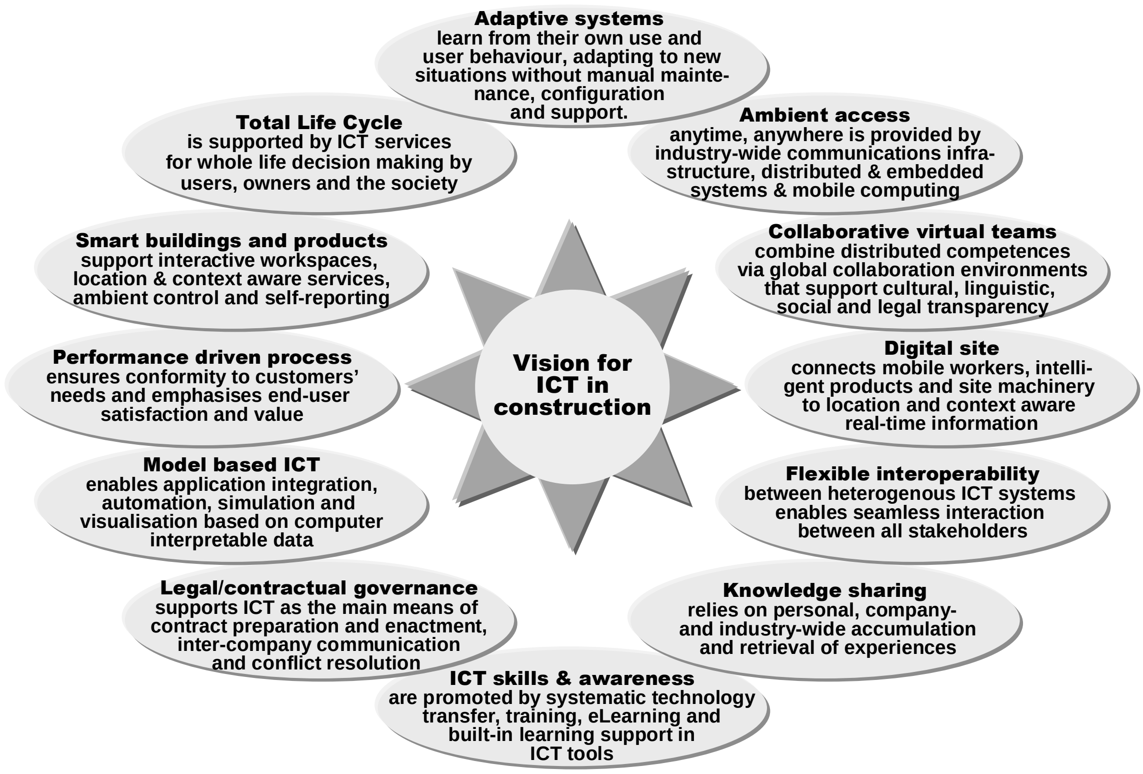

Figure 2: Vision for ICT in Construction [2]

One of the key steps in realising the transformation from the current state (figure 1) to the envisioned state (figure 2), is the mind shift in approach from data exchange and integration to interoperability. Efforts such as the nD modelling project [3] at the University of Salford, and the industry led initiative of the ProIT project [4] in Finland are major steps towards the realisation of the vision for ICT in construction and facilities management.

This book presents a global portfolio of ideas and perspectives in the development and use of ICT in construction and facilities management. The main coverage areas include ICT for design management, ICT in facilities management, the use of product models in construction, and the development and evaluation of ICT systems. While some cover research and development, others provide lessons learned from practice in the use of ICT for construction and facilities management. It is interesting to observe that all can to a certain extent be mapped on to one or more of the ovals (figure 2) contributing to the realisation of the vision for ICT in construction and facilities management.

Acknowledgements

This book would not have been possible had it not been for the untiring efforts of Dr. Kalle Kähkönen, Chief Research Scientist, VTT – Technical Research Centre of Finland, in championing the scholarly book series on *Combining Forces – Advancing Facilities Management and Construction through Innovation*. A special note of appreciation is extended to all contributing authors for their willingness and enthusiasm in sharing their research and experiences from practice.

ICT for Design Management

ICT and the Architectural Design Process – Introduction of an ICT Impact Matrix

Anita Moum
NTNU – Norwegian University of Science and Technology (e-mail: anita.moum@ark.ntnu.no)

Abstract

The essential topic of this paper is the impact of ICT on the architectural design process in the early planning stages. A fundamental pillar of a successful building project is a good design process. The use of ICT has over the years in different ways influenced and to a certain degree also changed roles and processes within the building project. An understanding of how ICT influences the complex mechanisms within the early stages of the planning process can be seen as central to achieve project success. The aim of this paper is to contribute to a better understanding and overview of the current situation regarding ICT related challenges and benefits within four essential aspects of the architectural design process. These aspects are: the generation of design solutions, the communication, the evaluation of design solutions and the decision-making. In the first section of the paper based on a literature review, some key elements from previous research in the area will be explored. Furthermore, an ICT impact matrix will be introduced, based on the four selected design process aspects and a definition of three hierarchical levels: the micro-, meso- and macro-level. The matrix outline suggests a way to organize the discussed design process topics on an overall level, and intends to contribute with a better overview of the ICT related impacts on the architectural design process.

Keywords: Architectural design process, ICT impact matrix, overview

1. Introduction

A fundamental pillar of a successful building project is a good design process. A primary idea emerges in a designer's head based on a complex iterative process between problem and solution. Taking into account different constraints set for the project the primary idea "materializes", eventually within a design team, into something that can become the conceptual fundament of the building project [1]. The future and development of a good architectural design solution depends on decisions made on several levels and by different actors. The architect will make his decisions about which design solutions are worth being put to the paper, and the client will be responsible for the crucial decision regarding which proposed concept should be developed further. The evaluation and decision-making due to a design solution depend among others of how it is communicated. The sender (e.g. the architect) of the information (e.g. the design solution) must encode the message in the form of some symbolic language, which is then transmitted, through a suitable medium (e.g. paper drawing scale 1:100), to the receiver (e.g. client) of the information. To access the design solution, the client must decode the message. Both the client and the architect decode and encode information based on their knowledge, or frame of reference [2]. Over the years, the ICT impact has lead to dramatic changes within the construction sector average working day. Both working processes and role definitions have been affected. The participants within the architectural design process face ICT related benefits and challenges at several levels. An understanding of how ICT impacts on the architectural design process and decision-making can be crucial for the overall success of the building project.

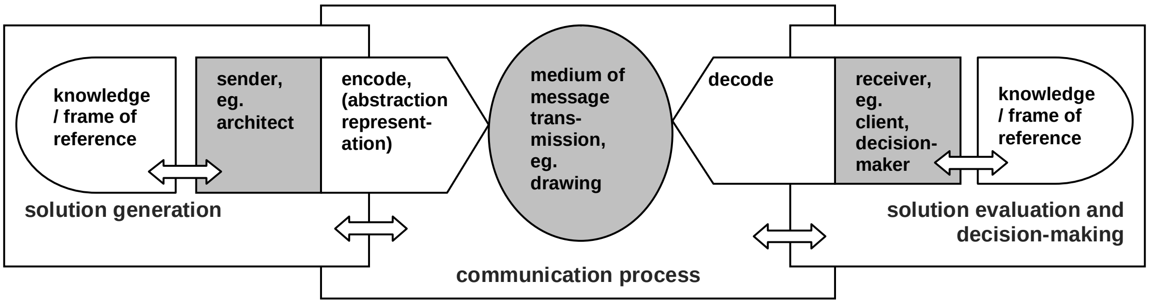

Figure 1: Illustration of the relations between the four selected architectural design aspects

The main topic of this paper is to contribute with a better overview and understanding of the today-situation of ICT related benefits and challenges due to four essential aspects of the design process: the generation of design solutions, the communication, the evaluation of design solutions and the decision-making. Figure 1 seeks to illustrate the relations between these four aspects, which are highly interdependent and iterative. The first part of the paper explores some key points, based on a literature review. This paper does not intend to give a complete picture of all ICT related impacts. Rather, the explored key points establish the background for the introduction of an ICT impact matrix, based on the four selected design process aspects and the definition of three hierarchical levels, the micro- (individual, e.g. architect), meso- (group, e.g. design team) and macro (overall/general, e.g. client)-level processes. The matrix outline suggests a way to organize the discussed design process topics, and could be one possibility to gain a better overview of the ICT related impacts on the different levels of the architectural design process. The introduction of the ICT impact matrix establishes the background for a theoretical framework and further research regarding the following issue: the ICT impact on building design management and decision-making – with focus on the architect’s role and contribution.

2. The Generation of Design Solutions

There has been a lot of effort to describe and explain the design process and the generation of design solutions since the early 1960s [3]. The first generation design methodologists focus on the design process as something sequential and linear, was to be challenged. Lawson [1] critically emphasizes that there is no clear distinction between problem and solution, analysis, syntheses or evaluation in the design process. The design process is a simultaneous learning about the nature of the problem and the range of the possible solutions. The design problem is difficult to define and reveal, is multi-dimensional and interactive. The challenge for the designer is to understand what really constitutes the problem, to recognize hierarchical relationships, to combine and to integrate [1]. The designer operates in a virtual world, a constructed representation of the real world in practice [4]. Abstract models or the media of communication (traditional: physical models, drawings etc.) allow the designer great manipulative and immediately investigative freedom without incurring time or costs, which would have been the fact if the ideas had to be tested directly at the building site [1]. However, the first generations aim to organize the design process in a rational and logical way, thus saving more time and resources for the intuitive and creative moments of the process [3], still have some relevance. One vehicle of achieving these early aims, although with other means, could be ICT.

2.1 Computer Aided Design or Drafting

The generation of design solutions is still perhaps the area, in which the ICT at least has gained a foothold [1]. For the moment, the CAD (Computer Aided Design) systems used within the design process, supports drafting and modeling rather than special design attributes and analytical capabilities and have not changed the task of drafting or modeling [2]. However, CAD systems have this far definitely brought benefits, such as the possibility of producing a huge amount of drawings in a limited amount of time, and the possibility of creating highly realistic and professional representations of the design solution. But can CAD support the generation of the design solution itself? Or is CAD rather what Lawson [1] calls Computer Aided Drafting? Designer skills such as intuition and the “feeling-of” are difficult to describe and map, and until now the computer has been unable to copy these parts of the human intelligence. In addition, the design process is still not fully understood; the human brain will for the next time probably remain the main media of the creative process.

2.2 ICT as Design Partner

However, there are parts of the solution generation process, in which the computer can support the generation of design solutions. The computer is able to handle enormous amounts of parameters, and combine them to alternative solutions, in much shorter time than the human being can. A research project at the ETH in Zürich, called “KaisersRot” [6], illustrates this. The computer generated solutions and alternative site patterns based on a huge amount of programmed parameters. The human brain would need substantial amounts of time in order to generate solutions matching all these parameters. The computer, however, could only generate sufficient solutions based on parameters recognized and programmed by humans.

Another research direction is the development of virtual reality (VR), which is based on geometrical and graphical representation. VR offers the possibility to navigate within and see the objects and their relation to each other in a 3D space. The possibility of a realistic imitation of a real world environment, combined with the spatial experience dimension, can become a powerful future design tool [5]. New experimental forms and constructions, without the real world constraints, can be realistically visualized. The possibilities of innovative form generation, can perhaps give the designer inspiration to develop an “evolutionary” architecture [1]. The success of such processes depends on how user friendly ICT is. Generally, the development of user-friendly interfaces of the ICT tools is a huge challenge. Thick user manuals and complicated operative surfaces can disturb the mediation of creative processes. Lundequist [5] compares this with driving a car: the driver should not be forced to concentrate on how to drive, but rather where to drive. However, Wikforss [5] compares the impact of the development of new computer media and graphical tools with the break-through of the central perspective in the renaissance. They both change our view of the world.

There is some effort to develop intelligent ICT systems that can carry out design operations on behalf of the human designer, so-called design agents [2]. A design agent can for example make a designer aware of inconsistency with building legislation, for example the minimum height of a staircase handrail. Thus, ICT would develop from being a tool to becoming a design partner. The development of design-agents is promising, but for the moment it seems impossible to replace the human brain completely as the generator of design solutions. ICT can be a tool or a partner supporting and relieving the designer, but the computer still cannot design without some sort of human interaction.

2.3 New Design Methods

The more intelligent ICT design systems could make it necessary to change the traditional methods of design. However, to make the designer change his working methods can be cumbersome. Kiviniemi [7] refers to Freeman's Attractor Theory describing an "energy landscape" in our brains; and he sees this as one reason why it is so difficult to implement new tools which influences the working methods (e.g. 3D product model), although such tools could offer obvious benefits.

3. Communication within the Design Process

The successful planning and realization of a building project depends heavily on the success of communication on many levels. Schön's [4] description of the designer's conversation with the drawing, or what Kalay [2] calls ideation or an intra-process role of communication represents one level. The dialogue between two individuals, the extra-process role of communication represents another. Failed communication can cause conflicts and misunderstandings, and negatively influence the building project, if not recognized and solved at an early stage. As illustrated in figure 1, the sending and receiving of a message (e.g. design solution) depends on the competence, knowledge and previous experiences of the participants in the communication process. If the client does not know the symbolic meaning, or the level of abstraction used, he will not understand what the architect tries to communicate, and this could lead to misunderstandings and conflicts. The architect can assume that the client knows which totality an abstraction represents, for example the plan drawing door symbol, but a problematic case of information loss could arise if the client does not know that the two lines on the paper actually symbolize a door. Generally, some of the knowledge playing a part within the design process is of tacit character. Explicit knowledge can be articulated and is thus accessible to others while tacit knowledge cannot be articulated [8]. Wittgenstein's language game theory is one illustration of this problem area [9]. Misunderstandings can occur when terms from one game are used within another. The language games are based on tacit rules embedded in the context, culture and way of life. Thus, such language games cannot be easily understood when viewed from another context or culture. A central part of the architect's competence is to understand the language games and to use terms in a meaningful way [9].

3.1 The Designer's Conversation with the Design Situation

Schön [4] describes the design practice (e.g. sketching) as a conversation or reflective dialogue between the designer and the design situation or design issue. This conversation is based on the designer`s "…capacity to see unfamiliar situations as familiar ones, and to do in the former as we have done in the latter, that enables us to bring our past experience to bear on the unique case." [4, p.140]. The designer conversation with the design situation allows a fluid thinking process without constraints like disturbing accuracy. The sketching act can mediate creative processes. Can ICT replace the scribbling with a pen at a sketch paper as mediator of creativity, without disturbing the fluid thinking process? Is the computer able to interpret sketches, which can often illustrate a variety of metaphors, and contain a high degree of uncertainty? According to Lawson [1], the answer is no.

3.2 Network Technologies and Collaboration

The importance of collaboration is growing, as globalization and increasingly complex technique and products require more teamwork, and the complexity of the problem becomes unmanageable for one individual. The focus changes from the individual to the collaborative design process, and introduces a new dimension in the idea finding process: the interaction between the individual and the group [1]. Participants with different backgrounds, preferences and experiences try to achieve a common goal. Barrow [10] introduces the term Cybernetic Architecture: "... cybernetic architecture is a return to the pre-Renaissance comprehensive integrative vision of architecture as design and building (…) the emerging architecture process is a "collective" body of knowledge and specialty skills found in many individuals."

Network technologies such as e-mail and the internet have contributed to the most radical changes within the average working day for the building process participants, for instance supporting processes independent of geographical and organizational borders. Collaborative design and communication within a virtual instead of collocated situation inherits many new properties, and this eventually leads to various challenges. The network technologies still offer neither the same social presence and information richness, nor the ability to transfer tacit knowledge that a face-to-face collaboration or conversation does [11]. Herein lies a challenge; to develop network technologies offering the communication possibilities necessary for the achievement of a common understanding, to solve complex problems or to generate complex design solutions. Within the communication process between two or more individuals, ICT have had a dramatic impact on the medium of communication. This could possibly require another use of language and level of abstraction and challenge the skills of the message receiver, hence to another culture of communication.

3.3 Information Access and Distribution

The network technologies make an easy and fast access to and distribution of information possible. This has been a huge benefit within the building project and has, according to Schwägerl [12], contributed more to accelerate the design processes than the CAD tools. The development of the data based technologies, server or internet-based, has been an important support of handling the huge amount of documents and drawings within building project. The pool of material is accessible to the different projects participants, anytime. The participants have to actively retrieve the information they need, and this is different from the traditionally passive "getting-the-plan-with-mail"; there is a development from a push to pull of information. The use of databases, network technologies etc. supports the distribution speed of information required to keep the project continuously running. However, much of the information could be considered more of a distraction than actually useful, given a specific situation. The negative effect of information overload is growing. Thus, the attention of the receiver is becoming an important resource [13].

3.4 Communication Standards and 3D Product Models

Another influential trend within ICT is the development of communication format standards between different programs and systems, ensuring interoperability. An example of such a standard is the Industry Foundation Classes (IFC) [5,7]. The development of communication standards is one of the fundaments for a research field by many seen as one of the most promising within the construction sector: the development of the 3D product model or building information model (BIM). Such models are based on the definition of objects (products) containing intelligent information. The main objects, such as doors and windows, are standardized. According to Fekete [14], such standardisation could become barriers within the creative process; design elements that fall outside the standardized repertoire of building objects could be difficult to generate without special ICT skills. However, every participant (design team, legislators, contractors, manufacturers etc.) in the building process can get access to, make contributions to or receive information from this model in parallel. All building project information is gathered in this one model, and there are no parallel illustrations of building parts comprised of plan, section, detail etc. This can reduce one of the main sources of building site failures: inconsistency within the fragmented drawing and document material [5,7]. From the model "traditional" drawings can easily be generated, and the density of information can be controlled.

3.5 Redefinition of Planning Stages, Roles and Responsibility

Through the use of ICT, processes can be accelerated and traditional stages can overlap. Already at a very early stage of the design process, traditionally later participants can get access to e.g. the 3D product model. Contractors, specialists and manufacturer can contribute with knowledge that helps to reduce uncertainty early in the design process. The "wheel of dominance" [15], illustrating which participants dominating the different planning stages of the design process, could change. But the overlap between earlier and later planning stages can perhaps contribute with constraints that increase the complexity of the solution and problem finding, making it more difficult to focus on the right aspects to the right time. The Figure “Island of Automation in Constructions” [16] illustrates the current construction sector as many separate islands in a big construction sector ocean. The ICT, in this case the product model, leads to a “land raising”, the many small islands transform to one big island. Thus, the traditional boarders between roles or planning stages blur and change. The separate bits of the planning process are melting and compressed to a conglomerate. The ICT development changes the human perception of distance and time. The understanding of these different changes is central. ICT impacts on the definition of work processes, roles and responsibility. How can such changes be handled within contract and procurement models? What about the traditional role and contribution of the architect?

4. Evaluation of Design Solutions

The architectural design process is in addition to the measurable, quantitative and conscious based on the qualitative, intuitive and tacit [1,7]. The crucial question within evaluation of design solutions is how to measure or judge the qualitative, tacit and intuitive aspects? “Is it possible to say that one design is better than another and, if so, by how much?”[1, p.62]. This aspect is also challenging within the other three aspects of the design process: the generation of design solutions, the communication and the decision-making. Lawson [1] emphasizes that a crucial skill of the designer is to balance qualitative and quantitative aspects.

4.1 “Almost Real”

ICT Offers A Most Powerful Support Of Evaluation. Through Simulation And Highly Realistic Visualizations It Is Possible To Get An Impression Of The Real-World Building Project Before It Is Finished. Unrecognized Problems Can Be Identified, Uncertainty Reduced And Errors Avoided Already At An Early Stage Of The Building Project. In The Management Area ICT Support Time-, Cost- And Resource Planning, In The Design Process They Simulate For Example The Financial And Climatic Effects Of The Ventilation-And Heating System. Presentation Tools Supporting VR, 3D-Modeling, Animations Etc. Can Support The Evaluation Of Visual Qualities [5]. However, A Conceptual Image Communicated In A Highly Realistic Manner Can Also Give A False Picture Of The Reality. There Can Be A Conscious Or Unconscious Mismatch Between The Intention Of The Sender And The Interpretation Of The Receiver [1].

These Tools Usually Require The Presence Of Something To Evaluate, And Also That Some Level Of Precision Has Already Been Reached. And Such A Level Is Often Not Feasible In The Early Design Stage. Lawson [1] Characterizes The Too Early Precision Temptation As The Design Trap Of Over-Precision, Which Can Become A Creative Process Impediment. Until Now, The Building Of ICT Models As Foundation For Simulations Has Been Cumbersome And Expensive. This Often Resulted In Simulation Of Limited Parts Of The Total Design. But The Design Problem Is Multi-Dimensional And Interactive. Interconnectedness Of Different Factors Is An Important Issue. The Focus Only On Parts Can Lead To A Lack Of Integration, Thereby Reducing The Quality Of The Project In Total [1]. The Possibility Of Importing 3D Product Models Into Simulation Software Reduces The Model Building Effort And Thus The Building Could Be Simulated And Tested In Total [7].

4.2 Information Overload

We do not now much about how the human being handles and edits information [5]. The ability to absorb information is limited, and when confronted with too much information, the receiver can lose the overview, or worse, completely ignore the message communicated; thus leading to crucial information being lost and unrecognized. An information overload could possibly result in a loss of focus on the important aspects within evaluation and decision-making. Valuable time must sometimes be spent filtering relevant from unimportant information. Some ICT development projects try to establish methods for the filtering of internet-based information [5]. Generally, who decide the filtering criteria by information distribution and exchange? How do we know that important, but perhaps not obvious, information actually passes such filters?

5. Decision-making

Faster information distribution, better access to information and more powerful communication tools contribute to an acceleration of the planning process, making a higher decision frequency possible [17]. An important skill of the designer is to juggle with several ideas at the same time, without forcing a premature precision or decision [1]. Does the use of ICT force too early decisions and generate artificial constraints? Is there a limit of time compression within the architectural design process and decision-making? Also Wikforss [5] emphasizes the importance of enough time for maturing in the planning- and decision process, and that there is enough time to reflect and understand the consequences of different solutions and decisions. He emphasizes that ICT tools, e.g. the 3D product model, must allow a step-by-step precision.

Seemingly, it is easier to make a decision if every uncertainty is eliminated. ICT offers the possibility of storing and capturing previous project experiences, as well as reusing and modifying these experiences from previous building projects within new ones. This is an often-used method to reduce the high degree of uncertainty in the early design phases, and to better support the estimate of cost and time factors before the concept has reached the required level of precision. Lundequist [5] sees a possible conflict between the established experience and the will to innovation. The knowledge reservoir is based on tested experiences, repertoires and routines. The inherent capabilities of ICT when it comes to knowledge storage and reuse could lead to a misbalance between previous knowledge and innovation in the creative process.

ICT offers the possibility to simulate and visualize the building in a nearly realistic way, to make information available whenever wanted and to make processes transparent and “reusable”. However, the nature of the design process is also qualitative, subjective and highly uncertain. As “the feeling of” is a part of the design process, intuition and the acceptance of risks are also part of the decision process. According to Griffith [8] ICT supports the declarative nature of explicit knowledge. Possibly the analytic, quantitative and explicit nature of the computer could disturb the balance between the qualitative and quantitative, tacit and explicit, intuitive and conscious. This could potentially lead to a bias within evaluation and decision-making, having negative effects on the total building quality.

6. Introduction of the ICT Impact Matrix

This paper presents a broad range of different ICT related impacts within the architectural design process and decision-making and focuses on four main topics, the generation of design solutions, the communication, the evaluation of design solutions and the decision-making. The main intention of the paper is to be a contribution towards a better understanding and overview of the ICT impact on the selected architectural design process issues. The overview, an ICT impact matrix, is based on the definition of three hierarchical levels:

- **The micro-level:** focuses on the individual and what is going on in the head of the designer, in this case the architect. The designer's conversation with the design situation is an example of micro-level communication. Example decision-making: which idea is worth being put to the paper etc.

- **The meso-level:** covers the mechanisms within the group, in this case the design team. Design management. Collaborative design generation and evaluation. Example decision-making: which concept should be presented etc.

- **The macro-level:** comprises the mechanisms on overall project level, including all participants, such as stakeholders, manufacturer etc. Project management. Example decision-making: which concept should be further developed and realized.

Within each of these levels, the ICT related benefits and challenges due to the four illustrated and described aspects of the design process are summarized. The introduced matrix is not intended to force aspects of the complex architectural design process into rigid categories, rather it could be a help in acquiring an overview and understanding of the complexity within the design of an building project.

Table 1:Outline of the ICT impact matrix

	Micro-level	**Meso-level**	**Macro-level**
Generation of the design solution Examples ICT: CAD, VR, sketching programs, design-agents etc.	**Benefits:** • Development from design tool to design partner. • Handling and combining of amounts of parameters and constraints in short time. • Advanced visualization of design idea possible. **Challenges:** • Computer systems requiring too much precision • Complicated user surfaces can disturb the mediation of creative processes. • ICT should support step-by-step precision.	**Benefits:** • Supporting the development of collaborative design. • Advanced visualization of design idea possible. **Challenges:** • Interaction between individual and group design generation – "cybernetic architecture ".	**Benefits:** • Advanced visualization tools as VR a possible trigger of innovation and "evolutionary" architecture. **Challenges:** • Computer as design solution generator without human interaction until now not possible. • Standardization of design elements leading to creativity barriers? • New methods of designing - difficulty of adapting new ways of work.
Communication within the design process Examples ICT: 3D product models, databases, network technologies (e.g. Internet, e-mail, WorldWideWeb) etc.	**Benefits:** • Better access to information for the individual. **Challenges:** • To replace the power of pen and paper as the media between the designer and the design solution generation. • How to transfer tacit knowledge with ICT?	**Benefits:** • Support geographically dispersed collaboration. • Less inconsistency of project material. • Interoperability within design team • Better access to and distribution of information within design team - speeding up of communication process **Challenges:** • Less social presence and info richness as F2F can lead to misunderstandings and conflicts. • Different knowledge reservoirs within design team–source of conflicts. • From push to pull of information.	**Benefits:** • Better access to and distribution of information within building project. • Interoperability on overall level. • "Land-raising" within construction sector – more transparency – better foundation of collaboration. **Challenges:** • Redefinition of roles, responsibility and planning stages • Misunderstandings due to represented decision material (intention not like intepretation). • New communication and collaboration culture.
Evaluation of the design solution Examples ICT: 3D product models, simulation tools (e.g. cost, time, climatic aspects), 4D models etc.	**Benefits:** • Almost real world simulation and visualization, early recognition of conflicts and problems. **Challenges:** • Information overload – loss of overview and focus for the important.	**Benefits:** • Almost real world simulation and visualization support coordination within design team – early recognition of conflicts and problems. **Challenges:** • Simulation or visualization of only building parts – loss of overview and total quality. • Information overload and loss of focus and overview.	**Benefits:** • More transparency of processes and better access to knowledge, not individual captured. • Almost real world simulation and visualization, early recognition of conflicts and problems. **Challenges:** • How to judge and measure the quality of a design solution? • Information overload and loss of focus and overview.
Decision-making within the design process Examples ICT: 3D product models, simulation tools (e.g. cost, time, climatic aspects), 4D models, VR, 3D modeling tools, network technologies etc.	**Benefits:** • Decision material more consistent and real-world like – reduction of uncertainty **Challenges:** • Realistic visualization and simulation forces too early decision? Obstruction of the creative processes and parallel lines of thought?	**Benefits:** • Decision material more consistent and real-world like – reduction of uncertainty **Challenges:** • Realistic visualization and simulation forces too early decision within design team?	**Benefits:** • Decision material more consistent and real-world like – reduction of uncertainty • Reuse of previous experience easier -reducing uncertainty. **Challenges:** • Misbalance between use of previous project material and innovation? • Forces too early decision not representative for the factual status of project? • ICT focus on quantitative - bias in the decision-making?

7. Conclusion

The introduction of the ICT impact matrix illustrates a possible way to approach the wide range of ICT impacts on the complex field of the architectural design process. The processes within architectural design and decision-making can perhaps be compared with the nature of the design problem itself: as multi-dimensional and interactive, based on an interconnectedness of different factors. On one hand, the four selected design process aspects: the design solution generation, the communication, the design solution evaluation and the decision-making are highly interdependent, as the figure 1 in the introduction part attempts to illustrate. On the other hand, the defined micro-, meso- and macro-level levels are closely interconnected. These issues constitute the challenge and main problem area behind the theoretical ICT impact matrix. In a next step the matrix could be discussed and tested using e.g. real life projects. It could also be interesting to study the interaction between different levels, such as the relation between the architect and the design team, or between the architect and the client. Further inquiry could lead to a modification of the ICT impact matrix, the three level approach and the choice of design process aspects. Generally, the matrix outline could be developed into a filter for deciding the direction and focus of further work and research. From the view of an architect, a crucial question is how the ICT related benefits and challenges impact his role, influence and contribution within the architectural design process and decision-making.

Abstract

The infrastructure client must know the relation between the variant decisions and the cost already in the beginning of the design process. That is the only way the client can influence on the important decisions made during the design process so that there is real influence on the final cost level.

The Laboratory of Construction Economics and Management in Helsinki University of Technology and Rapal Ltd work tightly together in order to create new methods and databases for cost management of infrastructure projects. There are two different studies going on at the moment.

The one is focusing on the client´s target setting process in planning before the actual design process. The aim of the study is to develop a method and tools for defining a project and it´s targets so, that the client´s needs and will can be clearly expressed. The other one is considering to the cost management during the design process. How the real cost level is estimated in every step of the process? And how the design alternatives are compared? These two studies are introduced in this paper.

The first step in the infrastructure management is to define the project. The definition documents produced, a project plan, form the target for designing. It is a description of the scope of the project. Project plan must not unnecessarily limit the technical solutions made in the following designing phase. During the designing phase the document is updated if necessary.

The cost management of the infrastructure starts from the scope definition of the project. The client defines the needs and the targets of the project. The first cost estimate is based on the costs of the reference projects. The targets and the needs are modelled with the end product elements, which consist of the building element based product model. The end product elements are big functional elements of the infrastructure, for example main route, intersections, lightning system, water management system. The product model gives the target cost of the project.

The product model based target cost gets more accurate when the design process goes on and the product model is changing to the real measured building elements. The price of building element is estimated based on the way the work is done usually in that kind of circumstances. The typical work processes are documented to the cost storage.

In the first study the project plan –document is created and tested for the needs of infrastructure projects. In the second study the cost estimate procedures (the end product element and building element systems) are created and tested. The both testing processes are made in the collaboration with the real infrastructure projects given by the clients of Rapal Ltd, the 10 biggest infrastructure clients in Finland (8 big cities, the Road Administration and the Rail Administration).

The studies are still going on. The project plan is tested and the first results indicate that the systematic scope definition with the project plan clear out the needs of the project more accurate than usually in infrastructure projects. The first results also indicate that the first end product element based estimate, the building element based estimate and the real market price can be inside the 5-10 % marginal. The new method is more accurate than traditionally used experimental methods.

Keywords: Infrastructure, design process, cost management, end product element, building element, project plan, product model

1. The New Infrastructure Design Process

1.1 Overview

Ten big infrastructure clients (property owner organisations) in Finland (National Highway Administration, National Railroad Administration, Cities of Helsinki, Espoo, Vantaa, Turku, Tampere, Kuopio, Oulu and Jyväskylä) and commercial private owned company Rapal Ltd have made an agreement for the cost management development project lasting 6 years (2003-2008). The target of the project is:

- To create a common used and tested infrastructure cost management system
- To create new consulting markets for construction economics in the infrastructure branch

The 10 client organisations made a consortium agreement with each other. The consortium and Rapal Ltd made a partnership agreement for the project. The systematic development project includes:

- The project plan – the systematic scope definition method
- The cost management systems

    - End product element based cost management system for the scope prizing
    - Building element based cost management system for the design solution prizing
- The systematic cost management database
- The economic trend description system

The target of the project is in year 2008 when all the methods cover the whole product life cycle of infrastructure. There are two specific studies going on related to the project. The first one is related to the project plan and the other one is related to the cost management process. The systematic cost management database and the economic trend system relate to the studies strictly.

1.2 Process Relevance

Nowadays the scope definition, the cost management systems and information databases are organisation related with no common rules. The mean of this project is to organise and to find out the best practise process of the infrastructure cost management in Finland.

The difference between the reasons of the infrastructure project cost is related to three categories:

- The scope
- The design solutions
- The economical situation on the market

The infrastructure (highways, streets, railways and big industry yards) investment and maintenance cost in Finland for example were worth of 1,8 billion euros year 2002. The relevance to the whole society is huge when cost management information is handled in one common and systematic way based on the cost classification (fig1).

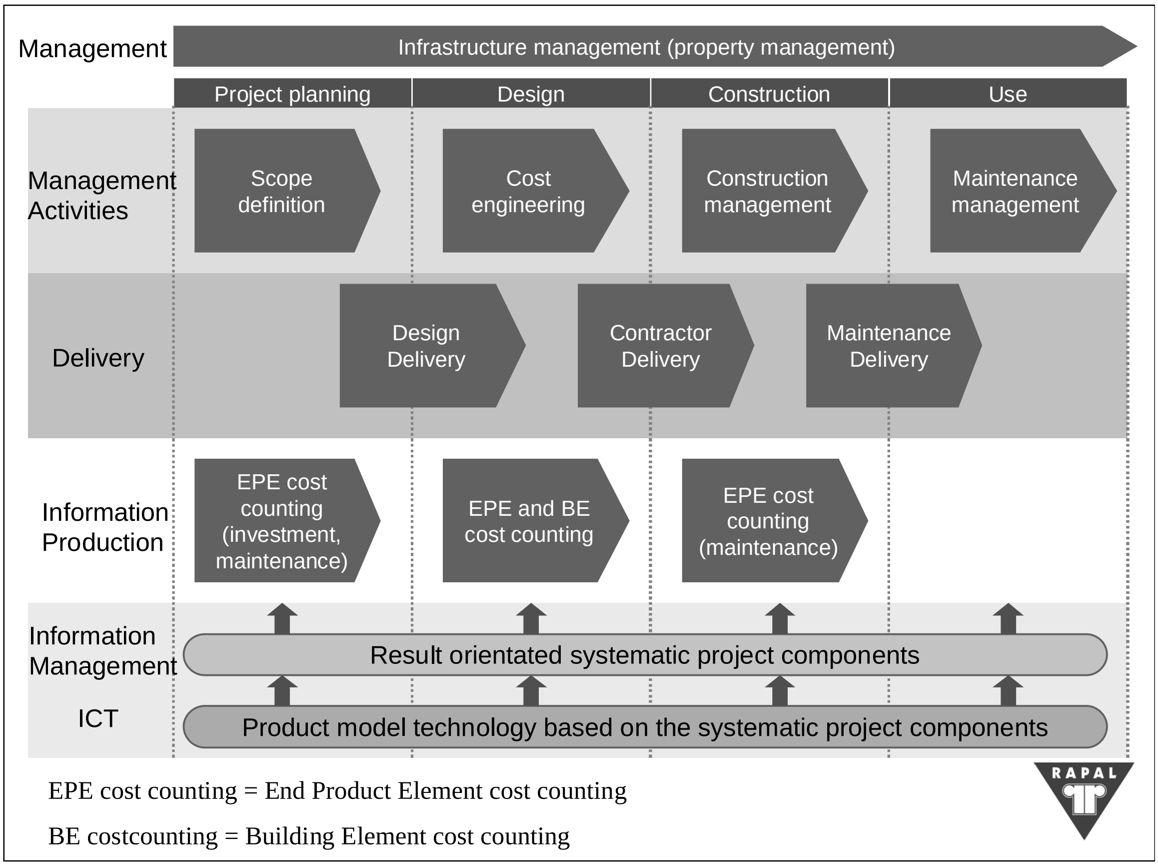

Figure 1 The process of the systematic infrastructure property management system

2. The Scope Management Process

2.1 The Systematic Scope Definition

The infrastructure projects are usually long term projects with lots of interest groups. The better the scope is defined the better the cost management is able to be done. In the development project Rapal has developed a systematic scope definition which includes:

- Project Plan – a document for the infrastructure scope definition
- List of end product elements - Systematic project component list

The project plan is a document which describes the result (the scope) of the project divided to the end product elements. Each element is based on the specific need (fig1) and is systematically described for the starting information of the design process.

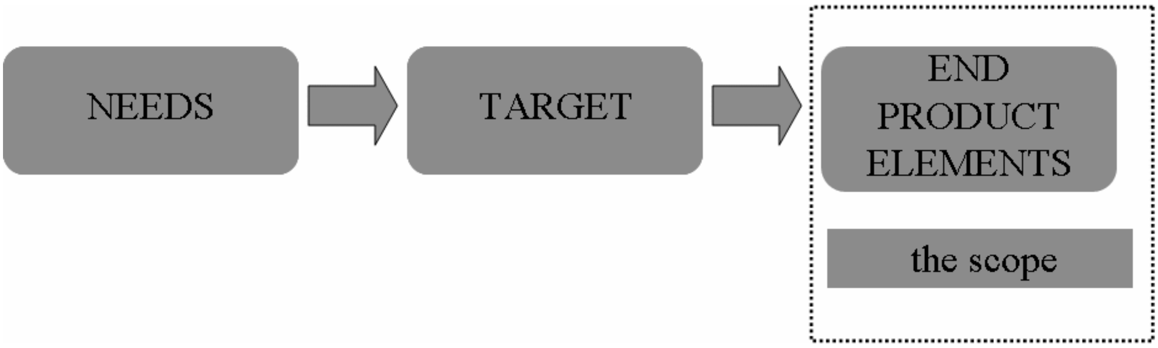

Figure 2: The needs of the project are changed to the targets, which are described as end product elements with the scope.

The end product element list includes the following subtitles:

- Routes for the motor engines
  - Highways
  - Streets
  - Railroads
- Tunnels
- Bridges
- The light traffic routes
- Other routes
- Parks and green areas
- Squares and market places
- Waste management
- Rock facilities
- Traffic areas
- Systems related to infrastructure

The project plan and the systematic project component definition have two major meanings:

- To describe the project
- To create the drivers of the project management

The scope of the end product element includes lots of sub targets (cost, quality, schedule). The cost management is the only one considered in this paper.

2.2 Cost Management by the End Product Element System

The scope defined in the project plan can be executed in many different ways. There are lots of combinations of design, cost, quality and schedule for example. The end product element based cost management system provides a price, which is typical solution of the kind of end product.

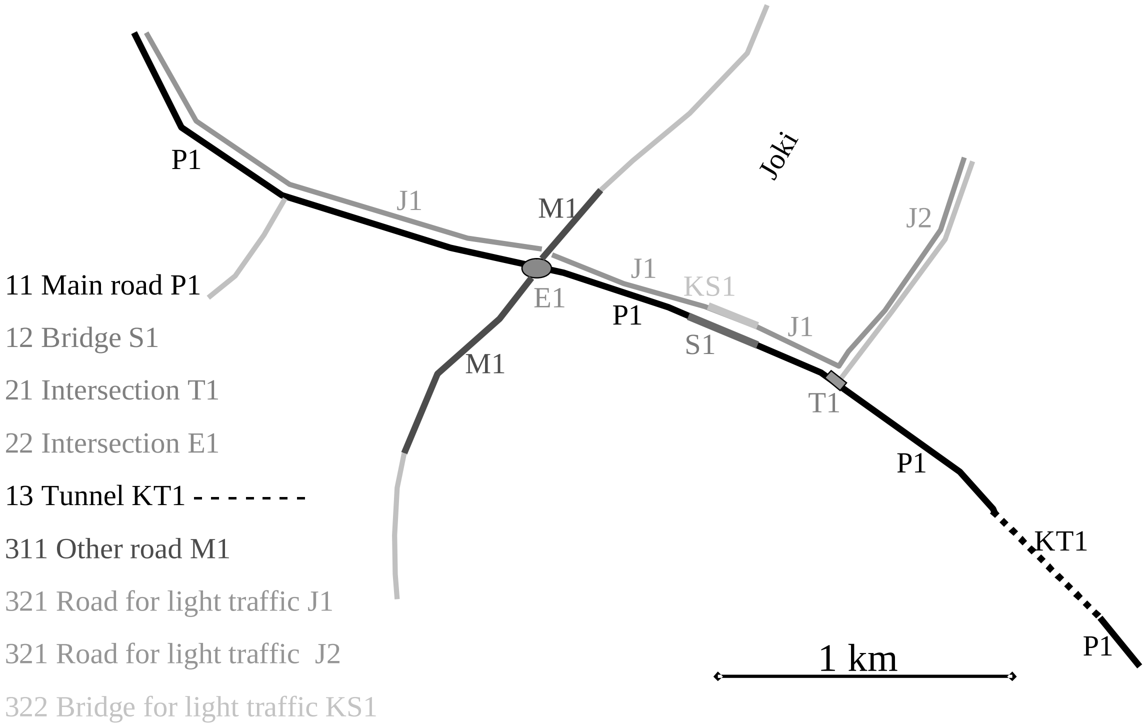

Figure 3Example of the end product element division

The cost management process by the end product elements has the certain steps:

- To identify the components of the project
- To identify the end product elements of the project components
- To get price for each end product element from the price list (fig 4)
- To identify the additional circumstances (for example environmental, interference caused by the built environment)
- To identify other additional costs
- To define the costs related to the project management (for example the difference between big and small projects)

The end product element price of the project depends on the made project plan. If all the big components are taken into account, the additional costs are identified and the desired cost allocations are made the projects scope can be estimated strictly in a very early step of the project. The rest of the project is all about project management.

PRICE LIST FOR TYPICAL END PRODUCT ELEMENTS

3. The Cost Engineering Process

3.1 The Cost Management by the Building Element System

The cost management by the standard building elements gives the answer for the question: "What is the price of the certain design solution?" The standard building elements consist of the recourse model, which is updated by the market related resource prices.

The building element system has three purposes:

- With the building element price the design result can be compared to the scope (the end product element price)
- It gives comparable prices for different design solutions
- It gives the market price estimate for the contract

The systematically used building element method requires that:

- Many separate nomenclature items are used
- Price lists are tested with the real executed contracts
- Pricelists are maintained (from the resources)
- The price list items and the used design items are comparative

Figure 5Example of the building element price list

3.2 The Cost Information Storage

The systematic cost management needs the systematic information storage. The end product elements have certain requirements for use, investment, environment and functionality. Those requirements can be modelled through the certain steps:

- the product elements (for example foundations, surface layers)
- the building elements (for example earth excavation, insulating layer, asphalt layer)
- The production elements (for example mass transportation, vibrations)
- And the resources (for example excavator, asphalt)

The modelling system needs a structured nomenclature for every step of the tree. Nomenclature gives every piece of data a certain individualized code number, which keeps the system in order.

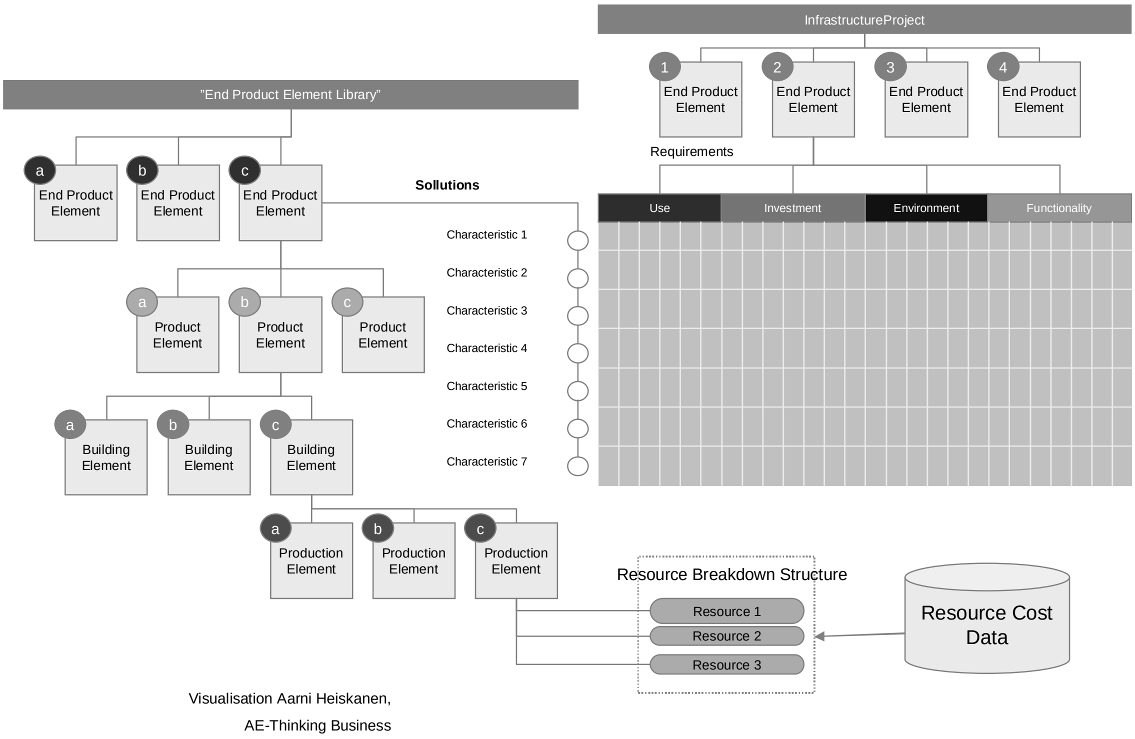

Figure 6 The systematic cost management information storage

The cost management system is built up to the database. The database has the strict structure to keep all the information in order. The Rapal Cost Management system is planned to follow the Finnish common Infra-nomenclature, which is developed by Rakennustieto and Helsinki University of Technology. The product model work is just starting in Finland, but in the basis of today´s information the product model and the end product elements have the same kind of main structure.

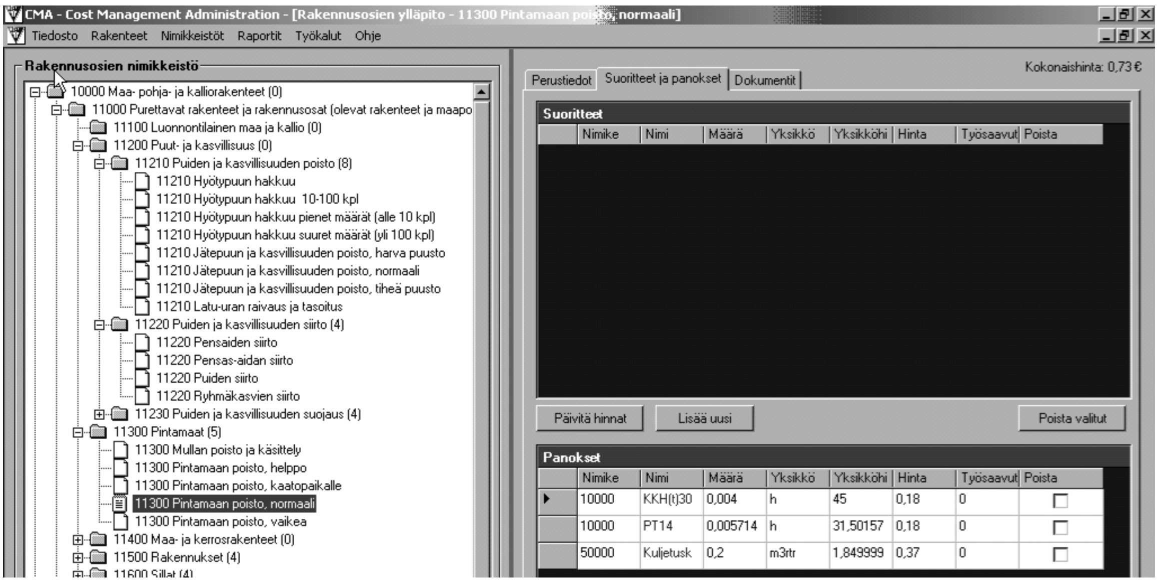

Figure 7 Example of the cost database

4. The Benefits of Process

The benefits of the systematic cost management system are:

- The real needs of the project are identified earlier with the project plan method and the update of the project plan during the process is easier because of the systematic description method

- The cost level of the project can be modelled earlier and more exact than before because of the defined scope

- The cost level in every step of the project is comparative because of the structured product elements

- There are comparative prices in different projects because of the common cost management system

- The feedback of the prices in the executed contracts is straight in the use of the system

5. Conclusions

The infrastructure cost management is said to be difficult because of so many various variables (natural environment, different ground, built environment). In this project Rapal has studied and investigated over 100 real infrastructure cases during 2003-04. The system development is still going on and more information especially about the maintenance is on the scope of the project.

Conclusion of the results so far is that:

- The systematic scope management before the design process is the key to the good cost management

- To get the good cost estimate in the early stage of the project we need new kind of requirement based end product element system

- The building element system needs systematic information storage and continuous systematic feedback from the real projects to remain valid and updated

- The common cost management system gives benefits of synergy to all the organisations

A Case Study of Project Document Management in Building Design

Linas Gabrielaitis
Vilnius Gediminas Technical University (email: linas@cadteam.lt)
Romualdas Bausys
Vilnius Gediminas Technical University (email: romas@fm.vtu.lt)

Abstract

The problem of managing all the information in building design is a real challenge. Electronic Document Management is growing rapidly and generates the need to structure of design information across building design companies. Lithuanian standardisation organisations, professional associations, user groups, individual companies don't have unified rules of CAD standards and guidelines in building design industry. The most important issue in efficient IT application is the standardized reference of all data definitions.

Keywords: Computer aided design, electronic document management, product data management, building information technology.

1. Introduction

In today's fast-paced economy, building design companies with multiple enterprises such as architecture, engineering and construction (AEC) are seeking for new efficient ways to streamline their business processes, so that the project development time and costs can be reduced. Project development time is typically long due to a considerable volume of documents that required to be transferred between the members of different project teams. Another possible reason for high project development time and costs is that even typical projects have to be developed from the bases, since there is no centrally and easy accessible information storage. It is based on well-know fact that designers spend 75% of their time searching for the appropriate documents, and only 25 % of the time actually modifying it [1].

As an efficient solution the mentioned above problems is the application of the product data management (PDM) systems, that facilitate the management of documents pertinent to particular enterprises, projects and work groups in computer networks. In addition to the basic file management capabilities, PDM systems contain enhanced features related to the life-cycle, revision history and version management of particular classes of documents [2]. A number of commercial tools have been created for document management, project information sharing, online communication, design workflow, construction workflow, time control, and securing information [3]. The case study presented in this work demonstrates how PDM system has become an important element in keeping control of company design activities. It served as a central repository for design information, and digital data documenting the progress.

2. Generic Model of Digital Design Data Archive

A growth of the work intensity in building design companies creates the difficulties of management information flows in the projects. In fact, project management can be accomplished as document life cycle control. The successful application of PDM systems strongly depends on the appropriate structure of the central archive for design information. Preserving information in digital forms is much more difficult than preserving information in forms such as paper. This is not only a problem for traditional archives, but also for many organizations that have never thought of themselves as performing an archival function. The workflow presented for the archive of the construction design documentation is based on ISO Reference Model for an Open Archival Information System (OAIS) for a data repository system [4, 5, 6] (Figure 1). The role provided by each of the entities in OAIS can be described briefly as follows:

- **Ingest**: This entity provides the services and functions to accept Submission Information Packages (SIPs) from Producers (or from internal elements under Administration control) and prepare the contents for storage and management within the archive.
- **Archival Storage:** This entity provides the services and functions for the storage, maintenance and retrieval of Archival Information Packages (AIP).
- **Data Management:** This entity provides the services and functions for populating, maintaining, and accessing both Descriptive Information which identifies and documents archive holdings and administrative data used to manage the archive.
- **Administration:** This entity provides the services and functions for the overall operation of the archive system.
- **Preservation Planning**: This entity provides the services and functions for monitoring the environment of the archive and providing recommendations to ensure that the information stored in the archive remains accessible to the designated user community over the long term, even if the original computing environment becomes obsolete.
- **Access:** This entity provides the services and functions that support consumers in determining the existence, description, location and availability of information stored in the archive, and allowing consumers to request and receive information products.

For the definition of information handled by OAIS the paradigm of the information object is applied. Every submission of information to an OAIS by a Producer, and every dissemination of information to a Consumer, occurs as one or more discrete transmissions. Therefore, it is convenient to define the concept of an Information Package. Three different types of the packages are implemented:

- Submission Information Package (SIP);
- Archival Information Package (AIP);
- Dissemination Information Package (DIP).

Within the OAIS one or more SIPs are transformed into one or more Archival Information Packages (AIP) for preservation. The AIP has a complete set of Preservation Description Information (PDI) for the associated Content Information. In response to a request, the OAIS provides all or a part of an AIP to a Consumer in the form of a Dissemination Information Package (DIP). The DIP may also include collections of AIPs, and it may or may not have complete PDI. The Packaging Information will necessarily be present in some form so that the Consumer can clearly distinguish the information that was requested.

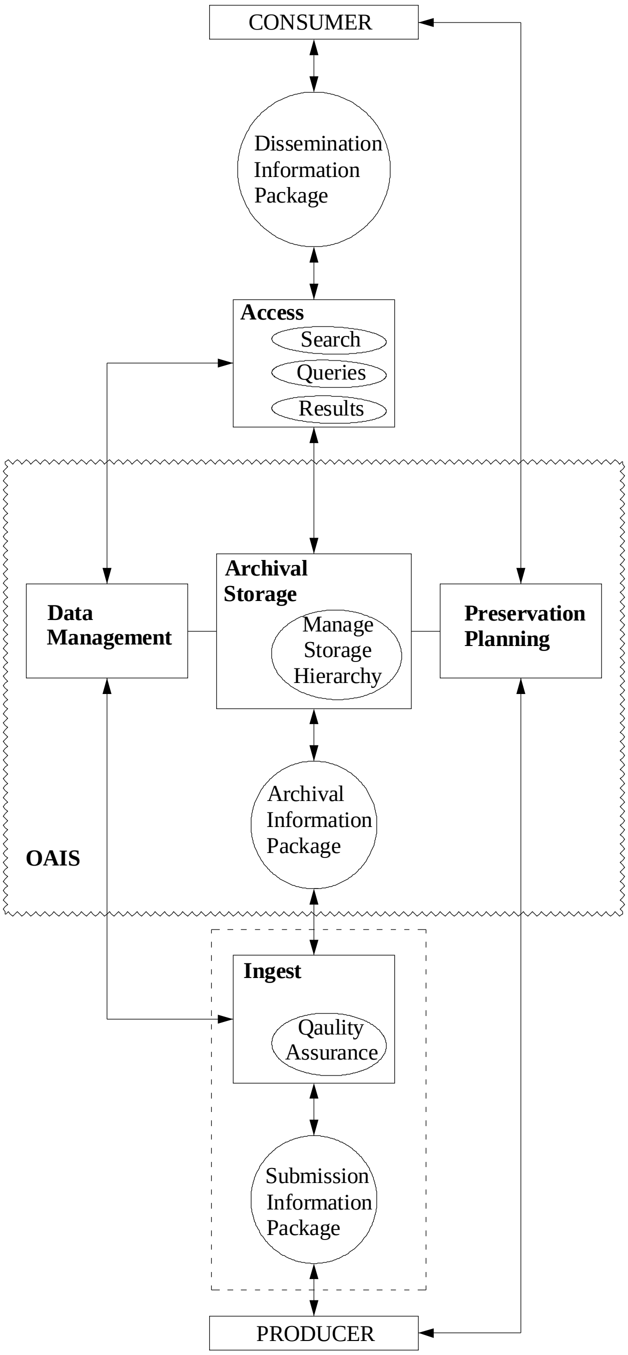

Figure 1: Archival information system

3. Framework for Archiving Digital Design Documentation

The structure of the digital design documentation archive have to be tailored towards the specific needs of the design company and requirements of the construction regulatory laws [7]. For the design management of the building, most documents and communication were exchanged electronically and reflect in a way the name of the project. The developed PDM system stores all documents and communications related to a project in a document repository that facilitates keeping track of those documents throughout the duration of a project and later on. The archive is meant to store in a structured way all kinds of documents and communications to clients, consultants, suppliers and subcontractors. Due the project-centric nature of the construction industry the structure of archiving of the design documents reflects the main parts of the project (Figure 2).

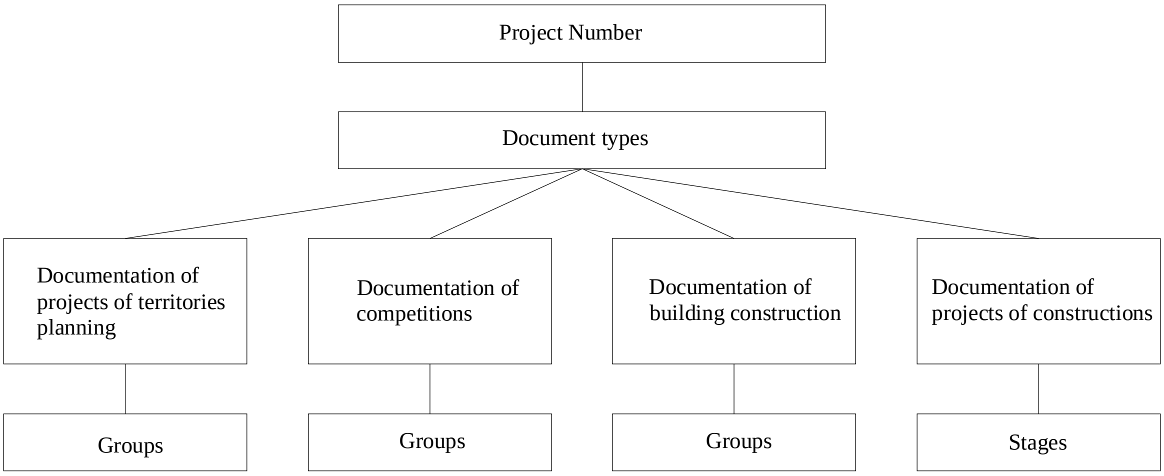

Figure 2: Lithuanian classification of the project documentation

This classification is governed by Lithuanian construction regulatory law [8]. For the illustration one part documentation of projects of the construction is shown separately (Figure 3). Lithuanian standardisation organisations, professional associations, user groups, individual companies don't have unified rules of CAD standards and guidelines in building design industry. This is a first attempt in Lithuania to provide unified reference of all document definitions. On the other hand, this standardized reference is the most important issue for development of the efficient IT applications.

The direct implementation of the document classification system leads to overcrowded hierarchical tree of project information. In order to overcome these difficulties document file naming schema is established for native CAD models. This file naming schema is associated with standardized design document classification. The specific CAD document is named beginning with an optional five digit project code followed by (Figure 4):

- Project number;
- Construction number;
- Project stage;
- Discipline designators;

- Version number.

In a similar way, file organisation structures are defined to represent the hierarchy of the building design project. File directory organization (Figure 5) together with file naming schema provide an effective framework for digital design information archiving.

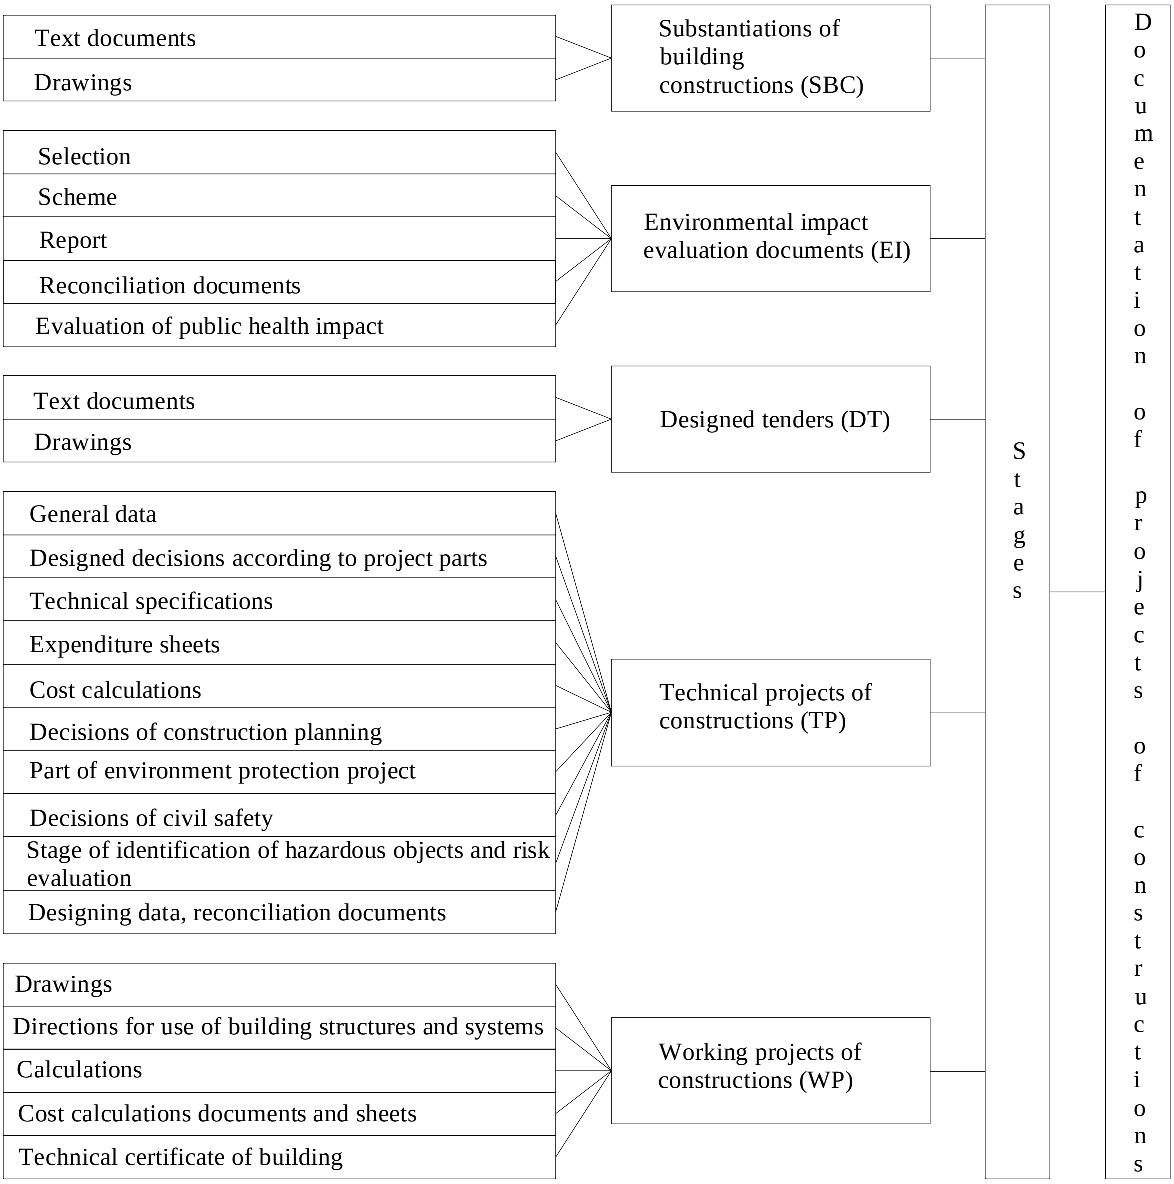

Figure 3:Document classification of projects of the constructions

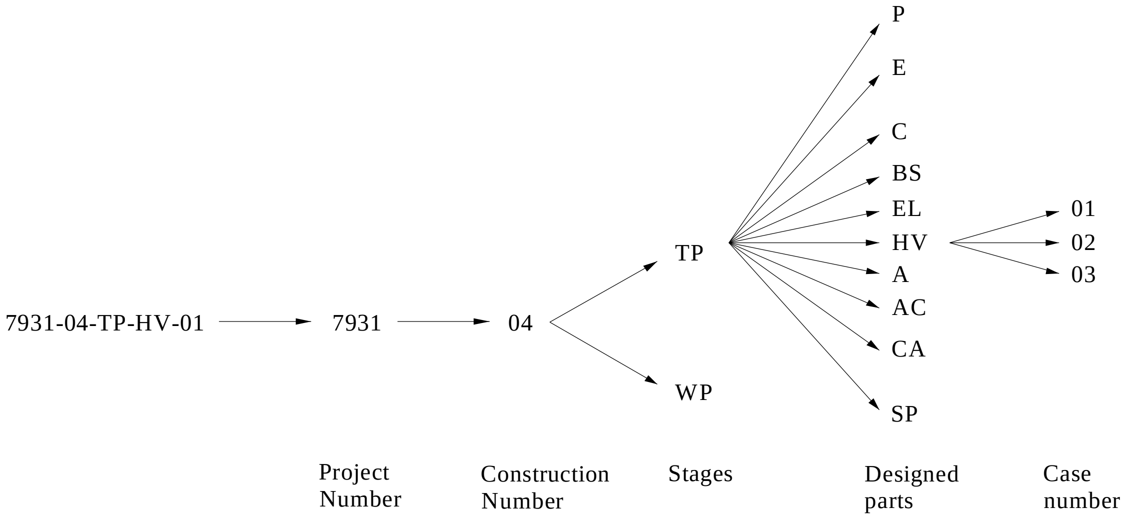

Figure 4: Naming schema of the design documentation

Lettering of designed parts: E – Estimates; C – Communications; EL – Electricity; V – Heating and Ventilation; A – Automation; AC – Architecture and Construction; BS – Building Structures; CA – Calorific; SP – Site plan; P – Plumbing.

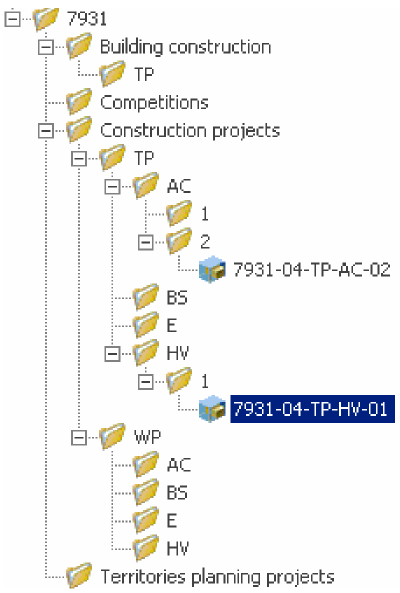

Figure 5: Design information file organization

4. Implementation Technology of AEC Design Archive

For the implementation of the developed model, the AEC digital design archive was chosen, that is “eChange” PDM software of the company ”Empresa Solutions”. For more information about basic features of “eChange”, the interested reader is referred to [1]. While “eChange” was designed with the CAD sector and engineers as the primary users, the system can be used to store any type of file that can reside on a computer’s file system. In our case the largest Lithuanian building design company use “eChange” to manage all of their office documents in addition to the CAD drawings they generate. Lithuanian company performs complete residential and industrial building design that includes architecture, construction and engineering (AEC). UAB Lithuanian Construction Design Institute (Lietuvos Statybu Projektavimo Institutas), which is engaged in the design of construction units and project management has increasing the number of projects per year, at the same time having designed more and more complex objects, the implementation of efficient PDM system has become essential. Tasks that need to be performed for implementation design document archive included (Figure 6):

- Initialization file organization sheet with prescribed project number selection of document format.
- Preparation of electronic document files.
- Automated transmission from SIP to AIP.
- Management of the development team.

The processing of implementation include following steps:

- The design company starting a new project activate structure for a new collection of the digital design data. The project leader or the administrator of the archive initiates this process by entering new project number. By this operation, in the vault of the technical documentation a new tree representing structure of the project documentation is appeared and the SIP of the new project is initialized.
- Each designer of the building design company working with "Architectural Desktop" software and using “Project Navigator” directly connects to general file organization system. By this way separate documents of CAD design are created. Each designer has knowledge about development of the whole project bringing CAD documents into project structure (Figure 5). If changes are made in one part of the project documentation the system automatically shows and other designer can follow what’s going on. That is maintained design chain. At each time the numbers of design chain have information about changes in CAD documents.
- The same tree structure of the project documentation is appeared in the AIP where is “eChange” PDM system. After synchronizing all electronic documents in SIP according to the design parts the archive administrator sets “Archived” status for the documents before that putting them into AIP “eChange” system. By this operation project structure with design information are automatically transformed from SIP into AIP. In AIP all project documents gain “Released” status and if all information is correct documents gain “Archived” status.
- After transforming from SIP into AIP all project documentation obtain metadata properties. The Dublin Core metadata scheme is applied as an initial basis on which the development of more specific relational standard within proposed digital design data archive is performed. There is underway of automated attribution of properties and all documentation that is placed in to project structure adequate catalogues. Hereby all project information being in “eChange” system are accessible for users and groups according to permissions for each document type. The “eChange” system also provides different levels of access rights to documents View/Copy, Check Out/In, Release, Archive, and Delete.

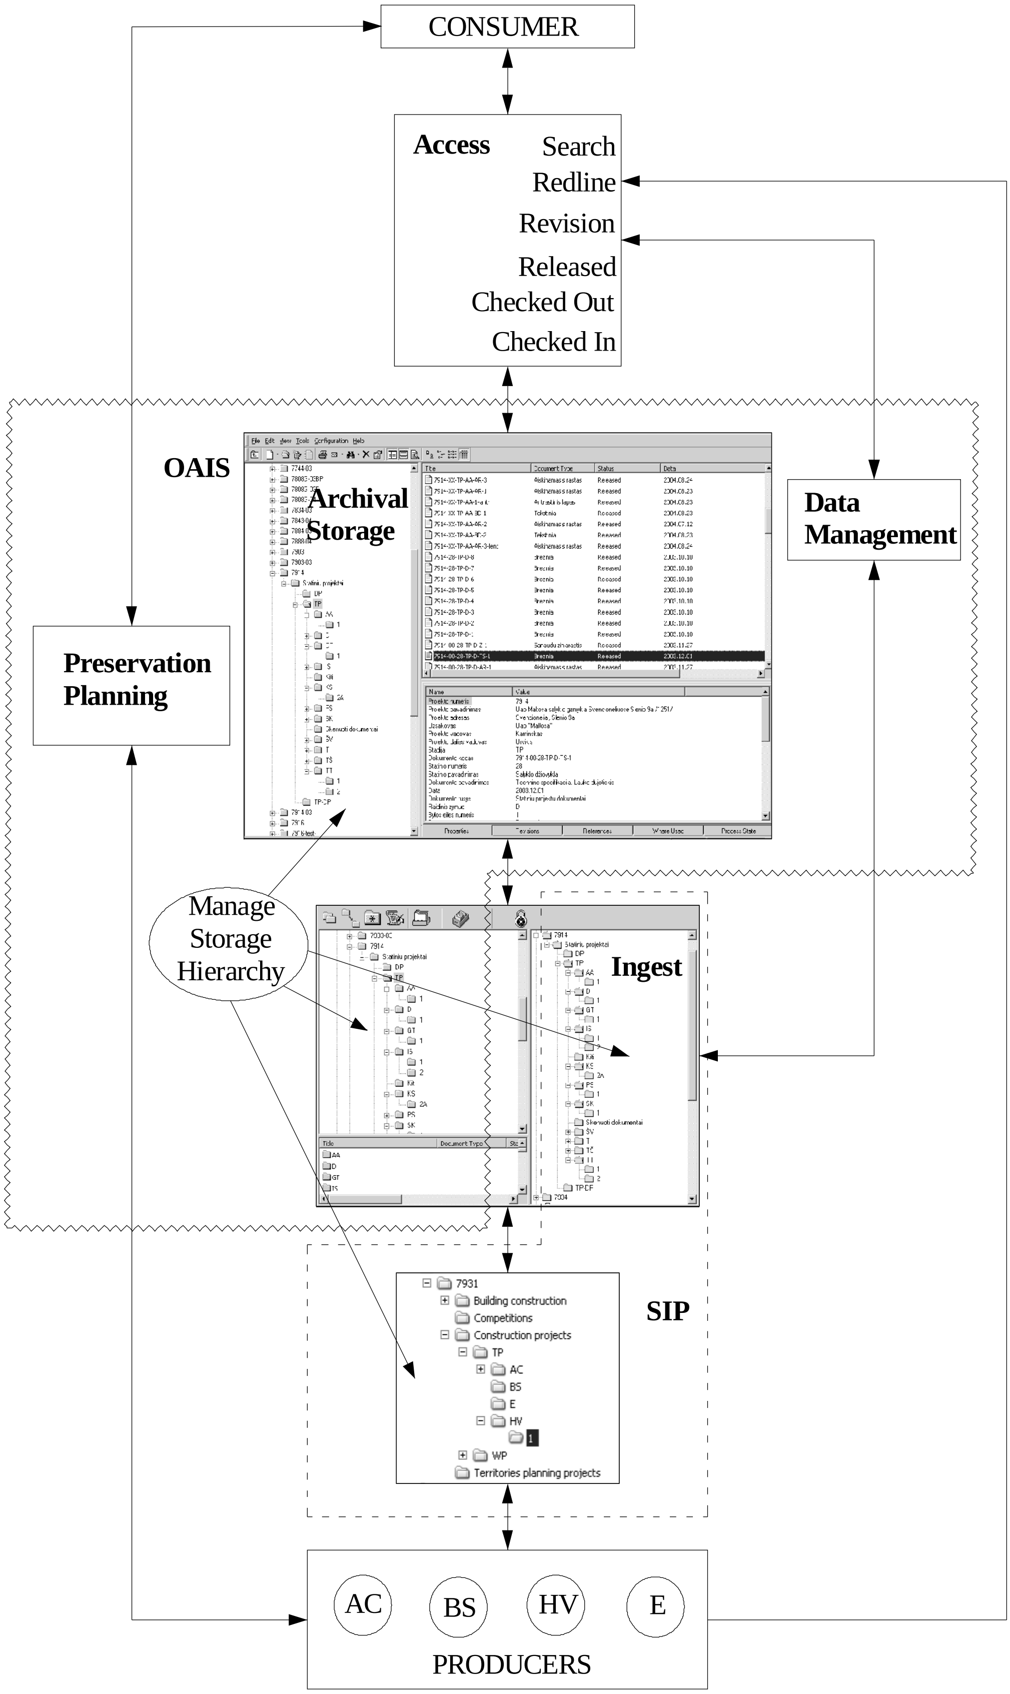

Figure 6: Design information structure

5. Conclusions

The first digital project documentation archive is developed in Lithuanian AEC industry. The modelling of the archive of the construction design documentation is based on reference model for an Open Archival Information System (OAIS). For the creation and management of this archive PDM system of "Empresa Solutions" is implemented. The main strategy was to develop the dynamic archive with information flows in the both directions of the design process chain: consumer-design-archive. The adoption of this digital archive provides a efficient basis for an automatization of Lithuanian construction regulatory rules for building design documentation.

Transformation of Measured Surfaces of Buildings to CAD Supported Wall Line Model with Joints

Mauri Laasonen
Tampere University of Technology, Finland (email: mauri.laasonen@tut.fi)

Abstract

The most central and most researched area of construction IT is the design and realisation of new building projects. However, if the building and real estate sector is viewed from the perspective of national economy or the ownership and use of buildings, the management of the existing real estate stock becomes more important.

The manageability of the real estate stock depends directly on the amount and correctness of available input data. The most valid and complete information on existing buildings can be acquired by measuring. Measuring is labour-intensive, but the utilization of results is still technically difficult. Therefore data processing should be as automatic as possible.

This article documents how a measured surface model can be transformed to CAD model. The new approach is based on the use of geometric documentation of intersections and visual marking systems to help the user finish the model.

The solution has been limited to walls and their joints. Other structural elements may be added to the model mainly by intersection methods of CAD programs. For example, a column can be added inside a wall afterwards.

The developed method aims at improving the integrity and technical perfection of models. The connectivity of structural elements is crucial for the usefulness of a model. If walls are not connected, intersections need to be remodelled by the user interface. Without the method presented here, the transferred data could at worst be used as a background image.

Keywords: Measuring of buildings, data transformation, CAD, wall generation

1. Introduction

There are two alternative methods for verifying or retrieving data on the sizes, spaces and structures of existing buildings: either reading the data from drawings or measuring them on site. Drawings have traditionally been made merely to serve the building process. If drawings have not been updated after that, they cannot be considered reliable.

In that situation the real estate sector has an acute need for methods that allow data on buildings to be saved effectively by on-site measurements. Such data are needed especially in renovation planning but they are also very useful for facility management. The main advantage of the on-site measurement method is the validity and completeness of the information

Existing methods for measuring buildings yield a surface model of the building, where the structural elements are depicted by visible surfaces. Invisible structures cannot be measured directly. The surface model is useful, for example, in visualisation.

CAD applications for building design model buildings based on structural elements. If measurements are linked to a special data saving application, the connection of surfaces to structural elements can be stored. A structural element can be generated if all of its limiting surfaces are known. Thus, for example, the surfaces of a fully visible column can be used to generate the actual structural element.

The central structural element in the modelling of a building is the wall, because spaces are usually limited by walls. After defining the walls it is possible to use the model to calculate floor and other areas which are crucial for the occupancy of the building. A major problem with the use of the measured surface model lies with the generation of wall structures, since it is not initially known which wall surfaces measured from different rooms limit the same wall.

2. Wall Generation to a Measured Model

2.1 Measurement of Building

Several methods are available for the measurement of outer surfaces and interior spaces of buildings. The oldest methods are based on measurements with a tacheometer. The method is described, for example, in publication [3]. Instruments designed for terrain measurement can be used to observe the three-dimensional coordinates of individual points. A measurement application can be used to combine the points into surfaces depicting structural elements. A drawback of the method is the slowness of measurement. Every time the measuring instrument is moved it must be set up carefully and its position determined.

The latest methods include modelling based on scanning where the surfaces are formed automatically. The method is described in publication [2] and its commercial application in publication [8]. In this method the distance information obtained by a laser distance meter is added to a digital image. The geometric shape of a surface can be calculated using algorithms derived from photogrammetry. The graphic elements constituting a surface do not necessarily follow the division of structural elements. Data on structural elements must be added to the model through human labour.

The simplest and cheapest measurement method uses a distance meter. A portable computer and a measurement application are also needed. The interface of the application can be used to assign the measured values directly to structural elements and to save the property data of the elements based on visual observations at the same. Although this method also requires much human labour, it is the quickest way to produce a model from measurements inside a building with data on structural elements. The weakness of distance measurements is that they do not include the angle of measurement. Then non- rectangular walls cause inaccuracies that must be addressed separately. There are several software packages on the market that utilise laser distance meters in the measurement of buildings. This method is described in publication [4] and its commercial application, for example, in reference [9].

2.1 Generation of Wall Elements

To enable the generation of structural elements from measured surfaces, the surfaces must be assigned type and material data. Moreover, one surface must not belong to two different structural elements. Otherwise the automatic processing of the model would not be able to make a distinction between such elements as columns and walls.

Many methods that generate walls from wall surfaces require either user intervention or are suitable only for the generation of rectangular walls. Such methods are presented, for example, in publications [6] and [7].

Publication [5] presents a method where wall direction can be used to find the closest other wall surface for each measured surface. The direction is known if wall surfaces of a room are measured in a sequential order when the measurement returns to the starting point. Then the walls can be generated even if the measured wall surfaces are not aligned with the rectangular coordinate axes. The method does not require setting an upper limit for wall thickness, either. The geometric shape of the generated wall base areas is limited to four points. The wall generation method is two-dimensional, which means that the line formed by the lower edge of the wall surface is used instead of the measured wall plane.

3. The Documentation of Wall Intersections by Geometry

3.1 Assumptions

If the wall structure is homogeneous in the vertical direction, the connectivity of walls can be studied based on the intersections of the base areas of the walls. An example of the calculation method is presented in publication [1]. Such a method could be difficult to program because of problems related to calculation accuracy.

The calculation becomes much faster and easier if the intersections can be calculated using lines. Two walls can be considered interconnected if any of their boundary lines intersect. Possible lines indicating an intersection are the boundary lines defining the base area of the wall and other lines defined within the walls such as the centre line of the base area.

The data structure of a wall with a simple geometry can be described by a single line. The wall thickness can be assigned to both ends of the line. The use of this method is supported by simplicity and the utilisation of standard basic functions of CAD applications.

Three-dimensional wall models can be described by base areas if the geometry of the structure does not change in the vertical direction. Then plane coordinates (x and y) remain constant while the z coordinate changes. If height can only change linearly between the end points of the wall, data on the three-dimensional shape can be stored using height data assigned to the corner points of the base area.

3.2 Used Symbols

Intersection types are classified using upper- and lowercase letters. The upper-case letter represents wall properties and the lowercase letter the connectivity of centre lines. The connectivity of wall lines is indicated by a lowercase letter added after the type letter. Connected lines are marked with "c" (connect) and others with "g" (gap).

Wall intersections are divided into intersections of two or more walls. In an intersection of two walls the real structure is usually continuous but the wall has been divided into two elements in the computer model. It was decided to use the capital letter "W" (wall) as the first character of the type designation of this intersection.

Intersections of more than two walls are indicated with a capital "C" (crossing). With such intersections the number of combinations is theoretically unlimited. The classification of these intersections is based on selecting the two walls that form a continuous structure as in the case of an intersection of two walls. All other walls join the walls that form the continuous structure.

The walls to form a continuous structure are determined on the basis of their property data. Exterior walls or bearing walls are primarily chosen as continuous. It is not always possible to reach an unambiguous solution based on these conditions, and additional conditions may therefore be set based on structural thickness and parallelism of walls. In the designations the walls of a continuous structure are indicated by the letters "CC" (crossing continuous).

The fourth letter indicating a wall intersection type is "G" (gable). It is used for cases where a wall gable bounds a space. A gable may be partial, in which case the letter is made part of other type designations. A partial gable is produced if all boundary lines of the connected wall areas do not intersect.

3.3 Types of Wall Joints Classified by Connectivity

In the method presented here walls are assumed to be modelled by lines, which are also used for documenting wall joints. Walls are classified under different categories based on their connectivity. The classification does not depend on the location of the line in the wall base area, provided that the wall line is straight and not, for example, an arc. The examples use the centre line of the wall base area. Intersection type refers to the type of each connecting wall, not the entire intersection.

Intersection types where a wall line is connected to another line are: Wc, CCc, Cc and WGc. Intersection types where the wall lines do not connect are: WGg, CCg, Cg, CCGg and CGg. There may also be walls that end without a connection: G.

Intersection types differ in terms of the intersections of their wall and boundary lines. Boundary lines are defined as discontinuous if at least one line is discontinuous. Then the wall gable bounds a space, and the letter "G" is added to the type designation. The following three illustrations present examples of different joints. There are three different types of two-wall intersections, as shown in Figure 1.

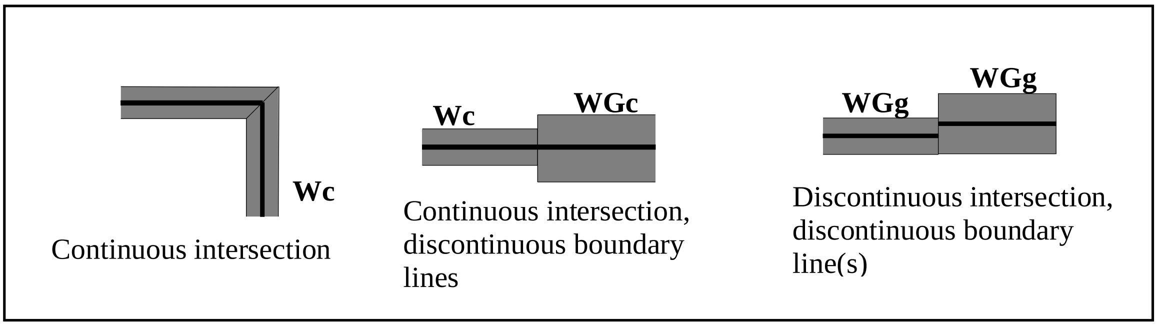

Figure 1. Intersections of two walls.

Figure 2. shows examples of intersections of more than two walls. The walls forming a continuous structure (CC) are darker. In the second example of Figure 2, the centre line of one wall has not been extended to make a connection. This is because one wall would be shortened by the operation. This would also change the original measurement result or the measured surface, which is not permissible.

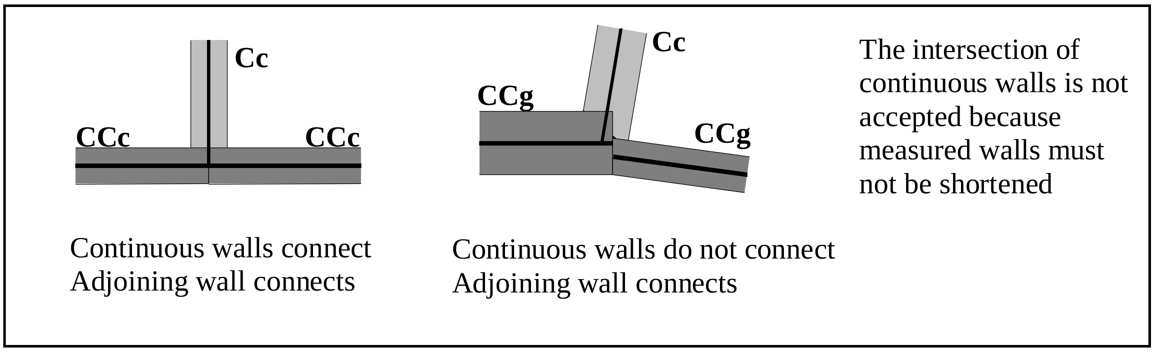

Figure 2. Intersections of more than two walls.

Figure 3. shows examples of intersections of more than two walls where a wall gable bounds a space. These cases occur rarely in actual buildings.

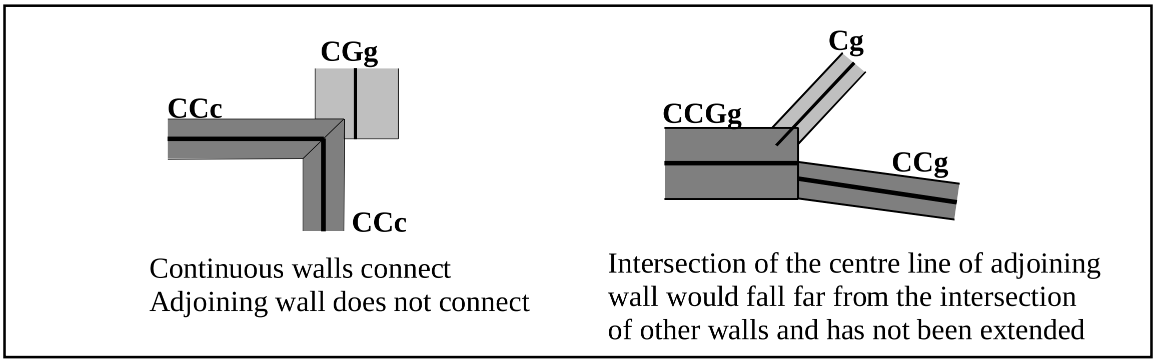

Figure 3. Special cases of wall intersections.

4. Implementation and Results

4.1 Wall Generation

Walls were generated using the method described in publication [5]. In the testing, it was assumed that all walls produced by the measured model are flawless. Actual 4 measured buildings were used as test material. Sample size was too small to be statistically significant, but it gives an idea of whether the method works. Buildings L and N are public buildings of complex architectural shapes. Buildings P and R are rectangular prefabricated buildings. In figure 4. is shown two dimensional drawings of buildings L, N and R. Building P is shown in figure 5.

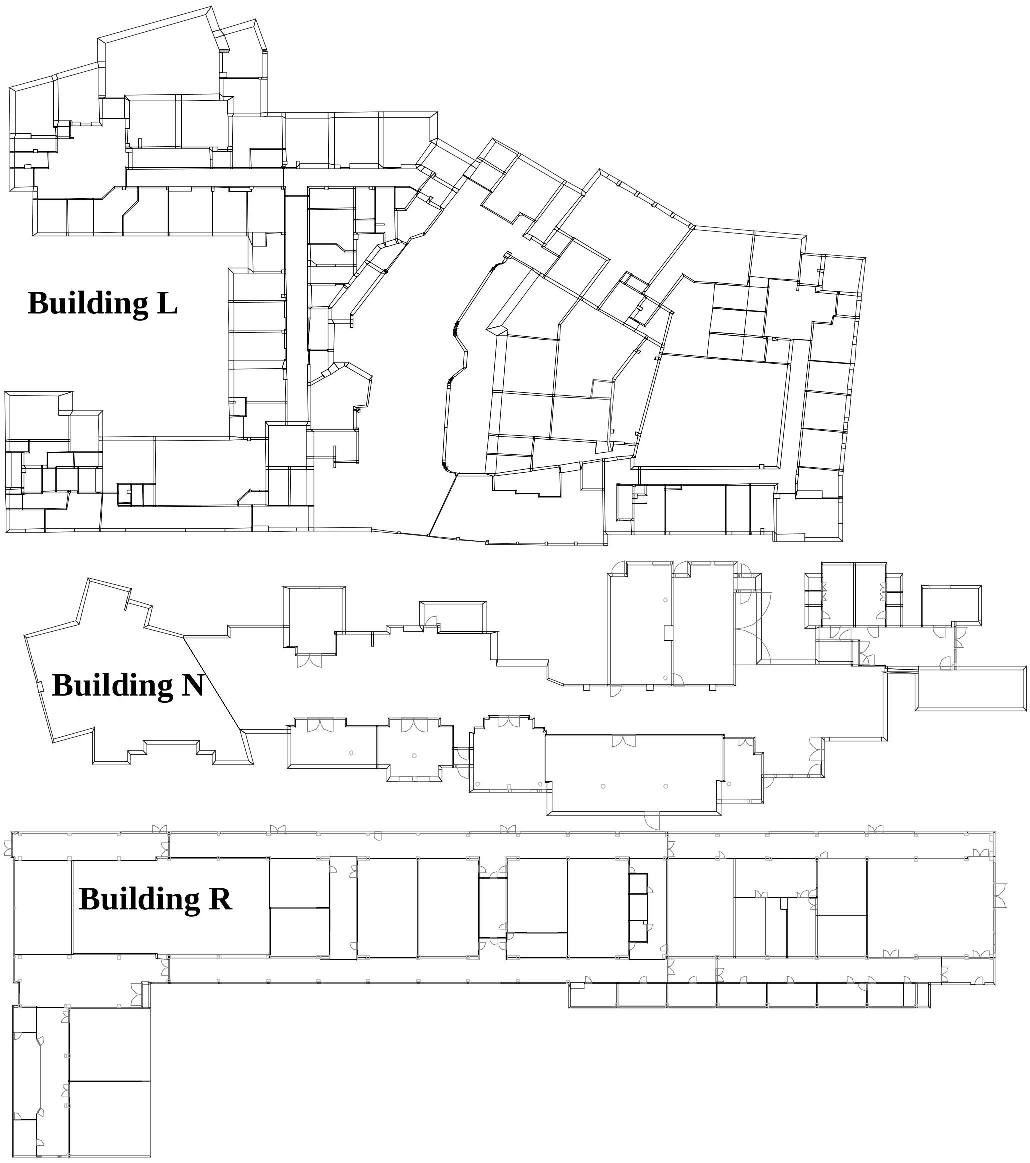

Figure 4. Two dimensional drawings of test material.

Table 1. presents the numbers of generated walls divided according to constant or non-constant wall thickness. If thickness is not constant, it may only change linearly between wall ends, as described above.´

Table 1. The number & percentage of different wall thickness types in the test material.

	Building L		Building N		Building P		Building R	
Thickness	no.	%	no.	%	no.	%	no.	%
variable	801	96.2	25	12.0	11	5.5	26	12.8
constant	31	3.7	182	87.5	187	94.0	176	86.7
unknown	1	0.1	1	0.5	1	0.5	1	0.5
All walls	833		208		199		203	

4.2 Joint Types of End of Walls

The centre lines of the generated walls were extended to intersect each other. Data on the connectivity of wall centre lines were recorded in the database. Different types of wall end intersections were recorded as described in Chapter 3. Table 2. presents wall end types by connectivity.

Table 2. Occurrence of wall end intersection types in the test material.

	Building L		Building N		Building P		Building R	
End type	no.	%	no.	%	no.	%	no.	%
Wc	508	31.1	218	52.7	84	21.1	90	22.2
CCc	150	9.2	99	23.9	121	30.4	77	19.0
Cc	259	15.9	0	0.0	70	17.6	72	17.7
WGc	0	0.0	0	0.0	0	0.0	0	0.0
WGg	132	8.1	30	7.2	20	5.0	46	11.3
CCg	488	29.9	39	9.4	69	17.3	96	23.6
Cg	41	2.5	15	3.6	20	5.0	4	1.0
CCGg	24	1.5	2	0.5	2	0.5	1	0.2
CGg	7	0.4	0	0.0	1	0.3	0	0.0
G	0	0.0	3	0.7	1	0.3	0	0.0
unknown	23	1.4	8	1.9	10	2.5	20	4.9
All ends	1632		414		398		406	
Walls	816		207		199		203	

The case WGc, where the centre lines of two walls connect at the intersection but the boundary lines do not, did not occur in the material. That would be possible only if exactly equal thickness changes were measured from different rooms. Although theoretical, the type cannot be excluded from the classification, because it produces a connection between walls.

Cases where connectivity could not be determined were examined by random samples. In all examined cases wall thicknesses were so small that connectivity could not be calculated. Small wall thicknesses resulted either from measurement inaccuracy or faulty type designations. Imaginary walls of zero thickness dividing spaces were used to facilitate measurements, and were excluded from calculation based on their type designation.

The number of walls is the numbers of wall ends divided by two. 17 of the originally calculated walls in the L building and one in the N building were removed. These walls were also geometrically flawed. For this reason, the number of walls from these buildings is smaller in the connectivity test than in Table 1.

Table 3. presents numbers of wall ends by connectivity. Table 3. reveals that over half of the intersections in all buildings could be documented geometry. On average, two thirds of the intersections in the entire material were documented.

Table 3. Share of connected wall ends in the test material.

	Building L		Building N		Building P		Building R	
Continuously	no.	%	no.	%	no.	%	no.	%
continuous (c)	917	56.2	317	76.6	275	69.1	239	58.9
non-continuous (g)	692	42.4	86	20.8	112	28.1	147	36.2
gable (G)	0	0.0	3	0.7	1	0.3	0	0.0
unknown	23	1.4	8	1.9	10	2.5	20	4.9
All ends	1632		414		398		406	

4.3 Joints of Walls

Table 4. presents the numbers of different intersections. The number of continuous wall intersections is obtained by dividing the number of the respective wall gables (Wc) by two. Likewise, the number of non-continuous wall intersections is obtained directly from wall gables (WGg). The connectivity data of the measurement database allows calculating the number of intersections of at least three walls. In the unknown cases connectivity of walls could not be calculated, and only one wall is connected to the intersection in the database.

Table 4. Number of wall intersections in test material.

	Building L		Building N		Building P		Building R	
Inersection	no.	%	no.	%	no.	%	no.	%
continuous wall	254	41.2	109	61.2	42	28.4	45	28.9
non-continuous wall	66	10.7	15	8.4	10	6.8	23	14.7
joints	291	47.2	54	30.4	94	63.5	88	56.4
unknown	5	0.8	0	0.0	2	1.4	0	0.0
All	616		177		148		156	

4.4 Output to CAD

The model was read from the database by an application written in C language and was transferred to ArchiCAD 7.0 using the functions of the programming interface. Transformed building P is shown in figure 5.

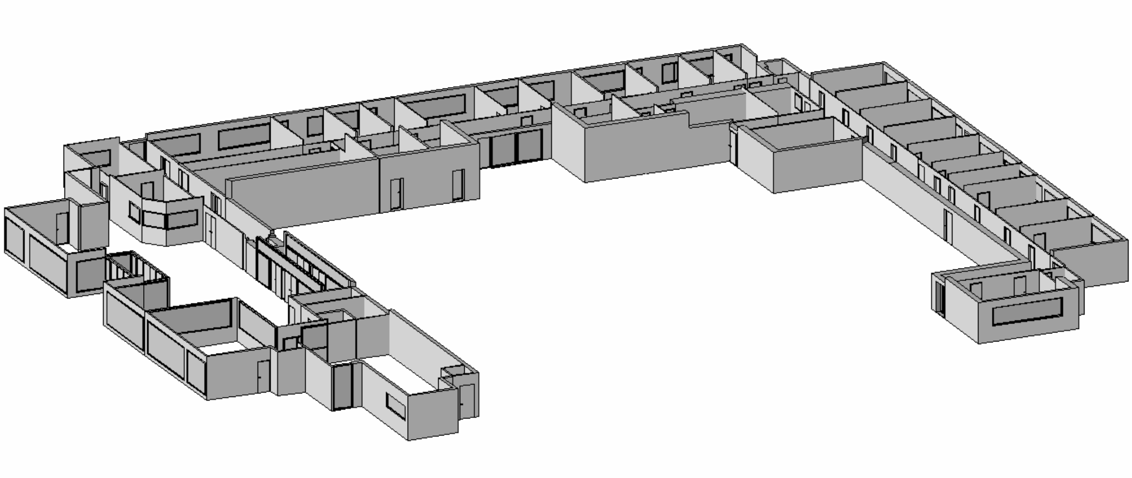

Figure 5. To CAD program transformed model of building P.

In this CAD application the wall line (reference line) may be located in the middle of the wall only if wall thickness is constant. In the other cases the wall line was moved to the edge of the wall when connections between wall lines failed. Building L was not transformed, because only 4% of its walls were of constant thickness

Wall intersections where the centre line of a joining wall did not connect to the others were marked by an alert symbol visible to the user. The example of marked join is shown in figure 6.

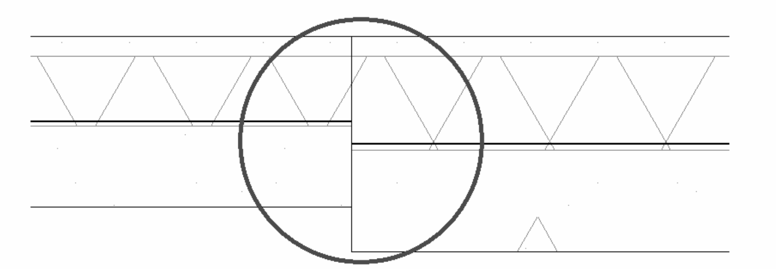

Figure 6. Marking of unconnected wall joint.

The number of marked intersections was calculated from the user interface of the CAD application. Table 5. shows the share of the marked intersections of the total.

Table 5. Intersections marked as non-continuous in the CAD output.

	Building N		Building P		Building R	
	no.	%	no.	%	no.	%
Marked intersections	68	38.2	63	42.6	76	48.7

5. Discussion

The method sets considerable limitations on the model to be used as input data. The requirement can be met by dividing actual walls into a sufficient number of sections in the computer model. In principle it is also possible to assign a wall line to a wall of complex shape, and use it to document connections. This, however, requires a separate data structure to maintain the geometric relationship between the wall area and the centre line. The other possibility is to edit the transferred model by rejoining small walls into bigger ones. This could be achieved by introducing a data structure to indicate which wall sections constitute a uniform continuous wall.

The outer surfaces of the external walls of building are normally continuous between the corners. The distances of wall surfaces between adjacent spaces are difficult to measure in exactly the same way. The wall of the other room may also have a special surfacing which makes it thicker. In both cases the result is that the centre lines of the external walls do not meet. Then the connectivity of intersections would be better if the outer surface were selected as the wall line.

CAD data transfer could be improved considerably. It can be assumed that the features, and in particular the programming interfaces of applications, develop constantly. With new CAD software versions theoretically calculated connections will before long be also attainable in practice.

The geometric documentation of intersections could also be used for general data transfer between CAD applications. Unlike in the measured database, it can be assumed that in the CAD model almost all walls are joined before transformation. The data transformation features for walls of CAD applications could be developed so that connections would occur in most cases. The location of the wall line could also be optimised to enable connectivity in as many intersections as possible. It is important that the method presented here is independent of the CAD application.

6. Conclusions

The main result of the tests was that about two thirds of wall intersections could be documented by geometry, even in the case of complex wall geometry. This leads to the conclusion that if the geometric model of a wall can be reduced to a line, the connectivity of walls can often be documented by simple markings and ten intersection types. The documentation is based on the intersections of wall lines, which means that connectivity can be expressed using geometry. This also means that the model can be transferred between applications with a minimum of external definitions.

Connections between all walls could not be achieved in any of the tested models. The detection and marking of non-connecting points reduced the work of revising and complementing the model considerably. Without the markings, the finding of a single flawed joint would have required reviewing all intersections. The number of connected walls is large enough to use the method compared to the situation where the connectivity of walls is not known.

Acknowledgements

I would like to thank Olli Nummelin of YIT Corporation for participating in the development and financing of the CAD importing program. I would also like to acknowledge Petteri Heiskari for writing the C code.

Abstract

Process improvement has been identified as a mechanism of achieving the desired performance improvements of the UK construction industry. During the recent past, researches within UK construction process improvement research paradigm have been influenced by the initiatives of other industries like manufacturing and software. Despite the success stories within such industries, the unique characteristics of the construction industry demand a careful consideration of the applicability of these approaches within a construction environment. Based on a literature review carried out by the authors, this paper discusses the nature of this applicability issue further.

In addition to the above applicability issue, construction industry has suffered from a slow information technology (IT) adoptability issue, while IT has been considered as an effective enabler for process improvement in other industries. This has hindered the potential synergetic benefits of using IT within construction process improvement strategies. As such, it is important to understand the reasons behind this slow IT adoptability in order to ensure successful deployment of process improvement initiatives within the UK construction industry. This paper discusses this issue, by reviewing the literature to compare IT adoptability issues of the UK construction industry and other industries, with the aim of learning lessons from those to improve the UK construction industry.

Keywords: UK construction industry, construction process improvement, IT adoptability, IT-process co-maturation, construction IT

1. Introduction

The need for a change within the UK construction industry is discussed within number of studies during the recent past [1,2,3,4,5]. Growing dissatisfaction found among both its private and public sector clients has been an effective motivator for these discussions [6]. These dissatisfactions are often attached to the poor performance of the industry. The required change has thus been identified to be in a form of performance improvement. Further studies about this requirement have revealed that the fragmentation and confrontational relationships are the major inhibits for performance improvement initiatives [4,3,5]. Fragmentation and confrontational relationships are sharpened due to the traditional functional view of construction projects, where the tasks are assigned to individuals based on their functions with minimum attention given to the integration issues [7,8].

Having identified this nature, Egan [3] highlighted that “focusing on the customer” and “integrating the process and the team around the product” as two of the key drivers to achieve the desired change within the UK construction industry. This emphasises the need of deviating from functionally oriented project structures towards a customer focused, process oriented project delivery mechanisms. It appears that the above recommendations from Egan are based on the view that the process improvement is the way forward to improve the performance of the UK construction industry [9].

2. Process Improvement

2.1 What is Process Improvement?

In literature “process” is often defined as a set of related activities attached to outputs, value and customers [39]. Davenport [10] states that “a process is simply a structured, measured set of activities designed to produce a specified output for a particular customer or market”. Hammer and Champy [11] defined a process as, “a set of activities that, taken together, produce a value to the customer”. As identified within above definitions, the process view integrates the product, procedures and the customer, so that the stakeholders of an organisation can view the big picture which they are contributing to. This essentially synchronises the individual functional objectives with the overall organisational objectives, enabling opportunities for improvements.

Literature covers a wide spectrum of terms related to process improvement. Business Process Improvement, Continuous Process Improvement, Business Process Re-design, Business Re-structuring, Business Process Re-engineering are some of those which appear frequently within literature [12,13,14,15,16]. All these concepts appear to have the major objective of achieving performance improvement within organisations, but vary from the magnitude of the desired level of change. It varies from continuously improving the processes to total re-structuring the organisation [17]. This determines the two extremes of the process improvement spectrum and defines the two major approaches to process improvement, the evolutionary approach and the revolutionary (radical) approach [18]. Within literature some times the term “process improvement” is synonymously used with the evolutionary approach and “process innovation” is synonymously used with revolutionary approach. Within this paper, “process improvement” is used for both the cases, and where appropriate, evolutionary and revolutionary approaches are explicitly indicated.

2.2 Process Improvement in Construction

Recent construction literature show a clear focus on construction process improvement strategies. Within these literature, the best approach for construction process improvement is often debated (see: [4,19,20,21]. Historically, most of the process improvement strategies have evolved within production line based industries like manufacturing. Business Process Re-engineering (BPR) is one such strategy evolved to address the supply demand gap existed within most of production line based industries during early 90's due to the globalisation trend. BPR is an attempt to eliminate chronic wastes within processes in practice, by introducing new processes. The focus here resides within the ultimate outcomes of the processes in place rather than on the processes it self. Thus the existing processes attract minimum attention when designing new processes and a whole new set of processes could be the ultimate result. Due to these radical changes to processes, often this approach claims to produce significant level of improvements. Despite being a fashionable theme within some of the industries, BPR has received number of criticisms as a construction process improvement strategy (see: [4,19,20]). Considering the applicability of this approach, Love and Li [4] pointed out that the implementation of the BPR within construction is difficult due to the fact that the array of construction have not been designed systematically but have evolved in an ad-hoc manner. Further, direct applications of BPR in construction might lead to complications, due to the fact that the construction often consists of complex supply chain arrangements. Due to these complex relationships, there is a danger that the re-engineering exercises might impose negative effects on construction organisational processes, which would not be apparent for some time after implementation [22]. In addition, since BPR pay less attention to the "human side" of an organisation [23], it may adversely effect the construction organisations as it is perceived as labour intensive.

Another process improvement strategy visible largely within manufacturing and automobile industries is the Continuous Improvement (CI). This is an evolutionary approach, based on the statistical process controlling. This strategy has its roots in the Japanese "Kaizen" approach to quality control, and to the Total Quality Management (TQM). It concentrates on planning and monitoring existing processes with the aim of continuously improving the same. The main problem of this approach, when applied to construction, is based on the project based nature of construction. Unlike in a production line environment, it is difficult to identify a linier relationship between processes in place within a project based environment. This limits the possibility of setting targets for processes in place and hard to monitor the performance of the same. On the other hand, this approach is largely depending upon repetitive nature of the processes visible within the production line environments. Thus, the "unique" nature of the construction product questions the applicability of this approach within a construction environment.

However, the above problems do not eliminate the possibility of using the principles of above process improvement approaches within a construction environment. As Lillrank [24] pointed out, the innovations in one industry do not provide direct solutions to the problems of other industries. Rather those innovations have to be recreated within the receiving industry considering the capabilities and the characteristics of the same.

Considering the apparent problems above, some studies have suggested that, irrespective of the approach to process improvement, construction organisations need to embark on adopting quality management principles if the desired improvement to be achieved [4]. Within this context, it is suggested that an underlying process improvement culture has to be established before embarking on process improvement initiatives [4,8]. The major emphasis here is to prepare the organisation to receive the process improvement initiatives by increasing the capability of the organisation in question. Considering the different maturity levels of different construction organisations, a stepwise approach to process improvement is suggested by some recent studies [9].

Being a project based industry and showing some similarities to the construction, software industry has exemplifies a successful process improvement initiative based on the principles above mentioned. This approach has gained its popularity under the name "The Software Capability Maturity Model (CMM)". This model was developed for the US department of Defence (DoD) who is a major software purchaser [25]. The use of CMM includes the evaluation of software manufacturing organisations prior to award them contracts. CMM is based on a five levelled structure. Within this, organisations are ranged from level 1 to level 5 based on their maturity. Within this framework, a maturity level has been defined as "a well defined evolutionary plateau towards achieving mature processes. Each maturity level provides a layer in the foundation for continuous process improvement" [26]. Level 1 organisations are the least matured organisations where as level 5 organisations being the most matured organisations. In order to achieve a specified maturity level, organisations must satisfy all the key processes defined within the immediate below maturity level. The organisations are tested against "key enablers" to determine weather they have satisfied each key process. Through this framework, organisations are guided to adopt stepwise process improvements. This framework ensures that the organisation in question is ready for the next level of process improvement. This, intern initialise a process improvement culture within the organisation and guides the procedures and the people towards improvements, using the available and potential tools.

Sarshar et al [25] have attempted to apply the principles of this model within the construction industry. This attempt was named as the Structured Process Improvement in Construction Enterprises (SPICE). This research was carried out in stages, and currently, the dynamics up to the level 3 of the CMM were explored and customised to the UK construction industry (See: [9,25] for further details about this approach). While lower maturity levels of CMM establish the required capability and the background of the organisation, the higher maturity levels are responsible for dramatic and sustainable process improvements. Within the SPICE, the dynamics of higher maturity levels were not explored thoroughly, leaving its full potential unexplored.

The above exemplifies that possible solutions for some of the problems identified within the construction process improvement, have already been explored within other industries. A careful consideration of the characteristic differences and unique requirements of the industries in question should then provide a mechanism for sharing knowledge between industries.

Apart from the process control mechanisms explained above, the information technology (IT) has been identified as the major enabler of the process improvement [10]. However, the construction industry has been criticised for its slow IT adoptability [27]. Further more; the industry has become frustrated with the falling of IT as many companies have invested in the wrong technologies without addressing the business needs [28]. The following section discusses the stand of the role of IT as an enabler for the construction process improvement.

3. Process Improvement and Information Technology

3.1 IT for Process Improvement

While process improvement is not purely a technological endeavour, Information Technology has been identified as a key process improvement enabler [10,11,29]. Within this context, new advancements of IT triggers new operational and management processes within organisations, creating a technology push for process improvements. On the other hand, the process improvement initiatives create an opportunity to change existing processes to be benefited from existing information technologies in place, creating a process pull for technological advances. This reveals a concept of duality between the process improvement and use of information technology [30].

The slow IT adoptability does not mean that the construction industry lags in implementing IT systems; rather, it suggests that the construction industry lags the other industries in impact of IT to the business [31]. Even though the issue has been identified as lack of awareness of how to exploit technology, a careful consideration of the "lack of awareness" relates the problem to the roots of "processes", as often immature management processes are responsible for internal and external communication gaps. In other words this suggests that, proper processes have to be in place in order to harness the actual benefits of the IT capabilities within construction organisations.

On the other hand, it could be argued that information technology has created a significant impact on some of the work patterns and processes of organisations irrespective of their industries. As an example, it is difficult to identify a an organisation today, which uses any report producing, letter writing mechanisms or tools other than personal computer based word processing solutions even within the construction industry. Further, emails have become a powerful and commonly used communication media commercially and individually. A survey conducted by Construction Industry Computing Association [32] based on over 400 construction organisations revealed that 97% of the construction organisations have access to email. Further, computer aided drafting tools such as AutoCAD have shown influential impacts during the recent past, and traditional drawing boards are becoming redundant rapidly. Above exemplifies the fact that, irrespective of processes in place, IT has influenced organisations to change their work patters and processes. This further stresses the existence of the concept of duality within the construction industry as described above.

4. IT as a Change Agent

The concept of duality discussed above, creates a clear link between the organisational processes in place and the IT adoptability. This suggests that IT adoptability in a particular industry or an organisation, especially with the intention of improving its performance, should not depend entirely on the capabilities of the technology in question. Rather, the organisation and industry specific characteristics and processes in place will have to be investigated prior adopting such technologies. The next section discusses some evidence from literature highlighting IT usage patters of construction and adoptability problems visible within other industries especially related to processes in place.

4.1 IT Usage Patterns in Construction and Adoptability Problems

In order to understand the IT adoptability problems within construction, it is vital to identify the IT usage patterns within the construction industry and at the same time it is important to identify the drivers behind these usage patterns. A study carried out by Construction Industry Computing Association (CICA) gives an insight to the IT usage patterns and drivers behind the IT usage in UK based construction companies. 73 construction related companies were surveyed and one of the objectives of the study was to identify the drivers of the investments in IT [33]. It is visible from the survey results that the IT investments in construction is generally driven by short term tangible benefits rather than long term strategic benefits. For an example, the survey results reveal that general client expectations / requirements attracted 68.5% response rate as a driver for IT investments where as only 17.8% have indicated strategic board level decisions as a driver for IT investments in construction. On the other hand it is visible from the same survey that an imbalance between the technology-push and process-pull is visible within the industry. For an example, 60.2% and 40.0% of the respondents have indicated that affordability of technology and exploration of new technologies respectively as a drivers for IT investments where as only 32.8% respondents have identified process improvement as a driver for IT investments. The statistics show that construction lacks the strategic usage of IT. It also reveals that IT usage within construction is largely technology push driven.

Few facts can be highlighted as reasons for this. Most importantly, there is a clear communication gap and a conflict of interests between the IT implementations and decision makers. This gap is widened due to the absence of dedicated IT specific functions (roles) within most of the current construction processes. This leads to another reason for the visible gap between actual IT potential and its usage, a lack of formal approach to incorporate IT within organisation’s development plans. It is also visible that the current usage of IT within most of the construction organisations are based on short term objectives such as gaining speed, minimising human errors, etc. And in many cases, little consideration has been given to understand the function of the system in relation to the business [34]. Thus the short term, tangible benefits of IT, has become the driving force of IT adopting policy, while hindering the possibilities of tailoring IT to support actual system and process improvement requirements. Hence, it is also visible that current IT usage within the construction industry is more functional oriented.

This leads to the problem of IT stagnation within the construction industry, as the use of IT is not being looked at from an organisational wide angle rather from an individual, functions based angle. This has witnessed by some of the existing IT usages. Software based project planning tools are widely being used within the construction industry. But the fact that, it is being used in an uncoordinated manner has hindered the possibilities of using those to the maximum potential. For an example, most of the modern project management software (e.g. MS Project) are capable of analysing financial capabilities and requirements (e.g. cash flows forecasts) of organisations in addition to the obvious scheduling capabilities. But at point of usage, most of these functions are neglected due to the functionally oriented work patterns. This complies a classical example of the need for an industry wide, process based approach to IT implementation strategies within the construction industry.

The above situation drives the construction industry to a dilemma, in terms of the process improvements and the use of IT. It is important to have matured processes that support IT integration to enhance the maximum benefits from IT capabilities, and at the same time, new IT capabilities lay solid foundations for successful process improvements [30]. This is not a construction specific problem; rather it is visible within some of the IT adoption initiatives of other industries. The following case highlights a similar scenario within the healthcare sector.

4.2 An Example from the Healthcare Sector

A number of information technologies have been adopted in medical practice over the last century [35]. Some of the attempts to adopt various technologies have found ready acceptance (e.g. digital transmission of X-Ray images) while number of others have failed so far to gain acceptance [36]. Videoconferencing has been one of such technologies which have been tried since 1950s in several countries [37]. Bower et al [36] have investigated the adoptability of videoconferencing technologies within the health care sector and have presented some insights to the problem.

A technology push for the use of video conferencing in Scottish healthcare sector was visible due to the rapid fall of equipment prices, improvements in quality of transmission and installation of the basic telecommunication infrastructure. This was further reinforced by the policy pull of the Scottish office since 1998. The Scottish office has advocated proactive adaptation of visual communication technologies in healthcare to share the same basic communication infrastructure with other information and communication technologies in place [38].

Despite the strong encouragement from technology push and policy pull for adopting visual communication technologies in Scottish healthcare sector, [37] have sighted a study of ICTs in Scottish healthcare delivery, which concluded that rejection of innovations and technologies was probable where these have shown significant disruptions to the crucial process of the established practices. It has further been emphasised that the problem was evident in use of videoconferencing where it had the potential to change the clinician / patient relationship and the relationship between the professional groups within the health care delivery context. Moreover, Bower et al [38] highlight that organisations with unstructured and ad-hoc processes have more tendency to reject new technology and innovation.

This example case stresses the fact that the mere balance between technology-push and policy-pull (again technology driven) does not provide the perfect platform for IT adoptability. The strong processes and cultural concerns have a major impact on innovations and technology adoptability within a particular industry. Construction industry can also put within the same context, as it demands strong relationships between various stakeholders as with the clinician / patient, professional groups relationships within the example above discussed. Further, it emphasises that the construction has the potential to take the examples from other industries and as exemplified by this case, there is a need of compiling a balanced and process oriented IT adoptability strategy. Further, this demands the construction to consider this IT adoptability strategy as an integral part of its process improvement strategies.

5. Conclusions

Process improvement has been identified as a mechanism to improvement the performance of the UK construction industry. Despite the various strategies available for process improvement initiatives, the characteristics of the construction product and the industry have created a discussion on direct applicability of those initiatives within a construction environment. Identification of these characteristics enables the construction industry to evaluate other industries experiences within a construction specific framework. Success stories of process improvement within the industries like manufacturing and software then provide a platform within the construction to learn process improvement lessons from other industries.

A close relationship is visible between the information technology and some of the existing process improvement initiatives. Construction industry has shown a slow IT adoptability creating concerns about synergetic benefits between IT and process improvement in construction. Studies related to IT and processes have identified a duality between the IT adoptability and the organisational processes in place, emphasising the importance of considering IT adoptability strategies within process improvement initiatives. Some literature have provided empirical evidence from the industries like healthcare to strengthen this importance specially to justify the significance of considering industry specific characteristics and processes within its IT adoption strategies. Similarities and differences between other industries and construction provide a comparison basis to evaluate the ability of the construction to learn these lessons from other industries with the aim of maximising the synergetic benefits of IT adoptability and process improvement.

Since this discussion has considered the common characteristics of the construction product and the production process, the genaralizability of the above conclusions are straightforward. This means that even though the examples discussed within this paper based on the UK construction industry, the arguments built upon those examples can easily be validated to the construction industry beyond geographical limitations.

ICT in Facilities Management

The Design of Best Practice Framework in Information and Communication Technology Management in Facilities Management: Case Study in Malaysia

Abstract

Information and Communication Technology (ICT) become more important nowadays. The Malaysia government has also define attractive policies to make our economy environment more attractive such as Multimedia Super Corridor which is emphasize the implementation of ICT in various economy sector and also to make ICT as an important agenda. This includes facilities management sector in Malaysia. Therefore, this research will be planned to build a best practice concepts of ICT Management Framework for facilities management in Malaysia. This framework is a strategy and synergistic combination of a number of key components, working in tandem. The framework is best viewed as an interconnected triangle consisting of three key elements, namely, people, infrastructure and applications. The ICT Management framework must identify the importance to innovation of building strong link between ICT and facilities management sector. These will enhance facilities management sector capability to produce and deliver globally competitive product and services, to facilitate growth.

Keywords: Best practice, frameworks, facilities management, information and communication technology

1. Introduction

As the use of computers and telecommunications have changed over time, the portfolios of information systems suitable to an era of inward-focus automation of basic activities are unlikely to be suited to an age which focuses on information to support executive decision making, connect the organization to another organizations in the business environment. According to Konsynski and Tapscott (1992), ICT is a factor in contemporary business environment to growth and as agent to link between two or more organizations with distinct and probably different structures, strategies, business process and organizational cultures. The companies must take part and alert with new ICT system because to enter in globalization business, all the management system must be up date and all staff in the companies should know about ICT very well especially for the management.

All the companies in Malaysia must take action to build their company ICT system and there must have a good ICT framework. Framework is very important because framework is a collaborative community based effort in which these commonly needed data themes are developed, maintained, and integrated by organizations. Companies see the framework as a way to share resources, improve communications, and increase efficiency. Framework is best viewed as an interconnected triangle consisting of three key elements, namely people, infrastructure and applications. Many types of organizations participate in developing and use the framework for their management. Although different organizations have characteristics data use pattern, all organizations need different resolutions of data at different times, particularly when they are working together. The framework represents a nationwide community for data sharing, and provides the benefits for the companies as a guideline to involve in globalization market.

Developing the ICT framework take a long time but, it is very important especially for facilities management in the companies. In Malaysia, facilities management stills a relatively new concept, which makes it difficult to present a definitive description. Facilities management can be described as multifarious because of the diversity of its core component such as technical, financial, administrative and management skill.

The scopes of facilities management will depend mostly on the company of which it is a part. Some companies may consider that the facilities management department should manage all non-core activities. This could therefore include departments such as purchasing, accounts, legal, and travel. Other companies may have their facilities management department incorporated into another support service function, such as finance or personnel. Nowadays, facilities management has become a profession. Quite different from the role taken on by the engineer in the early eighties which was described by Becker "Facilities management resided in the boiler room not the boardroom" (Becker, 1990). Facilities management is important and the companies should take serious with facilities department.

The companies can manage their facilities management very well if they have a good system. For this situation, a framework is important to clearly for organize their company as a guideline and basic step to make any changes their process management to enter in era globalization.

2. Materials

2.1 Information System Planning in the Modern Context

By the mid 1990's, it was arguably reasonably well established that some sort of formalized strategy information system planning was an appropriate undertaking for most organizations. Information system planning is to be closely allied to the organizations business planning activity, the accept wisdom at the time suggesting that ICT should only be attempt once a business strategy have been develop and articulate, and hence understanding reach of direction the organization planning to follow for the next few year, its goal, objectives, core business processes and its changes agenda, for examples. With this business strategy establish and share understanding reach among executives, an information system plan could be develop, determining the information and information system needs to support the business strategy, and thus guiding investment decision into the future.

An interactive and generative process is envisaged, recognizing a general trend of establishing a business strategy, then an information system strategy, and finally information technology, but acknowledging the constraints and pressures in the real world which may act to limit the strategies somewhat. Given the rate of technology change, and the potential and impact that modern ICT could have directly on business strategy, and the outset o this process it is important to be aware of technological advances that may impact or alter the chosen or desire course for an organization (Peppard,1993; Liedtka,1998). The examples for the strategy framework it shows at Figure 1.

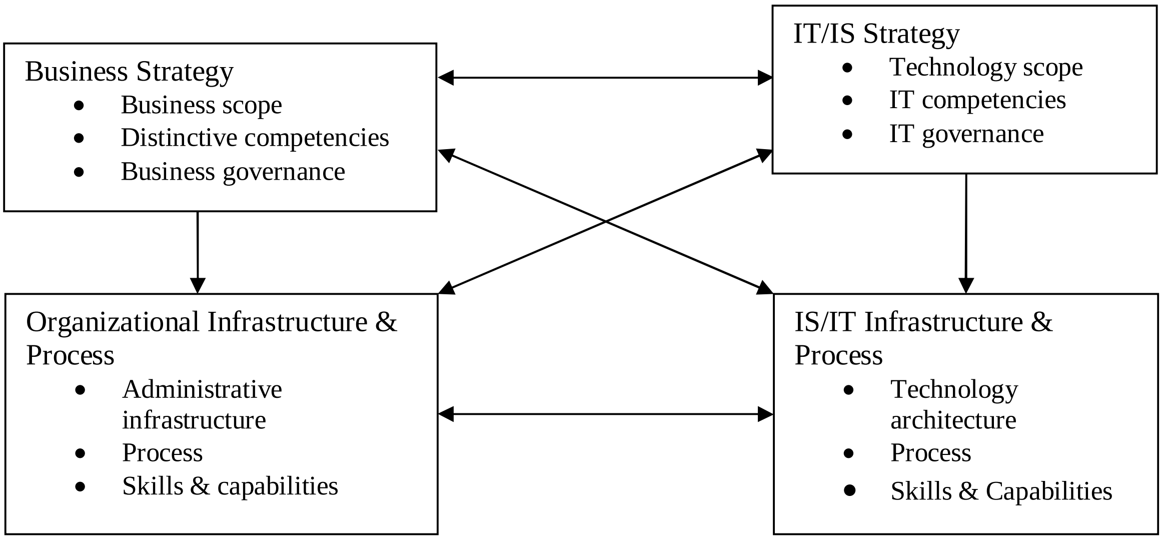

Figure 1: Achieving Strategic Alignment (Adapted from Henderson and Venkatraman, 1994)

3. Rationale for Facilities Management

Most buildings represent substantial investments for organizations and usually have to accommodate and support a range of activities, taking into account competing needs. Within those activities is the organization core business, for which an appropriate environment must be created in buildings that may not have been designed for the purposes on organization might be on its core business, it cannot lose sight of the supporting services-the non-core business. Company may have already considered the distinction between their core business and non-core business (such as cleaning and security) as part of the drive to deliver customer satisfaction and achieve better value for money. Since running costs account for a significant part of annual expenditure, there is bound to be pressure to look for savings in non-core business areas. Cutting operating budgets may be a financial expedient, but may not foster the company's long term development. Since the running of a company involve complex, co-ordinate process and activities, it is necessary to take an integrated view. A piecemeal approach to cutting costs in unlikely to produce the require savings and may impair the company's ability to deliver high-quality services.

Facilities management can therefore be summarized as creating an environment that is conductive to carrying out the company's primary operations, taking an integrate view of the services infrastructure, and using this to deliver customer satisfaction and value for money through support for and enhancement of the core business. Facilities management also can describe as something that will sweat the assets, that is make them highly cost effective, enhance the company's culture and image, enable future change in the use of space, deliver effective and responsive services, and provide competitive advantage to the company's core business. Relationship between core and non-core business in company shows at Figure 2.

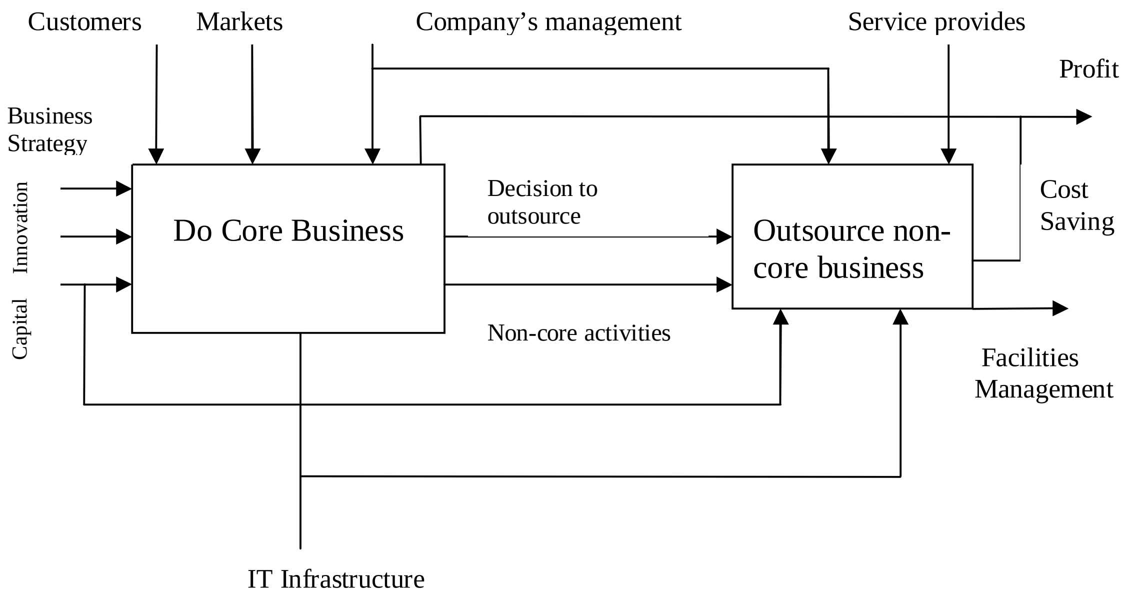

***Figure 2**: Basic relationship between core and non-core business*

Company may not be aware of the extent to which value for money in facilities management can be improved. There are common themes and approaches to facilities management, regardless of the size and location of buildings, although these may not necessarily result in common solutions to problems. In some cases, estate-related and facilities services outsourced (contracted out) and in others retained in house for good reasons in each case. There are also many companies that operate what might be described as a mixed sourced in some measure as well as being retained in house. Whichever course of action has been taken, the primary concern is the basis for the decision. Where the companies approach has been arrived at for entirely proper reasons, such as demonstrating better value for money from one approach as opposed to the other, facilities management is working effectively.

4. The development of ICT in Facilities Management

The use of information technologies without the overarching direction of and information system, more often than not, leads to generation of voluminous, poorly focused and irrelevant information. The creation of excess information in this way is a good reminder of the need to evaluate an information system on the basis of a cost-benefit analysis. The lack of information on products and components in terms of usage and cost can lead to difficulties in focusing the role of Facilities Management and establishing the supply chain within it. Difficulties in monitoring and tracking financial information can also prevent efficient budget control, accurate estimation of work, and contract and purchase management. Good planning in maintenance, operation and refurbishment can be hindered by the availability of life cycle information that is, for instance, crucial in the planning the replacement of components.

Currently, there are no standards that support information exchange and sharing across the building life cycle. Given that there is potential for improvement in business process though the exchange data on the facilities management process, there is a growing need to investigate the issues involve in developing a standard that can benefit this most important part of the business life cycle. This standard could then be use to assist in the development of an information management system to support the exchange of information and the assessment of facility requirements. Such an information system requires a large volume of data. Accurate assessment of a facility's needs requires knowledge of equipment standards from a design and construction information systems, access to accurate maintenance records and repair and replacement costs, access to operation and occupancy information, other operating costs, space management data, operation standards and data from occupational and health and safety information system and from a financial and commercial information system. An integrated information system as shown in Figure 3 could assist facility managers and other project tem members to combine data and information on a facility's life cycle, and base on the integration of cost and commercial data, design and manufacturing and construction data together with facility operation and maintenance data.

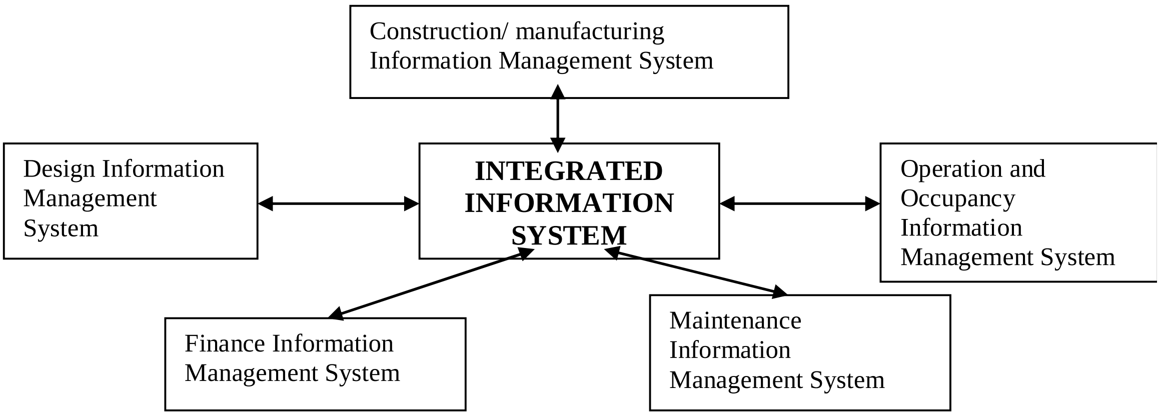

Figure 3: Integrated Information Management System

Technology systems used in FM have developed along a similar timeline to the development of technology in finance and accounting. Figure 4.0 is a diagrammatic interpretation of the fundamental components of an FM technology system. The arrow indicates the communication pathways between the various components of the system. Where each component is physically located is unimportant to the user of the system. There are four aspects that are fundamental to all information technology applications. They are relational databases, networking infrastructure, computer aided processes and data communications technologies. In present FM systems data communications technology is equivalent to Internet technology. Additionally, FM technology tracks advances and applications of technology to management in the manufacturing sector and to changes that have occurred in the management of workplace. Figure 5.0 illustrates the relationship between FM technology and management innovation (Stuart Smith, 2003).

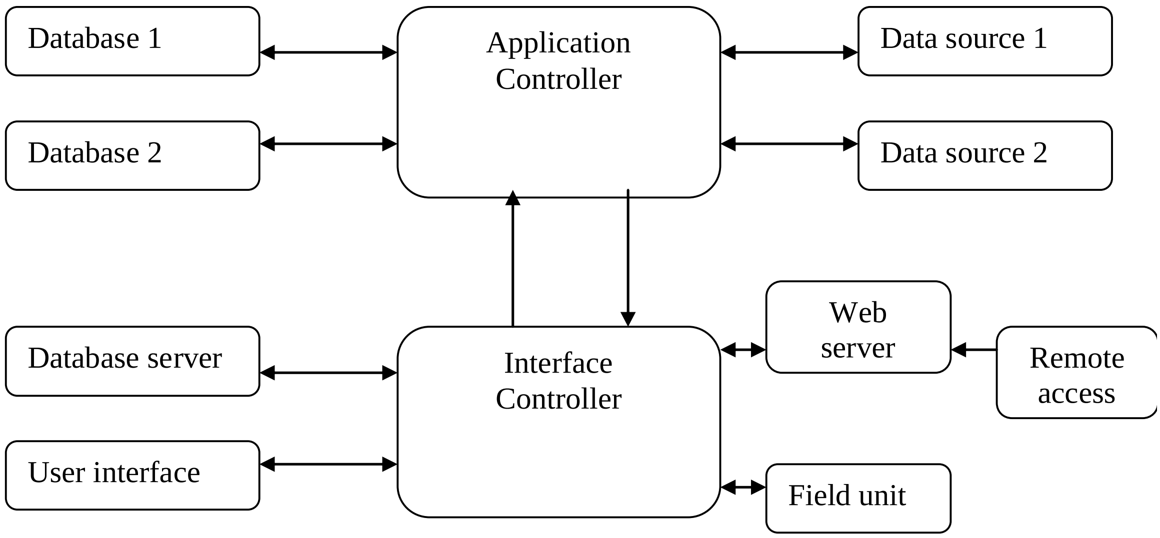

Figure 4.0: Basic components of an FM system

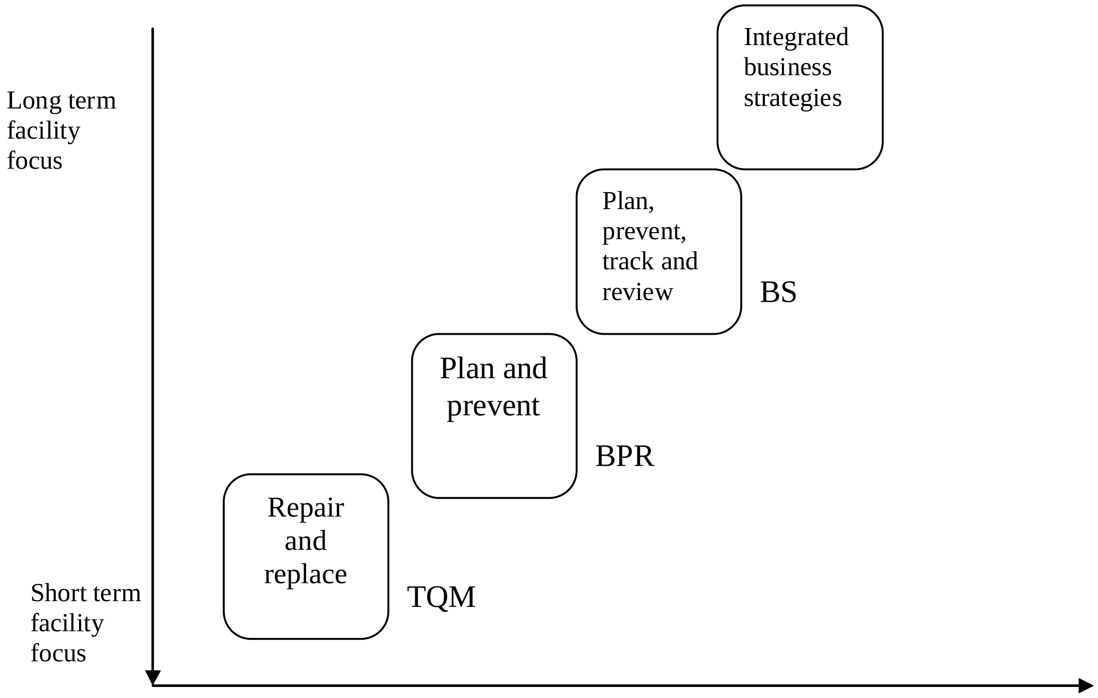

Figure 5.0: Focus and new business technology

5. Conceptual Framework

The overall conceptual framework that forms the basis of this pilot research project is shows at Figure 6.

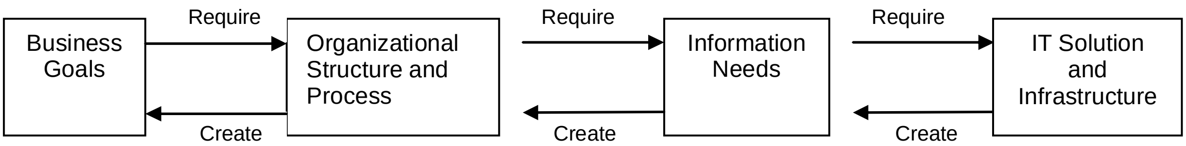

Figure 6 : Sample of Conceptual Framework

This conceptual model hyphenise that information technology acts as both amenable (provides new possibilities for organizations to achieve business goals) as well as a source of innovation (emerging technology provides new possibilities for organizational structure and processes and may generate new business goals)

In addition, this model may influence organizations in at least three different ways:

1. *Strategic positioning*

Information technology may provide a means for organizations to uniquely position themselves in the market place in a manner that would be impossible without the availability of information technology. Examples of strategic positioning are emerging in the form of 'virtual organizations' which provide substantially improved value to customers compared to traditional organizations. Strategic applications of information technology may involve inter-organizational information sharing, such as the use of distributed database.

2. *Work group productivity*

Instead of affecting the entire organization, work group productivity effect subsets of an organization. The use of groupware (e.g., Internet collaborative applications) has the potential to empower and integrate project teams for substantial improvements in project productivity and at the same time reduce the need for middle management.

3. *Process redesign*

Process redesign may affect the productivity of one or more individuals as jobs are reconfigured and processes simplified. Information technology can facilitate the task of process redesign by providing tools that eliminate routine jobs and decentralize decision-making.

6. Conclusions

In Malaysia, the facilities management concept is still relatively new concept. However, Centre of Excellence for Facilities Management, KUiTTHO is struggling to introduce this concept to government of Malaysia. Even tough this still new concepts, due to rapid development in ICT, FM in Malaysia also have to integrated with ICT. Strategies for use the ICT are not universal. Countries face different circumstances, priorities and financial means and should therefore adopt different strategies accordingly. The framework can be help in determining a strategy regardless of what goals have been established, since coordinated action along the five areas identified in the framework is always likely to yield more effective results. However, the evidence and analysis presented suggest that strategy that focuses its ICT interventions towards the achievement to development goals is more likely to achieve marked socioeconomic development. Facility management is essentially workplace management. In essence, it is a manifestation of facility management as the interface that manages changes in people, facilities and technology. They are many opportunities and expansion areas are it in properties, human resources, finance or ICT. Facilities management should have the ability to anticipate as to what organizations will require in future years. In the past, the role of facilities was merely that of service provider, and now, facilities management as business solutions. This paper hopefully can be a guideline for companies to implementing an ICT in their companies as well as facilities management concept especially in Malaysia.

Abstract

Traditional modeling efforts in AEC have generally focused on design descriptions. As a result they do not consider information on how settings perform during use in areas critical to building owners and users. The authors argue that integrating performance data in building models will greatly enhance the end-uses of conceptual modeling efforts in AEC in facility management and design evolution. The authors describe a modeling study that integrates descriptive and evaluative/ performance concepts in existing building models, and illustrate several end-use scenarios to support their assertion.

Keywords: Conceptual model, building performance, post-occupancy evaluation, building procurement.

1. Introduction

The lack of attention on the formal representation of data from building (facility) evaluations represents a missed opportunity in modeling efforts in AEC. Traditional modeling efforts were geared towards the ‘as-designed’ (‘as-designed’ as distinct from ‘as-used’ and ‘as-experienced’) environment to aid facility management. But are as-designed data sufficient? Can data from buildings-in-use potentially enhance end-use of building models? As-designed data pertains to data available up to the final stages of design development and specifications of a building. Such data relates to the properties and performance of the systems and sub-systems, and are based on existing knowledge on building physics and standard performance assessments in a-contextual settings, i.e. not specific to the context (social/ cultural/organizational setting) in which a building is situated. Typically the performance assessments are obtained from accepted building simulation practices that assume a “controlled environment with standard users” as the basis for the simulation.

The importance of context-specific data, from buildings-in-use, is beginning to get reflected in recent literature. For instance, Becker [1] advocates the necessity of data from buildings-in-use in the domain of material durability, and propounds the creation of predictive tools based on such data. Current building models, however, do not reflect the variations in usage pattern across setting types (from hospitals to schools, offices or courthouses) in buildings-in-use. The fact that such buildings-in-use data are becoming widely available brings this issue to an even sharper focus. Post-occupancy evaluations (POEs, or FPEs - Facility Performance Evaluations) are regularly conducted by large organizations with building portfolios. They are used not only in problem identification and modification in built settings, but also in informing portfolio management decisions. From a purely facility management viewpoint, buildings-in-use data could supplement existing data in two significant ways: 1) reduce uncertainties arising from simulations in controlled environments, and 2) reflect variances across setting/ occupancy types, and, thus, improve context specificity.

Performance can also be viewed beyond the performance of systems and sub-systems. Gross [2], for instance, underscores that users' requirements are not well understood at present. He emphasizes the variations that exist in culture, economic capabilities and expectations, and asserts that such human factors have not been accorded due importance in performance assessments, such as productivity in the workplace, health, and well being. POEs happen to address some or all of these issues. Integrating performance (POE) data with other descriptive data, thus, promises to enhance the end-use of building models in facility management, and possibly in design decision-making. POE and other descriptive data currently reside in disjoint representations and formats. This prohibits their integration in and joint use in decision making. The key question addressed in this paper is the need for a proper mechanism to capture rich facility evaluation data and integrate it with other building data in such a way that FM decision making is optimally informed.

2. Integrating Descriptive and POE Data

The investigators started off the study with two main questions: 1) can evaluation/ performance (more specifically, POE) data be meaningfully integrated with other descriptive (as-designed and as-built) data in a shared building model based on a unified conceptual building representation, and 2) if so, in what conceivable way could it expand the end-use of building models?

2.1 The Georgia Tech Study

This paper draws on a Georgia Tech modeling study that integrated as-built data and facility evaluation (POE) data in courtroom settings [3]. The study focused on courtrooms as setting types for several reasons. Courtrooms constitute setting types with a range of complex and conflicting functions, ranging from the instrumental (visual, auditory, and access) to more intangible symbolic functions (portraying the openness of the judiciary and authority of the State). Secondly, courtrooms are physically self-contained spaces, thus rendering the modeling effort relatively simple. Finally, the investigators had access to courtrooms and courtroom users (judges, deputies, reporters, attorneys, security staff, etc), courtesy of the CourtsWeb project at Georgia Tech.

2.2 Methodology

POE and descriptive data from 26 courtrooms in 16 courthouses were used in the model. The data included 43 descriptive and technical performance measures (lighting, thermal, acoustical, physical/ spatial configuration, etc.), 27 evaluation measures (users' evaluation of the supportiveness of their work setting for instrumental and symbolic functions), and, finally, six personal/ cultural measures (users' role, age, gender, etc.). A conceptual model integrating the different types of data was developed using EXPRESS-G [4]. The presented schemas of the model, for the purpose of this study, should be viewed as an aspect model [4] that would go through an integration cycle to be finally integrated with a comprehensive and complete building model such as the IAI-IFC [5]. Schemas of the aspect model were translated into database schemas and were instantiated with the data collected in the POE studies. A range of queries was implemented to assess its meaningfulness in supporting various end-use scenarios. Important modeling aspects such as extensibility, IFC integration, and others were not considered at this stage of the research as the emphasis was on the feasibility and adequateness of the proposed semantic integration of POE and other descriptive building data.

3. The Data Model

The primary focus of the modeling effort was in integrating data pertaining to the physical envelope, functions of settings defined by the envelope, evaluation/ performance data of such settings in use, and finally the attributes of the users using the built settings (figure 1 articulates the fundamental direction of this inquiry).

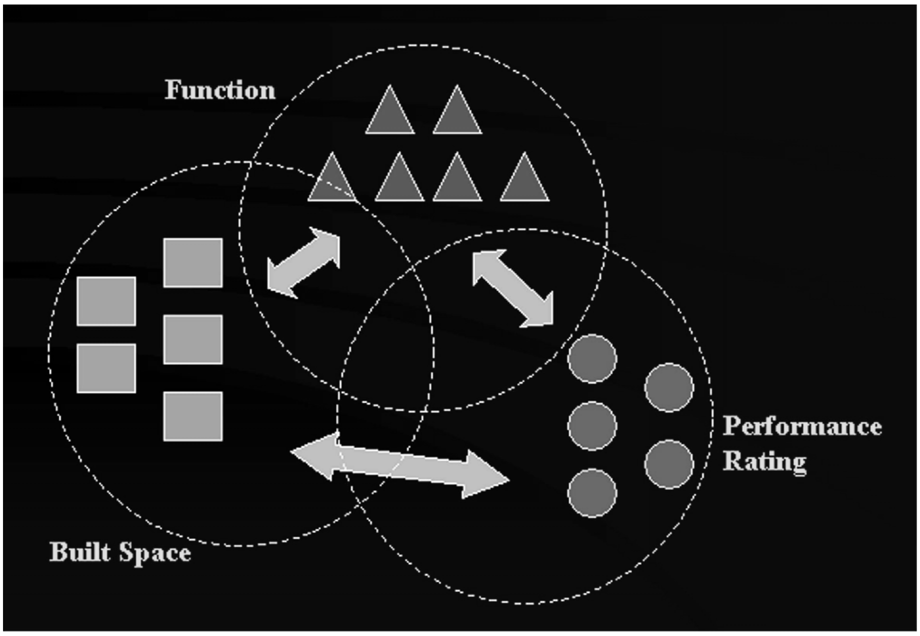

Figure 1: The key modeling concept involved the integration of as-built data with data pertaining to functions and performance.

Figure 2 shows a stripped-down model with entities alone (without the attributes) to provide a birds eye view of the relationship structure. The central concept of the model is 'space' The model can be viewed as four chunks of data, linked through the entity 'space': 1) identifiers that hold data that would enable identification of a particular site, project, building, and floor, 2) the enclosure system, 3) various functional areas within an enclosure system, and finally 4) evaluation data from POE studies.

Owing to paucity of space detailed schemas on the first two data chunks are not included in this paper, which are conceptually similar to the corresponding parts of the IAI-IFC. Data on site, building and floor are essentially used as higher-level identifiers and classifiers, such as city, state, jurisdiction, and building type. Schemas on the enclosure system are designed to hold as-built and as-designed data on elements that physically define (enclose) the courtrooms. Such elements include the walls, floor, ceiling, and the services support systems. The remaining model is described below.

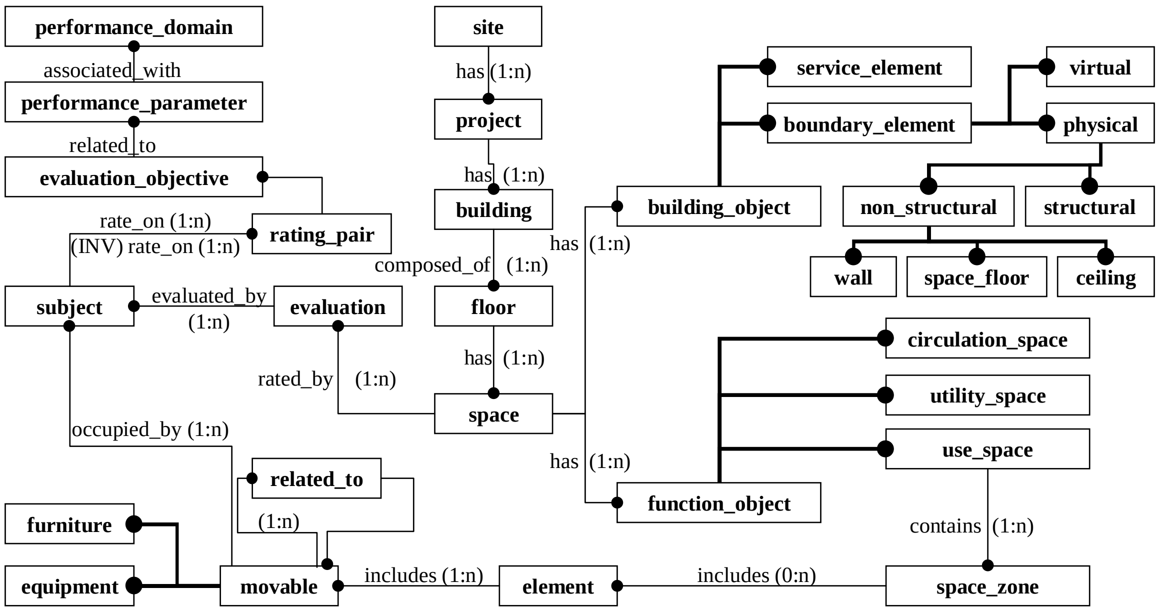

Figure 2: The model (without the attributes) showing the basic relationship structure.

3.1 Functional Entities

Functional entities hold data on spatial functions and sub-functions physically enclosed by the enclosure systems. The schema captures the major (higher level) functions, various sub-functions or functional zones that organizationally cluster together to define a functional unit, key elements within the functional zones, and movables (furniture and equipments) within the key elements. Relationships of interest between each pair of movables are included, such as the distance between elements or the level difference. At the highest level, each function type is described as a *function_object*. For simplicity sake, the *function_object* types have been defined as *use_space*, *circulation_space*, and *utility_space* (figure 3), while it is appreciated that various combinations of these function types are also possible. Each use space is identified by a *use_category* and a *use_type*. Use category refers to the primary function of the use space, such as ‘courtroom’. Use type provides further information by stating the particular subtype of the primary function, as in ‘magistrate judge’ (courtroom). Each use space could be host to one or more space zones (*space_zone*). These are more specialized functions conducted within a larger functional unit, for instance, courtroom “well” (the part of the courtroom where all trial

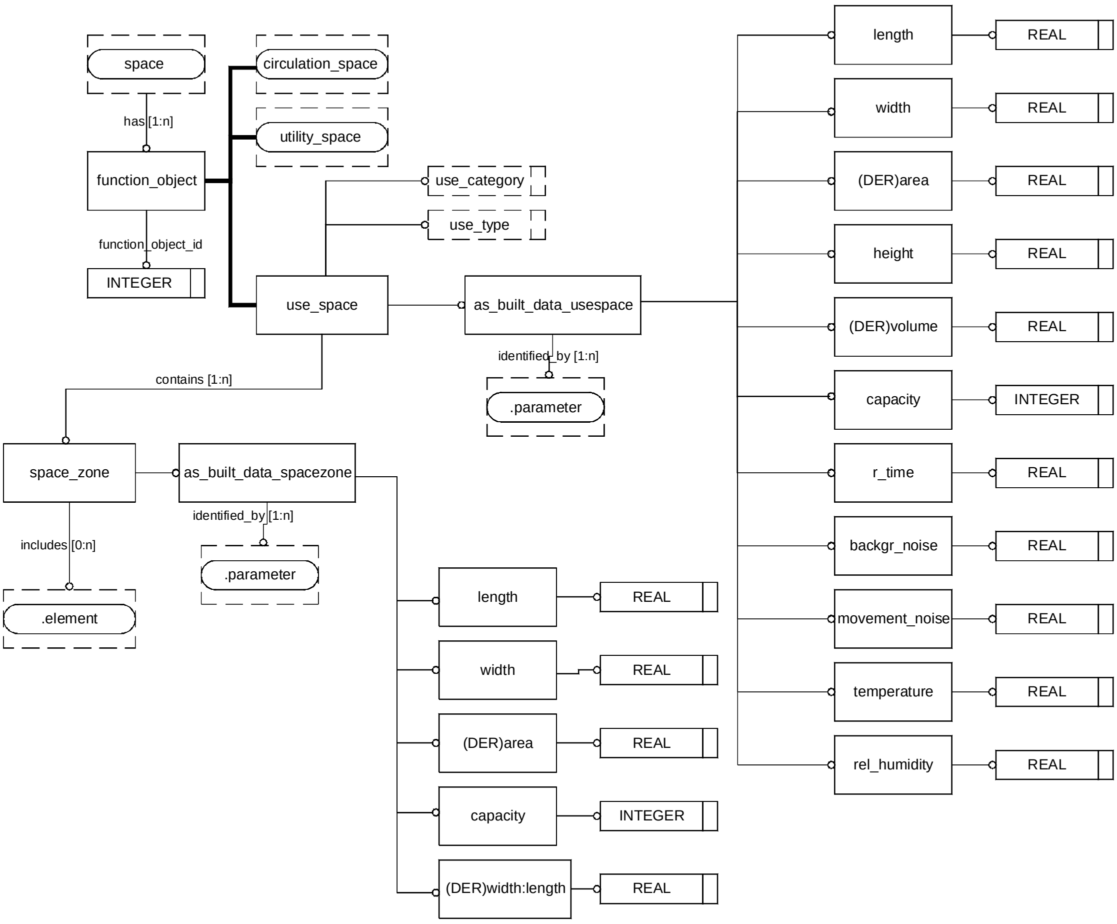

Figure 3: Use space and space zone as function entities.

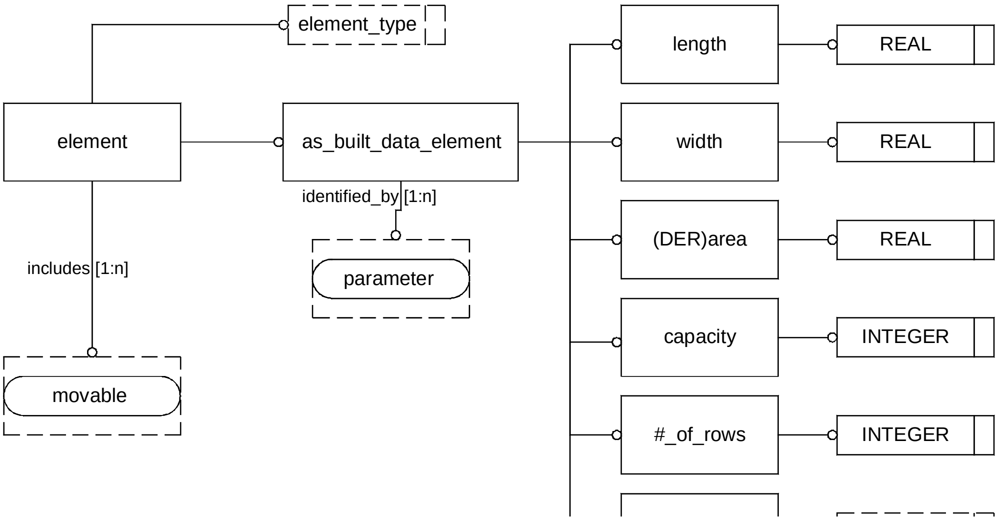
Within each space zone there can be none or more elements (element). Elements are base-level specialized functional units where very specific functions are performed. In a courtroom well, the elements include the bench, the reporter station, the deputy/clerk’s station, the security personnel station, the attorney area, the jury box, and the witness stand. Similarly, courtroom galleries have spectator seats. Figure 4 illustrates the element schema.



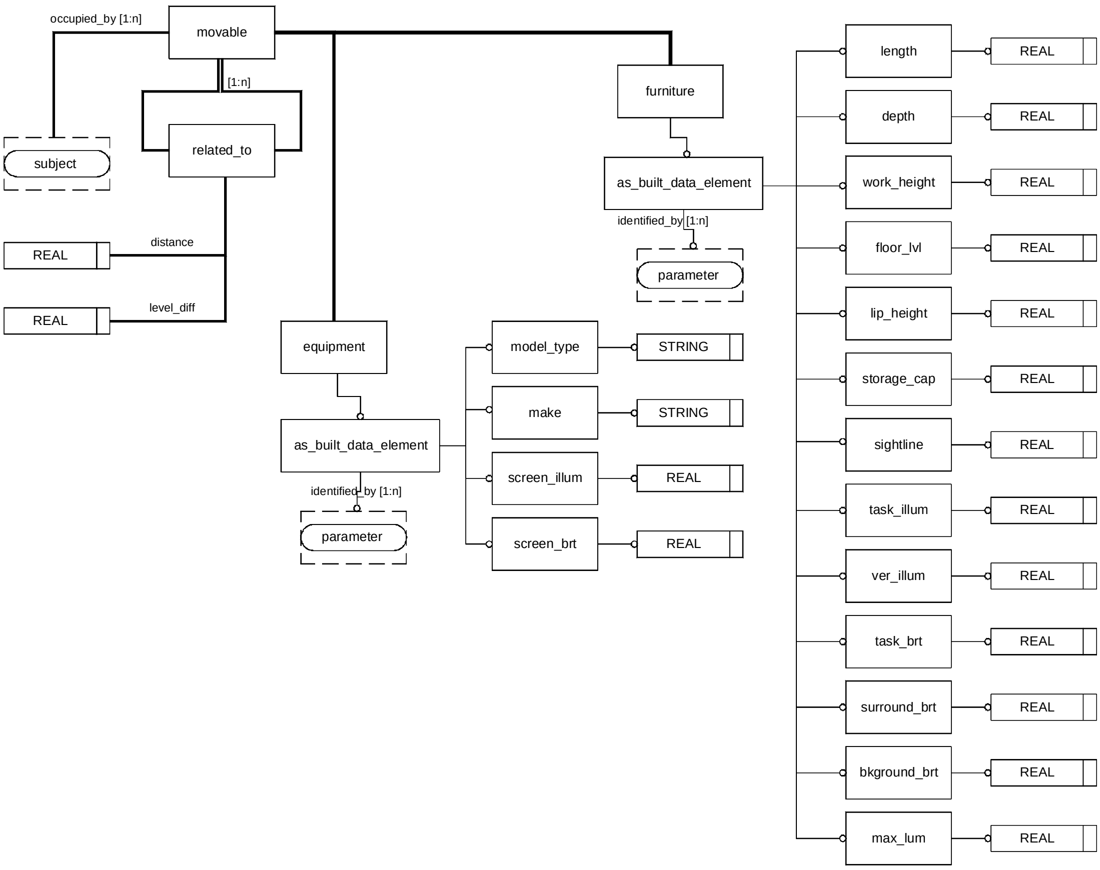


Figure 5: The movable schema.

Each element in a space zone includes one or more movables (*movable*). For instance, the reporter's station typically has only one piece of furniture (movable) where as a jury box can have as many as 21 or more piece of furniture. Movables are essentially *furniture* and *equipment* associated with a particular element, with base-level specialized functions (figure 5). Relationships between movables are some key areas of interest. For instance, the *distance* between each pair of movable in a courtroom well (witness to judge, for instance) influences the clarity of observing witness testimony. Similarly, the level difference (*level_diff*) between each pair of movable in a courtroom influences the lines of sight as well as the symbolic rendition of the courtroom.

3.2 User and POE data

The remainder of the model pertains to performance/ evaluation data. Data on performance issues/ dimensions and users constitute the main focus of these schemas. Evaluation of settings could be conducted on several issues or performance dimensions (this model is limited to issues specific to courtrooms, but expansion to other issues is straightforward). A classification structure for the issues, based on literature, is created to ensure better comprehensiveness of the data structure. Figure 6 shows the schema on user and performance/ evaluation data.

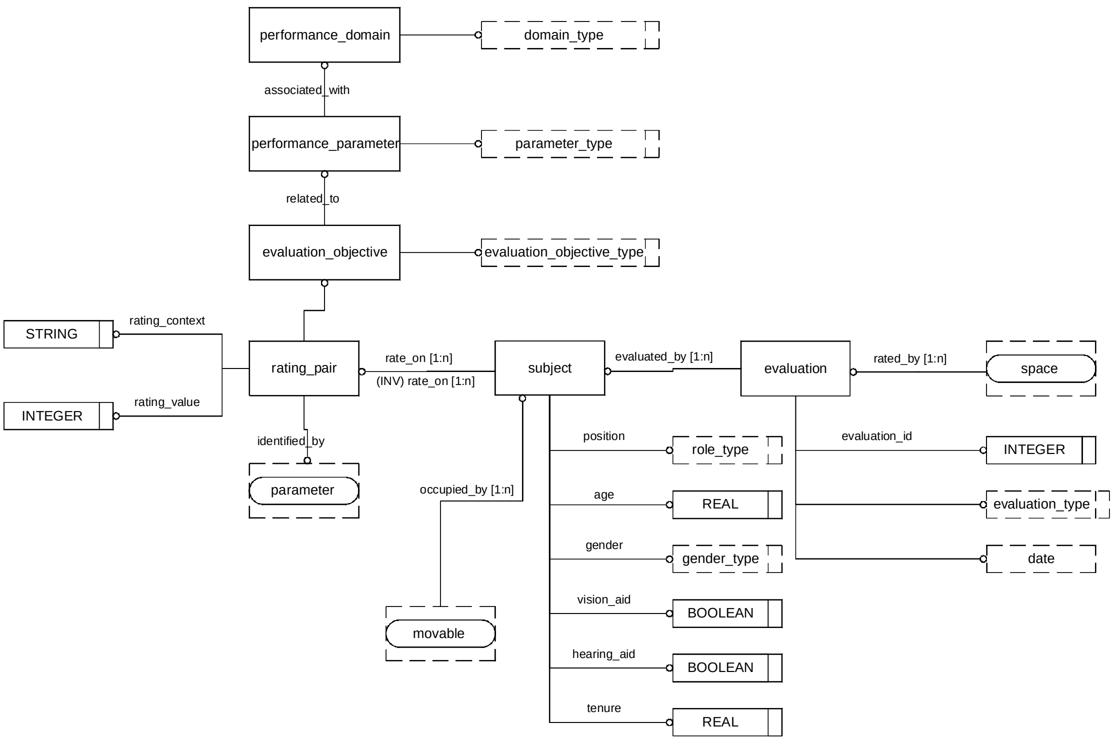

Figure 6: Schema representing data related to user and POE.

One or more users (a more generic term *subject* is used in the model) occupy each movable. The type of POE considered in this study is one where users of buildings-in-use evaluate their setting on an assigned scale. As a result, each instance of evaluation data is associated with a specific user who, in turn, is associated with a particular movable in an as-built setting. Further, POEs target one or more spaces in a facility, and each space is rated by one or more evaluation studies (*evaluation*). Each evaluation has an associated *date*, and an *evaluation_type* (POE, in this study). Typical POE studies collect various kinds of demographic data from the participants/subjects. In this study six types of data were collected. User *role_type* pertains to their position in the organization, for instance judge, reporter, and deputy/clerk. The data types *age* and *gender_type* are self explanatory. User *tenure* relates to the number of years the user has worked in the current position, which bears psychological connotations on evaluation data. Data on *vision_aid* and *hearing_aid* are yes/no Boolean data types that provide information on whether the user relies on the aid of hearing or visual devices for performing standard tasks in the courtroom. Evaluation data are captured in the element *rating_pair* where *rating_context* describes the context of evaluation (or the specific thing being evaluated) and *rating_value* is the actual numeric rating.

Rating pairs are classified based on knowledge from existing literature - the entities *evaluation_objective*, *performance_parameter*, and *performance_domain* provide the framework for classification. Gifford [6], for instance, lists performance, feelings, and stress as some key objective (outcome) areas in studies on office settings. Many POEs include user preference and productivity as study objectives. The objective associated with a rating pair determines the evaluation objective of that particular rating pair. Further sub-classification of evaluation data into parameters and domains is also supported by literature. For instance, Gifford [6] contends, “the work environment can be considered not only as a collection of physical stimuli (noise, light, temperature, etc.), but also as a physical structure (size, furniture, hallways, etc) and as a symbolic artifact” (p.340). The segregation of data into environmental (‘physical stimuli’) and physical (‘physical structure’) provides a meaningful classification structure that corresponds well with established classification structure in literature.

4. Outcomes

A database was generated according to the schemas of the previous section and filled with data from courtroom and POEs conducted in those courtrooms. The database was used to assess if and how the integrated information augments/ informs decision making in facility management and design decision-making. It is expected that the addition of evaluation/ performance data opens up potential end-use opportunities in at least four different areas: 1) monitor facilities, 2) identify best practices, 3) manage building portfolios, and 4) inform design evolution.

4.1 Monitor Facilities

As asserted earlier, in the absence of performance data one could predict performance of building systems based on standard simulations in a-contextual settings. Integration of evaluation data from buildings-in-use adds specificity to monitoring everyday performance. Moreover, facilities could be monitored in their supportiveness to the functions performed in the built settings, in addition to the performance of systems and sub-systems. In courtrooms, for instance, regular organizational POEs could inform courthouse building managers about how well the courtrooms support the major tasks/ functions conducted within it, which may change over time owing to physical and/or personal/ cultural/ organizational factors. A specific example will help illustrate this end-use scenario. Consider, for instance, a simple example of reading task in courtrooms (reading from legal documents, exhibits, etc.). Existing literature takes into account various factors to predict lighting conditions for certain reading tasks. Such predictions are generic, and applicable across setting types. The POE data augments such information is in two ways. First, it provides evaluation data from actual settings-in-use, and is specific to a context type (in this example, courtrooms). Second, it brings into consideration other personal and cultural factors that are not considered in lighting models. Thus, the data extracted pertains to specific areas in a building, dealing with a specific set of users, with known user characteristics (collected through POEs). Such specificity of information supplements the generalized prediction models in lighting. A more compelling factor is one of human psychology. Referred to as the 'halo effect' in psychological literature, users of built settings tend to consider newer settings more supportive irrespective of actual performance of settings. Such factors are reflected in POE data. The contextualized, specific, evaluation data would enable facility managers to monitor facilities in a more efficient way. Table 1 shows an example where the users' ratings of the supportiveness of the courtroom (on a scale ranging from 1 = very unsupportive to 7 = very supportive) for reading task, along with lighting data, are extracted from the database. In a similar manner, other important functional aspects of built settings could be monitored on a regular basis to identify areas that need improvement.

Table1: Query result showing users' evaluation of the supportiveness of the courtroom for reading task, in Clarke County Courthouse, and data on a sample set of lighting parameters.

building_name	work_plane_illuminance	vertical_illuminance	task_brightness	surround_brightness	background_brightness	user_role	rating_context_type	rating
Clarke County	155.3	94.1	482.4	79.17	165.1	judge	reading task	7
Clarke County	64.8	25.1	191.6	79.17	80.91	deputy	reading task	7
Clarke County	64.8	25.1	191.6	79.17	80.91	deputy	reading task	6
Clarke County	76.4	22.2	236.1	79.17	84.01	reporter	reading task	7
Clarke County	84.9	33	241.7	12.96	75.38	attorney	reading task	7
Clarke County	84.9	33	241.7	12.96	75.38	attorney	reading task	7

4.2 Identify Best Practices

While monitoring settings for improving context-specific performance, facility management could gain from knowledge on best practices in similar settings. Such information could enable the facility managers to arrive at improvement options that predict most favorable outcomes. Consider for instance, in case of a certain courtroom, a facility manager finds low evaluation rating from courtroom users, in the setting's supportiveness to reading tasks (same example as above). Querying the database enables extraction of data that shows the values of environmental parameters that could predict favorable evaluation. For instance, an end-user might wish to focus exclusively on best practices in illuminance for reading tasks (performance rating > 5) in Superior Courts Courtrooms. The outcome (figure 7) shows the proportion of users within each interval of illuminance level, across all courtrooms, that have rated a particular illuminance level above 5 for reading task support. It looks plausible from the chart that the best possibilities of favorable evaluation are associated with illuminance between 30 and 65 FTC. Since these evaluations are not immune to personal and organizational factors, they could vary from lighting guidelines and could vary across setting (building) type. The context-specificity of the information generated promises supplemental information support over traditional information available to stakeholders in facility management. Further, similar routines could be used to assess other environmental parameters in built settings.

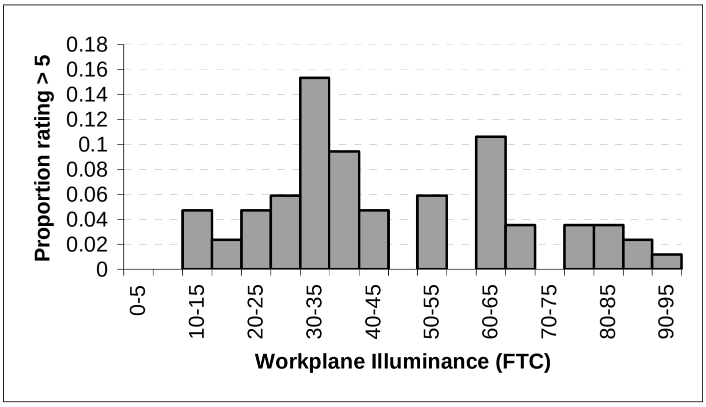

Figure 7: Chart generated from query showing the percentage of users rating their environment greater than 5 for reading tasks, within each interval of illuminance level.

4.3 Manage Building Portfolio

Regular POEs conducted in large organizations with building portfolios (such as US GSA, US Courts, USPS, etc.), that would enable the scenarios discussed in 4.1 and 4.2, would also aid in managing building portfolios. Since the evaluation data obtained in the example cited in this paper pertains to the functions carried out in a setting, longitudinal assessment of the data would provide visual as well as numerical feedback on the extent to which different facilities are supporting the functions they are designed for. The fact that the evaluation data captures psychological factors, such as the halo effect, contributes more utility to the feedback, since reduction in perceived supportiveness of settings to the functions conducted (irrespective of actual performance of settings) could contribute negatively to organizational objectives. Data on actual technical performance, as well as assessment of supportiveness by users, together, in longitudinal assessments, would provide information not only on the projected performance of systems but also on when users of settings could be expected to perceive their environment as unsupportive.

4.4 Inform Design Evolution

Many of the features described above bear potential to inform design evolution phases of facility procurement. Existing literature on the design process by Zeisel [7], Lang [8], and Kalay [9] articulates at least five end-use scenarios where the integration effort could inform decision-making: 1) case exploration, 2) precedence analysis, 3) identifying best and worst cases, 4) rating design decisions, and 5) predicting performance. The same features that aid in monitoring facilities support case exploration and precedence analyses. Similarly, identifying best practices is not only informative for facility management but also to design decision-making (owing to paucity of space only a few scenarios are described here; more scenarios and details are included in Pati 2004).

5. Conclusions

While the possible scenarios of end-uses could be many, the few illustrated above exemplifies how integrating evaluation/ performance data with traditional building models could provide (augment) meaningful services in facility/ portfolio management, and expand the utility of the modeling efforts to end-uses in design evolution. This begins to address needs expressed not only in the domain of building engineering, but also in the field of Environ-Behavior studies, where interfacing building research with design practice constitutes one of the primary objectives.

Although this study focused on just courtrooms as built settings, it can be asserted that the direction of inquiry could also fit other setting types. For instance, it could be argued that issues and classification structure developed in this model also hold true in (or can be expanded to include) office settings. Privacy, stress and many other issues seem to be common to offices and courtrooms. Similarly, relationships between movables (distance, elevation, angular dimension) are probably also important in office settings. Literature survey conducted for this study suggests that offices, schools and courtrooms share many of the issues included in this study. The definition of the elements and attributes in this model reflects possible generality to offices and schools, although expandability of the model to other setting types remains a question for further academic inquiry. Despite the limitations, the outcomes of this study suggest a robust and potent direction of inquiry for modeling efforts in AEC, leading to extensions of comprehensive building models such as the IAI-IFC.

Development and Implementation of an Open Source Software FM-System

Sigurd Nes
Bergen Bolig og Byfornyelse KF (email: Sigurd.Nes@bergen.kommune.no)

Abstract

Bergen Bolig og Byfornyelse KF (BBB) – a public housing company comprising 5000 dwellings – has been looking into the possibility to utilize some of the vast pool of open source software for maximal flexibility and minimized costs of tailoring a fm-system to its needs. This work has been undertaken as part of a phd thesis at the Norwegian University of Science and Technology by the same author as this paper.

The objective of this work has been to reduce license costs of software, improve the flexibility of software development, improve the information flow, to improve the quality of data (centralized documentation and history), to lower the general threshold for implementing a fm-system and to reduce manual handling of invoices through utilizing principle of e-commerce by the use and development / adaptation of open source software.

Keywords: Open source software, FM-system, web, php, e-commerce

1. Open source software

Open Source Software is not only about free software – but an important concept within decentralized software development founded on knowledge, idealism, interest, anti authoritarian rebellions and the communication power of the internet.

"It gives customers control over the technology they use instead of enabling the vendors to control their customers through restricting access to the code behind the technologies." [1]

Free Software Foundation (FSF) was founded in 1985 by Richard Stallman – and is dedicated to encouraging users to use, study, copy, modify and redistribute software.

The definition of free software is defined by [2]:

- The freedom to run the program, for any purpose.
- The freedom to study how the program works, and adapt it to your needs. Access to the source code is a precondition for this.
- The freedom to redistribute copies so you can help your neighbor.

- The freedom to improve the program, and release your improvements to the public, so that the whole community benefits. Access to the source code is a precondition for this.

1.1 A Hacker's Motivation / Ideology

Two degrees of variation [3] seems to describe the motivation and ideology for a typical hacker:

1. Zealotry; enthusiasm regarding open source software in itself.

2. Hostility to commercial software.

The most visible and best organized part of the hacker culture – represented by FSF - has been both very enthusiastic and very anti commercial. After the Linux explosion of early 1993-1994 the culture has moved towards the pragmatic end.

In addition to the ideology there are motivations like "ego-boosting" (status in the hacker culture) and that it is fun and intellectually stimulating to participate.

2. The Software Project

The project started out as an attempt to simplify the maintenance management provided by a commercial fm-system – which at the time seemed to be a very complex – and to some extent – rigid environment. One other motivation was the high costs related to customizing – and the fact that all customization was depended on the vendor.

In the search for an appropriate platform - an Open Source project came to attention that had some interesting capabilities which could serve as a base for development.

Since this project provided a high level free entrance to an appropriate system – it is also fair that the work based on this project should be free.

2.1 PhpGroupWare

phpGroupWare - is a multi-user groupware suite written in PHP that provides about 50 web-based applications, as there are the Calendar, Addressbook, an advanced Projects manager, Todo List, Notes, Email, Newsgroup- and Headlines Reader, a Filemanager and many more Applications.

The system supports user preferences, themes, user permissions, multi-language support and user groups. It includes modules to setup and administrate the working environment. The groupware suite is based on an advanced Application Programming Interface (API).

There are currently about 25 active developers/contributors.

The project is hosted at savanna.gnu.org which is a central point for development, distribution and maintenance of GNU Software.

2.2 Property – A FM System

Property is the name of the FM-module of phpgroupware. It started out as a rewrite of the project module – where the most significant change was the change in perspective from vendor to buyer – and the introduction of a location hierarchy. Later on it has evolved as a fullblown maintenance / project management system with e-commerce and documentation capabilities.

2.2.1 Model - Context

To place this software in its right context – it is useful to locate a spot for it in an information system model.

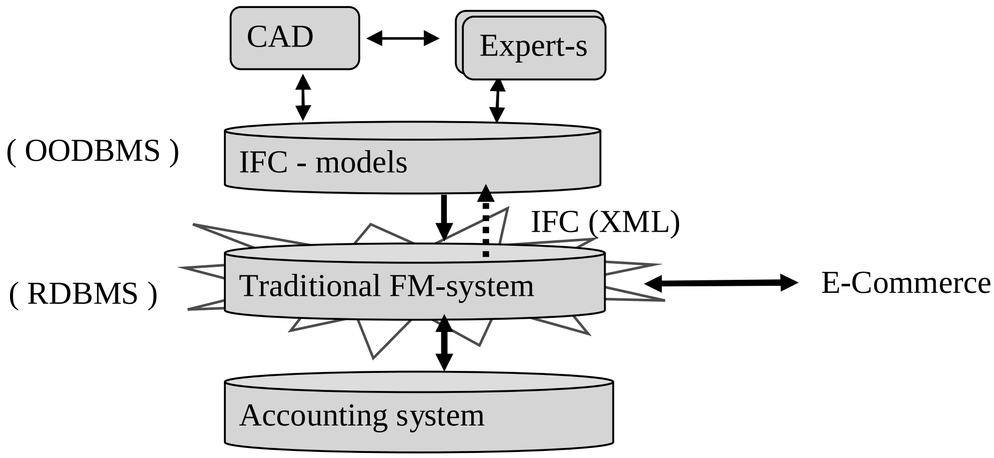

Figure 1FM-system related to IFC

It is the author's opinion that the introduction of IFC-models [4] not for many years will become a common platform for operation phase data handling due to the costs related to converting existing models to IFC. In addition – as IFC is based on an Object Oriented Database management system – performance (speed) – might be an issue. This leads to the assumption of the need for a RDBMS FM-system that is fed by relevant data from the IFC-model where this is possible.

2.2.2 Technology / Principle

There are some fundamental blocks to relay on: A database, a script interpreter and a web server. This kind of technology is often described as a 3-tier architecture [5] – which means that the system is separated into a client-tier, an application-server-tier and a data server tier. The client tier is in this case a standard web-browser, the application server tier is the collection of scripts used by the web server and the dataserver tier is the databaseserver.

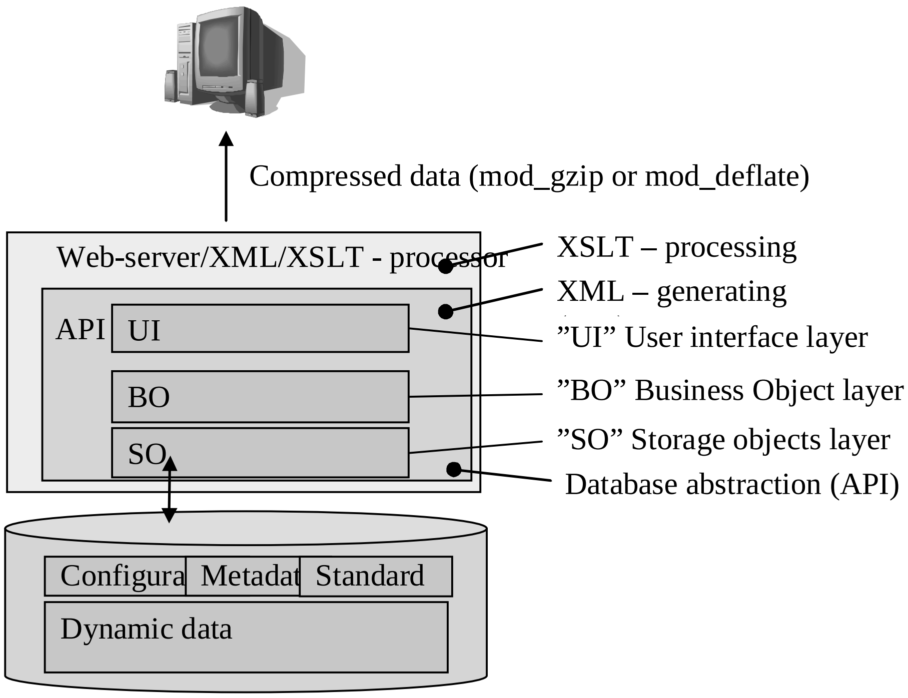

Figure 2 Principle technology

The middle –tier is the actual “program” – representing the logic operating on the data. This tier is also separated into a common API for the whole project – and a set of layers within each module which represents a typical responsibility.

The output from the UI-objects is an array – which is converted into XML and fed into a set of XSL-stylesheets for processing to XHTML.

2.2.3 Architecture

The database is in general built on some fundamentals as locations, physical objects, documents, actors, their conditions, relations and operations:

- *Locations* – is organized in a highly customizable hierarchy
- *Entities* - is a generic class of objects, that can be defined as reports, equipment and so on - which can be linked to locations or other entities
- Actors
- Tenants/User of location
- Vendors
- Owners
- Operation/events
- Request for action of any kind
- Workorders - organized into projects

- Service agreements
- Payments/Cashflow

2.2.4 Meta-database

Certain elements in the application as location, service agreements, entities, actors, are organized in a meta-database which contains information of tables, columns, relations and attributes.

The database queries and name of columns to return (visible and hidden) is dynamically created on the fly the first time - and stored in a cache table (fm_cache) for later use to save processing overhead.

2.2.5 Location

"Location" is a physical part of the property - and it is common to organize the locations in a hierarchical structure with "part-of" relations

- Name Level
- -- Property 1
- /-- Building 2
- /-- Entrance 3
- /-- Apartment 4
- /-- Room 5

Example 1: location hierarchy

The hierarchy is configurable in both width and depth - that is: one can define as many levels as one like - and each level can also have as many attributes as one would like

- Name Level Relation
- -- Property 1 <--- Owner,part of town
- /-- Building 2
- /-- Entrance 3 <--- Street
- /-- Apartment 4 <--- Tenant
- /-- Room 5

Example 2: location hierarchy with configurable external relations

Each level has a primary key - composed by the foreign key to the parent - and this levels ID. In addition - there is a "superkey" named *location_code* for indexing and searching across the hierarchy

location_code	loc1	loc2	loc3	loc4
5000-01-01-001	5000	01	01	001

Example 3: part of the table location4

- Primary key: loc1 + loc2 + loc3 + loc4
- Foreign key: loc1 + loc2 + loc3
- Superkey : Location_code

Example 4: keys for level 4: Apartment

When querying location on a certain level - it is joined with all its ancestors to make inherited information available.

2.2.6 Entities

Entities is a generic class of objects that all have in common that they can be placed in a location and/or linked to other (only one) entities.

Entities are organized in class of entitity and entity category: each entity_category is represented by their own table:

- Equipment
- Elevator
- Fire alarm central
- Cable TV
- Building components
- Reports
- Condition report
- Insurance damage
- Elevator control report

Example 5: Structure of entities at the BBB implementation

Reports are configured to be linked to both Equipment and location — that is: One can write reports on both Equipment and location.

The table representing the category elevator in the entity-class Equipment is here named fm_entity_1_1

Information about the different attributes and their datatypes is held by the metadatabase

2.2.7 Projects

A project is a collection of orders/contracts. The project is linked to a location or entity_category (equipment). Projects are separated in orders/contracts that could be subject to bidding contest amongst vendors. Each order is linked to its parent project and to a vendor - and consists of a series of work-descriptions to perform and / or items to deliver.

An order can be defined as simple as a brief description of simple tasks - or as a detailed complex tender document with a full blown deviation auditing system per record in the contract.

The perspective of the projects is from the receiver of the product delivered.

2.2.8 Helpdesk

The HelpDesk submodule is a hacked version of the phpgroupware's standard Trouble Ticket System application (TTS). The main differences is that the tickets are fixed to a location or entity_category - and that one is able to start projects and entities (i.e. reports) from a ticket - which enhance the trace-ability

The owner of a ticket is notified by mail when the ticket is updated if the user doesn't choose not to.

2.2.9 Invoice Handling

A very important feature is the ability to interact with accounting systems. The invoices are imported into the system by fileformat agreed upon by the vendors – granted for payment by users based on roles – and then exported to the accounting system for payment. Both import and export filters are very easy to adapt to the current implementation – and appear as independent drop in filters.

2.2.10 Alarm Handling

It is possible to notify alarms on timers as email – along with any other predefined task. This is accomplished by a cron job that checks if there is something scheduled.

2.2.11 Documents – File Handling

Drawings, pictures, signed contracts is examples of documents that is handled by the vfs – virtual file system. This enables any type of file to be uploaded as attachment to a range of elements in the system.

2.3 Development

The work on the system has been done in very close cooperation with the organization in a dynamic process with the users as a very important source for demands, feedback and bug testing. There is a set of roles and their needs to satisfy related to the topography of the organization and the surrounding systems which it interacts with.

The work has derived advantage from the open source community as it has been designed as an add-on module to the open source project phpgroupware – and has had access to their development resources and a handful of very skilled programmers.

The source code is stored into the main phpgroupware project at http://savannah.gnu.org – using cvs (Concurrent Versions System) - which allows the project member to revise the code and collaborate on joint development.

The property module is developed at BBB – and implemented gradually as it has evolved. The first feature implemented was the ability to place a simple workorder – linked to a location. In the beginning this system overlapped with the former system in that way that it also wrote a copy of the order to the former system. This strategy made it possible to go back if it turned out to be a bad solution.

The system has been developed on a dualboot windowsXP/Linux laptop – that is – written on Windows and tested on Linux.

The actual data stored in the database-backend is organized as a well normalized relation database – which makes it an easy task to convert data from or to other FM-systems. The logic operating on the data is located as the middle tier in a three-tier architecture implemented on a centralized web-server which simplifies the administration and maintenance of the software as no client installation is needed.

All files have been saved to the cvs-server at savannah.gnu.org – this enables in theory simultaneous remote collaboration by many parties in addition to enable a view of historical changes. The cvs-server allows parallel versions to live together (branches). The idea is to have a stable release where only bugfixes is performed – and one (or several) development branches where new features and ideas is tested.

Savannah also provides some other useful collaboration tools:

- Several informal mailing lists (for users and developers) where questions and opinions are posted.
- A helpdesk in four categories where items are assigned to part of the system and a developer:
  - Support – user questions
  - Bugs – for registering errors found in the software

- Patches – fixes and codesnips prepared for reviewing.
- Requests – feature request for the next release

3. Sample Implementation at BBB

Phpgroupware with the application property is implemented as part of the total FM-system at Bergen Bolig og Byfornyelse KF (BBB) – integrated with a tenant / lease administration system and the company's accounting system.

The webserver is a linux box based on a Mandrake 10.1 distribution which communicates with a database server (MSSQL) and a fileserver (Windows 2000).

So far 25000 orders are served by the system.

3.1 About BBB

BBB is a public housing company comprising 5000 dwellings located at the city of Bergen, Norway.

BBB has about 40 employees organized in a central head quarter in downtown and three satellite offices. All employees have access to both intranet and the Internet.

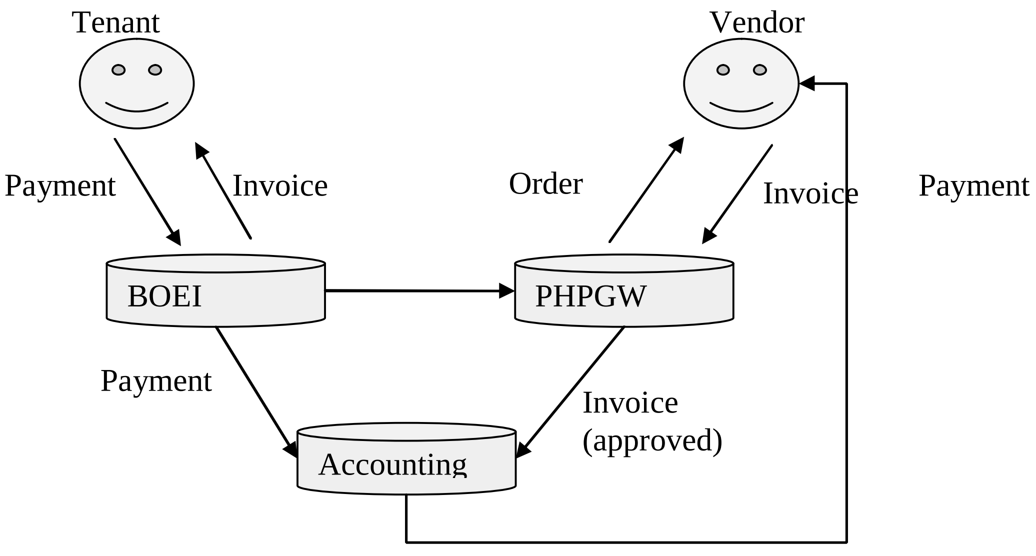

Figure 3Integrated systems at BBB

3.2 Integration

The location hierarchy and tenant information is "owned" by the tenant lease system (BOEI) – that is – all such information are originated in BOEI – and automatically transferred (or updated) to phpgw. The initial integration was implemented as two databases at the same database server (mssql) – and the synchronization was performed as scheduled jobs by executing stored procedures. Later – the database for phpgw was transferred to the linux server at a postgresql database. This was decided due to a 5 times gain in speed.

Now the synchronization is kept in order by a shadow set of synchronization tables at the originator database server to identify changes to transfer. The jobs are run as cron-jobs from the linux server via php-scripts that connect to phpgw_postgres and phpgw_mssql. To perform the actual comparison one need the master-tables from BOEI_mssql – and these tables are mapped as views in phpgw_mssql.

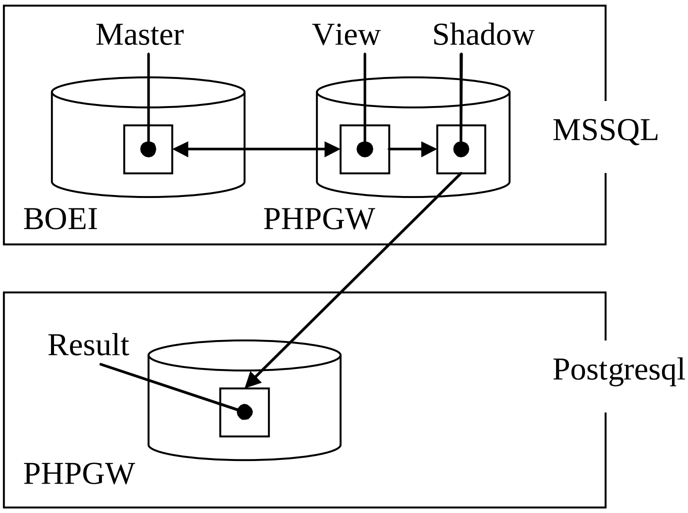

Figure 4 Synchronization model

3.2.1 Accounting System

Orders are sent by email to the vendors – which return the invoices at a monthly basis – and imported into the system for approval. Both approved and not approved invoices are exported to the accounting system to reflect the total claim for payment. During the import – the invoices are assigned to a supervisor and a budget responsible which both have to approve the invoice for payment.

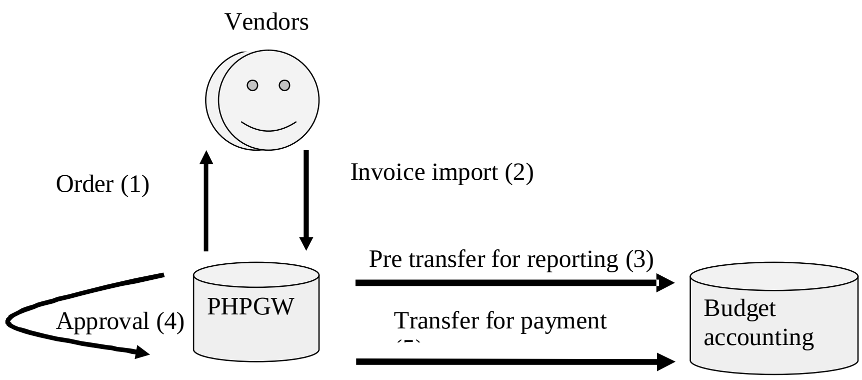

Figure 5 Dataflow –order/ invoice

Export:

The invoices are exported to the accounting system at a remote ftp-server as a set of files - and a backup-file is kept locally as reference. In case of error during import to the budget accounting system – the error is reported back – and a rollback is performed in order to correct the error.

4. Conclusions

The open source fm-system built upon phpgroupware has proven very successful – and has replaced commercial fm-system previously implemented in the organization. The system is very flexible as the organizing of locations and components are modeled in a metadatabase. The system is also integrated with the municipal accounting system as an automated e-commerce solution which greatly has reduced manual handling of orders and invoices – and increased the quality of control, workflow and the ability to do historical analysis.

The system is very adaptable and integration-friendly, given a certain general competence on programming database- and web-technology.

Abstract

For the different parties of a building construction project, product modelling is an efficient data management method. Product model based data can be utilised and exchanged in various ways in and between different sectors of design, construction site management, and product industry. The product models of the different parties in a construction project can be integrated into a shared model which is augmented with data as the project progresses. In designing, both common product libraries and company-specific product libraries are used, enabling the transfer of product data from design to manufacturing. Creating guidelines for architectural, structural and HVAC design is necessary in order to make sure that data is stored in a concise way and that each designer can make use of the other designers' plans. In addition to design guidelines, another important prerequisite for this is IFC, a data transmission standard that allows information to be trustworthily stored and transferred between different software. Product model based construction process has been tested in several pilot projects where the results have been promising. Developing common principles and operating methods further will speed up and streamline product modelling in the building construction industry. As a whole, a product model -based process will improve companies' customer service, productivity, and construction quality.

Keywords: product model, data transfer, product component libraries, IFC data transmission standard

1. Introduction

During years 2003 and 2004, the Finnish construction industry has developed design, construction and maintenance in the building construction process based on product modelling. The development has taken place within the framework of a technology project called Pro IT –

Product Model Data in the Construction Process, in which businesses, research organizations, governmental organizations as well as interest organizations have participated. More information on this technology project can be found in a recent article [1].

A product model means a description of the building in such a way that, in addition to the geometrical 3-D visualisation, the model contains data defining the building and its components. The data may apply for example to the finishing structures in spaces, the characteristics of the materials, fire-resistance, colours, environmental impacts or sound insulation.

A product model is composed of product components, which can be modelled either on a case-by-case basis or by using ready-made product component descriptions in a product library. A product library is a collection of product components in an electronic form. The libraries contain the components commonly used in design, such as walls, doors and windows. It is also possible to make libraries of other product components, such as furniture and interior design accessories.

In the Pro IT project, a standardised method is developed for the design of a product model in the stages of architectural, structural and HVAC design. The starting point in the different design stages is the model created by an architect. The data exchange between the parties is developed on the basis of the international Industry Foundation Classes standard (henceforth referred to by the abbreviation IFC [2]). The main advantage of the IFC standard is that a number of designers from different fields can take part in construction projects irrespective of the software and file formats they use.

In construction industry, product modelling is still a relatively young technology and is not in widespread use. Despite the shortage of published information on or studies about practical applications and working methods of product modelling, there are some pilot projects on which the method has been tested with good results.

This paper proceeds as follows. In section 2, the benefits of the construction process based on product modelling as opposed to traditional processes are described, before the new process is briefly summarized. Subsequently, the need for developing general guidelines for product modelling designers is established in section 3, and the existing design guidelines as well as those still under development are described. Section 4 examines the IFC data transmission standard which is essential for the practical exploitation of product modelling, and section 5 casts a brief look into the different product libraries currently being developed. Section 6 sheds light on the pilot testing of the project. Finally, the conclusion summarises the essential points about product modelling and sets some directions for future development of the method in construction industry.

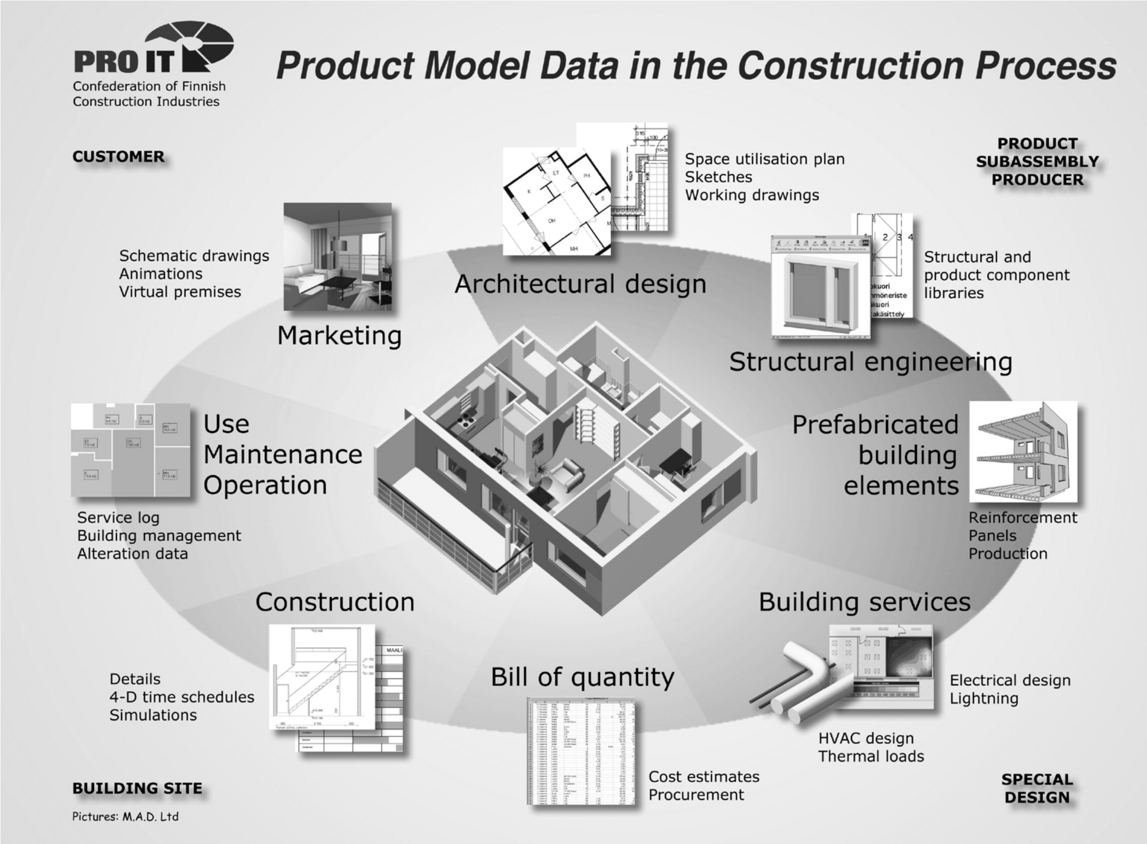

Figure 1. Product model-based data management for a construction project integrates the data needed for design, product manufacturing, construction, and the use and maintenance of the building.

2. The Advantages of the Product Model Based Process

2.1 Product Model Based Data Management

With the help of a product model, it is easier to keep under control all the data needed for the design, construction, usage and maintenance of buildings. The data can be managed in real time and in an intelligent and graphical form. The huge quantity of information needed in the successful realisation of a construction project can be transmitted between participants as well as managed more reliably and efficiently than before. An important possibility is to employ the structure and data content of the standardised product model to streamline and speed up the planning and control of construction projects. One of the most tangible direct advantages of standardised product models is that bills of quantities can be generated directly from the model for use in cost estimating, production planning and procurement.

The product data used in product modelling opens up a number of possible applications for the product industry [3]. Using a product description selected from a product library as part of a plan ensures a good technical and economical result, transfers the product data to manufacturing in good time, and also serves as a marketing tool.

Product modelling transforms building design from traditional line-drawings to visual 3-D design. In addition, a product model has in-built information available about the spaces, structures and furnishings it consists of. The structures of a product model such as walls and slabs contain information for instance on the materials they are made of, the measurements needed, and their thermal insulation, strength and environmental qualities.

When a 3-D product model and a time schedule are combined, the result is 4-D design. It enables site management to determine the most advantageous order of construction and the most economical time schedule from within an array of possible options. 4-D design also visualises the flow of worksite production and particularly problematic stages which demand more attention than usual from the site management.

After the planning and implementation phase of a construction project, it is possible to use product modelling to create a data store covering the entire life cycle of a building. The final product model shows all the materials and products used for the building, and can be updated when needed.

2.2 Product Model Based Operating Process

When one changes over from 2-D drawing to 3-D modelling, the production and management of designs are made more efficient: there is less routine work and fewer design flaws. Input data, such as quantities, are obtained automatically for various purposes and in the form of time-saving lists. The design geometry and dimensional accuracy come in handy in the design and manufacture of components.

Expertise from various fields of design and construction specialists is, through product modelling, usable in a practical form from the start to the end of a construction project. The inclusion of construction specialists in the design process improves cost-awareness and the possibility to figure in technical aspects of installation and manufacturing as well as allows room for innovative solutions. Instead of viewing the economy of a building in separate parts, it can be planned and assessed as a whole.

The last but not least of the ways in which product modelling improves construction processes is that it helps to achieve the goals the construction industry sets for customer satisfaction. It is crucial that the clients and end users of buildings are aware of the characteristics of the buildings built for them, that the buildings as end results correspond to their needs, and that unpleasant surprises are kept to a minimum. With the help of product modelling, the clients and end users of the building are provided with more information and specialist assistance to support their decision-making. The techniques used for this are visualisation and simulation.

2.3 Description of the Product Model Based Construction Process

The product model-based process supports exchanging and sharing data throughout the life cycle of a building. The ultimate aim is a process in which the product model data is produced, exchanged and utilised in an easy-to-use digital format between different software packages and participants. In order to arrive at this aim, it has been deemed most necessary that the participants of construction projects and the flows of information between them are systematically listed and described with respect to the different stages of projects.

The product model-based process has therefore been described by a systematic method (so-called IDEF0), in which the process is divided into sections. These are pictured as compatible diagrams which constitute a hierarchy. The diagrams represent the functions of each section, the programs used, the participating partners, and the data flows between them and their design software. The process model covers the life cycle of the construction project and the building from the preliminary design to the operating and maintenance.

3. Design Guidelines

3.1 Basics and Objectives

Uniform modelling guidelines for various designers of the construction process are necessary in order to transfer product models from one program to another. Being able to transfer product models between programs is a prerequisite for clash detection analyses of the models created by different designers and for ensuring that the bills of quantities extracted from the models are accurate. Furthermore, the data on the characteristics of product structures stored in a product model should be defined by a commonly shared method.

The modelling guidelines for the architect are the most crucial and demanding, as the model made by the architect serves as the input data for quantity surveying, for structural and building services design, and for marketing. It must therefore contain information for many different purposes – for example, spaces, building components and the principles of their connections. It is particularly important to transfer measurements to other plans correctly.

A key aim of the modelling guidelines for structural design is to provide basic data and instructions for the product-model-based description of structures and to influence that computer programs and the libraries on structural parts, details and joints are drawn up in line with the same principles of product modelling. General modelling guidelines also serves as an aid for drawing up project-specific modelling instructions. The guidelines can also be used to harmonise and standardise terminology, operating procedures and working methods.

So far, the third version of the guidelines of architectural design has been published in Finnish under the name Product Model Design Guidelines for Architects – General Rules and Fundamentals [4]. The first version of the guidelines for structural modelling has been completed, and at the moment it is being tested on real construction projects. The guidelines for modelling building services have also been started: currently, the content of the guidelines is being defined.

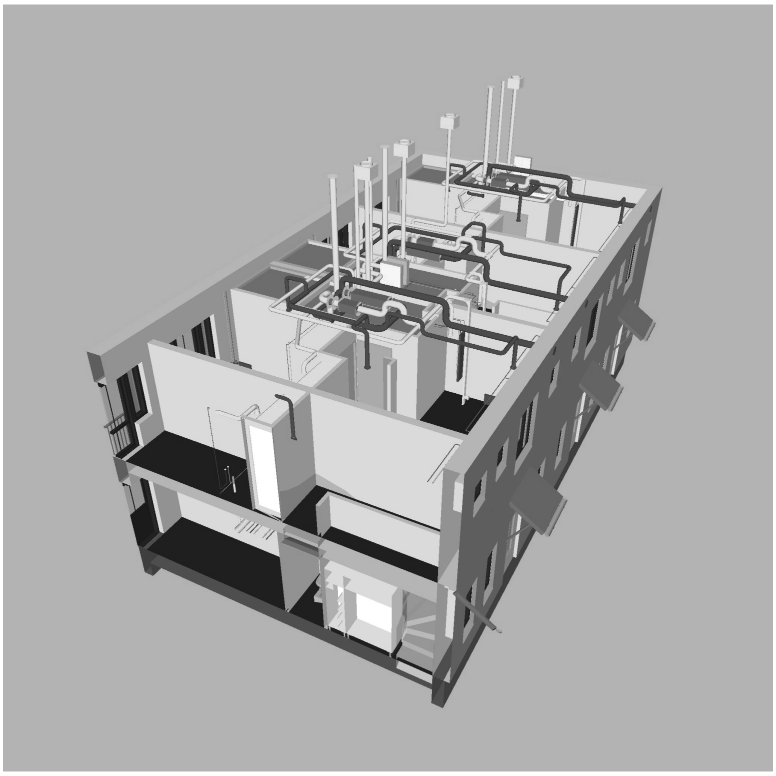

Figure 2. Combining the architect's model and the building services model and clash detection analysis reduces errors on the worksite.

3.2 Stages of Product Modelling

The designing of product models is divided into stages in accordance with the construction process as a whole. Descriptive terms have been agreed on for the different stages. These differ from the conventional terms, because product model-based design does not comply with traditional practice. The design model includes four stages: the requirement model, the space model, the preliminary building element model and the final building element model. The requirement model may be for instance a description of the client's needs and the building authorities' requirements, as well as the parameters set by conditions. This model may be represented in a spreadsheet application or other digital format.

The space model, in its turn, covers spatial solutions. The model does not yet necessarily include walls distinguishing the spaces from one another. The basis for formulating this model is the space utilisation plan together with its data on the individual spaces.

The preliminary building element model includes the elements which delimit the spaces and correspond to drafts in present-day design practice. Requirements are set for the elements, such as the fire class and thermal conductivity, but the structural solution is not yet selected. The building elements are defined at a construction type level. Ready-made construction types from the general product libraries can be used to create this model.

In the final building element model, the construction types shown are building elements together with product data, like the actual products of suppliers. In this model, supplier-specific data have been added to all the elements, accessories and so forth. The final element model may also include other information, such as time schedules and job plans. The models following the four actual stages of the design model are the as-built model together with site and installation data and the maintenance model in a life-cycle program. The maintenance model can later be updated with spatial alterations and additional construction.

4. Data Exchange and the IFC Standard

4.1 Data Exchange Use Cases

One of the key aspects in the product model-based building process is the interoperability of computer programs, and the support for the life cycle of the building information throughout the construction and operation process. A prerequisite for the realisation of this is to enable the digital data exchange of building information between the participants of the process and their programs. Then information once created by a participant and his or her program can be exchanged and shared with the downstream programs of other participants.

To enable the support for the many required data exchanges within the multidisciplinary building process, these exchanges need to be first defined, and then implemented as data exchange interfaces in the programs. The definition of the exchanges can be done by so-called *data exchange use cases*. A data exchange use case is 1) an identification of a business need for the data exchange, 2) definition of the information to be exchanged, and 3) definition of its implementation, for example, using a data exchange standard.

In the pursuit of advancing the practical product model data exchange, the Pro IT project has defined a set of necessary data exchange use cases. The use cases defined include the following exchanges:

- from architectural design to quantity take-off and cost estimation
- from architectural design to HVAC design
- from architectural design to structural design
- from various designers to design coordination and clash detection
- general quantity information exchange, e.g. from quantity take-off to tendering
- from product libraries to various programs.

4.2 The IFC Standard and How It Works

A data exchange specification called IFC (Industry Foundation Classes, [2]) has an important role within the data exchange use cases defined by the Pro IT project. The use cases define how IFC is used to implement the support for the exchanges.

The IFC is an open specification for AEC/FM interoperability. The scope of IFC is AEC/FM over the life cycle of buildings. IFC is developed by IAI (International Alliance for Interoperability, [5]). IAI's mission is to develop, promote and support the implementation of Industry Foundation Classes.

IFC specifies a neutral format in which programs can exchange digital building information. Using IFC, an architect can for instance send a digital building model created with a model-based CAD programs to an HVAC designer. The HVAC-designer could then use the model, its spaces, building elements, and 3-D geometry directly as input data for the thermal simulation program to calculate thermal loads and requirements. The same building model could also be used by a cost estimation program to automatically extract a bill of quantities and to calculate an initial cost estimate for the building.

All the Pro IT use case definitions follow same content structure: In the first part of it the purpose and scope, typical participants, and their program types are identified. Then the data content or the information requirements of the exchange are defined. The second part of the use case defines the subset of IFC object model which is required to support the use case. Examples and usage rules of the IFC are also given. The use cases are defined using a methodology including re-usable definitions, such that new data exchange use cases can easily be addressed and defined.

The data exchange use cases serve the purpose of a proposed common agreement on how IFC can be used to address real-life exchange requirements. The target audiences for the use cases are on one hand the participants of the construction process, and on the other hand the software developers, who may be implementing exchange interfaces for their design and construction programs.

5. Product Libraries

The Finnish construction industry has sought to standardise the data content and presentation of product structures so that the various participants in the construction process can use them. Both the definition of data with building component cards and product libraries for use in 3-D design are needed, so that designers are able to plan and manage customer demands, builders are able to estimate quantities and costs, and operators are able to use completed buildings and perform maintenance tasks.

One of the completed tasks is creating a structure library common to the construction cluster containing the most frequently used types of structure. The library currently includes over 200 different structures, which are mainly structures used in housing construction. However, the principles used there could be applied in the future to describe other, even totally new structures. With the common product model library as their starting point, companies will be able to create their own product libraries compatible with commonly agreed specifications.

The next challenge in the development of product libraries is to establish a link between common product libraries and specific products included in the product portfolios of manufacturers. The link would make it possible to choose specific products suitable for the design based on the general characteristics defined in common product libraries. The search for the specific products needed could be carried out for example by Internet search devices.

6. Pilot Testing

The piloting of the use and exchange of product-model-based data is an important prerequisite for the broader utilisation of product modelling. The construction companies involved in the Pro IT development project for product modelling are responsible for this. In the course of 2004, two contractors implemented and further developed the model-based process in their own housing output [6]. The software packages used in Skanska Oy's pilot project were ArchiCAD (architectural design), Tekla Structures (structural design), MagiCAD (building services design), Solibri Model Checker (checking models), ScaleCAD (element design) and NavisWorks (integrating different models and clash detection analyses). On NCC Construction Ltd's pilot, Bentley MicroStation Triforma (architectural and structural design) and MagiCAD (building services design) were used. The subjects of the testing were the use of modelling guidelines and product libraries, the transmittance of product models between programs, and the utilisation of product libraries in the design process.

In a pilot project of a shopping centre extension by Lemcon Oy, Tekla Structures software was used to model the structures. After the modelling of the steel frame, precast concrete units and the façade's thermo spar elements, these submodels were combined into a single structural model for the worksite. The main emphasis in the piloting work was on time schedule planning for the frame work stage and on monitoring installation data. By specifying the order of installation of the building components of the 3-D model and by inputting the scheduled installation dates of the building components into the product model, a 4-D model was obtained, containing the time schedule data for the construction project. The product model was placed on the Internet, enabling all the partners in the project to view a real-time 3-D image of the situation for installation on the worksite using nothing more than an Internet browser.

Advantages of product modelling among others that were repeated in different pilot projects were that it facilitated change management as well as the production of bills of quantity and various images and views. In principle, it is possible to generate all the conventional design documentation, such as drawings, from the product models drawn up. Product models have also permitted quantity listings of all the modelled construction components. As an example of the main benefits, it was noted that the time taken to calculate bills of quantities was reduced by an estimated 30-50% when using the new method. It must be admitted, however, that it is a prerequisite for such significant time savings in calculations that the subject building has been modelled comprehensively and extensively enough. The quantity data taken from the model have been estimated to be as much as 80–90% usable in making a time schedule for the construction project. In the project for an extension to a shopping centre, a graphic 4-D model proved itself to be an efficient tool for time schedule planning.

Other advantages include, for example, the possibilities to use three-dimensionality to assist design work and in integrating the work of different fields of design. A further prime advantage of product modelling that has emerged was the reduction in errors. For example, it was possible to eliminate measurement errors from designs almost entirely. It was also possible to use the product model on the worksite in many ways in the management of installation, logistics and complex delivery chains.

Most needs for further development were identified in data exchange between different software packages. Because IFC standard data exchange did not yet run satisfactorily, it was necessary to exchange data also using other, program-specific formats. The piloting will continue in 2005 on projects by four different contractors, in which the operating model and data exchange will be developed on the basis of the feedback received.

7. Conclusions and Directions for Further Development

The experience gained of the use of product modelling in the construction industry indicates that there is considerable scope for increasing efficiency in various subdivisions of the design and construction process made possible by this new method. The increased efficiency requires that common product modelling operating methods and data content definitions are finalised and taken into more widespread use.

The feedback so far indicates that compliance with architectural modelling guidelines and the use of general product libraries facilitates fast and efficient calculations of quantities. On the basis of the quantities, one may separately derive the costs and time schedule data. Quantity calculation and time scheduling are the first widely usable application methods where product modelling has proven its benefits. These methods are increasingly being used by construction companies.

Structural modelling is developing dynamically, and models can already be used not only for design but also for worksite 4-D time scheduling and production management. The structural model yields considerable benefits for the worksite using visualised plans and material listings. A structural model can also be used in the further design of building components, as has been done on the pilot sites of the Pro IT project. Building services modelling provides a visualised image of systems for purposes of installation, and it permits clash detection analysis and the design of the necessary provisions. The building services model can be used, for example, for simulating indoor air conditions and for dimensioning the energy consumption.

The main requirements for the onward development of product modelling relate to data exchange and the improvement of overall levels of expertise. For the development of data exchange, systematic work for the adaptation of the IFC standard must be continued so that it can be used to transfer the data required for different plans and for production between program solutions. Current data exchange is still based on file transfer. In the future, however, efficient team design will require the use of dynamic product model servers. From these servers, each designer will be able to access only the part required and to update the plan back onto the server. The first product model server solutions based on the IFC standard have already been created.

As a whole, the product model-based process is expected to yield substantial benefits to all the parties in the process. However, widespread adoption will still require considerable efforts. Particular attention should be devoted to developing standards for data exchange between design software, determining product attributes and creating product libraries.

Data exchange between different software should be developed by making it possible to widely apply the IFC standard. In practice, this will mean developing and expanding the IFC standard in such a way that it covers all the usage of data exchange required by the industry better than at present. Also, greater efforts on the implementation of the standard will be required of the software industry so that software will support the standard. Therefore, the standard needs to be developed a strong and international one.

The use of product data in the design, construction, use, and maintenance stages of a building requires information on the materials and solutions used as well as efficient and reliable electronic archiving. For it to be possible to create electronic product descriptions on the basis of the product data, the attributes of the product data should be defined internationally. On the basis of common attribute definitions, it will be possible to build jointly used product libraries and product symbols for software and to establish connections from them to different types of product libraries. This kind of product libraries will facilitate efficient marketing and comparisons between different products as well as promoting procurement on a broad level.

Abstract

- There is a great need to develop the following sectors of the infrastructure branch:
- The quality of the design process
- The cost management during the design process
- Information management and communication between the different members of the design team

The result and the major cost level of the infrastructure project are defined in the beginning of the project planning and during the design process. Then the scope of the project is defined and the project is designed. Traditionally there have been problems related to the scope and information management. Now three companies have developed together with the Helsinki University of Technology the new product model based infrastructure design process. The process uses the best practise process of the cost engineering and the common product model.

Rakennuttajapalaute Rapal Ltd has developed with 10 major Finnish infrastructure clients (Cities of Helsinki, Espoo, Vantaa, Turku, Tampere, Oulu, Kuopio and Jyväskylä and the Finnish Road and Rail Administrations) the best practise process for scope management costing and cost engineering during the design process. Viasys Ltd is a member of the worldwide Vianova Systems Network and has developed the design software called Novapoint based on the product model. DSS Ltd has developed a program called DYNARoad for optimizing the earthmoving operations. Three companies have developed together a design process based on the product model, which is compatible with the InfraRYL (the new common finnish civil engineering terminology system). The product model based design process contains:

- The project scope setting method for infrastructure client before the design process
    - Systematic project scope definition method for the use of design management

    - The cost estimation based on the scope definition
- The design of the highway based on the previous definitions
- The optimizing of the mass operations in the project
- Cost engineering during the planning process
- The final cost estimate based on the infrastructure building element method
- Quantities of the final result of the design are given to the contractor for further studies

The developed design process with the common product model saves the great amount of resources during the long design process. The result of the design process matches the defined scope better than in traditionally used processes. The cost engineering and the product model can save millions of Euros in the big highway projects.

1. The New Infrastructure Design Process

1.1 Overview

Three commercial companies (Viasys Ltd, Rapal Ltd, DSS Ltd) has collaborated with the Laboratory of Construction Economics and Management of Helsinki University of Technology to create new kind of product model and systematic cost management based infrastructure design process. Traditionally in the infrastructure branch there are many different kinds of data models in use and that makes lots of information waste during the process. The cost management process is not scope oriented and cost engineering in the means of getting economical and quality oriented design solutions compared to the scope is not in the common use. The new infrastructure design process is described in this paper concentrating on the cost management and data transportation.

1.2 Process Relevance

The difference between the reasons of the infrastructure project cost is related to three categories:

- The scope
- The design solutions
- The economical situation on the market

This article concentrates on all three categories in the view of cost management and the data transportation. The main benefits of the new design process are:

- The result of the design process corresponds to the defined scope better

- Data is not wasted during the long process
- The focus of the planning process is getting to the earlier stage of the process than before
- The focus is on the result of the process, not in the process

The infrastructure (highways, streets, railways and big industry yards) investment and maintenance cost in Finland for example were worth of 1,8 billion euros in year 2002. The relevance to the whole society is huge when lots of working hours are saved because of the more complete design process.

2. The Cost Management Process

2.1 The Systematic Scope Definition

The infrastructure is build because of the need to develop or to maintain the basic functions of society. The maintenance of the infrastructure is based on the need to sustain the standard of service of the invested infrastructure network. The change in the functions or the standard of service creates the need to invest more. The needs of the public and the resources in use with the property owner organizations are usually not at the same level. The building process of infrastructure is a long term process including lots of public organizations and ordinary people related to it.

The infrastructure cost management process described in this paper starts with the definition of the needs of the project. The client of the process (usually the public organization) has the responsibility to describe the need, give reasons to the need and take care of the cost management process to reach the target. The needs are modified to targets which are described with end product elements, which are big work breakdown structure components of the project like for example the main way, intersections, bridges and the lightning system (fig 1).

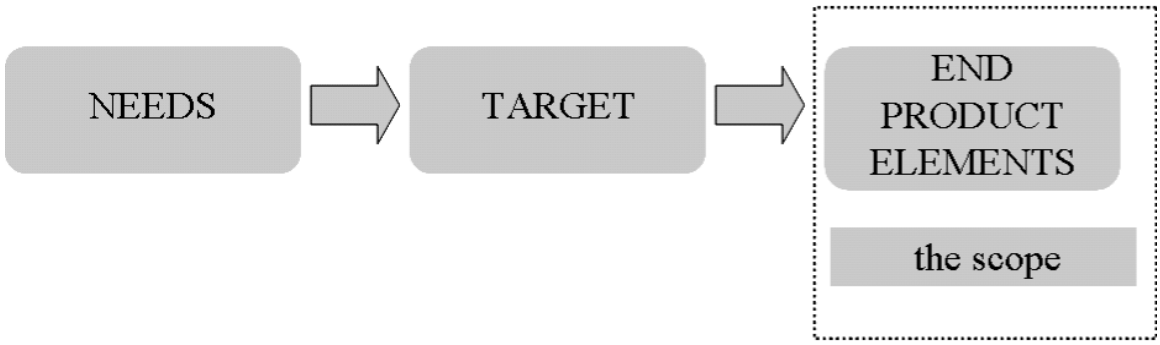

Figure 1: The needs of the project are modified to the targets, which are described as end product elements with the defined scope..

The list of the end product elements creates the framework to the project management based on the systematic and strictly defined project components. The systematic project component division with the end product elements has two purposes:

- To describe the result of the project
- To create the drivers of the project management

Traditionally in the infrastructure branch the process is design and project orientated. In this systematic scope definition the focus of the design process is moving to the earlier stage. There are three benefits of the earlier target orientated scope management:

- The design organisation has clear definition for the scope
- More cost orientated decisions can be made
- The design process can concentrate to the design process and innovations instead of definition of the whole project

2.2 Cost Engineering During the Design Process

The cost management of the project can be based on the estimate theory or on the steering theory. The difference in the two theories becomes concrete in the decision making points (fig2). According to the steering theory the decisions are made so that the cost is under the cost level accepted with the scope.

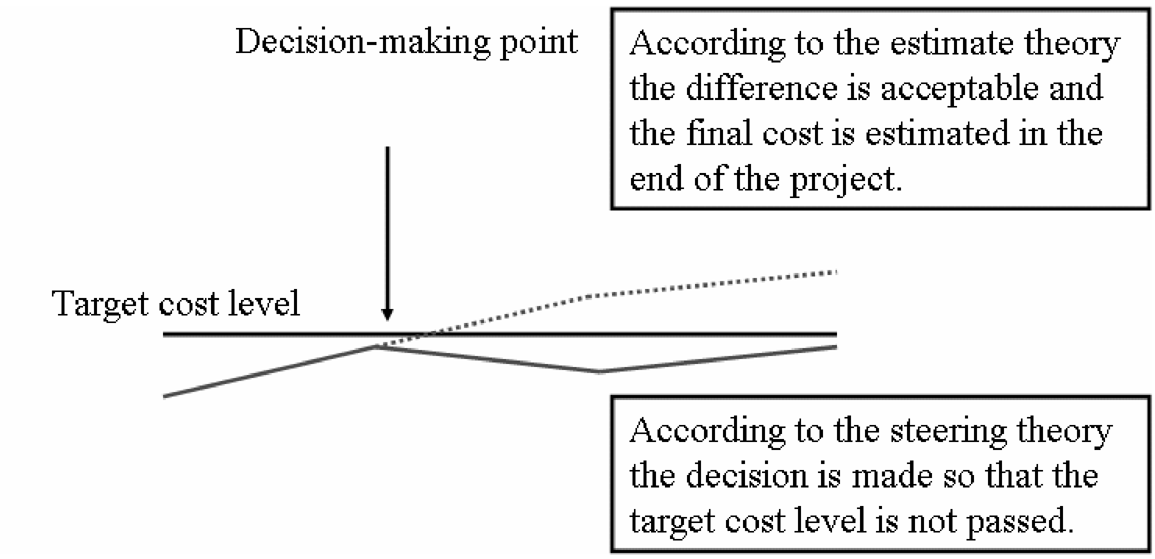

Figure 2: The difference between the estimate and steering theories

Traditionally the cost management is the final action of the design process and the result is more or less declaratory. The cost engineering during the new process is a continuous decision making process. It has three purposes:

- To get comparable prices for different design solutions
- To compare the design solution with the scope
- To estimate the market price for the execution of the project

The cost management during the design process is made with the building element system. The building element is a piece of the product defined in InfraRYL - the new common finnish civil engineering terminology system. The building element consists of the typical production structure in use and the price consists of the prices of resources (work, material, machines). The resource list is updated continuously by the data received from the markets.

2.3 Earth Moving Operation as The Important Part of the Infrastructure Cost and Schedule Management

Mass economy consists of the cost of earthmoving operations and the effect that used design alternatives and the available schedule have on them. These costs are always project specific and that is why it has been difficult and time consuming to estimate them in the past. If this has been done, the results have always has a high degree of uncertainty in them. DSS Ltd has developed a tool called DynaRoad to simplify parts of the process and remove some of the uncertainties related to it. The mass haul planning in DynaRoad is assisted by algorithms that do the all the haul and some of the schedule calculations for the user.

Mass economy calculation yields two major benefits to the design process: the cost of earthmoving operations and the weak spots in the designs that are likely to cause unnecessary costs during construction. The costs and weak spots are discovered by creating a resource based schedule and mass haul plan. This plan can be done in early stages of the project by using information on haul and resources costs that are readily available in the industry. A finished schedule and mass haul plan show an estimate of the project’s haul amounts, distances and resource and time requirements that are then combined with other cost calculation information. Analysing the mass haul plans gives the weak spots in the plan. These are for example:

- Structures that have a mass deficit or surplus.
- Structures that have long and large hauls related to them.
- Structures that may cause unnecessary delay to other tasks.

This information can then be taken back to the designers that can check if it possible to alter the plans in some way to get rid of these problems. For example, a mass deficit or surplus could be avoided by changing the vertical alignment of designs or changing the structure type to something that is (or can be made) readily available near by. Structures that cause unnecessary delay to other tasks could for example be embankments that rely on a cut that can only be done later in the project. This causes a delay on the fill and also all the tasks succeeding the fill.

The use of product models in mass economy calculation speeds the process by eliminating many of the complicated stages that have been previously necessary to get the required data from a design platform to a mass economy calculation system. Instead of using a day to set up a complicated project in the system the required data can now be imported directly from the design platform. After the product model development is complete it will be possible to visualise all the mass economy related information directly in the design software. This will further ease and speed up the work of the designer.

2.4 Benefits of the Systematic Cost Management

The cost management based on the scope management, the active cost engineering and active earth moving operation design gives the systematic approach to the infrastructure cost management. The new process makes different costs comparative and easily managed. The focus of the cost management and the planning of the earth moving operations are moving earlier than traditionally in the process. The more cost oriented design process gives resources to important points of the process and is feasible especially in the tight economic situation when the real cut resources are lower than needed (fig 3).

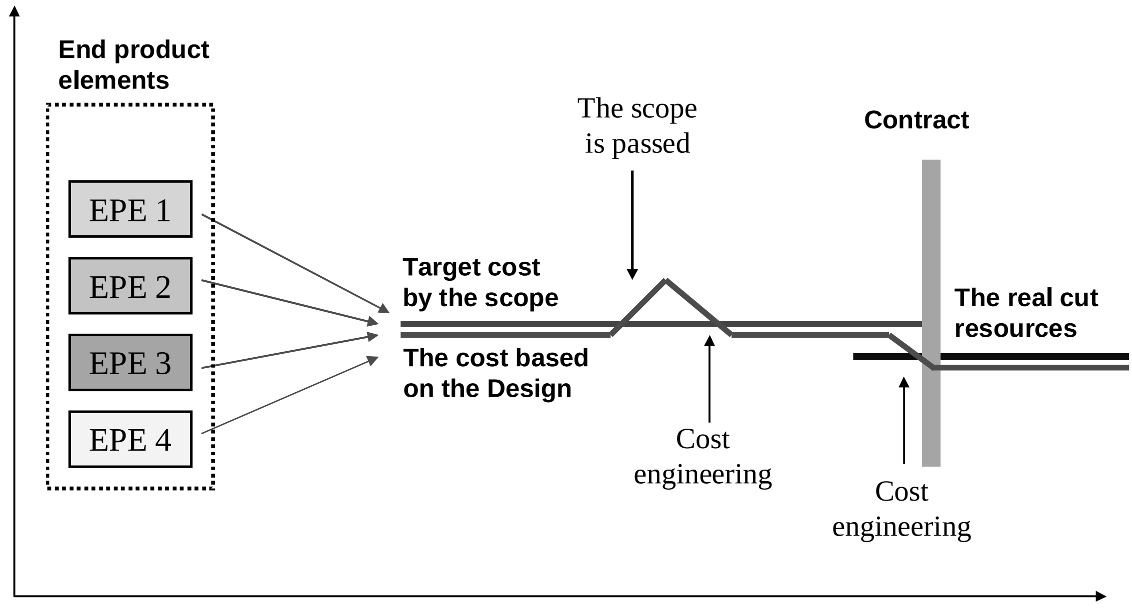

Figure 3: The systematic cost management process in the infrastructure design

3. The Information Process

3.1 The Common Product Model Description

Product model, in general, is an abstract class model describing real life objects and phenomena. Each class describes one type of real-life object. Class description consists in properties and methods. Classes are hierarchically associated with each other and properties and methods are inheritable based on association type. When any class in initialized, it becomes an object signifying a real-life object. During the object initialization, initial values of properties are supplied and initial methods are carried out. Thus, an object always contains some information. Furthermore, each object has a life-cycle and state of existence. With these basic construction blocks and rules, rather complicated real-life models and systems can be reproduced and utilized in computer memory.

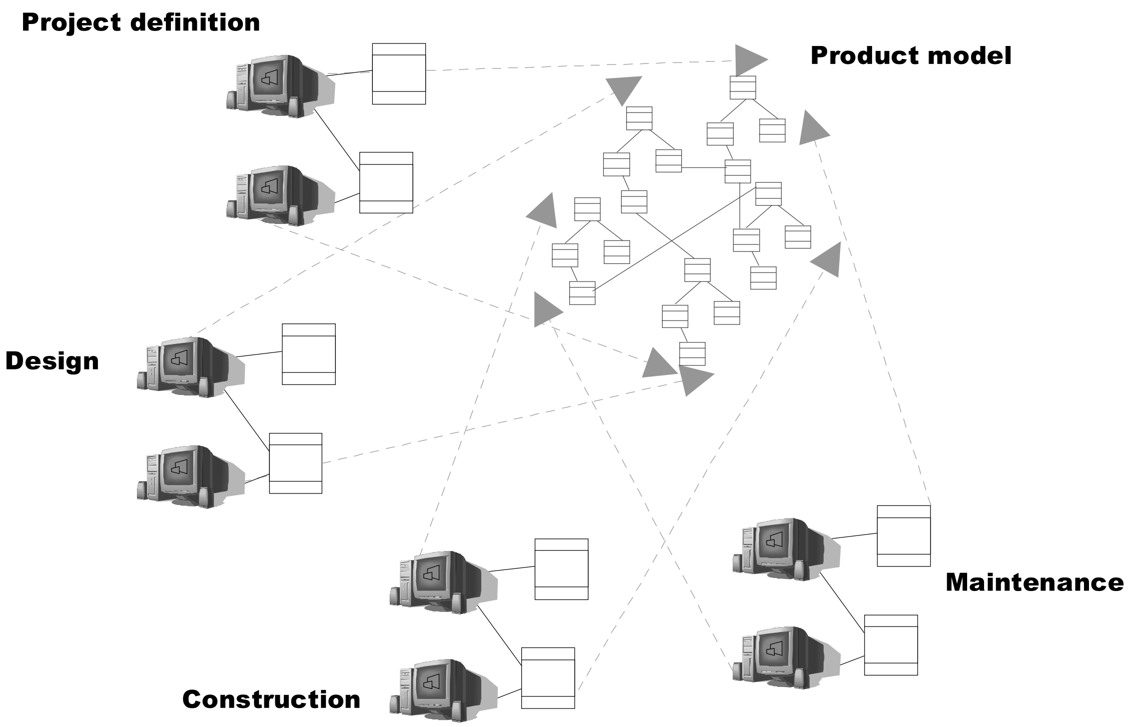

Figure 4: Different views to common product model.

Comprehensive and commonly accepted product model enables communication between different software with minimal or any data-loss. In ideal case the product model is well considered so, that the same product model is utilized in all software used in particular field of expertise. Figure 4, illustrates how the same product model is shared by different software in each phase of a public infrastructure management project. In each phase the product model is updated and developed further to meet the demands and outputs of the project phase at hand.

General methods and tools for holding a product model are, for example, databases, XML-files, text and binary files, in general, and data models in computer memory. Each application is able to read the common product model, or suitable parts of it, into application memory. Depending on the needs of the task at hand, the application view to the product model can be rather different from another application. For example, a cost management application does not need a detailed 3D-model view of a road, when a CAD-system is rather dependent on one.

Software used to produce and maintain the infrastructure design product model, in the concept described in this paper, is Novapoint product family (http://www.novapoint.com). These product model based design and management products are developed to meet the needs of Civil Engineering computing. The individual application modules, sharing the same product model, used in this concept are:

- Novapoint Road Professional
- Novapoint Terrain
- Novapoint Noise
- Novapoint Traffic Signs & Road Markings
- Novapoint Civil Construction & Novapoint SiteTools

3.2 Engineering with Product Model

The product model based infrastructure design process builds up gradually the road model in different project phases. Other relevant models included in infrastructure design process are some basic models, like ground and map models, and some domain models like road, water & sewer, traffic sign and road marking models. Thus, the comprehensive infrastructure design product model consists all of these models associated in strictly ruled ways. Each project phase uses the road model and other relevant models to achieve ones objectives and passes the evolved road model to the next project phase. This data flow in infrastructure design process is illustrated in Figure 5. Process phases are taken from a road design process and they are shortly described in paragraphs after this picture.

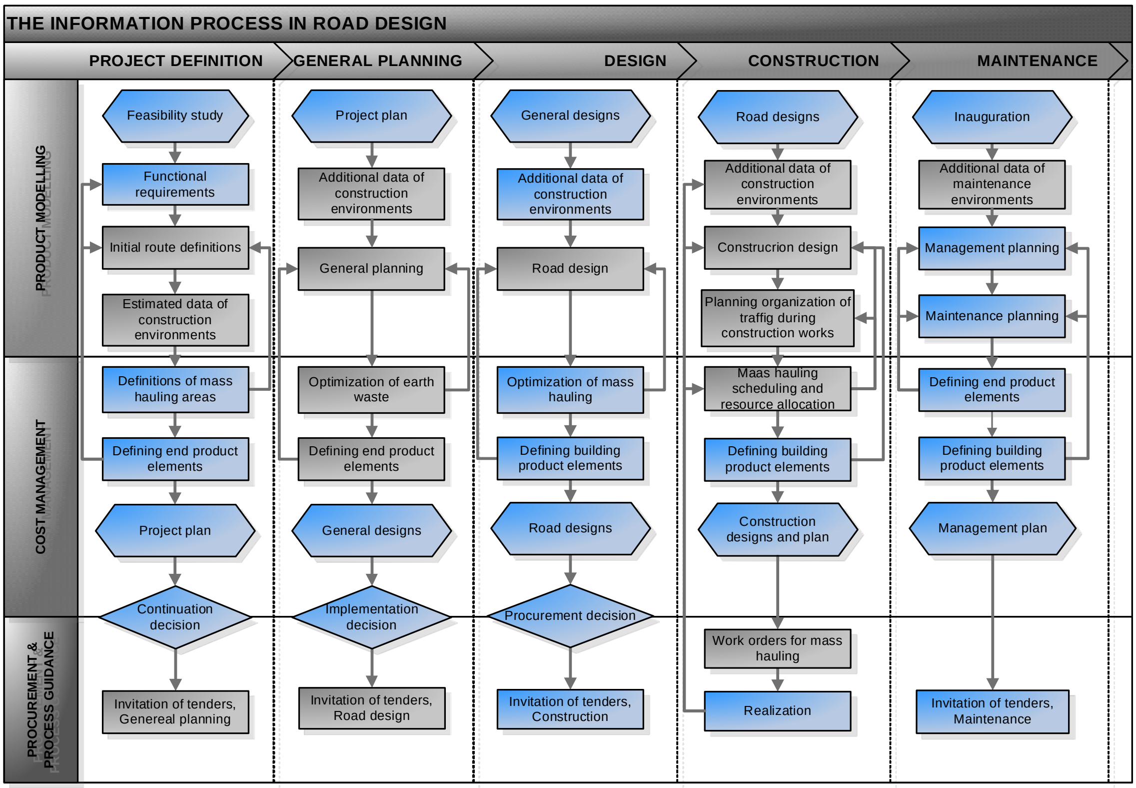

Figure 5: Road design, data flow in the information process.

In *project definition phase*, the product model is initialized against one or more very roughly defined routing alternatives. Systematic project scope definition process generates initial product models and sets of end product elements, with different functional requirements and routing, for comparison. Construction environments conditions and characteristics are roughly estimated in order to gain comprehension of construction difficulty level and costs. Also the first definition of mass hauling areas should be carried out. The risk of miss-approximating the costs, at this phase, are relative to the level of information about construction environment. The systematic project scope definition process outputs are one or more product models with "one-dimensional" parametric road model. The road model, in this phase, lacks any geographical manner of expression. The parameters of the road model set rules for design process in following phases.

In ideal design process the designer receives, after project definition phase, the initial product model in digital form. The designer is able to start more detailed design work immediately. The design work is guided by the product model parameters. The designer is able to deviate from rules set by parameters, but the designer is obligated to have good arguments for any deviation. *General planning* includes also environmental impact evaluation, like noise calculations. Combining all available information the designer is able to produce further developed product model. The road model gains initial alignment and horizontal profile. This enables first trend-setting mass calculations and optimization of mass usage. Basic information gets more specified and the set of end product elements can be decided. After the first ground setting designs, the costs of the construction are quite fixed with some deviation limits. Cost deviation is possible within the allowed change-limits of alignment and horizontal profile. Also the costs of actual building process elements can vary.

During *road and construction design* phases the product model is developed into very specific level. The product model is completed and the basic information of construction environment is detailed enough for construction planning purposes. Based on completed road model, the designer and the contractor are able to decide the comprehensive list of building process elements. The completed product model is delivered to mass optimization software for analyzing. The mass hauling optimization process is carried out and earth moving operations scheduled with allocated resources. The mass hauling optimization process is iterative in nature. If it becomes obvious, that in order to achieve mass balance, there has to be some design changes, the product model is returned to design software for revision. After this, the economical risks are again estimated based on the amount and accuracy of construction environment information.

The mass hauling schedule becomes the backbone of infrastructure construction project. Surprisingly, in modern road construction projects the mass haul planning can be quite demanding task. In major, road construction projects realize in road sections already in traffic-use. Construction works are not allowed to cause disproportionate blocks of traffic. Based on mass hauling plan, the planning of traffic organization during construction works is carried out. This action requires that the product model enables delivery of mass hauling plan to design software. In design software, the mass hauling plan is analyzed and required temporary structures, traffic signs and markings are designed.

During the construction works, the product model is utilized again. By the use of product model, the contractor is enabled to produce, within design software, daily or weekly work orders with guide maps for mass handling actions. The work order can also be used for reporting the realization of mass hauling works. These reports are inputs for realization analyzing. Based on realization analyzes, the contractor can produce estimates and revision of the construction schedule. Quality control of the infrastructure is carried out by as-built measurements during the construction works. As-built measurements are inputs for analyzing, among other things, realized masses, structure thicknesses and slopes, as well as keeping the agreed tolerances. While analyzing the as-built measurements against the product model, one builds up the product model of realized infrastructure.

3.3 Benefits of the Product Model and the New Design Process

The benefits of product model based design process are quite obvious when one thinks the process trough. One might ask, is there any other intelligent way to do this? All information produced during the process is somehow linked or based to previously produced data. So called rule based designing, managing data in similarly controlled way in all project phases and utilizing common product model in design process enables guidance of the design output and ensures that the functional requirements of the structure are fulfilled. This process approach also brings more economical predictability and fewer risks to infrastructure design and construction. Also, when the product model is sensitive against inaccurate or faulty basic data, the economical magnitude of possibly realizing risks is known and can be budgeted for.

4. The Benefits of the Process

The benefits of the new product model based design process are:

- The cost management is based on the real defined scope, which is a target for the cost management
- The scope and the design solutions are comparative through the design process
- The data transportation between the systems and the organisations is fluent because of the product model and data is not wasted
- The systematic cost management and data transportation save the amount of the working hours, which were used to routine work
- There is more time to research the alternatives and innovate

5. Conclusions

The infrastructure management is traditionally organised by public organisations. The cost management and the data transportation were developed by the organisations in the branch separately with no collaboration. Now the world has changed. In Finland the public sector is concentrating to the property owner duties. The actual construction and maintenance work is done by the private companies. The property owner has to concentrate to the role of owner in the world of tighter resources. The product model based design process is still developing. The companies are building up a new development project with the University. The results from the piloted process so far indicate that:

- The focus of the design process needs to be in the earlier stage of the process
- The design should be more cost oriented, now many cost effective decisions are passive parts of the process
- The new common nationwide or even more nations covering data model should be developed and taken in the use
    - now too many resources are wasted to routine work
    - now too much data is wasted

Abstract

The main objective of our research is to develop a tool that helps the management of a building project and aids cooperative design. In this paper, we present a cooperative system called Bat'Map developed according to the model of the Virtual Cooperative Project. This new model of cooperative design takes into account the relational organization of the project and the semantic meaning of works. This system lets geographically dispersed project actors model the project context of a building. More specifically, it allows interpreting, using and exchanging project works in a centralized virtual environment during the building life cycle. This system uses IFC objects which associate in the same model the semantic and the 3D representation of building works. This research represents a new approach because it not based on management of documents but on all data relative to works. So, in the first part of this article, we propose to view collective typology of building domain activities and the exchanging data mode of cooperation tools. The second part of this article illustrates the IFC model. Then we justify the interest shown in a model of cooperative design used for defining a design-aided tool, to deduce advantages and limits of the "Virtual Cooperative Project".

Keywords: Cooperation model, cooperative work design, project management, digital mock-up

1. Introduction

Architecture design is by nature an integrative discipline, drawing upon a wealth of knowledge. It has a strong tradition of interpreting its results not by scientific metric knowledge but through self-referential validation [1]. In fact, an act of design is a designer's interaction in a group of designers. Points of view are often shared between contributors, and decisions about different project aspects are submitted for common approbation. The global organization of the design process allows actors to develop and to prescribe tools and methods improving design. Most of these tools are unsuitable because they don't sufficiently take into account the cooperative dimension and the implicit nature of building designer work [2]. It does not enable them to treat all the semantics of the works especially the one relative to cooperative design (difficulties in tracking actor's work, lack of all the required information, coordination problems, etc). So, in this paper, our objective is to define a tool that must help designers to obtain maximum project context data and structure works semantic meaning, which allows good objectivity in decision evaluation. This will be able thanks allowing actors to get reliable data concerning the state of the project in order to determine what the actions to be carried out are.

This paper will briefly review collective typology of building domain activities as well as the data exchanging modes. It will then illustrate one vision of the digital project deduced from the analysis of the IFC object model "Industry Foundation Classes" imported for construction. The aim is to identify the capacity of the current IFC digital mock-up to structure the cooperative design activity. After that we justify the interest shown in a new model of cooperative design where the relational organization of the project and the semantic meaning of works are taken into account. Finally, we use this new model for defining a design-aided tool, to deduce advantages and limits of the “Virtual Cooperative Project”.

2. Cooperative Design in the Building Domain

Design activities correspond to a sharing of a space, which contains common and shared objects. This space is always extended by individual contribution (in cooperation) and by collective contribution (in collaboration). This co-production is structured by actors’ coordination.

2.1 Collective Typology of Building Domain Activities

We differentiate three categories of collective building domain activities:

- Cooperation is defined by acting jointly through a non-structured informal relationship. The rules are invented progressively. The coordination is founded on an implicit mode between the actors.

- Some authors like Dillenbourgh (1995) and Lonchamp (2003) [3,4] explain that collaboration is one elaborate form of cooperation. It consists of teamwork producing common work. It requires a large amount of explicit coordination with precise and hierarchized progress (Table1).

- Coordination allows the group members to articulate each action to design and to realize together collective products. Coordination is the mechanisms through which individuals integrate their productive activities [5]. It interferes either at the moment of the final assembly of the partial contributions in a cooperation setting, or throughout a task realization in a collaboration setting. The coordination organizes and structures the cooperation and the collaboration activities: it is inseparable from either of them. The coordination constitutes the mode by which the collective activity is sure to be efficient.

Table 1: The difference between cooperation and collaboration.

	Cooperation	Collaboration
Work mode	Acting jointly	Working in a team
Objective	Actors have a common objective but don't have a common underlying objective	Actors have a common objective and a common underlying objective
Evaluation method	Actors are evaluated in group	Every actor is evaluated independently
Relation nature	Relations are not definite and are unstructured	Relations are lasting
Activities progress	The rules are invented progressively	Activities' progress is known and hierarchized
Coordination type	Large amount of implicit coordination	Large amount of explicit coordination

The collaboration, cooperation and coordination operations are the basis of group activities. Collaboration is an activity where processes are known and repetitive. On the other hand, every building actor works to carryout underlying tasks, and cooperates to assemble their contributions in a common production using coordination. Design is an important building collective activity of reciprocal prescriptions. In a design project, actors cooperate to achieve a same objective, which can be the production of documents, solutions, comments, etc. Criticism and negotiation represent important decision actions. Because of the implicit character dominating in the building domain, a great number of heterogeneous variables are taken into account to design and to construct. As result of this, actors must cooperate successfully and have assistance to save time and money. Today, actors use more and more tools to assist their work, and technologies to structure their exchanging of data and to manage building project.

2.2 Data Exchanging Modes in the Building Domain

In construction, there are two types of cooperation approaches. The first one is founded on documents and exchange files. It is structured by several data exchange practices: manual management of exchanges (sending disks, maps, etc.), exchanges by electronic Email, exchanges through PDM, cPDM[1], etc. Some of these practices save time and are efficient through big projects, etc. Some others show little trace of sharing and are submitted to precise structuring rules for drawing up documents, etc. The second cooperation approach is based on the use and the manipulation of the semantic meaning of a project. It constitutes an experimental practice

[1] Product Data Management (PDM) is a component of the technologies of data products. This concept covers the set of techniques, methods and tools aiming to communicate, on an electronic support, the product data within a company. CPDM is a cooperative Internet version of the PDM.

which consists of sharing a digital mock-up[2] and modeling building projects with interoperable objects. This practice has not yet shown its efficiency, but is being followed with great interest.

3. IFC Digital Mock-up Model

A large variety of CAD software is proposed in the engineering domain. CAD software is specialized for civil engineering professions and has its own modeling concepts [6]. The data exchange between CAD software is so difficult, due to the heterogeneity of the modeling field. Most of these software solutions are based on proprietary solutions with their specific technical model [7], and model the building with 2D geometry. In this formalism, no semantic information specific to the building objects is modeled. To bridge this gap, the International Alliance of Interoperability has proposed a standard called IFC that specifies object representations for construction projects. Industry foundation classes[3] (IFC) include object specifications, or classes, and provide a useful structure for data-sharing among applications. A door IFC, for example, isn't just a simple collection of lines and geometric primitives recognized as a door; it also has a door's attributes (material specifications, prices, etc.). The adoption of this standard by all the leaders of CAD software allows a better interoperability in the exchanges of information between the various civil engineering professions.

The IFC product model is a universal model for the description of buildings over their complete lifecycle. It has been one of the strongest aims of research and development since the early days of Computer Aided Design in the building industry [8]. In the IFC, we found a "product model" that uses the STEP[4] norm. IAI had adopted many STEP industrial standards, but their building sector adjustment raises some data exchange problems:

- The trace of actor actions: IFC model show tangible blanks about intervention traces and the actor role definitions in the development process of a digital mock-up. Until today, we cannot indicate whether an object has been proposed or validated by an actor (IFC 2.X release) [9].

- The project evolution cycle in digital mock-up: During the design of the different objects making up the project, the IFC model doesn't permit us to assign them the progression levels defining the project evolution. We cannot know if an object is under design, under modification or already validated.

---

[2] The digital mock-up is a graphic computer representation, in 3 dimensions, of project works and spaces evolving throughout a life cycle. This representation is partial and reflects a given point of view of an actor. (Ex: the digital mock-up of a climatic engineer, of a structure engineer, etc.)

[3] Industry Foundation Classes are currently the more successful to constitute the shared digital mock-up realization in the building domain. The IFC represent a standard of exchange and sharing of data [10].

[4] Standard for The Exchange of Product data model: are international computer exhaustive descriptions of physical and functional features of any industrial product type during its life cycle.

- Semantic meaning used to design works: In the latter IFC update, we cannot attach to every object its manufacture constraints, its rules for setting up, etc. (Among the set of model attributes, there is no specification about regulation rules, structural characteristics, plastic qualities, etc.)

Thus, IFC model shows lacks relative to the cooperative dimension. This model must takes in account the flexibility of current practices and operating mode of project building: so the structure interest of the all exchanged semantic meaning relative to project works.

4. A Cooperative System Developed According to the Model of the Virtual Cooperative Project

In a design cooperation process, the fact that building actors get reliable data concerning project states, helps them to determine what the actions to be carried out are. When concentrating on the data exchanged during the project design, the works are the main focal point. In the same way, every project work holds some relation with its ‘environment’: with the actors who designs it, the documents that represent it and the activities that create it. Our objective is to provide actors with a real vision of the design process evolution thanks to a digital project (Figure1).

The digital project constitutes the set of data defining works constituting a building. It is an expanded data representation of the different updates of digital mock-ups during the building’s life cycle. This project is created and shared by all building actors (according to right to access) on an Internet platform. Every actor’s action on documents and works is traced and linked back to the actor. In a digital project, exchanges are managed and facilitated thank to the use of interoperable standard data. The digital project constitutes a virtual cooperation environment for structuring cooperation and communication activities.

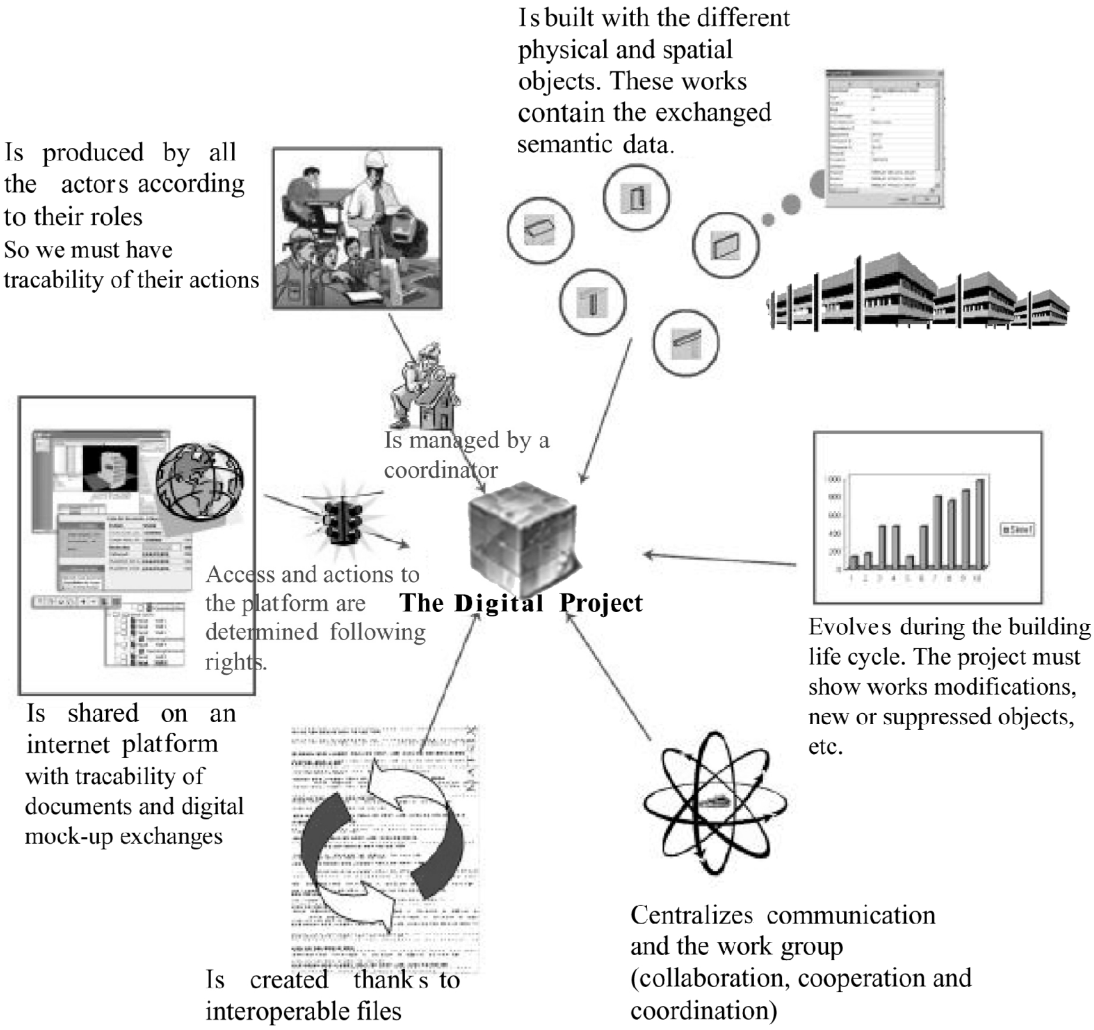

Figure 1: The different dimensions of a Digital Project

4.1 The Meta-model of Cooperation and the Work Model

We propose a cooperation meta-model[5] that allows the taking into account of the existing relations between the elements of a project (actors, activities, documents and objects). The instantiation of the objects allows the definition of the VCP. The Virtual Cooperative Project (VCP) is a project that we have initiated in the co-designing domain, having as a target the definition, the design and the realization of a model able to assist cooperative design in architecture using works (instantiation of objects).

---

[5] This meta-model is described in MOF 'Meta Object Facility' [11], and used to distinguish concepts, which are common to every design project practice.

A work represents a physical object making up the basic brick of a digital mock-up. This object is characterized by its geometrical and topologic data but also by its semantic meanings. Every work belongs to a class, possesses attributes, relations and is set according relative constraints. A work is the result of coordination activities given during the project and throughout the design cycle until the realization. The works have different design phases and indicate the modifications that they have incurred as being associated with the actors who use and modify them. In the Virtual Cooperative Project, the model of work is structured on 'simple work' (indivisible building work) and 'composed work' (composed of simple works)

The work's semantic meaning represents all data excluding geometrical and topologic data, and is used to define work all along its life cycle. So, in the objective of structuring an aid to the works' design, trying to group maximum data throughout their creation, we have set up a classification table of semantic meaning used to design a work (physical attributes, regulation constraints, structural properties, financial aspect, etc.) However, we distinguish five subtype classes of the 'simple work' following a professional logic taking account of the notion of design evolution during building life cycle: we design structure works first, then those of partition, of equipment, of cladding and finally accessory works. Finally, works maintain four types of relations:

- The relationship between activities and works is distributed in time and shows the works' evolution during the building's life cycle. It is a dynamic relationship. For example: a project generates a digital mock-up; a digital mock-up evolves in a phase; tasks and requests concern works, etc.

- The relationship between actors and works is referential and associative. It indicates actor's interventions on works. It is a dynamic relationship and allows us to distinguish each actor's design work and reflect point of view. For example: an architect creates, modifies, deletes, or validates a work, etc. The study of the relationship between actors and works allows us to identify the relevant semantic meaning related to building works, for each actors' profession. So we have used the classification of works' semantic meaning and the several actors' professions, to set up a table identifying semantic types that interest mainly each actor[6]. This table enables us to develop in Bat'Map a personalized digital mock-up visualization for the different actors.

- The relationship between documents and works is relative to the data specifications. It is a static relationship. For example: a document describes a category of works, a work makes reference to some documents, etc.

- The relationship between works is relative to their design. We distinguish those linked to their development and those linked to their space organization, as a dynamic relationship. We distinguish too those linked to the nature of the relationship between physical parts, as a static relationship. For example: a wall is set on a floor, a beam holds a column, a window is situated in a wall, a digital mock-up evolves in another update, a wall is subdivided in to several walls, etc.

---

[6] This table is established thanks a statistical survey applied to a several number of actors in four French building analyzed projects.

4.2 The implementation of Bat’Map

To manage a project ‘type VCP’, which generates a great quantity of information; we have used an interactive navigation interface to develop Bat’Map. This graphic interface constitutes a tool for the cooperative management of a digital project. Bat'Map aims at total structure of the project context using nodes and links. Different types of icons represent the fundamental concepts of a Virtual Cooperative Project (Figure2).

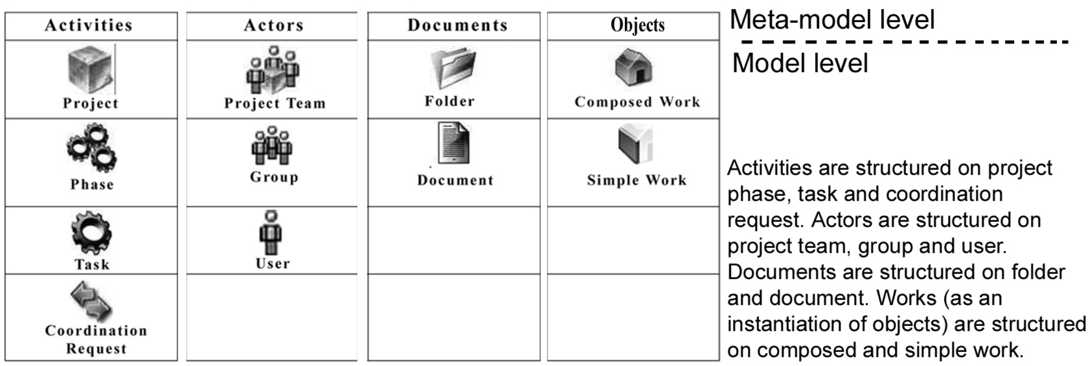

Figure 2: Icons representing concepts of cooperative activities in Bat’Map

On the other hand, Bat’Map is a computer-based system that supports actors engaged in a goal and provides an interface to a shared environment. Bat’Map allows users to initiate a cooperative project environment by identification of actors, activities and documents. When the first update of the digital mock-up is created (‘.ifc’ type file), a coordinator proceeds to its download from a Bat’Group[7] web platform (Figure 3). The system interprets (thanks to a parser[8]) IFC’s data relative to the works; visualizes digital mock-up using a “composed work” node and the works composing it using a “simple work” node. When deposing this first version of the digital mock-up (for example by the architect), the creator will have an automatic link with all works making this digital mock-up.

---

[7] Bat’Group is a groupware developed in our laboratory CRAI-France. Bat’Group as Bat’Map gives to each actor an adapted vision of the project context, concepts of actors, activities and documents [12].

[8] We have developed a parser, which converts data relative to works contained in the IFC file (written in Express) to compatible data with Bat’Map interface (written in Java)

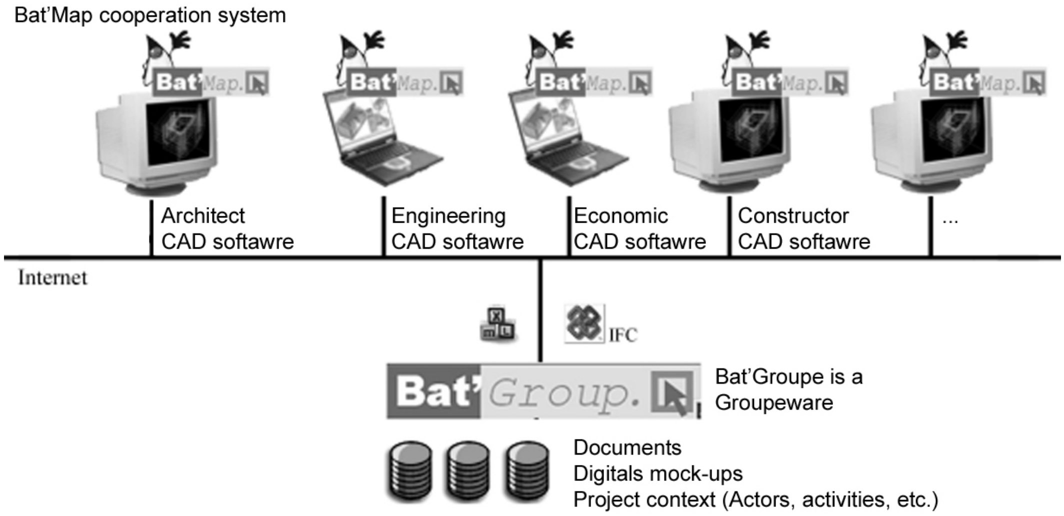

Figure 3: The Bat'Map context use.

When updating digital mock-up, the works evolve. So to identify the new modifications, we adopt 8 states relative to the works. Every work evolves and has different states. A node state represents one work evolution context and is represented by different icons. We have used colors to distinguish cooperation states: inactive object, active object, an object submitting a problem and an approved object. Then, we have used different icon forms to distinguish development states: a suppressed work, a new work, a modified work and a work without change.

Every digital mock-up update, the system proceeds automatically with identifying changes to works, thanks to a comparison between the ".ifc" data. Then, the system proceeds with linking works to the actor (author of the new update) as the one responsible for the suppressed, modified and new works. Works without change are linked to the last update designer, etc. These links between actors and works allow action tracability during the project design.

To facilitate navigation in Bat'Map, we have developed filters and functions allowing an adapted navigation following user needs (to show only works nodes, only actor's nodes, etc.) On the other hand, we have integrated an 'IFC 2.X Release' viewer to allow designers to visualize works. A 3D visualization lets participants move around and in the building. That allows designers to obtain information about the objects that comprised it. Likewise, users can specify in Bat'Map links to other software, in the objective of visualizing text documents, pictures, maps, etc. Finally, we have adapted and developed in Bat'Map works representation and semantic table visualization for each actor's profession.

We conduct two experiments to test the Bat'Map capacity to assist cooperation design in a building project. The script adopted for the experiments describes the design of two buildings (a wooden salt store[9] and a building extension in France). Actors coordinate themselves in a distributed asynchronous mode. The script steps cover: the building evolution throughout analyzed phases, the cooperation activities solving design problems, the digital mock-up updates, the validation of phases, etc (figure 4).

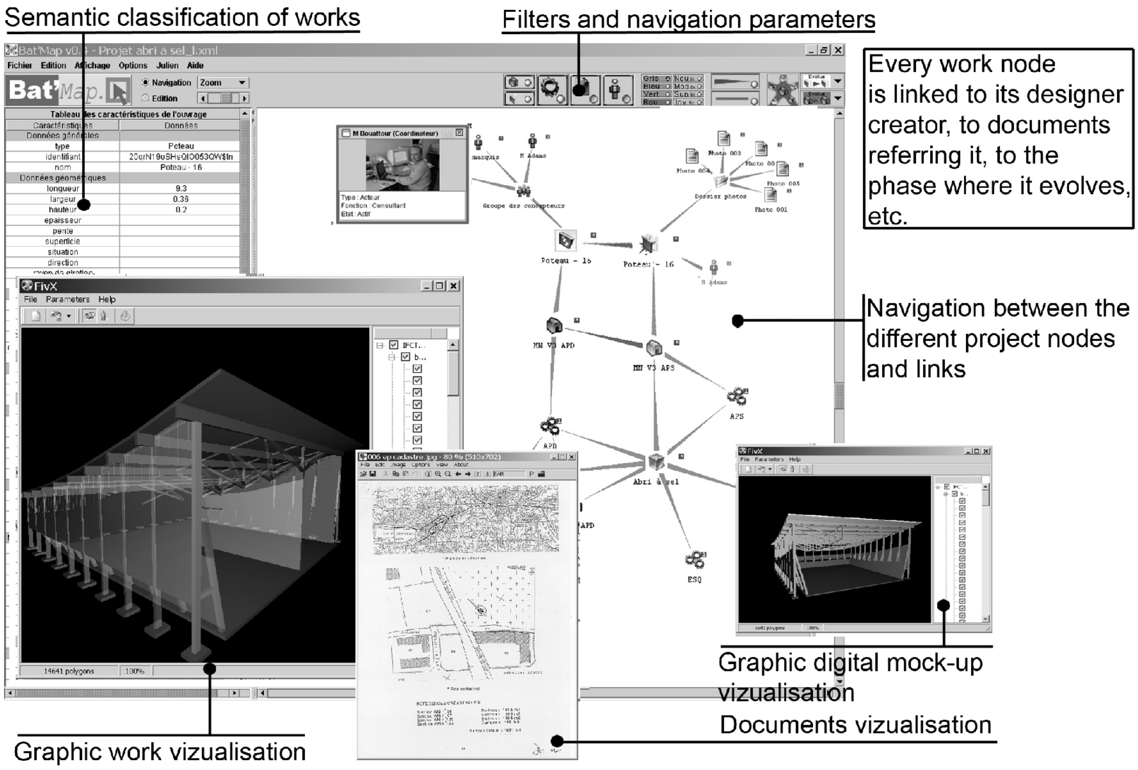

Figure 4: Visualization of the project context of the salt store with Bat'Map.

As a result of experimentations, we notice firstly that the representation of cooperation design context of a building permits a global view of the project: actors, phases, tasks, documents, works and relations between these concepts. Secondly, comparison of several digital mock-up updates during all the phases of the project allows designers to save time when they have to identify changes between updates. Bat'Map allows users to have a clearer view of the building life cycle, and to trace all actors' actions on works and documents. This constitutes a great assistance to the project management. Thirdly, semantic meaning management of works represents a design aid. The fact that designers use all the documents and data relative to a given work, allows for good objectivity in their choices, and enables them to take into account a maximum constraint. Finally, like filter functions, the visualization adapted to actors' professions allows users to have a clearer personalized vision of digital mock-ups and work semantic meaning (figure 5).

---

[9] Salt store is a building used to protect salt against damp. It is employed for the bulk storage of salt. Salt is sprayed on roads against to protect frost.

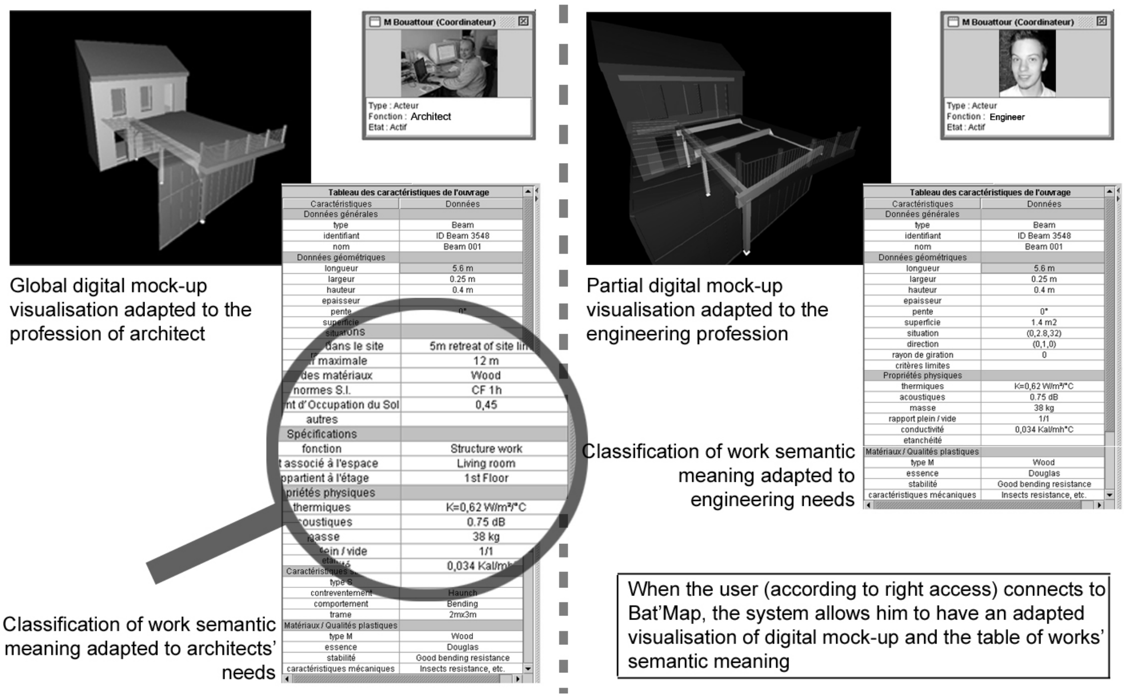

Figure 5: Adapted visualization in Bat'Map.

5. Conclusion

The European Building and Construction industry is to a great extent dominated by small and medium size enterprises. The fragmented nature of this industry necessitates cooperation assistance tools to enable users to design buildings efficiently and manage projects. This paper presents a new approach of cooperation aided-design, which proposes a new data organization of building context, by the representation of the existing relations at same time on the site, and also inside the project. The works are on the basis of Bat'Map (V4.0) development. This cooperation system provides a set of processes, functions and databases placing the IFC at the heart of the project context. The main advantage of using these objects is to provide actors with structured data related to the semantics and the 3D representation of building works.

Bat'Map is developed according to the model of the Virtual Cooperative Project in order to reinforce cooperation and group awareness. This system proposes the structuring of a cooperative project context. It proposes partial views which allow actors to navigate in a virtual environment, to be informed of the progress state of cooperation activity, to study latest digital mock-up updates and changes brought about, etc. The identification of the different states of works allows actors to have a clearer idea of every work and digital mock-up statute. The semantic meaning thus obtained permits actors to adapt their vision of the design evolution and to avoid wrong decisions. The results of the study also show that the visualization of the different digital mock-up updates allows us to have a trace of actors' actions (author, date and modification objects), saves time in the identification of changes and allows us to specify the respective responsibilities linked to modification, creation or forgotten works.

Abstract

In this paper, preliminary results from the ongoing Finclad2 project are described. Finclad2 is an enterprise driven synthesis of two bridging projects coordinated by the Finnish Constructional Steelwork Association (FCSA). The focus in these projects is on the development of design and decision support tools and on combining requirements management with product model environments. Foundations for the current work date back to the earlier Finclad1 project (2002-2003).

The requirements management process is to ensure that we know the customer needs and that the solutions efficiently meet those requirements, thus increasing the final products value. Even though life cycle approach has become increasingly popular, an illusion of sequential process phases still dominates esp. in construction industry. In practice, due to the parallel nature of design and construction phases (and to some extent, even operation), requirements setting, updating and verification have to take place throughout the project.

Recently, the open international standards for building design information exchange have become more robust and more widely used. In particular, the International Alliance for Interoperability (IAI) is continuously developing the Industry Foundation Classes (IFC) open model based information exchange specification. The coverage of IFC product model has enlarged during past few years, and nowadays it contains project information related to, for example, actors and assets; elements and spaces; structures and zones; systems and environmental impacts; schedules and costing; equipment and work plans; associated documents and classifications. Focus has also started moving towards service life and requirements management. This shift is expected to enable and motivate developers and practitioners moving towards consumer driven process.

In the present IFC version (IFC 2x2) expressing product requirements is supported in a modest way. However, it is evident that product model technology has developed to a level where extensive requirements management could be enabled. This progression leads to increased interoperability between customer needs and design solutions, by defining explicit “requirement”-objects and their relationships to design objects. The authors highlight though that there are still many open questions needing answers.

The results from Finclad2 project define classification for requirements managed in product model environment, as well as guidelines for their attachment to IFC product model design object. It is apparent that in this approach requirements are set in various levels, such as component, system, space, zone or building (or even project) levels. Traditionally, requirements have been captured on a very generic level (project or building), whereas in the Finclad2 case the target is on exterior wall level, which introduces challenges in linking of space requirements to wall properties and production planning; also, design application developers have challenges in including requirements management in their software. In result, a test environment for requirements management is created and set of requirements is exported in an IFC file.

Keywords: Requirements management, classification, IFC, interoperability

1. Introduction

Finclad2 project was launched at the beginning of 2004. It is an enterprise driven synthesis combining two bridging projects, led by Finnish Constructional Steelwork Association (FCSA) and Tekla Corporation, respectively. Results introduced in this paper are a part of a research activity carried out by Technical Research Centre of Finland (VTT) and belonging to the FCSA part. Foundation for the current work was laid in Finclad1 (2002-2003) project, which among other tasks, described common cladding wall structure types and the use of IFC specification for exterior walls, as well as listed the basic requirements to be considered [1].

The goal of Finclad2 is to implement previously described wall structure types as adaptive objects to software. Firstly, the purpose is to take advantage of the previous development results in practice. Secondly, the project emphasizes production chains by offering means to exploit product models more efficiently, especially for capturing and managing requirements during a project.

This paper discusses the issues of requirements management in general, and possibilities of model based design and requirements management using IFC product model in particular. Main goal is to find solutions on cladding wall structures and how their properties can be managed and how the process can be supported by ICT tools and model based information exchange/sharing, through the life cycle of buildings.

The final outcome of the project will be presented at the end of year 2005. Finclad2 is financed by Tekes, the National Technology Agency of Finland, and the enterprises participating.

2. Requirements Management

2.1 Requirements Management in Building Process

Requirements management is targeted to increasing final products value; it is a process assuring that the building performs as expected or better in its intended use. Overall goal is ensuring customer satisfaction. It is described in numerous sources as a set of procedures helping to understanding, modelling and analysing the needs of users and other participants' processes, and tasks in a realisation process towards a common vision [2, 3, and 4]. Life cycle view has become stronger and the ideology is supported by various practices, such as value management and commissioning, that are used for assuring convergence of building performance towards user needs set in the beginning.

In construction industry a false illusion of sequential process phases still dominates. Clear indication that is also understood in practice is parallel nature of design and construction phases. Kiviniemi represents difference of sequential and parallel process view clearly (see Figure 1) [5]. In this context the requirements management practices need improvements; the procedure evolves during project execution and at the moment the practice doesn't support rapid changes taking place in projects, especially during design phase.

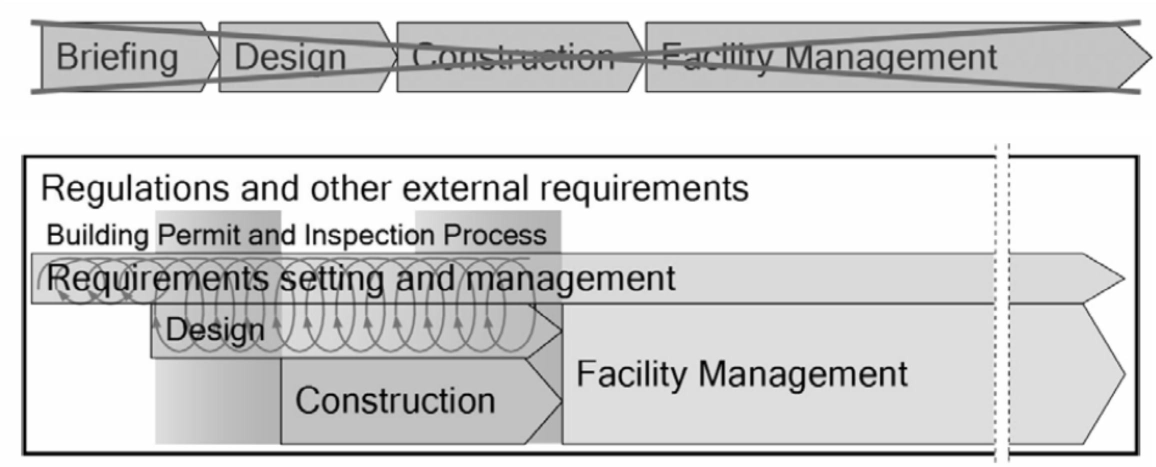

Figure 1: False illustration of sequential process and more realistic parallel process view (Kiviniemi 2005).

General requirements management process phases are:

1. Requirements setting,
2. Requirements updating
3. Verification of the requirement realisation in practice.

Buildings are unique solutions, each having individual requirements. Careless requirements setting increases risk of ending up in significant problems later. If the purpose of requirements management is not understood correctly, it might be seen as a mandatory task producing nothing, which is not the case. Actually, great potential lies in requirements management: it should be seen as an intermediate tool between user and design team, helping to reach satisfactory end result. The most critical step should be capturing user requirements instead of getting straight into technical solutions. Users look for a building that is customisable to their operations, not vice versa. Far too often requirements are lost or misinterpreted during design and construction phases. Figure 2 describes the possibilities of loosing or adding value. Practitioners should be able to offer new and innovative solutions along the building process; at the moment tools enabling this are still lacking.

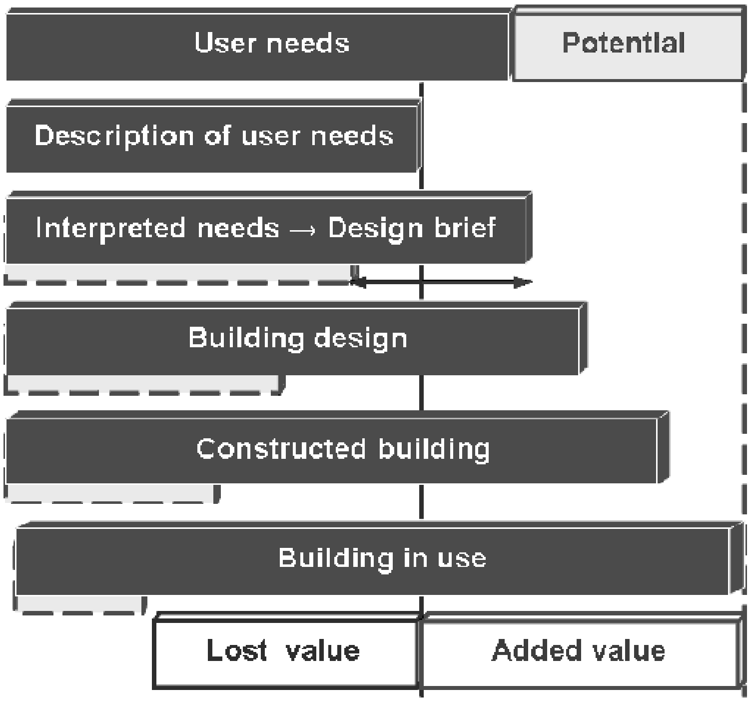

Figure 2: Potential of Requirements Management [6].

There are many kinds of problems existing; such as [7]:

- Communication problems (between process phases and in connection to users),
- Lacking of a systematic and standardised data transfer,
- Binding strength of requirements and design solutions,
- Inadequate change management practices,
- Insufficient verification practices

Change from prescriptive approach to performance based approach is taking place. Prescriptive approach describes first building parts and attributes and comes backwards to requirements (technical solution oriented). Performance approach specifies requirements for building parts and then various solutions meeting these conditions are provided by designers [8].

2.2 Requirements Management in Exterior Cladding Walls

Investigation of current practises in requirements management was carried out. Since the current development efforts are directed towards model based design, the ProIT process model [10] was analysed and the essential feedback gathered from participants was projected on it. Figure 3 describes main information flows in current process and it is intended to visually express certain bottlenecks and weak spots. Main processes are: 1) Architectural design 2) Structural design 3) Manufacturing 4) Installation 5) Use and maintenance.

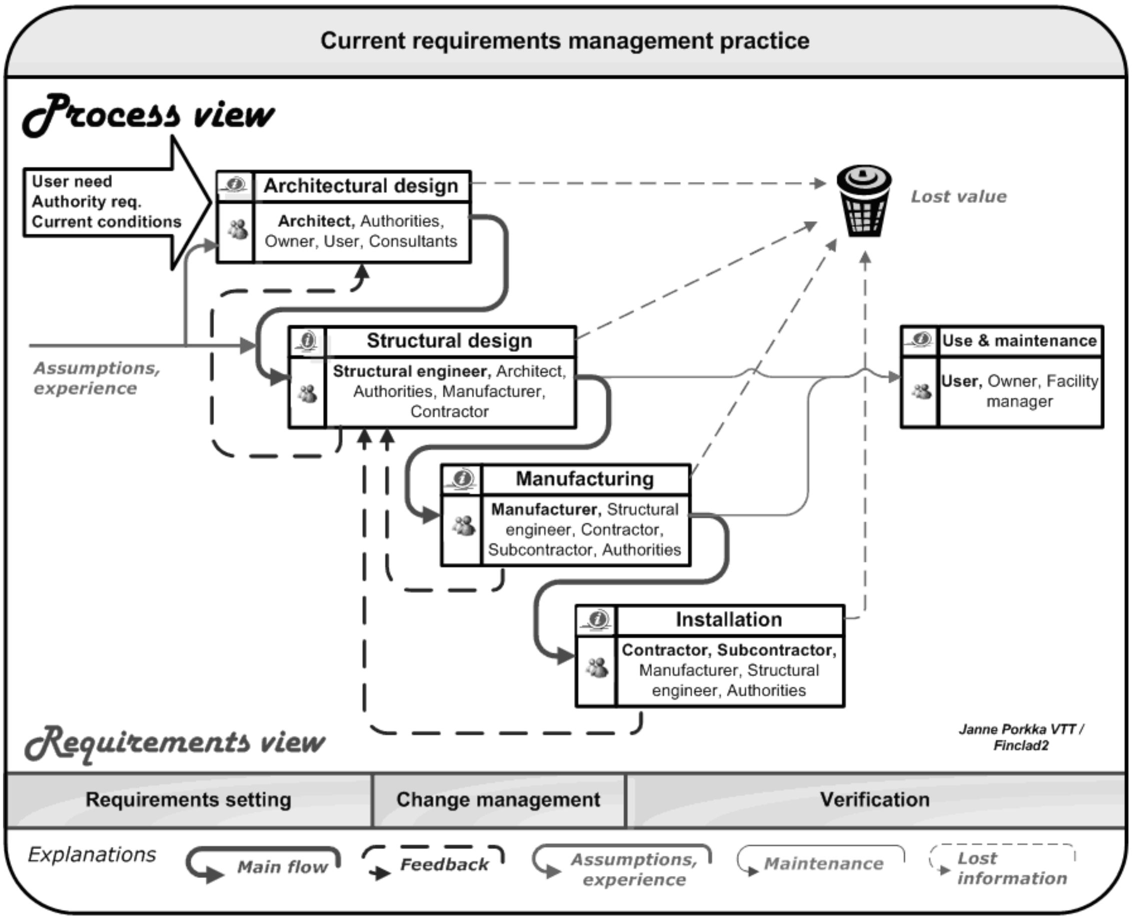

Figure 3: Current requirements management practice in Finland according to cladding walls.

Nature of requirements setting is consistent; process goes from general level towards details and specifications. Practices of requirements management by individual participants vary greatly. Even with the most organised practitioners improvement needs exist. When individual participants express requirements differently– the overall process with interfaces to many participants gets even more problematic. Main bottleneck in current requirements management practice is lack of standardisation and large part of requirements never get documented during architectural design. This knowledge reserve is covered by tacit knowledge - or leads to lost value.

Architectural design captures main requirements set by owner, users, authorities (standards, specifications) and current conditions (location, surroundings). Finnish construction practise is rather well standardised and therefore large share of requirements come directly or implicitly from standards such as National Building Code of Finland [9]. Only a limited group of owners are willing to put more effort in setting requirements; additionally, user requirements are described rather in every-day-language than technical terms. In detailed cladding solutions architects rely on experts and consultants. Requirements are expressed in drawings and textual documents, such as design brief. Bottleneck in current practice is data sharing between architectural and structural design. Large part of the requirements remains only in architects mind and do not reach the structural design and later phases. From experts point of view information is partly considered too obvious and standardised way of sharing requirements is missing.

Structural design provides detailed requirements for product manufacturing, installation and also to use and maintenance phase. As described earlier, the starting point is the weak spot. Shortage of requirements in kick-off increases iteration work and leads to assumptions; this also increases the risk of ignoring essential requirements. Overall, the nature of requirements management in structural design evolves from requirements setting to change management and finally to verification. Standard on how requirements should be described is missing, and current practise vary by case.

Manufacturing and **installation** have very specific requirements. Manufacturing produces also requirements back to structural design, and further to installation. It requires active cooperation with structural engineer, especially when making iterations on change management. Phase includes also detail and product reviews. In installation, the end result is verified against the set requirements. Installation is considered as a task producing feedback to structural design on work sequences; the working order must be considered already in structural design, and therefore details of installation must be considered at early stage.

Overall, the weak spots detected in current practice are:

- user requirements capturing,
- communication between architectural and structural design,
- the quality of set requirements, standardisation lacks,
- specific manufacturing and installation requirements and maintenance manual,
- change management and verification of set requirements and end result,
- knowledge reserve among stakeholders – tacit knowledge (or lost value).

A lot of headache is caused by the gaps between participants: fragmental data exchange leads to rework and confusion. Other development needs are seen in the learning process; past mistakes should lead to immediate development and to process changes if needed. We should consider methodical development possibilities, such as commissioning and performance based approach. Both highlight the continuous requirements management as a development enabler.

3. Model Based Requirements Management

Recently, the open international standards for building design information exchange have become more robust and widely used, in particular the product model specification for AEC/FM, the Industry Foundation Classes (IFC) [13]. The IFC is developed and published by the International Alliance for Interoperability (IAI), established in 1995 and currently operating as a not-for-profit company in the UK, with 10 active chapters globally (about 500 member companies and other organizations in these chapters). The mission of the IAI is to enable ICT interoperability, based on open specifications, in the AEC/FM industry processes throughout the building lifecycle. The IFC is a specification for data exchange and information sharing between computer applications used by project participants in design and construction as well as operation and maintenance phases.

The first set of IFC was published in 1998 as Release 1.5; current version IFC2x2, released in 2003 utilizes extensibility mechanism by which new concepts can be added to support areas not previously existing in the IFC model (e.g. structural engineering and steel construction were introduced in 2x2); a new release (IFC2x3), extending the IFC model in the same manner as IFC2x2 did, is expected in spring/summer 2005 (with some improvement in requirements management).

The IFC specification aims to cover information in all aspects of buildings and processes encountered in their production and operation; the IFC product model may contain information related to e.g. actors, assets, elements, spaces, structures, zones, systems, environmental impacts, schedules, costing, equipment, work plans, associated documents and classifications. At the moment the focus of development is moving towards life cycle management, meaning improvements on requirements management support also. In practise this would mean that in addition to ‘conventional’ design objects, such as *IfcBuilding*, *IfcSpace*, *IfcWall* etc., also objects representing requirements as *IfcConstraint* could be defined independently and associated to those design objects as (and when) appropriate. The requirement objects would also have capability of being classified (an essential feature, as discussed later) and having owner and history, as well as relationships to other requirements.

Many research and development efforts are aiming to take advantage of product model technology. Finnish ProIT project has targeted to improvements in practice [10]. It declares information management of whole life cycle where data management takes place in process by product models. Product models in different phases suggested in ProIT are:

- requirement model
- design model

- planning model
- as-built model
- maintenance model

It's evident that model based approach has more strengths than weaknesses - though application interfaces need to be developed to support the exchange cases. For requirements management this means that early phases of projects are seamlessly connected to later ones. Industry is provided with means to set more detailed requirements separately for certain types of cladding walls. Overall target is to provide way to transfer data in same format through the architectural and structural design further to manufacturing and installation as well as use and maintenance - with requirements and verification data. In this context individual requirements are better managed and verification of received quality improved.

3.1 Combining Requirements from Authorities and Users

In this context a user means relevant project stakeholders, like occupants, owners and financiers of the building [11]. Requirements management in the building process deals with unique solution and diversity of participants. There are certain mandatory requirements steering the process, such as laws, standards and directives set by authorities. Amongst requirements there are also recommendations and rules that can be waived. Mandatory requirements contain basic conditions such as safety, conformity, performance, functionality and usability. Another group of requirements is optional requirements, such as user requirements.

During the requirements management process the set of user requirements is adapted to authority requirements. The compliance of design with the requirements should be verified constantly during the project. Participants should be involved in project from the very beginning; other enabler is functional communication. Purpose of requirements management is establishing a complete, consistent and unambiguous requirements specification [2]. There are certain characteristics portraying good requirements, such as being complete, unambiguous, consistent, feasible, solution neutral, traceable, necessary, used for right purpose, concise, correct and verifiable [10].

3.2 Considering Stakeholders

Nature of construction projects includes large variety of participants in decision making. It is very common that opinions vary greatly. In these cases judging methods and decision support tools are needed. It's suggested that the ranking of stakeholders' opinions is based on three attributes - power, interest and proximity [3]. This means that participants with high ratings are very likely to have their requirements accepted. Using the same analogy, stakeholders with low ratings don't have as strong influence to the performance of final product. Various stakeholders also see the requirement management effort differently – some like it while others see it as a disturbance to their routine work [3]. In cladding walls the requirements are mostly transferred simultaneously with drawings. It’s important to name the responsible people for requirements management. Also judging methods for prioritising requirements should be defined. At the moments standards in data transfer in requirements management are lacking, therefore actions of change management should be clarified.

3.3 Temporal Progress of Requirements Management

Phases of requirements management are described in Figure 4. In the beginning the emphasis is on requirements setting. After setting of requirements the overall process starts finding technical solutions and emphasis evolves towards change management and verification. The possibility to influence the end result is biggest at the project start. This is also the period when the practitioners have the best possibilities to effect the costs. Owners may allow certain investment cost for cladding walls per square meter; yet the solution must fill certain other requirements such as energy efficiency in buildings life cycle. Therefore, the most of the requirements management effort is committed to projects two first phases, architectural and structural design. Effort should diminish after these phases and change nature to change management and verification. The cycle defined in Figure 4 is done multiple times while adjusting requirements management; nature of setting requirements is consistent.

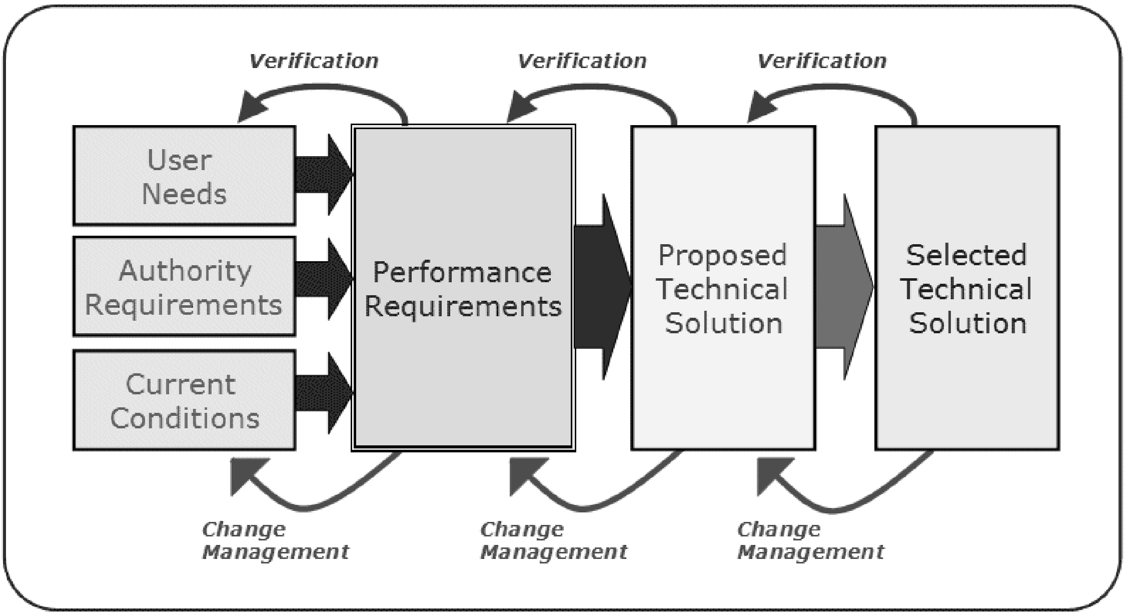

Figure 4: Requirements management process in performance based building [6].

3.4 Detecting Hierarchy of Requirements

Hierarchy of requirements means in this context the requirements classification. Classification is the way how the large information content can be managed. During Finclad2 project the requirement classification for exterior cladding walls, VTT ProP® Finclad2, was specialised form the general VTT ProP® classification. Classification contains structural description of requirements, expressed by categories such as safety and adaptability (see Figure 5) and individual requirements placed under these categories. One of the categories, adaptability is opened in Figure 6. Classification is important for meaningful data transfer between applications. It is also a guideline for producing complete and consistent information for later project phases; classification expresses the data in a form understood by all participants.

VTT ProP® Finclad2 CLASSIFICATION	
A CONFORMITY	**B PERFORMANCE**
A1 LOCATION	B1 INDOOR CONDITIONS
A1.1 Site characteristics	B1.1 Indoor climate
A1.2 Transportation	B1.2 Acoustics
A1.3 Impact on surroundings	B1.3 Illumination
A2 SPATIAL SYSTEMS	B1.4 Vibration conditions
A3 SERVICES	B2 SERVICE LIFE AND DETERIORATION RISK
C COST AND ENVIRONMENTAL PROPERTIES	B3 ADAPTABILITY
C1 LIFE CYCLE COSTS	B4 SAFETY
C1.1 Investment costs	B4.1 Structural safety
C1.2 Operation costs	B4.2 Fire safety
C1.3 Maintenance costs	B4.3 Safety in use
C1.4 Demolition and disposal costs	B4.4 Intrusion safety
C2 ENVIRONMENTAL PRESSURE	B4.5 Natural Catastrophes
C2.1 Biodiversity	B5 COMFORT
C2.2 Resources	B6 ACCESSIBILITY
C2.2.1 Energy consumption	B7 USABILITY
C2.2.1.1 Non-renewable energy consumption	**D PROCESS**
C2.2.1.2 Renewable energy consumption	D1 GENERAL INFORMATION
C2.2.1.3 Process energy consumption	D1.1 Collaboration
C2.2.1.3.1 Process electric energy	D1.2 Participants
C2.2.1.3.2 Process fossil energy	D1.3 Materials
C2.2.1.3.3 Process bio-energy	D2 BRIEFING
C2.2.1.4 Transportation energy consumption	D3 DESIGN AND CONSTRUCTION
C2.2.1.5 Feed stock energy	D3.1 Design
C2.2.1.5.1 Feed stock fossil energy	D3.2 Construction
C2.2.1.5.2 Feed stock bio-energy	D3.3 Tolerances and dimensions
C2.2.2 Raw materials	D3.4 Quality assurance
C2.2.2.1 Non-renewable raw materials	D4 MAINTENANCE AND REPAIRING
C2.2.2.2 Renewable raw materials	D4.1 Maintenance
C2.2.2.3 Hidden raw material flows	D4.2 Repairing
C2.3 Emissions	D4.3 Replacement
C2.3.1 Emissions to air	D5 DEMOLITION AND DISPOSAL
C2.3.2 Emissions to water	D5.1 Demolition
C2.3.3 Process waste	D5.2 Disposal
C2.4 Specifications	D4.3 Recycling
	D4.3 Reuse

Figure 5: VTT ProP® Finclad2 classification.

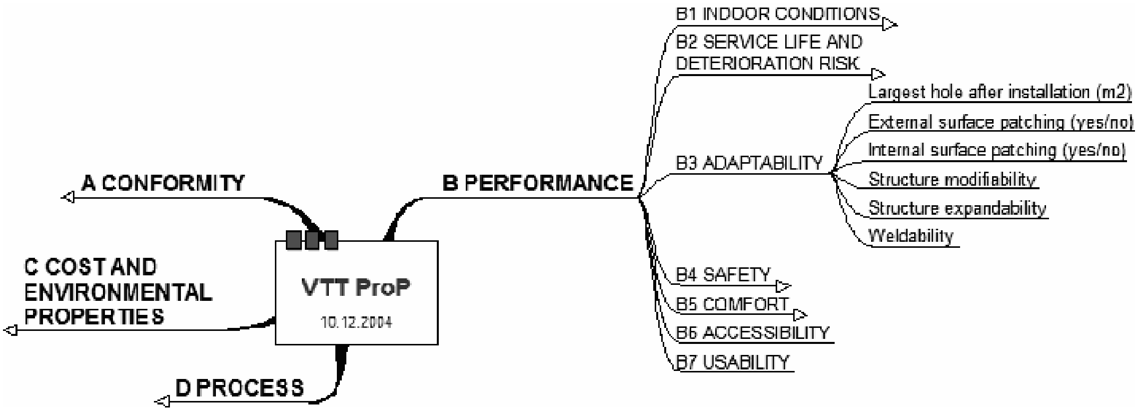

Figure 6: VTT ProP® Finclad2 classification, adaptability opened.

The nature in construction projects also is that level of detail changes during projects; from scheme in the beginning to details for the manufacturing. Biggest advantages of using classification are gained when early architectural design starts using classification and produces data in a form updatable in later phases. This procedure also helps to verify fulfilment of user requirements. Hierarchy of requirements is different from building model hierarchy or configuration which can be set up in various ways, e.g. as: building level, zone, space, system, element, component and property.

3.5 User Interface to Software

Linking model based technology and requirements management offers new possibilities for software development. Imagine an architect or structural designer viewing requirements parallel to actual design and verifying that everything is in order. Development of requirements management features should also be remarked in the next generation quality assurance systems. But before model based technology can be utilised in this respect, the appropriate data structures must be built into design systems and interfaces must be developed. At the moment this is still lacking; an illustration by a user interface mock up was presented by Kiviniemi as a link from CAD software to requirements setting [5].

4. Conclusions

Building process has been analysed with respect to present requirements management in exterior cladding wall models. Appropriate techniques and reference models for this purpose have been selected. Overall, the process deals with many problematic issues and at the moment combining requirements management with model based information technology is rather unexplored field, but product model technology is very promising for future development in requirements management procedures.

In general, it is often remarked that complicated system is the main limitation of wider exploitation. According to requirements management, a user friendly and understandable systematic structure is brought to practice by classification. For the case of cladding walls, new performance based classification, VTT ProP® Finclad2, has been introduced at the national level; the model based exchange specification is using IFC, with eventual additions as appropriate. Requirements representation in IFC model, as well as the classification is part of VTT task report (to be published).

The various participants and ICT tools used by them in activities concerning requirements are identified. At the moment the field of requirements management lacks appropriate tools, especially model based ones. Requirements management can form the basis of specific software or it can support larger content, such as guide designers as part of a modelling tool.

The target process for the future is capturing requirements, verifying satisfaction and thus increasing the quality and value of the product. A corner stone of the target process is highly semantic interoperability between various applications - enabled by product models.

Abstract

In order to enhance the e-learning for engineers participating in construction projects, it is necessary to provide these engineers to a learning platform to study and understand how the construction operation and important events concerning about construction projects in advance before or during the construction execution. The online use of the system and project discussions help the engineers to relate better their previous academic knowledge to “real-life” problems, enhance their creativity, and increase the level of retention of the new knowledge acquired. Future enhancements and learning possibilities are discussed with the use of additional capabilities of information technology. Integrated with the application of Problem-based Learning (PBL), the e-Learning system can provide the engineers with an active role in learning and to allow the engineers to take responsibility for learning. The e-Learning system has integrated different disciplines and input from the project managers, engineers, and instructors of different disciplines. This system includes hypertext links to past experience, knowledge and stratified information including text, graphics, and videos. The e-Learning system presents a teaching platform that enables junior engineers to learn about construction phases of a construction project. Main contribution of this system are as the following; (1) Provide safety learning environment (2) Maintain and manage effectively the past knowledge and experience from past projects; (3) Reduce the cost and time of training and education; (4)Overcome the time and space

barriers of learning. Finally, the efficiency of the proposed system is demonstrated through case examples.

Keywords: E-Learning; problem-based learning; knowledge management; construction project.

1. Introduction

E-learning refers to any form of learning delivered or supported by the use of web-based technology or other electronic media. Compared with traditional classroom learning, e-learning has shown its advantages by its nature of flexibility, accessibility and convenience to learners. Given the broad deployment of network technology and increasing on-line communication in teaching and learning, there is an urgent need for a guidance on web-based instruction. From a combined perspective of constructivism and semiotics, e-learning is regarded as a process of Knowledge Management (KM). Many organizations are now engaged in knowledge management efforts in order to leverage knowledge both within their organization and externally to their shareholders and customers (Malhotra 2000, 2001). Knowledge management in the construction phase mainly deals with the process of creating value from construction operation, organization to company knowledge. Valuable knowledge can be available in different forms and media, such as in the mind of experts, in operation procedures, and in documents, databases, intranets, etc.; however, knowledge management in the construction phase of projects aims at effectively and systematically collecting and sharing the experience and knowledge of the project by web-based and intranet technologies.

Problem-based learning (PBL) is a teaching strategy that applies complex real-world problems to introduce concepts to students. PBL got its start in medical education and is now used at most medical schools (Hendley 1996). Integrated with PBL concept, the reuse of information and knowledge from past projects enhance learning quality during the construction phase of a construction project. By sharing experience and knowledge, the same and similar problems do not need to be solved over and over again. To improve the learning quality for engineers special in practice, this paper provides web-based learning system for "lifelong" learning and applies techniques integrated with PBL concept for engineers. Learning environment give engineers freedom to perform learning from different paths. In this way, engineers are put in the centre of a learning process, and construct knowledge through their own experience. Based on the construction project characteristic, the specific course - Taiwan Expressway Project is chosen to be an example for illustration. The outcome of our work is expected to be applicable for e-learning platform in construction practice.

2. Problem Statement

Construction projects are intricate, time-consuming undertakings. Usually, construction projects are typified by their complexity, diversity and by the nonstandardized nature of their production (Clough 2000). Professional competency in project management is attained by the combination of knowledge acquired during training, and skills developed through experience and the application of the acquired knowledge (Edum-Fotwe and McCaffer 2000). During the construction phase of projects, one of the improvements for construction management is to share experiences amongst engineers, which helps prevent mistakes that past projects have encountered already. Reusing experience also avoids problem-solving from scratch, i.e., already solved problems do not need to be solved over and over again. However, there are no suitable platforms to assist senior engineers or experts with sharing and collecting their know-how and experiences when general contractors execute the project. This is a major loss for general contractors who do not preserve the know-how and experiences of senior engineers and experts. When these engineers and experts finish the projects or leave the company, they usually take the domain knowledge with them and leave little or nothing for the projects or the company. In the view of knowledge management, these know-how and experiences of construction engineers and experts are the most valuable because they not only need manpower; they also require major cost and time to be accumulated.

3. Research Objectives

The main purpose for conducting this research is to develop a Construction Problem-based Learning e-Learning (ConPBL learning) system for general contractors, to provide knowledge exchange and management service in the construction phase of a project for the reuse of domain knowledge and experience in future and other related projects. Usually, it is possible for general contractor to execute similar or same projects. Therefore, problems in executing those projects can be considered to refer and learn for other similar projects (see Fig 1) Thus the capture, transfer, reuse, and maintain of the construction project knowledge are critical (Kamara et al., 2002). Knowledge management in the construction phase of a project is a knowledge-intensive organizational environment where knowledge creation has critical importance for general contractors. To be competitive, a general contractor has to make innovative use of knowledge created and accumulate through project activities, and share it across the rest of other relative projects. Engineers and experts participating in projects act as knowledge workers facilitating the collection and management of knowledge between current and past projects. In order to apply knowledge management to construction projects, the process and content of working construction knowledge need to be modified because of construction project characteristics. With the evaluation of the case study on the Taiwan highway project, the results show that the ConPBL learning system is effective in sharing the knowledge for a construction process. The case study also highlights the need for improvements to knowledge management and exchange platforms.

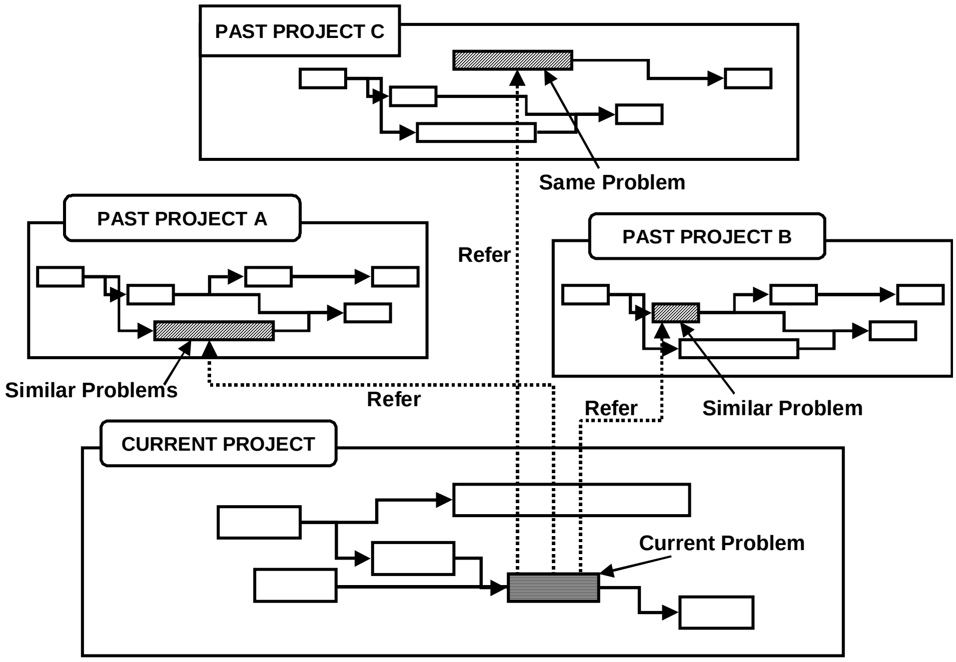

Figure 1 Problem-based experience management used in the construction phase of a project.

4. Knowledge Management in Construction

In construction projects, knowledge management is a discipline that promotes an integrated approach to the creation, capture, access, and use of a profession's domain knowledge on products, services and processes. During the construction phase of a project, most project-related problems, solution, experience, and know-how are in the heads of individual engineers and experts. Implicit knowledge usually is not documented or stored in a system database. To reuse the knowledge in other projects and also preserve it as corporation property, how to capture the implicit knowledge and make it become available as explicit knowledge is important in the execution of knowledge management in the construction phase. Experience, problem-solving, know-how, know-what, and innovation are created in the construction phase of any project. By practicing knowledge management, tacit knowledge can be reused for other projects and speed the improvement of operations in the construction phase. Undoubtedly, tacit knowledge is corporate property.

Usually, knowledge content in the construction phase of a project can be classified into two broad categories; tacit knowledge and explicit knowledge. Tacit knowledge is personal, context-specific knowledge that is difficult to formalize, record, or articulate; it is stored in the heads of people (Hart 1992). The tacit component is mainly developed through a process of trial and error encountered in practice. Tacit knowledge is personal knowledge embedded in individual experience and is shared and exchanged through direct, face-to-face contact (Tiwana 2000). Tacit knowledge can be communicated in a direct and effective way. By contrast, acquisition of explicit knowledge is indirect: it must be decoded and re-coded into one's mental models, where it is then internalized as tacit knowledge. Explicit knowledge that is formal knowledge can be codified and transmitted in a systematic and formal language; documents, database, website, etc.

It can be found in the documents of an organization: reports, articles, manuals, patents, pictures, images, video, sound, software, etc. It can also be found in organizational documents such as organizational charts, process maps, mission statements, domains of experience, etc.

Explicit knowledge is easier to collect and manage during the construction phase of a project because the information and knowledge are available in document form. With document management, information and knowledge can be preserved and managed effectively without explicit knowledge extraction. Therefore, explicit knowledge is easier than tacit knowledge in the field of knowledge management. However, the main problem in the view of tacit knowledge is how the tacit knowledge can be extracted into structured information and unstructured information effectively. After the extraction of tacit knowledge, the explicit information can be maintained and managed with the assistance of document management tools.

5. Problem-based Learning in Construction

Problem-based learning emphasizes learning by doing. It also provides a motivating context for learning. In construction projects, junior engineers are given a real-world problem similar to those they would face as professionals. They take ownership of the problem, and the problem solving process. Instructors (senior engineers), in turn, take the role of a cognitive coach. A pedagogical goal of PBL is to help junior engineers develop their own problem-solving skills, rather than tell them how to solve the problem.

The literature on problem-based learning in engineering education suggests many educational and professional benefits of this approach (Hendley 1996; Dutson et al. 1997; Johnson 1999), which support the findings of other professional literature (Albanese and Mitchell 1993; Chen et al. 1994). The benefits of PBL are examined here, focusing on five main themes—applicability, problem solving, active learning, motivation, and professional skills (Anne 2003).

In order to reduce the training time for junior engineers participating in construction projects, it is helpful to provide these engineers with a learning platform to study and understand which problems the construction process happens and related solutions concerning problems. With the application of PBL approach, the problems and solutions from past projects can be reused and learned with junior and senior engineers. The integration of PBL and knowledge management in construction is shown in Figure 2.

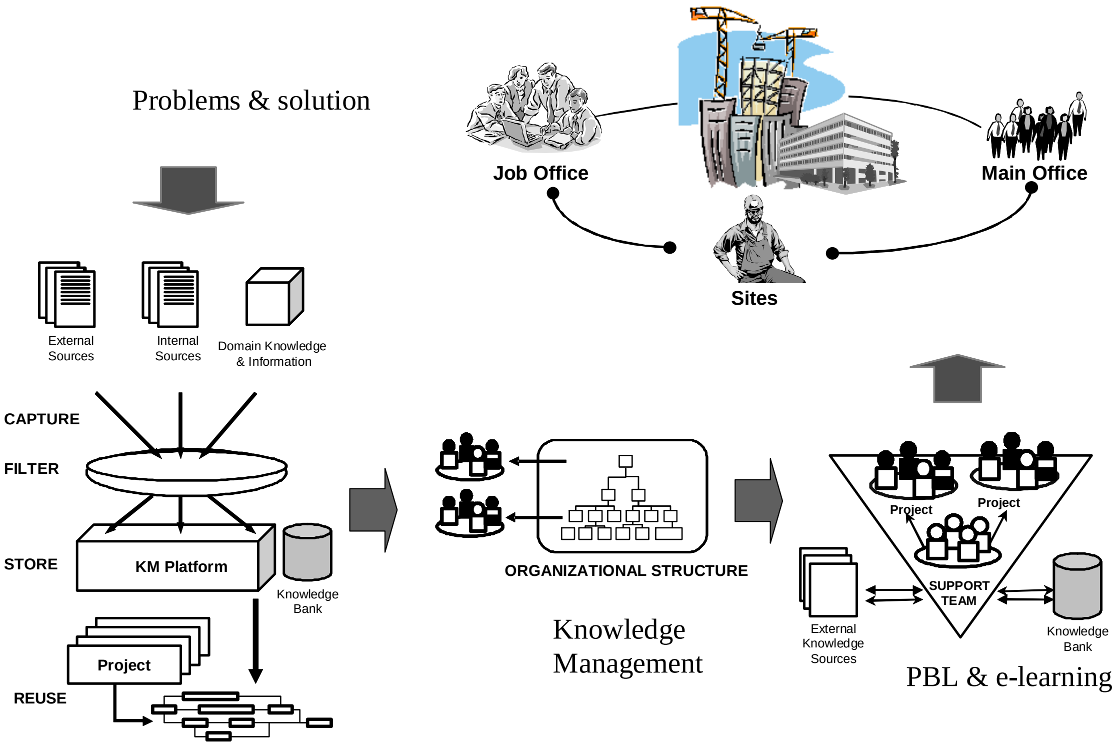

Figure 2 Construction knowledge management integrated with PBL Concept

In construction projects, the knowledge includes both tacit and explicit knowledge. In terms of explicit knowledge, project-related information or knowledge usually include specification/contract, reports, drawing, change order and data. Actually, each project does not contain one-to-one information or knowledge because some of them belong to project-oriented information. In contrast, tacit knowledge may include process records, problems-faced, problems-solved, expert suggestions, know-how, innovation, and experience notes. The relationship of current and past same or similar problems is important for users to link related information and knowledge together. Furthermore, not only the information and knowledge of the current project can be applied, but also same or similar solutions of past projects can be referred to as experiences are recorded. When experts or engineers have problems they cannot handle in the project, they may learn the solutions regard to the same and similar problems. Figure 3 shows e-learning environment designed by PBL concept.

With the assistance of e-learning and knowledge management, junior engineers may acquire the know-how and experience directly from past projects, reducing the time and cost of training. By sharing past experience and knowledge, the same and related problems in executing projects do not need to be solved over and over again. Furthermore, the junior engineers can understand how the construction process works more quickly and easily by utilizing an e-learning platform.

In order to enrich the knowledge bank in the system, the system is designed to encourage all engineers and experts to submit their domain knowledge and valuable experience to the knowledge bank. Traditionally, companies included mostly numeric, structured data in their data warehouse. From this point of view, decision support systems are divided into two camps: data warehouses deal with structured data; knowledge management involves unstructured data (Ponniah 2002). It is a need to integrate both structured (such as data and text) and unstructured information (such as image, video, audio, image, and drawing) in the knowledge bank for further decision-making and reference. The main purpose of a knowledge bank is to provide the rich source of content concerning all projects and gather project-related explicit information and tacit knowledge together for involved engineers and experts.

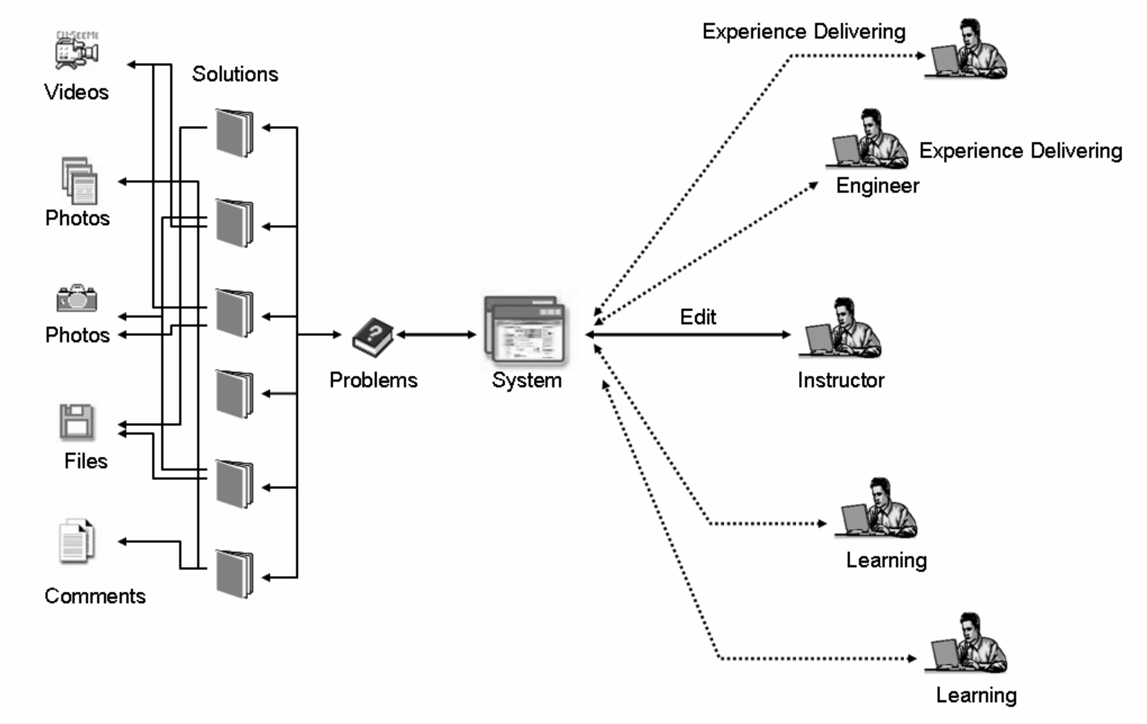

Figure 3 Problem-based Learning (PBL) E-learning for knowledge management.

6. System Development

The system is developed and implemented with an interactive e-learning platform using web-based technology and knowledge management concepts. The multimedia courseware provides junior engineers with illustrations specific to operation procedures using web technology. In addition, digital films record the whole construction operation. The digital films helps the junior engineers understand the process easily and effectively. Furthermore, digital films are recorded and clearly describe the progress and operation of the construction operations. In other words, junior engineers can access the digital illustrations and digital files for each activity or event in the system. Of course, those e-learning materials must be confirmed before being published in the system.

In construction projects, most project-related problems, solutions, experiences, and know-how are recorded into multimedia-based content. Also, multimedia systems are particularly suited to interactive applications since they allow huge collections of visual media, text, and other data to be stored in a single digital document and accessed easily and quickly. Usually, implicit knowledge is not documented or stored in a system database. It is important to capture the implicit knowledge and make it available as explicit knowledge. In this study, most tacit knowledge will be recorded as multimedia-based content for knowledge and experience exchange during the construction process. In other words, the valued knowledge can be collected and edited into explicit knowledge by the knowledge management team.

A detailed description of the ConPBL learning system will be given in this section. Figure 4 shows the system architecture. The server of the ConPBL learning system provides four distinct types of layers: interface, access, application and database layers, each with its own distinct responsibilities. The interface layer defines administration and end-user interfaces suited to his/her work. The users can access information through web browsers such as Microsoft Internet Explorer or Netscape Navigator. Administrators can control and manage information through the web browser as well as a separate server interface. The access layer provides system security and restricted access, firewall services, and system administration functions. The application layer defines various applications for information collection and management. These applications provide indexing, full text search, collaborative work and document management functions. The database layer consists of a primary SQL Server 2003 database and a backup database (also based on SQL Server 2003).

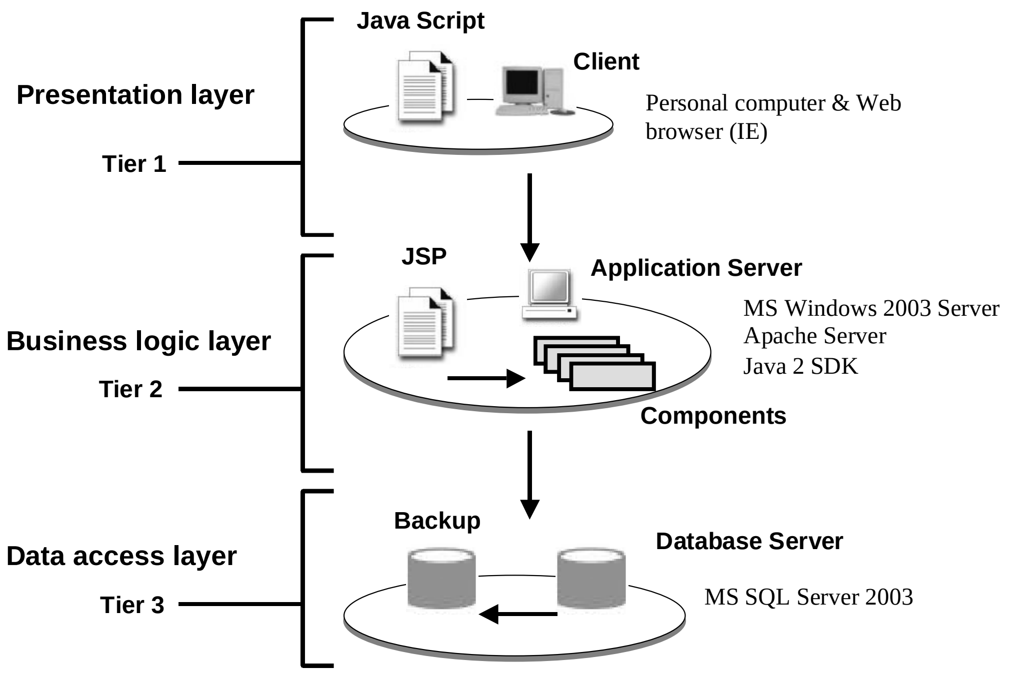

Figure 4 System architecture.

The ConPBL learning system services described in this paper are made available to all the participants of the company through a specially designed portal, which also serves as a messaging (mail) server for the company (organization). The portal is a key element of the proposed system and it consists of three content areas: public, member, and knowledge manager areas. The public area is open to anyone who is interested in the project. On the contrary, the project member and knowledge manager are restricted to members with password protection.

Since anyone can access information from the public area, it is a logical place for project managers (or developers) to utilize for public relations – to post project descriptions, news, announcement, etc. In the project member area, project members can use ConPBL learning services, such as messages, data, and files. Any information and knowledge concerning the projects can only be accessed by project members. Only knowledge managers have the rights to log onto the manager area, where they can access all information in the project server. Figure 5 illustrates the application of knowledge sharing in ConPBL learning system.

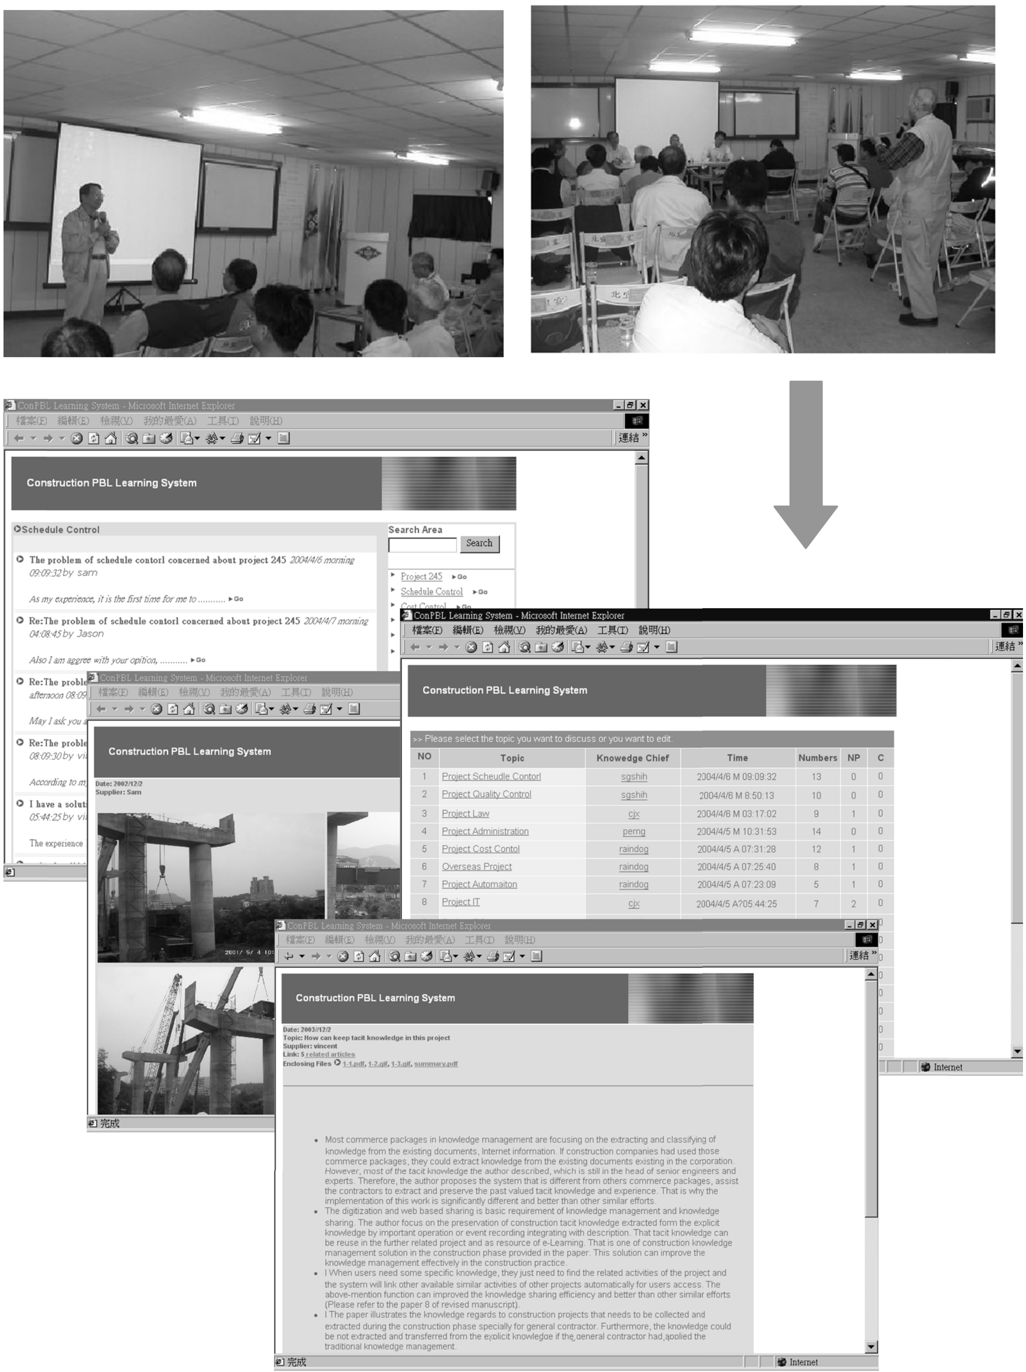

Figure 5. The application of knowledge sharing in ConPBL learning system.

7. Conclusions

The application of knowledge management for construction project in the construction phase is discussed in this paper. Also, the main purpose of this paper presents a construction Problem-based Learning (ConPBL learning) concept and system for general contractors as a knowledge-sharing platform. Construction Project-oriented knowledge management maps the valued information and knowledge into project units for a project during the construction phase. The development of the ConPBL learning System employing the integration of web technology with a portal is delineated and it has been illustrated through a case study in the Taiwan Highway Project. The ConPBL learning system is advanced at least in the following aspects: the ConPBL learning system enables gathering insight into the factors having impact on construction management activities; in turn this will help engineers share knowledge to improve operation performance. Junior engineers can interact with the computer so that they can understand the domain knowledge to prepare and participate in a construction project. In short, the ConPBL learning system is able to assist engineers by providing accurate and rich information for knowledge reuse and reference. The integration of knowledge management and web-based technologies appear to be a promising way to improve construction operation management during the construction phase of a project.

The collection of explicit and tacit knowledge for any project and non-project in construction projects allow engineers and experts to reuse most project-related knowledge/information during the construction phase. The content of the knowledge bank in the system not only provide the specific problem-solutions, but also support all area domain knowledge and experience from the projects. Although effort is required to update the explicit/tacit knowledge for various types of projects, the developed system will benefit construction management by (1) providing an effective and efficient computerized environment to assist knowledge management tasks, and (2) facilitating the implementation of a web-based knowledge management system pertinent to these activities in the projects. With the evaluation of the case study in the Taiwan expressway project, the questionnaire results show that a ConPBL learning system is effective in sharing knowledge for construction projects. The case study also highlighted the need for improvements to knowledge management and exchange platforms.

Realising Electronic Purchasing in the Irish Construction Industry

Alan Hore
Dublin Institute of Technology, Republic of Ireland (alan.hore@dit.ie)
Roger West
Trinity College Dublin, Republic of Ireland (rwest@tcd.ie)

Abstract

The use of Information Communication Technologies (ICT) in construction purchasing has been sporadic and piecemeal. Very significant inefficiencies and problems still exist in both paper transactions and non-integrated electronic solutions. At the simplest level, the electronic transmission of business documents offers savings in paper and postage. By going a step further, businesses can make strides in communicating with their partners, at relatively low cost, through direct links between their computers. Existing ICT such as the Internet, Bar-Coding, Radio Frequency Tagging, Electronic Data Interchange (EDI), Electronic catalogs and Enterprise Resource Planning Software (ERP) have facilitated electronic commerce (EC) functionality within many business sectors. However, the adoption of such technologies in the Irish construction industry has been very slow with only limited evidence of their application. The results of a Proof of Delivery (POD) pilot project carried out by the Construction Information Technology Alliance (CITA) in 2004 indicates that significant cost savings can be achieved by trading partners by the adoption of existing technologies.

Keywords: Construction, e-commerce, information technology, procurement, purchasing.

1. Background

CITA is a collaborative organisation aimed at bringing together academia and practitioners, with a common purpose to promote the application of ICT in the Irish Construction Industry [1]. A Special Interest Group within CITA was formed in 2002 to consider specifically the administration involved in ordering, delivering and invoicing of building materials. CITA approached a number of interested parties within the Alliance to lead a proof of concept pilot project to show how costs can be minimised and efficiencies gained in the ordering, receipt and payment of construction materials by the effective use of ICT.

It is generally accepted that building materials account for up to 50% of all construction costs. In this field of business-to-business (B2B) interactions, there is a huge untapped potential for productivity gains. In Sweden [2], Finland [3] and in the UK [4], materials management has been identified as an area where significant cost savings could be made. Laage-Hellman and Gadde gave an account of the progress made by the Swedish construction company Skanska in its attempts at introducing EDI into its purchasing system. The cost of processing an invoice was found to be SEK 300 (approximately US$45). Laage-Hellman and Gadde concluded that this cost could be reduced by 90% by using EDI.

The purpose of this paper is to share the experience gained by the authors in carrying out a pilot study and to identify the main problems that exist with the current mainly paper-based process adopted in the purchasing of materials in the Irish Construction Industry. The authors conclude that the re-engineered solution proposed will explicitly deal with all the problems that currently exist.

2. Traditional Purchasing Practice in Construction

Purchasing procedures typically involve a paper-based communication process between the purchaser and supplier. Evidence shows that the construction industry is lagging behind other industries globally in adopting new technologies [5]. The process invariably commences with the sourcing of the materials. This typically involves site personnel requisitioning the project material requirements on a daily basis. Once a suitable supplier has been selected, the next step is to raise and issue a purchase order to the supplier. On delivery of the materials to site, a delivery docket is signed by the contractor and forwarded to head office as proof of delivery. Payment of the invoice is made following the matching of the invoice to the original purchase order and signed delivery docket. Kong et al identified the limitations of the traditional material procurement process [5]. As every step is reliant on input from one or more individuals, there are frequently problems in the process. For example, the requirements of the contractor are misinterpreted by the supplier, a docket goes missing, transcription errors occur, the invoice is not correct, the goods are not all delivered at the same time, the delivery docket does not match the order, payment is held pending matching of documents, etc. Any of these problems can add significant delay and cost to the process.

3. Available Technology

Technologies are in place to process electronic transactions more easily and at less cost than one can process paper transactions [6]. ICT is changing almost all functional aspects of a modern business in Ireland, particularly in industries such as financial services, travel and retailing. With the continued expansion of the Internet, EC provides unparalleled opportunities for businesses to bring greater efficiencies in transaction based commercial activities [7]. Technologies such as Automatic Identification (Auto-ID) and bar coding have become widespread within manufacturing, medicine and retail industries. However, the rate of adoption in other business sectors, such as the construction industry has been very slow and piecemeal [8]. Li argues that the benefits of ICT deployment are marginal, if simply imposed on an already inefficient construction process [9]. He argues that the processes should be redesigned to maximise the use of ICT. Hammer described how heavy investments in ICT in the 1980's delivered disappointing results, largely because companies tended to use technology to mechanise old ways of doing business [10].

4. The Pilot

4.1 Aims and Objectives of Pilot

The overall aim of the pilot was to prove that delivery data can be captured electronically and be acceptable as "Proof of Delivery" for the construction industry by use of readily available technology. The underlying objectives of the pilot project included: -

- To develop a clear understanding of how the existing purchasing systems operated in both contractor and supplier organisations.
- To confirm ICT operational systems and their current reliability in both the contractor and supplier organisations.
- To investigate the ease/constraints with which information can be captured from or added to contractor and suppliers existing purchasing systems.
- To test and confirm ICT handheld usability in a construction environment.
- To confirm productivity improvements and potential savings as a direct result of this pilot with both the contractor and the supplier.

4.2 Methodology

The methodology adopted for the pilot included five inter-related steps, involved: -

1. The vision/scope of the pilot,
2. proof of concept,
3. pilot itself,
4. evaluate pilot and
5. post pilot evaluation.

The methodology process is shown in Figure 1.

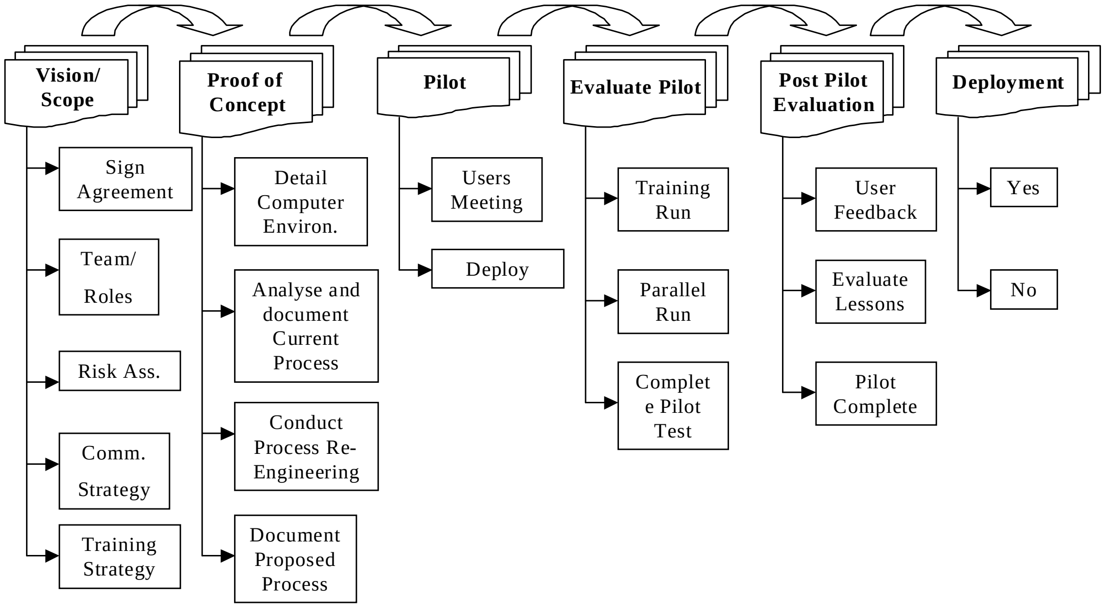

Figure 1. CITA Pilot Project Methodology

4.3 Pilot Team

The pilot team members principally included the lead author, main contractor, building supplier, ICT providers and an independent monitoring consultant, all of which were members of CITA. Figure 2 illustrates the communication relationship between the parties.

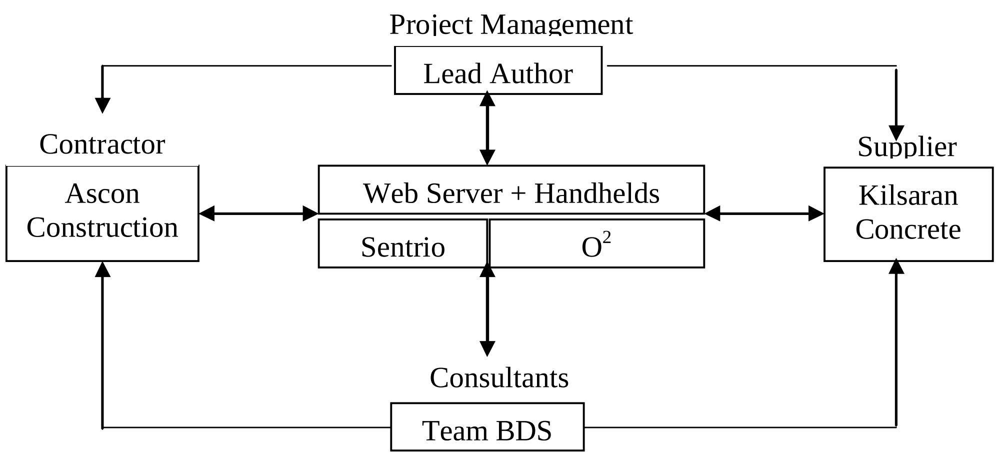

Figure 2: Pilot Team

4.4 Problems to be Addressed

The main problems encountered by the contractor and the supplier included very large volumes of paper generated in their purchasing processes; a significant amount of time spent in carrying out repetitive tasks such as scanning, photocopying, matching documents; inaccuracies in the ordering and delivery process and the degree of mislaid delivery dockets, leading to delays in payment and in many cases non-payment. Table 1 documents the magnitude of the documentation that are created annually within the contractor and supplier organisations.

Table 1. Estimates of purchasing documentation created by contractor and supplier

Pilot Contractor	Pilot Supplier
78,000 invoices per annum with an average of 5 lines per invoice	31,000 invoices per annum with an average of 20 lines per invoice
390,000 goods received notes per annum	1,250 invoice queries per annum
20,000 missing documents per annum	375,000 delivery dockets for scanning per annum
10,000 order amendments	

It was decided by the pilot team to approach the pilot project in two phases. The scope of Phase 1 sought only to address the delivery aspect of the purchasing process as illustrated in Figure 3. The precise scope of phase 2 would be decided following an evaluation and review of Phase 1.

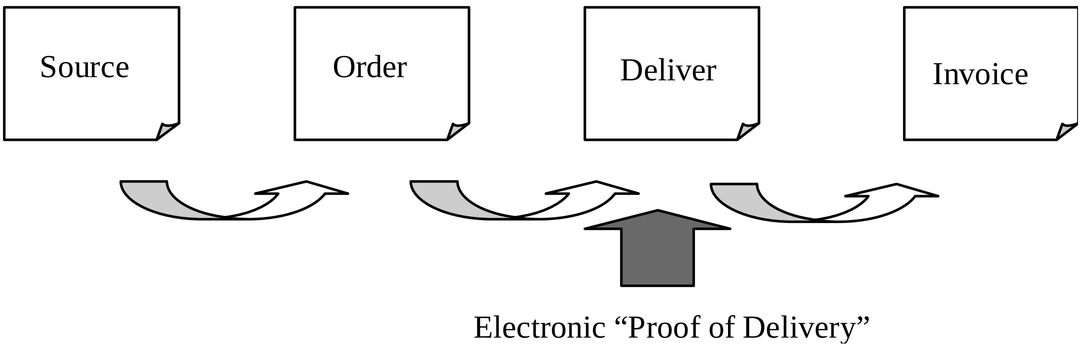

Figure 3. Focus of Pilot

4.5 Technology Landscape

The technology landscape selected for the pilot was a web-based solution, as illustrated on Figure 4. This allowed for the capturing of the POD on a handheld device. The ICT landscape adopted did not in any way require the contractor or the supplier to re-configurate their back-end ICT systems. The technology simply allowed for the purchase order to be captured on a mobile handheld device, which in turn allowed for the POD to be captured by way of a wireless connection on an independent website.

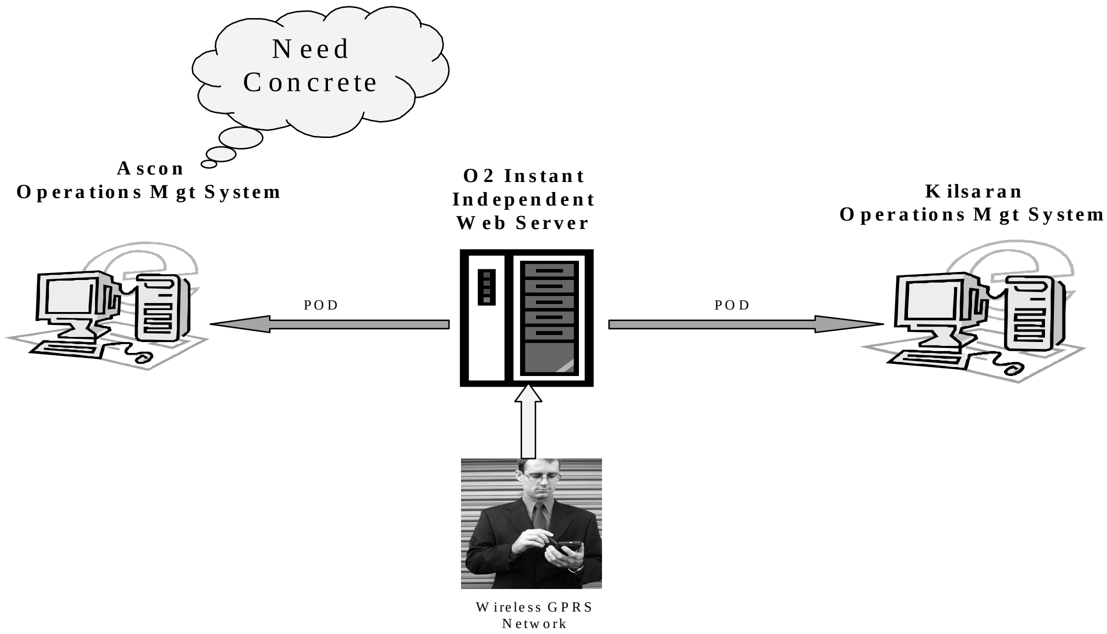

Figure 4. Technology landscape of Pilot for concrete supply

4.6 Pilot Process

A more detailed overview of the pilot process is shown in Figure 5. The pilot process commenced with the contractor calling-off material by phone call and confirming their request by use of facsimile. The supplier in turn generated the order details onto their ICT document management system and simultaneously onto the central web repository. Order details were then transferred onto a handheld device, which, on delivery to the site, were presented in an electronic format for signature on the device. Once signed the POD was instantaneously sent back to the central repository. This allowed both companies to check the delivery information and customer signature online. This enabled the parties to query delivery information using the central web application.

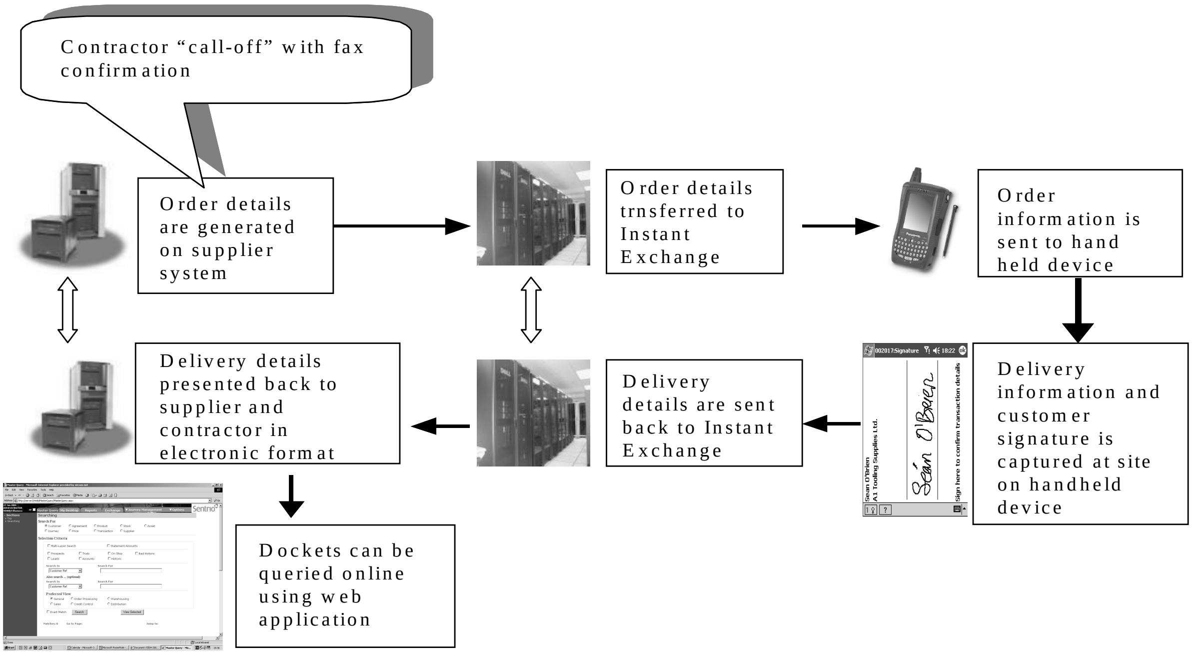

Figure 5. High Level Process for POD Pilot

4.7 Remaining Constraints

The pilot project allowed both the contractor and the supplier to report on the business benefits that would accrue if ICT was deployed in the ordering, receiving and invoicing processes of the purchasing cycle. Table 2 and 3 summarise the internal processes, constraints and opportunities for a further pilot project. It can be seen from both tables 2 and 3 that the pilot project only addressed the delivery element of the process. There remained a large number of constraints in both the contractor and supplier purchasing processes. For example, it was still necessary for the contractor to manually input a Good Received Note (GRN) of the POD information into their ERP systems. It is intended that all these constraints will be systematically dealt with in Phase 2 of the pilot, which is due to commence in spring 2005.

Table 2. Contractors constraints with existing process

4.7.1.1 Contractor – Processes and Current Constraints				
Process	**Current**	**Constraint**	**Pilot Objectives**	**Opportunities**
Ordering	Supplier "Open Order"	Keep order adjustments	Auto order adjustments based upon delivery information	SIG 1 – Phase 2
Receiving/ GRNs	Hard copy Delivery Dockets	Missing documents. Scanning documentation. Manual creation of GRN in ERP system.	Electronic proof of delivery. Eliminate scanning. Auto generation of GRN in to ERP system	SIG 1 – Phase 1 SIG 1 – Phase 2 SIG 1 – Phase 2
Invoicing	Cross referencing Invoice with scanned delivery dockets/GRNS	Missing GRN/scanning documents.	Auto generation GRN in to ERP system	SIG 1 – Phase 2

Table 3. Supplier constraints with existing process

4.7.1.2 Supplier – Processes and Current Constraints				
Process	**Current**	**Constraint**	**Pilot Objectives**	**Opportunities**
Demand from customer	Phone and facsimile	Need to put manually into system	Auto ordering into system from customer	SIG 1 – Phase 2
Delivery	Hard copy Delivery Dockets	Missing documents. Packaging of delivery dockets from site. Scanning of delivery dockets in accounts.	Electronic proof of delivery. Electronic proof of delivery. Eliminate scanning.	SIG 1 – Phase 1 SIG 1 – Phase 1 SIG 1 – Phase 2
Invoicing	Invoice issued once delivery initiated	Missing GRN/scanning documents.	Auto generation GRN in to ERP system	SIG 1 – Phase 2

4.8 Pilot Results

As a direct result of the pilot project, both the contractor and the supplier reported the savings that would potentially accrue should the technology be adopted in a second phase pilot to address the constraints identified in Tables 2 and 3. Tables 4 summarises these savings.

Table 4. Summary of Potential Savings for Phase 2 of Pilot

Contractors Annual Costs in Euro			Suppliers Annual Costs in Euro		
78,000 Invoices per annum 390,000 GRNs per annum			60,000 Invoices per annum 2,400 queries per annum		
Process	Ordering	20,000	Process	Demand from customer	20,000
	Receiving/GRNs	15,000		Delivery	100,000
	Invoicing	67,000		Invoicing	24,000
Total Savings Projected		102,000	Total Savings Projected		144,000
Add Work Study Factor +30%		31,000	Add Work Study Factor +30%		43,000
Other savings		5,000	Other savings		5,000
Total Savings Projected for Phase 2		138,000	Total Savings Projected for Phase 2		192,000
Less predicted technology costs		38,000	Less predicted technology costs		108,000
Nett Saving predicted for Phase 2		100,000	Nett Saving predicted for Phase 2		84,000

The savings reported in table 4 are based on calculations and data furnished by the contractor and the supplier during the pilot and not by a direct work study. The figures presented by the authors are considered to be conservative, as additional indirect savings in regard to office expenses such as use of paper, printing and copier consumables are not included.

From a pilot perspective the supplier gained the more immediate and tangible benefits, from the first phase of the pilot. Table 4 summarises the financial benefits that should accrue to both the contractor and the supplier should the technology be deployed in a second more dynamic B2B pilot project.

4.9 Pilot Feedback in Phase 1

Feedback has been seen as a critical part of the pilot study, as it not only provides "lessons learnt" but also substantiates the credibility of the technology deployed in the first phase of the pilot. There were teething problems in using the technology, however these problems bated as familiarity emerged during the pilot study. Both the contractor and the supplier felt that there needed to be more time spent on training personnel on using the technology. They also felt that the website was not user friendly and did not produce suitable reports for their records. There was also strong opinion that the Personal Digitised Assistant (PDA) screen was not displaying the requisite information prior to signing the PDA screen. All the feedback gathered from the participants will be consulted in the planning and implementation of the second phase pilot.

5. Proposed System Architecture for Effective ePurchasing

The first phase of this pilot project only dealt with the delivery aspect of the entire purchasing process. Figure 6 illustrates how existing technologies can be fully integrated to eliminate paper-work from the entire purchasing process. All purchasing documentation, such as requisitions, purchase orders, delivery dockets and invoices can be passed electronically through the central web server, which in turn can be electronically posted into both the contractors' and suppliers' ICT back-end systems. The architecture of the platform will enable a handheld application with an electronic signature capture capability to transmit wirelessly a POD from the PDA to both the suppliers and contractors ICT systems via an independent central web-based server. The web-based solution will provide on-line access to an image of the signed POD, which will allow for automated matching of the order, the delivery record and the supplier invoice.

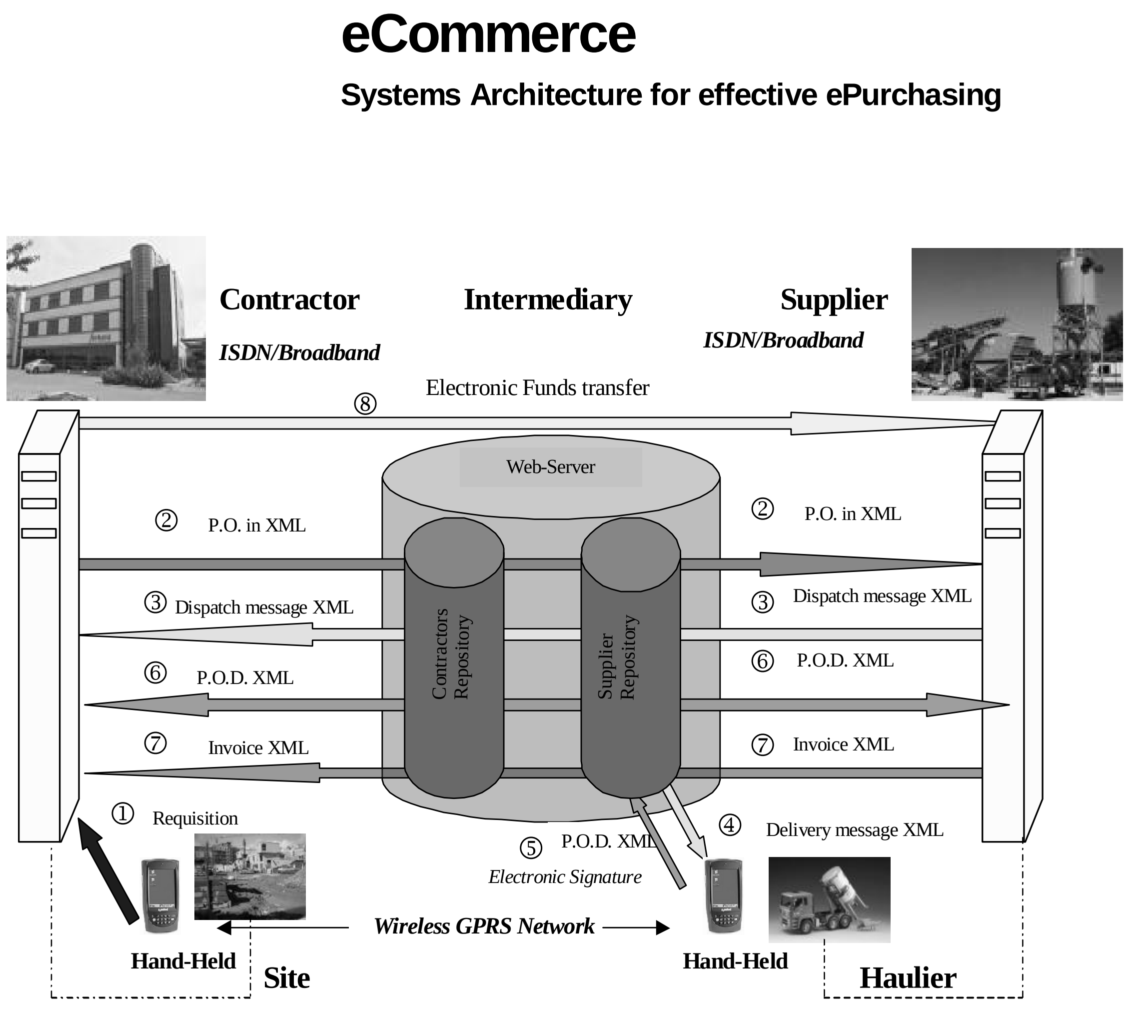

Figure 6. Systems Architecture for Effective ePurchasing

The operation of the proposed solution will involve the following sequential tasks, as identified in Figure 6.

1) Site requisition goods via a hand held device or mobile data terminal.

2) Contractor ICT system passes purchase order to the independent web-server, which ensures that the purchase format is correct and passes it to the suppliers ICT system.

3) The suppliers ICT system creates a dispatch notice and informs the contractor system if there is any variation between the order and dispatch notice.

4) The delivery details are sent to a delivery driver's hand-held device in XML format via a GPRS network. This message is triggered from the independent web-server based on the supplier dispatch message.

5) Once the delivery is complete the driver captures a signature on site, that is transmitted back to the independent web server.

6) The POD is then sent from the independent web-server to both the supplier's and contractor's ICT systems.

7) Supplier invoices the contractor via the independent web-server, using XML messaging technology.

8) On electronic invoice approval the contractor authorises electronic funds transfer direct to supplier.

6. Conclusions

Technologies are at last in place to process electronic transactions more easily and at less cost than one can process paper transactions [6]. ICT is changing almost all functional aspects of a modern business, particularly in industries such as financial services, travel and retailing. With the continued expansion of the Internet, EC provides unparalleled opportunities for businesses to bring greater efficiencies in transaction based commercial activities [7] and [11].

Specific EC deployment is having a varying impact on different business sectors. It will take the main players within each sector to adopt a new technological strategy. ICT is this driver that will force companies to embrace EC in B2B purchasing transactions. The technology behind EC is not the problem. The problem is getting the buy-in from all parties concerned. The biggest savings from eBusiness can be achieved from exchanging orders and invoices electronically. B2B savings can be realised on the elimination of duplicate data entry by achieving a three-way match of the purchase order, delivery advice note and the invoice. Increased awareness within the Irish construction industry is likely to be the key factor in encouraging wider uptake of EC technologies. An industry-wide education initiative, which combines the results of a pilot programme with dissemination of information within the technical press, could, in part achieve this goal. Such an initiative would most fruitfully comprise of a special interest group to pilot test the technology [12]. Particular efforts should be made to increase awareness of EC technologies among contractors and suppliers with lower levels of ICT utilisation [13] and [14].

CDBKM- A Construction Draw-based Knowledge Map System

Yu-Cheng Lin
Institute of Civil Engineering and Disaster Reduction Technology, Ching Yun University, Taiwan (email: d89521016@ntu.edu.tw)

Abstract

Knowledge Management (KM) has become an important term in the construction industry. Knowledge management involves creating, securing, capturing, coordinating, combining, retrieving and distributing knowledge. Most know-what, know-how and experience exists only in the minds of individual participants during the construction phase of construction projects. The knowledge can be reused and shared among the involved engineers and experts to improve the construction process and reduce the time and cost of solving problems. Sharing and reusing knowledge depends on acquiring and preserving both tacit knowledge and explicit knowledge as the property of a corporation. This study addresses application of knowledge management in the construction phase of construction projects and proposes a construction draw-based knowledge management (CDBKM) concept and system for engineers. This paper proposes a practical methodology to capture and represent construction project knowledge by using shop drawings. Using shop drawings as knowledge maps, users can get an overview of available and missing knowledge in core project areas and take appropriate management in tacit and explicit knowledge. Also, a web-based system is developed to assist and present project-related knowledge by providing keyword and map search on the Internet environment. The CDBKM system is then applied in a case study of a construction precast building project in Tainan to verify our proposed methodology and demonstrate the effectiveness of sharing knowledge special in the construction phase. By effectively using information and web technologies during the construction phase of a project, knowledge can be captured and managed to benefit future projects. The combined results demonstrate that, a CDBKM -like system can be an effective tool for all experts and engineers participating for construction projects by utilizing the knowledge management concept and web technology.

Keywords: Knowledge management; knowledge map; web-based application; information systems; construction project

1. Introduction

Thousands of construction drawings are produced for each construction projects. During the construction phase, engineers usually execute the project according to the shopping drawings. Therefore, the experience and knowledge concerned about the project will be resulted from those engineers. Recently, many organizations are now engaged in Knowledge Management (KM) efforts in order to leverage knowledge both within their organization and externally to their stakeholders and customers (Malhotra, 2000, 2001). Knowledge management in the construction phase mainly deals with the process of creating value from construction operation, organization to company knowledge. Valuable knowledge can be available in different forms and media, such as in the mind of experts, in operation procedures, and in documents, databases, intranets, etc.; however, knowledge management in the construction phase of projects aims at effectively and systematically collecting and sharing the experience and knowledge of the project by web-based and intranet technologies.The reuse of information and knowledge minimizes the need to refer explicitly to past projects; reduces the time and cost of solving problems, and improves the quality of solutions during the construction phase of a construction project. If experience and knowledge are shared, then the same problems in construction projects do not need to be repeatedly solved. Reduced problem-solving has the following advantages. (1) The cost of problem solving is reduced and (2) the probability of repeat problems is decreased. Several enabling activities should be considered to help to achieve the ultimate goal of efficient experience and knowledge reuse; experience and knowledge should be preserved and managed; that is, they should be captured, modeled, stored, retrieved, adapted, evaluated and maintained (Bergmann, 2002).

2. Problem Statement

Construction projects are characterized by their complexity, diversity and the non-standard nature of the production (Clough et al., 2000). Professional competency in project management is attained by combining knowledge acquired during training and skills developed through experience as well as the application of the acquired knowledge (Edum-Fotwe and McCaffer, 2000). Whatever successful and unsuccessful projects have been executed by the general contractors, a valuable record of each one should be kept to identify best and worst company practices. During the construction phase of projects, an effective means of improving construction management is to share experiences among engineers, which helps to prevent mistakes that have already been encountered in past projects. Drawing on experience avoids the need to solve problems from scratch: problems that have already been solved do not need to be solved again. According to a survey conducted for this study, most engineers and experts agree that KM is necessary and expect that knowledge management may benefit a construction project. However, no suitable platforms exist to assist senior engineers or experts in sharing and collecting their know-how and experiences when general contractors execute a project. This situation represents a major loss for general contractors who do not preserve the know-how and experiences of senior engineers and experts. When these engineers and experts complete projects or leave the company, they normally take domain knowledge with them and leave little or nothing that will benefit subsequent projects or the company. From the perspective of knowledge management, this know-how and these experiences of construction engineers and experts are the most valuable because their accumulation depends not only on manpower but also on the spending of much money and time.

3. Research Objectives

The main purpose for conducting this research is to develop a Draw-based Knowledge Management (CDBKM) system for engineers, to provide knowledge exchange and management service in the construction phase of a project for the reuse of domain knowledge and experience in future and other related projects. Usually, the management of knowledge in general contractor revolves around projects. Thus the capture, transfer, reuse, and maintain of the construction project knowledge are critical (Kamara et al., 2002). Knowledge management in the construction phase of a project is a knowledge-intensive organizational environment where knowledge creation has critical importance for general contractors. To be competitive, a general contractor has to make innovative use of knowledge created and accumulate through project activities, and share it across the rest of other relative projects. Engineers and experts participating in projects act as knowledge workers facilitating the collection and management of knowledge between current and past projects. In order to apply knowledge management to construction projects, the process and content of working construction knowledge need to be modified because of construction project characteristics. In order to improve the knowledge capture function, knowledge map assists the user as a tool to quickly note key concept, identify important processes and tools, and gain insights into associated behaviors.

4. Concepts of Draw-based Knowledge Management

A knowledge map is used to categorize the content within a particular discipline area. Knowledge map (Wexler, 2001) is a consciously designed communication medium using graphical presentation of text, models, numbers or symbols between makers and users. Knowledge mapping helps to understand the relationships between knowledge stores and dynamics. Davenport and Prusak (1998) note that developing a knowledge map involves locating important knowledge in the organization and then publishing some sort of list or picture that shows where to find it. The knowledge map plays important roles in implementing knowledge management. All captured knowledge can be summarized and abstracted through the knowledge map. The knowledge map also gives a useful blueprint for implementing a knowledge management system. The knowledge map in the system mainly deals with the assistance to find the needed knowledge easily and effectively. Furthermore, applying knowledge mapping technique has following two advantages. First, the knowledge map is represented in a simple, clear visual presentation in the knowledge management system. Second, the mapping methodology helps users to identify key most critical and available knowledge areas to the project. A knowledge map can be defined as a diagrammatic and graphic presentation of knowledge linking the relationships between knowledge and knowledge attribute.

Knowledge and information associated with units of shopping drawings in previous projects may be reused and applied in future projects. Information and domain knowledge from all projects are divided and saved as units for knowledge maps uses in categories related to the projects for collection and management. The main advantage of Draw-based knowledge management is easy for engineers to understand and find which past information and knowledge are available to refer and reuse.

When knowledge is captured duration the construction phase, the knowledge should be recorded in the platform for exchanging. In terms of explicit knowledge, project-related information or knowledge usually include specification/contract, reports, drawing, change order and data. Actually, each project does not contain one-to-one information or knowledge because some of them belong to draw-unit information. In contrast, tacit knowledge may include process records, problems-faced, problems-solved, expert suggestions, know-how, innovation, and experience notes. The information and knowledge is better to save by draw units as knowledge map because the result makes it easier to be classified and searched by users. In addition, users may search and refer to related information and knowledge from related activities in past projects. The tacit and explicit knowledge of Draw-based knowledge management is the same as the duration and relationship of Draw-based project management.

The relationship of current and past draw-units is important for users to link related information and knowledge together. Furthermore, not only the information and knowledge of the current project can be applied, but also same or similar draw-units of past projects can be referred to as experiences are recorded. When experts or engineers capture related information and knowledge regard to the project, they may edit information or knowledge into the drawings in the project. Of course, the system is designed to link among same or similar activities together based on high similarity automatically or manually. As shown in Figure 1, using draw-unit as knowledge map applies for knowledge management.

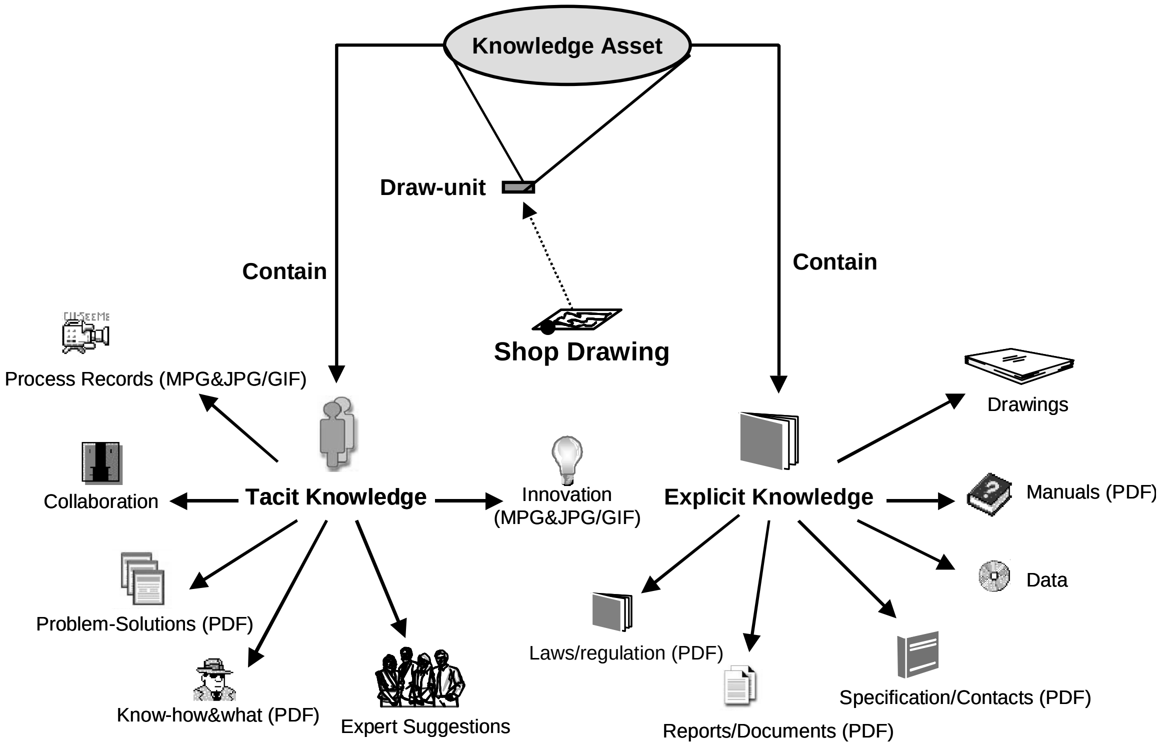

Figure 1. A concept map of the Draw-based knowledge management integrated with drawing units

4.1 Procedures for Utilizing the Knowledge Map

According to the construction knowledge management framework, procedures are proposed for applying the knowledge map in the CDBKM system. The procedure consists of the following three phases: knowledge determination phase, knowledge attribute phase, and knowledge linking phase.

4.1.1 Knowledge Determination Phase

The purpose of this phase is to provide a uniform, text-based intermediate representation of the knowledge types specific to construction projects. This phase includes defining knowledge and baseline taxonomy within a project. The scope of the knowledge map decides whether the knowledge map is constructed throughout a specific project. After deciding the scope, we determine the detail level of knowledge analysis. It is necessary and important to determine the proper level of detail to meet project-based knowledge demand effectively. When analyzing the source of knowledge within a project, activity is suggested as a unit to analyze the construction project knowledge. We analyze related knowledge based on draw-units of shop drawing. Tacit knowledge and explicit knowledge may exist in any project. After identifying knowledge through those activities of the project, we decide which knowledge needs to be extracted from the activities of the projects. Following suggested knowledge extraction techniques include interviewing with experts, making system analysis, and digital process record.

4.1.2 Knowledge Attribute Phase

A knowledge attribute illustrate the basic description of extracted knowledge and derive relationships with project and similarity draw-unit. The main purpose of knowledge attribute is provides the relationship and available knowledge information for knowledge workers and general users. Knowledge attributes include the keywords, description, project name, activity name, contributor, and attached files.

4.1.3 Knowledge Linking Phase

The knowledge link is identified after completing the knowledge attribute. The knowledge link is first indicated when the tacit or explicit knowledge is available and documenting, and is later confirmed. Two types of knowledge linking are proposed in the paper. One is draw-unit link draw-unit based on high similarity. Second is draw-unit link knowledge based on relationship between draw-unit and project. When the contributor creates a new link, the link needs to be examined and confirmed before knowledge map is published. Finally, all knowledge map need to be validated before the map is published. All the validation process must be communicated with domain experts, knowledge worker, and knowledge map producer in the enterprise knowledge management division.

5. The System

This section describes in detail the CDBKM system. The system architecture includes the Presentation Layer, the Business Logic Layer and the Data Access Layer (see Fig 2). After the user logging in, user is taken to the respective interface wherein information is classified under sections of ‘Project Info’, and the related entity. The architecture used is a three tiers model, with HTML, JavaScript /Servlets forming the user interface (presentation layer), the connection layer (JSP / JDBC) (Business Logic Layer) and the SQL RDBMS forming the Data Access Layer. The server of the CDBKM system supports three distinct layers - interface, access, application and database layers; each has its own responsibilities.

- *Presentation Layer:* Presentation Layer is responsible for the presentation of data, receiving user events and controlling the user interface. HTML/DHTML with JavaScript is used for developing User Interface Screens. Furthermore, Uses Socket class to communicate with server and Client side validations are done through JavaScript.

- *Business Logic Layer:* Business logic layer is created using ServerSocket class. It keeps listening for the clients to communicate with it for service. Every time a new client logs on, a separate session is created for processing its the following modules are developed in the Business Logic Layer.

- *Data Access Layer:* Data Access Layer tier is responsible for data storage. Relational database systems and MS SQL 2003 is adopted in the system. All the changes to the database occur after the exceptions are caught handled and confirmation for changes received. Also, system is developed to backup the system database automatically whenever required.

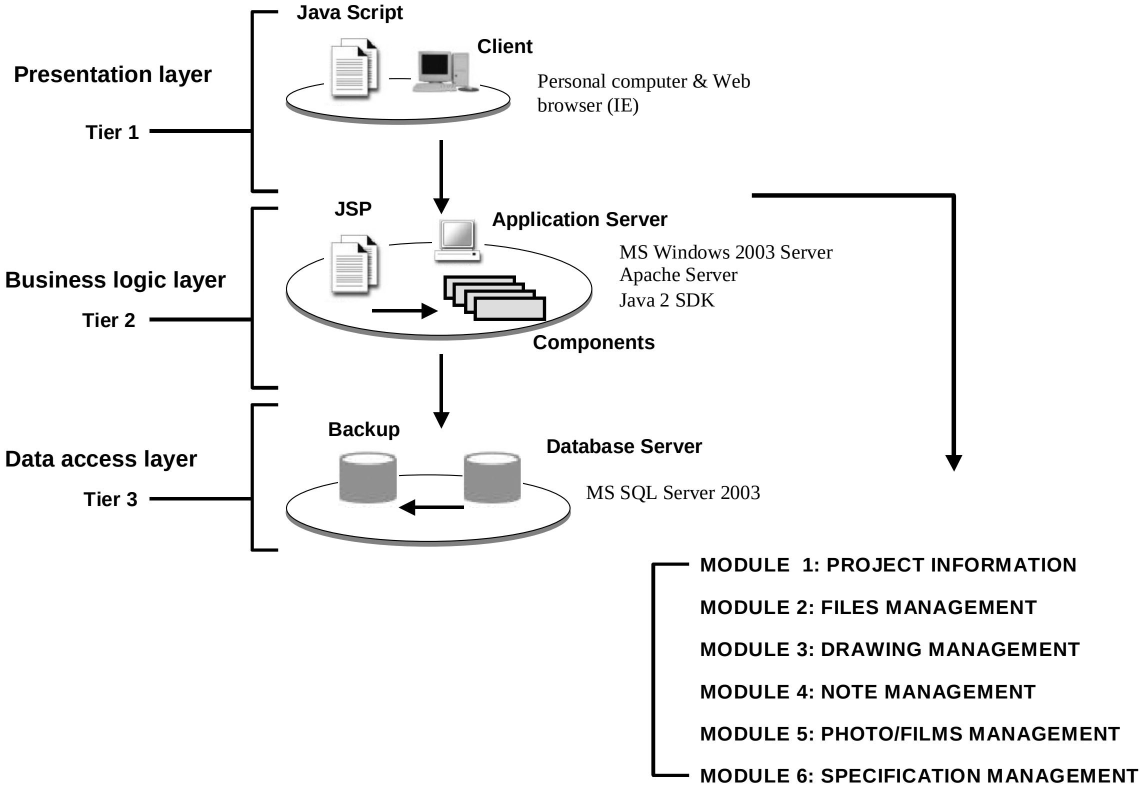

Figure 2. The system architecture and function modules

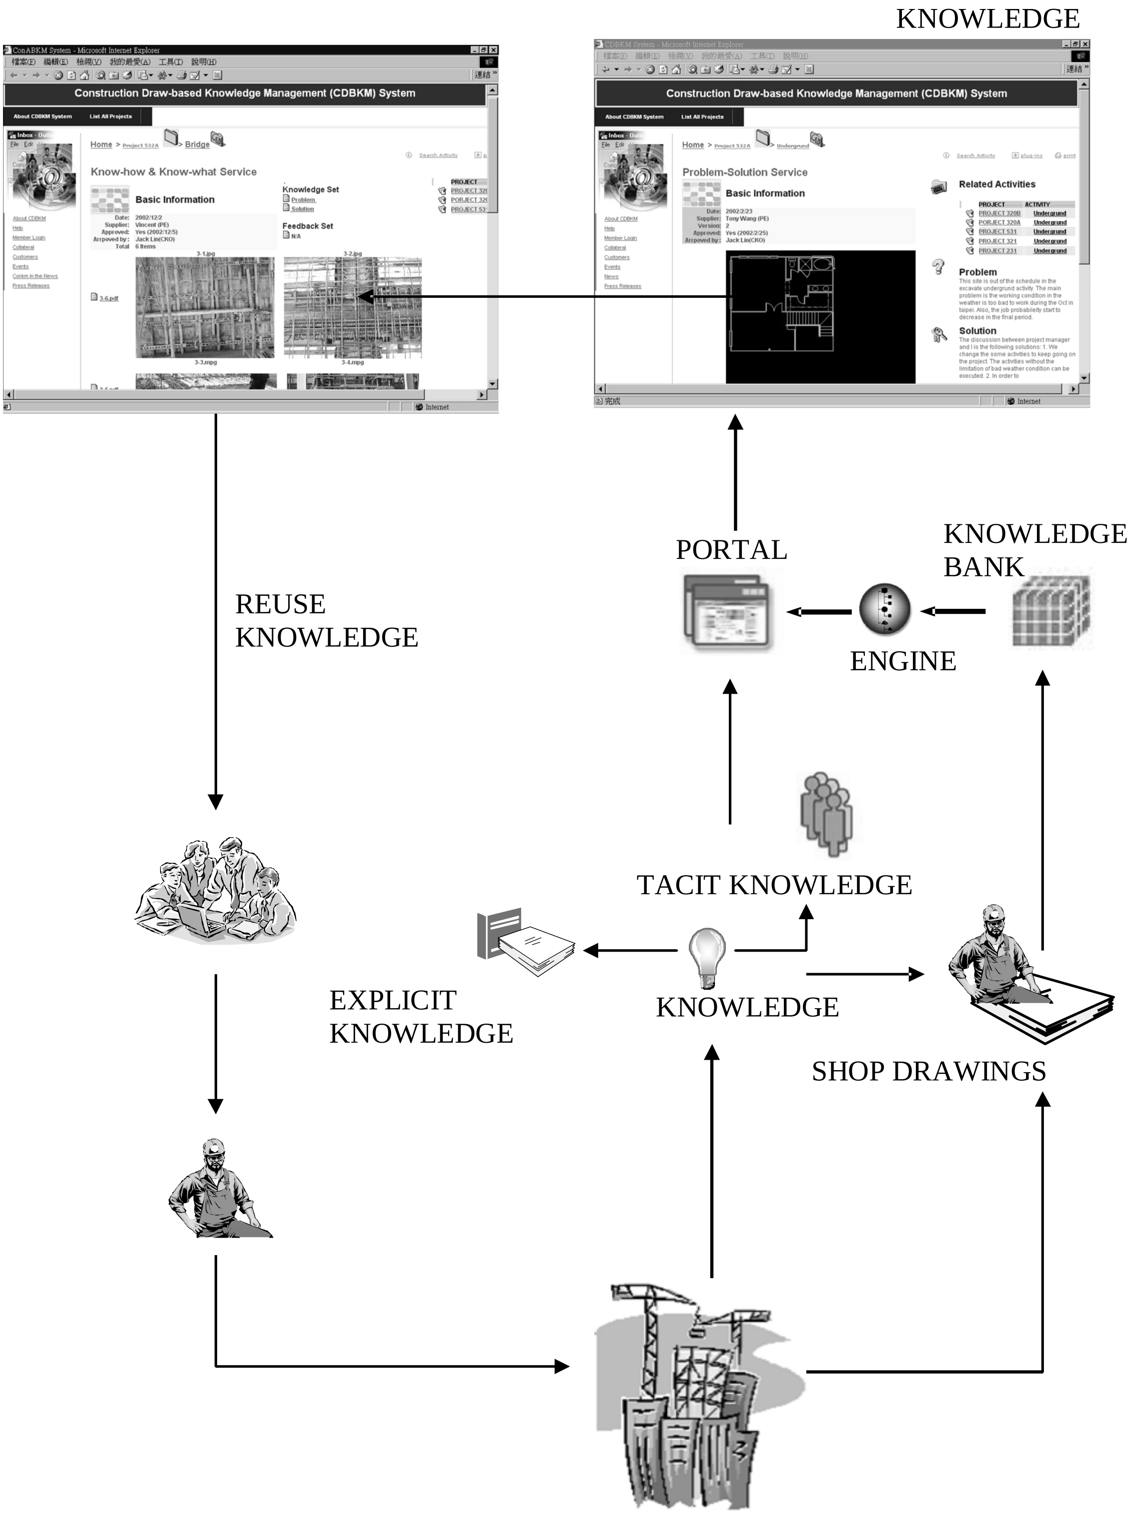

Figure 3. The application of knowledge sharing in CDBKM system

6. Case Study

In the following case, the general contractor won the bid of a precast project, to construct a High-tech office building within one year in Tainan. However, the contractor has no experience of precast construction and the contractor wants to record the whole valued experience and knowledge regard to the new project for further reuse. Therefore, the contractor decided to hire three construction specialists, particularly in precast construction to assist the senior engineers in order to finish the project on time as required. For the future precast projects could process more easily, the company decided to take a good advantage of knowledge management to pass on the valuable know-how to the engineers and manage it well to keep the knowledge inside the company. The following case study is the contractor applied and practiced knowledge management by using construction draw-based knowledge map system.

6.1 Knowledge Acquisition Phase

Knowledge workers help the senior engineer to collect related information/documentation and coverts it into digital format. After the related information and documentation have been digitized, the senior engineer edits descriptions/notes concerning that digital information and packages them as knowledge set into the related drawing-units.

6.2 Knowledge Extraction Phase

The senior engineer and knowledge workers record all the operating procedures by taking digital video and photographs. The senior engineer discussed problems with experts every week twice to accelerate the solving of the problem in question. All discussions were recorded and summarized as suggested by experts. Discussions and meeting with experts continued for ten months, until the problem was solved. The senior engineer recorded and summarized his experience and domain knowledge into the draw-units in the system to enable the problem's solution to be reused in other and future projects. The domain knowledge included the problem description (including documents, photographs, drawings and specifications), the problem's solution (including related documents and photographs and video of processes), and expert suggestions (such as notes, discussions and meeting records). Knowledge was extracted according to each process defined as related to the draw-units of shop drawings. Domain knowledge and experience was organized according to the attribute of the draw-units concerned. Furthermore, every senior engineer in the project is required to provide his own knowledge concerning the tasks for which he is responsible.

6.3 Knowledge Storage Phase

When the submitted knowledge set is approved, knowledge workers manage knowledge sets and classify this knowledge by placing it in an appropriate position (the draw-units of shop drawings) in the system. In other words, users can find and read related domain knowledge directly just clicking these draw-units of shop drawings. All knowledge map (draw-units of shop drawings) need to be validated to perform well before the map is published. All the validation must be conducted with domain experts, knowledge worker, and knowledge map producer in the enterprise knowledge implantation term. Finally, the knowledge set is automatically backed up from the knowledge bank to another database. After approving and storing knowledge, the system sends a message regarding the updating of the knowledge to the appropriate users automatically.

6.4 Knowledge Sharing Phase

The general contractor bid another precast project after the High-tech office building constructed six months ago. A senior engineer with no prior High-tech office building experience meets a similar problem and tries to locate past knowledge/information to help him solve the problem. The senior engineer uses the keyword search to find the expert who has domain knowledge concerned precast building. The senior engineer finds the experts and retrieves, refers to and studies the knowledge set (including digital video and documentation) supported by these senior engineers. He starts to apply and reuse the knowledge in his own project. Also, the senior engineer gives some feedback and offers knowledge that can be reused when others face new problems. Additionally, some senior engineers in other projects and reuse the same knowledge to solve the same problem at reduced cost.

6.5 Knowledge Update Phase

After applying knowledge and information to the other similar projects, the senior engineer solves his problem and finds a new solution in collaboration with other engineers. Finally, the senior engineer notes and submits the new suggestion and experience to project map, associated with the original knowledge. Furthermore, the knowledge is updated later because further feedback and another solution is provided regarding the same problem. After the approval process has been completed, the updated knowledge set is republished in the draw-units of shop drawings and notice message will be sent to the authorized members.

7. Conclusions

This study proposes the application of knowledge management in the construction phase of construction projects using a web-based technology and portal. The integration of knowledge management and web-based technologies appears to be a promising means of improving construction operation and management, especially in the construction phases of projects. The concept of Draw-based knowledge management (CDBKM) is presented, and a system for use as a knowledge-sharing platform in construction projects is presented. The construction Draw-based knowledge management system maps valuable information and knowledge into draw-units of shop drawings during the construction phase. The CDBKM system is advanced, at least in the following respects; the CDBKM system provides insight into the factors that have an impact on construction management, and so helps engineers to exchange knowledge and enhance the quality of the project. Participating engineers can interact with the computer to gain domain knowledge, and thus prepare for and participate in a construction project. Briefly, the CDBKM system can assist engineers by providing structured and unstructured information and knowledge by referring draw-units of shop drawings. The knowledge map in the system mainly deals with the assistance to find the needed knowledge easily and effectively. The primary purposes of using draw-units of shop drawings as knowledge map in the system are as follows; (1) the draw-units of shop drawings is represented in a clear and visual way to identify key knowledge areas that are most strategic and critical to the project, and (2) deals with the assistance for users to find the needed knowledge easily and effectively. The major contributions of the study are as follows; (1) proposing better solutions for construction knowledge management using draw-units of shop drawings, and (2) developing a construction knowledge management system specific for managing construction projects with reference to activities by using a knowledge map.

The demonstration of the system in a case study of the new precast office building located in Tainan indicates that the CDBKM system effectively promotes the sharing and reuse of knowledge for new construction projects. The case study also highlighted the need for improving knowledge management and exchange platforms. However, the received feedbacks based on the use of the system are as follows; (1) the content of knowledge bank in the system is not enough to support and provide the junior engineers to get past experience and knowledge in the beginning; (2) most of senior engineers and experts have low willing to share their knowledge and experience without the proper reword policy and strategy; (3) it takes time and is very inconvenient for senior engineers to edit and record the knowledge without any assistance form knowledge workers; (4) it takes time for knowledge workers to convert shop drawings into system, and (5) most senior engineers agree the CDBKM system is a useful platform for them to edit and manage their knowledge and experience.

Dept. of Architecture, The University of Tokyo (smatsu@buildcon.arch.t.u-tokyo.ac.jp)

Abstract

This paper reports how to use the Unified Modeling Language (UML) as a methodology of the development of computer systems, especially for project management in building construction. First, the paper introduces the features of construction project. The authors value the end user computing (EUC) from the viewpoint of organization, and Design Pattern of user interface from that of viewpoint of computer system structure. Secondly, the paper explains the role of UML, and design patterns of user interface with UML. Thirdly, the paper describes the process of actual system developments with UML: Mobile Computer-Aided Management System, Schedule Simulator for Repetitive Construction Work, Long Term Repair Planning System, and Life Cycle Cost Estimation System. Moreover, it develops the evaluation of system with UML. Finally, the paper summarizes the methodology and discusses the effectiveness.

Keywords: Project management, building construction, computer-aided engineering, end user computing, modelling, unified modeling language

1. Introduction

1.1 Building Construction and Project Management

Building Construction has some features as follows. It is unique and local production. The design and specification is unique. Production is usually executed as a project. So, members in a project such as an architect, a general contractor and subcontractors are usually organized each project. On the other hand, project management for construction has unchangeable and important core. For instance, quality, cost, deliver, safety and environmental control are essential these days. Many check points for them have already arranged. However, at the same time, project managers must cope with the diversity of projects. The strategy in project will change priorities in project management. The structure and specification of building may affect the process and the point in project management. The adoption of construction methods such as precast concrete will change the work flow of management. That of construction methods such as the division of work area will change the frequency and time of management work. So, project management for construction needs the variability corresponding to the project[5, 7].

1.2 Rapid Expansion of Information Technology

Information technology has rapidly expanded in construction project. Construction managers have recently handled various types of digital information such as drawings, specification, checklists and daily reports. They use computers for construction planning and management. They also use networks: the internet, the intranet, and LAN for the communication among project stakeholders and their data exchange. On the other hand, they need to access the real construction site to manage the construction project. Now the current mobile computing can improve the management work in construction site, and enhance the total productivity of construction management. They have recently used mobile computers for the site management [3, 7, 8]. Information technology is essential in the current construction project. At the same time, it must have the variability corresponding to the feature of construction project.

2. Application of IT in Project Management

In the application of information technology in project management, the authors have practiced the application of EUC and design pattern. The former is the approach from the viewpoint of organization, and the latter is that from the viewpoint of computer system structure. Both are the mechanism to get the variability in computer systems.

2.1 End User Computing

The authors recognize that EUC is a useful concept corresponding to enhance the customer satisfaction. Strictly speaking, EUC means that end users develop computer system to support their own work. However, it is still unrealistic that end users, architects and/or construction managers, develop the whole of the computer system for their work. In general, their current literacy for the development of the system is not enough. So, the authors have promoted that end users, architects and/or construction managers, take part in the development of computer system supporting to project management for construction. The EUC means that the collaboration of end users and system developers. The EUC makes it easy to consider the opinion of end users. However, there is another opinion that EUC derives many poor imitations from the original easily. As a result, the use of computer in the organization gets confused. So, a useful mechanism about the structure of computer system is necessary.

2.2 Modularity and Design Pattern

The authors adopt Modularity and Design pattern as key concepts to realize the EUC. Figure 1 shows their overview. A module is a part that performs a particular function. A system component is an embodiment of module in computer system. The feature is the encapsulation of the internal mechanism, and the interface between the internal and the external. The interface means the connection between components. The components realize Object-Oriented Design.

The practice of Object-Oriented Design produces design pattern. Design pattern is repeated and regular forms in the diverse combination of system components. For instance, there is a scrollbar. This is a system component about user interface for the change of objects such as data and/or screen. If the object is the second dimension, the user interface with two scrollbars is adopted. If it is the third dimension, the user interface with three scrollbars is adopted. Either of them is mostly used in real works. They are design patterns. The rule about design pattern, including how to combine system components and how to combine design patterns, is design rule. The authors regard design pattern of user interface as important. End users can take part in the design of user interface because it is directly related to them. That is, they can customize and combine the design patterns of user interface freely under the design rule. After the completion of the preliminary design with design patterns by end users, system developers can complete the computer system easily. They can develop the computer system corresponding to unique features of project quickly. This is the mechanism of diverse and rapid design [2, 4, 8].

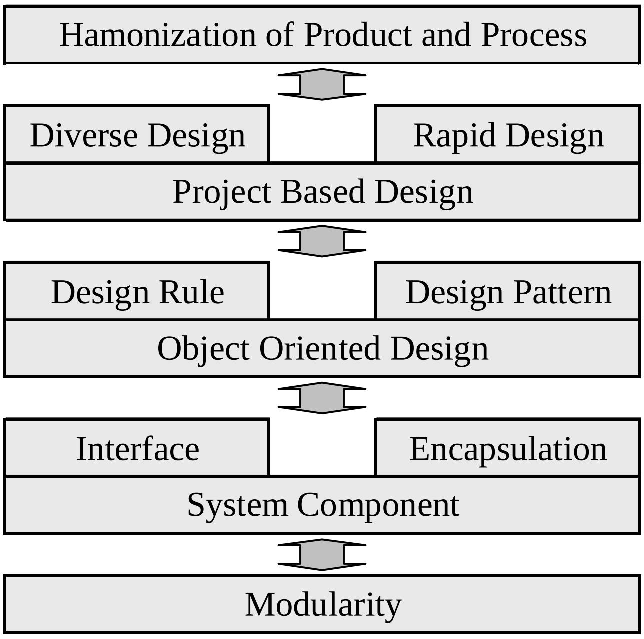

Figure 1: Concept of Modularity and Design Pattern for Product and Process

2.3 Problems to be Solved

The authors have developed actual computer systems based on EUC and design pattern: Mobile Computer-Aided Management System, Schedule Simulator for Repetitive Construction Work, Long Term Repair Planning System, and Life Cycle Cost Estimation System. Through these developments, the authors understand that the modelling, which both end users and system developers can understand, is necessary and important. There are two points in the modelling. One is the expression of system mechanism such as design pattern and system component. It is necessary for end users to recognize the function, control, and behaviour of computer system. It is also important for system developers to be able to build a computer system with the model. In other words, the modelling must be a design tool from the view point of end users, and be the blueprint from that of system developers. Design pattern can satisfy both requirements. The other is the function of a communication tool between end users and system developers. Common language between them is necessary. A useful language not only between end users and system developers but also among system developers is important.

3. UML as Methodology of Description and Evaluation of Management System

UML is a graphical language for visualizing, specifying, constructing, and documenting the artefacts of a software-intensive system. UML offers a standard way to write a system's blueprints, including conceptual things such as business processes and system functions as well as concrete things such as programming language statements, database schemas, and reusable software components [10]. UML defines some diagrams to describe complex systems. There is some possibility of using UML as a useful design and communication tool.

The authors arranged UML diagrams and set up the modelling flow for this research. Figure 2 shows the flow and the role of each diagram. Users in this modelling are end users and system developers. Diagrams are classified in three broad categories. They are basically used in ascending order, but sometimes in parallel.

- The first category is the description of use case. Step 1 is the description of use case. Users arrange actual use cases and define the relationship among them with Use Case Diagram. Users describe a scenario each use case. The scope and use of system becomes definite.
- The second category is the description of model behaviour. It is the description of dynamic structure of system. Step 2 is the description of model process. Users describe the work flow of the model with Activity Diagram. This helps the definition of scope of computer system. Step 3 is the description of message flow. Users describe the message flow in the model with Sequence Diagram. This helps the definition of data flow in system. Step 4 is the description of the flow of user interface model. Users describe the flow with Sequence Diagram. As mentioned above, user interface is an important component in EUC. Authors arrange the model with UML diagram. Step 5 is the description of state transition. Users describe the state transition of the system condition with Statechart Diagram. This is especially useful for the description of the repetitive procedure.
- The last category is the description for the implementation of system. Step 6 is the description of class structure. Users describe class structure with Class Diagram. Class is an abstract concept and is refined through the description of case studies and model behaviour. Step 7 is the description of system structure. Users describe the dependencies among software and the structure of hardware with Component and/or Deployment Diagram.

Case Study	1	Use Case Diagram	Description of Use Case
Model Behavior	2	Activity Diagram	Description of Model Process
	3	Sequence Diagram	Description of Message Flow
	4	Sequence Diagram	Description of GUI Flow
	5	Statechart Diagram	Description of State Transition
System Structure	6	Class Diagram	Description of Class Structure
	7	Component Diagram Deployment Diagram	Description of Ssytem Structure

Figure 2: Flow in the Use of UML

4. How to Describe Management Systems with UML

Examples of the description of systems with UML from the viewpoint of both the definition of system and the communication between end users and system developers are as follows.

4.1 CASE 1: Mobile Computer-Aided Management System

The inspection system with the personal digital assistants (PDA), especially for finish work of dwelling apartment, is a subsystem of Mobile Computer-Aided Management System [7, 8].

The first step of modelling in this research is the description of the use case. Figure 1 shows Use Case Diagram of the system. It shows that an inspector is an actor of using the system, and that a rectifier is one of receiving the benefit of the system. Clients, supervisors, construction managers and foremen can be the user of the system. Foremen are the rectifier of defects. Moreover, the diagram shows that the system includes five sub works such as “record the position” and “issue site instruction”. These sub works show a scenario in the case that an inspector inspects dwelling units. In a scenario, a construction manager in general contractor uses the system, and issues site instruction to foremen. The work of “record defects in dwelling units” extends to the overview of the system. The inspection for common corridor is possible as another use case.

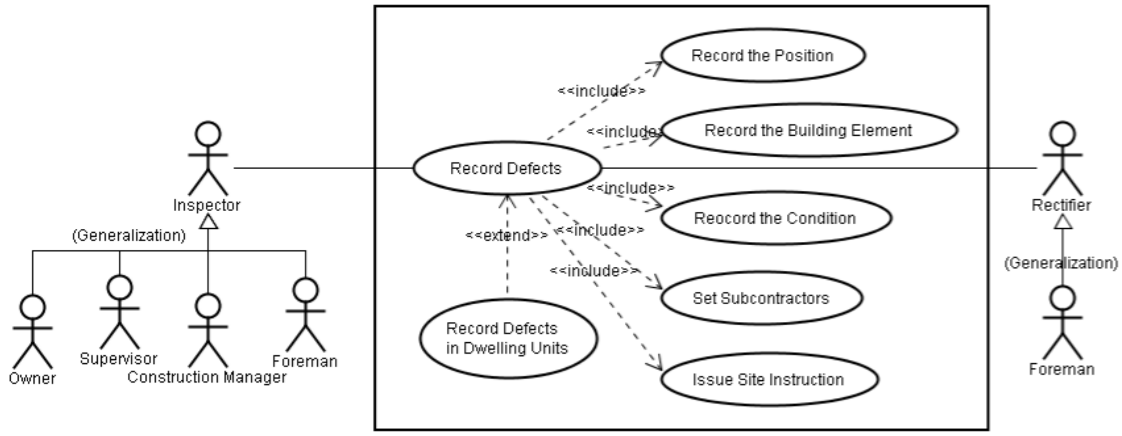

Figure 3: Use Case Diagram of Mobile Computer Management System

The second category is the description of system from the dynamic view point. The data exchange in the system and the state transition of the system are described as the behaviour of system. Activity Diagram basically indicates a flowchart. It makes clear of the flow and sequence of sub works. It usually sets the lane for the persons concerned. The lane makes clear each role in the inspection. Moreover, works in the diagram can be classified by the type of content such as decision making and data input. This classification is related to the scope and role of computer system. Figure 4 shows Sequence Diagram. It focuses on the message flow. The related subjects are the sender and receiver on messages. They are the actors such as an inspector and the parts of the system. This diagram is also related to the scope and role of computer system.

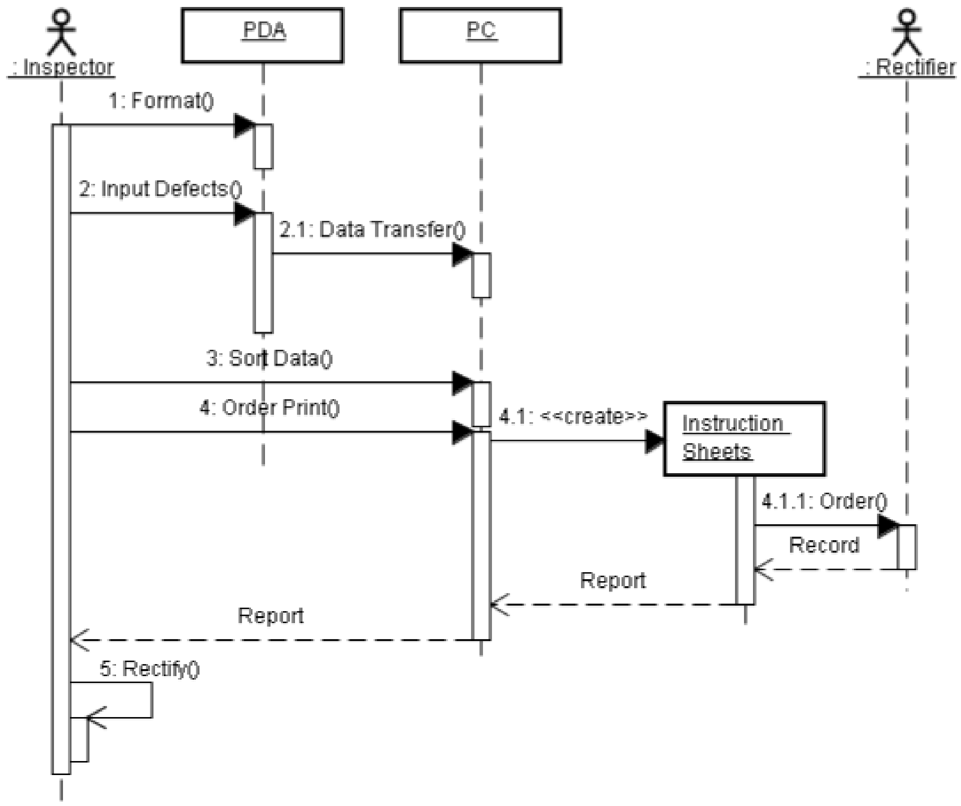

Figure 4: Sequence Diagram

The authors recognize the graphical user interface (GUI) as the important object of design pattern for EUC. It is familiar to both end users and system developers. The left sequence diagram in Figure 5 shows the message flow around GUI model in the inspection system. This model, which the authors have arranged for EUC, has five properties. The first one is the name of design pattern such as pattern-A and pattern-B, which is just for the identification. The second one is the type of control of system component such as the list and the scrollbar. In this case, this means a tool in data input. The third one is the type of access to GUI such as the selection of item and the direct input of information. The forth one is the type of data such as Integer, String and Boolean. The fifth one is the number of system component. The type of data is related to the control and access. For instance, the selection of an item from the list is suitable for the input of an item. The use of scrollbar is suitable for the input of numerical data, especially by construction managers with gloves out of doors in construction site. As Sequence Diagram shows the message flow, the input and output in the system becomes clear. The content of this GUI model is also familiar to both end users and system developers. Therefore, this flow can be designed by the collaboration of end users and system developers. Once GUI models are established, the development of actual GUI is easy and doesn't need much time because the model, design pattern, has designed the detail of the specification in advance. The right one in Figure 5 shows the development of actual GUI in the system.

The third category is the description of system structure from the static view point. Figure 6 shows Class Diagram of the inspection system. Class Diagram is a graph of classifier elements connected by their various static relationships [10]. The diagram shows the structure of elements and the relation among the elements in the system. The information of the inspection for buildings is composed of inspection information, building information, drawing information and defect information. The information has the properties. The diagram also shows the relation between the actors and the system. The description of overview of organization including the actors and the system will be able to become a tool for the description of business model. Figure 7 shows Deployment Diagram of the inspection system. First, it expresses the component of hardware. Processors are PDA and PC. Secondly, it also expresses the structure of the software including the relation the software and the operating system.

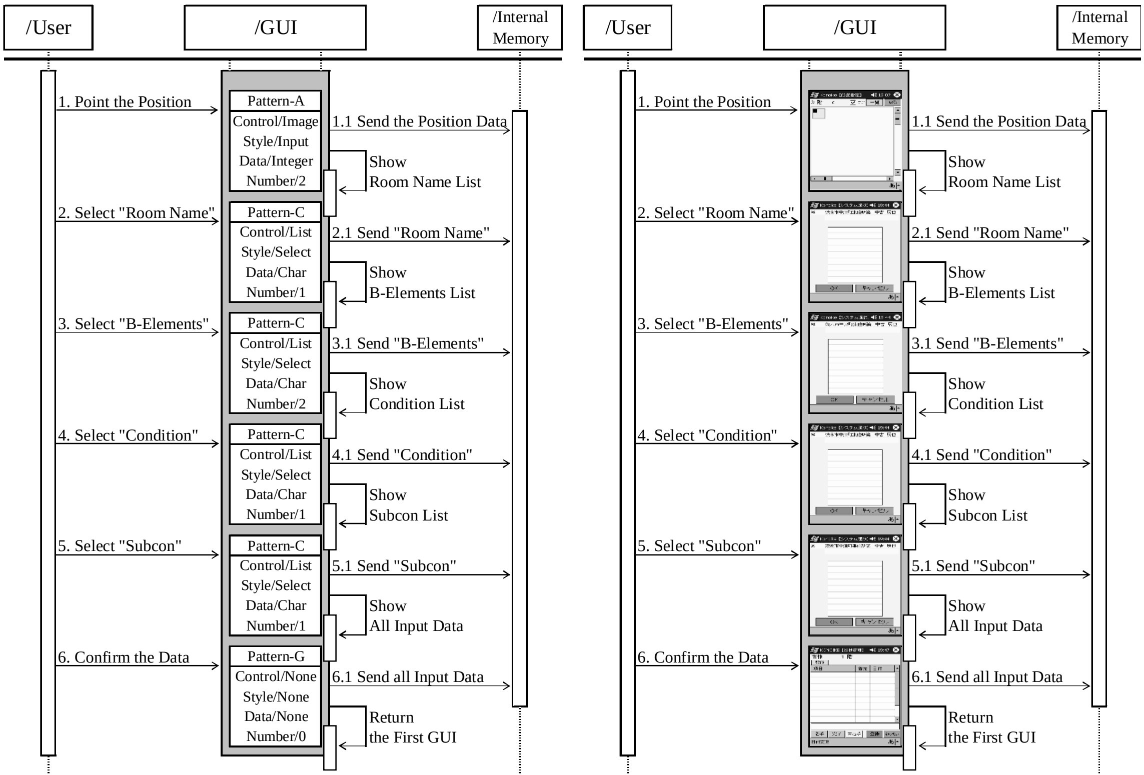

Figure 5: From User Interface Model to Real Graphical User Interface

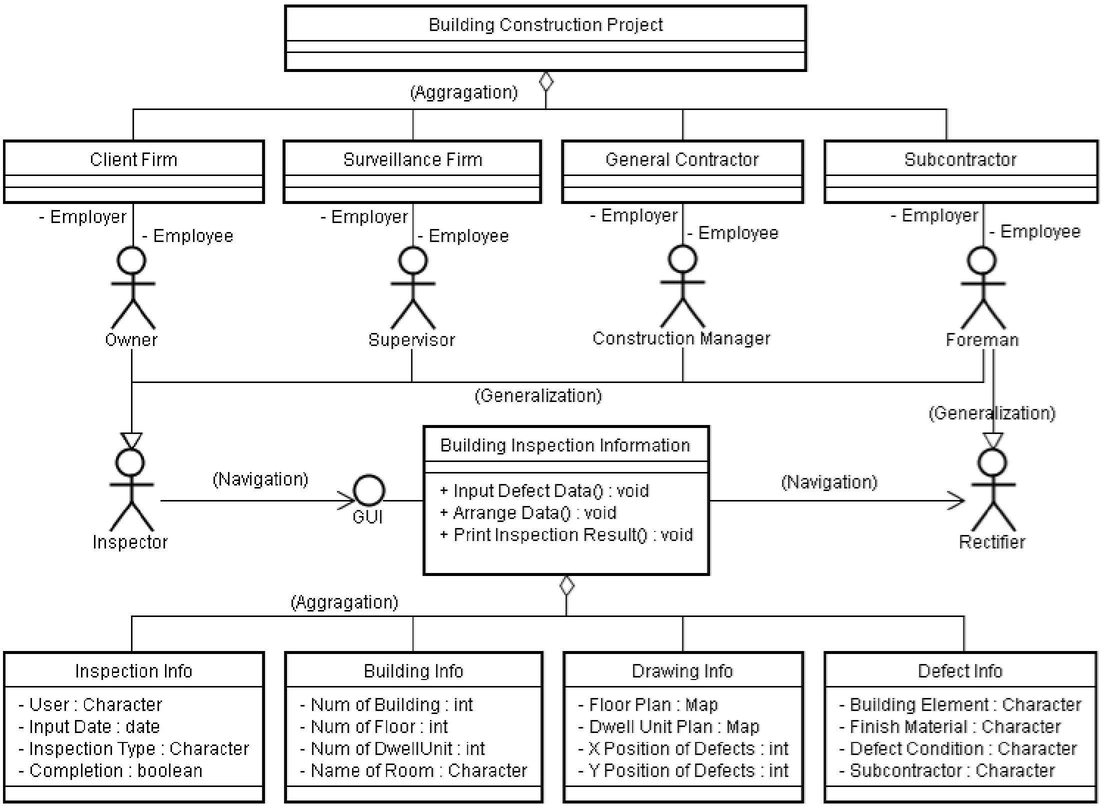

Figure 6: Class Diagram of Mobile Computer-Aided Management System

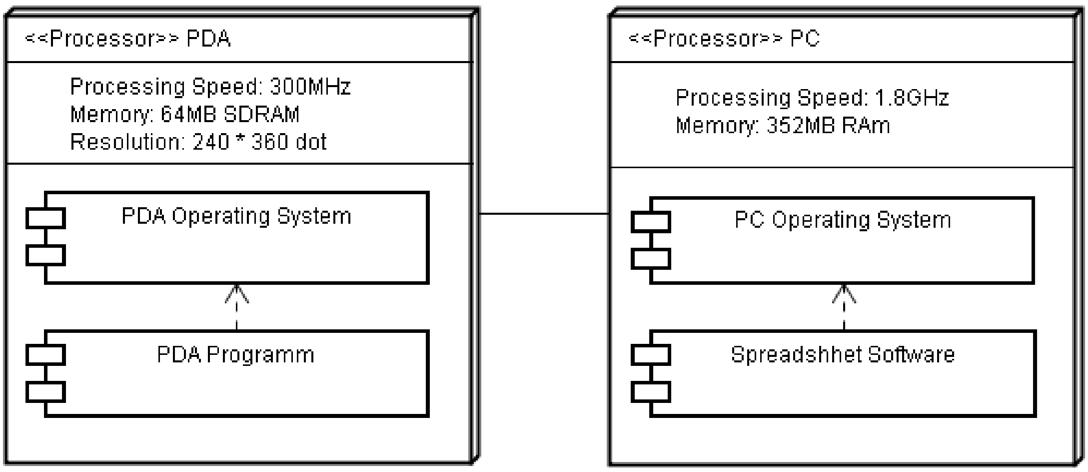

Figure 7: Deployment Diagram of Mobile Computer-Aided Management System

4.2 CASE 2: Schedule Simulator for Repetitive Construction Work

Figure 8 shows Use Case Diagram of Schedule Simulator [5]. The meaning is as follows. The system is an interactive one. Construction managers use the system for their own construction planning. They set up the system and get the answer. The planning of cycle schedule with the simulator is composed of three sub works: “set a construction plan”, “get the schedule” and “evaluate the schedule plan”.

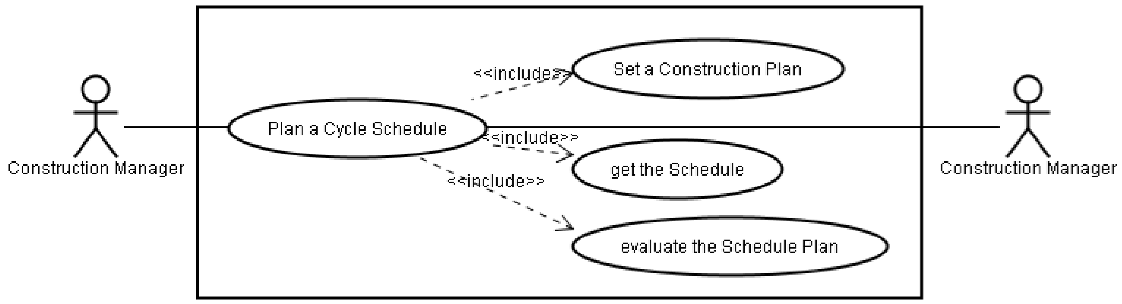

Figure 8: Use Case Diagram of Schedule Simulator

Figure 9 shows Class Diagram of the system. The meaning is as follows. Class in the system is divided to two categories: the planning and analysis, and the scheduling. The former has three classes: Plan, Database and Plan Analysis, and the latter has three classes: Relationship, Schedule and Graph. Figure 10 shows Deployment Diagram of the system. Spreadsheet software takes charge of the category of planning and analysis. Scheduling software takes charge of that of scheduling. The graphical user interface is directly connected with the spreadsheet software. End users use the function of the scheduling software by way of the spreadsheet software.

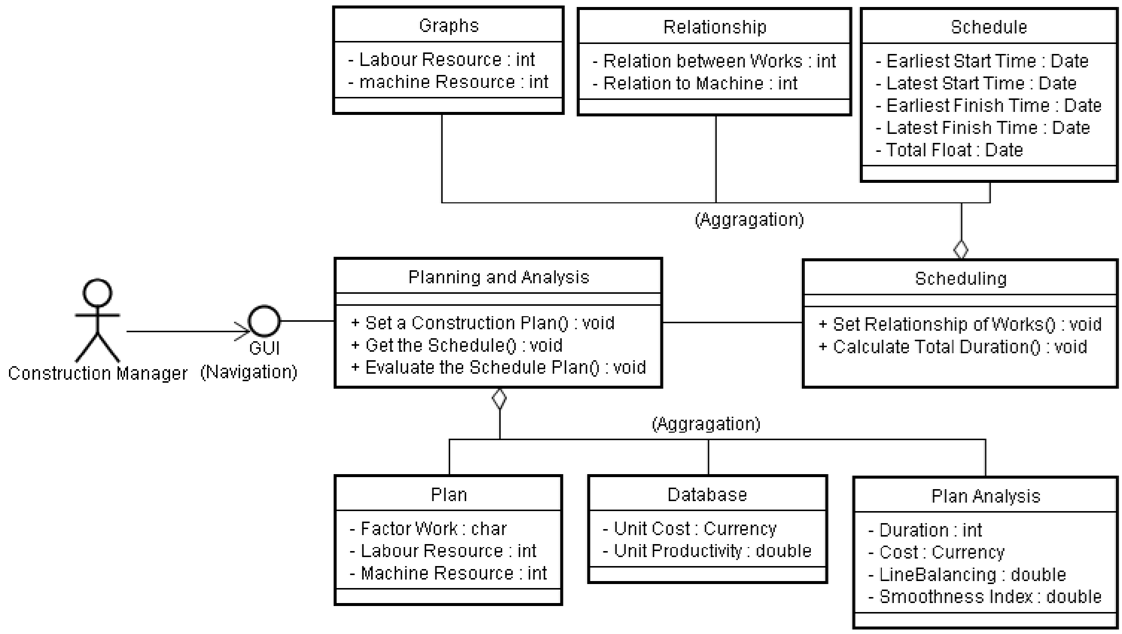

Figure9: Class Diagram of Schedule Simulator

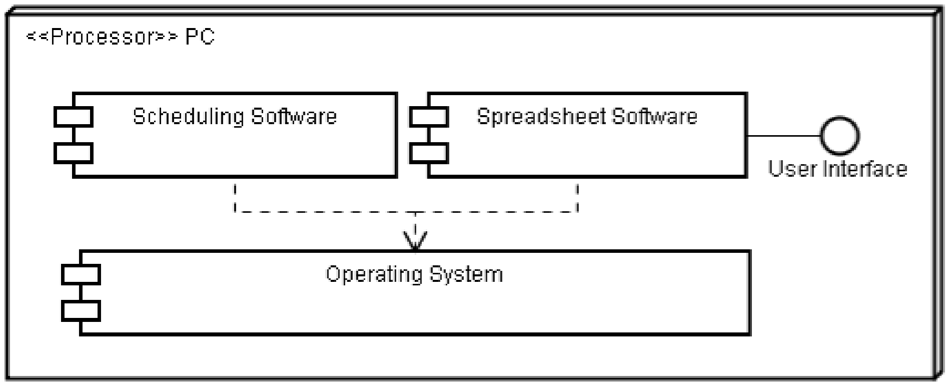

Figure 10: Deployment Diagram

4.3 CASE 3: Long Term Repair Planning and LCC Estimation System

Figure 11 shows Use Case Diagram of Long Term Repair Planning (LTRP) System [6]. It shows that construction managers and equipment engineers use the system, and that the owner and facility managers get the result. The system is composed of making a long term repair time table, and calculating the annual expense.

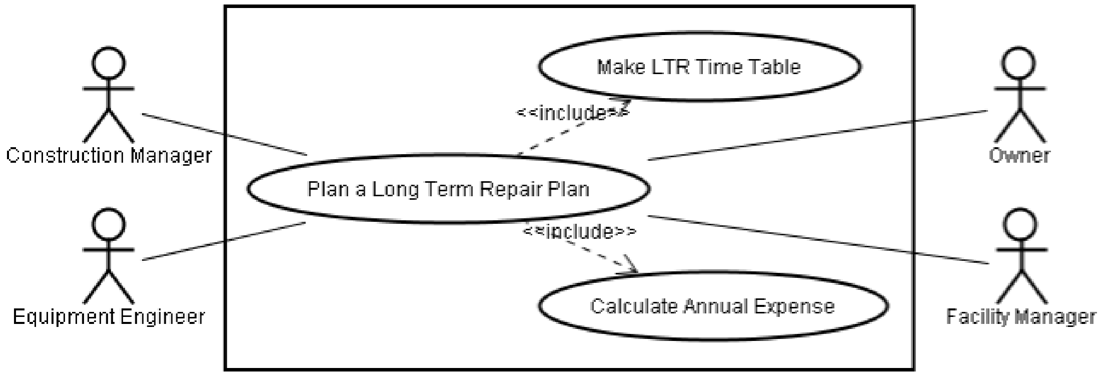

Figure 11: Use Case Diagram of Long Term Repair Planning

Class Diagram in figure 12 shows the structure of the systems: LTRP System and LCC Estimation System. These systems hold the data of cost and repair cycle for buildings in common. The diagram also shows the users. Sequence Diagram in figure 13 shows the message flow between users and LCC Estimation System, and that between the system and the database.

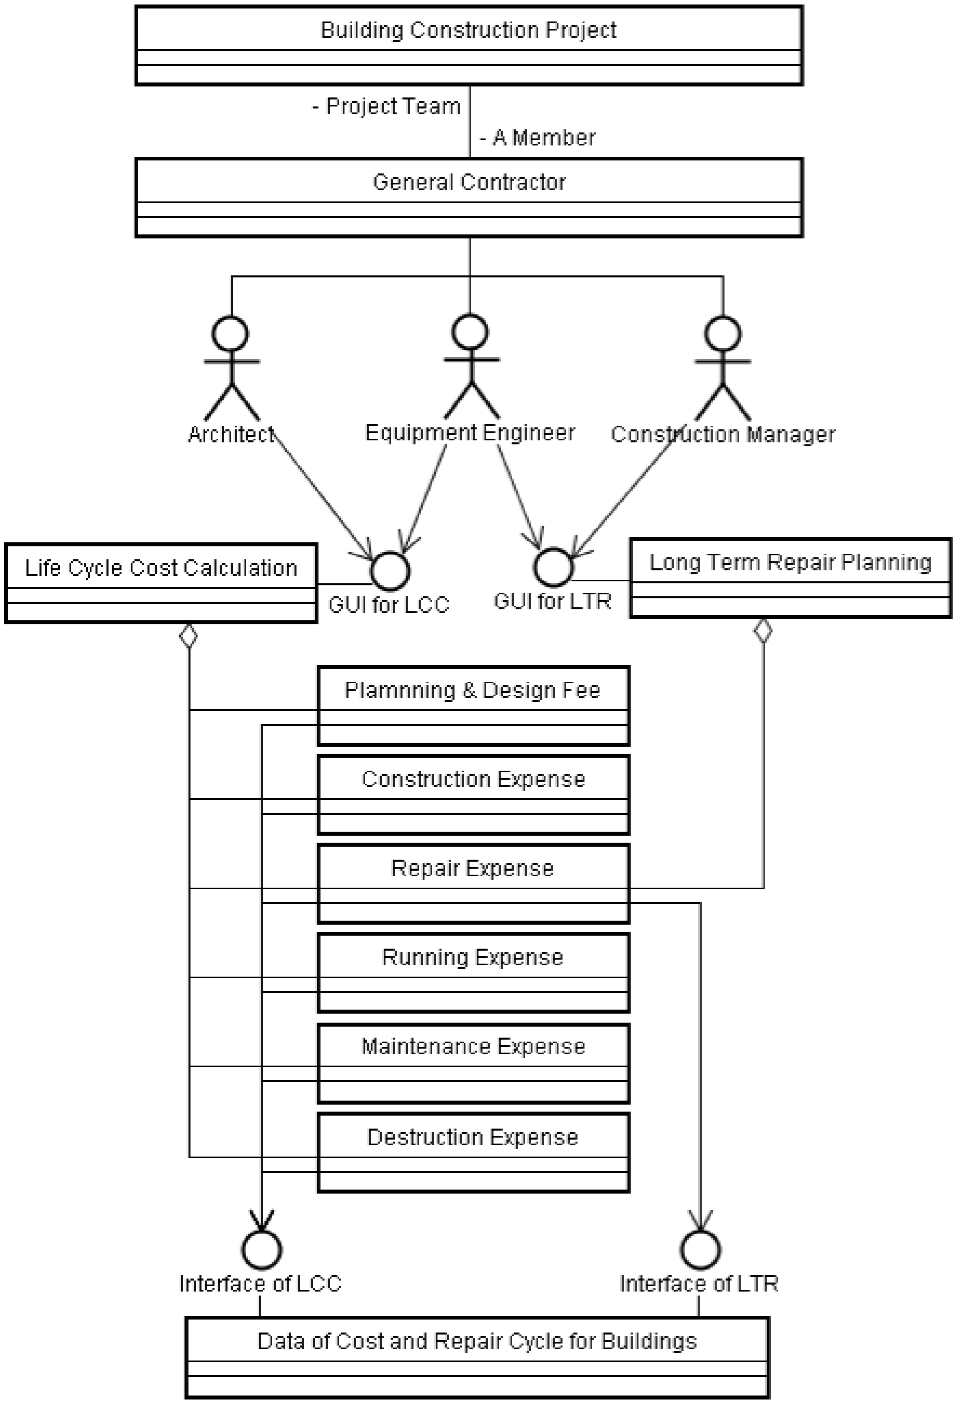

Figure 12: Class Diagram of LTR&LCC System

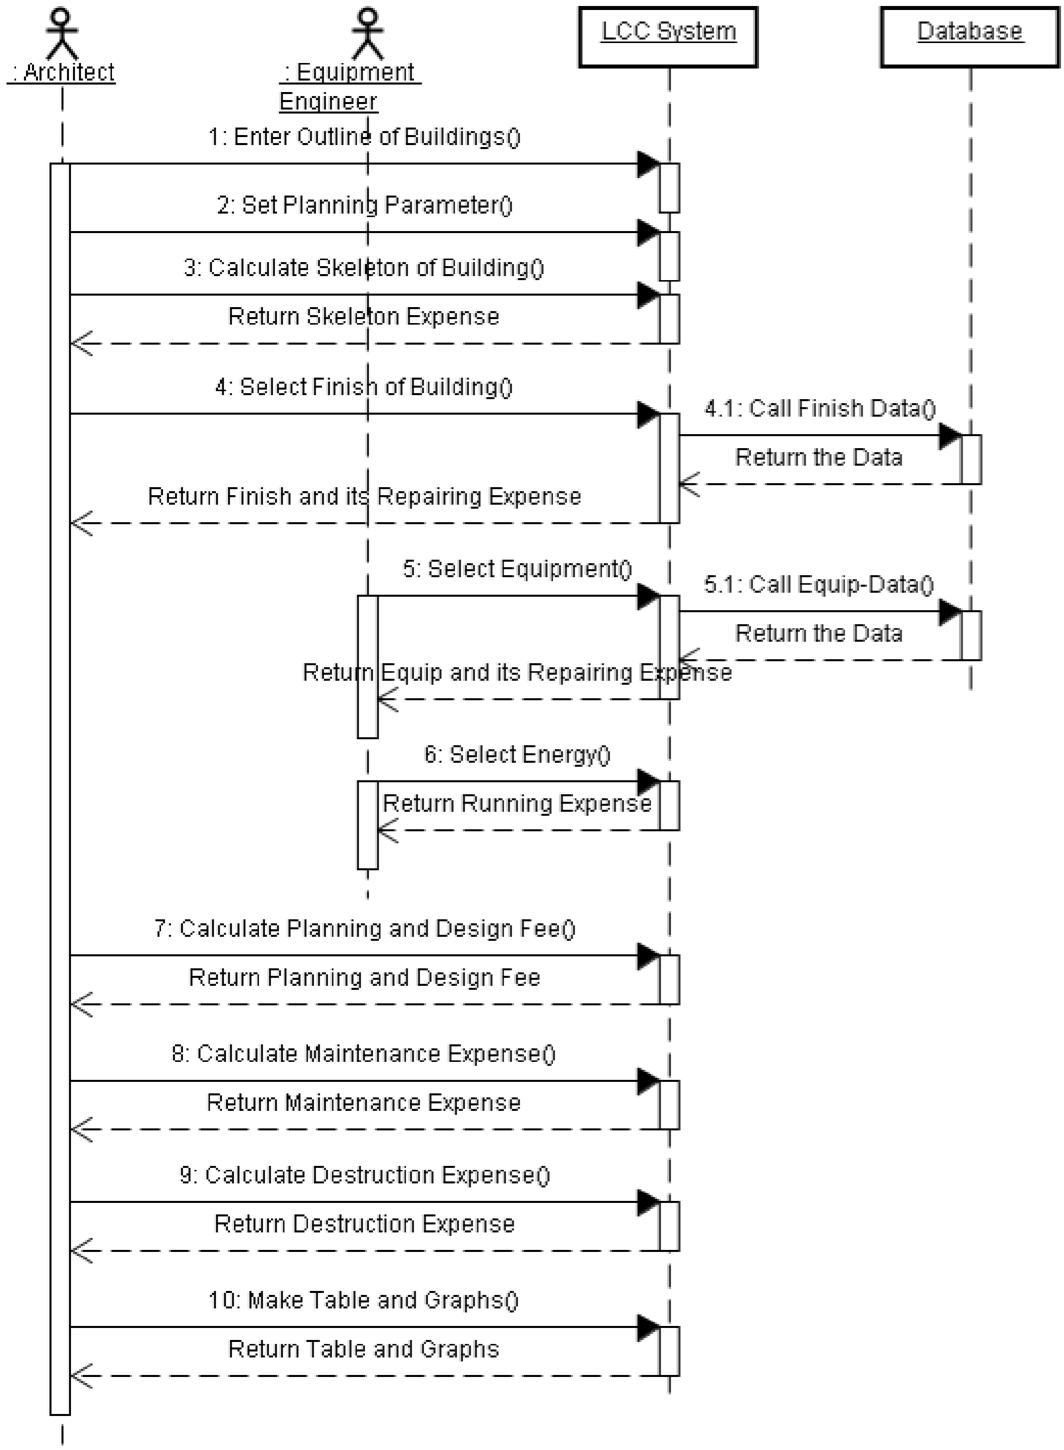

Figure13: Sequence Diagram for LCC

5. How to Evaluate Management System with UML

The introduction of IT systems usually aims the improvement of productivity and/or the extension of the function in the system. Therefore, end users and system developers must estimate the change, examine the effect, and evaluate the new system carefully. The tool for them is necessary. There is some possibility in the description of the system with UML.

5.1 Analysis of Shorter Working Hours and Working Saving

UML is a graphical language for visualizing, specifying, constructing, and documenting the artefacts of a software-intensive system [10]. Therefore, it can express the difference between systems visually. Figure 14 shows sequence diagrams of two models about the inspection work. Model 1 is the traditional way with paper sheets for both the data input and the rectifying order. Model 2 applies Mobile Computer-Aided Management System for inputting the data and making the order sorted by subcontractor. The comparison shows that the working hours and volume of inspectors decreases at the transition from Model 1 to Model 2. Moreover, Model 2 holds the data and creates the inspection sheet as a digital form. This means the door open to the further development. For instance, the analysis of the defect data is possible. All stakeholders will be able to hold the result in common through the network.

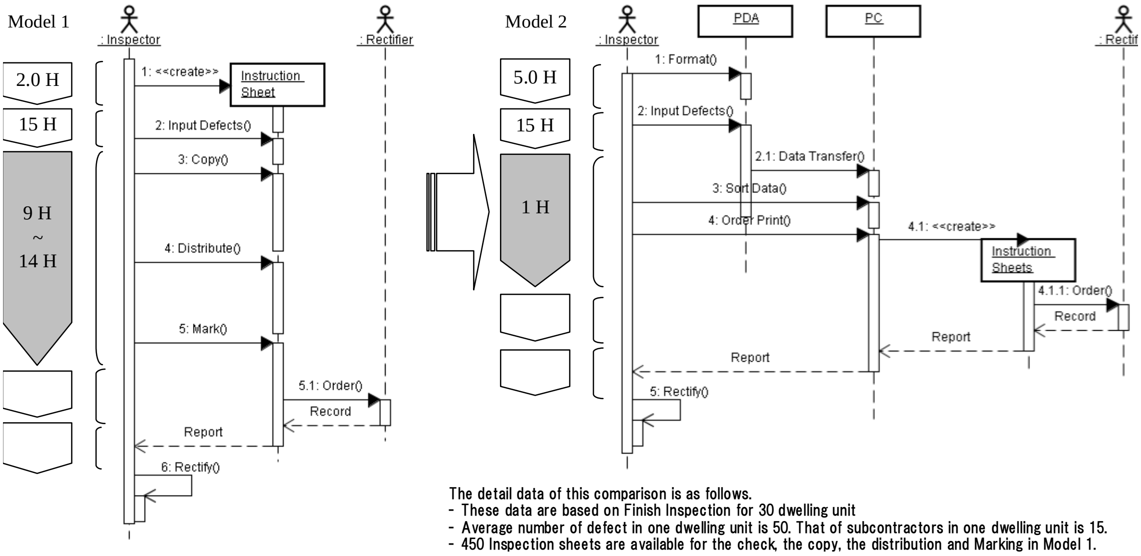

Figure 14: Comparison of models with Sequence Diagram

5.2 From Project-based Analysis to Company-based Analysis

Not only project-based analysis but also company-based analysis is necessary in the improvement of work because the work out of project such as the development of the system and the maintenance of database exists. The consideration of added value of systematisation with IT is important. So, the description of business model has been more important [1, 9]. The enlargement of the description scope will improve the precision of the evaluation.

6. Conclusions and Discussion

This paper describes the methodology of the description and evaluation of management system with UML. Especially, the authors aim the information system based on EUC and design pattern at a target. EUC is the approach from the viewpoint of organization, and design pattern is that from the viewpoint of computer system structure. Both are the mechanism to realize the diverse and rapid design of information system.

First, the paper shows the function of diagrams and the order of their use. The paper demonstrates the description of three systems with UML. Use Case diagram can show the use case of the systems. Sequence diagram can show the data flow in the system. Class diagram can show the organization of actors and information in the system. Deployment diagram can show the composition of hardware and software in the system. The paper shows the description of the actual systems and confirms the function of UML as a useful tool to describe the diverse of computer system.

Secondly, the paper proposes the user interface model in sequence diagram. The model is the key in the communication between end users and system developers because end users can give their opinion to the user interface. Moreover, the authors propose design pattern for the model. It makes it easy for end users to approach the model. Once the model is established through their discussion, system developers can develop the system easily and rapidly because design pattern has designed the detail of the specification in advance. In Mobile Computer-Aided Management System, the authors have actually derived some subsystems with design patterns: the inspection system, the progress monitoring system, the position check system, and the checklist and reference system. The paper indicates that EUC and design pattern are useful for the project-based development of computer system corresponding to project management for construction, and gives demonstrations.

Finally, the paper shows the comparison of two sequence diagrams as the evaluation of the system with UML. The one shows the traditional way with paper sheet for the inspection work. The other shows the application of Mobile Computer-Aided Management System. The comparison indicates the difference of data flow clearly. However, sequence diagram doesn't show the work volume. The authors add the information of necessary time for factor process. As a result, the diagram makes clear of the shorter working time by the introduction of the computer system. The evaluation of computer system needs the company-based analysis. More extension of UML is necessary. Marshall, Erickson and Penker have extended the function of UML for the description of business model [1, 9]. On the other hand, UML has spread as a tool for the description of computer system in actual business. The authors have tried to extend UML from the viewpoint of the evaluation of computer system in business. The authors expect that this result compensate the gap between at the tool level and at the business level.

ICT in Construction and Facilities Management

ICT today is maturing fast and is seen as a key enabler for the better planning, monitoring and control of construction and facilities management activities. It has gone beyond the simple functional purpose of scheduling projects or estimating costs. In fact integrated ICT systems are being used to manage the complete building lifecycle. The use of product models in the form of complete building information models are but one step in this direction.

This book provides a portfolio of ideas and perspectives into the use of ICT for construction and facilities management. How can it be used for design management, management of facilities, and management of construction projects and processes through a shared product model, for managing knowledge, etc. are some of the aspects that are covered. The key question is whether ICT will transform construction and facilities management, or will it serve as a catalyst and enabler for this change.

This book is part of a series of scholarly books on *Combining Forces – Advancing Facilities Management & Construction through Innovation*.

Other books in this series include:
-Understanding the Construction Business and Companies in the New Millennium
-Global Perspectives on Management and Economics in the AEC sector
-Systemic Innovation in the Management of Construction Projects and Processes
-Facilities Business and its Management
-Performance Based Building
-Learning from Experience – New Challenges, Theories and Practices in Construction

Section IV: Lessons from the Field - Case Studies

Preface

The construction industry is a project-based one with the delivered product changing from project to project under the influence of many different factors, one of them being context. This context could as an example be simply the physical conditions surrounding the landscape where the product (the building) is to be delivered. Consequently each day on the construction site brings forth a new problem and a new solution. These problems and solutions are rarely well documented and valuable lessons learned confined to the minds of only those who experienced them. There is little, if at all any follow-up or analysis that may yield valuable lessons learned or new ways of managing projects more effectively and efficiently. Is this due to the way projects are managed in construction, or does the root cause of this lie elsewhere? Based on our experience, do we need a fresh new look at how construction projects are planned, monitored, and controlled?

In Evolution of Physics, Einstein and Infeld [1] state:

> "*Creating a new theory is not like destroying an old barn and erecting a skyscraper in its place. It is rather like climbing a mountain, gaining new and wider views, discovering unexpected connections between our starting points and its rich environment. But the point from which we started out still exists and can be seen, although it appears smaller and forms a tiny part of our broad view gained by the mastery of the obstacles on our adventurous way up*."

Through considerable reflection on the way projects are managed in the construction industry, there has been a move towards an analysis of the underlying theory of project management and its applicability to construction projects. Different viewpoints/perspectives have been presented [2, 3, 4, and 5] and surely more are to follow. Section I of this book is a brief insight into some recent developments.

In the coming years, the construction industry will lose a large portion of its skilled force [6]. It is not only the loss of this skilled force that is a matter of concern for construction organisations, but also the experiences and knowledge that this skilled force will take with them. According to Albert Einstein, "*The only source of knowledge is experience*"[1]. This has been one of the earlier guiding principles of the construction industry where, skills were passed on from master to student, from one generation to the next; the construction industry of yester years was a pool of skilled craftsmen. Industrialisation, large scale projects, and a large mind shift to profitability over the years have changed the very nature of the way industry operates today. In the past, focus was on the transfer of skills to maintain a set of skilled craftsmen, whereas today the focus is on shortening construction times, minimising costs, and effectively utilising resources. Organisations

[1] http://uk.encarta.msn.com/text_761562147___4/Einstein_Albert.html

today are waking up to the reality that their most valuable asset is the intellectual capital (knowledge and experience) of their employees. Significant efforts are being put in place to try to manage this knowledge through social interaction, and to transform organisations into *learning* organisations.

This book is a collection of how learning from experience has contributed to the identification of new challenges, development of new theories, and management of knowledge in construction. Case studies provide practical insights into the subject matter.

How has project management evolved, what have we learnt, what are future research frontiers, should we be managing projects as if we were managing production, can public institutions stimulate innovation in construction, how do social networks contribute to organisational learning and knowledge sharing, etc., are some of the questions this book provides answers to.

Acknowledgements

This book would not have been possible had it not been for the untiring efforts of Dr. Kalle Kähkönen, Chief Research Scientist, VTT – Technical Research Centre of Finland, in championing the scholarly book series on *Combining Forces – Advancing Facilities Management and Construction through Innovation*. A special note of appreciation is extended to all contributing authors for their willingness and enthusiasm in sharing their research and experiences from practice.

Evolution of Project Management – New Perspectives and Research Frontiers

Project Management in Chaos

Juhani Kiiras,
Helsinki University of Technology, Construction Economics and Management
(email: juhani.kiiras@tkk.fi)

Abstract

Traditionally, project management (PM) has been seen as a stable and non-dynamic, linear process. By using traditional risk analysis, one will find only the most probable risks. In reality, the big risks that have never occurred before will remain unidentified. The traditional tools in projects are the Work Breakdown System (WBS) and network planning (PERT). A careful breakdown of a process is of no use if activities are unknown. The network approach does not approve of feedback loops. In addition, the correlations between the durations of activities are forgotten in both the planning and the risk analyses. The PERT or the risk analysis works if external disturbances, feedback loops, and internal correlations are ignored. However, they are not applicable in a state of chaos, on the edge of chaos, or in chaotic environments. Herein, the general chaos theory is applied to the context of project management and an attempt is made to design a new framework for managing versatile projects under unstable circumstances. Chaos in a project is defined as a state where project plans are updated or changed frequently and, moreover, no renewed plans are executed. Projects are potentially chaotic. Large stochastic simulations have been run in order to find out how to prevent the consequences of randomly varying durations, interdependences and correlations, feedback loops and the effect of unknown activities. The results of the simulations are presented in this paper. Some measures have been developed to keep a complex project (operations) on the edge of chaos. One should cut any feedback by using paced project planning, make the WBS independent through separate resources, prevent external effects by using partnerships, and set up an open grass-root communication system.

Keywords: Chaos theory, construction, project management, simulations

1. Introduction

In the 1990s, chaos theory was applied by many scholars in attempt to understand the organizations' ways of operating in extremely dynamic environments. In this paper, chaos theory is applied primarily to the context of project management. Traditionally, project management has been seen as a fairly stable and non-dynamic, linear process (see PMBOK, for instance). A part of traditional project management is risk management: risk identification, risk estimation (probability and consequences), risk response, and risk control. The requirement to estimate the probabilities of all indentified risks implies that traditional risk management is useless in a state of chaos. **Traditional risk management** does not provide us with answers in chaotic and unstable environments. By running this risk analysis, one usually find only the most probable risks coupled with small consequences, and organizations mainly plan their responses to deal with these kinds of risks. In reality, those risks that have big consequences and which have never occurred before remain unidentified.

In turn, **chaos** is a deterministic, non-linear, dynamic, fractal system that produces results which appear to be random. In a state of chaos, a system remains in a restricted area, but it has no equilibrium. In a chaotic system there are several factors, dependencies between these and feedback loops. Changes are irreversible. This description suits organizations well with inherent interdependent feedback forces. The well-known butterfly effect suggests that a chaotic system is sensitively dependent on its original state (and thereby also sensitively dependent on any of its states). In particular, the behavior of project management organizations has traits of vulnerability. In bifurcation, the state of a system is suddenly split into two states. Consecutive bifurcations create chaos. Organizations change due to bifurcation. Development paths are unpredictable. An attractor is a state to which a system strives to re-establish. We are familiar with the habits of organizations to revert back to 'the old way' of doing things despite management's efforts to make changes. Chaotic organizations have so-called "strange" attractors (or states), that they try to achieve. Herein, the term chaos is used quite freely to mean 'uncertainty' and 'instability' as opposed to stable conditions.

The rationale of the paper is as follows. First, chaos is dealt with in both the case of managing an organization and a project. Second, the results of four large simulations are reported on. Third, an attempt is made in order to design a framework for managing versatile projects under unstable circumstances. The reasons for the authors interest in managing projects in chaos stem from the turbulent and unpredictable construction conditions in Russia. Finally, the validity and the consequences of the proposed framework for advancing construction project management are discussed.

2. Chaos within an Organization

Thiertart and Forgues (1995 [1]) have presented **the following hypotheses** about organizations and chaos:

- Organizations are potentially chaotic due to feedback.
- A change from a stable organization to one in chaos happens unnoticed.
- In a state of chaos, small changes may have unpredictably big consequences
- In a state of chaos, new "strange" organizations are created on any level or process.
- The same action leads to a different result in different organizations and at different times.

The more actors, feedback forces, and different time spans of action an organization has, the greater the chance it ends up in chaos. An organization is always in one of three states, i.e. a stable state, moving in a periodically stable state, or in chaos. The moving state is called **the edge of chaos**. Organizations move from one state to another with consecutive bifurcations; i.e. by splitting in two parts. In a chaotic state, the long-term effects of a change are unpredictable. Identical measures within the same organization at different times lead to different results.

A chaotic organization constantly approaches strange forms. A chaotic organizational and process form has a fractal structure. A given chaotic organizational and process forms can be found at the corporate, department, and team levels.

The principles for keeping the operations of an organization on the edge of chaos consists of [2]:

- advancing with small steps and making short term decisions (trying to make a non-linear system linear),
- keeping simultaneously a track-record on what's happening at all levels of the organization and within all its processes,
- trying to detect the first bifurcation at any level or within any process; quickly expanding, and changing immediately your actions according to the perceived consequences.

In a chaotic environment, mere experience is not enough because repeating the same action that worked before does not necessarily result in the same outcome in a subsequent situation.

3. Chaos within a Project

Chaos in a project is a state where project plans are updated or changed frequently, and moreover no renewed plans are executed. Herein, the hypotheses of Thiertart and Forgues [1] are applied to a project as follows:

- Projects are potentially chaotic.
- The more parties involved and the longer the project, the more potentially chaotic it is.
- A project is always in either a stable or chaotic state.
- A change in relations between two or more variables may cause a project to move from a stable state into a state of chaos.
- The consequences of changes taking place in a chaotic project are impossible to predict.
- In a chaotic state, identical actions taken in the same or different project do not lead to the same results.

Internal chaos occurs when its source is one (more) of a project's own actors. When the objectives of an owner, users, or their needs change, disturbances emerge in financing and, thus, keep project plans in flux. On the one hand, poor project planning or control may also be a source of chaos or project planning and control would be means of controlling internal chaos.

External chaos is created by factors that are beyond the influence of the organization. An organization operates in an environment where changes are created, i.e. laws and the regulations of authorities change, deliveries are late, and the loyalty of employees is lost. Business environment seems to be chaotic if one does not understand the way it works. Thereby, the environment and the behavior of people in a foreign culture may seem to be chaotic to an expatriate, even if locals understand it well. There are no chaotic environments – just ignorance about the environment. External human chaos is thus prevented by a better understanding of the environment and the culture.

Chaos takes place in a project, when project control spots **non-planned events** such as (for instance):

- activities change and evolve,
- new activities are created and original ones are not executed,
- activities have to be carried out all over again,
- activities are not finished and everything remains incomplete or almost ready,
- there is a positive correlation between durations of activities,
- new interdependencies suddenly appear and external dependencies occur unexpectedly.

As a result, the objectives of the project are not met, timing fails, and costs get out of hand.

The traditional literature on project management emphasizes what should be done: plan, control, and make corrective actions. In a state of chaos, it is more important to have a general understanding **how to handle the situation** than what to do. Chaos is usually caused by people, not forces of nature, so the key questions should be: who, how, where and when – not what. For preventing chaos, one should thereby ask **WHY things can go wrong**, not WHAT can go wrong? This means that one should understand the mindsets and goals of the project participants as well as the environment and culture in which one operates. This may require an “adapter” (“facilitator”), a cultural interpreter.

4. Why Does Traditional PM Not Work in a State of Chaos?

In projects, a traditional tool of activity analysis is the Work Breakdown System (WBS) and the other tool for scheduling is the network planning technique (PERT). A careful breakdown of a process is of no use if activities within it are unknown, nor does the network approach approve feedback loops. In addition, correlations between activities are often not taken in account in planning and risk analyses. **The traditional PERT or the risk analysis** works if external disturbances, feedback loops, and internal correlations are ignored. In turn, neither works in a state of chaos or on the edge of chaos.

At the TKK/CEM, project scheduling has been simulated stochastically (Monte Carlo) in a number of ways during a long period of time as follows:

- Preventing consequences of randomly varying durations (Vehkaoja J., 1989 [3] ; Porkka-Aarnivuo S., 1989 [4])
- Preventing consequences of interdependencies and correlations (Simppa model) (Ristikartano P., 1994 [5])
- Preventing consequences of feedback loops (Ericsson H., 1999 [6]).
- Preventing a chaos state in complex construction project (ATOSim) (Ristikartano P. 2002 [7])

In these simulations, a feedback loop is described by a positive correlation between the durations of the activities. A positive correlation means that if the preceding task is late, the following task will take longer to perform as well. In a similar way, **project control** can be described by a negative correlation: if the preceding task is late, the duration of the following task will have to be made shorter.

Some key results of the TKK/CEM simulations are as follows.

(a) **In the context of project division, stages, and activities,** a project has to be cut into stages so that disturbances can be "squeezed into seams". Long peaceful activities that can be corrected should be preferred. Starting activities in intervals so activity planning can be done are preferred, and buffers are reserved at the end of the stages.

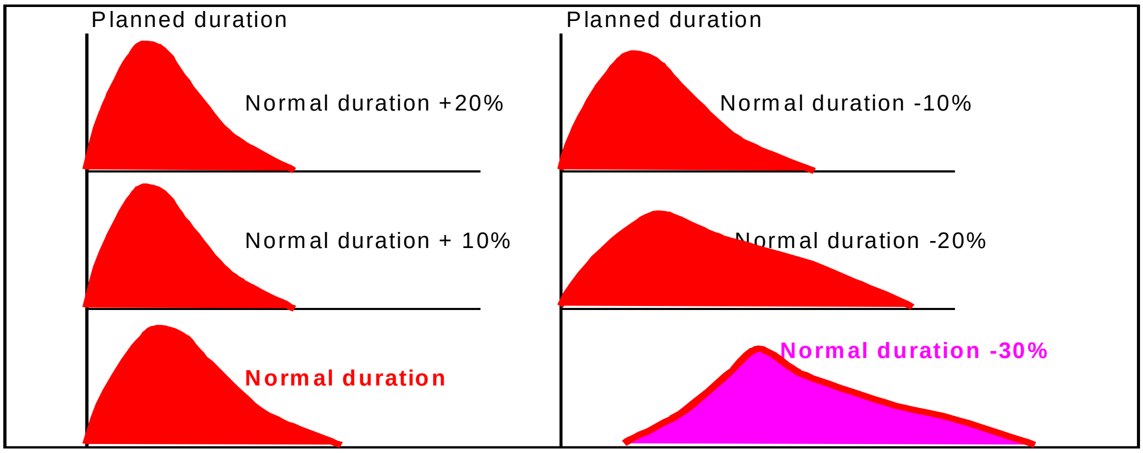

Figure 1: The distributions of the total durations when the schedule is extended or shortened. First chaotic features appear when shortening is 30%. (Vehkaoja 1989).

(b) **In the context of control, dependencies, and correlations**, even a small positive correlation leads to chaos, if control is not exercised, resulting in great variation. The use of the same resources for subsequent activities that cause positive correlations should be avoided. The control of workplaces is more efficient than control of the resources, and even a reasonable negative correlation, i.e. constant control is enough.

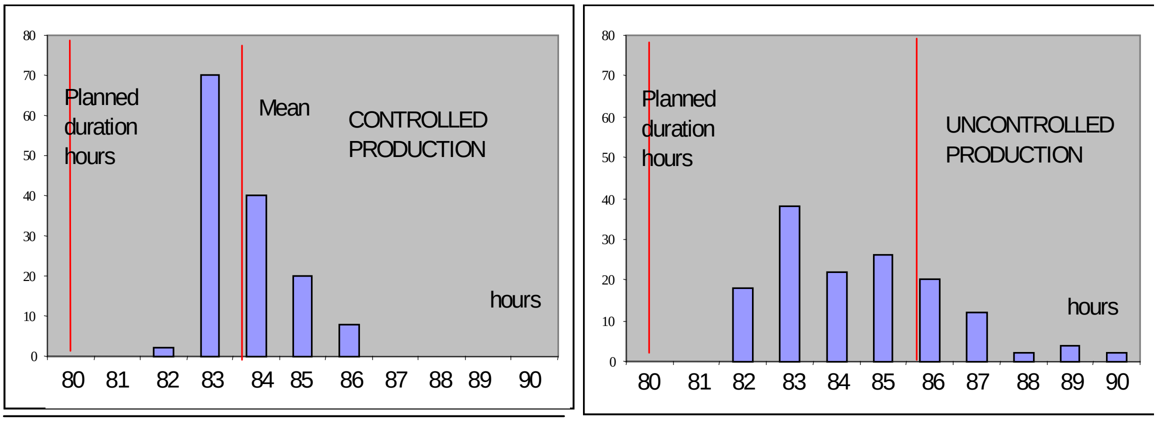

Figure 2: The distributions of the total durations (in hours) in the simulation of repetitive short throughput time (2 weeks) renovation of flats.(Ristikartano 1994). Control actions work well.

(c) **In the context of feedback and loops**, loops lead to bifurcations and spread out the duration of the project. Even if the probability of the loop is low, it will result in chaos and early signs of chaos are be seen as small trembles in durations.

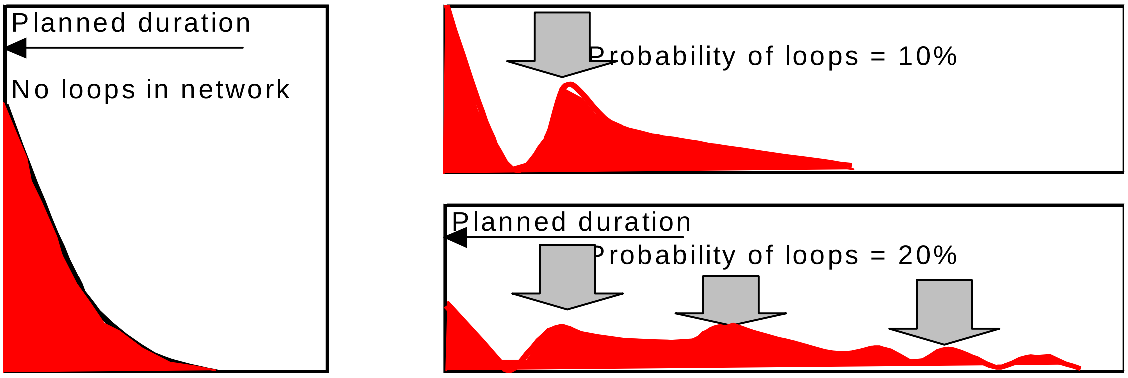

Figure 3: The distributions of the total durations in the simulation of the effect of loops in a schedule. If loops occur, the project is falling into a state of chaos.(Ericsson 1999).

Over the years, we have applied these results to practice when developing (among other things):

- A work sections technique for construction projects.
- A model of balanced schedules (advanced LOB) for construction projects.
- A model of short throughput times for repetitive projects.
- A staged execution model for a project in a chaotic environment.

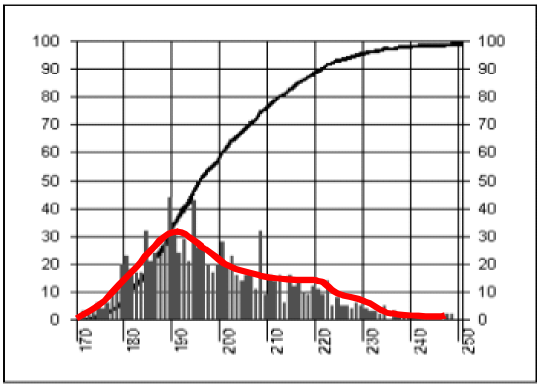
5. Results of Advanced Schedule Chaos Simulator ATOSim 2002

The most recent research tool is called ATOSim from the year 2002 (Ristikartano [7]), **the advanced schedule simulator of the project.** The simulation model describes the effects of the duration variation and the starting disturbances of activities. Furthermore, it tries to capture also the effects of different control actions. With this model we have analyzed especially in what kind of conditions the project falls into a state of chaos and how the control can be used to repel the chaos.

The ATOSim model is based on the network technique and the Finnish place-time diagram (advanced LOB). The deterministic model consists of activities and their workplaces with durations, dependences between the activities, and external dependences. The statistic simulation factors of the model are the variation of the duration of activities, the probabilities and the duration of delays and the interruptions at the beginning of the activities, and the probability of the external dependences. As it is normal in the Monte Carlo simulations, the model gives the distribution of the total duration of the project as a result. During the research work, over 100.000 networks were calculated altogether.

In addition there are resource correlations between activities (the same resources are used). Control actions are described by the activity level and the project level. In the activity level control, the durations of activity in question is reduced. In the project level control, the durations of the remaining activities are changed. In the simulation, we tried different probabilities of internal and external disturbances, different schedule solutions, and different forces of control actions. The productivity disturbances were measured by the waiting time of resources.

Uncontrolled Production



Controlled production

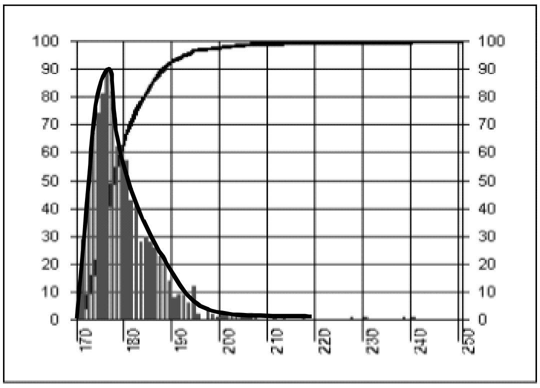


Figure 4: The distributions of the total durations in the simulation of the effects of the control actions. (Ristikartano 2002).

A probability of interruptions affects significantly the variation of the total duration. It does not depend upon whether it results from the late start of activities or from the external dependencies. The tight activity control degreases the variation. Continuous control actions have to be carried out. Productivity weakens rapidly when disturbances increase. Chaos is created when the probability of interruptions is high. Chaos is seen as both the lengthening and the large variation of the total duration, especially as the peak-less distribution of the duration.

In the schedules, the place of the buffer, the solutions of the critical activities, the number of the workplaces and the number of activities were varied. The buffers have to be placed at the end of the project or in the seams of the stages. However, the durations of tasks should be dimensioned tightly. There must be a lot of workplaces in the plan so the control has time to become effective. However, there should be fewer and bigger activities so that enough buffer time are obtained in the same total duration.

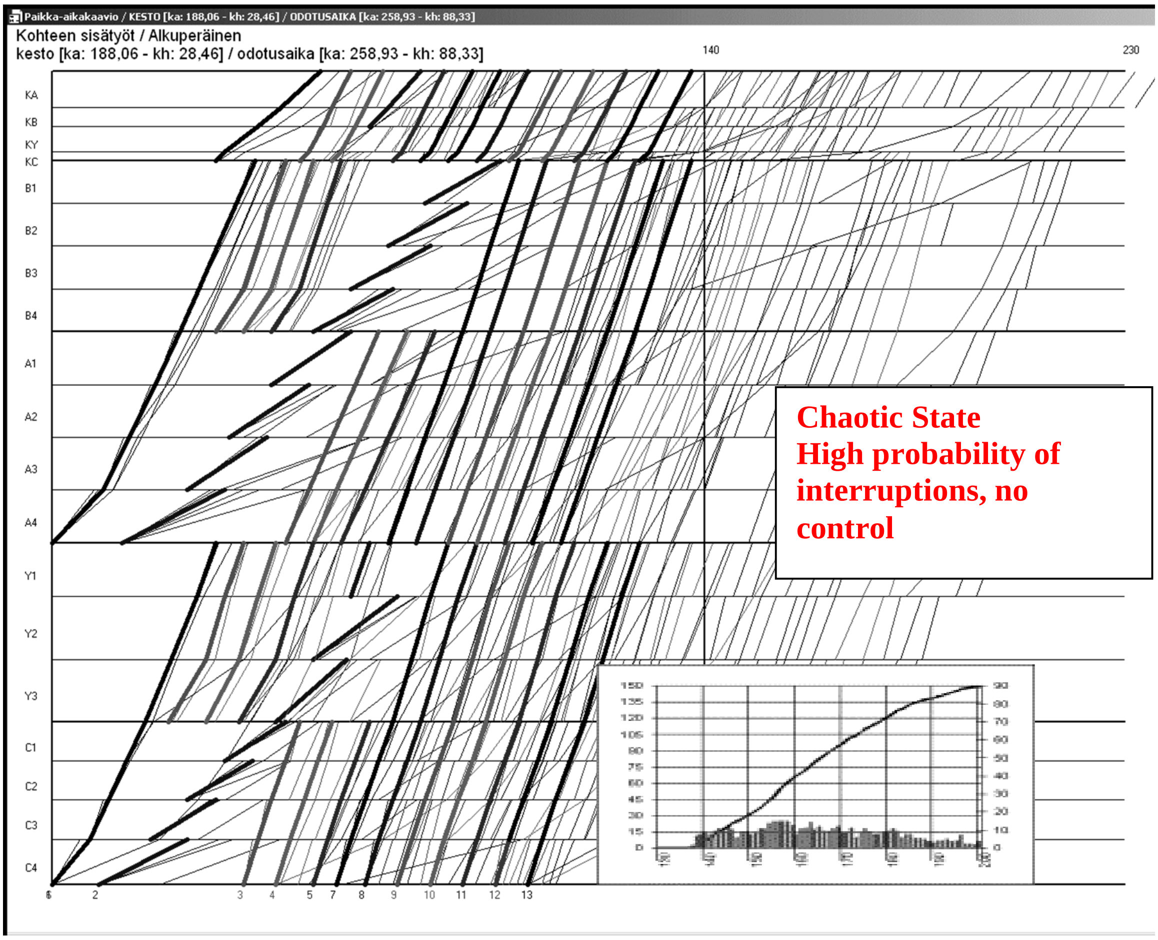

Figure 5: The place-time diagrams and distribution of the total duration in the simulation of the state of chaos. The thick lines are the planned schedule and the thin lines are the results of some simulation cycles. (Ristikartano 2002).

In the simulation model, the chaos is identified from the **form of the distribution,** which is nearly even (it does not show a clear peak). Furthermore, the clear growth of the waiting times is perceived. If the probability of a chaos is high, the production must be phased. In a workplace, the start of chaos can be repelled by isolating and condensing.

When **phasing** is used, the activities causing chaos are made ready before new activities are at all begun. In that case, the total duration is naturally prolonged considerably. When **isolating** is used, the resource dependencies are removed by using new crews and a workplace dependence is retained by preparing workplaces complete. In **sealing,** a workplace dependence is removed. This takes place by “jumping” over a workplace and moving the resources to the following workplace. The works of the “overjumped” place are then performed by separate resources (crew). When a probability of interruptions is high, it is not a big advantage to use balanced activities. It is then better to use the shipbuilding model in which "every workplace has separate resources".

6. How to Keep Your Project on the Edge of A Chaos

Herein, the initial framework for keeping a project on the edge of chaos is designed as **a set of rules for project management in chaos** as follows. In part, the generic rules are illustrated by the likely conditions in the Russian construction markets in the early 2000s.

1. Prevent feedback dependencies using project planning: Pace the project, divide it into stages and further into consecutive and independent activities. Divide the project into workplaces (production sections and areas). Interrupt the project immediately if a crisis takes place. Fix the problems of the preceding stage as a part of the next stage.

2. Make the WBS independent: Plan the work and procurement packages carefully with the proactive prevention of a chaotic state in mind. Packages should be independent from one another. All procurement packages, especially local or from a third country, should have pre-negotiated back-up contracts, respectively.

3. Prevent non-linearity by control: Control all the small tasks and on a short time span, change course immediately when needed. Have weekly meetings, make a special activity plan for each activity before its execution. Make pilots or models of new and difficult things beforehand.

4. Prevent the first bifurcation by ”fractal” control: Strive to detect the first weak signs of bifurcation. Exercise control of actual activities down at the site level. Control simultaneously all parties at all levels and in all processes. Act immediately when a problem is encountered. Do not put trust only in the compiled reports of the project as a whole.

5. Prevent external effects by using partnerships: Try to identify the influential stakeholders and enter proactive partnerships with them in advance. Align cultural differences by using cross-cultural and professional ”interpreters”. Use local designers for help. Listen to the local authorities.

6. Set up an open communication system: Create a fast, simple, and open communication system and test its performance constantly. Assume always that “they” do not understand. Coach and train your partners by a joint information system. Do not arrange academic lectures or teaching.

7. Support your goals with ”cultural” incentives: Clarify to other parties what outcomes you want the organization and the project to perform. Create rewards so that each culture accepts these as incentives for the joint realization of your goals. Try to support the egos of other decision makers, not your own.

Pacing the project squeezes chaos together. Chaos may occur in separate stages, but it does not move forward to the next stage. The results of a previous stage must be approved by all parties before the start of the next stage. Pacing causes longer total duration. This pacing procedure has been used in construction projects in Russia.

Non-linearity and a sensitive dependence of an initial stage are prevented by linearization, proceeding in small steps and, thus, making effects immediately known. In the suggested project management in a state of chaos, this means continuous planning and controlling instead of the traditional project planning before a start and reporting during it.

7. Conclusions

Herein, the validity and the consequences of the proposed framework for advancing (construction) project management are discussed as follows.

In these simulation studies, it was noticed that **schedules with different risk levels** can be made for the same project. The activities must be dimensioned right, they must be balanced. Especially, the whole schedule must be controllable. A tight control of the schedule reduces the risk of exceeding the scheduled duration and having a lot of waiting time. The control actions have to be made immediately and continuously. When more certainty is wanted, some **buffers** would be used. However, this extends the total duration of the project and increases costs.

At the beginning of a project, there are many possible completion dates. Different schedules can be made for the same project and the execution can be controlled in different ways. The schedule is fulfilled as such only if everything goes according to the plan. However, this does not happen in reality. The planned completion date is not necessarily even the most probable completion date. The Monte Carlo simulation can be used to test these alternative schedules. As a project proceeds, the disturbing factors are realized and they cause waiting time, the lengthening of the total duration, and the need for additional resources. In the worst scenario, a state of chaos is created which leads to repeated planning. The project reporting as typically found in textbooks does not help at all in a chaotic situation. All activities must be controlled from the grass-root level to avoid chaos.

To repel chaos, **an advanced planning system** [8] must be used in which the workplaces and the coarse general planning are combined, the detailed activity planning ís done just before the beginning of each activity, and a short time rolling window is used troughout the whole project. The corrections must be performed immediately. If work stops in one workplace, it should be jumped over immediately and a new team would be put in place.

Abstract

Construction is dominated by project-based production, and production organisations are constructed from relatively independent participants joining in constantly changing one-off coalitions of firms. This has influenced the industry's structure and methods leading to a highly fragmented sector with many different types of firms. As a consequence, the level of complexity of production in construction is relatively high and efficiency levels are relatively low. In this paper, construction as a project-based industry and construction as a project-based one-off undertaking are critically reviewed. Alternatively a more project-independent approach to construction is discussed and assessed, whether this would be more beneficial, for what kinds of construction, and under what conditions. First construction is characterised as a project-industry and the complexity of the sector is explained, including specific characteristics and contextual and structural features, as well as the benefits, basic problems and generic effects. Next reasons and rationale for project-independent construction are discussed, and paths to project-independent construction and supply chain integration are identified, both from the client and the supply chain perspective, for different sector in construction. Finally a possible future perspective is given on construction when developing towards a more project-independent industry.

Keywords: Construction, industry typology, project-based industry, project-independent production, supply chain integration.

1. Introduction

In contrast to manufacturing, construction is by nature vary much dominated by project-based one-off approaches and "pull"; often every project is different and delivered to a different client. In recent years, manufacturing has moved from process-driven "push" to more client-driven "pull" and to some extent a more project-based approach to production. Still, manufacturing has been dominated by a search for even higher levels of efficiency and alignment of supply chains through long-term but flexible relations between firms. In this paper, this path is inversed for construction – from a project-based to a project-independent approach – but aimed at the same goal: higher levels of efficiency and alignment of the supply chain.

The characteristics of the industry have often been observed and criticised, and in by some it was even questioned whether construction is actually an industry [1], or rather a “loosely coupled system” of projects [2]. In these observations the nature of construction and particularly the strong project focus within the industry has often been identified as a basic cause of many of the limitations and problems of the industry [3]. Some have identified specific peculiarities of construction causing the problems, including the temporary organisation, one-off product and site production [4]. Construction projects have been described as coalitions of firms; ‘a number of independent firms coming together for the purpose of undertaking a single construction project and that coalition of firms having to work as if it were a single firm, for the purposes of the project’ [5]. Alternatively, the parties involved in construction projects have been interpreted as ‘organisational units joining and operating together as a single production organisation when it is advantageous’ [6]; a ‘temporary multiple organisation’ [7]; or a “quasi-firm” [8]. However, there are significant differences between different types of firms in terms of what they regard as important to project success. The determinants of project success are not always straightforward and unambiguous [9].

2. The Nature of Construction as a Project-based Industry

2.1 Typology of Industries: What Kind of Industry is Construction?

Characteristics of project-based industries vary from industry to industry. The production system of each industry has been shaped by the industry characteristics and history. Project production systems in project-based industries are aimed at a product mix that is ‘one of a kind or few’, process patterns are ‘very jumbled’, processes segments are ‘loosely linked’, and management challenges are dominated by ‘bidding, delivery, product design flexibility, scheduling, materials handling and shifting bottlenecks’ [10]. In addition, the fragmentation of the construction industry has been identified since decades as a major point of the complaints about the state of practice [11], reflected most characteristically by the predominant one-off approach in construction projects, or ‘unique-product’ production [12].

Construction can be typified as a specific kind of project-based industry. Construction has been related to engineer-to-order products (ETO) viewing construction as a type of project-based production system, rather than a type of manufacturing, referring to Assemble-to-Order (ATO), Make-to-Order (MTO), or Make-to-Stock (MTS) types of production system. ‘Treating construction as a type of manufacturing obviously neglects design, and arguably subordinates value generation to waste reduction, which inverts their proper relationship’, however ‘certain aspects of construction should move into the realm of repetitive making’ [13]. Production system types of different industries could be dominated by either (one-off) designing or (repetitive) making (Figure 1).

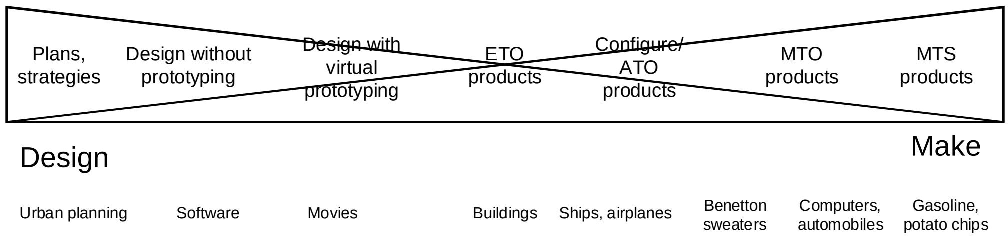

Figure 1: Production system types [13]

The production situation in construction could also be related to assemble-to-order production and "capability oriented production" systems [14]. Alternatively, construction could also be observed as a make-to-order, design-to-order, or even concept-to-order kind production system [15]. The characterisation of the production system of construction is largely dependent on the view taken and the definitions used.

When observed from a make-to-order perspective, the main management challenge is to capture the client order, avoid problems on interfaces in the supply chain and reduce time buffers in the information and materials flows [16]. In addition, compared to other project-based industries, whether it is site installation of prefabricated parts on site or mere on-site production, production in construction is always locally bound and dependent on physical factors such as soil and weather conditions. In addition, compared to most other project industries the volume and repetitiveness of projects in construction is mostly extreme low. The organisation of production and the supply chains is strongly adapted to these basic characteristics, and aimed at the convergence of logistics to one site, and delivery of the one-off, and often highly customised and capital intensive product to a single end customer [17].

2.2 Cultural, Structural and Management Characteristics of Construction

The culture in construction is rather multiform and inhomogeneous, caused by the relatively high fragmentation of the industry in different types and sizes of firms, and necessitated by the varying organisational configurations of projects. The culture within construction is a typical "project culture" and is often relatively informal compared to the often more formal "corporate culture", which has dominated in other industries such as manufacturing. The high status of projects explains the existence of two cultural identities within the construction industry: the corporate culture (office), and a distinctive culture within each separate project. The rather strong disconnection between the more regulated office environment and the less regulated project environment often disables corporate innovation programmes effectively reaching the production on site (project). However on a construction site workers are continually producing new solutions to problems that occur on site every day, but may be taken for granted, and not regarded, managed and communicated as an innovation. This explains why construction industry is deemed being less innovative than for instance manufacturing. The fragmented production system, strong influence of project culture, relatively weak corporate culture, and lack of shared values particularly among subcontractors is also regarded as a reason for the low customer focus and lacking possibilities to achieve value for the client. Main contractors must try and manage the rather random nature of subcontractor, which is amplifying the negative effects of project culture. Improved relationships, increased levels of supply chain integration and partnering with subcontractors should be aimed at increasing the identification of subcontractors with the main contactor's values, culture and the ultimate goal to achieve project success and customer value [18].

The structure of the construction industry has been rather fragmented, including many SMEs. Project characteristics differ noticeable across project-based industries. Usually the normative resource in construction projects is the budget and the completion date. The project success measure is cost, and completing the project by the scheduled date is often the most important scheduling objective [20]. Although this will be not quite different in various other project-based industries in general, there are differences in scope, for instance in the movies and software industries, where the emphasis is far more on the profits to be made when a movie or software is distributed and rights and royalties are yielding revenues.

Because of the central role of projects in construction, the project management function and the project manager have an important role. The project manager has the responsibility for the design as well as the execution, matches the project and the customer needs, and takes care of the entire production management. The dilemma is that the more complex and large the project is, the more empowered the construction manager must be to exercise control and authority, but also the more he should delegate and trust his people [21]. The type of project management in construction differs much from other industries. The standards and models used in construction industry are relatively basic and tend to have similar characteristics for all types of projects, compared to many other industries. The relatively low level of competition and the economic stability in construction have played a role here [22]. Compared to manufacturing, project manager qualifications, project size and uncertainty characteristics are found to be relatively low in construction [23]. In terms of quality management, significant differences have been found between industries regarding to the level of quality management implementation and quality output performances [24]. Levels of quality management implementation and the emphasis on quality management in construction companies is relatively low compared to utilities and service companies. In construction the attitude tends to be oriented towards conformance to contractual specifications and not gaining additional financial benefits or competitive strength from quality improvement. Construction has been to be less customer-oriented or responsive, but oriented more towards production and getting the work done on time and within budget. Particularly in construction the management challenge is mainly focussed on projects, which together with the relatively informal culture, and the fragmented structure of the industry as a whole as well as the production system, causes basic differences with other technology-driven industries, and particularly with non-technology industries (Table 1).

Table 1: Construction compared to other technology-driven industries and non-technology industries [25]

	Construction	**Other technology-driven industries**	**Non-technology industries**
Culture	Informal	Formal	Dynamic
Structure	Fragmented	Consolidated	Integrated
Management	Project driven	Process driven	Customer driven

3. Project-independent Construction

3.1 Problems and Deficiencies Caused by Construction Nature

Basic characteristics of construction cause limitations to technology and problems to management [3]. The limitations and problems have been found to be very closely related to the nature of construction. Basic problems in the construction supply chain are caused by construction peculiarities. These may be called endemic problems that are difficult to resolve, including the causes behind them and the deficiencies stemming from them [26]. In most analyses, fragmentation of the industry and the predominant one-off approach to production are indicated as major characteristic as well as problematic factors. However, paradoxically, fragmentation, meaning involvement of many different specialised firms in projects, does not need to be associated with low levels of efficiency, but instead may increase efficiency of resource allocation and speed of information exchange between parties, particularly in the post contract period of construction projects. But still, these benefits combined with long term relationships are found to provide the potential for further benefits for supply chain parties involved [27].

3.2 Reason and Rationale of Project-independent Approach to Construction

From the notion that the one-off approach in construction is a major problematic factor, a more project-independent approach to construction has often been advocated explicitly and implicitly. Project-independent approach have been suggested, dependent on the construction sector to which it applies, varying from modular product concepts and pre-engineered housing concepts, to multi-project procurement. The usefulness of applying concepts from other industries has been discussed and demonstrated many times, for instance between automotive and housing [28]. It has been discussed also that translation is needed when studying the possible transfer and application of “exotic” concepts to a construction context [29].

The basic shift from a one-off approach to a project-independent approach in the construction supply chain is to stabilise the project and production environment, and achieve operational and competitive improvements across projects and firm boundaries. In that sense, supply chain integration and management play an important role to achieve project-independent construction.

From a client perspective this must be achieved through altering procurement strategies, and from a contractor/supplier perspective through altering production and marketing strategies, to increase the level of integration and alignment between the different "stages" in the supply chain, e.g. between the materials supply and the construction site (Figure 2).

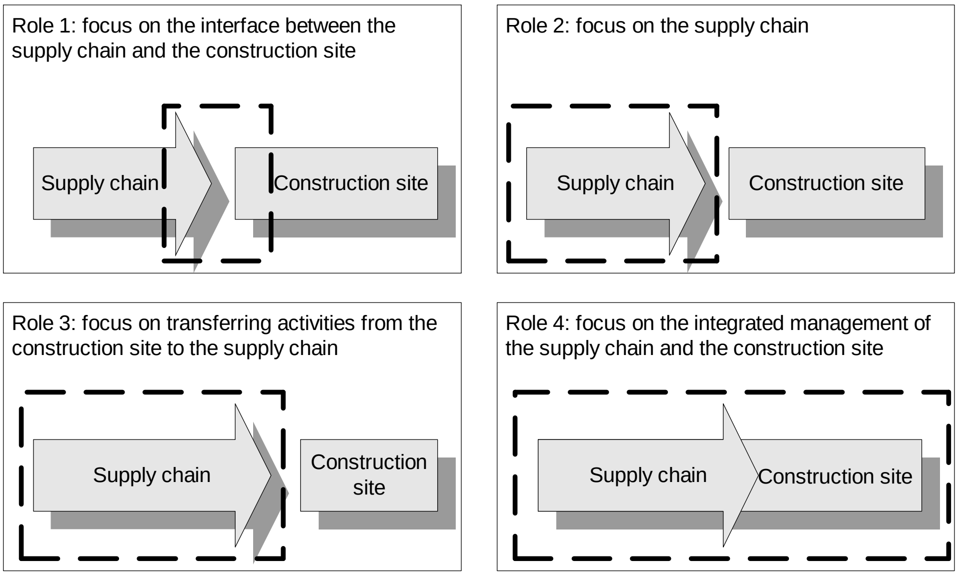

Figure 2: Four roles of supply chain management integrating materials supply and the construction site [26]

4. Paths Towards a Project-independent Approach to Construction

4.1 Client Driven Initiatives Towards Multi-project Procurement Strategies

Since construction is still project driven, obviously, there is lack of comprehensive guidelines for managing multi-projects in construction [30]. However, some advanced and "professional" clients with "buying power" can and have created multi-project environments and manage their procurement through a programmed or "portfolio" approach, based on the repetitiveness and similarities between multiple projects and the degree of project certainty within a programme [31]. In some cases, clients have successfully introduced a strategic long-term approach to procurement, which has proved to be particularly effective for certain sectors in construction [32]. Through these strategic approaches, clients have integrated project activities and procured these packages to integrated supply chains or "clusters" for longer periods of time by applying alternative procurement methods, such as prime contracting and framework agreements, and alternative contract formats, such as PFI en "DBFMOT" kinds of contracts [33].

However, the majority of clients are not in the position to exercise power over the supply chain, because they are too small or their portfolio of projects is, but also because of ad hoc procurement methods and sometimes misunderstanding of the marketplace. A lack of continuity of relationships hinders gaining the full advantages of long-term collaboration and transfer of experience and knowledge across projects [34]. Clients who have the power to alter their procurement strategies vis-à-vis the marketplace are in the position to align the supply chain effectively, and implement supply chain integration successfully [35]. Performance and financial incentives are to be applied by clients to the whole team, sharing pain and gain, relying on the positive effect of long-standing supply chain relationships [36]. Ultimately, the incentives are aimed to reinforce relationships and commitment, and foster trust for longer periods of time, which cannot be achieved through one-off approach to single projects [37].

4.2 Supply Chain Driven Initiatives Towards Project-independent Production Strategies

At the supply side, parties may evolve towards more integrated production and business formats, through project-independent collaboration with neighbouring parties in the supply chain as well as internalisation of neighbouring activities of businesses. In both cases operational and competitive advantages, through higher levels of productivity and efficiency as well as delivering better client value must be the drivers for this kind of supply chain integration. In the case of vertical integration, often the so-called make-or-buy decision is often dominant whether or not to internalise or outsource a business activity. In practice consequences of integrating or outsourcing activities are not always clear. Often this is driven by mere economic arguments, but for successful business integration need to observe more relational aspects between firms than economic aspects only [38].

Companies in different industries, including automotive, but also construction, where design information and new product development play an important role, could benefit from applying multi-project strategies to design information and product development activities, reusing information, components and establishing long-term relations with closely linked parties, including suppliers, resulting in competitive and operational advantage in relation to competitors [39]. In same cases, these kind of inter-organisational formats are referred to as modular production networks, where fixed relations and reuse and interchange between standard components and firm in the supply chain (production network) are the basis of speed and flexibility of assembly, and this collective competitive advantage [40]. In construction the modular approach to product development, including flexible customisation and postponement of decisions, has been reflected by the concept of open building, including integration is trades and the supply chain, and project-independent approach to construction [41]. Generic project-independent production strategies, such as platform strategies and modularity, in some cases, particularly housing, have thus demonstrated to be possible as well as beneficial [42].

4.3 Differentiating between Sectors of Construction

Construction is consisting of various relatively different and disconnected sectors. As such *the* construction industry does not exist. Per sector possibilities, obstacles, paths and implications project-independent construction are different. Here, three major sector are distinguished: housing, commercial building (offices etc.), and civil (roads, railways etc.). Per sector client driven and supply chain driven initiatives can be identified in construction practice (Table 2). Besides many different other sectors may be distinguished.

Table 2: Differentiating between client driven and supply chain driven initiatives towards project-independent construction in different construction sectors

Initiatives towards project-independent construction	Client driven	Supply chain driven
Housing	Individual clients generally lack power to integrate the supply chain; large housing corporations may develop a supply chain strategy	Supply chain parties may engage in strategic collaboration to develop and introduce pre-engineered housing concepts to the marketplace
Commercial building	For instance real estate developers or large companies may involve integrated supply chains for their real estate stock	Supply chain parties may join to develop multiple commercial buildings, however commercial risks and variability of design etc. may be too high
Civil	Particularly public or semi-public clients may introduce portfolio procurement strategies for multiple projects	Supply chain parties may deliver multiple integrated projects, but mostly initiated by the client; but not through pre-engineered concepts

5. Future Perspective on Construction: Project-based or Project-independent?

5.1 From One-off to Repetitive Construction?

Still construction is dominated by one-off approaches and ad hoc production organisation. Many projects are being planned separately from others, even within one construction company, or client. Traditionally this is mainly because many projects are unique, or regarded to be unique. Particularly large projects are complex undertakings involving a vast spectrum of demanding (clients, users, stakeholders etc.) and supplying parties (contractor, subs, suppliers, consultants, architects etc.). For these kinds of projects in specific sectors of construction, project-based working will stay to be the dominant management format. However, in some sectors, in some cases, clients or contractors or other parties in construction have developed such procurement, business and production strategies that aim to increase the repetition between projects, within the own organisation and for the own business, or with other parties in strategic cooperation arrangements.

5.2 From Construction to Manufacturing??

Some companies in construction (contractors, specialty contractors, suppliers etc.) have increased the repetition factor between projects by developing and introducing complete product concepts (e.g. housing concepts), or integrated components of building (e.g. integrated facades for offices), to the marketplace including all engineering, parts manufacture, logistics and site assembly, rather than delivering one-off projects, based on mere project specifications. To certain extent these companies have redefined their traditional business and processes towards a manufacturing kind of format. In construction practice, one can see that these companies choose to be excelling in a certain niche market, where they think and mostly succeed in being successful in terms of achieving higher productivity and profit levels, compared to traditionally operating competitors.

5.3 Implications for the Construction Supply Chain

The increase of repetition and move towards project-independent construction has considerable consequences for the supply chain. When taking initiative towards project-independent construction, one or few parties in the supply chain will increase their power and leadership vis-à-vis other parties in the supply chain through strategic collaboration or integration of businesses and activities. As a consequence the level of integration will increase and the level of autonomy of parties in the supply chain will decrease. Clients who take initiative to project-independent construction and supply chain integration arrangements will generally involve teams for longer periods of time, e.g. through prime contracting and framework agreements. Supply chain parties who take initiative to project-independent construction and supply chain integration will generally need to concentrate their business to certain niche markets and integrate all activities needed to deliver complete products to the marketplace, either concentrate on core capabilities within strategic collaboration with other supply chain parties in order to deliver integrated products to the marketplace collectively.

6. Discussion and Conclusion

The construction industry has traditionally been dominated by project-based one-off production. Often the traditional approach to construction, particularly the one-off approach to projects and the fragmented structure of the industry has been criticised for not being efficient. For most kinds of projects and sectors of construction though, the project-based approach is logical and sometimes inevitable, particularly for large civil projects. However, for smaller kinds of projects, in certain sectors, and by developing an alternative strategic approach to procurement or delivery it is possible to achieve project-independent construction to different extents and in different forms. Both clients and supply chain parties may choose to follow the path of project-independent construction. This requires certain strategic decisions and playing another role in the supply chain, and higher levels of supply chain integration, through internalisation of more activities or through strategic collaboration with other supply chain parties.

Construction as Production by Projects

Graham M Winch
Centre for Research in the Management of Projects, Manchester Business School,
University of Manchester UK M15 6PB (email: graham.winch@mbs.ac.uk)

Abstract

This paper responds to the invitation to debate the theory of production in construction from the advocates of lean construction (LC), and in particular, to their critiques of the theory of project management represented in the PMI's PMBoK, and the "economics-based" approach to construction project management presented by Winch. The paper reviews the theoretical and practical contributions of LC before moving on to address the specific criticisms made. The paper then suggests that LC theory has its own limitations and requires further development in the areas of the definition of process, the concept of organisation, the theorisation of risk and uncertainty, and its unitary concept of value.

Keywords: Lean construction; construction project management; transaction cost economics; value; risk and uncertainty.

1. Introduction

The organisation of the construction process is the subject of intense debate and intensive research in a number of countries. The aim of this paper is to respond to the invitation to constructive dialogue from the advocates of lean construction (LC) and, thereby, to move the debate onwards in the development of a perspective which views construction as a distinctive mode of production by projects. Lean construction (LC) synthesises an original perspective based on a *transformation/flow/value* view of the construction process with distinctive operational methods such as the *last planner* approach to construction project planning. In sharpening their development of the concepts, explanations, and implementations of LC, its proponents have developed a number of critiques of different perspectives on the management of construction projects. Engagement with two of these critiques in this paper, it is hoped, will facilitate the development of a theory of production applicable to the construction process to move on. These are :

- the critique of the economics-based approach [1]
- the critique of project management theory [2]

2. The Theory of Lean Construction

The work of Lauri Koskela is an ambitious attempt to provide a theory of production applicable to construction. His principal contribution is contained in his doctoral thesis [3], and elaborated in a number of subsequent publications [e.g. 4, 5]. Koskela's thesis draws on a wide range of literature in production and operations management to develop a three-part theory of production which he calls transformation/flow/value (TFV). The literature review identifies three different perspectives on the production process that have been deployed during the 20th century – the transformation concept; the flow concept; and the value concept.

The *transformation concept*, Koskela argues, focuses on the transformation of materials from one state to another. Economically, it is associated with Walras' production function, while in production terms it is associated with the scientific management approach of people such as Taylor. Its basic tenet is the detailed pre-planning of the production process which is broken down into a series of tasks, each of which is progressively optimised. One result of the concern to optimise individual task execution is the recommendation that tasks with different characteristics be buffered from each other. While this approach has many advantages, particularly associated with the development of sophisticated production technologies, it also suffers some significant disadvantages such as rising costs of work-in-progress created by the buffers, the risk of sub-optimisation at the system level, and inflexibility in response to changing market demands. So far as the design process is concerned, the transformation concept is represented in attempts to standardise the design process and to apply project management techniques.

Koskela argues that the *flow concept* takes a very different approach. Here the principal influence is the Toyota Production System. From the flow concept point of view, the objective is the minimisation of waste. Analysis of work flows designed around transformation concept principals reveals that materials typically spend very little time actually being transformed, and most of their time waiting to be transformed, being moved, or being inspected or otherwise controlled. The argument is that by focusing on reducing time taken to flow through the manufacturing system as a whole, greater economy can be obtained than by focusing on the efficiencies of particular sub-processes. The key to this reduction is to reduce variability in the execution of particular sub-processes rather than to increase their efficiency. Coupled with simplification of production processes, this attention to cycle time can lead to greater flexibility as well as greater system-level efficiencies. In the design process, the flow concept is represented in the use of concurrent engineering and related techniques.

For Koskela, the *value concept* derives from the quality movement originated by Shewhart and contributes by bringing the customer into the perspective. Flows and transformations of materials are only of value if the resulting product meets the needs of those who are expected to purchase it, and so the definition of customer requirements is central to the value concept. Once those requirements have been effectively captured in the design process, the role of the manufacturing is to meet the requirements processes of quality management and control. Within design, the value concept is represented in requirements capture processes where techniques such as quality function deployment are appropriate.

3. The Practice of Lean Construction

The TFV conceptual framework supports a variety of different tools and techniques that allow the principles to be applied to the management of construction projects as part of the Lean Production Delivery System (LPDS) [6]. The best known of these is *last planner* [7] which was developed “in-house”, and is a way of buffering task execution by only allowing those “quality assignments” which are completely ready to be started in the context of effective lookahead planning, and close monitoring of “per cent plan complete”. Other applications are taken from mainstream lean manufacturing such as value stream mapping [8], and from developments in design management such as dependency structure matrix [3], and in supply chain management [9]. A number of other organisational innovations are also recommended such as involving downstream players in upstream decisions; deferring commitments to the last responsible moment; aligning the interests of participants; and the effective use of buffers.

The last planner approach to construction planning is an important innovation, and anecdotal evidence suggests that it is diffusing well. Many of the other elements of the LPDS are widely accepted as having the potential to improve significantly the management of the construction project process. There are, perhaps, at least two surprising omissions from the LPDS toolbox. The first is the apparent lack of attention paid to new forms of organisation of the project to form the context for the implementation of the LPDS. For instance, the use of supply chain clusters based on Thompson’s [10] principle that appropriate organisation designs cluster together those functions which have the greatest interdependence, and hence the greatest requirement for mutual information processing. Different applications of this concept have been developed by Lahdenperä [11] and Gray [12], and applied with apparent success [13]. While Koskela [3] does discuss Lahdenperä’s new construction mode, and the *demarche séquentielle* [14], these innovative ideas do not seem to have been taken forward into the LPDS. A second is the lack of attention paid to the work of Goldratt – particularly the theory of constraints [15] and its project-specific application in *critical chain* [16]. Critical chain directly addresses the problem of slack in task execution time estimates, and suggests trust-based relationships as the solution, while introducing resource constraints into project planning – a revolution in a context when construction project planners have typically assumed infinite resources.

4. The Critique of the “economics-based” Approach[1]

In developing their concept of LC, its proponents have provided a detailed critique of what they call the *economic-based approach* to analysing production in construction [1]. They choose as

[1] All citations in this section are to [1] unless otherwise specified.

representative of this approach *Managing Construction Projects: an Information Processing Approach (MCP)* [17], and make a number of critiques to the effect that it :

- Focuses on transactions rather than production;
- Focuses on information flows rather than materials flows
- Places uncertainty reduction at the heart of the process
- Deploys a tectonic approach to organisation

4.1 The Focus on Transactions

The LC critique argues that the focus on transactions means it "views production as a series of transfers", and that it "disregards the flow aspect of production" meaning that production is "organized just on the basis of purchasing costs". These assertions display a misunderstanding of transaction cost economics (TCE), because transactions are defined as "changes in ownership" through "purchasing", and it is held that TCE argues that "those organizational forms that minimize transactions costs are in the long run preferred" [3 p. 104]. However, Williamson defines a transaction as occurring whenever "a good or service is transferred across a technologically separable interface. One stage of activity terminates and another begins." [18 p.552]. A technologically separable interface is one that is not constrained by the nature of the production technology – in other words, the production technology chosen does not foreclose the possibility of allocating two different parts of the production process to different parts of the organisation, or to separate organisations. Thus, the theory focuses on the question of whether to purchase or not - the classic make/buy problem - not on purchasing alone. Rather than being "fully compatible with the decomposition principle of the transformation model of production", TCE is – arguably - a critique of the focus on the costs of decomposed transformations alone, without taking account of the cost of coordinating *between* those transformations. Through a TFV lens, TCE can be seen as posing the question of how flows within and between organizations are to be organized – or "governed".

The argument that the sole focus of TCE is on transaction costs also displays a misunderstanding – "transaction cost economizing needs to be located with a larger economizing framework and the relevant trade-offs need to be recognized" (*ibid*). Thus, the fundamental insight of the transaction cost approach is that in order to economise on the total cost of a good or service, *both* production costs and transaction costs must be taken into account. While a traditional economic analysis can identify the most efficient choice of production technique, it cannot explain the most effective use of that production technique. Thus total costs are the sum of the costs of production and the cost of governing the transactions inherent in that choice of production technique. A production technique that has the lowest production costs might not be the economising choice if transaction costs are also taken into account[2]. The resolute focus on transaction costs rather than production costs in TCE research is simply a strategy of focusing on where it makes its distinctive contribution.

The structure of *MCP* is based on an earlier analysis [19] of generic project processes, and only one of the four generic business processes[3] is developed drawing on TCE. It is never argued that the costs of buying should be the sole basis for the organization of production in construction. The argument in *MCP* is simply that they need to be taken into account in a full theory of construction production, the conceptual link between the TCE contribution and the rest of the theory is made through construction project organizations being information processing systems. Unless the argument is that construction production should be organized in a fully integrated Soviet-style *Kombinat*, then the make/buy problem is central to the organization of production in construction and any theory of construction as production needs to include an analysis of how transactions in the flow of production are governed through markets, hierarchies and various hybrid forms.

4.2 Organisation as an Information Processing System

It is argued that *MCP* views “organization as only an information processing system [and] the production of goods and services, the *raison d’être* of the organization (in normal cases), is abstracted away”. Again, this is not the position argued in the book. The full argument is developed in [20] on metalworking production which fully analyses both information *and* materials processing and the relationships between them in terms of the information flows initiating and controlling the materials flows. However, MCP is about *project* management, which is, in essence about the *coordination* of the activities of all the resource bases mobilized on the project which are responsible for materials processing as well as a variety of information transformation tasks such as in design. This is made clear in [17 table 15.1], which summaries the differences in responsibilities between the project manager and the resource-base managers working on the project. *MCP* is not intended to cover how bricks should laid or structural joints detailed – these are the responsibilities of the managers of the resource-bases engaged to carry out these tasks. The task of the project management function is to coordinate these transformations so that they move into the flow of the project life-cycle. This coordination task is essentially an information problem – who should do the task, when they should do it, can it be started now, and has it been completed fully to the specification?

---

[2] Winch [51] provides an analysis of UK rail maintenance projects arguing how the failure to take into account transaction costs in outsourcing led to serious inflation of total costs.

[3] These four are “defining the project mission”; “riding the project life-cycle”; “leading the project coalition” and, under discussion here, “mobilising the resource base”.

4.3 Uncertainty Reduction as the Principal Challenge

The objective of uncertainty reduction, it is argued, "in and of itself is not the objective, but it is rather a means for getting the facility built, generating value and reducing waste". I totally agree with this statement, but submit that the principal obstacle to achieving these worthy aims is the uncertainty pervasive to decision-making on the project. Construction project clients and their suppliers engage in a "future perfect" strategy [21] of conceiving where they want to be at a specified point in the future in terms of value added and budget spent, and then, in essence, working backwards from that point. We, by definition, cannot know the future, and so the journey through time from the present state which we can know about to that desired future state can be a long and fraught one, with many surprises along the way. Only to the extent that the past is like the future can the information that we already have tell us about the most appropriate path to take to that future, and we can never be sure how like the past the future will be. On some projects, this is a high proportion of all the information required, on others it is a relatively low proportion. Some elements of information, such as the structural properties of a specified steel can be expected to change little in the future; other elements, such as the condition of the ground are less predictable, while elements such as the spot price of bricklayers two years hence may be subject to considerable change. These factors are handled within the concept of risk – the condition of uncertainty where enough information is available to assign a probability to the occurrence of an event – but many aspects of uncertainty on projects are not amenable to the *meaningful* assignment of probabilities. They remain *unk-unks*. The vital issue that a project manager has to address is how representative is past data for the particular project that he or she has been asked to manage – a problem that is captured in the concept of "mission uncertainty" [17 p. 7].

The advocates of lean construction argue that "decisions in a project are ordered so that each decision is based on information produced in earlier decisions, and produces information, in turn, for subsequent decisions". This is true, but it does not then follow that "each decision can be made based on all information needed, without any uncertainty,"[4] because the information to hand is frequently only part of the total information required for the decision – this is Galbraith's [22] definition of uncertainty. Information is arriving all the time on the project as "news" about the possible range of future states [23], and some of it will not be as envisaged when the commitment to a particular course of action was made. The LC view of information processing on the project is inherently a backward looking one, and not one that looks forward to the completed asset that will generate value for the client. It is suggested that any remaining uncertainty can be reduced to variability and handled using analysis techniques such as queuing theory. Where this can be done – typically when operations are repetitive – it is of course advantageous to use queuing theory and related techniques derived from operations research. However, most operations on projects are not repetitive for the simple reason that this is why

[4] They do recognise that there are practical limitations to this condition – the argument here is about epistemological limitations.

they have been organised as projects. The whole point about projects is that they are about unique activities – repetitive operations are not appropriately organised in project mode. This, of course, begs the question of whether all construction production should be organised in project mode, and there are clearly some forms of construction production, such as housing [24], where this is inappropriate. It is also the case that repetitive transformations within a unique project such as shear walls [25] are appropriately organised in non-project mode. None of this gainsays, however, the fundamental argument that a construction project is essentially a proposition about a unique future state, and that uncertainty in decision-making is inherent to the process of achieving that future state.

4.4 The Tectonic Approach to Organisation

The tectonic[5] approach to organisations was initially developed in [20] and argues that information processing in organisations cannot be directly managed, but is managed through changes in organisational structure in terms of both internal and inter-organisational arrangements. The point is reinforced in MCP through the metaphor of the river where what is of interest is the flow of water which has the potential to provide power, transport, food and the like, but this potential is realised and enhanced by alerting the structure through which the water flows by constructing dams, weirs, bridges and the like. It is argued by the advocates of LC that "this approach neglects the management functions of (production) system operation and improvement". I submit that it does not, because production system operation and improvement – to the extent that it is about materials flows – *is* susceptible to direct management. Hounshell's magisterial history of the American system [26] shows how this was done during a profound revolution in manufacturing techniques. However, these changes in manufacturing techniques need to be placed in the context of the revolutions in business organisation which enabled them [27]. Manufacturing techniques for optimising materials flows can only function in the organisational context of the information flows that support them [20].

5. The Critique of Project Management Theory

Implicit in many of the responses in the previous section is a difference of perspective on the nature of project management and organisation. The advocates of LC have addressed these issues in a brave paper[6] [2] which takes the Project Management Institute's body of Knowledge (PMBoK) as its principal point of reference[7], complemented by reference to Turner's [28]

---

[5] "tectonic" in this context means "a series of arts which form and perfect vessels, implements, dwellings and places of assembly" (*Oxford English Dictionary 2nd ed.*)

[6] Brave, because it was presented by Greg Howell at the Project Management Institute Research Conference.

[7] There are other project management bodies of knowledge which have much in common with the US one.

influential text. They argue that the implicit theory behind these texts is symptomatic of a focus on the transformation view alone where management is about planning, executing, and controlling in a cybernetic model of the process. This is particularly manifest in the decomposition of the total process inherent in the development of the Work Breakdown Structure (WBS).

Perhaps the most obvious critique of this position is that few – if any – researchers in project management take the PMBoK as a theoretical orientation for their work. PMBoK was developed as part of the strategy of achieving full professional status for project managers as the basis for certification programmes for aspirants. Its efficacy in doing this is debatable [29], but beside the point here. In the context of the debate about theory in project management it is an irrelevance, as most researchers would accept Morris' critique [30] of its limitations as a theory of project management. However, the LC critique cannot be dismissed as easily as this. The substance of their critique focuses on the centrality of the WBS in PM theory, because this forms the basis for the classic project management tools such as critical path analysis and earned value analysis. It is true that WBS is inherently a decomposition, but LC techniques also decompose the process in, for instance, value stream mapping [8 fig 2] and process flow charting [25 fig 8]. The point is not the act of decomposition, but what is then done with the decomposed structure.

In critical path analysis, the WBS is used to identify sequential dependencies between tasks and to indicate expected task execution times. This information is then used to find the longest route through the network thereby created which identifies the critical path, or shortest possible time for total project execution. The LC approach also requires this information, but applications such as MS Project provide it more neatly than in, for instance, process flow charts [25]. The other main type of information mapped in the LC approach is who is to do the work. Conceptually, the supplier of the task execution services is handled in PM theory within the organisational breakdown structure (OBS), and is implemented in the resourcing tables of MS Project. This information can then be used for resource levelling, as well as in the much more sophisticated applications of critical chain (which is a resource-constrained critical path) such as ProChain. Where operations are repetitive - such as in the shear wall and pipe support examples - scheduling techniques such as line-of-balance may be appropriate. The advantage of applications such as MS Project is that they add analytic intelligence to the process representations (e.g. critical path, resource levelling) which is absent from the LC applications. It can also be suggested that critical path network and line-of-balance are inherently about flows as work moves from one task to another. The choice of tools and techniques for process representation and analysis is a pragmatic one – the argument here is that there is no theoretical reason to reject those tools and techniques based on the WBS. A more valuable strategy would be, therefore, to follow Goldratt's approach of enhancing these tools to meet contemporary requirements, rather than to trying to develop new tools from scratch for use within the LPDS.

However, this debate about tools and techniques misses a rather more important issue – what is theory in project management about? Many of the comments above in response to the LC critique of *MCP* have implied that the there is a misunderstanding in what project management is about. The argument in *MCP* is that it is inherently an organisational innovation, a position derived from a reading of the history of project organisation [30, 31]. The tools and techniques which are so often synonymous with "project management" are simply that – tools and techniques, and not the core of what project management is about. Projects as a distinctive form of organisation emerged during the 19th century as society started to create complex systems, and were developed and formalised in the US aerospace sector in the post-war period. They are now rapidly diffusing in a large number of industrial sectors [32]. In a very important sense, they are a response to the transformation-orientated organisational forms that emerged with the development of new volume production techniques such as the American system and mass production. As Womack and Jones argue, "the concept of a project engineer to oversee the entire value stream foreshadows the lean principles described in this book" [33 p 156].

The perspective on project management underlying *MCP* draws on the work of authorities such as Morris [30] and Turner [28] to theorise project organisations as temporary systems for the definition and execution of unique, time-limited objectives which are capitalised by clients. In order to achieve these objectives on behalf of clients, project organisations mobilise the *resources bases* which act as the permanent repositories of the human and physical resources required for project definition and delivery. These resource bases may be internal or external to the client organisation – in construction they are almost always external. It is the resource bases which are responsible for the transformation of materials – project organisations and their managers are the coordinators of the flows of information that govern the transactions between resource bases and responsible for ensuring that the value originally identified in the investment appraisal for the project is captured by the client. This position accepts that not all construction production is appropriately organised in projects – housing production, for instance, is outside the scope of *MCP*. As the project organisation moves through the project life-cycle, project managers deploy a variety of tools and techniques for the planning and control of the flow of information that coordinates the transformation and flow of materials within and between resource bases. However, such a mechanistic approach is inadequate, and leadership remains essential for organisational and cultural coherence in definition and execution. MCP concludes by arguing that effective construction project management needs to be design led (i.e. focused on value for the client) and performance driven (i.e. focused on effective and efficient processes).

6. Engaging with the Theory of Lean Construction

The range of reference underpinning the TFV approach is wide and it is, perhaps inevitably, more syncretic than synthetic at this stage of its development. A review of the history of manufacturing and the application of its development to construction which provides the historical context for this critique is provided elsewhere [34]. I will leave also for others the task of detailed examination of the review and analysis underpinning the three pillars individually and in comparison, and focus in this paper on what I consider to be some conceptual weaknesses that all three conceptual pillars share :

- The focus on the physical processing of materials as an engineering problem;

- The absence of a concept of organisation in the analysis;
- The lack of any analysis of the implications of risk and uncertainty;
- The unitary concept of *value*.

6.1 Production as Materials Processing

The overwhelming emphasis – either explicitly or implicitly - of the TFV approach is on the processing of materials as a technical problem in engineering. This is manifest in both the selection of the sources for the development of the three pillars, and in the overall tenor of the argument. While attention to the physical processing of materials needs to form part of any theory of manufacturing for the production of artefacts, it can only form part of an overall theory of production for two reasons. The first is that not all production is of artefacts – many phases in the production process involve no physical transformation at all, and many firms in the construction industry supply services to the client such as consultancy rather than artefacts such as shear walls. Second, and more generally, important shifts are taking place in the market for manufactured goods, where, increasingly, what is purchased by the client is the service that the artefact provides, not the artefact itself, in *integrated solutions* [35].

Koskela's analysis does encompass design processes, but the notion of design appears to be limited to fitness for purpose defined in engineering terms as opposed to design as symbolic value defined in cultural terms. Clark and Fujimoto [36] argue persuasively, based on their extensive work in the automobile industry, that the essence of successful design is *product integrity* which has two facets. The first is *internal*, and is essentially the same at the familiar fitness for purpose criterion. The second is *external* and refers to the consistency between the product's performance and customer expectations which include measurable performance criteria, but also synergy with the customer's lifestyle and aspirations. Koskela does not argue that design is the same as manufacturing, rather he suggests from a value perspective that it is "analogous to mining…. The issue is to find the ore (requirements) and to have it processed so that no metal is rejected in slag (avoidance of loss), and to produce an end result with as little impurity as possible (optimization)" [3 p. 118]. This conceptualisation of the design process finds little resonance with the analysis of the design process articulated by such authorities as Lawson [37] as a messy process of finding solutions to wicked problems, and I submit, presents a very limited notion of what the design process in construction is about. Although more recent formulations by LC [6,1] have suggested that effective design has more emergent properties than this citation suggests, there is still a strong sense here of the now discredited [38] design methodologies approach.

6.2 The Organisation of Production

A notable feature of the principal contributions to current debates on the transformation in manufacturing associated with the Japanese challenge over the last 20 years is the considerable attention paid to organisational issues. The contributions from both Harvard and MIT which have led this debate all combine analysis of flows of information and materials with analysis of changes in forms of organisation. The reason for this is that processes cannot exist on their own – they are always embedded in an organisational context, and that context is as important an influence on how information and materials flow as the configuration of machine tools on the factory floor [20]. While it is certainly possible to analyse operational flows in isolation from their organisational context using techniques derived from operations research, any implementation of the results of such analysis, or indeed the implementation of any new technology designed to improve that process, requires organisational change to provide the context for the effective use of that technique [20]. This lack of attention to organisational issues is surprising given that last planner [7] is, in essence, an organisational innovation in that it proposes weekly meetings to determine which "quality assignments" can be scheduled for the following week's work.

This analysis of structure and process in organisations draws on the contingency approach to organisation design authoritatively reviewed by Mintzberg [39]. Despite its importance to research in the development of lean processes, the reference to this literature is both very limited, and a misinterpretation. The contributions of Thompson and Galbraith – two of the leading contributors to the contingency theory of organisation – are discussed solely in terms of their relationship to the transformation concept of buffering [3 p. 44]. The term does not appear in the index of Galbraith's major synthesis of his contribution [22], nor his more recent management guide [40]. The misinterpretation of Thompson's [10] discussion of buffering is of greater interest in the context of this paper, because Thompson's principal concern is how organisations seek certainty in the face of exogenous uncertainty in order to protect their technical core, and buffering of that core from the external environment is one strategy for doing this. In this sense, last planner is a classic buffer technique in that quality assignments are those assignments that have had the uncertainty associated with their execution minimised.

6.3 Risk and Uncertainty at the Heart of the Organisation of Production

This point leads us nicely to the third critique of the TFV which is the lack of any conception of uncertainty or risk, where risk is uncertainty to which a probability distribution can be assigned. A basic tenet of organisation theory is that one of the major – arguably the major – influence on the design of organisations and the production systems they support is the level of uncertainty that they face. This uncertainty may be environmental [41], technical [42] or transactional [43], but it is pervasive. It is particularly pervasive in project organisations due to their non-repetitive nature – indeed risk management is arguably the most important development in project management tools and techniques since the 1960s [30]. Stinchcombe [44] argues in his comparative analysis of the construction and car industries that it is the level of uncertainty that contractors face, and therefore, their need for flexibility that most clearly distinguishes them from car manufacturers.

One of the major changes in the environment for organisations and their production systems over the last 40 years since the era of the contingency theorists is that levels of uncertainty have increased as organisations' abilities to buffer themselves from those uncertainties have decreased. The dynamics of change in the market environments and technologies of production have intensified across all sectors, and construction and the other project-based industries face relatively high levels of uncertainty compared to other production sectors. I submit that any viable theory of production must have a concept of uncertainty at its heart – in other words, we need a theory of how production systems vary contingently with the levels of market and technological uncertainty that they face as part of any theory of production.

The fundamental role of uncertainty in the design of production systems means that information is critical. Uncertainty is defined as the difference between the information required for a decision and the information available for that decision [22]. Decision-makers coping with uncertainty are forced to make provisional decisions which are then adjusted as uncertainty-reducing information arrives as "news" [23]. While the physical act of production in manufacturing and construction inevitably involves materials flows, those materials flows are connected with the organisation within which they are housed and the markets which they are intended to serve through information flows. Thus, I submit, any theory of production needs to be a theory of both information and materials flows in the process – what has been called the *tectonic* approach to production [20].

6.4 The Unitary Concept of Value

The LC approach stresses the importance of the generation of value through the construction process – it is the third pillar of the TFV theory. More recent work on *revaluing construction* [45] has identified three dimensions to the value concept applicable to the construction process :

- The contribution that the asset created by the process makes to the client's business processes

- The contribution that the process makes to the supplier's business processes

- The contribution that the asset makes to society as a whole.

The fundamental issue is that these three dimensions of value exist in all projects, yet they are not necessarily aligned. A major issue in realising value in the constructed product is that they are typically seen as artefacts with a cost, rather than assets worthy of properly evaluated investment. One reason for this is that there is remarkably little research on how buildings add value for clients – the state of the art is reviewed in Spencer and Winch [46] and Macmillan [47]. In societal terms, a new road may add value for the government that constructs it and the travellers who use it, but can destroy value for those who live near it, or who value the natural environment that it destroyed. For this reason, stakeholder management [48] is a vital element in construction project management. Within the supply chain, the capture of greater value for one actor in the process – typically in the form of profits – can be at the expense of another. This is why a theory of how to align incentives within the project value system is a central part of construction project management theory [49] in order to avoid the cycle of adversarial relations and over-engineering [17 fig 6.5]. The members of the project value system are typically independent organisations which must make a profit from their participation in that system or die – a coalition of interests, rather than a team is the appropriate metaphor for the construction supply chain, even where there are formal joint venture arrangements in place as part of *integrated teams*. Thus value in the construction process and product is inherently contested, and we need to develop methods of ensuring that incentives are aligned both within the project coalition, and between the project coalition and external stakeholders. A unitary concept of value derived from quality management is, I submit, inadequate for such a task.

7. Conclusions

There is much agreement between the two positions articulated in this paper, although debate inevitably emphasises disagreement. Certainly, last planner is an important and distinctive innovation in construction project planning, and the other techniques adopted for the LPDS are appropriate. It was suggested that additional techniques such as critical chain could also be adopted with benefit. It was also suggested that the existing project management toolbox still has much to offer – arguably what is at issue is how it should be used, not whether it should be used. The TFV theory is based on a refreshing reading of the production and operations management literature, and moves the debate on the organisation of production in construction forward considerably. It was argued, however that it would benefit from further development because of the strong focus on the physical processing of materials as an engineering problem; the absence of a concept of organisation in the analysis; the lack of any analysis of the implications of risk and uncertainty; and its unitary concept of *value*. We need theories of production, because without them we cannot determine which tools and methods it is appropriate to adopt from manufacturing industry, and which are inappropriate due to the site specific nature of construction [5, 34], but such theories need to be based in the social science of organisation [50] as much as in the techniques derived from operations research which form the principal foundations of LC [3, 4].

The theory underlying MCP has been elaborated elsewhere [19, 20, 34, 49]. The aim of this paper has been to engage in a debate with the advocates of lean construction as we jointly and severally attempt to develop a theory of construction as production by projects. Arguably, the most important thing that construction can learn from manufacturing production is something that it gave away in the first place – the fundamental role of project forms of organisation and their effective management in the production of unique, site-specific products under time constraints.

Abstract

The past decade has seen several governmental initiatives in the UK aimed at improving the performance of the construction sector. These initiatives have resulted in the establishment of various bodies promoting best practice and the release of highly influential reports, which, despite being heavily criticised, have had a marked influence on industry discourse and research agenda alike. These reports are increasingly influencing not only the UK and other Anglo-Saxon countries but also countries with disparate regulatory systems, customs and construction practices. The research presented here explores the influence on the Swedish construction sector of the construction best practice discourse emanating from the UK. In particular it investigates how the discourse of partnering has invaded the Swedish market. Conclusions are drawn based on an extensive compilation of partnering related articles in Swedish press and the preliminary findings from an interview survey targeting construction practitioners. The paper concludes by highlighting ambiguities surrounding the purported improvements and the experienced realities on projects and questions are raised concerning the motivations and possible hidden agendas of those promoting partnering in Sweden.

Keywords: Best practice, partnering, change, resonance

1. Introduction

Recent years have seen increased attention and resources given to construction reform initiatives in a host of countries. Exactly how these initiatives have played out is quite obviously dependent on the specific country in question, but they all have in common their call for a change in a sector that is believed not to be performing. The UK could be singled out as a country with a long history of government initiatives aimed at evaluating and improving the construction sector. Over the last decade several policy makers and their respective organisations have been instrumental in highlighting the problems facing the sector and recommending the changes necessary to alleviate such problems. A variety of initiatives have been undertaken resulting in the publication of several highly influential reports (cf. [1][2][3]). These reports have, in turn, been poured over by numerous construction management researchers and used as pivotal arguments for research projects seeking government funding.

This paper sets out to explore the influence and diffusion of UK change initiatives, the movement for change, onto the Swedish market and its effect on policy makers and industrialists. It does so from the viewpoint of contextual understanding. In particular the paper sets out to illuminate the questions of why the some actors are keen on promoting and implementing partnering and why attempts might fail. The first part of the paper explores and sketches out the discourse for change in the UK construction industry that is finding a purchase within the discourse of change in other countries. The second part of the paper challenges the assumptions underpinning this discourse of change and highlights some fundamental issues that are missing in the adoption of this discourse in other countries. The third part of the paper explores a specific example of the best practice discourse related to partnering in the context of the Swedish construction sector. Support for the arguments presented are taken from numerous discussions and interviews with representatives, both junior and senior, from a variety of Swedish construction companies including architects, clients, contractors, designers and technical consultants. The final part of the paper presents preliminary conclusions to this largely desk based study and a framework for further research.

2. Discourse of Change in the UK

The UK has a long history of reports bemoaning the performance level of the construction industry. Indeed, it has for the last 60 years been the subject of a steady stream of governmental reports. Since 1975 these have been conducted with an interval of between 3 and 5 years [4]. Whilst these reviews have been influenced by contemporary issues of concern, Murray and Langford conclude that they have more often than not uncovered similar industry ills. It is, indeed, evident that the reviews share similar messages regarding the sectors performance and only show subtle differences in the reasons that are given thereof. The rhetoric might have changed and new buzzwords have been introduced, but in essence the underlying issues have been the same. Aspirations of integration, teamwork, trust, partnering, standardisation, value for money pervade and the need for alternative managerial practice within the sector to facilitate these aspirations is a common theme - especially in contemporary reports. Likewise, the presented challenges or barriers to these aspirations are remarkably similar: resistance to change; undesirable culture; and fragmentation. However, a change in governmental policy can be detected as of the Latham-report in 1994. The contemporary movement for change has taken a more hands-on approach by recommending and introducing particular methods of delivery that are believed to facilitate their aspirations of change in the sector. The influence of clients during this period is worth noting as the ongoing commitment to regularly procure from the sector by particular clients is clearly reflected in the change agenda. This dominant position of clients is not serendipitous; Murray [5], for example, points out that the CTF deliberately excluded contractors. Despite a more balanced representation within the ‘Movement for Innovation’ and ‘Construction Best Practice Programme’ client dominance still prevails. The contemporary movement for change is captured articulated and rooted within publications and initiatives from 1994 onwards:

- the Latham report [1];
- the CTF’s widely cited *Rethinking Construction* report [2];
- its sequel the *Accelerating Change* report [3];
- the *Better Public Buildings* report [6];
- the *Clients’ Charter Handbook* [7];
- the *Modernising Construction* report [8] and;
- the establishment of Constructing Excellence

Even though it is not without its critics [9,10,11,12] the movement for change has a strong hold over the industry discourse and is largely responsible for the introduction of management initiatives throughout the construction sector and has been given considerable support from Government.

The actual change sought after is promoted through identification, implementation, monitoring and measuring of ‘best practice’. The kind of best practice sought after is, in turn, largely designed to address and revisit the aspirations of integration, teamwork, trust, partnering, standardisation and value for money, mentioned above. The identification of best practice, which is largely achieved through ‘learning from other sectors’ and benchmarking, is, therefore, driven and biased by these aspirations.

Partnering serves as a prime example of best practice imported into the construction domain. In a fashion partnering is seen as a remedy for several of the performance deficiencies that have been around for the last 50 years and claims are commonly made along the lines of performance benefits in terms of cost, time, quality and a range of other criteria. The concept has, thus, found its place within the contemporary movement for change and has been highlighted in a number of reports (e.g. [1, 13, 14, 15, 16, 17, 18, 19]).

3. Discourse of Change in Sweden

At times the Swedish construction sector is praised for its international competitiveness, leading architectural design and high overall quality; a common description in international benchmarking studies (cf. [20]). Yet, more and more often the sector is accused of being conservative and adversarial to clients and blamed in the national press for all sorts of malpractice and more or less dishonest behaviour, e.g. technical faults, poor safety and ignorance of environmental issues. The last five years has seen issues such as alleged cartels in asphalt and material supplies, malpractice on high profile projects and perceived unreasonably high costs of construction being scrutinised in the mass media. This has lead to an increased awareness amongst members of the public of failings in construction projects. In particular, the exposure of malpractice and faults on a series of high profile projects during the first two years of the century placed the debate in the national newspapers.

Governmental initiatives have been undertaken to investigate the underlying reasons for the sector's perceived failings. Examples include the forming of the Building Cost Delegation [*Byggkostnadsdelegationen*], under the auspice of the Ministry for Industry, Employment and Education in 1996; and the Building Commission [*Byggkommissionen*], within the Ministry of Sustainable Development in 2002. The specific objective of the Building Cost Delegation was to determine the underlying reasons for the high costs of construction. Whilst the objective of the Building Commission was to propose measures that would foster competition and prevent competition hampering behaviour, use of illegal labourers and the forming of cartels. At the same time various interest organisations (cf. [21]), individual firms (cf. [22,23]) and industry commentators (cf. [24]) also started to make their voices heard, providing their own set of causes, explanations and solutions.

Although the messages that have been conveyed vary slightly and the underlying motives most probably differ, most of the arguments and recommendations put forward, from the public and private side, have in common a reliance on the 'movement for change' discourse emanating from the UK. In the case of the government initiatives the Building Cost Delegation's final report [25] was influenced by the Latham Report [26] and the work of the Building Commission was heavily influenced by the Egan report and the Rethinking Construction agenda [27]. From the private sector side the arguments have been supported on the perceived benefits of initiatives such as Rethinking Construction (e.g. [28]), but more often on the broad recognition of consistently higher performance in other sectors – e.g. automobile sector – and pockets of higher project performance within the construction sector itself, provided in the movement for change discourse. In particular, the concept of the transferability of 'best practice', in the form of partnering, is central to their recommended content of change.

Partnering has, indeed, been placed high on the agenda amongst those looking for a change within the sector. Whilst it could be argued that this development has been industry led, in particular by contractors, see for example [22,29], it has also been the subject to a relatively high degree of attention within the Swedish construction management research community (e.g. [30,31,32,33,34]). Several powerful arguments in favour of partnering have been put forward and the advocates present strong cases for its use. Yet, the concepts differ and could be considered to be imprecise, inclusive and subject to continuous redefinition. It is difficult at times to distinguish between the promoted version of partnering as a distinctive practice or as managerial rhetoric. Indeed, confusion continues to prevail at a variety of levels, as for example, in distinguishing between partnering and collaborative working.

4. A Critical Perspective on the Discourse of Change

Failure to understand and relate initiatives to context is understood to be the reason why many contemporary change programmes consistently fail to deliver [34]. Following this line of reasoning it is argued here that in seeking to change managerial practice it is essential that context is recognised as an influential aspect of any analysis of managerial practice. Indeed, from a change management perspective it is surely common sense to fully understand why and how organisations and individuals legitimise current practice before prescribing a need for change and how such change might be implemented. This point is not lost on theorists within organisation studies who have recently explored the use of theories such as structuration [35], institutionalism [36], and evolutionary economics [37] that highlight the importance of various aspects of context.

Historically, industry commentators as far back as Higgin and Jessop [38] have, indeed, made attempts to conceptualise and understand context when addressing such issues as interdependency, communication and uncertainty in the construction sector. However, almost paradoxically, the contemporary change agenda in the UK construction sector appears to be narrowly focused on the need to adopt alternative managerial practice, and, hence, tends to underplay or ignore the importance of context in their analyses (cf. [10,39,40]).

Underplaying or ignoring context could be equalled to assuming that the particular best practice in question, be it partnering or something else, is similarly interpreted by all individuals involved in its implementation. Such assumptions fail to take into consideration the infinite number of reasons why employees and managers within an organisation may object or even obstruct management initiatives recommending alternative practice. Furthermore, a key issue that is likely to be missed is the concept of ‘resonance’ [41] whereby legitimacy is given to creative ideas if, and only if, they resonate with the concerns of individuals (or groups of individuals). Hence, whilst rhetoric based on common sense such as team working is difficult to refute, what is easy in principle is not automatically easy to achieve in practice, and might not even be advisable. Could it not be possible that perceived barriers to change in the sector such as adversarial contractual relationships and opportunistic behaviour are legitimate actions of practitioners embedded in the context of the construction sector? If so, simplistic calls for change associated with collaborative working will continually fail to resonate with practitioners. Therefore, what is questioned here is not the existence of potential benefits of the cornerstones of partnering, such as trust and mutual understanding. Rather it is its legitimacy in regards to existing practice and context.

Further support could be found in the widely spread criticisms of universalistic assumptions regarding the application and implementation of best practice. It has, for example, been argued that best practice has to be coupled with the need to understand the circumstances within which it is used, when it is used and why (e.g. [42,43,44]). Essentially the above authors argue for a move away from imitation on the basis of simplistic cause and effect to a position that concedes learning to be drawn from understanding and challenging ‘cause and effect’ in its context.

Effectively it is argued that notions of learning and knowledge sharing have much to contribute towards achieving better organisational performance and understanding the link between practice and performance.

5. Partnering in Context: Discussion

There are notable papers that broadly criticise the movement for change in the UK on the basis of an unreflective allegiance to instrumental management techniques [9,11,45,46]. Indeed, Green [45] rather gratuitously used the phrase ‘technocratic elite’ as a broad descriptor for those responsible for promoting change. It would be naive to think that vested interests are the only forces at work. But it would be equally naive to argue that the promoters of partnering are motivated solely by altruism.

The core argument presented in this paper is that practice is not enacted within a vacuum. In essence, analysis of change, recommendations for change and implementation of change, must be sensitive to the dynamic relationship between context and practice. Failure to do so run the risk of making any associated change initiatives partly or wholly irrelevant. It is contended that such thinking and sensitivity is under developed within the promotion of methods such as partnering. To further put this into perspective it is worth noting that that there historically has been a clear resistance amongst Swedish clients to change the traditional allocation of responsibilities and ways of working [26]. Thus, whilst it in the UK could be argued to be the client side that has been more active in pushing for a change, in Sweden this has not been the case, as clients, in general, have been sceptical to the idea. Also, contractual relations are thought to be less antagonistic in Sweden than in the UK and US. In their review of dispute resolution and conflict management practice in Sweden Bröchner et al. [47] found that very few conflicts are settled by formal dispute resolution mechanisms. Furthermore, competition is to a certain degree limited on the Swedish construction market. A long term development of mergers and acquisitions has led to an industry structure of three dominant construction contractors, a handful of contractors specialising in housing and an abundance of very small contractors. A similar development has also taken place in the area of consultants and material suppliers. This limitation in competition could in itself be an incentive for long term buyer-seller relationships [26]. It is notable that although the Building Cost Delegation arguably sparked the debate it did not identify conflict as an important topic for improving the sector.

Context is, however, by no means a simplistic or static entity since it concerns a raft of highly complex, dynamic and influential factors. Organisations themselves are highly complex, dynamic and influential contexts. Practice, in turn, is embedded within and mediated by context. This relationship is symbiotic as context is also shaped and reinforced by practice. Attempts to change context can, therefore, be as influential and important as attempts to change practice when challenging the status quo. In essence, context and practice should be viewed as different aspects of the same reality [48] and the temptation to treat them as separate units of analysis should be resisted. Research is needed that engages with this reality by similarly engaging with practitioners within the construction sector to understand the legitimacy of their actions and their reactions to the content of change.

The preliminary findings from the interviews support the above argument. The impression given by the interviewees is that they have difficulties in seeing the difference between what is being forced upon them in the form of partnering agreements and guidelines and what they consider to be common practice. Collaboration is considered to be common place on ‘traditional’ projects though most agree that it is informal and perhaps slightly over reliant on personal relations. Compromises are common and the degree of mutual understanding is considered to be high. Problems arise if personnel do not get along, but as one of the interviewees pointed out: ‘it might be in the agreement [on a partnering project] to change the people in the team, but that is what we do on traditional projects’. Thus, the concept of partnering, as imported and adapted from the UK context into the Swedish discourse of change, is failing to fully resonate with those who are charged with the day-to-day work.

The potential value of change is found in its resonance and applicability to the surrounding context and it is this context itself that determines both the applicability of and opportunity for change. It is therefore clear that for any proposed change to find legitimacy it has to resonate with current or contemporary concerns and issues [41] in the context that they are played out. Several of the interviewees did, indeed, struggle with this. One interviewee phrased it: ‘*partnering to me is when you open up a new shoe shop with a partner, sharing risks and rewards. That is partnering*’. It seems that very few of the people involved in the actual work see it as if something new is taking place. The feeling is that of superimposing a new word to describe something that has been around for decades. This was also the view of a project manager with experience from a couple of partnering projects: ‘*I’ve always been positive to partnering. Not the word partnering, but long term collaboration and collaborative working… I don’t like partnering. I don’t like the debate on partnering. There is nothing substantial behind it*’. The company he represents has been working closely with a number of clients for a long time and at present none of their work in the particular region has been won through competitive tendering. Furthermore, it was a common impression amongst the interviewees that the promotion of partnering as a new and tangible phenomenon was the result of a rather aggressive marketing drive by one of the large contractors and that others had chosen to follow suite. “*It is that large contractor that is pushing*”. Even so consensus was that companies could not afford not to officially support partnering: “*It is politically and commercially correct to like partnering*”. Again this points towards that the concept of partnering, as promoted and implemented on the Swedish construction market, is failing to find resonance amongst those charged with the day-to-day work.

6. Conclusions

It is unclear why the UK movement for change has failed to engage in an exercise to understand the legitimacy of managerial practice in the construction sector over repeated attempts to describe the sector as ‘ill’ and in need of change. The amount of attention that it is getting in other countries, such as Sweden, is therefore puzzling. The recognition of context and the pivotal role it plays in shaping contemporary managerial practice should be of prime concern to policy makers, practitioners and academics engaged in advocating change within the sector.

This paper does not contend that the Swedish construction sector is faultless and not in need of change. Neither is it contended that partnering is necessarily a bad thing, in fact the main criticism of partnering is the vagueness of the term. What is contended is that the promotion and adoption of partnering in Sweden is based on misconceptions of the concept its origins and context. There seems to be a broad recognition of the need for change within the sector. However, it is not entirely clear if the change that the sector wants is in the form of how it is perceived by the public or in how business is done. Whilst the latter quite obviously affects the former it is by no means a prerequisite.

The first phases of the research have shown that there is reason to be restrictive in taking the debate on partnering in Sweden at face value. The importance of context is as of yet under explored and does not seem to be taken into consideration amongst those advocating partnering; be it the companies that are leading the way or the posse of industry commentators and at times academics that are backing them. As could be expected there is a resistance amongst the workforce who cannot understand what all the fuss is about. The concept has, as of yet, failed to find resonance and individuals fail to see the difference in working and, furthermore, do not understand how a contract/agreement specifying what they consider to be ‘practice as usual’ can lead to the improvements they read about in the papers or are told about at various seminars etc.

Abstract

This study sought to determine whether critical change project management did improve project completion times and/or completion certainty. The study used social housing projects as the basis for the study and adopted an experimental approach. Three experimental projects; all social housing schemes had their construction managed using the critical chain technique. To provide control projects, three comparable projects were constructed and managed without the use of critical chain. An additional number of comparable projects that had already been built without the use of critical chain, were analysed post-completion to increase the available data of control projects.

The results were presented separately for dwellings and for flats. The results for flats revealed that the experimental project using critical chain did perform better than the control projects when measured against a number of criteria, notably, a) time per dwelling, b) value produced per working day and c) area constructed per working day. The results for flats were mixed and can only be regarded as inconclusive at this time, although there is data to show improved performance in a number of criteria. All the control projects were completed within their contracted completion date. Further analysis of the data is being undertaken to increase the certainty of the results.

Keywords: Critical chain, planning, performance, housing

1. Introduction

Critical chain is one of a number of recent developments in the techniques of project programming and management that have come about because of perceived deficiencies in more traditional programming and scheduling tools; most notably their failure to control time overruns during the construction phase of the work. The critical chain technique purports to provide project managers with the ability to better manage and control time overruns.

This paper reports the initial results of a study to determine the effect of using the Critical Chain technique on the construction of a number of similar social housing projects. The study specifically sought to determine if a time difference exists between projects managed using critical chain and those that were not and if so to quantify the difference. The hypothesis stated that; critical chain would improve the construction time of projects. In addition to determining the time performance of critical chain, other subjective observations were made with the aim of discovering any other implications that derive from employing critical chain, together with any anomalies produced by the use of the technique. Subjective issues such as, the ease and extent that the technique is adopted by site staff, the effect of using the technique on the management of the projects, and any developments that lead from the application of the technique.

1.1 Critical Chain

The principles underlying the critical chain technique of project programming derive from the application of certain aspects of the Theory of Constraints to a project environment. [1]. Critical chain uses a project programme that has been planned and programmed using a precedence or CPM network, the key areas of difference between critical chain and these traditional forms of project management using networks and critical paths, is in the way that Critical chain handles, a) activity durations and b) the float time for each activity.

Critical chain is based upon the premise that in every activity duration, there is by default, a certain amount of spare time or 'buffer' included in the duration. Even where the activity is critical, a small but identifiable amount of spare time exists and that if all these spare times can be collected together into a 'buffer', they can be used usefully to keep the project on schedule. Critical chain introduces a range of specific terminology as part of its system, 'buffers' describe float or spare time, an 'activity buffer' occurs within each individual activity. It is these individual 'activity buffers' that the critical chain technique identifies as being unrecognised and unused, and which in other programming systems become wasted. Critical chain collects these individual 'activity buffers' and places them in a 'strategic project buffer', which sits at the end of the project and is used to the benefit the whole project.

Having established a strategic buffer, critical chain uses a system called 'buffer management' to monitor and control the progress of the project. This records the extent and rate at which the strategic buffer is being consumed by any delays that may be occurring within the project. A traffic light system provides a quick way of assessing how critical the rate of buffer usage is and indicates to management where action is required to rectify the situation. This provides a means of prioritising management action to deal with the causes of the delays. In essence it provides a continuous indicator of buffer usage and a mechanism for making decisions on whether or not to instigate recovery actions.

The critical chain approach requires the reduction of task durations from those estimated with a high probability of delivery to ones that were 'challenging but achievable', this approximately equates to reducing task durations with a probability of 80% certainty of completion to 50% certainty of completion. The 'Prochain' project management software identifies the critical chain through the project, calculates the strategic project buffer and the 'feeding buffers', that are required for the application of the 'buffer management' project control process.

2. Methodology

The study adopted an experimental approach. Three experimental projects, all social housing schemes, were selected and their construction managed using the critical chain technique. To provide control projects, three comparable projects were constructed and managed without the use of critical chain. To establish as large a control or baseline data set as possible, an additional number comparable projects were selected that had already been built without the use of critical chain, these were analysed post-completion to increase the available base-data of projects constructed without the use of critical chain.

From the outset, the biggest issue with respect to the design of the experiment and the collection of data was that of comparability. Despite being selected to be as similar in size, character and construction as possible, none of the projects used in the study was exactly the same as any other, there were always a number of differences that would, or could, be sufficiently significant to alter the comparability of the projects under study. These variables were identified as site layout and size, mix of dwellings, location, site management team, client, time of construction, labour usage, plant usage,

Site layout was invariably different for all the projects included in the study, however this did not present as great a variable as at first envisaged. By only including data from comparable building types, such as low rise dwellings and flats in a single block, significant errors were eliminated. The second factor that smoothed-out the difference in this variable was density. The sites studied were developed to a similar building density and were sufficiently comparable within type to eliminate without adjustment from the comparison.

The extent of external works does present a significant difference between projects, depending upon the site itself plus the extent of excavation, drainage, roads and paths, etc. External works seldom featured as a critical activity on any of the projects, except occasionally and very briefly on some of the projects. The absence of any major enabling works prior to the commencement of construction of any of the projects, together with their non-critical character, indicates that the time taken for these works does not significantly contribute to the overall time for each project and can therefore be ignored as a variable. They do however affect the results for value erned per working day.

The size and mix of dwellings within each project also fell within acceptable limits of comparability, as the majority of the projects were for comparable clients, namely social housing providers, whose specified requirements for size, mix and quality were generally equivalent if not exactly the same. For the purposes of analysis, variability in the size, mix and quality of the dwellings were initially ignored, however this is now subject to detailed review. Data that was time sensitive, such as costs, was updated using tender price indices. All the projects were in the same regional location, which eliminated regional differences in cost, construction, weather, etc. as variables between the projects.

Progress and performance data was collected for the experimental and control projects on a weekly basis, together with a range of other data relating to project specific factors that might distort the performance of each project, such as weather, breakdowns, labour shortages and any incidents that materially affected progress.

2.1 Cross-contamination

The critical chain technique was introduced to the site managers of the experimental projects through a series of workshops, these consisted of two day training programmes, which explored the principles behind Critical Chain project management and how it could be applied to the construction projects. The need then arose to prevent the managers who would be using critical chain on the experimental projects from influencing the managers of the control projects who would not. Leaking of ideas from the ‘new’ system to the control projects would, if substantial, ruin the validity of the study. In the normal day to day operation of the firm, contact between site managers was minimal, however there were collective events at which the managers interacted. Managers on the training courses agreed not to discuss the critical chain technique or any related aspects with colleagues until the experiment has ended. Similarly, contract managers with responsibility across both types of project also undertook not to discuss any aspects of the experimental or control projects with the respective site managers. Finally in order to ensure that no cross-contamination had affected the management of control projects, a number of control projects that had already been completed prior to the experiment, were added to the analysis.

A number of events had a significant effect on construction progress that were specific to each project, events such as weather, stoppages and any incident/event that caused lost production time. These were deducted from the total working days to complete the project to produce a net figure.

3. Results and Analysis

The results have been analysed and presented into two comparable sets of data, those for traditional dwellings and those for flats (apartments). Analysis of the data for each project has not been adjusted to take into account the different sizes of each respective project, apart from showing the total construction time in working days, the data has been related to criteria that are not so susceptible to overall size of the project, such as working days per dwelling, floor area per working day and value per working day.

3.1 Traditional Dwellings

Table 1: Data for traditional dwellings

	Kings Hill 3	Hobbs Lane	Kings Hill 1	Kings Hill 2	Herne Road	Kings Hill 4
No. of dwellings	20	10	32	15	23	26
Constructed building area	1732.5	***900***	1549	1450	2006	1939
Area per dwelling	86.63	90	48.41	96.67	87.22	74.58
Cost £ (000's)	1850	930	1190	1230	1972	***2405***
Construction time [wkg.days]	214.5	215.5	260.5	206	374	297
Working days per dwelling	10.73	21.55	8.14	13.73	16.26	11.42
Area constructed per working day	8.08	4.18	5.95	7.04	5.36	6.53
Value/working day (000's)	8.62	4.32	4.57	5.97	5.27	8.10

An initial analysis of the results indicates that the critical chain technique did improve the performance of the projects in terms of time. The experimental project [Kings Hill 3] achieved a faster construction time than all the control projects with the exception of one [Kings Hill 1], when measured in terms of working days per dwelling. This discrepancy may be the result of the smaller unit size constructed on the Kings Hill 1 project, a point still to be confirmed.

Table 2: Working days per dwelling

Kings Hill 3	Hobbs Lane	Kings Hill 1	Kings Hill 2	Herne Road	Kings Hill 4
10.73	21.55	8.14	13.73	16.26	11.42

The result for Hobbs Lane [21.55] is significantly different to the results on the other projects, which raises the question of comparability, because of this and other anomalies in the results the project will be subject to further analysis to determine the validity of the project and data derived there from.

Table 3: Area constructed (M2) per working day

Kings Hill 3	Hobbs Lane	Kings Hill 1	Kings Hill 2	Herne Road	Kings Hill 4
8.08	***4.08***	5.95	7.04	5.36	6.53

Analysis of the results on the basis of the area constructed per working day shows the experimental project to produce at a rate of 8.08 m2/day that is greater than the control projects, which all performed below this figure. Similar results are produced when performance is measured in terms of the value produced per working day, the experimental project out performs the control projects (Table 4)

Table 4: Value (£,000's) per working day

Kings Hill 3	Hobbs Lane	Kings Hill 1	Kings Hill 2	Herne Road	Kings Hill 4
8.62	4.32	4.57	5.97	5.27	***8.10***

The time taken to construct any of the projects could have been distorted by introducing exceptionally different construction methods, either throughout or for part of the project to overcome problems that were encountered during construction. Thus far the analysis of the projects in the study has not revealed any unusual construction methods that would be sufficient to influence the results. Labour returns from the main contractor and all their sub-contractors were collected and analysed for every project. These were analysed in relation to the programme and the progress to determine whether sufficient numbers of workers had been flooded into a project to distort the construction time. The analysis revealed no peaks in labour supply that were greater than those that would be expected in the normal operation of sub-contractors working on multiple projects simultaneously. The analysis to date of the labour used per dwelling and value earned shows an acceptable level of consistency across all the projects.

3.2 Flats

Table 5: Data for flats (apartments)

	Prince Regent Lane	Harrow Road	Somertrees	Lord Warden Avenue	Burnt Ash Hill
No. of dwellings	50	46	40	10	13
Constructed building area	2736	3212	3759	659	***1200***
Area per dwelling	54.72	69.83	93.98	65.90	92.31
Cost £1000's	2900	3700	3600	720	1200
Construction time [working days]	302	393	331	182.25	240.5
Working days/dwelling	6.04	8.54	8.28	18.23	18.50
Area constructed per working day	9.06	8.17	11.36	3.62	4.99
Value/working day	9.60	9.41	10.88	3.95	4.99

The results for the performance of the experimental projects for flats, namely Prince Regent Lane and Burnt Ash Hill, are inconsistent with respect to each other and in relation to the control projects used in the experiment. Initial analysis of the performance achieved by the various projects shows that the experimental projects did not out-perform the control projects. Prince Regent Lane was faster in terms of working days per dwelling [6.04], but was lower than other projects when measured in terms of area constructed per working day [9.06] Somertrees [11.37].

Similarly the criteria of value per working day showed Somertrees [10.88] to be better than either of the experimental projects. The second experimental project, Burnt Ash Hill, exhibited significant differences in performance with the control projects, except Lord Warden Avenue and Prince Regent Lane. The analysis has confirmed concerns regarding the comparability of some of the projects, which will now be subsequently re-analysed. It is suspected that underlying these divergences may be the size of project with regard to number of dwellings plus the amount of ancillary facilities and space that forms part of these projects. Re-analysing the experimental projects in comparison with the control projects of a similar size provides a different perspective. These are shown in Tables 6 and 7.

Table 6: Data for Prince Regent Lane and comparable projects

	Prince Regent Lane	Harrow Road	Somertrees
No. of dwellings	50	46	40
Constructed building area	2736	3212	3759
Area per dwelling	54.72	69.83	93.98
Cost £1000's	2900	3700	3600
Construction time [working days]	302	393	331
Working days/dwelling	6.04	8.54	8.28
Area constructed per working day	9.06	8.17	11.36
Value/working day	9.60	9.41	10.88

Analyses of these results show a closer fit in terms of number of dwellings and project size. The time performance for the experimental and the control projects are more comparable, the time per dwelling shows the experimental project to be faster, 6.04 working days per dwelling. However in terms of area constructed per working day and the value produced per working day, the experimental project was outperformed by one of the control projects.

Table 7: Burnt Ash Hill and comparable control project data

	Burnt Ash Hill	Lord Warden Avenue
No. of dwellings	13	10
Constructed building area	***1200***	659
Area per dwelling	92.31	65.90
Cost £1000's	1200	720
Construction time [working days]	240.5	182.25
Working days/dwelling	18.50	18.23
Area constructed per working day	***4.99***	3.62
Value/working day	4.99	3.95

There are problems and deficiencies with these data sets and projects that will require further analysis to resolve. Not least the limited number of projects may invalidate the results and further data collection may be necessary to resolve the performance issues.

4. Conclusions

All three experimental projects were completed ahead of, or on their contracted time, in contrast to similar previous jobs that had consistently finished late. The results produced by the study indicate that critical chain does improve the performance of constructing the dwellings. It could be argued that this was more to do with the 'Hawthorne effect' surrounding the new technique, rather than a result of using the critical chain technique itself. This could indeed be the case, but the facts of the matter are that the projects did achieve their contract completion dates whilst operating critical chain and there is data to support this deduction.

The anecdotal evidence coming from the study suggest that critical chain has had some success in effecting cultural change amongst the site managers and contract managers involved. They acknowledge that critical chain has obliged them to properly plan the construction programme in order to provide the base for the application of critical chain. Whether this should have been done in any case is not the point; it was not. The fact is that it is now being done and should improve the management of future projects irrespective of whether critical chain is applied or not and must be considered a positive development. The operation of critical chain has also forced site and contract managers to focus on important issues and to prioritise their efforts towards important issues.

All these points suggest that critical chain has achieved a measure of management development regardless of its original intended method. It could also be claimed that the results achieved using critical chain could potentially be achieved using a number of other techniques and systems of management. This could be true, but critical chain has actually achieved these results in these instances. All three projects performed better than previous similar projects and on a number of criteria, better than the control projects. With regard to the performance of critical chain on the construction of flats, the results are far from certain and must be regarded as inconclusive. Further larger scale studies will be needed for both dwellings and flats to determine the specific effects of critical chain.

Acknowledgments

The study has been part-funded by the Partners in Innovation scheme operated by the Department of Trade and Industry.

Abstract

The paper explores the interdisciplinary nature of the construction management research and considers the contribution that the law subject discipline can make within it. It distinguishes academic legal research from empirical research and explains the distinction between doctrinal and socio-legal research. It argues that construction-related legal research is necessary to address areas which are beyond the scope of empirical investigations, and which have also been neglected by mainstream legal scholarship. Using examples it suggests that this has a particular role to play in challenging areas of practice which are not in conformity with legal requirements.

Keywords: Construction management, epistemology, methodology, inter-disciplinarity, law

1. Introduction

This paper explores the role of academic legal research within the construction management field. It describes the nature of this form of enquiry and contrasts it with more familiar styles of investigation within construction management research. It suggests that academic legal research has been a largely neglected activity within our field and that this has been to the detriment of the construction industry. It argues that this style of research has a particular role to play in the context of certain problems within the industry that are incapable of resolution by empirical or theoretical scientific enquiry.

It begins its analysis with an attempt to understand the nature of construction management research by placing it in its broader disciplinary context. It then discusses the different types of academic legal research that might be employed within the field and explores the value of these approaches to the construction industry. Finally, it introduces two different examples of construction-related academic legal research and discusses how these are providing benefits for the industry.

2. The Disciplinary Nature of Construction Management Research

Like all other academic fields, construction management is an activity that defines itself by reference to its particular subject of study. In other words it lays claim to a particular portion of the wider field of academic knowledge to justify its place in the academy. This raises questions about the characteristics of its particular portion of academic knowledge, and about the boundaries between it and those of its nearest academic neighbours. These can best be answered by reference to the Biglan [1] disciplinary model which is now widely accepted as a basis for cross disciplinary comparisons. This groups the various fields of academic study within a matrix, broadly according to a two-fold art/science and pure/applied categorisation. Based on work by Biglan [1] and Kolb, [2] the position of individual academic disciplines can be plotted on the matrix as illustrated by Figure 1.

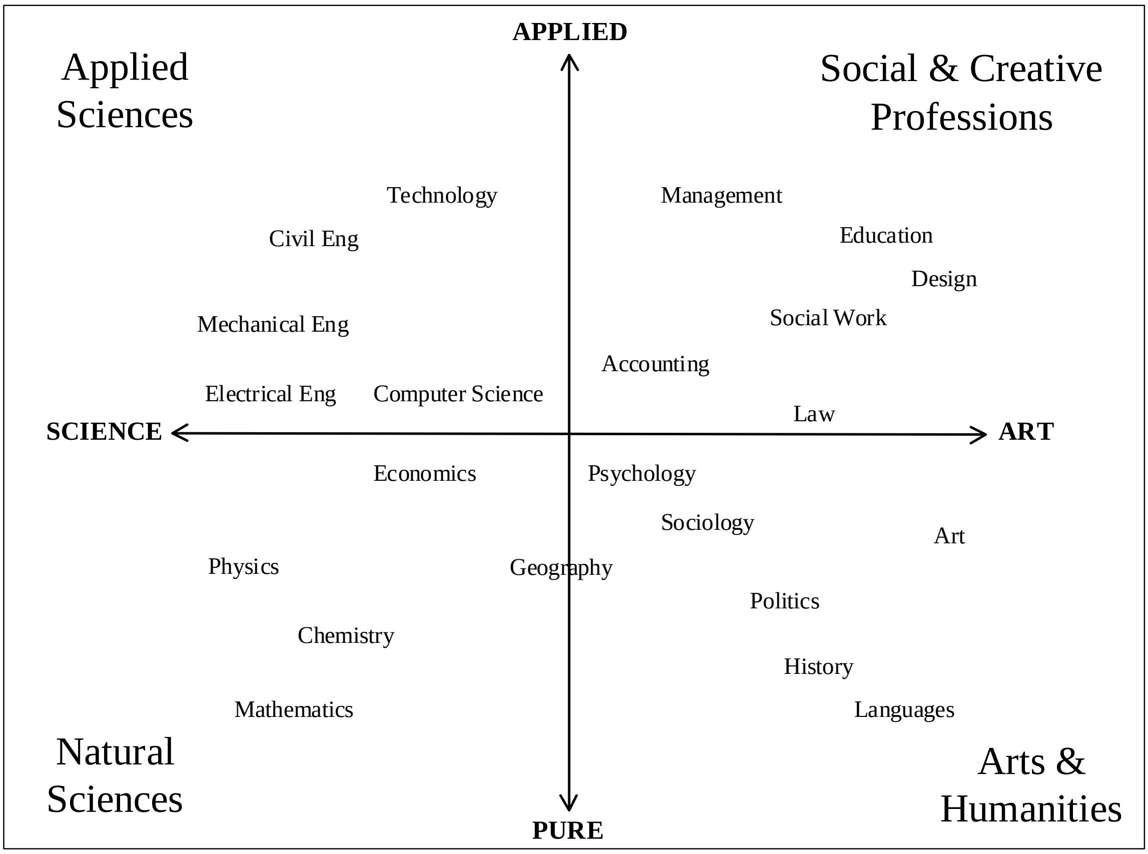

Figure 1: Disciplinary Model (after Biglan)

If the construction management discipline is considered in the context of this model the diverse nature of the field becomes apparent. There is a wide level of agreement within the field that, at a cognitive level, it is actually a combination of traditional sub-disciplines rather than a homogeneous discipline in its own right. These may be described in a variety of ways but, for the purposes of this paper, they are taken to be: Management, Economics, Law, Technology and Design.

The location of the various sub-disciplines within the matrix demonstrates the predominantly applied nature of construction management's academic territory. It also highlights its diversity in spanning academic practices across virtually the whole spectrum of the arts and sciences. This is significant in the current context as these different academic practices (or sub-disciplines) are naturally involved in the production of very different types of knowledge. They must therefore embrace different epistemologies when assessing the validity of the knowledge with which they engage, and employ different and appropriate methodologies in its production.

It is submitted that the approach of the construction management academic community should therefore vary, according to the nature of the problem being confronted. It should have the collective capability to provide solutions to the industry across the whole range of its sub-disciplines, but can only do so effectively if it fully understands the epistemologies and methodologies which are appropriate for different styles of investigation.

3. The Nature of Academic Legal Research

3.1 Epistemological and Methodological Approaches

The epistemologies and methodologies employed in academic legal research are rarely made explicit. Nevertheless, based on a model proposed by Arthurs [3], it is possible to construct a matrix of legal research styles which broadly follows the generic disciplinary model described above (Figure 2). Once again, a distinction exists between pure and applied research and this is again represented by the vertical axis on the matrix. However, the more interesting distinction is that between doctrinal and socio-legal research which is represented by the horizontal axis.

3.2 Legal Doctrines

Doctrinal research is concerned with the formulation of legal doctrines through the analysis of legal rules. Within the common law jurisdictions legal rules are to be found within statutes and cases (the sources of law) but it is important to appreciate that they cannot, in themselves, provide a complete statement of the law in any given situation. This can only be ascertained by applying the relevant legal rules to the particular facts of the situation under consideration.

Deciding on which rules to apply in a particular situation is made easier by the existence of legal doctrines (for example, the doctrine of consideration within the law of contract). These are systematic formulations of the law in particular contexts. They clarify ambiguities within rules, place them in a logical and coherent structure and describe their relationship to other rules.

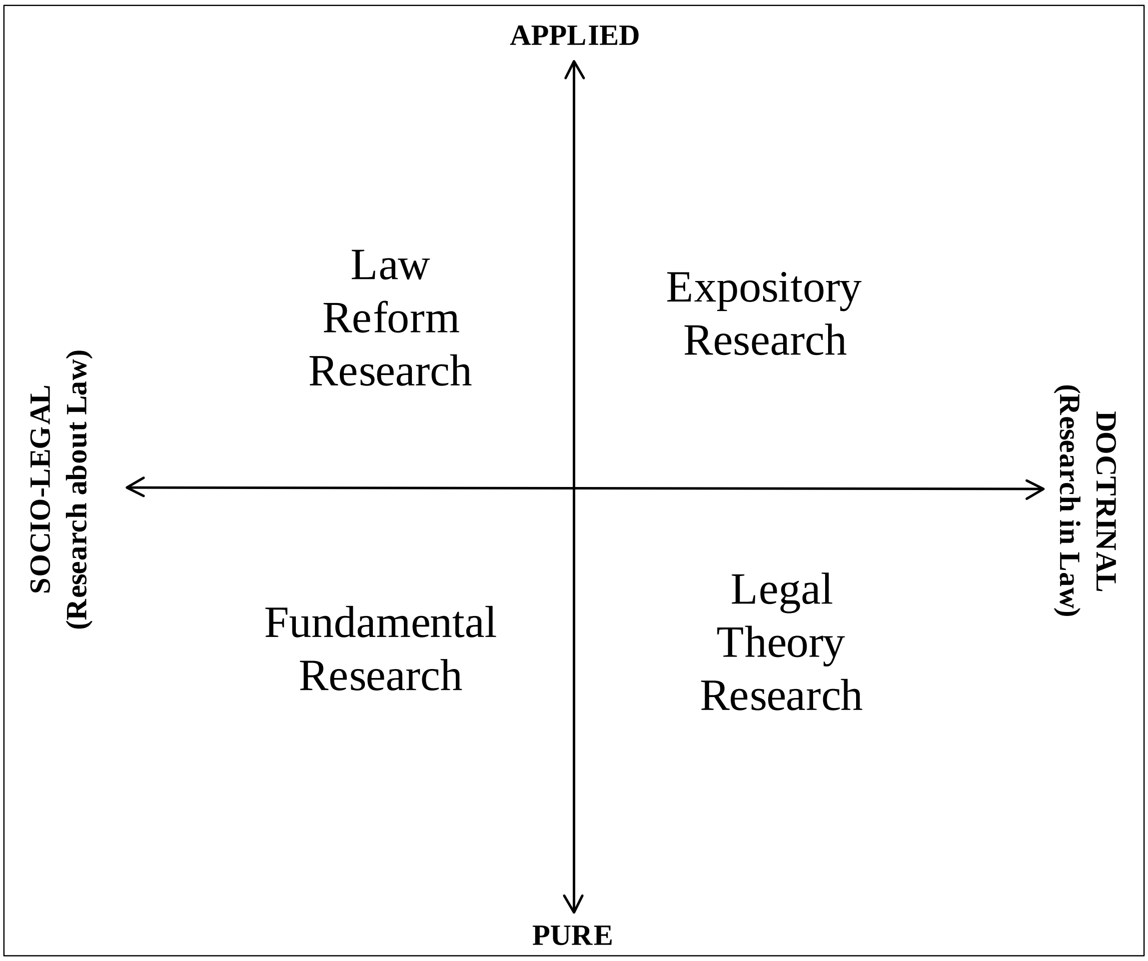

Figure 2: Legal Research Styles (after Arthurs)

3.3 Doctrinal Legal Research

Doctrinal legal research is concerned with the discovery of legal doctrines and its research questions take the form of asking “what is the law?” in particular contexts. At an ontological level this differs from the questions asked by empirical investigations in both the natural and social sciences.

This is perhaps most obvious in a comparison with research in the natural sciences which typically seeks to explain natural phenomena through studying the causal relationships between variables. This is clearly very different from the interpretive qualitative analysis required by doctrinal research which bears a superficial resemblance to the *verstehen* tradition of the social sciences [5].

However, this resemblance with the social sciences is misleading. Scientific research in both the natural and social sciences relies on the collection of empirical data, either as a basis for its theories, or as a means of testing them. In either case therefore, the validity of the research findings is determined by a process of empirical investigation. In contrast, the validity of doctrinal research findings is unaffected by the empirical world. Legal rules are normative in character in that they dictate how individuals ought to behave. They therefore make no attempt either to explain, predict, or even to understand human behaviour. Their sole function is to prescribe it. In short, doctrinal research is not therefore research about law at all. In asking "what is the law?" it takes an internal, participant-orientated epistemological approach to its object of study [6] and, for this reason, is sometimes described as research in law [3].

The actual process of analysis by which doctrines are formulated owes more to the subjective, argument-based methodologies of the humanities than to the more detached data-based analysis of the natural and social sciences. The normative character of the law means that the validity of doctrinal research must inevitably rest upon a consensus theory of truth, rather than on an appeal to an external reality. The underlying moral or theoretical basis for the consensus is a matter of considerable philosophical debate and must remain beyond the scope of this paper. Nevertheless, for present purposes, this could probably best be summarised in terms of a search for internal coherence within the existing body of legal rules.

3.4 Socio-legal Research

In practice, even doctrinal legal analysis usually makes at least some reference to other matters as well as seeking answers that are consistent with the existing body of rules. For example, an uncertain or ambiguous legal ruling can often be more easily interpreted when viewed in its proper historical or social context, or when the interpreter has an adequate understanding of the industry or technology to which it relates. As the researcher begins to take these extraneous matters into account the enquiry begins to move leftwards along the horizontal axis in Figure 2, in the direction of socio-legal research.

There comes a point, towards the left hand side of the matrix, when the ontological nature of the research changes from that of internal enquiry into the meaning of the law, to that of external enquiry into the law as a social entity. This might involve, for example, an evaluation of the effectiveness of a particular piece of legislation in achieving particular social goals, or an examination of the extent to which it is being complied with. In taking an external view of the law each of these examples could be described as research about law rather than research in law. As one continues to move leftwards along the axis one encounters a greater willingness to embrace the epistemologies and methodologies of the social sciences and there comes a point where the terms socio-legal research and empirical legal research are used interchangeably.

3.5 Pure and Applied Legal Research

Finally, let us return to the distinction between pure and applied legal research represented by the vertical axis in Figure 2. Within the context of socio-legal research this distinction simply represents that between pure academic knowledge about the operation of the law and knowledge of the same kind which has been produced with a particular purpose in mind. That purpose will generally be to facilitate a future change, either in the law itself, or in the manner of its administration. Arthurs [3] therefore describes the latter category of research as law reform research and distinguishes this from the production of pure knowledge which he refers to as fundamental research.

The applied form of doctrinal research is concerned with the systematic presentation and explanation of particular legal doctrines and is therefore referred to as the expository tradition in legal research. This form of scholarship has always been the dominant form of academic legal research [4] and, has an important role to play in the development of legal doctrines.

When doctrinal research is undertaken in its pure form it is variously described as legal theory, jurisprudence, or legal philosophy. Although aspects of the present paper draw on conceptual research within this tradition the other three categories of legal research will undoubtedly be of greater practical relevance to the field of construction management.

4. The Role of Law in Applied Construction Management Research

4.1 A Theoretical Underpinning for Practice

The predominantly applied nature of the construction management field has already been noted and this defines the nature of the research undertaken within it. One aspect of construction management research is therefore concerned with developing the necessary theoretical underpinning for the practice of construction management.

Research of this kind, when carried out within the law sub-discipline, may be undertaken on either a doctrinal or socio-legal basis. Unfortunately there is a dearth of both types of research. There is undoubtedly a small amount of high quality socio-legal research undertaken within construction management. Work by Stipanowich [7] on dispute resolution and that by Kennedy, et al [8] on set off clauses in sub contracts may be cited as particularly good examples of this. However, these are the exception and much empirical work within the field, for example on contracts, claims and disputes, lacks the necessary legal content to provide a real basis for law reform by policy makers.

The situation with doctrinal research is equally unsatisfactory, although for different reasons. The construction management field has certainly produced its fair share of expository legal textbooks and many of these achieve a very high standard. The work of Card, Murdoch & Murdoch [9] and that by Murdoch & Hughes [10] certainly fall into this latter category. However, construction management researchers have generally failed to explore difficult areas of law to the level of detail appropriate for journal publication, and this leaves important gaps in the professional knowledge base. By way of example, some of the complex legal issues concerning causation, concurrent delay and global claims might be capable of resolution if subjected to doctrinal study from the unique interdisciplinary construction management research perspective.

4.2 Critical Research

It is submitted that a further aspect of construction management research, within all its sub-disciplines, should be to constantly challenge aspects of practice which are at variance with theory. For present purposes this will be described as a critical research function although this should not be confused with the various ideologically driven forms of research which are often collectively referred to as critical theory research. Critical research is simply that function of scholastic activity which is concerned with challenging assumptions, and with opening up the possibility of debate.

This function has a particular role in the context of academic fields like our own which underpin professional work. By challenging existing practices it can help to ensure that custom and practice reflect the latest standards of professional knowledge, rather than being led either by habit or by uninformed pragmatism. This currently has a special prominence within the UK public services professions due to government support for the concept of evidence based practice [11].

However, with or without government support, a critical approach to all areas of construction management research can play a part in safeguarding and enhancing the standards of custom and practice within the industry. Academic legal research (both doctrinal and socio-legal) can play a part in this process by challenging those areas of practice which have drifted away from their formal legal requirements. This can perform an important role in avoiding civil or criminal liability for those involved. As will be demonstrated towards the end of this paper, it also has the potential to eradicate restrictive professional practices which undermine the productivity, and public credibility, of the industry.

4.3 The Importance of Interdisciplinary Legal Research

Some might argue that the types of research outlined above should be left to those within the mainstream academic legal community. It is suggested that this approach would not be in the best interests of the construction industry, and that in any event it is not a practical proposition. This is for a number of reasons.

Firstly, not all areas of law fall within the province of mainstream legal scholarship. The academic legal community has been heavily influenced by the needs of the legal profession and some areas of law have traditionally been dominated by other professions, including chartered surveying. These areas, including construction law, commercial arbitration and aspects of the law of easements, have therefore received relatively little sustained scholarly attention [12]. In consequence, legal doctrines in these areas remain undeveloped, and the legal requirements for practitioners lack clarity. As the academic legal community has no intention of addressing these areas it is suggested that they must form a legitimate subject for research by scholars within construction management.

Secondly, as already noted, legal rules do not exist in isolation but are only given meaning by being applied to factual situations. In situations involving specialised or complex facts a professional understanding of the factual context is often as important as a mastery of the relevant legal rules. Therefore, even if mainstream legal scholars had the desire to undertake research in the construction management field, they are likely to be less well qualified to do so than those operating in an interdisciplinary construction management context.

Finally, as illustrated by the earlier discussion of legal doctrines, the law is far more than a collection of fixed rules. It is actually a fluid entity which is constantly evolving. This evolution takes place through the ongoing development of doctrines, and through the process of legislative reform. Academic legal research contributes to both of these processes and therefore provides an important opportunity to shape the future direction of the law. It seems right that the construction management academic community should contribute to this process on behalf of the industry that it serves.

5. Two Examples

5.1 Party Wall Practice

The paper concludes by outlining two examples of legal research projects undertaken from within the construction management field. The first project sought to clarify the legal requirements for those acting as appointed surveyors under the Party Wall etc Act 1996. In large part the statute simply extends a piece of legislation which has operated in London since 1855 to the whole of England and Wales. It makes provision for notice to be served on neighbouring owners before construction work is carried out to shared (or “party”) structures. Following service it provides for the appointment of surveyors by each of the neighbouring owners. The surveyors then have power to issue “awards” regulating the conduct of the works, and providing for the payment of compensation where damage is caused to a neighbouring owner’s property.

For generations of surveyors the legislation has been notorious for its ambiguities, inconsistencies and its general lack of clarity. However, as an area of practice undertaken by surveyors rather than the legal profession, its provisions received almost no scholarly attention in over a century of use and the field is characterised by an almost total lack of doctrinal analysis. Surveyors were therefore left to make sense of the legislation as best they could, often, according to Leach [13] by simply “not being too analytical or too inquisitive as to the exact scope of their powers thereunder”.

It was not so much that custom and practice drifted away from the legislation’s formal legal requirements. In the absence of any authoritative legal analysis it was more a case of them developing in parallel to it, guided instead by the largely oral tradition of facts, myths and half-truths which circulated within the profession. This situation may have been tenable when confined within an enclosed geographical and professional community but it could not survive the transition to new pastures where practitioners were eager for authoritative guidance regarding the legal requirements.

The current research project was, in large part, a response to this demand for a more authoritative statement of the law in this area. The detailed nature of the research is beyond the scope of this paper but, in seeking to answer the question: "what is the law?" it, of necessity, adopted a doctrinal approach. It involved an examination of the various legal decisions affecting the legislation [14] together with an analysis of the law as it related to areas of practice which were causing particular difficulty. On this basis it was able to identify the judicial approach when interpreting the legislation [15] and from this, to articulate authoritative statements about the various issues. These included the surveyors' jurisdiction, duties and the nature of their power to award compensation. Through the researcher's involvement in the publication of relevant professional guidance it has also been possible to incorporate the research findings into standard professional practice in the field [16].

5.2 Rights to Light Practice

The second project is currently addressing expert witness work in actions for loss of light. Where a building owner has a legal entitlement to daylight English law establishes that he is entitled to a quantity of light that is sufficient for the normal use of his building, according to "the ordinary notions of mankind". A developer who obstructs the light to his neighbour's building and leaves it with less than this quantity will therefore be liable in nuisance.

Where actions are brought against developers in these circumstances the courts will rely heavily on expert witnesses when judging the sufficiency of the remaining light as well as the valuation of any damages which they decide to award. Experts invariably use a standard approach when deciding these matters. This has been agreed between the small number of practitioners in the field, and is based loosely on the ideas proposed by Waldram in the 1920s [17]. However, a lack of published information makes it extremely difficult for outsiders to gain the necessary expertise for practice in this area and the suspicion is that the existing experts are operating a restrictive practice.

The current project involves testing the validity of the experts' approach from a variety of perspectives and therefore takes a socio-legal stance. It includes an element of doctrinal analysis in questioning whether any aspect of the approach can properly be described as a rule of law. The remaining aspects of the research will use a variety of methodologies to test whether there is any other basis for using this approach, apart from a legal one. This will involve elements of historical archival research as well as experimental and survey research in order to test the validity of its measurement and valuation techniques. Preliminary findings suggest that there is little basis for the current approach, either of a legal or other nature.

6. Conclusions

The paper has explored the interdisciplinary nature of construction management research and has proposed that it should have the capability to provide industry-relevant solutions across the whole range of its sub-disciplines. It has also noted the importance of understanding the different epistemologies and methodologies which are appropriate for the different styles of investigation within the various sub-disciplines.

Within the context of the law sub-discipline it has introduced the concept of legal doctrines. It has examined the central role of doctrinal research within the law subject area and contrasted this with socio-legal research, and with other forms of empirical enquiry. It has suggested that research which asks: “what is the law?” is ontologically different from empirical studies and that, in taking an internal approach to the law, it also differs epistemologically. It has also shown how these differences enable this form of research to address certain types of problems which are not suitable for resolution through empirical enquiry.

The dearth of academic legal research within the construction management field has been noted and it has been suggested that this is ultimately to the detriment of the industry. The benefits of this form of research have been illustrated by reference to two projects which have challenged industry practice in areas which are insufficiently supported by mainstream legal scholarship. It has been proposed that similar investigations could deliver benefits to the industry in other areas of law, particularly those which also fall outside the influence of the legal profession, and which therefore lack an established doctrinal tradition.

Abstract

This paper presents additional results of an on-going research aimed at mapping the structure and the evolution of the construction engineering and management (CE&M) discipline and its diffusion around the world. The contents of the papers, published by two leading international academic publications, the *Journal of Construction Engineering and Management* (JCEM) and *Construction Management and Economics* (CME), are assessed over a 12-year period, from 1989 to 2000. The study considers approximately 1,200 papers analyzed according to two main dimensions: 12 types of subject and 5 types of research contribution (insight, theory building/modifying, analytical/systemic constructs, and problem solving) to the field of CE&M. In a broader perspective, the analysis shows the evolution of the construction engineering and management discipline, as represented in the journals. The analyzed data show that the contents of the journals differ in terms of type of research contribution. CME's papers focus more on broader issues, the theoretical aspects of CE&M, and interpretation of construction phenomena, whereas the contributions in JCEM tend to present narrower and pragmatic contents with an emphasis on problem solving, as applied to the "hard" and "soft" aspects of the construction process.

Keywords: Data analysis, construction engineering and management, classification criteria, research contributions.

1. Introduction

Construction engineering and management (CE&M) is a relatively new discipline in the international construction realm. In U.S. practice, CE&M emerged as a result of delivering construction projects with the so-called "Professional Construction Management" approach some forty years ago. The driver of this phenomenon was essentially the result of economic pressures felt by two main groups: 1) private clients who wanted to achieve a better value for their investments and 2) contractors wishing to expand their line of business, away from the cutthroat practice of competitive bidding [1]. Recognizing the increasing technological and organizational complexity of construction projects, some US civil engineering departments concurrently started developing construction management related programs in the late Sixties. Currently these programs are offered all over the world. In the USA these programs tend to be concentrated in civil engineering departments, while in the rest of the Anglo-Saxon world they are also offered by construction, surveying and architecture schools. In recent years CE&M has established itself as an academic and research area that builds upon a long series of publications of scholarly work and debate. Academic journals within any specific discipline play a vital role because they are the primary means for communicating and exchanging research experience, shaping educational programs, and assessing academic careers. Equally important, however, is the historical analysis of the contents – as well as the evolution - of academic journals through bibliometric analysis. In addition bibliometric studies show patterns of evolution within a discipline, particularly as young as CE&M, and play a crucial role in revealing an academic field's structure and the changes in its contents over the years. This type of analysis is also useful in assessing the impact of academic contributions on construction practice. The examination of contributions to the CE&M discipline is not novel. In the past, the content of journals concerned construction-related research issues were investigated to provide a partial map of the discipline of construction management and project management [2], [3]. More recently, the perspectives on construction research were addressed in terms of challenges of US academic communities [4]. This paper contains additional results of an on-going investigation aimed at assessing the past and possible future developments within the CE&M discipline [5], [6]. The study considers the papers published by the *Journal of Construction Engineering and Management* (JCEM) and *Construction Management and Economics* (CME) during a 12-year period, from 1989 to 2000. Approximately 1,200 papers were analyzed according to two main dimensions: the type of subject (based on a 12-item list) and the type of research contribution (insight, theory building/modifying, analytical/systemic constructs, and problem solving) to the field of CE&M.

The paper initially presents some essential information about the two academic journals, including a brief historic introduction, their objectives, and key statistical data. Successively the methodology for data gathering and the classification criteria, according to which the journals' content was analyzed, are addressed. The last part of the paper outlines the breakdown of papers' focus in terms of CE&M subjects and type of research contribution.

2. History, Objectives and Statistical Data of the Journals

JCEM, first published in 1983, is part of a series of periodicals that are promoted and published by the American Society of Civil Engineering (ASCE). Prior to 1983, the topics of that journal had been covered with the title "Journal of Construction Division," which began publication in 1957. The original aim of JCEM was "to advance the science of construction engineering, to harmonize construction practices with design theories, and to advance education and research in construction engineering and management." In practice, the journal's content had a focus on the technical aspects of the CE&M discipline, particularly as applied to the management of civil engineering projects.

CME was founded in 1983 by the publishers E&FN Spon, in conjunction with the founder editor John Bennett at The University of Reading. Originally, one of the principal objectives of the journal was to foster links between industry and academia. In the UK, recently launched CE&M programs were not supported by established theories or research methodologies and, at the same time, practitioners saw the journal as a forum for accelerating positive changes in the industry [1]. Under Bennett's editorship the journal doubled in size, from three yearly issues in 1983 to six issues in 1991. Ranko Bon and Will Hughes took over the editorship of the journal in 1992, and Will Hughes became sole editor in 2003. CME focuses on the management and economics of building and civil engineering as well as the management of built facilities. For the purposes of this study and to facilitate the analysis of historical trends, the statistical data are organized into four 3-year periods of observation that span 12 years, from 1989 to 2000. In the observed period, a combined 1,209 papers appeared in the journals, with 2,486 authorships, as shown in Table 1.

The number of papers published in JCEM increased 29 % in the observed period, from 138 in 1989 to 178 in 2000. In the case of CME in the same period, the number of papers increased at a much higher rate: 146%, from 91 in 1989 to 224 in 2000. The statistics for the "number of authors" (note that some authors did publish more than one paper in any given year) are also shown in Table 1. JCEM experienced 50 % overall increase in the number of authorships, from 267 in 1989 to 400 in 2000, while in CME a steeper increase is noted, approximately 200%, from 159 in 1989 to 482 in 2000. There is also an increase in the ratio of "authors per paper" over the observed period. In both JCEM and CME this ratio increases from 1.93 and 1.75 to 2.15 to 1.96 respectively. Both journals show increasing international contributions over the observed period, particularly by authors from Asia and Oceania. The average rate differential (55% in CME and 28% in JCEM) in terms of international authorship can be explained in the size of UK and US academic communities as well as the traditional UK links with the universities and professions of the Commonwealth countries. Nevertheless JCEM data show that the number of papers originating outside the USA has been increasing at the steady rate of 20% per each 3-year period.

Table 1: Size of journals over 1989-2000 period

JCEM	89-91	92-94	95-97	98-00	89-00
Issues	12	12	12	18	54
Number of Papers	138	162	163	178	641
Number of Authors	267	364	344	400	1375
Authors per Paper	1.93	2.25	2.11	2.25	2.15
Percentage of international authors	0.21	0.25	0.30	0.36	0.28
CME	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
Issues	14	18	18	20	70
Number of Papers	91	117	136	224	568
Number of Authors	159	219	251	482	1111
Authors per Paper	1.75	1.87	1.85	2.15	1.96
Percentage of international authors	0.55	0.52	0.52	0.59	0.55

3. Gathering of Journal Data and Classification Criteria

The content of this paper builds upon two different databases that were developed separately. A Microsoft Access database was created in previous studies [5], [7] for the classification of the JCEM. This database records the title of each paper, abstract, key words, author/s, their affiliation, and country of origin. Data were drawn from the Civil Engineering Database [8] that is available on line. As for the CME database, a Microsoft Excel file was created by manually inputting data directly from the volumes published during the observed period. Fields for this database include titles, authors' names, organizations, and countries. Those time consuming operations entailed the inputting of approximately 18,000 entries. As stated above, one of the goals of the research was to classify and group the content of the papers according to subjects. To this purpose the following and previously developed classification framework [5] was used:

1. Management of the firm

2. Construction planning and control

3. Site and equipment management

4. Time scheduling

5. Cost estimating and control

6. Construction methods and materials

7. Management of human resources

8. Project management

9. Project delivery systems

10. Contractual issues

11. Industry issues

12. Technology development issues

The order of the above-listed subjects reflects three broad “perspectives” according to which the contents of the papers were interpreted: the first seven subjects focus on the general contractor's operations and business, the following three subjects focus on the project planning, organizing and control by a client (or his/her representative), while the last two subjects focus on issues related to the construction industry at large. A third classification criterion pertained to the type of research contribution published in the journals. The CE&M discipline builds upon an array of knowledge domains from social sciences and engineering science, among others. Since its establishment by practitioners, there have been efforts by the academic community to systematize its knowledge, traditionally based on experience. These efforts encompass exploratory studies of construction phenomena, analytical constructs, modification/application of theories from other disciplines and applications of techniques (often drawn from operation research) to solving soft and hard construction process problems. In this regard Table 2 lists five types of research contributions: 1) Insights, 2) Theory building/modifying, 3) Analytical/systemic constructs, and problem solving in the context of construction management (4) and construction engineering (5). The first three types attempts to capture research efforts of theoretical nature, while the last two reflect contributions with pragmatic intents.

Table 2: Classification criteria of research contributions

TYPE	CONTENTS/PURPOSE	EXAMPLES
1. Insights	General Understanding Analysis and Explanation of Phenomena, Processes	Literature Reviews, Discussions, Personal Experiences, Case Studies, Comparative Analysis
2. Theory Building/Modifying	Application/Adaptation of Theories Substantial Justification of a Research Subject Statistical Analysis Cause/Effect Relationships	Analysis of Surveys and Census Data Methodological Notes for Research
3. Analytical/Systemic Constructs	Synthesis and Representation of Phenomena and Processes	Classification Systems Databases Flowcharts
4. Problem Solving in the Construction Management Context	Application of Engineering Science Mathematical Models Algorithms Deterministic and Nondeterministic methods Decision Making Tools Forecasting	Cost Planning and Control Time Planning and Control Control Systems Resources Allocation Selection Criteria of Contractors Project Delivery Systems Constructability Analysis
5. Problem Solving in the Construction Engineering Context	Application of Engineering Design and Analysis Principles	Robotics Applications Construction Techniques Components and Materials Evaluation/Selection of Physical Technologies Equipment Design Site and Work Area Design

4. Evolution of the Journal Contents

As stated earlier, one of the objectives of the study was to assess the contents of the journals and their evolution over the years. Table 3 shows the counts of the papers (in percentage format) according to the 12 identified subjects over the examined period. In JCEM, these subjects tend to be more uniformly distributed than in the case of CME, in which the first four most frequent subjects account for approximately 57% of all published papers (46% in JCEM). As expected, JCEM's contributions tend to focus on the engineering and "quantitative" dimensions of the CE&M discipline, with emphasis on construction technologies and activities.

Table 3: Classification of papers by subject (in percentage)

	JCEM	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
1	Management of firm	8.7	8.6	8.6	12.9	9.8
2	Const. planning and control	18.1	12.3	13.5	14.0	14.3
3	Site/equipment management	13.0	13.0	9.8	9.6	11.2
4	Time scheduling	5.1	5.6	5.5	6.7	5.8
5	Cost estimating and control	2.9	4.3	1.8	7.3	4.2
6	Const. methods and materials	13.0	12.3	8.0	6.7	9.8
7	Management of human resources	8.0	12.3	10.4	13.4	11.2
8	Project management	6.5	4.9	8.0	7.3	6.7
9	Project delivery systems	2.2	8.0	9.2	6.2	6.6
10	Contractual Issues	8.0	7.4	8.6	5.6	7.3
11	Industry issues	7.2	4.9	11.7	7.3	7.8
12	Tech. development issues	8.0	6.2	4.9	2.8	5.3
	CME	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
1	Management of firm	11.0	13.7	10.3	11.6	11.6
2	Const. planning and control	8.8	14.5	6.6	5.4	8.1
3	Site/equipment management	4.4	1.7	2.9	4.5	3.5
4	Time scheduling	1.1	3.4	4.4	3.6	3.3
5	Cost estimating and control	11.0	9.4	9.6	8.0	9.2
6	Const. methods and materials	1.1	5.1	3.7	7.1	4.9
7	Management of human resources	11.0	2.6	3.7	8.0	6.3
8	Project management	12.1	8.5	10.3	15.2	12.1
9	Project delivery systems	5.5	3.4	3.7	4.9	4.4
10	Contractual Issues	4.4	4.3	9.6	5.8	6.2
11	Industry issues	23.1	24.8	28.7	22.3	24.5
12	Tech. development issues	6.6	8.5	6.6	3.6	5.8

These subjects are consistent with the mostly civil engineering base of JCEM's contributors and tend to be addressed in a narrow way. Differently, CME's contents address broader and softer issues, such industry operations and markets as well as management topics both at the firm and project level. These different interests are reflected in the "perspective" dimensions as shown in Table 4. In JCEM the large percentage (66% in the observed period) of papers with a perspective for construction firm operations shows stability over time. The papers suggest an image of a construction firm that self-performs a large share of its work and consequently is interested in optimizing the use of in-house resources. In CME client and industry perspectives prevail over time (53% in the observed period). Undoubtedly, these perspectives reflect the need for change in the UK industry, particularly in terms of professional practice and roles as well as modus operandi (e.g., the persistence of inefficient and labor intensive construction activities) of the industry.

Table 4: Classification by perspective of the papers (in percentage)

	JCEM	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
1	Construction firm	68.8	68.4	57.6	70.6	66.3
2	Client	16.7	20.3	25.8	19.1	20.6
3	Industry	15.2	11.1	16.6	10.1	13.1
	CME	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
1	Construction firm	48.4	50.4	41.2	48.2	47.0
2	Client	22.0	16.2	23.5	25.9	22.7
3	Industry	29.7	33.3	35.3	25.9	30.3

It should also be mentioned that the US and UK contexts differ in terms of national priorities for research agendas as well as academic disciplines concerning the construction realm. In this regard a sizeable number of CME papers on industry issues pertain to construction economics, a discipline that is not well established in the USA.

The contents of both journals share a common evolution of interests in two main broad issues, information technology and management of firms. These two issues approximately appear in the first (1989-1994) and second (1995-2000) period of observation respectively. The first period was characterized by the growing use of personal computers and software applications in the industry, as they were applied to the various activities of construction management and operations. The second period coincides with the emergence of new broad issues, such as environmental concerns, public infrastructure systems and market competition that affect the management of construction firms and operations. The second period witnessed a large number of papers on topics such as business and competitive strategies, re-engineering of firms, and inter-firm relationships. These changes reflect a parallel evolution of the CE&M discipline ever since its initial establishment in academic programs. The task of managing projects is no longer concerned with planning and controlling construction only, but also with project programming, financing, design, and selection of construction services. Similarly, the focus of construction firms is not only on successful bidding and production costs reduction, but also on strategies for expanding services and increasing competitiveness (basically away from the traditional "competitive bidding" culture).

5. Classification of Research Contributions

In addition to subjects, journal content was analyzed according to five types of research contributions. As stated before, the first three reflect efforts of a theoretical nature, while the last two encompass applications of engineering science and design to the soft and hard challenges of the construction process. As shown in Table 5, these types of contributions appear to be more equally distributed (with the exception of analytical/systemic construct) in JCEM than in CME in which the small percentage (4%) of contributions of a technological nature is to be noticed. In this last journal theoretical contributions have been increasing over the observed period, from approximately 70% in the 1989-91 years to almost 76% in the 1998-2000 years.

Table 5: Classification by type of research contribution

JCEM	89-91	92-94	95-97	98-00	89-00
1. Insights	33.1	20.5	22.1	18.4	23.1
2. Theory Building/Modifying	15.8	18.0	28.8	24.0	22.0
3. Analytical/Systemic Constructs	10.1	16.8	11.7	14.5	13.4
4. Problem Solving in the Construction Management Context	22.3	21.7	17.2	24.6	21.5
5. Problem Solving in the Construction Engineering Context	18.7	23.0	20.2	18.4	20.1
CME	**89-91**	**92-94**	**95-97**	**98-00**	**89-00**
1. Insights	37.4	42.7	33.1	22.3	31.5
2. Theory Building/Modifying	22.0	25.6	27.9	33.9	28.9
3. Analytical/Systemic Constructs	11.0	7.7	11.0	21.0	14.3
4. Problem Solving in the Construction Management Context	24.2	21.4	25.7	17.4	21.3
5. Problem Solving in the Construction Engineering Context	5.5	2.6	2.2	5.4	4.0

The sizeable share of engineering applications in JCEM (almost 42% in the observed period) and the high rate of theoretical contributions in CME raise the issue of the foundations of CE&M and of the provider of this type of services. While a large number of CME's contributors are concerned with the interpretation of existing industrial phenomena and attempt to reinforce and further develop the discipline domain, JCEM contributors appear to be more focused on narrowly presented issues that can be quantified or modeled and are less concerned with framing these issues into a larger and general reference context. Consequently two different interpretations of the provider of CE&M services emerge. CME's contributors, with their emphasis on interpretations and reflections, seem intent on developing an autonomous professional discipline, as distinct from those of the design or construction professions. JCEM's contributors, most affiliated with ASCE, suggest that CE&M is one of the possible services offered by civil engineers working for consulting or construction firms. Over the years CME and JCEM seem to have consolidated their theoretical and quantitative emphasis respectively. There is evidence, in fact, that international authors have been shaping their contribution according to the editorial intents of the two journals.

6. Conclusions

The analysis of the contents of the two journals under consideration shows that the CE&M discipline has been attracting growing international participation over the years. JCEM's papers tend to focus on the engineering and technological dimensions of the discipline. Without doubt these interests result from the civil engineering base of most of its contributors. Management and industry subjects prevail in CME's papers. This thrust is probably driven by the need for change in the industry, as advocated by several government reports. The UK context, in addition, appears to be characterized by the debate about existing professional roles, particularly in regard to the source of construction management services. The academic orientation of both journals is evident and more pronounced in CME than in JCEM. Notwithstanding the very large amount of theoretical oriented contributions, the temporal analysis of both journals shows few efforts to systematize the various dimensions of the CE&M discipline, particularly in terms of integrating its social science and engineering/science dimensions. Since their establishment in 1983, the journals have witnessed decreasing participation by practitioners in editorial boards and contributions; thus, one opportunity for narrowing the gap between theory and practice has been missed.

All Good Architecture Leaks - Witticism or Word of Wisdom?

Ævar Hardarson
architect FAI, PhD research fellow, Norwegian University of Science and Technology – NTNU
(email: avarh@ark.ntnu.no)

Abstract

The phrase *"all good architecture leaks"* can be traced back to Oslo School of Architecture (AHO) in the 1970s. The history and context of this phrase now form the basis for a doctorate study on design-related construction defects. Supported by social-anthropological thought models, the frames of interpretation for the phrase were examined [1]. As part of this examination, the driving forces of architecture as a subject were studied supported by simple explanatory models [2]. Data were collected through interviews and detailed literature studies, and resulted in deep insight into the problem area. The study revealed the existence of several phrases about the same phenomenon, i.e. architecture with quality deficiencies. One of these phrases came from a foresighted senior researcher at the Norwegian Building Research Institute (NBI) knowing that being creative and original in architecture can be risky: "*All prize-awarded buildings have multiple defects*." Another was coined by the famous American architect Frank Lloyd Wright: "*If the roof doesn't leak, the architect hasn't been creative enough*" [3]. In a simplified manner, these humorous words of wisdom express a well-known and complex yet tabooed phenomenon. Through the study, two cultural representations have emerged – one belonging to the experimental avant-garde architects, and the other rooted in down-to-earth and practical architect engineers. These opposites nurture a tension that influences the phenomenon of construction defects. The revelation of this mechanism is significant in further research on the topic design-related construction defects.

Keywords: Building defects, leakages, good architecture, noted, ignored.

1. Introduction

As an introduction to the topic, follows a short narrative: "I first heard the sentence 'all good architecture leaks' some time in the early 1980s, when I was a young student at the Oslo School of Architecture (AHO). At the time, leaking houses was old news to me. To explain this, I would like to tell a story from where I grew up. In 1968, my parents moved into a new house with a flat roof. From the very first moment and as soon as it started raining into the snow up on the roof, we had to start removing the wet snow from gullies and joints. Inside, we had to place containers on the floor because of the water dripping down in buckets. Our house was located in a suburban residential area in the outskirts of Reykjavik and was designed by an engineer. It was not a great comfort to know that our neighbour's house was subject to the same phenomenon. His house was designed by a well known architect and had been awarded a prize. When I went home on holiday and told my parents that according to my professor at Architect School "all good architecture leaks", they were furious and a very emotional discussion followed. Once the storm was over, they asked a probing question about the education at this architect school, and what they had allowed me to study."

This story touches the most important elements in this case; the fact that human-made buildings carry inherent potential for defects and deficiencies. This often results in leaks, as mentioned above, but it also to people involved in the same project interpreting and referring to the same phenomenon differently. This appears to be related to the interests they represent.

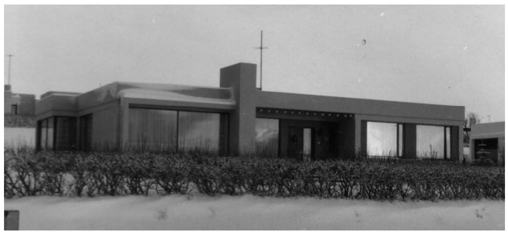

Figure 1 -2: The two buildings in the story, to left Bakkaflöt 1, from 1965, designed by architect Högna Sigurdardotter. To right Bakkaflöt 3 from 1966, design by building engineer Kjartan Sveinsson. (Photo Ævar Hardarson)

The study presented in this article is part of a PhD research project within the priority area Metamorphosis at NTNU in Trondheim. The topic for this PhD project is: Architecture and design-related construction defects. The purpose is to extract new knowledge on how construction defects come into being when new buildings are designed and built. Focus will be on the design process, where a majority of all construction defects originate, but also on the architect's work, as he is an important participant in the discussion on the construction's quality. The main question this research project seeks to answer is: *How and when in the design and production process does the construction defect come into being?* The method developed to research the origin of construction defects is called "The Nebula Metaphor". The basis of this method is that the design process is a highly complex matter which is difficult to describe and predict. It is defined as a co-called "soft or complex system", i.e. a system or process with several elements and numerous interrelations [4]. The name – The Nebula Metaphor – is inspired by a personal and intuitive experience of the design and building process as a cyclic and complex phenomenon. In the imaginations, this process appears as a dynamic shape, a spiral belt of events and relations. The origin of the process, or should we say its genesis, is the formation of pioneer ideas. This phase constitutes the power centre of the process. To discover how and when construction defects come into being, qualitative research methods will be employed. A specific construction project with construction defects is selected. The researcher finds a physical construction defect and tries through examinations, document

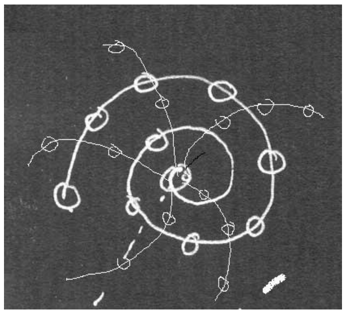

Figure 3: The Nebula Metaphor. The idea abode design and building process as a cyclic and complex phenomenon ore soft system.

analyses, and interviews of the parties involved to shed light on the course of events.

In this article, results from subparts of the research project are presented. The main focus is on examining attitudes and cultural circumstances in the building industry which may influence the construction defect phenomenon. The idea was to explore the phenomenon behind the phrase "*all good architecture leaks*". The question is whether this phrase is a "witticism" or "words of wisdom". Several similar phrases about buildings with quality deficiencies have been revealed. One such phrase is: "*All prize-awarded buildings have multiple defects*" and can be traced back to a research institute. Another is credited to architect Frank Lloyd Wright, who said: "*If the roof doesn't leak, the architect hasn't been creative enough*" [3]. Interviews with relevant participants from this industry have been an important part of this study. The interviewees all had some connection to the topic; they were architects, engineers, researchers and lecturers at Norwegian universities. I also carried out literature studies to find out whether anyone else had studied this topic, and I found that there are very few scientific texts which deal with the topic of design-related construction defects [5].

Assisted by social-anthropological thought models the frames of interpretation for expressions are examined [1]. The driving forces in architecture as a subject are also studied through the reference "*Architects: the Noted and Ignored*" [2]. The study reveals several paradoxes in the way humans think and create buildings. This study has also been used to study how elite persons refer to the phenomenon of construction defects. Cultural representations have emerged from the wings, one belonging to the "architect culture" and the other to the "engineer culture". These two cultures try to entrench themselves in relation to each other and in relation to the discussion on concepts such as architectural quality and quality deficiencies. By use of explanatory models important driving forces were revealed, i.e. the artists on the one side and the practical architect on the other [2]. The revelation of these mechanisms appears to be significant to the interpretation of how design-related construction defects come into being.

2. Theoretic Basis

The study is theoretically anchored in studies within theory of science and social anthropology. These studies can be used to examine the frames of interpretation from which a sentence or a concept originates [1]. The focal issue is how resourceful people, often called ELITE people (i.e. persons who give statements on a subject by virtue of their position and exercise great influence when the content of an opinion is made) speak of a phenomenon. These people may be professors and lecturers at universities, as well as researchers and creative architects. To deepen the study, references explaining the main driving forces in architecture as a subject have been used: "*Architects: the Noted and Ignored*" [2]. According to this reference, Architects can be ordered on a scale from the artistic "avant-garde" to the practical "down-to-earth" architect / engineers A majority of the architects are somewhere in the middle, between the extreme endpoints of the scale. However, in principle is that all want to be artists. This mechanism runs automatically and is supported by the cultural elite. The explanation is that artistic success confers infinitely more status and holds out the lure of immortality, whereas the practical side can only bring in more money

Other concepts of analysis of scientific character are: Knowledge regimes, a concept from Foucault defining the arena from which the object should be discussed and handled. Figured worlds. Figured worlds is another concept, which refers to the implied knowledge that defines normal, rational and possible actions. Both concepts are taken from Gullestad [1].

It became clear that the problem area has been only marginally explored [5]. On this basis, and in accordance with methods developed through the PhD project, I decided to use an explorative approach and qualitative methods. For this reason, interviews have been central when collecting empirical data, where the theoretical anchoring in Kvale [6]. The following guiding questions were formulated: What are the origins of the cited phrases? What are their contexts and impact? What can these phrases tell us about attitudes and the cultural situation in the building industry?

The interviewees were selected qualitatively. The first were picked from the environments to which the phrases had been traced, i.e. AHO and NBI. Other interviewees were picked out based on tip while the interviews were being carried out. Due to my localisation in Trondheim, several interviews were conducted over the phone. Whenever possible, I met the interviewees in person. A majority of the interviews were recorded on tape, always with the interviewee’s consent. Alternatively, notes were taken. Notes and tapes were used as the basis when writing reports for analysis and interpretation. The interviews were conducted between December 2003 and January 2005, a total of 10 interviews. Most of the interviews were conducted in connection with this article, some in connection with the data collection. In the final text, the interviewees are made anonymous by using fictitious names, because the topic is regarded as sensitive and unpleasant to discuss. I find it easier to refer to interview findings this way. Interviewees who are referred to through written sources, on the other hand, are presented with their full names.

In order to ensure a critical focus and as a quality tool for the analysis and the interpretation, certain concepts are employed. These concepts include *critical distance* formulated as “critical preservation of memories and experiences” [1], *critical reflection* on personal prejudices, and strangifying [1]. That involves seeing what is well known from a different or strange perspective. The strangifying can, if successful, puzzle people and trigger reflection. The final paragraph in this article is an attempt of such strangifying.

3. The Findings

This chapter gives an account of findings, both from the literature studies and from the interviews. For a further illustration of the problem, I have also included examples of buildings belonging to the category ‘good architecture with construction defects’.

Defining good architecture or architectural quality seems to be a difficult task (cf. chapter 3.3). The discussion involves time periods, cultures and fashions, at the same times as the general value debate in society is reflected upon. The opinion regarding what constitutes good or poor architecture is partly related to the general spirit of the time, but also to the so-called “good taste”, usually defined by the cultural elite of the subject. However, as time goes by and the buildings reveal their lasting ability and their qualities, some sort of agreement on the characteristics of quality and what may represent our cultural heritage is shaped.

In principle, the words *damage, defect, deficiency, mistake* or *failure* mean the same, i.e. some sort of deviation from a given reference level. However, these words have negative connotations in the ordinary language use. Therefore, in recent terminology the concept *quality deficiency* is used as a collective term. This concept is composed by the Latin *qualitas* (state, nature), which is commonly perceived as a positive term, and *deficiency,* which has negative connotations. The compound *quality deficiency* carries some of the same implications as the phrase "all good architecture leaks", i.e. a battle between the positive and the negative. A subcategory of quality deficiencies includes damage by damp or leaks. Water damage is the largest category – it makes up approximately 2/3 of all construction defects – and the most common cause is water leaks. This damage could be caused by damp being transported to the wrong place, based on given premises, i.e. into the construction or into residential rooms. The causes are many, leaky roofs or walls being the most common. A subcategory of water damage is damp accumulating inside the construction because the hydrogen pressure is too high. In addition comes poor or defective ventilation. This kind of damage has increased in recent years, mostly due to changed living habits, new construction materials and methods. Damp damage is troublesome, as it reduces the technical, aesthetical and functional life of materials and constructions. It also creates biological processes that result in mould and rot, which again cause health problems.

3.1 From Vitruvius to Today’s Architecture

Figure 4 - 6: Leaning Tower of Pisa 1174, (Photo Tore Haugen). Falling water 1935, (Photo Edvard Horton). History Faculty building at Cambridge 1967, *(Photo Dag Nilsen)*

Vitruvius Pollio, Roman architect and engineer, defined architecture using three concepts: "*Utilitas, Venustas, Firmitas*" [7]. In more recent terminology it translates to technique, function and form. This has been the prevailing approach to architecture up until quite recently. With the emergence of functionalism in the 1920s, new strategies and perspectives materialized. One of the characteristics of functionalism was that the ornaments had to go. The clean lines were pursued and the slogan was "the form follows the function". The functionalists also wanted to challenge the natural forces and to use experiments in accordance with the contemporary dominating view of science, positivism. One important characteristics of the functionalist style was the flat roof. One of the great men in modernism, the American architect Frank Lloyd Wright (1867—1959), experimented with form and material like other architects, often producing interesting results. The word is that houses designed by Frank Lloyd Wright always came with a small present – one or more leaks from the roof, naturally causing furious owners. His humorous expression in this connection is quoted in an article on rehabilitation of his famous building Falling water in Mill Run, Pennsylvania: "*If the roof doesn't leak, the architect hasn't been creative enough*," and when the owner of the building continued complaining about the roof leak, Wright said: "*That's how you can tell it's a roof*" [3]. For the design of Falling water, Wright was honoured by the American Institute of Architects with the description "*the best all-time work of American Architecture*" [8]. One of the most famous leakage histories involves Herbert Johnson, owner of Johnson's Wax. At the time when Falling water was designed, Wright designed a domestic house for Johnson in Wisconsin. The story goes that Johnson called Wright during a Thanksgiving dinner to complaint about the leak from a skylight. The water was dripping down on their food. Wright in his chivalry answered "*move the table*" [3].

Another famous avant-garde modernist associated with construction defects is the British architect James Stirling (1926—1992). One of his most famous constructions is the History Faculty building at Cambridge from 1967. Charles Jencks describes the building as one of late modernism's most significant works with new and radical solutions and extensive use of glass [9]. Steward Brand, on the other hand, criticises the modern architecture and comments the issue with the following quote: "*The History Faculty building at Cambridge (1967) leaked torrentially, also dropped its roof tiles dangerously, and faced the wrong way. So the sun cooked its contents – people and books"* [8].

A few more examples are included to further describe the phenomenon of "the good architecture with defect". Many more could have been included, but these are representative and fall under the concept of "the power of example" according to Flyvebjer's definition [10].

Figure 7 - 9: The Nordic house in Reykjavik, the University building in Dragvoll Trondheim, (photo Ævar Hardarson). The Mortensrud church Oslo, (Photo Helge Solberg)

The first example is the Nordic House in Reykjavik from 1968, designed by Alvar Aalto. The building is beautiful and well functioning, boasting many great qualities. It is regarded as an important monument in the architectural history of Iceland. Nevertheless, the owner of the building has been struggling with several roof leaks for over 30 years.

Example number two is the university campus at Dragvoll in Trondheim from 1978, designed by Henning Larsen's architect firm. It is an innovative building with extensive use of glass over an internal communication artery or “street”. Damage by damp has long been a problem in relation to the glass-covered indoor street. *"As colleagues humorously put it – it has to leak to make the architect famous,"* says Per Knutsen, Norwegian architect and project manager for the building project [11]. In an interview, Per Knutsen claims that leaks also occur in ordinary buildings, the ones nobody talks about.

The most recent example in this category is Mortensrud Church in Oslo from 2002, designed by architects Jensen and Skodvin . This building is praised for its high architectural quality and has been awarded several prizes, including three international prizes for outstanding architecture, but it is also associated with leaks. The building project was discussed in an article with the following headline: “*The church that became a constructional hell*” [12].

3.2 The Phrases’ Origin and Context

In this chapter, findings from the interviews are described. The first interviewer is called Thorvald. He was a teacher at AHO in the 1970s and 1980s, and remembers the phrase “all good architecture leaks” very well, but he did not know where it came from. He points to possible connections to visits to England in the 1970s with the students, where constructions by James Sterling were in focus (see previous chapter). The next interviewer is called Johann. He studied architecture at AHO in the late 1970s and early 1980s. Johann associates the phrase quite clearly with Professor Sverre Fehn, since he heard professor Fehn utter this phrase himself. Sverre Fehn (1924) was a professor at AHO from 1971 to 1995. He is one of the most distinguished architects in Norway with a long list of publications. He has also been awarded several national and international prizes. Sverre Fehn is characterised as an avant-garde architect and supporter of the international school, yet still having bonds to the national movement (see report later in this chapter). Several interviewers referred to Sverre Fehn as an inspiring lecturer, with a sense of humour bordering on the absurd. The phrase “*all good architecture leaks*” is given particular meaning coming from Fehn’s own lips, as it is commonly known that some of Fehn’s buildings had construction defects, including leaks. In the interview with Johann, we are told that several phrases concerning the same phenomenon exist. He mentions Mortensrud Church in Oslo, reported to "*leak like a sieve*”. Johann was not familiar with the phrase “*all prize-awarded buildings have multiple defects*”, but in his opinion this phrase could be interpreted in a positive way for the architects, implying that inventive architecture was particularly prone to construction defects because when borders are traversed, room is created for new architecture and eventually new technical solutions. Johann used the expression "*those who venture wins*".

The next interviewer was called Bjørn, a former student at AHO from the 1980s, who clearly recalled the phrase “*all good architecture leaks*”. Bjørn said that when this phrase was uttered, the speaker often added that this did not necessarily mean that houses with leaky roofs were examples of good architecture. He associated the phrase with Knut Støre, lecturer at AHO. Bjørn also refers to Wright's famous utterance "*move the table*", which also was around at the time. Knut Støre lectured at a department called Bygg 1 (Building 1*)*. He is also described as a great humorist. Apparently, Knut Støre proclaimed this phrase both during lectures and when correcting papers, as a sarcastic remark to the international style. To grasp this and the situation at AHO, reference is made to Karl Otto Ellefsen who described the conflict between two groups or schools after the war [13], both represented at AHO. This conflict also existed in architect firms and other schools. The issue was the international style on the one hand and the national style on the other. At AHO, these opposites were represented by the founding fathers Arne Korsmo (the international Korsmo School) and Knut Knutsen (the national Knutsen School). The conflict is described as a kind of internal debate or dualism between leading persons with different architectural views. According to Karl Otto Ellefsen, the Norwegian architects inherited the "artist role" from Korsmo, while the down-to-earth and practical Knutsen School won the battle [13]. Sverre Fehn belonged to the Korsmo School while Knut Støre definitely supported the Knutsen School since Bygg 1 was seen as the Knutsen School's most important bastion. The two lecturers' comments to the phrase "*all good architecture leaks*" should be seen in this connection.

The second phrase, "*all prize-awarded buildings have multiple defects*", was traced back to people working at the Norwegian Building Research Institute (NBI) in Oslo. I first contacted a construction defect senior researcher at the institute, called Ole. He was familiar with the phrase "*all prize-awarded buildings have multiple defects*". He claimed this phrase was a witticism that had emerged in the work place, but was based on the reality that several prize-awarded buildings ended up in NBI's archives of construction defects. He said that the more the architects work on the building to create new solutions, the greater the risk of construction defects. Therefore the logical thing to do would be to follow up with massive technical support, but this did not happen. Ole had heard the phrase "*all good architecture leaks*" and claimed that both phrases described the same phenomenon. According to Ole, it is unlikely that the phrase "*all prize-awarded buildings have multiple defects*" ever will be tested out in a research project, despite this phrase sounding like a research hypothesis. That would have created too strong reactions among "*the breed called architects*", according to Ole, and the Building Research Institute would not profit strategically or financially from such projects.

In order to check the spread of these phrases, more people were interviewed. It has been established that the phrase "*all good architecture leaks*" is unfamiliar to most architects at NTNU. Two lecturers at the Faculty of Architecture who were interviewed had heard the phrase "*all prize-awarded buildings have multiple defects*", uttered by leading persons from the building research environment in Trondheim. One of them thought the phrase was a research hypothesis. Both interviewees expressed the view that the two utterances reflect two groups with opposite interests and could be interpreted as an expression of a certain arrogance and hostile attitude towards each other.

3.3 Architectural Quality

A relevant reference in this debate was the book *Arkitektonisk kvalitet* (Architectural Quality) by Arge and Bleiklie [14]. This book discusses how good architecture or architectural quality comes into being. The main conclusion in this book is that this happens in the interaction between builder and architect. The book's analysis material is built on case studies of four Norwegian, prize-awarded buildings from the 1990s. Both architects and builders were interviewed to find out what characterizes the processes where architectural quality is created. The main criteria for the case selection are that the building project has been awarded a prize, has been published in the architectural press and was designed by renowned architects. I interviewed one of the authors, Kristin Arge. During our conversation, it became clear that construction defects are not discussed as a topic in the book... For this reason, no knowledge was available about the selected and prize-awarded case study objects as to whether or not they have construction defects. According to Arge, this was not a part of their field of interest, but she recalled a remark which touched upon this problem. A project manager, who was interviewed in connection with the study of one of the case objects, mentioned some high-risk technical solutions and concluded: "*we will have to live with that when we are dealing with great architecture.*" During the interview, we discovered that examining prize-awarded buildings with construction defects could be of great professional interest, particularly since this type of research is non-existent. This would involve looking at the evaluations each jury made as regards quality – including quality deficiencies. Arge was familiar with the phrase "*all good architecture leaks*", but had never heard the phrase "*all prize-awarded buildings have multiple defects*", despite having worked at building research in Oslo where the phrase originated. She said these phrases could be interpreted as expressions of a certain level of hostility towards architects. Such attitudes are common among engineers, including those who work with building research, because they feel that architects are not concerned about technical solutions, all they care about is aesthetics, according to Arge. She claimed that architects and engineers have a love and hate relationship.

3.4 From Witticism to Words of Wisdom

To find out whether the phrases had been discussed in the media we conducted an Internet search. The phrases were not found, but we did find a dissertation from NTNU dealing with construction defects. The dissertation was reported in the Norwegian newspaper *Aftenposten* 31 June 2002, and the magazine *Forbrukerrapporten* (lit. The consumer's report) wrote the following: "*prizes are awarded for good architecture, but unfortunately very few prize-awarded buildings have outstanding technical solutions, Mørk writes in his dissertation*" [15]. To examine the basis for this claim, and because it resembled the content of the phrases discussed in this article, the dissertation was procured. The dissertation was on classification and mapping of construction defects with emphasis on quantitative collection of data. The point of interest was that the quotes in the media were taken from a minor paragraph from a large and extensive dissertation. There were no references pointing towards any research or findings from the literature on construction defects which could have been the basis for these claims. So on what were the claims based? Is it possible that this so-called witticism from the Research Institute "*all prize-awarded buildings have multiple defects*", had escaped the closed laboratories and entered the public sphere? Bruno Latour is often quoted with it is difficult to come from being right to having right [16]. Could Latour's principle, in reverse order, have manifested itself?

3.5 The Two Cultures

Several findings point to a tense relationship between architects and engineers. This is strongly emphasized with the phrase "*all prize-awarded buildings have multiple defects*". Expressions such as "hostile towards architects" and "love and hate relationship" are employed. Both expressions could be interpreted as statements revealing two groups with opposite interests. There seems to be tension across institutions and inherited from one generation to the next. The architect thinks the engineer shows little respect for the noble art of architecture, while the engineer claims the architect does not understand engineering. To some people, the phrase "*all good architecture leaks*" is evidence that architects are not interested in technical quality. Several findings suggest two ways of thinking or two cultures, as P.C. Snow described in his essay "The two cultures", where he elaborates on the gap between Natural Science and the Humanities [17]. Students in Trondheim tell jokes and stories pointing in the same direction. One such story is about the engineering student envying the architect student his free and playful studies and later takes revenge. One expression confirming these different ways of thinking is taken from an interview with Sverre Fehn where he talks about his childhood and why he became an architect: "O*ne of [my parent's] close friends was an engineer and taught at the technical college in Trondheim. My parents were very interested in hearing about the conditions there, about the engineering education and the field of engineering in general, and finally, my father asked: What about the architects at the school? The engineer answered:"Architects, they never study, they just run around with large hats and enjoy themselves." It was then I decided to become an architect"* [18]. Through this discussion it has become evident that there is a cultural gap between architects and engineers. This gap could also be described as an internal tension between the few and famous artists and the numerous practically oriented architect engineers, as described by Prak [2].

4. Conclusion

These phrases are undoubtedly humorous, but they also carry a great deal of wisdom. The humorous and deep element in the phrases are the paradoxes they reveal about human ways, but also the fact that constructions created by man have inherent paradoxes, i.e. they could be simultaneously good and poor. The history of architecture includes several such paradoxes, such as the famous Leaning Tower of Pisa and the Opera House in Sidney, which both are major constructional scandals, yet success stories and landmarks. Less famous buildings in the same category which are mentioned in this article are Falling water, History Faculty at Cambridge, The Nordic House, the University campus at Dragvoll, and Mortensrud Church. However, construction defects, including leaks, also occur in ordinary buildings, as reported in this article. A Norwegian proverb seems to be appropriate here: "When it rains on the vicar, it will drip on the sexton."

Both main phrases have been traced back to institutions producing knowledge, that is, a school of architecture and a research institute. The examination of these phrases has been used to study how elite persons refer to a phenomenon and to each other. A situation has emerged from the wings which according to my references could have several names. Some call it two knowledge regimes, while others call it two Figured worlds [1]. The concepts include cognition models both for concrete situations and abstract ideas, where one belongs to the “architect culture” and the other to the “engineering culture”. These two “cultures” try to position themselves in relation to the other. This emerges quite early from different attitudes to concepts such as architectural quality and quality deficiencies. If employing Niels L. Prak’s explanatory model, important driving forces could be indicated [2]. On the one hand, there are the few “avant-garde” architects who constantly try to create something new, experimental and revolutionary. They have their artistic reputations to protect and seek acknowledgement, as this quote implies: *“it has to leak to make the architect famous.”* On the other hand, there are the many "down-to-earth" and practical architect engineers who occasionally have to give their frivolous, artistic colleagues a flick. It appears, however, that both groups live in a mutually dependent relationship, where one has its living of the other’s occupation. The revelation of these mechanisms are significant to further research into the topic design-related construction defects and an understanding of the PhD project's main question: *How and where in the design and production process does the construction defect come into being?*

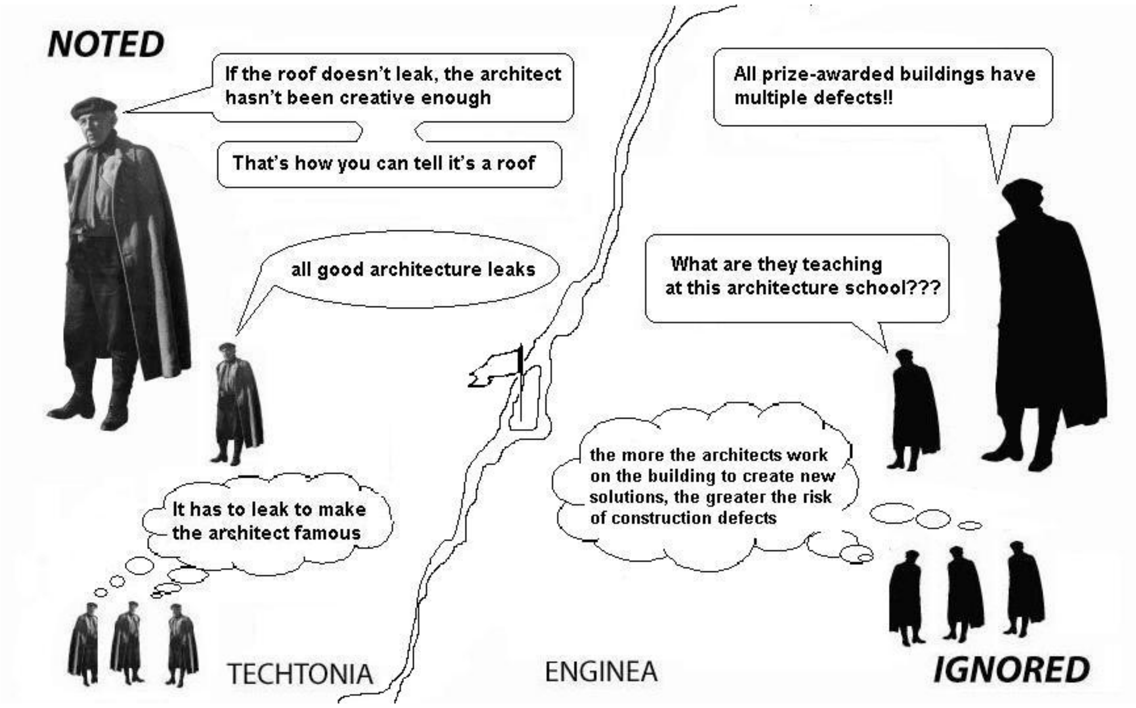

Figure 10. The Theory “Noted and Ignored” related to the sentences analysed in the article

Finally, the principle of “"strangifying” is employed: *Somewhere, in the great universe, there was a planet called Architectura. This was a so-called different planet because it was flat as a pancake and consisted of to areas divided by a rift. These areas were called Techtonia and Enginea. The rift, or split, as some called it, was at times visible, but other times it was beyond any observation. This rift was surrounded by myths regarding its age and origin. Some stories referred to it as a construction defect, while others interpreted this phenomenon as an entrance to the hidden resources of the planet. But the inhabitants of Architectura did not like this rift –*

they dared not cross it and many tales of the situation on the other side were created. They say echtonia was so beautiful, so enchanting, while Enginea was safe and stable.

Acknowledgements

This work has been financial supported by the Research Council of Norway under project Metamorphose 2005. I would thank my supervisor Professor Tore Haugen for important advice. Also Assoc. Professor Dag Nilsen and Professor Tore Brantenberg for constructive comments. At last all the good people who have answered and discussed my questions.

Managing Project Change in Construction: A Soft Approach

Sepani Senaratne, Martin Sexton, Andrew Fleming, Ming Sun*, Ghassan Aouad,
Research Institute for the Built and Human Environment, School of Construction & Property Management, University of Salford, Salford, M7 1NU (email: s.senaratne@pgr.salford.ac.uk)
*- The University of West of England

Abstract

Unplanned changes during the construction phase of projects are inevitable, with potentially adverse implications for project cost, time and quality. Rework that is due to changes can cost between 10-15% of a contract's value. By managing these changes more effectively, these disruptive effects can be minimised or avoided. Therefore, the research study, on which this paper is based on, aimed at developing and testing a toolkit to guide construction practitioners to manage project change in construction. The toolkit is developed based on the findings that are drawn through a comprehensive literature review, followed by case studies. The toolkit captures both soft and hard issues relating to project change and thereby introduces both soft and hard approaches in managing project change. On the hard side, the toolkit first proposes a prediction software tool to 'predict change' and manage it proactively. Second, it proposes a software tool to 'manage the workflow' during change, so that reactive change can be managed efficiently. On the soft side, first the toolkit provides an understanding of dependencies: cause-effect relationships of change, through a detailed framework. This framework (labelled as change dependency framework) assists construction practitioners to understand the complete change management process. Second, an understanding of the significant role of knowledge that the stakeholders bring into the change situation is provided through a set of principles. These principles assist construction practitioners to manage knowledge and teamwork issues during change. While explaining the total contribution of this major research project, the paper will mainly focus on and discuss in detail these soft approaches to change.

Keywords: Project change, change management toolkit, change dependency framework, knowledge management guide

1. Introduction

1.1 Background Research Study

Construction projects often undergo project delays, cost overruns and non-conformance to quality, leading to poor performance and dissatisfied parties (for example see [1] & [2]). An understanding of the driving forces behind such problems is a necessity if the performance of the industry is to be improved. Change can be a major contributor to above raised problems in construction [3] & [4]. The major cost due to change is by the cost of rework and this can amount to 10-15% of contract value [5]. Indirect effects of change are also considerable. Examples of indirect effects are loss of productivity, interruption to workflows and cash flows [6]. These disruptive direct and indirect consequences of project changes demand effective ways of managing them. The appropriate management of change is thus essential to the minimisation of the disruptive effects of change in construction projects.

CIRIA [4] view construction project change as "an alteration or a modification to the pre-existing conditions, assumptions or requirements." These project changes are the additions, deletions or revisions within the scope of a project contract that alter the cost, duration [3] or quality. Effective change management allows change to take place in a controlled way so that viable alternatives are identified, developed and the impact is defined before implementation. Change management in construction is central to the project management process. Previous studies have attempted to approach construction project change management from different perspectives. For example CII [3] and CIRIA [4] take a change management perspective by introducing principles of project change management: anticipate change; recognise change; evaluate change; resolve change; and, learn from change. Love et al [7] take a more technical perspective, by addressing the rework effects of project change. Other studies have approached project change from a process management perspective. Kagioglou et al [8], for example, introduce a separate change management process within the generic design and construction process protocol.

Drawing from these previous approaches to project change management, it is evident that existing solutions only address the problem partially. To reach effective construction project change management, it is important to first gain a complete understanding of the change process throughout a project cycle and second to suggest solutions combining both hard and soft issues of team collaboration and knowledge management. The Managing Change and Dependency in Construction project was initiated to address these issues. The project is funded by the EPSRC and is undertaken collaboratively between The University of Salford, The University of The West of England and Loughborough University. The next section describes the aims and objectives and the methodology of this project.

1.2 Managing Change and Dependency (MCD) Research Project

1.2.1 Aims and Objectives

The aim of this research project is to examine the way in which all of the project elements are co-ordinated towards managing change and to propose a more flexible project co-ordination system that supports the total change management process. In the course of achieving this, the project will consider both hard and soft issues covering the change process. To achieve the research aim the project's objectives are to identify the key task dependency variables for the change process; identify strategies adopted in practice; and, propose an integrated project coordination system to deal with changes.

1.2.2 Methodology

The research commenced with a comprehensive literature review of the issues and implications of unplanned change in construction. The team then captured and represented the attributes of the change process in a taxonomy: nature, causes, consequences and tools. The taxonomy was first validated through internal workshops. In order to sort and structure the research material relating to these four elements, it was necessary to develop change dependency framework. This framework provides an effective way of presenting a process view of the four elements of the change process (see section 3 for a detail account of this framework). Subsequently, the research team conducted exploratory interviews and workshops with industry practitioners to develop, refine and test the framework. Following this first stage, to achieve project objectives in-depth case studies of real life change events were performed. Construction projects were identified according to case study criteria that included projects that have escalated in cost, suffered from delays and/or high degrees of rework. The data were collected through interviews with the construction participants of these selected projects and also through document surveys. Based on the findings of these case studies, a comprehensive toolkit was developed that include both hard and soft approaches to managing project change. The next section briefly explains this complete toolkit.

2. The Managing Change Toolkit

The change management toolkit that is developed by the MCD project is illustrated in Figure 1.

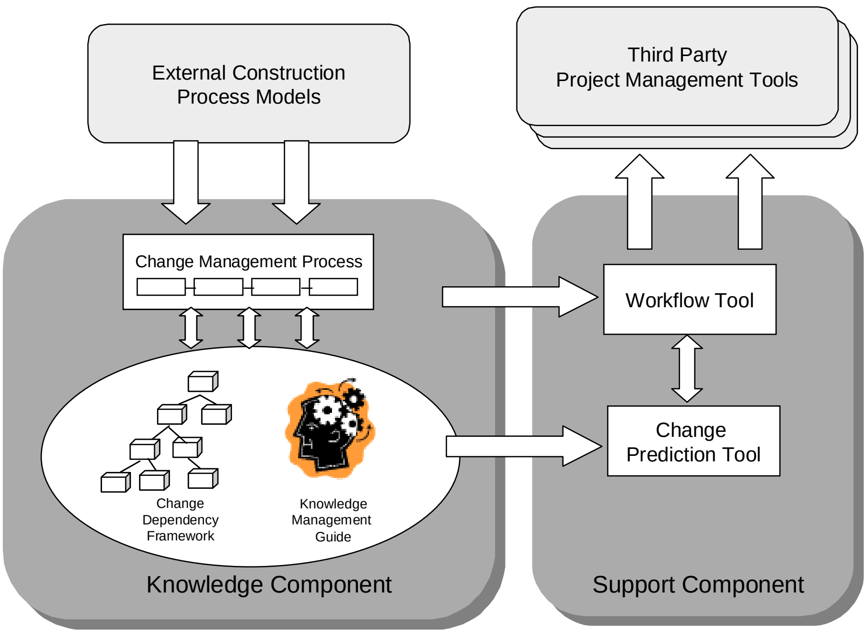

Figure 1: Change Management Toolkit

As Figure 1 depicts the toolkit consists of two main components: a Knowledge Component and a Support Component. The Knowledge Module contains a high-level generic change process that interfaces with a project change dependency framework to identify, evaluate and approve changes. It also contains a Knowledge Management Guide, which can be used either as a standalone guide or to be interrogated and manipulated by the support tools. The Support Tools comprise a change prediction tool that assesses the likelihood of changes occurring and a workflow tool to assess the effect of change on the project programme. The toolkit can be used as a standalone tool during construction projects. It can also be integrated with other project management tools and methodologies, such as external construction process models and third party project management software tools. The toolkit is mainly aimed at organisations involved in the delivery of construction projects. It is designed to prompt thought and discussion of the issues that surround project change. It is envisioned that organisations that use the toolkit will further refine and develop it in accordance with their particular needs. The next section discusses in detail the soft approaches of this toolkit, namely, the development of change dependency framework and the knowledge management guide.

3. Change Dependency Framework

Change dependency framework (subsequently referred to as The Framework) has been developed to consider the cause, consequence and project characteristics in greater detail. The Framework enables users to produce a rich description of the change event. It covers all aspects of project change, including the types of change, causes, effects and the inter-relationship between them. It is, in essence, a taxonomy of construction project change management. The project characteristics considered by The Framework are project scope, team, delivery, execution and control tools. The causes of change are mainly identified from two forces: project level forces and organisational level forces. The Framework identifies direct and indirect consequences. Direct consequences are directly attributable to a change event and will have an identifiable and clearly defined effect on the project, whereas indirect consequences require qualitative measures.

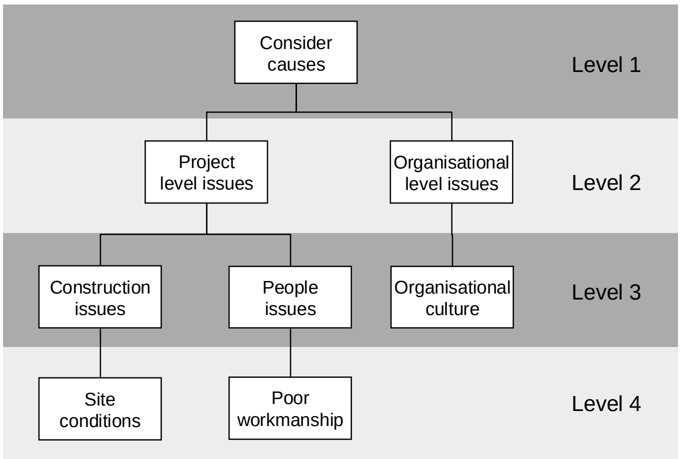

Figure 2: Illustration of Change Dependency Framework Hierarchy

The Framework has a hierarchical structure with four levels (see Figure 2). Level 1 describes the key activities of the generic change management. Levels 2, 3, and 4 are decompositions at increased degree of details. The Figure 2 is an illustration of the Framework, using “Consider causes of change” as an example. The whole Framework is presented as a set of diagrams similar to this illustration. No special or technical skills are required to interpret and use the Framework. Furthermore, the definitions included in this Framework are used directly by the supporting tools of the MCD toolkit. The causes may be examined to help with forecasting and planning activities. The consequences may be examined to help identify changes that have occurred and to aid understanding. The Framework also prompts consideration as to how the project is equipped to manage change. Over the course of several projects a library of change events could be developed that can be integrated with an IT application to compare future scenarios against past cases. The next section explains the knowledge management guide of this toolkit.

4. Knowledge Management Guide

4.1 Importance of Managing Knowledge during Project Change

Managing change in construction projects is a collective problem-solving process. According to previous construction project change literature it is evident that the change problem-solving has been viewed essentially as an information-processing activity [9] & [10] rather than a knowledge intensive activity. Recently, an alternative theory of the firm has been proposed which recognises ‘knowledge as the key asset’ or ‘knowing as a key process’, in delivering organisations’ competitive advantage. This knowledge-based view of the firm [10], [11] & [12], we argue, opens new avenues to approach effective project change management in construction.

Construction literature that address knowledge management, learning and innovation studies, show a trend towards identifying construction problem-solving as a knowledge intensive activity. For example, Winch [14] explains that knowledge and learning are generated in solving problems that involve team discussions and dialogues during the construction process. For such problem-solving to become true innovation the solutions reached for particular problems, should be learned, codified and applied in future projects {15]. Similarly, other learning and innovation literature in construction identifies the importance of integrating project experience to the organisational business processes, to generate learning and innovation (see for example [16] & [17]). However, the extant knowledge-based construction literature is arguably limited in providing an in-depth understanding on the role of knowledge during construction problem-solving and especially during managing change context.

To this end, the general knowledge management literature aids in understanding the fuller role of knowledge during problem situations that is facilitated by team interactions. Accordingly, during shared activities such as problem-solving, individuals bring various forms of knowledge that could be shared and converted into new knowledge [18] & [19]. Most literature identifies two types of knowledge: tacit and explicit. Polanyi [20] explains the tacit knowing by saying that we can know more than we can tell. Tacit knowledge is highly personalised and hard to formalise, making it difficult to share with others. On the other hand, explicit knowledge is codified knowledge, which is transmittable in formal systematic language, often found in rules, policies, procedures, specifications and documents. When considering team knowledge during change events, the theory of knowledge creation [18] shows how a team can advance knowledge and learning through team interactions by different modes: socialisation, externalisation, combination and internalisation. However, as Snowden [21] argues tacit knowledge need not necessarily go through a costly codification process to create new knowledge. This understanding on knowledge conversion offers significant contributions in understanding role of knowledge during shared activities. In order for knowledge, which is generated through change experience to be useful, it needs to pass from project to organisation level and back to subsequent projects. This inter-project learning can emerge when team knowledge is stored and transferred within the organisation for re-use in future projects. Thus, knowledge transfer and learning literature brings useful insights in understanding the inter-project knowledge transfer following project change events. This led to the exploration of the role of knowledge during team interaction as explained in the knowledge management literature.

4.2 Case Study Description

A detailed case study was conducted to address this role of knowledge during project change situations. The case study project comprised a supermarket store extension and refurbishment. The project was procured under Design & Build path. This was one of the series of projects that the client and the project team contracted, on a partnering arrangement. The project duration was 29 weeks and was valued at £ 7.0 million. A major change event was selected and fixed as the unit of analysis for the case study. The change event considered in the selected project was a ‘change in the store flooring design’. The project team members who actively participated in this selected change problem-solving event were interviewed. Accordingly, the interview sample included the D&B Contractor, Architect, Client Agent and the Client. Interviews of 2-hour duration using semi-structured interview guidelines were carried out with each of these team members.

The original floor design of the store required a shut down of the store. However the client realised belatedly that they have not considered the loss of six weeks trading. Therefore the client wanted the D&B contractor to change the original design and consider other floor design options that will minimise the store closure. The floor options evaluation and decision-making went on for about 4 months at the initial stage of the construction works. The change was disruptive and created lot of uncertainty and re-programming. There was a change order system in place to record and communicate change. The project team discussed the change problem mainly at the progress team meetings, which took place fortnightly. In addition, special meetings were held incorporating the specialist knowledge of the flooring sub-contractor. Other modes of communication were e-mails and telephone conversations. The D&B contractor had led this change event involving the client party, architect and the client agents. The team had prior working relationships, being on a partnering arrangement and this had led to good team working. The team was distributed nationally. However the distance barrier had not affected the team collaboration. The team composition was the same throughout the change. Based on the findings, a knowledge management guide was developed, which is explained in detail next.

4.3 Knowledge Management Guidelines

This Guide provides a set of guidelines from knowledge management perspective. The guidelines are explained in this section, which are supported by the case study findings.

- Identify and use team members' expertise in change decision-making.

The extent to which team members hold past knowledge and the extent to which they know one another prior to discussions can affect how they make decisions. Therefore team members need to know who knows what and make effective use of both tacit and explicit knowledge in appropriate balance during the process.

One of the key observations of the empirical study was that team members relied heavily on their previous experience during problem solving. They recalled their past experiences and built upon this knowledge and applied this tacit knowledge to the new situations, rather than referring the codified documents that contained past project lessons in the explicit forms. This was clearly evident in the D&B contractor's statement, "*you always have to relate old knowledge with the new condition, to come with a practical solution. We are dealing with an existing floor. So we did not collect various documents and develop the idea, rather used our experience and the existing knowledge to the practical situation*". This finding is consistent with the construction literature, for example, [22] recognise that construction problem-solving significantly relies on experiential knowledge.

- Consider face-to face settings for change decision-making.

Tacit knowledge that originates at a collective level is the most strategically significant type of knowledge. Therefore it is important to promote team interactions to create this tacit-collective knowledge. Virtual communication techniques are insufficient to this end and face-to-face settings at regular intervals are crucial.

According to case study findings, the decisions related to change problem-solving were mostly considered at team progress meetings, along with e-mail and telephone communication in between these meetings. This finding was confirmed by the Architect's words "*Mostly at meetings issues were discussed in detail*" and the D&B contractor's words "*Decisions were made mainly in the design team meetings where all parties sign up for the final decision*". This reliance on face-to-face settings, despite distance barriers and the availability of virtual collaborative mechanisms, reaffirms that face-to-face settings are the key to team decision-making.

- Create a knowledge-sharing team culture.

It is important to create a team culture that use shared language / narratives and improve personal relationship through trust, care and openness. This can be facilitated by collaborative team approaches such as partnering arrangements, design & build approaches and concurrent engineering.

It was evident from the case study that the collaborative team approaches, in this case the design & build path and especially the partnering arrangement, have created good team working and a long learning curve between the parties. As the D&B contractor stated, "*The long term working arrangements that had been developed over the years had allowed the client projects to operate independently*". However, the D&B contractor further stated "*Due to the long learning curve that the team had developed over the years, it is difficult to bring in new members to the projects and those who worked throughout tend to stay*". Thus, confirms Leonard's [23] views on core capabilities that could lead to core rigidities. Therefore it is important to identify the balance between collaborative arrangements.

- Encourage socialisation activities during managing change.

Tacit knowledge can pass between team members through observation, imitation and practice when they share their knowledge during team discussions. Socialisation activities such as apprenticeships and training; participation in outside activities (such as site visits, fairs and social functions); and informal working arrangements (community of practices and informal networks) can improve members' tacit knowledge base.

It was apparent from the case study that tacit knowledge was created when the team members engaged in shared problem-solving in face-to-face context; that is through socialisation mode. Members tended to learn from each other, thus leading to horizontal learning rather than vertical learning, where juniors learn from seniors. In D&B contractor's words "*Hierarchical learning is limited as there tends to be similar level people involved. But learning across other disciplines is present.*" The client agent too supported this point by stating, "*at project meetings I had opportunity to observe other members and their work.*"

- Encourage members to make their tacit knowledge explicit during team discussions.

Tacit knowledge can be made explicit by effective use of stories, myths, examples, metaphors, analogies and models during team discussions. As well as listening to others' experience and opinions, it is important to encourage each member to express and clarify their thoughts.

The externalisation stage where tacit knowledge is put into explicit knowledge through discussions mainly had taken verbal forms rather than written forms, in the case study project. Even the few written forms that existed were insufficient in detail to be of use in other similar contexts. The D&B contractor emphasised this when he stated, "*Meeting minutes are a way of bringing things that we discussed together. But a drawback is the discussions are not reported in detail at these minutes. We talk for about 40 minutes and include in the minutes what we agreed at last and not the pathway of reaching that decision.*"

- Encourage team members to codify their change experience.

It is important to organise ideas raised in discussions and make conclusions. These need to be codified in documents such as review reports, manuals, databases, publications and/ or computer programmes, in order to disseminate to the wider organisation. Access should be given to all members in the organisation to refer these codified documents.

According to the case study, the existence of combination mode during change events was limited. The codification process after change events was insufficient. D&B contractor stated that "*No special reports were written after the meetings other than these minutes of meetings"* and the architect affirmed "*No formal project review reports were prepared."* However, the views of client were contradictory to the practice as he mentioned, "*We request project review report for large scale projects like this. Otherwise there's no re-collection of what you went through. Because people move on and company changes, without such document we might get to another similar store and find out that we do not have any information on that*."

- Encourage team members to learn after the change experience.

Team members should be provided with time and resources to reflect, learn and experiment from their immediate change experience. Further, team members should be allowed to interact with other members within their individual organisations, so that their experience can be shared through further socialisation.

In terms of internalisation, it was apparent that the team members created new tacit knowledge and generated learning, by going through the change experience. Architect professed, "*In addition to learning how to deal with the new technical issues we have become more flexible and understanding of change.*" D&B contractor stated "*After going through that experience and the problems we encountered, we come to a situation where we can handle that problem a lot quicker and better.*" Even the client admitted that he learnt "*probably to push harder higher up the line and try and get the decisions quicker*" next time.

- Balance personalisation and codification strategies during project change

In summing up, in terms of knowledge conversion and creation, the formation of knowledge conversion cycle, through project changes, was found to be different to that of [18]. The tacit knowledge appears to transfer from socialisation to internalisation while not necessarily passing through the codification stages that involve externalisation and combination modes. Even the limited codification that takes place, such as change record forms and minutes of meetings, lack sufficient detail, to be of use in other similar contexts. Thus, the key conclusion, which can be drawn from the case study investigating the role of knowledge during managing change in construction, is the existence of a process view of knowledge as opposed to an asset view. This process view to knowledge, where knowledge pass from individuals involved through shared activities, limits the transfer and dissemination of knowledge to a wider group. Thus, team members lack the opportunity of learning from others lessons. Therefore, it is very important to create an appropriate balance between asset and process views of knowledge; and decide on the level of codification and dissemination that should be present against the cost of codification and the usability of that knowledge in similar contexts.

5. Conclusions

This report describes a change management toolkit, which aimed at providing support for construction projects. The project Change Dependency Framework ensures that all team members will use standard procedures and terminologies at different phases of a project and for different projects. The Knowledge Management Guide provides advice not only on how to use this system but also on how to better understand project change and change management as well as on how to learn from the process of managing project changes. The system will help a project team to reduce unnecessary changes and to minimise the negative impact of unavoidable changes, thus, help to reduce the project delay and overspending problem of construction projects.

Abstract

The concept of Knowledge Management is now familiar to the construction industry and various attempts are being made for the effective management of knowledge in the industry. This paper addresses the importance of people factor and tacit knowledge in construction and examines the current focus of knowledge management initiatives to find out the alignment with the industry requirements. Labour and knowledge intensive nature of industry is revealed with challenging aspects of construction performance. Dominant hard model of human resource management is uncovered and finally the mismatch between the current focus and industry KM requirements is unearthed.

Keywords: Tacit knowledge, knowledge worker, knowledge management

1. Introduction

In recent times, the UK construction industry has been forced to critically examine its performance as an industry which lags behind most other industries in terms of technology and productivity [1, 2, 3]. A number of government and academic reports [4, 5, 6] have repeatedly highlighted this issue and the necessity for a fundamental cultural and technical change in the construction industry (CI). It is argued [7, 8] that the publication of Latham's report [4] and the Egan's report [5] as very crucial milestones in the CI addressing issues such as fragmentation, client dissatisfaction, low level of investment in R&D and lack of skills in terms of improving productivity which have adversely affect the performance of the CI. The need for improvements within the industry was so acute with growing pressures exerted by these major reforms.

Within the CI, it is increasingly being acknowledged that Knowledge Management (KM) can bring about the much needed innovation and improved performance the industry requires [9, 10, 11, 12]. This has been further highlighted in a recent survey [7] by Management of Knowledge and Innovation Research Unit of the Open University: the move towards the change initiated by the Latham and the Egan reports as the mostly cited driving force behind the KM in the CI. Yet, the term 'Knowledge Management' is relatively new to construction organisations [11], nevertheless, a growing number of organisations within CI [12] now perceive KM as an integral part of their competitive strategy for providing long term benefits for the organisation. The emphasis on KM reflects the growing realisation that it is a core business concern, particularly in the context of the emerging knowledge economy, where know-how of a company is becoming more important than the traditional sources (capital, land etc) of economic power [13, 14]. There is an emerging importance placed on the people factor in the CI, as one of labour intensive sectors of the economy, which is still considered to be an "under-charted territory" [15] within construction organisations. Yet, this issue has often been ignored or placed with less importance as evident from previous work on KM in CI, which has focused heavily on the delivery of technological solutions [11] probably due to increased concern in Information Technology (IT) in the eighties and early nineties.

The paper aims to highlight the mismatch between KM requirements of CI and its current focus by critically analysing the state of the art KM initiatives and frameworks through a comprehensive literature review and synthesis. Accordingly, paper is organised into three sections: the first section explore the salient features of the CI together with challenging aspects of construction performance and human resource management. The second section examines the apparent limitations and various efforts to improve KM in construction in terms of existing KM initiatives and frameworks, whereas in the final section, the disparity is outlined by considering the industry features, challenges, requirements and KM frameworks in a form of a discussion.

2. Construction – an Overview of Nature, Performance and People Management

Construction is an industry which utilises a variety of separate firms in a temporary multidisciplinary organisation, to produce investment goods like buildings, roads, bridges etc, which are custom built to unique requirements. The industry is generally driven by single and unique projects, each creating and disbanding project teams made up of varying combinations of large and small firms from across the supply chain spectrum. The short-term temporary project based nature is considered as an intrinsic characteristic of construction and industry is considerably more fragmented than many other industries with a much greater concentration of small firms [16]. The scale of small firm activity in the UK CI is considerable, with, in 1999, 99% of UK construction firms having 1-59 staff [17, Table 3.1] and by 2002 delivering some 62% of the industry's workload [18, Table 3.3] and accounting for 122,220 small and medium construction firms in 2003 [16]. Further, the number of professional service firms within CI has risen from 48,202 in 1995 to 52,490 in 1998 [19] and the services offered by these professional service firms are characterised by being highly knowledge intensive in nature [20]. This in a way evident the shift towards the knowledge economy in UK CI and there is significant agreement that the principle means by which this growing body of professional service firms creates value through the successful management of knowledge [21]. The UK Government's Competitiveness White Paper, *Building the Knowledge Driven Economy* [22], refers to more effective use and exploitation of all types of knowledge, particularly in the traditional CI in order to give the UK a competitive edge. In addition, there are a wide range of professionals involved in construction sector, working as an inter-disciplinary team in delivering the construction products. The UK CI employed 19,130 workers per £1 billion output (total of 1,599,000 workers) in 2003 [16], hence considered to be one of the labour intensive sectors of the economy. In this context, CI is perceived as one of the labour and knowledge intensive value creating sectors of the economy.

The value-creating performance of the CI for its clients, however, has often been questioned. Firms in the CI are frequently being blamed for inefficiency of its operations and industry has been accused of being, at its worst, wasteful, inefficient and ineffective [23]. Construction also perceived as an industry which delivers products and services which are often of inappropriate quality and which fails to meet client's demands for price certainty and guaranteed delivery. The industry has long been recognised as having problems in its structure, particularly with fragmentation that has inhibited its performance [4, 5]. Latham's report, *Constructing the team*, was very much concerned with improving the performance of the CI by reducing conflict and construction cost; whilst Rethinking Construction [5] lamented that 'too many of the industry's clients are dissatisfied with its overall performance' (para. 3). This was further extended in Fairclough's report [6] with its reference to the "old fashion" nature of the industry. As a consequence, Fairclough report has identified the need for significant performance improvement as an urgent issue while stating that "the emphasis should be on key competitiveness & productivity" [6]. Thus, the next section discusses the challenges and problems faced by the CI in terms of their performance, which has gained much concerned in recent time due to aforementioned reforms.

2.1 Challenging Aspects of Construction Performance

Despite the importance of business performance measurement in construction, it has received "scant attention" [24] within mainstream construction management literature, particularly concerning its role in "offering real-aid" [24] to improved construction performance. This little attention has resulted construction business performance measurement to rely on "traditional" performance measures, which is considered to be predominantly project specific and profit orientated with hard factors; failing to take account of broader intangible or softer issues. Business performance measurement in construction tends to rely on performance measures, such as efficiency, return on capital employed and profitability. At the construction project level, traditional success criteria centre on the achievement of cost, time and quality targets, failing to take a wider picture into account. These measures have been criticised by a number of authors, mainly because they:

- Over-rely on financial aspects;
- Encourage short-termism;
- Are retrospective (and hence always to some extent out-of-date); and
- Do not accurately reflect the interests of stakeholders.

Thereby, a broader knowledge on organisational technical, structural, contextual and more importantly human factors are essential to better understand why some organisations are more successful than others. Moreover, as Gann [25] criticised, the prevalence of short-term views within the CI has promoted the usage of strategies that yield superior quarterly or annual results even though they may cause long-run ruin for the whole organisation. Also it has been argued [26] that the short term perspective of construction promotes sub-optimisation and hampers innovation and technical development which adversely effect to the organisational performance. In addition, the project based nature of the construction too has fuelled the under performance in the industry to a certain extent. Though the construction team undergoes forming, storming and norming stages of the team development, just when the team has got to its performance level it is disbanded because the project is finished [27]. Hence, this reflects that intrinsic characteristics of the industry too have contributed to hinder its performance in the CI.

However, the ignorance of the people factor within the construction context has contributed to a great extent for the under performance of the industry as lamented by many authors. As contended by Nesan & Holt [28], the issue of the critical role that employees play in fostering an effective construction business (the people factor) has often been overlooked. According to Cooke-Davies [29], “it is people who deliver the projects and not processes and systems”, which gains increased validity in the context of construction, as a labour intensive industry. Hence it is argued [24, 30] that there is a necessity for the CI to define more appropriate performance criteria for both project and organisational level by redefining “traditional” success parameters to consider the knowledge, skills and behaviour inputs which contribute to superior performance. Hence, the following section deals with the human resource aspects of the CI with the view of exploring the current practice within the industry.

2.2 Human Resource Management of the industry

There is established dichotomy in the literature between ‘hard’ and ‘soft’ Human Resource Management (HRM) [16]. The former treats people as a resource to be provided and deploys as necessary to achieve organisational objectives. In contrast, later sees people as valued assets who offer a source of competitive advantage [31]. Construction as an industry which has a reputation for its dominant culture of command and controls consistently emphasises and correlates with the hard model of HRM. Also the culture of subcontracting and self employment marginalises the importance of people management and thereby reflects and reinforces the dominant industry receipt of hard HRM. Even though Dainty et al [30] argued that construction managers have always had significant discretion over problem solving and employment issues, the work employee relations survey [32] which investigated employee participation across twelve sectors revealed that in CI, participation in problem solving groups occurred in only 21% of workplace, which is the second lowest when compared with all other sectors. This dictates that the hard model of HRM dominates not only for the construction labour force, but also for professional and managerial staff.

Soft HRM policies based on empowerment and commitment are much more prevalent within organisations orientated towards creativity [16]. This is true when it comes to the professional service firms within the CI, who compete successfully internationally by investing heavily in knowledge based services. As such it is an urgent matter for the CI to move towards the softer approach based teamwork from hard model of HRM to enhance the collective efforts due to several reasons. Firms within CI frequently claim that ‘people as their greatest asset’ [11] in a situation where literature on HRM repeatedly emphasises the need to treat people as a key resource. This is especially true in relatively low-tech, labour intensive industries such as construction [16]. However, people also represent the most difficult resource for organisations to manage. As highlighted in the intrinsic characteristics of the industry, construction employs extremely diverse range of people from a wide range of occupational cultures and backgrounds, including people in unskilled, craft, managerial and professional positions, challenging to manage people effectively to ensure organisational success. Nevertheless, the importance of the construction worker is highlighted by the fact that industry relies on skill and on the capacity to bring different skills together effectively [33]. Thereby the concept of the knowledge worker has long been important to construction organisations [16] and in recent years, with the growth of the service sector, this emphasis placed on the construction knowledge worker has gradually increased. Having discussed about the significant role of construction worker (people factor) within the industry in terms of intrinsic features, performance and management, the following section examines the current KM initiatives to unearth the importance given to the people factor within such frameworks.

3. Knowledge Management within the Construction Industry

KM is not entirely new to the CI. What is new is the terminology used and the increased awareness that knowledge should be managed in a more structured manner [34]. This has been largely brought about by a number of factors such as the increased global competition, company size, geographical spread and employee turnover [34] and also as a consequence of construction domain becoming highly information intensive [35]. Knowledge is a valuable yet frequently intangible asset. Work by Polanyi [36], Nonaka and Takeuchi [37], divided knowledge into tacit (that which is stored in people’s heads and is acquired through experience) and explicit knowledge (that which could be documented and therefore physically stored). Within construction, the type of knowledge varies enormously, yet gains increase concern on tacit knowledge as a labour intensive industry. Specially, Engineers, Architects and other professionals within CI are not in a position to ‘cut and paste’ best practice [38] from the past due to the unique and the complex nature of the construction projects. They have to draw on the past to find solutions for the future. Tacit knowledge evolves from these shared practices and experience which need to be managed for the project and the organisational success. According to Wetherill et. al [35], knowledge in construction domain can be classified into three categories as illustrated in Table 1.

Table 1: Classification of Knowledge in construction domain

Domain Knowledge	The information available to all companies and is partly stored in electronic data bases
Organisational Knowledge	Company specific and intellectual capital of the firm which also comprises knowledge about the personal skills, project experiences of the employees
Project knowledge	Which includes both project records and the recorded and unrecorded, memory of processes, problems and solutions

By taking a different stance Stahle [39] suggests organisations into three-dimensional system i.e. mechanistic, organic and dynamic nature, depending on the different challenges presented for management of knowledge. Wetherill et. al's classification reflects the organisational hierarchy and when one moves from domain knowledge to project knowledge the concentration on knowledge too moves from explicit to tacit nature, which further highlights the knowledge worker concept in construction. Stahle's suggestion indicates both the management and the production of the knowledge. In a similar sense Moodley et. al [40] contends that the tacit knowledge is developed through the individual or project teams, while the explicit knowledge is created through process, procedures and other routines that can be codified.

Review of current literature reveals numerous definitions and techniques of KM due to wide range of interest, perspectives and issues represented by different authors. These fall mainly into the IT perspective (Explicit knowledge) where authors focus on IT tools to deliver KM solutions [41, 42], the Human Resource (Tacit knowledge) perspective that relies on the people aspect to provide KM solutions [43, 44] and the integrated perspective which acknowledges that both the IT and HR perspectives complement each other [45,46]. Nevertheless, KM is defined as 'process of creating, acquiring, capturing, sharing and using knowledge, wherever it resides, to enhance learning and performance in organisations' [45], which emphasis both aspects. Managing knowledge more effectively offers construction organisations a possible mechanism for improving their performance in times of greater competition [34].

However, despite the interest and the effort put into KM by many leading companies, the discipline is still in its infancy in the CI and is at an embryonic stage in UK construction [21, 34]. As Rezgui [47] cited, there are few key reasons that limit current approaches of KM in CI. Among the key factors for these limitations are;

- Much construction knowledge, by necessity, resides in the minds of the individual working within the domain;
- The intent behind the decisions is often not recorded or documented;
- The individuals who have knowledge about the project are likely to left for another project at the end of the construction stage; hence their input is not captured.

As such all these three limitations indicates the direct correlation with the human factor in the CI and highlights the importance of tacit knowledge and the people-centred approach of the KM to overcome these limitations. This further stresses the importance of the concept of knowledge worker which has long been central to CI performance. Despite difficulties in KM approaches in construction, several KM projects and initiatives have been undertaken, which are outlined in the succeeding section.

3.1 Knowledge Management Frameworks in Construction

CI is evident with paucity of academic research and inadequate empirical studies on KM and even the limited number of studies that have been conducted focused heavily or solely on explicit knowledge [7] and on the role of information technologies [11]. Too often, KM is limited to the appropriation and exploitation of explicit knowledge. Tacit knowledge or people aspect is either ignored or 'converted' to explicit knowledge. In academia, research papers published on KM relevant to construction include: the provision of a KM framework [8]; knowledge transfers between organisations [48]; the role of IT [11]; the impact on construction innovation [10]; the impact on business processes and performance [21]; and case studies within specific construction companies [40]. In addition, following table identifies examples for research projects carried out within construction, in terms of managing knowledge.

Table 2: Research projects in construction to improve KM

CLEVER	Cross-Sectional Learning in the Virtual Enterprise (CLEVER) focused on 3 key aspects of KM- intra-project, inter-project and cross-sectoral- with the view of developing a generic multi-disciplinary framework covering the organisational & cultural implications for knowledge-based businesses.
KnowBiz	Knowledge Management for Improved Business Performance (KnowBiz) concentrated in improving construction organisations business performance through their improved management of the knowledge resources. The development of KM framework and the supporting IT architecture highly emphasised on the use of KM principles to facilitate construction companies in collating and keeping track of the data required for input into key business performance measurement models.
CSanD	Within construction projects, knowledge about sustainability is being developed continuously, but there is little understanding of the best ways to foster the creation of this knowledge, less about how to capture such knowledge and even less about how to ensure that knowledge is available quickly and easily to other individuals and projects. Creating, Sustaining and Disseminating Knowledge for Sustainable construction: tools, methods and architecture (CSanD) aimed at addressing this pertinent problem by developing software tools for capturing and retrieval of relevant knowledge.
E-COGNOS	Methodology, tools and architectures for electronic COnsistent knowledGe maNagement across prOjects and between enterpriSes in the construction domain (E-COGNOS) aimed at specifying and developing an open model-based infrastructure and a set of tools that promote consistent KM within collaborative construction environments with a particular emphasis on a web based infrastructure.
KLICON	Knowledge and Learning In CONstruction (KLICON) focused on the role of IT in capturing and managing knowledge for organisational learning on constructional projects.

As evident, these frameworks have concentrated on different aspects of construction KM other than knowledge workers within the industry, with a very high emphasis on the role of IT. Yet one apparent finding of a research carried out by Management of Knowledge and Innovation Research Unit [7] was that the Information Technology's incapability of transforming tacit knowledge to explicit knowledge and IT as a tool to transform tacit to explicit knowledge was considered as 'a step too far'. Therefore, it was suggested that the extensive use of IT could reduce the chances of face-to-face communication which they considered to have a significant role to play in effective KM. Having examined the state of the art KM initiatives, frameworks and research work in construction; following section outlines and critically discusses the disparity between KM requirements and current focus in CI.

4. Discussion

The labour intensive and knowledge driven nature of the CI together with other intrinsic characters were outlined in the initial section. Further, the importance of recognising the people factor and the necessity of managing construction knowledge worker with softer human resource approach was highlighted in the paper. Yet, as Egan [5] asserted;

"*….much of construction does not yet recognise that its people are its greatest asset and treat them as such. Too much talent is simply wasted, particularly through failure to recognise the significant contribution …… We understand the difficulties posed by the fragmented structure of the industry, but construction cannot afford not to get the best from the people ……*" (para 17; p14).

In this context, Management of Knowledge and Innovation Research Unit [7] has empirically established that problem solving, managing change and innovation as the main triggers of the knowledge production in construction organisations and even out of these three categories, majority of the triggers were associated with problem solving aspects of the professionals. Also in this survey the majority of respondents have noted that they rely on their colleagues as a primary knowledge source and in addition, 'the construction project team' has been cited as the second mostly used knowledge source. Yet another survey [49] of 170 UK construction organisations, indicated that communities of practice as the most widely used technique for KM particularly in large construction organisations. Further, Robinson et al. [21], in a study of the state of KM within the UK construction sector, discovered that over 70% organisations intended to have a KM strategy in place by the end of 2002. The main three reasons for this were:

• The need to encourage continuous improvement (92.5%);

• To share valuable tacit knowledge (88.7%);

• To disseminate best practices (86.8%);

All these empirical studies highlight the importance of the people factor and their tacit knowledge than the explicit knowledge in the construction context. Despite the contextual differences, the tacit knowledge obtained from the colleagues and the project team were considered highly in 'enabling' the respondents to solve the problems they were faced with [7].

As discussed elsewhere, much of the KM frameworks in the CI have orientated towards the management of explicit knowledge via IT tools, in a situation where people-centred tacit approach of KM, as evident from Robinson et al's [21] work, is demanding by the industry. This indicates the mismatch in terms of KM initiatives in the CI. The early focus on KM resulted in technological solutions with a bias towards the use of IT, however, many of these were not successful because they ignored the people required to make them work in construction [34]. More recent work has focused on the importance of HR in KM but these have yet to be developed in terms of concepts and frameworks [50]. It is noted that employee participation in problem solving groups occurs in only 21% of construction workplace when problem solving in the CI is recognised as the major trigger of the knowledge production. Also in a situation where colleagues and project team are considered as the primary knowledge sources and communities of practice as the widely used KM technique, the necessity to shift from hard model of HRM to Soft HRM policies based on empowerment and commitment is much more compelling than ever to foster KM exercises through which CI performance could be enhanced.

5. Conclusion

KM is evolving rapidly but construction organisations are at the emerging level and there is a lot of work to do. The alignment between the KM focus and the KM requirements of the industry is of utmost importance to enhance the performance and to achieve the competitive edge in the CI. This paper has revealed the disparity between the current KM focus and the KM requirements of the construction as a labour intensive and tacit knowledge driven industry. This provides the basis for more empirical research on people centred KM approaches in the CI.

Managing Knowledge in Construction Disputes

Patrick S.W. Fong
Department of Building & Real Estate, Hong Kong Polytechnic University
(email: bspafong@polyu.edu.hk)
Ivy N.P. Tong
Levett & Bailey (email: 01592347d@polyu.edu.hk)

Abstract

Knowledge has always been recognized as one of the most important assets that one can possess. Various studies have revealed that the management of knowledge is able to increase efficiency as well as enabling professionals in an organization to make more accurate decisions. The construction industry in Hong Kong is highly fragmented, resulting in a considerable number of disputes over contracts and interests, and the resolution of construction disputes by litigation is costly, timely and complicated. This research is conducted to explore views on knowledge management in construction litigation, so as to determine the potential for using knowledge management in construction disputes.

The results of this mixed methodology research show that (1) law firms are more concerned with time efficiency when implementing knowledge management, (2) knowledge management is very helpful in their professional practice, (3) the development of a knowledge management system requires a substantial input of resources, (4) the success of knowledge management is essentially attributable to staff participation and top management support, (5) individual construction companies are not likely to set up a knowledge management system for disputes, and (6) law firms have amalgamated construction disputes in their knowledge management system.

From this study, it seems that there is a need for a knowledge management system for construction disputes. However, further research should be conducted to study the feasibility of setting up an independent and neutral organization to handle sensitive information and tackle the obstacles of mistrust within the industry and the conflict between routine business activities and the extra workload resulting from knowledge management.

Keywords: Construction disputes, knowledge management, litigation

1. Introduction

Disputes are inevitable within the construction industry because of its highly fragmented nature. Although many dispute resolution centers promote alternative dispute resolution (ADR), litigation and arbitration are still common forms of dispute resolution used by construction companies. Court cases can consume millions of dollars and take years to settle, thus how legal professionals advise and assist their clients in resolving such disputes has important implications for the construction industry.

Knowledge management has many advantages in assisting lawyers to effectively deliver appropriate information and advice in a timely manner. An effective knowledge management system can also respond to an emerging trend for major clients to ask for an arrangement whereby they are connected electronically to a law firm's knowledge base.

Law firms represent an industry that seems very well suited to conducting knowledge management investigations. They are knowledge intensive, and the use of advanced technology may well transform these organizations in the future [1]. Therefore knowledge management practice in law firms can be a good reference for the construction industry in implementing knowledge management. The market for construction litigation is huge and there appear to be many advantages and little risk to applying knowledge management in construction disputes. Nevertheless, there has been little research into the application of such specialized systems in Hong Kong. This research aims at exploring this issue.

2. Management of Construction Litigation

The nature of the construction process is that it is a multi-party business that involves an owner, consultants, a general or prime contractor, subcontractors, and other related parties such as insurers, sureties, and lenders, all with different needs. These parties are expected to cooperate and coordinate their efforts. One party's failure to perform is likely to place a burden, financial or otherwise, on one or more of the other parties.

There are various factors that lead to conflicts and disputes in a construction project. They include different interpretation of contract clauses, inadequacy of plans, workmanship, defects, lack of supplies, tort, lack of insurance proof, indemnity, third person liability, safety and non-payment [2]. The most common way to deal with contractual disputes in construction is to file a lawsuit.

Litigation can be expensive and complicated as it involves many court procedures; in addition, it takes a long time to bring a case to a conclusion [3]. In Hong Kong, the waiting time simply for a case to be heard at the High Court exceeded 190 days in 2003 and is expected to be longer in 2004 due to the growing backlog of cases [4], and this does not take into account the preliminary arrangements, discovery of documents, submission of evidence and other complicated procedures in litigation. The quantum of the legal fees for such proceedings will likely exceed the amount of compensation payable, if any. There are also many complications, such as the fact that lawsuits must be brought before expiry of the relevant statutes of limitation, or handling the tedious discovery process [5]. Thus construction litigation places a heavy burden on the disputants if the case cannot be skillfully and efficiently settled; locating lawyers who are familiar with construction disputes for appropriate advice is crucial to clients if they are to minimize costs and delays and ensure that correct decisions are made.

2.1 The Role of the Legal Profession in Construction Litigation

The implications of the involvement of legal counsel in the construction industry is not limited to the representation of clients at trial, but also involves the leverage of expertise and experience to provide commercially focused solutions and to minimize the litigation process, thereby achieving the client's business objectives [6]. Cautious construction companies will, prior to signing any construction contract, retain lawyers who are experienced in construction matters, to review the contract terms and identify future problems, as well as specifying how they will be resolved in the course of the project. This measure will allow them to make early pragmatic determination of the cause of construction disputes and identify the parties responsible for any defective performance, resulting in an efficient resolution and savings in future litigation.

2.2 Knowledge Management for Legal Practices

Compared with other professions acting in an advisory capacity on construction claims, law firms are in the most need of managing knowledge for the purpose of feeding information and giving advice to their clients. In common law jurisdictions, where the Doctrine of Precedent is in practice, court cases are of utmost importance to lawyers for giving legal advice to their clients. If not efficiently managed, the vast amount of cases accumulated from several hundred years ago to the most recent, many other cases that did not go to trial and were settled out of court, and the know-how in settling cases without trial, would be difficult for lawyers to use in the course of performing their duties. In a recent survey of the use of information technology by law firms [7] the top three challenges identified were:

- Improving efficiency
- Winning new clients
- Improving client service

These challenges have led to a growing interest in knowledge management as an alternative means of creating a competitive edge [8] so that law firms can create, share, and use knowledge effectively [9].

The Head of Education and Know-how in a city law firm stated that,

> "firms that do efficiently accumulate their wisdom in an accessible manner are likely to produce immediate advantages for their clients and to compete more successfully" [10]

Knowledge management is a viable means of enabling law firms to identify and capture their 'knowledge assets' and to protect them well, so that legal counsels can fully exploit them as a source of competitive advantage [11]. This knowledge-based view of a law firm suggests that knowledge assets may produce long-term sustainable competitive advantage for the firm because knowledge-based resources are socially complex to understand and difficult for other firms to imitate [12].

The significance of knowledge management was further confirmed by the research findings of the 2001/2 Global Law Firm Knowledge Management Survey [13], in which leading law firms in the US, the UK and Australia recognized that knowledge management is a key business driver.

According to Rusanow [14], law firms typically place heavy emphasis on core explicit legal knowledge, as shown in Table 1:

Table 1: Knowledge types in legal firms

Knowledge Types	**1.1.1 Categories**
Externally created knowledge	Case law, commentary and interpretation
	Legislation and commentary
Internally created knowledge	Best practice (or model) documents
	Precedent (or form) documents

Externally created knowledge is supplied to the firm by external providers such as commercial publishers or the government: typically made available in the library either electronically or in hard copy, such files can be easily accessed by lawyers. According to research by Taylor [15], the external sources of legal information and knowledge most frequently used by legal professionals in the UK are journals (100%), followed by official publications (84%), textbooks (76%) and law reports (69%).

Internally created knowledge can be found in (1) specific documents that a firm has identified as high quality and a good example of its work product, and that could be re-used in a similar factual situation, and (2) precedent documents, which are generic documents in whose development the firm invests for use in many matters, and which will be collected and reused to ensure the baseline quality of work done, as well as to maintain consistency and save time.

Other than traditional legal knowledge, there are many categories of non-legal knowledge that are critical to a lawyer in giving sound advice tailored to the unique needs of clients [14]. For example, in construction litigation, lawyers must recognize the construction industry’s operation and job specification. Therefore, knowledge from expert or external consultant forms an essential part of the knowledge of a construction litigation lawyer.

3. Research Methodology

In Hong Kong, the practice of knowledge management in legal practices is a relatively new concept. The government has positioned Hong Kong as a legal service center in the region, and Hong Kong is also renowned for its international construction standards. However, escalating litigation costs place a burden on construction litigants. This study aims to explore the prospect of nurturing knowledge management for construction litigation in Hong Kong by studying the adoption of knowledge management in law firms.

The exploratory study was mainly conducted through a structured questionnaire. The aim of using a questionnaire was to collect objective data about knowledge management practices from legal service providers. Questionnaires were sent via mail to 170 law firms with construction litigation practices in Hong Kong, which were selected from the law firm directory of The Law Society of Hong Kong. The total number of questionnaires received was 35, yielding a response rate was 20.59%.

4. Data Analysis

About 70% of the respondents had been working in the firm for more than 6 years, and all were experienced lawyers (Table 2). Also, about half of the respondents were partners in their firms, therefore they had a thorough understanding of their firms' management polices and knowledge management practices (Table 3).

Table 2: Respondents' work experience

Work Experience in the Firm	Frequency	Percentage
< 3 years	5	14.29
3-5 years	5	14.29
6-10 years	11	31.43
>10years	14	40.00
Total	35	100

Table 3: Respondents' positions within their firms

Position in the Firm	Frequency	Percentage
Solicitor/ Lawyer	13	37.14
Senior Solicitor	6	17.14
Partner	16	45.71
Total	35	100

4.1 Knowledge Management Practice in Law Firms

Regarding the respondents' knowledge and preferences with regard to knowledge management, 42.86% of the respondents' firms had adopted knowledge management, 22.86% preferred not to adopt knowledge management and 34.29% had never heard of knowledge management. In other words, 57.15% of law firms did not know about or choose to use knowledge management.

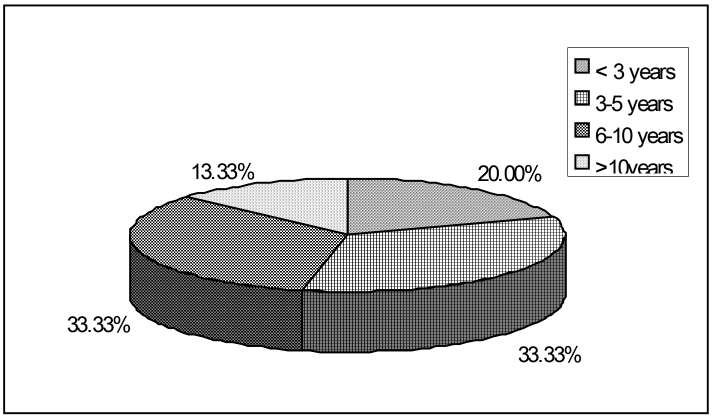

Figure 1: Years of implementing knowledge management system

Of the 15 respondents whose firms had adopted knowledge management, a high percentage said their firms had been using knowledge management for three to ten years, thus it seems that there is mature knowledge management development in law firms, even up to 15 years. This indicates that most of the respondents whose firms had developed a knowledge management system were working for large corporations with long histories.

4.2 Knowledge Management Practice Analysis

Among the 15 respondents whose firms had adopted knowledge management, 14 were in firms that had a company library and 13 in firms that used presentations/seminars for knowledge management practice. These popular methods were followed by discussion (11) and internet-based information sharing systems (10) (Table 4).

Fewer than 30% of law firms applied project briefings or special interest group meetings as their knowledge management practice, and only one respondent's firm used newsgroups.

When respondents were asked about which knowledge management practice is helpful in the process of resolving construction dispute, the result was quite similar to the frequency rank, with the same number thinking that the company library and discussion are helpful. Also, only 20% of respondents thought project briefings, special interest group meetings and news cutting services were helpful, and no respondent thought newsgroups to be helpful.

About 86.67% of the responses indicated that practice group meetings are helpful. It was found that many law firms did not have practice group meetings, but that most thought them helpful. Table 4 shows the frequency and effectiveness ranks of various knowledge management practices.

Another significant difference was in the adoption of presentations/seminars: only 33.33% of lawyers considered them useful; however most of the law firms (86.67%) had adopted them as a knowledge management practice.

Table 4: Adoption frequency and effectiveness of various knowledge management practices

Knowledge Management Practices	**Frequency Rank**	**Effectiveness Rank**
Company library	1	1
Presentations /seminars	2	8
Discussion	3	3
Internet-based information sharing system	4	5
Workshop	5	5
Practical checklists and guidance notes	6	4
Record keeping	7	7
Practice group meeting	8	2
Reviewing sessions	9	8
News cutting service	9	10
Project briefing	11	10
Special interest group meeting	12	10
Newsgroup	13	13

4.3 Analysis of Reasons for Adopting Knowledge Management

The results indicate that respondents were mostly concerned with working efficiency: time saving and improved operational efficiency, with 100% answering agree and strongly agree (Table 5). Other reasons, such as improving documentary administration, enhancing effectiveness in problem solving and enhancing knowledge transfer, were also the expected outcome of adopting knowledge management.

However, some respondents might have been confused on the issue of protection of intellectual capital, resulting in the lowest mean score of 4.13. Protecting intellectual capital was not regarded as a reason for adopting knowledge management.

Table 5: Reasons supporting the adoption of knowledge management practices

Reasons Supporting the Adoption of Knowledge Management Practices	Mean
Saving time	5.53
Improving operational efficiency	5.53
Improving quality of work	5.47
Saving resources	5.40
Improving documentary administration	5.33
Enhancing effectiveness in problem solving	5.27
Enhancing knowledge transfer	5.27
Encouraging knowledge sharing	5.20
Risk management	5.00
Improving communication	4.93
Enhancing improvement incentive	4.80
Protection of intellectual capital	4.13

4.4 Analysis of Factors Leading to Effective Knowledge Management

There are mainly four types of factors that lead to effective knowledge management: human, organizational, technical and financial. Colleagues' attitudes, with the highest mean of 5.8, colleagues' experience and trust between colleagues, with means of 5.27 and 5.07 respectively, were the major human factors leading to successful knowledge management application. Technical support was the second highest mean, 5.67, and is considered essential for the development of knowledge management systems, such as databases and internet-based knowledge sharing systems. In addition, resources/funding (5.47) were the third most important factor for setting up a knowledge management system. It is interesting to note that confidentiality was ranked as the lowest of all the factors, which indicated that it is not a significant reason for not implementing knowledge management (Table 6).

Table 6: Factors leading to effective knowledge management

Factors Leading to Effective Knowledge Management	**Mean**
Colleagues' attitudes	5.80
Technical support	5.67
Resources / funding	5.47
Company culture	5.33
Incentives	5.27
Colleagues' experience	5.27
Top management's commitment	5.20
Trust between colleagues	5.07
Learning atmosphere	5.00
Knowledge management policy	4.93
Recognition of belonging	4.73
Complication of the litigation	4.73
Clarity of information	4.27
Confidentiality of the litigation information	4.00

4.5 Analysis of Difficulties in Adopting Knowledge Management

All respondents agreed that the major difficulties were lack of time and lack of staff incentive, since setting up a knowledge management system and capturing knowledge were time consuming. Resources/funding ranked as the third most difficult aspects in adopting knowledge management, accounting for the mean score of 5.67. It should be noted that poor communication skills and competitive working environment were considered as least problematic (Table 7).

Table 7: Difficulties encountered in adopting knowledge management

Difficulties in Adopting Knowledge Management	Mean
Lack of time	5.87
Lack of staff incentive	5.73
Lack of resources / funding	5.67
No knowledge sharing culture	5.00
Lack of top management support	4.93
Lack of collaboration between staff	4.79
Lack of technical support	4.47
Staff lack of construction knowledge	4.00
Lack of experienced colleagues	3.87
Poor communication skills	3.71
Competitive working environment	3.53

4.6 Analysis of Benefits Generated by Knowledge Management Initiatives

Enhancing worker capability and enriching professional knowledge were the most important benefits generated from knowledge management from the individual point of view; both means were 5.4. From the company's viewpoint, knowledge management can improve quality of work (5.27) and service quality (5.2), which are important for the sustained business of a company. Though increasing company revenue was ranked lowest as a benefit, it is anticipated that profitability can be increased through proper management of a firm's knowledge (Table 8).

Table 8: Benefits generated by knowledge management initiatives

Benefits Generated by Knowledge Management Initiatives	**Mean**
Enhancing employee capability	5.40
Enriching professional knowledge	5.40
Improving quality of work	5.27
Improving service quality	5.20
Increasing working morale	5.13
Enhancing dispute resolution progress	5.07
Improving problem solving efficiency	5.06
Increasing client satisfaction	4.93
Enhancing organizational competitiveness	4.87
Raising company professional image	4.80
Improving communication	4.67
Enhancing innovation	4.53
Increasing company revenue	4.47

4.7 Analysis of Reasons for Not Adopting Knowledge Management

The main reason for not adopting knowledge management was immature development of knowledge management systems, scoring the highest mean of 4.63. Lack of incentive and high cost were the second most frequently-cited reasons for not applying knowledge management, both with a mean score of 4.5. Other reasons include lack of time and lack of top management support (Table 9).

Table 9: Reasons for not applying knowledge management

Reasons for NOT Applying Knowledge Management	Mean
Immature development of knowledge management systems	4.63
Lack of incentive	4.50
High cost of establishing knowledge management system	4.50
Lack of time	4.38
Lack of top management support	4.13
Company culture	4.13
Lack of technical support	4.13
Security	3.88
Lack of construction knowledge	3.88
Knowledge management is not practical	3.75
Insufficient understanding about knowledge management	3.75
Lack of resources / funding	3.50

5. Conclusions

This research explores the implementation of knowledge management practices in legal firms which specialize in construction disputes. It reveals that less than half of the respondents' firms had knowledge management systems in place. For those who did implement knowledge management, some had just started up the system and others had already had one in place for 15 years. It can be concluded that knowledge management practices vary from firm to firm and are most often adopted in large organizations.

Law firms rely heavily on their company library for knowledge and find it effective. Respondents found practice group meetings effective but did not use them frequently in their offices. When asked about reasons for adopting knowledge management, the top three selected are time saving, improving operational efficiency and quality of work, which are understandably important issues in today's competitive fee environment.

The three main factors leading to effective knowledge management included colleagues' attitudes, technical support, and resources/funding. Confidentiality was not deemed to be an important issue in this respect. Respondents found that lack of time, staff incentives and resources/funding were the major difficulties in affecting the implementation of knowledge management. Firms which implemented knowledge management found that enhancing employees' capability and their professional knowledge were key benefits generated from their knowledge management initiatives. This basically gives employees the right knowledge to deal with the right tasks.

When firms were asked about the reasons for not adopting knowledge management, they cited the immature development of knowledge management systems, lack of incentive and high cost. Though it is far from common for law firms in Hong Kong to adopt knowledge management practices, it is anticipated that with the advance in technological solutions, immense competition pressures both locally and internationally and increasing client demands, knowledge management will soon be a fad in the legal industry as the "proof of the pudding is in the eating".

Abstract

This paper focuses on the basics of knowledge management by exploring offered, needed and wanted knowledge. We aim at exploring what kind of issues are critical for succeeding in projects. The research is qualitative aiming at exploring the challenges of knowledge management in construction projects. The paper is based on four case studies in public construction projects in Finland.

We study how difficult it is to know what kind of knowledge you need in a project and how people filter the information they don't want to learn. This filtering may also include issues that they should learn. People do not utilize all the available knowledge recourses. These resources might be people or tools that give new knowledge e.g. on the state of the building they are renovating. The offered knowledge may not be trustable, or you don't need the knowledge at a moment.

Keywords: Knowledge management, project, construction, learning

1. Introduction

The article is based on the findings of the PROLAB-project. The project seeks to find solutions for how the information can effectively be used in project management, specially in construction projects, what kind of procedures help the management of the knowledge and how the obstacles for efficient ways of administrating the information can be removed. These obstacles can be either related to use of new technology or to organization culture.

This paper focuses on the basics of knowledge management by exploring offered, needed and wanted knowledge in construction projects. We aim at exploring what kind of issues are critical for succeeding. However, we don't discuss on success criteria rather we try to find out how knowledge resources are critical and why they are accessed or even more why they might not be accessed. We also discuss how the managers are able to know what offered knowledge they should take seriously in the project environment?

2. Method

The research is qualitative aiming at illustrating the challenges of knowledge management in construction projects. The paper is based on literature review and four case studies in public construction projects in Finland, in three towns. The amount of inhabitants in these towns vary between 23 000 to 185 000. The four construction projects we have been studying were:

- Renovation of a school that had mould problems, total area 7000 m^2 and budget 4 000 000 euros. Project started 1997 and ended 2002.

- Renovation and partly new construction of a school that had mould problems, total area 3000 m^2 and budget 2 7 000 000 euros. Project started 1998 and ended 2005.

- Hospital for senior sitizens, the renovation of the nursing home, total area 7 000 m^2 and budget 5 700 000 euros. Project started 1996 and is still going on.

- University project, 24 000 m^2. Alteration of an old factory into a university and partly new construction. The project started 1997 and was finished at 2004.

We used theme interviews as a means to collect information but we have also collected artefacts of the projects like drawings, memos, and observed the meetings in two projects also we have action research going on in two towns – there we discuss new ways of organizing the knowledge management in the construction projects.

3. Information, Knowledge and Knowledge Management

Knowledge is often defined to be meaningful information. Knowledge is derived from information. What makes difference between data and information is their *organisation* and what makes difference between information and knowledge is their *interpretation* [1]. Knowledge is understanding one gains through experience, reasoning, intuition, and learning. We expand our knowledge when others share their knowledge. New knowledge is born when we combine our knowledge with the knowledge of the others. Wisdom and insight can be included to the definition of knowledge. *Wisdom* is the utilization of accumulated knowledge. [2]

Lillrank [4] defines information in a hierarchic manner. According to him, data are symbolic representations of entities, properties and their states. They have content and form that allow storage, transfer, and retrieval. Data are turned into information by giving them meaning and context. Thus information includes data, meaning, and context. The difference between information and knowledge is in their way to approach the world. Information reveals how the world *is*, knowledge tells how it *works*. Lillrank [4] is interested in information's ability to elicit meaning. Meaning is a function of data and their context. This can be formalized as $M=f(D,C)$ where M is meaning of data, D is data, C is context, and f is the relevant knowledge of how world works in this framework. By means of f an actor can assign meaning to the piece of data and turn it into information. This happens in a communicative act or sensemaking process where the meaning is negotiated with other agents. Negotiation in informal, open system is needed, if data, context, and the knowledge function are fuzzy, otherwise formal, closed systems can do.

Perkins [5] is also more interested in the way information is used or processed than its content. His perspective is called *the access framework.* Access characteristics are divided into four categories. *Knowledge* concerns what kind of knowledge is available: procedural knowledge, facts, strategies, and routines. *Representation* concerns how the knowledge is represented. *Retrieval* concerns how and how effectively knowledge can be found. *Construction* concerns the system's capacity to assemble the new knowledge structures from the pieces of knowledge.

There seem to be no agreement on definitions of "data", "information", "knowledge", or "wisdom". However, there are some aspects all of the authors share. Whether information or knowledge are seen as separate concepts or not, the transformation of data to knowledge or information happens when meaning is given to them. This happens in a shared action, where meaning is negotiated or constructed together with other actors. If we want to improve the processes of project management we should concentrate on the concept of meaning.

According to Bruner [7] our culturally adapted life is based on shared meanings and shared modes for negotiating differences in meaning and interpretations. He describes how this negotiation takes place by means of *narratives*. Narratives are not needed if things proceed in an ordinary fashion. We have theories of mind called "folk psychology" or "common sense": normative descriptions of what makes human beings "tick", what one can expect situations to be like, what our minds and those of others are like, what are possible modes of life and so on. We believe (or "know") that the world is organized in a certain way, that we want certain things, that people hold believes about the past and the future. We believe in coherence of all these believes, that people should not want "irrational" things. We have very strong opinions about how things *should be* and how one *should behave*.

If these rules are broken, narratives are constructed. We need some kind of an explanation of why things are not in the way they should be. Narrative are stories which bring the world together again. They give a reason or meaning to the deviation from canonical cultural patterns. [7, 10] In the world of narratives, no explanation is needed for ordinary or routine, only the non-routine or a deviation needs an explanation or special meaning. The greater the deviation, the more meaning-making is needed.

The problem with the human thinking is, that we are *not* computers or we cannot even be compared to computers. The matter of team work and the shared meaning building has probably more to do with literature and related fields than with IT-studies. If we talk about literature, we talk about qualitative material and qualitative analysis. Bruner seemed to be very strict about this. Studying human thinking as computing is as wise as studying computer programs as literature. They are two different things.

Quinn et al. [8] divided the knowledge of a organisation at four levels: (1) know what: the cognitive knowledge; (2) know how: the ability to translate bookish (know what) knowledge into real world results; (3) know why: the ability to take the know how to unknown interactions; and (4) care why: self motivated creativity, this level of knowledge exists in a organisation's culture.

Knowledge management (KM) is according to Brelade and Harman [3] obtaining and using resources to create an environment in which individuals have an access to information and in which individuals obtain, share and use these information to raise the level of their knowledge. In addition to this individuals are encouraged and enabled to obtain new information for organization.

4. Knowledge Creation and Learning

Knowledge is one of the most important assets in organizations today. The big question is, as Davenport and Prusak [9] state, how organizations manage what they know? Knowledge management should naturally begin with realizing what kind of knowledge is there to be managed. Järvinen [11] has introduced five different types of knowledge:

1. Conseptualized knowledge
2. Operationalized knowledge
3. Cultural knowledge
4. Grounded knowledge
5. Coded knowledge.

Järvinen also defines what kind of forms these different types of knowledge get in organizations (see figure 1).

Types of resourses \ Types of know-ledge	Consept-ualized knowledge	Operatio-nalized knowledge	Cultural knowledge	Grounded Knowledge	Coded knowledge
Long-lasting phycical resources				Products, prototypes, process technology	
Human resources (individual)	fatcs, concepts, principles etc.	know-how, tacit knowledge	Behaviral models, values		
Human resourses (community)	Collective beliefs	cooperation and commu-nication procedures	Values, goals, ideologies etc.	Roles, routines, rituals	
Knowledge and infor. base resourses					Web-pages, databases, manuals etc.

Figure 1. *Types of knowledge and resources [11].*

Next step in knowledge management is to assure that new knowledge, that is needed, is created and also used by right people. Nonaka and Takeuchi [14] have introduced a model of knowledge conversion (see figure 2).

From \ To	Tacit knowledge	Explicit knowledge
Tacit	Socialization	Externalization
Explicit	Internalization	Combination

Figure2. *Four models of knowledge conversion [14].*

Explicit knowledge is something formal and systematic. It can be expressed in words and numbers and it can be easily communicated and shared. Tacit knowledge is subjective and intuitive and thus difficult to process or to be transmitted.[15]

The process of turning either tacit or explicit knowledge into tacit knowledge means learning. A person or a group learns something new so that they internalize the matter. After this learning process it is likely that this person or group is also able to utilize the new knowledge acquired.

The process of externalization means turning tacit knowledge into explicit so that it can be shared. Sometimes this process can be very difficult because people don't necessarily even know what they know. People can learn (internalize) new things and new knowledge in almost every situation and they may begin to use this new knowledge e.g. at their work but how to put it into visible form?

Combining explicit knowledge with another piece of explicit knowledge may create new knowledge under favorable circumstances. And then the circle begins again: learning, sharing, creating new knowledge. And all these processes are needed in every organization.

Miller [13] argues that "there appears to be no one formal or structured process that an organization can adopt to lead it along the pathway to successful workplace learning and to become a learning organization". In practice several different methods are applied from very strict formal ways, like courses, to informal, almost "invisible" ways, like communities of practice (see e.g. [12]; [6]). However, Garvin [22] has provided a three stages that must be gone through if learning is wanted to be useful. The first stage is cognitive, in which new ideas are welcomed as well as new ways of thinking. The second stage is behavioral change that means that the new ideas of the first stage are learnt and used in practice. The third change is the effect of the two earlier into the organization.

5. Available and Used Knowledge Resources

The knowledge resources are studied in the following order (1) long lasting, (2) knowledge and information based resources, (3) individual, and (4) human community resources. The aim is to study the resource types and discuss the availability and level of usage of each resource.

5.1 Long-lasting Physical Resources

The grounded knowledge of the construction projects can be found for example, in the products like windows. The window is not designed from the very beginning they can be picked up from the available lists. The ventilation systems are tailored for the building but after that there is a lot of knowledge grounded in the system. The designers cannot study all the possible technical solutions often they are satisfied in the first solution that fits the purpose.

5.2 Knowledge and Information Based Resources

Knowledge and information based resources are the type of knowledge that is possible to be delivered in written format. It is often called coded knowledge. In practise it may be manuals, drawings, text books, papers, web-pages and other computer systems. Laudon and Laudon [19] classify IS for knowledge management into four main categories (1) those for creating knowledge (knowledge work systems); (2) those for processing knowledge (office automation systems; (3) those for sharing knowledge (group collaboration systems; (4) those for capturing and codifying knowledge (artificial intelligence system). I would say all these systems are knowledge and information based resources.

The designers produce coded knowledge for the construction companies so that they are able to construct the building. The coded knowledge is saved in drawings in 2D or 3D format and specifications or product models. The rules like fire protection or load bearing calculation methods can be partly saved into the computer system and they help the designer to select the right protection style etc.

Also we have systems to give contracting guidelines so that we don't need to invent every time everything from the beginning we have for example, general conditions of contract or task lists of an architect or designer or developer. All this information can be called coded knowledge that can be picked up nowadays from the computer system earlier they were in paper format(in Finlad so called RT cards, in Germany DIN norms) .

We have also found out that if the coded knowledge system is changed the parties have difficulties to take it – like if the project definition plan was made more accurate than normally, people had difficulties to capture the knowledge from them. The project manager even had doubts that they ever read this document. One of the project managers also said he has not time to study all the documents when they bid. The site manger also was sorry to tell that he is not able to study all of them before he starts to work at site.

5.3 Human Resources Individual

The individuals may be inside the project core team or external to that. Each individual plays his/her part in the project based on his knowledge about co-operation and about the construction process. The end users seldom have any previous knowledge on construction project and the need to learn everything but the construction experts often have some experience that is similar to the project at a hand. All of them try to create some kind of mental model what is happening in the project.

A knowledge structure is a mental template that individuals impose on an information environment to give it form and meaning. There are basically two fundamentally different ways of structuring knowledge: theory driven or data driven. Often the professionals in our case projects use the theory driven approach. This way of thinking help individual to understand but they also encourage in stereotypic thinking and; subvert controlled information processing; fill data gaps with typical but perhaps inaccurate information; prompt one to ignore discrepant and possibly important information of the existing knowledge structure; and inhibit creative problem solving [15]. This could be seen in design stage as thinking “this is just a normal school”. That makes it impossible to listen to the real needs of the customer and the normal solutions are seen the only possible solutions.

An individual works often in a routine way and he avoids to evaluate the meaning of every fact. We don’t even use our existing knowledge in an optimal way. I know it is wise to write down in the diary all the meetings but I fail sometimes to write some meetings there or I can fail reading the diary in the morning and miss the very important meeting. I should have known better to write it down, to read it and prepare for the meeting but for some reason I did not do that. The failures are very human. The invaluable issues get less attention like the site manager might find it difficult “writing the official minutes of the meeting”. An other example of this type of happening: the site manager has the information of the building, he has planned the timetable and he is able to understand that the purchasing process should start e.g. two months before the windows are installed but he fails to read the documents and he has to improvise and make the man to do something else before the installation of the windows.

Sometimes the project manager has questioned the need to change the design during the renovation when new things appear and the internal expert claims that the predesigned solution is no longer valid. What the internal expert has to do: he/she has to find external experts that support his/her opinions. In a hasty situation this might not happen and the internal expert might either change the design solution without negotiating or just leave it as it is knowing that the solution will not last – perhaps he she writes about it in the logbook of the site.

5.4 Human Resources Community

The collective beliefs rule our behaviour. One example of such behaviour is the belief that the architect is not able to think economically. As a matter of fact, we assume to know the values, goals and ideologies of our partners though every party is individual. However, the cultural knowledge is important to be understood. For example, the nurses found first the contractors rough and difficult to cope. The co-operation became more comfortable after the both parties had learned to know each other. At the end nurses got all the needed knowledge in order to be able to run the hospital during the construction period. After learning they could create procedures to deliver the information. The knowledge of the other culture was needed before the co-operation and communication procedures were established.

Organisational knowledge structures rely on consensus and agreement [16, 17, 18]. That can be seen as shared frames of reference, recall past events, the creation of events, the creation of stories and myths, vicarious learning, unlearning and memories [20]. This can be seen in construction project in the stories of heroic site managers or engineers that solve impossible problems. But also in the stories that the computer databank cannot help in management of the project or that the software is not yet mature enough to be used. These stories are sources of knowledge for the practitioners. The key decision makers sense and interpret the changing environmental events, they frame them in problem formulation process as problems, opportunities, or crisis [20]. Socio-political themes, such as credibility and power, influence the acceptance of the view [21]. It is so understandable that an old expert can select rather freely his perception to the usage of new knowledge like computer systems. People let them to select their opinions freely younger ones have to show first how much they understand before they are heard. This kind of thinking - who knows what - is accepted and the people who have either formal or informal power can easily reject new ways of working or new knowledge – if they tell that this is not trustable the rest of the construction team believes and everybody shall continue their normal life.

In the beginning of the design process the people that shall utilize the building communicate their knowledge to the professionals – how much we as professionals are able to learn and understand is questionable. Often it might also happen that the power filter effects on who is asked. The managers of the office or kitchen or what ever function are asked what kind of spaces should be designed. The majority of the users have very little possibilities to tell what kind of spaces might make their work more effective. It is most demanding to study all the ideas coming from the workplace – how many should be asked and how to organise this process. Currently it is believed that the managers organise the opinions of their subordinates. This process is seldom supported by the construction project. Following four examples of the knowledge management processes give ideas what kind of possibilities there are available:

- mock up room: different groups of the end users are able to study the mock up room and test how it functions. The comments can be either gathered on the table or the whole group can join in the test use of the space. This kind of rooms were found most helpful

- activity cards help the users to describe what kind of qualities of the space are most important to them. The architect could then read the cards and discuss with the user groups later

- excursions with the professionals. The comments of the users help the designers to understand the special needs of that building. However, the users the designers most often make the excursions separately.

- ICT tools like virtual models of the building make the design solutions visible.

When the designers study the building with the users there should also be the cost expert involved. Since often new ideas appear that often raise the costs and before further developing the ideas there should be some kind of critical checkpoint with the whole project group. However often the users get the impression that when asked what they want they are not heard when the critical checking and finding out how the expenses can be lowered is done without them and the end result is introduced to them afterwards – then they claim that the most important things might be eliminated while the more expensive nice but not that important things were left.

6. Conclusions

The study revealed the many folded resources of knowledge and that it is impossible to utilize all the available resources. The study also showed that the knowledge resources are difficult to be utilised since we as human beings are not able to change our perceptions easily but also that the human communities might prevent the fast changes.

Construction project concern many people and at best the co-operation inspires to better solutions but at worst we hurt the feelings of other person and that might affect their motivation. The individuals can learn to think in two ways data driven and theory driven. Data driven approach helps us to see things in new ways and listen to other parties. Theory driven approach understands the phenomenon via theories and makes it possible to understand without all the facts but misunderstanding is also possible.

There are not available any formal process that ensure the needed utilisation of the knowledge resources. We can, however, claim that by sharing the knowledge with the project parties they are able to improve the knowledge management and gain new innovative solutions to the old problems and that the mental models can be broken in the teams. If you work alone your mental models are not tested as often.

In the introduction we promised to discuss how the managers are able to know what offered knowledge they should take seriously in the project environment. More relevant question is how the manager enables the learning in the team and makes people to learn form each other. The project manager is not able to select what knowledge is reliable but he should be able to know how the project is organised and who knows what and so who is able to select what offered knowledge should be taken seriously.

Effectiveness of National Institutions in Stimulating Construction Innovation in Singapore

Lim Jay Na

George Ofori
National University of Singapore (email: bdgofori@nus.edu.sg)

Abstract

In this paper, based on qualitative system dynamics, a model of the National System of Innovation (NSI) is structured with five main NSI actors: National Institutions; Contactors; Clients; Related and Supporting Firms; and Government. This model, based on the assumption that the key motivation for innovation by national institutions is based on maximising social benefits, highlights the social pressure for higher productivity and quality as the main driving force of construction innovation by national institutions within the NSI. The research findings indicate that technological advance from national institutions that cultivates a competitive environment is able to first, stimulate a direct increase in construction innovation, and second, develop industry clusters that increase contractors' research capabilities. This will encourage contractors to adopt innovation as a long-term strategy towards sustainable competitiveness. Hence, we concluded that the ease of adoption of technological advancements is paramount towards developing a competitive industry and it should be considered in national institutions' innovation policies.

Keywords: Institutions, innovation, national system of innovation, system dynamics

1. Introduction

1.1 Overview of the Role of National Institutions in Construction

Institutions are understood as norms, habits and rules that are deeply ingrained in society and which have a major role in determining how people relate to each other and how they learn and use their knowledge. National institutions involve exploring the national mechanisms, such as governments, higher educational systems and national research institutes, by which new technologies are developed and transferred. Various authors [1,2,3] have recently brought the concept of national institutions as a linkage between the common infrastructures of the national economy and that of the cluster network of inter-relating firms in the theories of National System of Innovation (NSI). It encompasses the "transfer factors" that strongly influence the effectiveness of linkages, the flows of information and skills, and the absorptions of learning that are essential to the firm's innovative capabilities.

In construction today, the dynamic environments that challenge firms in their management of technological innovations and uncertainties across organizational boundaries reveal the significance of the role of national institutions in the industry. Technical know-how is required first, for construction firms to stay viable in the market, and second, as a key tool for competition through innovation. Hence, many researchers [4,5] have identified institutionalised R&D as a possible major source of technological innovation in construction and have asserted the urgency of an increased level of investment in construction R&D. In this paper, using System Dynamics, a model of the NSI is developed to illustrate the role of national institutions in stimulating higher levels of construction innovation within the NSI. From this, it is intended to investigate: (1) the role and effectiveness of national institutions within a nation in stimulating construction innovation; and (2) the possibilities of reformulating national institutional policies to attain higher levels of innovation in Singapore's construction industry.

The time is right for an analysis of the role of national institutions in facilitating higher levels of construction innovation at the national level to be undertaken as it is believed that the innovation capabilities of firms are key sources of competitive prowess and that such capabilities can be built by national action [6]. Moreover, lessons from developed nations such as the US, UK and Japan illustrate the need to provide a rationale for further investments in national institutions as they are progressively facing the economic challenge of decreasing return in research investments [7]. On the other hand, there is a growth in private associations that are modernizing management and improving technical capabilities without the aid of governments [8]. Examples include Japan Association of Representative General Contractors, the Electric Power Research Institute (EPRI) in the US and a consortium of major private building owners in Canada. These associations have sponsored major studies to develop new technologies for application in their industries [9]. Hence, there is a need for a realignment of investments in national institutions and the reconfiguration of policies to achieve greater efficiency and effectiveness from strategies within the dynamic environment of the NSI.

1.2 Methodology

In this research study, secondary statistical data for Singapore were collected from various publications such as the *Yearbook of Statistics* and the *Economic Survey Series*. By applying non-linear regression to the data for the period 1981-2002, a logical deduction of the significance of each NSI determinant to construction innovation is obtained. This aided the formulation of the NSI model. The Statistical Package for the Social Sciences (SPSS) was used for the non-linear regression, while Vensim was used for the development of the NSI system model.

2. The National System of Innovation

2.1 Logics of the National System of Innovation towards Construction Innovation

Freeman defines the NSI as the network of actors in the public and private sectors whose activities and interactions initiate, modify, and diffuse innovations and implement them in new products, production processes, and organizational forms [1]. However, there is no agreement on the key structural elements of an NSI, and how these elements interact to determine the overall pace and performance of innovative activities in a country, as there is no one best way to describe the elements in an NSI when countries are of diverse sizes, stages of economic development, and history [2]. However, from the various models of the NSI [3,10,11], four similar and critical variables can be highlighted:

1. Firms and their dynamic factors that shape innovation in firms such as networks of collaboration with firms' related and supporting industries, rivalry and firms' structure;

2. Transfer Factors – issues of effectiveness of linkages for the transfer and absorption of technology, knowledge and skills between firms and the common innovation infrastructure;

3. Common innovation infrastructure – basic national infrastructures that sets the range of opportunities for innovation such as human capital and financial resources available for R&D activity, policy choices and other national resource commitments; and

4. Chance – a set of factors that exist regardless of any consideration of innovation.

Hence, the main actors of the NSI in the context of the construction industry are:

1. Firms and their dynamic factors that shape innovations in firms - *Construction Clients, Contractors, Suppliers* and other *Related and Supporting Firms*;

2. Transfer Factors – *National Institutions*; and

3. Common innovation infrastructure- *Government.*

Chance, is not considered here because, as Schumpeter observed, innovation cannot take place if the economy does not develop and is only dragged along by changes in the surrounding world. Thus, the impact of chance on innovation, is secondary, and depends on the internal efforts of the economy rather than on chance [12].

In the NSI model presented in this paper, the NSI actors are within the national system of interconnecting relationships, which are further linked by NSI variables. Together, under influence of the key driver for construction innovation through the national institutions, they structure the level of construction innovation undertaken by contractors. The relationships between the NSI variables and the level of construction innovation are defined by the results of the non-linear regression analysis in Table 1. Table 2 shows the measurement frameworks of these variables. The findings from the regression analysis demonstrate that all proposed NSI variables are significant except for Construction Demand. This may be due to quality aspects that are imperfectly reflected in the national income accounts indicator. Nonetheless, abiding by the regression results, construction demand is not included in the model.

Table 1: Non-Linear Regression Analysis Results

Variables	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	42.300	41.631		1.016	.326

Dependent Variable: LCI

R^2 value = 0.933

Table 2: Variables Measurement Framework

Connotation	Variables / factors	Measurement framework
LCI	Local Contractor's Level of Investment in Innovation	Annual R&D Expenditure of Local Contractors
CLP	Construction Labour Productivity	Annual Percentage Change in Labour Productivity
GDP	Construction Demand	Construction's Industry's Contribution to Gross Domestic Product
INI	National Investments in National Institutions	Annual R&D conducted by Government and National Institutions
RDC	R&D Capability of Local Contractors	FTE[#] value of R&D Personnel in Construction
COM	Level of Competitiveness in the Construction Industry	Annual Number of New Construction Companies
CBL	Available funds for private investments in construction innovation	Bank Loans and Advances to Local Contractors

[#] FTE: Full Time Equivalent – Methodology based on Frascati Manual (OECD, 2002)

2.2 Driver of Construction Innovation in the National System of Innovation through National Institutions

Markets do not necessarily lead to the optimal production and distribution of knowledge because there are gaps between the social and private returns from investment in knowledge-enhancing activities. While private returns refer to the gains realized by the firm undertaking the R&D, social returns are based on total benefits, including those flowing to consumers and other producers [13]. Seaden notes that the social rate of return from construction R&D may be several times larger than the private rate of return [9]. A survey by Griliches indicated that between one-third and two-thirds of the economic benefits of R&D are not captured by the organization that performs it [14]. Mansfield observes that innovation in construction materials presents one of the greatest divides, with social returns of 96 percent and only 9 percent of private returns [15]. This may be because construction is a fragmented and highly competitive industry; firms are less able to translate their innovations into higher profits due to their low shares of the market [9]. Hence, there is a call for the government to be involved in controlling these positive externalities, and national institutions offer a possible avenue to do so. Since innovation is largely a public good with social desirability often exceeding those of the market, this desirability is revealed through the social desire for higher construction productivity and quality. Thus, the difference between the desired construction productivity and quality and the actual level provided by the contractors present the pressure on the national institutions to reduce the 'spillover effects' of knowledge benefits. Hence in this paper, the social pressure for innovation is recognised as the key driver of innovation by national institutions in the NSI.

3. Dynamism of National Institutions in the Construction Industry

3.1 The System Dynamics Approach

A qualitative systems model was applied that utilises causal loop diagrams to structure a modeller's understanding of the system and to show the dynamics of the variables. Table 3 presents the typical denotations used in causal loop diagramming. At the foundation of the systems approach are positive feedbacks, represented by a reinforcing loop that is structured by none or an even number of negative links, and negative feedbacks, represented by a balancing loop that is structured by an odd number of negative links. Positive feedback creates reinforcing behaviour and negative feedback moderates a system towards an equilibrium position. The identification of positive and negative feedback structures in economic and management systems is key to modelling and gaining insight into the development of innovation [16].

Table 3: Denotations for Causal Loop Diagramming (Sterman 2000)

Types of causal links	Denotations
	All else remaining equal, an increase (decrease) in the variable 'A' increases (decreases) the variable 'B' above (below) what it would otherwise have been.
	All else remaining equal, an increase (decrease) in the variable 'A' decreases (increases) the variable 'B' below (above) what it would otherwise have been.

3.2 Creation of a Competitive Environment for Stimulation of Construction Innovation

Institutional economists note that the influence of a country's institutions on its ability to master and advance technology is a central way that the institutions affect economic performance [17]. Similarly, Porter observes that national institutions provide the basic factors constraining national or any specific industry's productivity [18]. This relationship is reflected in the NSI model, where construction productivity and quality directly influence the pressure on the national institutions' decisions in deploying resources for technological advancements (Figure 1, B1). Following feedback B1, a higher deployment of resources in national institutions' R&D will lead to technological advances that will once again affect the level of productivity by increasing it at the pace of the adoption of the new knowledge by contractors. However, this flow of activities is structured as a balancing loop that will moderate the level of productivity and quality towards an equilibrium position over time. For example, with a higher level of productivity and quality, there will be lower social pressure on the national institutions to innovate, hence, lowering the pace of technological advancements that will in turn reduce the level of construction productivity.

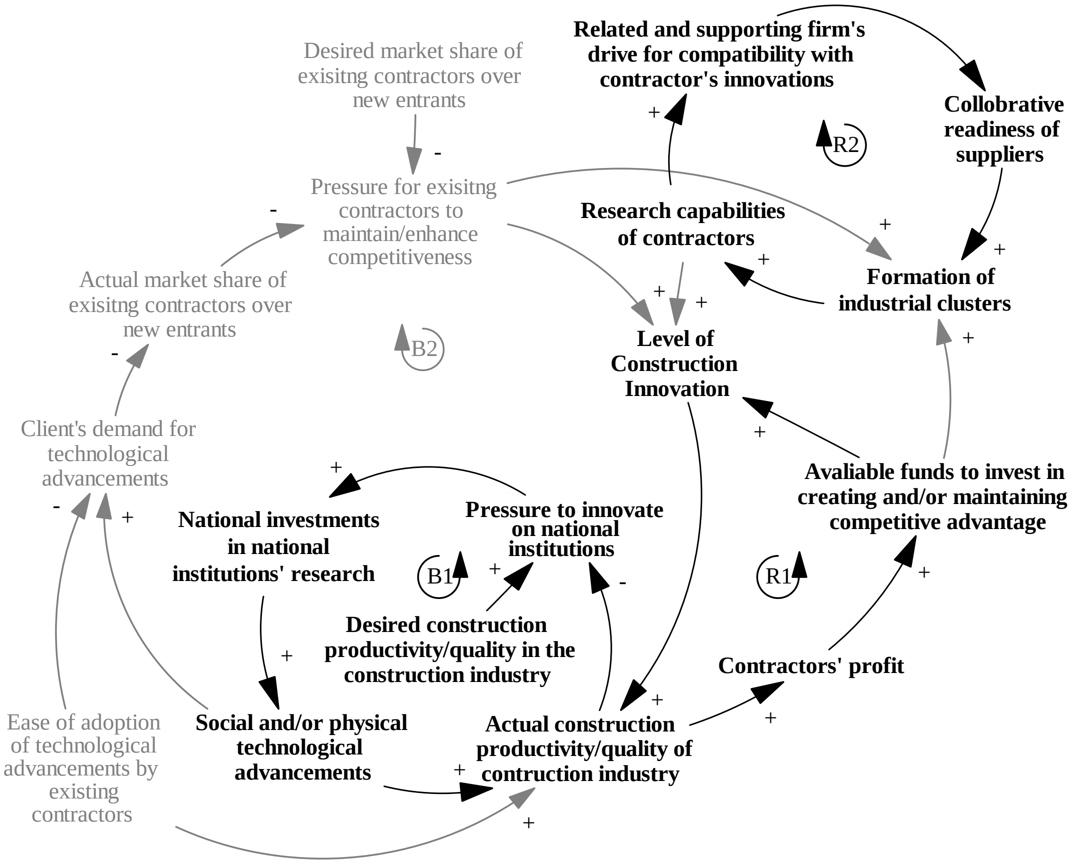

Figure 1: The NSI model for Stimulation of Construction Innovation through NSI

Consequently, it is observed that based only upon national deployment of R&D resources, it appears rather inadequate for promoting innovation in construction [19]. Furthermore, Milford observed that while the role of the government-supported research institutes and universities in the development of the construction industry is without question, the extent of their contribution or influence is difficult to quantify [20]. Hence, the question remains if technological advancements from national institutions are able to stimulate increases in the level of innovation by contractors. Expanding on the feedback loop B1 to the involvement of construction innovation (Figure 2, B2), the regression analysis presents an inverse relationship between productivity and quality, and innovation. Structuring this within the dynamic flow of feedbacks within the NSI, a fall in productivity can trigger higher pressure to innovate on the national institutions. With new technological advances developed by national institutions, clients will demand that contractors implement the new technology. This will trigger a higher level of competitiveness in the industry, as new entrants with the latest technology will enter the industry while incumbents struggle to implement these changes and/or engage in further innovation that will allow them to maintain their competitive advantage and market share. This will cause a higher level of innovation that will cause a second new wave of momentum through the cycle by influencing the level of productivity and quality. The positive relationship between the level of competition in the industry and innovation is supported by the regression results. Thus, although B2 is similar to B1 in encompassing a balancing nature, B2 differs from B1 by first, simulating innovative behaviour by firms and second, enabling the formation of industrial clusters that cultivates higher research capabilities of companies, hence, reinforcing the level of innovation by firms.

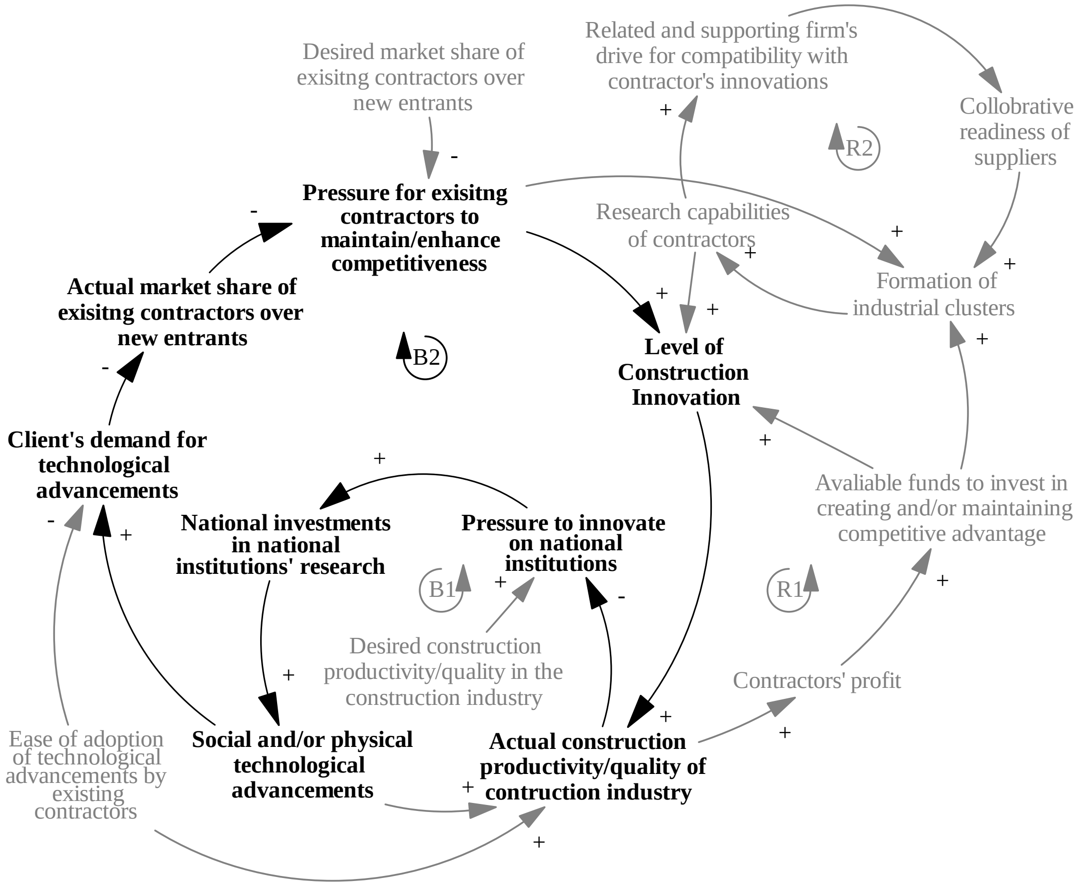

Figure 2: Stimulating Construction Innovation through a Competitive Environment

These observations offer a riposte to the belief that the level of investments in national institutes is already high and any further investments in resources will yield meagre, if any, returns and could even entail a waste of resources [7]. Clearly, even if technological advances by national institutions do not provide adequate returns through a direct increase in productivity and quality, national institutions can still play a significant role in stimulating higher levels of innovation by contractors through developing a competitive environment. However, this requires a reconfiguration of strategies and a careful choice of the type of technological advances. From the feedback and logics in the NSI model, the key variable that determines if technological advances are able to cultivate a competitive environment is the ease of adoption of new knowledge by firms. This is mainly dependent on whether the new technology involves roughly the same kind of knowledge and skills as the old. If so, firms tend to be able to switch over to it rapidly to maintain entry barriers. If not, the presence of new knowledge tends to dilute the extent to which existing firms have advantages over potential entrants and new firms tend to enter the industry [17].

3.3 Competitiveness, a Push Factor for the Formulation of Industrial Clusters

Clusters are defined as 'the geographical concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries, and institutions (such as universities, standards agencies and trade associations) in particular fields that compete but also cooperate' (Porter, 1998, p.199). Clusters can be seedbeds of innovation because of the potential of intellectual spillovers and agglomeration economies [7]. The Survey of Cambridge notes the difficulty of cultivating dynamic industry clusters as although government's pressure on the corporate and research sectors backed by financial incentives can create an agglomeration of establishments devoted to research, the spillover effects of such action can be slow to materialize [21].

Nonetheless, Porter notes that the underlying motivation for cluster formation is firms' ability to gain competitive advantage as through industrial clusters, firms are able to form commercially useful forms of collaborative interaction that encourage deeper inter-firm transactional engagements [18,22]. This view is reflected in the NSI model (R1, Figure 1) where the pressure for existing contractors to maintain and enhance competitiveness in the industry can lead to the formation of clusters as firms search for membership in established networks to develop their competitive base. This will increase the research capabilities of contractors that will, in turn, attract related and supporting firms as they align their compatibility with contractor's innovations. Hence, this cultivates collaborative readiness among the parties that will once again facilitate the formation of innovation clusters that further enhance firms' research capabilities. With such a reinforcing behaviour, the higher the number of clusters formed, the higher the contactors' research capabilities developed. This will eventually increase the level of innovation in the industry. This positive relationship between contractors' research capabilities and the level of innovation is supported by the regression results. Hence, the competitive environment which national institutions are capable of providing not only stimulates contractors to engage in innovation, but it also compels firms to engage in the formation of clusters that will engage in innovation as a long-term strategy.

3.4 A Financial Perspective

Although it was established earlier that there is an inverse relationship between construction innovation, and productivity and quality, the model shows that productivity and quality can also provide a reinforcing impact on the level of innovation. Figure 1, R2 indicates that higher productivity and quality will bring about higher profitability to firms. This will led to more funds being available for innovation, thus creating a higher level of innovation. This relationship is supported by the regression analysis where the higher the level of bank loans and advances to contractors the higher the level of construction innovation. Nonetheless, as the regression results show, an inverse relationship exists between innovation and the level of productivity and quality. Therefore, it can be deduced that construction productivity has a greater impact on the level of construction innovation through competition rather than the financial support.

4. Policy Recommendations

Nelson notes that empirical scholars of technological advance have always understood that the rate and character of technological advances are influenced by the institutional structures supporting it, and that institutions also strongly condition whether and how effectively new technologies are accepted and absorbed into the economic system [17]. Nonetheless, it was observed that supplementary to the effectiveness of technology transfers between national institutions and contractors, the ease of adoption and the type of technological advance provided by national institutions also determines the extent of influence national institutions can have in stimulating contractors to innovate. As Metcalfe notes, the scope for technological improvements, the likely productivity of innovative efforts and the significance of the developments in the underpinning of knowledge bases must be understood if policy is not to collapse into vague generalities [23]. Yet too often development of new knowledge by national institutions tends to lend strength to prevailing technologies that favours incumbents and that involve a direct improvement in productivity and quality rather then the stimulation of innovation.

Moreover, it was deduced that construction productivity has a greater impact on the level of innovation through competition rather than profit. Hence, direct improvements in productivity and quality has limited stimulating effect on the level of innovation. In stimulating innovation through national institutions, competitiveness offers a much better avenue. Thus, there is an increasing need for a reconfiguration of institutional strategies of nations not because increasing national resource mobilizations and investments are inadequate recipes to embrace but due to the need to recognise that the extent of latent economies of scale differs from technology to technology, and the variation in the ease of learning by incumbents is of major significance compared with providing more generally accessible sources of technological know-how.

From the analysis, to enable the creation of a competitive environment that will stimulate greater levels of innovation in the construction industry, new knowledge from national institutions should facilitate a radical shift away from old practices. For instance, in Singapore, the Housing and Development Board's (HDB) Prefabrication Technology Center (PTC) was set up in 1994 to spearhead the use of prefabrication technology in Singapore. Its main activities include conducting research and development (R&D) on materials and systems and to design, develop and produce prefabricated building products [24]. Although this industrialisation programme has enabled the local construction industry to improve productivity and quality, it has little or no stimulation effect on the level of innovation within the industry.

However as the balancing nature of the feedback in B2 indicates, competitiveness depends on the oscillating nature of social pressure that obstructs the continuous growth of innovation through competitive pressures. However, this oscillating behaviour is due to the socially desired level of productivity and quality remaining constant throughout the interaction time. In the first cycle, high levels of innovation induce improvements in actual construction quality and productivity. This leads to lower pressures to innovate as the gap between social desire and actual construction quality and productivity contracts. Hence, with a lower pressure to innovate carried over into the second cycle, the level of innovation will be lower compared to the first cycle. This leads to a lowering of the construction quality and productivity, widening the gap between socially desired and the actual, hence, causing the pressure to innovate to oscillate upwards once again into the third cycle. Therefore, to reduce the magnitude of the oscillation, social intentions must be frequently reviewed as the industry develops, to convey the right signals to firms.

5. Conclusion

To address the effectiveness of national institutions in stimulating construction innovation in Singapore, this study employs the concept of the NSI through qualitative system dynamics. A series of supporting logics that aid the analysis of national institutions' technological advancements towards stimulating greater innovation by contractors are identified. The social desire for higher productivity and quality emerged as the main driving force for technological advancements by national institutions within the NSI. From further analysis of the NSI model, it is concluded that the ease of adoption and types of technological advances provided by institutions supplement the effectiveness of technology transfers between national institutions and contractors in stimulating a higher level of innovation by contractors. However, this analysis is based on the restricted analysis of monetary investments without the consideration of other social factors such as the impact of personal mobility in the construction industry.

Nonetheless, it is shown that the system approach can assist national institutions in developing more robust and responsive policy initiatives in their choice of technological advances. In addition, the institutional structure has a profound effect on and reflects, the technologies that are in use, and which are being further developed. However, the findings from this study need to be augmented with further research such as work aimed at quantifying each variable within the NSI. Moreover, applying this NSI model quantitatively across several countries will enable the derivation of the magnitude of influence each NSI determinant has on construction innovation.

Organisational Learning

The Influence of Social Networks on Inter-firm Exchange in Construction

Abstract

The choice of an appropriate governance form is seen to be essential for the effectiveness and efficiency of construction projects. However, the insufficiency of legal mechanisms to govern inter-firm exchanges in construction has been perceived. Formal contractual relationships have to be complemented and even substituted by social mechanisms in order to allow an efficient cooperation among autonomous parties within an uncertain and complex environment. This conceptual paper addresses the foundation of social mechanisms and their role in coordinating and safeguarding exchanges in construction projects. As part of an ongoing research project it develops a framework that establishes the relation between the social network of construction firms and the inter-firm exchange in projects.

Keywords: Social network, social mechanisms, inter-firm exchange, project governance

1. Introduction

During the last decades the search for appropriate governance structures for construction projects has become one of the main tasks to meet the fragmented structure and adversarial nature of the industry. Particular attention has been paid to the role of contracts for the suitable allocation of liabilities and responsibilities of each project party [1, 2, 3]. It is argued that the contract is the means by which the clients define the project organisation and align their objectives with those of other parties [4] and that the relationship of project participants largely depends on the choice of a proper contracting strategy [1, 5]. The transaction paradigm of Williamson [6] is mostly used as the theoretical framework for identifying alternative contractual arrangements and explaining their efficacy in terms of avoiding claims and disputes and leading to a win-win situation. In the light of transaction cost economics, previous research has also stressed that due to the unique and uncertain nature of construction projects, formal contracts are ineluctably incomplete, leaving project parties vulnerable to opportunistic behaviour of other project participants [2, 4, 7]. The inadequacy of legal mechanisms to govern inter-firm exchange in construction has been perceived [2, 7]. Relational contracting is regarded as the basis for alternative forms of governance coordinating and safeguarding construction transactions. Formal contractual relationships have to be complemented and even substituted by non-legal or social mechanisms in order to allow an efficient cooperation among autonomous parties within an uncertain and complex environment [1, 2, 3, 5, 8]. Although the literature strongly emphasises the importance of social mechanisms for the efficacy of construction projects, little is known about how these mechanisms evolve and how they can resolve coordinating and safeguarding problems of inter-firm exchanges in construction. The social network theory advances our understanding in this regard. Since the critique of Granovetter [9] and the growing importance of inter-firm alliances, the economic behaviour of firms has been considered as socially embedded. It is postulated that the structure and the quality of all a firm's relationships shape expectations of exchange partners and create opportunities "that are difficult to replicate via markets, contracts, or vertical integration" [10]. Based on that, it can be proposed that the economic exchange in construction projects is also affected by the social network of the project participants, including the dyadic and the overall relations of these participants [11].

This paper addresses the foundation of social mechanisms governing construction transactions and their role in coordinating and safeguarding exchanges in construction projects. Its intention is to develop a framework that establishes the relation between the social network of construction firms and the inter-firm exchange in projects. Specifically, it shows that exchange conditions in construction require certain exchange behaviour of project parties to diminish transaction costs. Furthermore, the paper explains how social mechanisms may facilitate this exchange behaviour by acting as informal rules between construction firms. Finally, it demonstrates how these social mechanisms may emerge from the relational context in which the economic action of construction firms is embedded. The paper represents the conceptual part of an ongoing research project which aims to determine the role of social networks in construction and their effects on inter-firm exchanges.

2. Exchange Conditions and Exchange Behaviour

The importance of social networks for inter-firm exchanges in construction derives from specific transaction features in that industry, under which neither market nor hierarchy are efficient forms for governing the construction process. The exchange conditions of construction rather call for a cooperative engagement of autonomous firms within projects.

The dependency of the constructional task on clients and locations represents the primary condition explaining the necessity of cooperative behaviour of independent parties for construction transactions. Firstly, it results in *transaction uncertainty*, which refers to the inability of individuals and organisations to predict the probability of unexpected events during the course of transactions [6, 12]. Since in construction it is the client who triggers the planning and erecting of a building, construction firms are confronted with a fluctuating and uncontrollable demand. This is intensified by location-bound, weather-influenced activities which lead to seasonality. As a result, construction firms face long-term uncertainty about getting contracts. Although other industries also show similar kinds of environmental uncertainty, construction firms are insufficiently able to balance fluctuations through e.g. stock-keeping or creating a market for their services. Demand is the factor that directly determines the utilisation of their resources. As a response to a changing demand rate, subcontracting services increases flexibility and minimises fixed assets by reallocating resources cheaply and quickly [7, 13]. Not only long-term but also short-term contract uncertainty pushes firms towards the decoupling of services. Short-term contract uncertainty is based on binding offers for products which do not exist. Construction firms can consider the associated risks through a supplement to the quoted price, but this lowers the chance of getting the order. Passing a part of the uncertainty to other firms who might be better able to bear the risk reduces the danger of costs not covered by the bid price. Thus contract uncertainty facilitates the fragmentation of constructional tasks, the activities of which are carried out by a number of independent firms.

Dependency on clients and locations is, secondly, combined with *transaction complexity*, which refers to the number, diversity and interdependence of inputs needed to complete constructional tasks. Many construction projects not only entail a variety of components and equipment for the realisation of foundation, carcass, façade, ventilation or heating systems, but also have to process a wide range of technical, legal, environmental and organisational information. In addition, due to the different requirements of clients and locations, these inputs vary within and between projects to a certain extent. Numerous, interconnected and variable inputs lead to mutual dependency of activities which in turn boosts the need for coordination. Time pressure, a very common characteristic of construction, heightens the necessity of coordinated activities additionally, as reducing the time to complete a project requires activities carried out simultaneously [13]. Due to transaction complexity, increased management effort is required to direct decoupled activities resulting from contract uncertainty in order to achieve the overall project objectives.

Thirdly, dependency on clients and locations entails *post-contract asset specificity*, which refers "to the degree to which an asset can be redeployed to alternatives uses and by alternative users without sacrifice of productive value" [14]. Winch [8] points out that, in most cases, asset specificity has no relevance in construction before the contract is let. As firms offer services which have to be yet transformed into a building meeting the requirements of client and location, construction services tend to be exchangeable. That is, the procurement of disaggregated services based on lowest price seems to be most advantageous. However, once the contract is made, specificity arises due to the difficulty of replacing the firm without prohibitive costs [8]. A reversed situation occurs, as construction transactions themselves do not occur in a pure spot market. The costs and course of the project process rely on temporally bounded services completed on time and within budget.

It becomes obvious that construction projects have to combine two diametrically opposed organisational principles. On the one hand, contract uncertainty and pre-contract asset specificity push firms to fragment the construction process. On the other hand, transaction complexity and post-contract asset specificity intensify the need for integration and coordination of the activities to be fulfilled during the course of the construction process. Contractual arrangements are inadequately able to overcome this problem of coordinating and safeguarding transaction processes between autonomous firms, as they cannot cover each possible change of circumstances without increased costs for negotiating, drawing and enforcing the contract [2]. Legal mechanisms alone cannot prevent opportunistic behaviour and assure cooperative behaviour among project parties. Rather social mechanisms are needed to balance the competing demands of exchange conditions by “sanctioning cooperative behaviour in today’s transaction positively and sanctioning uncooperative behaviour negatively in future transactions”[15].

3. Exchange Behaviour and Social Mechanisms

If autonomous firms cooperate, they acknowledge their mutual dependence and their willingness to work for the success of the project. This implies, first of all, confidence that transaction partners will not act opportunistically. Trust is a significant characteristic of cooperative behaviour, which allows project parties to interact through the collective constitution of meaning and shared expectations about their future behaviour [16]. It provides the basis for an effective information exchange and a joint problem solving, both essential for complex and uncertain project environments. A lack of trust eliminates communication processes and leaves conflicts unsolved with destructive impacts on project outcomes. As mentioned above, under the specific conditions intrinsic to construction, contracts can absorb uncertainty and complexity of construction transactions only to a certain extent. Trust also has to be evolved “out of shared background assumptions and shared experience” [17]. Social mechanisms facilitates trust include *experiences from the past*, *expectations of the future*, *reputation* and *a common normative context* [13, 15]. They all have in common that they reduce uncertainty about the future behaviour of project partners and thus allow a more efficient interaction.

Experiences from the past refer to previous transactions between parties and are shaped by the duration, frequency and success of these transactions. Former exchanges allow firms to directly collect information about the behaviour of project partners. Granovetter [10] points out that information from one’s own past relations with an organisation is better than information from a trusted informant who is reliable. First-hand information is cheap, richer, more detailed and accurate [10]. Thus, through past experiences the behaviour of project partners becomes more predictable and, in case of a successful collaboration, more trustworthy [15]. A first indication of the effect of past experiences on inter-firm exchanges in construction was provided by Eccles [18]. In his investigation of homebuilders’ subcontracting practice, he found that general contractors built up stable relationships with specialised subcontractors and that this repeated exchange was in conjunction with lower use of formal bidding and contracting [18]. Similarly, Zaghloul and Hartman [3] found that the willingness of clients and contractors to use a different method of risk allocation regarding disclaimer clauses increases with the previous working experiences the contracting parties have with each other.

Expectations of the future refer to forthcoming transactions between parties and are shaped by the assumed significance of these future transactions. This means that the possibility of future exchanges between same project parties influences the current behaviour of these parties. If anticipated gains of future transactions outweigh short-term benefits from cheating in the present, cooperative behaviour is more likely. It is suggested that violating an ongoing agreement decreases the probability of cooperation in the future, whereas cooperation during the current transaction can also bring on cooperative behaviour during the next exchange [19]. However, future transactions have to be sufficiently important to make opportunism unproductive. The chance to interact again and the relevance of coming exchanges have to be large enough to promote cooperative behaviour through reciprocity [19]. One can argue that expectations of the future play a minor role in construction, since the necessity of allocating different resources for each constructional task leads to changing organisational constellations. However, Constantino et al. [5] suggest that business relationships between contractor and subcontractor differ in various construction sectors. They investigated commercial contractors and compared them to the homebuilding sector by referring to the aforementioned study of Eccles [9]. Their results revealed that the market extent in terms of geographical spreading differs between homebuilders and commercial contractors. Homebuilders operate in a geographically limited area that reduces the possible choices or substitutions of specialised services, which in turn leads to good working relationships. Commercial contractors show a lower tendency to durable relationships with subcontracting firms, as they are active in a larger geographical area. This can be seen as an indicator for the effect expectations of the future have on construction transactions. Because of the chance of repeated exchanges, the likelihood of cooperative behaviour in regionally restricted markets increases.

Reputation refers to the expected behaviour of persons or organisations based on information about or observations of its past behaviour. It is bestowed upon by others and reduces uncertainty as it allows a firm to know something about the reliability, capability and goodwill of potential transaction partners [13]. Analogous to expectations of the future, the value of reputation evolves from reciprocity. Cooperative behaviour in the present can induce cooperation in the future through recommendations of third parties. Likewise, opportunism can prevent cooperation in coming transactions due to warnings of the same parties [15]. Winch [8] points out that reputation is of paramount importance in construction, since "(f)or a professional firm to lose its reputation for consummate project execution is a serious, and sometimes fatal, penalty" [8]. However, as mentioned earlier, first-hand information is preferable. Due to the diffusion across several organisations, information about reputation may be inaccurate, misinterpreted or give a false colour [13].

A common normative context refers to shared assumptions and values of a group of persons or organisations which guide activities of and create typical behaviour patterns among members of these groups [13]. It coordinates the interaction of autonomous parties by generating convergence of expectations and establishing an idiosyncratic language [6]. These generically understood rules, being valid for a range of transactions, facilitate cooperative behaviour. A common normative context also defines and reinforces the parameters of acceptable behaviour, the violating of which can lead to collective sanctions [13]. An indication for the influence of cultural issues on cooperative behaviour in construction projects is mostly provided through the negative effects the absence of a common normative context has. Particularly the strong affiliation to a professional or organisational group seems to shape the attitude of project parties to each other. It is argued that the similarity of persons allows the maintenance of a self-image, which in turn prompts these persons to treat others belonging to the same group more favourably than persons from other groups [7, 20]. More generally, it may take a long time to establish a common understanding among autonomous project parties.

Although several studies contain references to the impact of social mechanisms on exchange behaviour in construction projects, theoretical and empirical knowledge about how they may facilitate the coordination of construction transactions is scarce. Moreover, until now little has been known about the foundation of social mechanisms in construction. Thus, the following paragraph will shed light on the role of social networks in this regard.

4. Social Mechanisms and Social Networks

A social network can be defined as a specific set of relations among a defined group of persons or organisations, the characteristics of which may be used to interpret the social behaviour of the persons or organisations involved [21]. Thus, social networks in construction include dyadic and overall relations of clients, contractors, subcontractors or suppliers. It is argued that the social network comprises the context in which economic activities occur and that the social relations affect transactions, their outcomes and the behaviour of transaction partners [10]. The project-based nature of construction – construction exchanges are conducted within projects - suggests three types of social networks: *project-dependent networks*, *cross-project networks* and *project-independent networks*.

The project-dependent network comprises all temporary relations among persons or organisations involved in realising the constructional task in a project. Through project-dependent networks the actual inter-firm exchange in construction takes place. Due to the dependency of constructional tasks on clients and locations, the interaction of project parties to complete the transactions and to ensure their efficiency requires, to a certain extent, the evolvement of alternative governance mechanisms. Thus, through project-dependent networks, the social context in which transactions are embedded is activated. In doing so, social mechanisms are not only applied but, simultaneously, reinforced or diluted. Interacting in projects also enhances the likelihood of mutual contacts, experiences and diffused information which future transactions may refer to. Particularly reputation and experiences from the past strongly depend on the current behaviour. Based on that, the extent to which cooperative behaviour is prevalent in project-dependent networks may be seen as an indicator for the existence of social mechanisms. The more trustful relations among project parties exist and the better the communication and problem-solving techniques are, the more it is likely that social mechanisms govern the ongoing transactions.

The cross-project network includes all recurrent relations among persons or organisations that go beyond single projects and span a series of constructional tasks. They may arise consciously through joint agreements or are due to regionally restricted or specialised markets. In all cases the number of possible exchange partners is reduced, which leads to repeated transactions between the same parties. Cross-project networks create one part of the social context which is capitalised through project-dependent networks. Particularly experiences from the past and expectations of the future are founded in the linkages of projects the same parties are involved in. Continued interactions may permit transaction partners to learn from each other, to develop common working routines and to reduce the amount of monitoring activities. Moreover, repeated exchanges may increase the commitment among parties, allowing the achievement of individual and joint goals. Finally, intensive and intended long-term cross-project relations may establish a common normative context which renders the behaviour of network firms more reliable and predictable. Given this, it can be argued that frequency, duration and success of repeated transactions determine the degree to which social mechanisms contribute to cooperative behaviour in construction projects. However, until now there has been a lack of empirical research that substantiates the link between variables of repeated transactions and social mechanisms. For example, it is still ambiguous to which extent project constellations differ and, thus, influence the role social mechanisms play for transaction governance. A strong change in constituting projects seems to inhibit the evolvement of a social context, whereas a moderate movement among firms may tie different groups together and may activate reputation through circulating information. Furthermore, there is little evidence whether the activation of social mechanisms requires the allocation of the same persons in project teams.

The project-independent network contains all permanent relations among persons and organisations that are built up besides the transactions necessary to realise constructional tasks. It generates the other part of the social context project-dependent networks make use of. Project-independent networks may evolve through the participation of persons or firms in social, trade, professional or other voluntary organisations [22]. This participation allows information about third parties to be collected and spread across organisational boundaries, which in turn may lead to valuable reputation. It can be expected that the more project parties are connected through project-independent networks, the more information each party knows about the other parties and the more a party's behaviour can be sanctioned. Participation in voluntary organisations may also lead to the development of a common normative context. On the one hand, similar preferences and values can emerge. On the other hand, professional organisations in particular provide guidelines which regulate the practice of their members by specifying roles, procedures and accepted solutions to problems. It can also be assumed that the membership of project parties in project-independent networks fosters collective knowledge, shared sense-making and understanding among these parties [23]. Similar to cross-project networks, little is known about the importance of personal relationships in contrast to organisational membership with respect to the effect of social mechanisms.

5. Conclusions

There is an ongoing discussion in theory and practice about the possibilities and ways for more collaborative relations in construction or alternative forms of project governance. It is proposed that a closer relationship between firms is beneficial to the overall performance of the industry. However, Dubois and Gadde [23] conclude that modifications of the current relational pattern may reduce some uncertainties and increase others. They describe the construction industry as a combination of tight couplings in projects and loose couplings in the permanent network of firms. On the one hand, loose couplings complicate coordination by preventing inter-firm adaptations to complexity and uncertainty. On the other hand, loose couplings provide slack and flexibility to handle tight couplings in projects. Dubois and Gadde [23] emphasise that the combination of tight couplings in projects and loose couplings in the permanent network appears to be appropriate in terms of project efficiency but less favourable in terms of learning and innovation. It is obvious that for finding an appropriate governance form, the mechanisms coordinating and safeguarding construction transactions have to be considered. Besides contractual arrangements, social mechanisms appear to be indispensable to ensure the effectiveness and efficiency of construction projects.

This paper highlighted the role of social mechanisms for inter-firm exchange in construction and the foundation of these informal rules in the social network of project parties. It developed a framework which deepens the understanding about the efficacy of the social context for transactions in construction. As part of an ongoing research project, the framework depicts the starting point for the forthcoming empirical investigation. The investigation focuses on medium-sized contractors (50-100 employees). The choice was made on the assumption that this type of firm mostly operates regionally, which increases the possibility for recurrent transactions with other project parties. Additionally, personal relationships seem to be particularly beneficial to these firms, as executives are formative for the firms.

The empirical study is divided into two parts. The first part includes semi-structured interviews with the top management of medium-sized contractors. The aim is to put the relations of the framework into a more concrete form and to make them operational. The second part consists of a questionnaire survey aiming to give a broader support for the previous findings. At the conclusion of the research project a more detailed picture about social networks and their influence on inter-firm exchange in construction should be obtained.

Abstract

This paper discusses the facilitating role of social networks in trans-organisational learning in the construction industry. A qualitative learning model is used to illustrate how knowledge diffuses from an individual to the industry. Social networks are classified as intra- or inter-organisational. Empirical research based on 395 questionnaire responses received in the Hong Kong construction industry shows that knowledge transfer in intra-organisational social networks is stronger than that in inter-organisational social networks. Learning activities such as knowledge-sharing workshops are recommended to exploit hidden organisation's knowledge created by social network learning, which should be a valuable asset that organisations and their members own in common.

Keywords: construction, information, knowledge transfer, organisational learning, social network

1. Introduction

Information is permeable across construction organisations, given the openness of organisational boundaries. Organisational-barrier-free information exchange reflects the spontaneous nature of organisational learning as noted by Nelson and Winter [1], Levitt and March [2], Huber [3] and Glynn et al [4]. Social networks play an influential role in spontaneous organisational learning by forming the major channel for boundless human interaction across organisations [5]. Organisation's knowledge created in such a way is of social, community-based nature [6], and most likely a raw, valuable asset that organisations and their members own in common [7]. Departing from a theoretical consideration that spontaneous organisational learning is ineluctable organisational behaviour, this paper first discusses the facilitating role of social networks in trans-organisational learning in the construction industry by modelling a ripple effect stemming from individual learning. The empirical work that follows compares potentials of intra- and inter-organisational social network learning using a data sample collected in the Hong Kong construction industry.

2. Spontaneity of Organisational Learning

Organisation's knowledge originates from organisation members. Organisational learning denotes a process over which knowledge of organisation members is shared, developed further by interaction, and then transmitted throughout the organisation. Organisational learning of this nature is partially emergent, relatively unplanned and inspired by some incidental processes [8]. A distinct feature of such emergent organisational learning is spontaneity. In other words, learning is not intentional.

Although many construction organisations have recognised the need for learning as observed by Jashapara [9], it seems that the concept of intentional organisational learning has yet to root firmly in the strategic minds of many construction executives, as revealed by Kululanga et al [10]. This paradox should not negate learning construction organisations, however. In practice, spontaneous organisational learning in the construction industry is common.

As Nelson and Winter [1], Levitt and March [2], Huber [3] and Glynn et al [4] point out, organisational learning may have no intent. Organisational learning loosely denotes learning with or without intent. Perhaps all organisations are learning. The only difference should be the presence of learning intent. The positive relationship between organisational learning and competitiveness accruing as a result of improvements in actions [11] or organisational performance [12] should be the prime strategic issue of learning with intent. Learning intent would influence the organisation's outputs, experience and knowledge. Organisational learning of this nature is planned organisational learning, which is intentional and formally planned [8]. Organisational learning should be considered as a two-layered learning system. The outer layer is coated with learning intent. The inner layer is made of spontaneous texture, which is the primary focal point of this research.

3. Organisational Learning as an Open System

Spontaneous organisational learning is osmotic, given that organisations are not closed systems. There are influxes and leakage of knowledge in organisational learning. Very often knowledge would drain out from or enter organisational learning as a result of inter-organisational interaction through, for example, strategic alliances, joint venture projects, inter-firm staff rotations, subcontracting and mergers.

Inter-organisational human interaction highlights the openness of organisational learning. People working for different organisations would contact one another beyond the organisational boundary. Social networks are major channels facilitating boundless human interaction across construction organisations [5]. Organisational learning considered here is practical. It takes the role of social networks into account. Organisations being the agent of organisational learning at issue allow the penetration of knowledge. Knowledge is absorbed from the external environment, and refined in the organisation. Such refined knowledge will then be exported to the external environment.

4. Social Networks

Social networks can be regarded as a social relationship among actors, who can be people, groups, organisations, communities or even society [13]. As Brown and Duguid [14] point out, social networks linking actors for common practices or knowledge domains facilitate rapid dissemination and assimilation of knowledge in common. The role of social network in learning should originate from its cognitive context. It holds that people keep social relationships to secure mutual support of their interpretations of issues and events, which are important but ambiguous [15]. Focusing on their use in learning, Fu et al [5] consider social networks as individual networks of friends and acquaintances; practitioners thereby can earn other network members' support in dealing with problems encountered at work [16]. For concise discussion purposes, the terms 'social network' and 'social learning network' are considered synonymous in this paper.

Trustworthy behaviour, which coheres with friendship, is a significant trait of social networks. As Liebeskind et al [17] point out, social networks crystallise shared norms of trustworthy behaviour, based on which practitioners can exchange information. Friendship is not merely a social context embedded in inter-organisational ties for quality information exchange [18, 19, 20, 21]. Rather, friendship contains both sentimental and instrumental elements [22], which collectively bring forth routine reciprocity of nominations [23]. By linking people working in the same field of work, friendship lubricates social network learning. Learning takes place when people share knowledge with those who are appropriate, helpful and reliable.

5. Intra- and Inter-Organisational Social Networks

Intra- and Inter-organisational social learning networks are emergent products of intra- and inter-organisational interaction. Inter-firm staff rotations contribute greatly to the formation of inter-organisational social networks. Organisation members not only develop social networks with present colleagues, but also keep friendly contact with former colleagues. This situation occurs concurrently among organisations. It can be seen that not only inter-organisational social networks are intertwined, but also many inter-organisational social networks are extensions of intra-organisational ones.

Knowledge transfer needs networks channelling useful information. Interpersonal ties constitute the structure of social networks for use in this respect. According to Podolny and Page [24], interpersonal ties are interpreted as a nexus of relationships between two or more individuals who keep contact for recurring and enduring exchange. Given the organisational boundary, two independent types of interpersonal tie are identified. They are the organisational tie and the embedded tie. These two types of interpersonal tie constitute a distinct feature differentiating inter-organisational social networks from intra-organisational social networks. The structure of inter-organisational social networks contains no organisational ties, whereas intra-organisational social networks are a hybrid structure of organisational and embedded ties.

The organisational tie refers to the structure of organisation members' networks for work. It exists within the organisational boundary. Organisational ties are formed mainly based on the colleague-relationship. Organisational ties substantially remove physical barriers to face-to-face communication. As a traditional medium of intra-organisational communication style [25], face-to-face communication is useful to knowledge transfer because of the tacit nature of knowledge. In face-to-face communication, organisational members can share knowledge with words, supplemented with graphics or even gestures. Interpersonal contact proceeding of this hybrid nature can enhance the effectiveness of knowledge transfer, especially when the topic of discussion cannot completely be verbalised.

The embedded tie refers to the structure of communication and friendship networks. It exists within or beyond the organisational boundary. With no organisational governance, friendship is the major context of embedded ties. Embedded ties facilitate the transfer of fine-grained information, the growth of trust, joint problem-solving arrangements [19, 26], all of which enable and enrich social network learning.

6. Social Networks Bridging Organisational Learning to Collective Learning

Social networks connect organisational learning to collective learning. Knowledge transfer by interaction recognising the influential role of social networks is depicted in Figure 1. Four levels of learning are identified according to the institutional structure of the construction industry as follows: individual learning (of organisation members); organisational learning; inter-organisational learning (between organisations in various fields of business in a construction sector); and collective learning (between all construction organisations, in particular stakeholders including the government, educational institutions, professional bodies and trade unions).

Individual learning works as a process of continuous, incremental modification of the current behavioural mode to improve the quality of recurring action responding to a set of given situations recurring with high similarities. A datum is the element of information, moving at large in the external environment. In the words of Corner et al [27], information is 'potentially meaningful data that deserve attention'. Interpretation denotes a process of organising data in a particular context [28]. Data are assigned with meanings by interpretation. Individual learning is endowed with adaptive behaviour as a continuous data interpreting process over which useful data are retained but useless data are discarded [29]. Knowledge is loosely considered as useful interpreted data. An interpreted datum is defined as the elemental unit of knowledge.

Knowledge transfer is simply considered here as the dissemination of interpreted data. It proceeds as a dyadic interaction between two learning agents: the knowledge provider and the knowledge receiver. As depicted, the four levels of learning meet at a common point, which is also the centre of individual learning. An interpreted datum stems from an organisation member (a knowledge provider). Organisational boundaries are permeable, as denoted by non-solid lines. Knowledge moves freely over different learning levels. This responds to a prior research assumption that organisational learning is an open system. A ripple effect of knowledge transfer departs from this common point. Knowledge may be transferred to knowledge receivers at any one of the learning levels or both via social networks. A few scenarios of learning are given as follows. When the knowledge receiver is a colleague, organisational learning will stem. When the knowledge receiver is a friend working for another firm, inter-organisational learning will take place. When the knowledge receiver is a friendly practitioner working together for a committee in a professional institution, collective learning will begin.

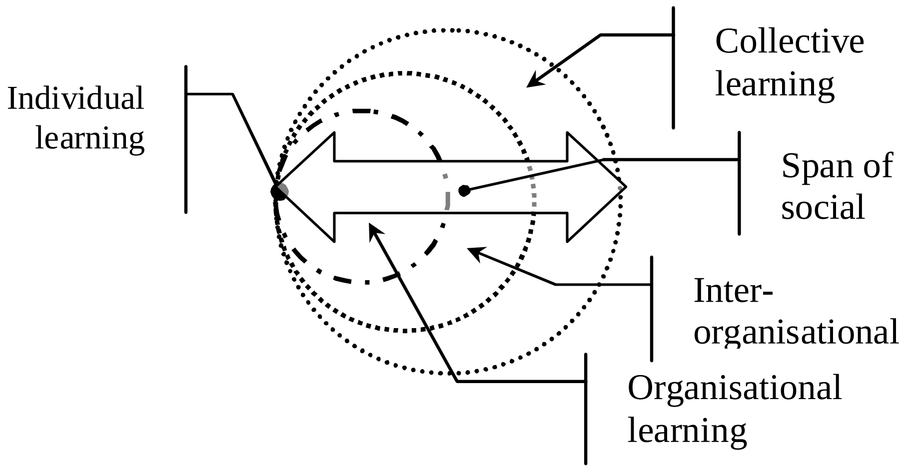

Figure 1: Knowledge transfer by social networks in construction

7. Effect of Intra- and Inter-Organisational Social Networks on Knowledge Transfer

Intra-organisational social networks are made of organisational and embedded ties, whereas inter-organisational social networks specific to the present research are solely made of embedded ties. Given that embedded ties exist in both inter- and intra-organisational social networks, it is argued that the frequency of face-to-face communication, which is technically called the 'intensity' of social networks [13], is an overwhelming factor accounting for disparities of the speed of knowledge transfer.

The rationale for this argument is practical. When an individual encounters a problem at work, colleagues he/she knows should be the preferred people from whom useful advice may be sought. This is understandable in two aspects. First, responses from colleagues are convenient and quick. Friendly practitioners who can offer the same advice working in another office may not be immediately reached. Second, discussion in an office can keep a common focus on the object turning the problem up. For instance, a design engineer is disturbed by a problem of construction details. Face-to-face communication between colleagues keeping a common focus on drawings in this instance is effective interpersonal contact. Frequent contact at work empowers knowledge transfer by providing people with more opportunities of face-to-face communication.

8. Empirical Evidence

The empirical work reported below aims to justify the research hypothesis that knowledge transfer in intra-organisational social networks is stronger than that in inter-organisational social networks.

Empirical data were collected through a questionnaire survey conducted in the Hong Kong construction industry from May 2003 to March 2004. Questionnaires were distributed to practitioners by the use of the authors' social networks in the industry. Friendly practitioners of the authors were first requested to answer the questionnaire and forward it to their friendly practitioners, who are actors at the second level of the authors' social networks. Those friendly practitioners at farther levels of the authors' social networks were requested to do so. This referral method produces a ripple effect in data collection. Finally, a sample comprising 395 (N) valid responses received from practitioners in 17 fields of professions and technical work having on average 10 years of work experience in the construction industry is used for empirical analysis.

In the survey, respondents were requested to express their attitudes towards the dissemination of a lesson learned (expressed as a failure case experienced by another practitioner in the questionnaire) in their social networks. The question reads as follows:

Suppose that one of your friends or acquaintances, who also works in the construction industry, tells you a failure case (including the background and the consequence) that is largely a technical mistake of a practitioner. Will you tell this story to others whom you know?

Respondents were requested to answer the question in respect of the following five categories of people 'whom they know':

1. Superiors (S);

2. Colleagues very familiar to (Cvft);

3. Colleagues fairly familiar to (Cfft);

4. Colleagues not familiar to (Cnft); and

5. Friends, but not present colleagues (F).

Respondents have seven choices of equal-appearing intervals in the form of a Likert scale in answering this question. The score is arranged in ascending order in relation to the magnitude of the descriptive choices. 'Extremely unlikely' scores '1'; 'Very unlikely' then scores '2', and so on until 'Extremely likely' scores '7'.

Results of the survey show that Cvft and F are the top two categories of people to whom respondents are willing to convey the lesson learned. Cvft and F are representative categories of actors of intra- and inter-organisational social networks, respectively. Survey results of these two categories can provide empirical evidence to justify the research hypothesis.

Differences between scores for Cvft and F are compared. A score difference (S_{Cvft-F}) is simply the net difference between scores for Cvft (S_{Cvft}) and F (S_F) given respectively by a respondent. Then,

$$S_{Cvft-F} = S_{Cvft} - S_F \tag{1}$$

An S_{Cvft-F} obtained by Eq. 1 ranges from –6 to 6. An S_{Cvft-F} value of 6 indicates that a respondent would be 'extremely likely' to tell a friendly colleague (Cvft) the lesson learned, but 'extremely unlikely' to do so when the knowledge receiver is a friend (F). An S_{Cvft-F} value of –6 is a reverse indication of an S_{Cvft-F} value of 6.

The frequency distribution of S_{Cvft-F} values is shown in Figure 2. Results of the S_{Cvft-F} distribution indicate that many respondents prefer Cvft to F in disseminating the lesson learned. The range ($0 < S_{Cvft-F} \leq 6$) is regarded as the Cvft-preferred Region, which indicates respondents' preference for Cvft. 219 positive S_{Cvft-F} values are observed. They represent 55.4% of *N*. It is about 7 times larger than the corresponding percentage of another range ($–6 \leq S_{Cvft-F} < 0$), which, representing 8.1% of *N*, indicates respondents' preference for F (regarded as the F-preferred Region).

Summary statistics of score differences are shown in Table 1. Statistical inference proceeds to check if paired-differences in S_{Cvft-F} observations are statistically significant. Now the null hypothesis is that the population mean of S_{Cvft} is equal to or smaller than that of S_F. The alternative hypothesis is that the population mean of S_{Cvft} is greater than that of S_F. The *t* test statistic 14.042 (d.f.=394, *p*=0.000) is significant at the 1% level. The null hypothesis should be rejected. It is concluded that the population mean of S_{Cvft} is significantly greater than that of S_F. These empirical observations provide evidence supporting the research hypothesis.

Table 1: Summary statistics of S_{Cvf} , S_F and S_{Cvft-F}

	N	Mean	SD
S_{Cvft}	395	5.660	1.081
S_F	395	4.635	1.454
S_{Cvft-F}	395	1.025	1.451

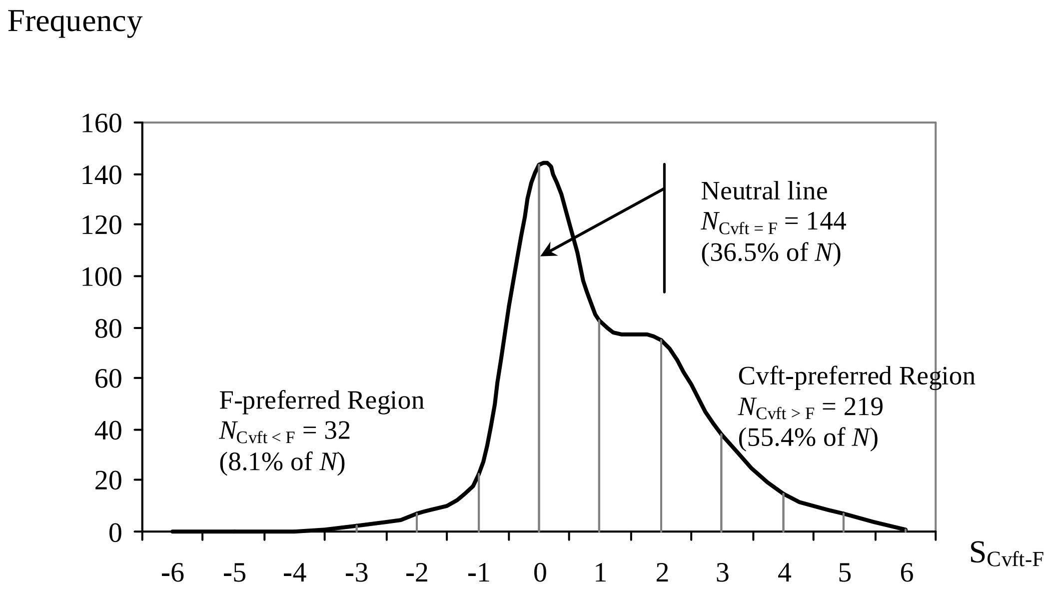

Figure 2: Score differences between Cvft and F (N=395)

9. Conclusions

Social networks bridge organisational learning to collective learning by facilitating organisational-barrier-free knowledge transfer. Intra-organisational social networks will emerge when the organisational structure is coated with a social context. Inter-organisational social networks this paper speaks of are largely extensions of intra-organisational social networks, resulting from inter-firm staff rotations. The questionnaire survey provides empirical evidence showing that knowledge transfer in intra-organisational social networks is relatively stronger. This finding highlights the value of hidden organisation's knowledge created by social network learning. Knowledge embedded in organisational members' social networks will definitely be a source of competitive advantage if it can be fully exploited. Learning facilitators are recommended to institutionalise social network learning by, for example, organising regular in-house workshops to provide organisation members with ample knowledge-sharing opportunities.

Abstract

Organizational learning (OL) is a set of activities to obtain organizational memory (OM) by acquiring, sharing, interpreting, integrating and institutionalizing knowledge. Although the OL process of construction firms has been discussed for several times, utilization of the output of these activities has not been investigated in depth. All companies can learn but the advantage of learning is revealed when companies enhance their decision-making abilities through their OM.

The major objective of this study is to explore how construction companies create OM and how they exploit this asset in strategic decision-making process. Within the context of this research, a framework is constructed to model the OL process in a construction company and based on this model; an interview study has been conducted with eight leading Turkish contractors.

This survey revealed the strengths and weaknesses of the firms in terms of OL competence. The most significant point is that although some perceptions and attitudes are common to all companies, some may change due to the differences in cultures, strategies, structures, ages of companies and the markets they are in. Results show that construction companies make use of several knowledge sources and mechanisms to acquire knowledge; they are successful at the collection and storage of knowledge but they are weak in exploitation of the corporate knowledge in strategic decision-making stage. In addition, they are unable to increase their OL competence due to some company and industry specific barriers. One of the key outputs is that companies are not familiar with the decision support systems (DSSs) that benefit from OM. Such systems enable OL by assisting decision-makers in processing, assessing, integrating and organizing knowledge.

In this paper, a case-based reasoning (CBR) model is proposed as an OL enabler and to facilitate decision-making in international market entry decisions within the construction companies. This tool is generated under a software package by adopting CBR as the problem solving approach, which finds solutions to new problems making use of the past experiences which are based on 215 cases from the Turkish construction industry. The model produces two outputs that are indicators of attractiveness of a project and competitiveness of a company,

which are the key decision criteria in an international market entry problem. The application of the tool will be demonstrated by a case study and potential benefits of using the proposed model as an enabler of OL in a construction company will be discussed.

Keywords: Knowledge management, organizational memory, decision support systems, case-based reasoning

1. Introduction

Strategic management of knowledge requires intuiting, interpreting, integrating and institutionalizing of knowledge flows [1] which take place at individual, group and organization levels respectively. Formation of an organizational memory (OM) is a critical knowledge management activity which facilitates organizational learning (OL) process. Stein and Zwass [2] define OM as the means by which knowledge from the past is brought to bear on present activities, thus it helps learning from previous experiences. OM becomes a corporate asset by capturing, organizing, disseminating and reusing the knowledge created by its employees [3].

This paper is based on the findings of a research study carried out to investigate how construction companies create their OM and how they exploit this corporate asset in strategic decision-making. The OM formation process has been modeled considering that the companies mainly learn from their own experiences, from the experiences of competitors and from external sources [4]. Knowledge gained through different sources are shared, interpreted and institutionalized to create OM. Based on this model, a semi-structured interview form has been prepared and interviews have been conducted with 8 leading contractors in Turkey.

Findings of this study reveal that construction companies are successful at acquiring knowledge but they are weak in sharing and utilizing the acquired knowledge in decision-making. Although companies need the tools to support their strategic decisions, they are not familiar with this kind of systems. As a result of the interview findings, a knowledge-based system is decided to be developed to support international market selection, for which the companies necessitate a tool to assist their decision at most. A CBR-based decision support system (DSS) has been developed, which facilitates learning from experiences of competitors in international markets.

2. Organizational Memory in Construction Companies

Since the construction industry is project-based, discontinuous and fragmented, OL is difficult for the companies. For this reason, as well as the systematic knowledge management activities, construction firms should also provide a culture that can facilitate continuous learning in order to benefit from the advantages brought by OL. A successful culture of OL can influence performance, long-term effectiveness and survival of an organization [5, 6]. Lehner and Maier [7] stress the function of OM in connecting past and present decision-making situations that directly influences the performance of a company.

Robey et al. [8] define OL as an intentional and unintentional organizational process, which enables the acquisition of, access to and revision of OM and finally guides to organizational action. Using the logic behind this definition, an OM framework is constructed [4]. Figure 1 illustrates how OM is formed, utilized during decision-making and finally revised. Although companies create OM as a result of the learning practices, the advantage of possessing such an asset should be revealed in the quality of the strategic decisions made in the company.

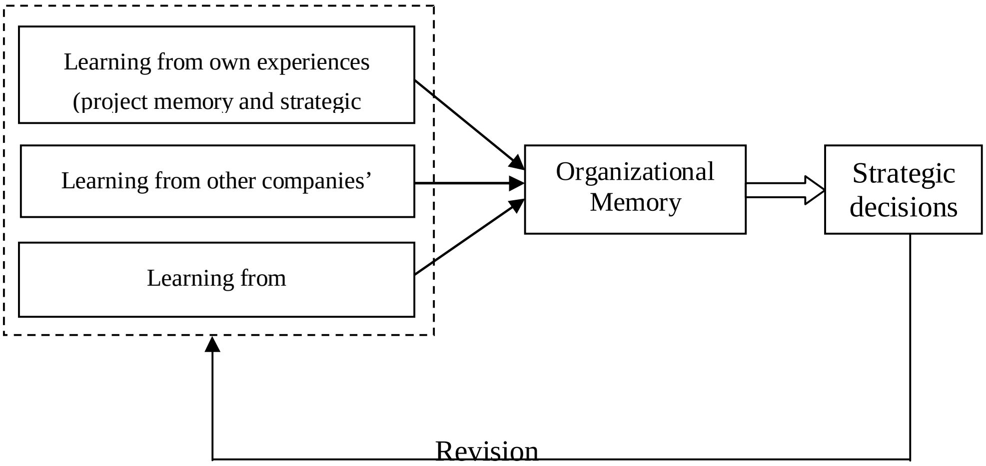

Figure 1 Framework explaining the OM formation and utilization

The three components that constitute OM are own experiences of the company, experiences of other companies and knowledge gathered from external sources. OM is used to improve strategic decisions and after the actions are taken, new experiences are added to OM. This is a cyclic process rather than a sequential process as newly acquired knowledge from the given decisions should be used to revise OM. How this cycle operates in each company depends on company characteristics and the height of OL barriers.

3. Research Study

Semi-structured interviews are carried out by company professionals in order to highlight the realities of the Turkish construction industry in terms of OM. 8 companies volunteered to participate in the research. The structure of this interview study is demonstrated in Figure 2. Questions are grouped under eight headings, one of which is the company information and other seven topics are related to the knowledge management practices are discussed below.

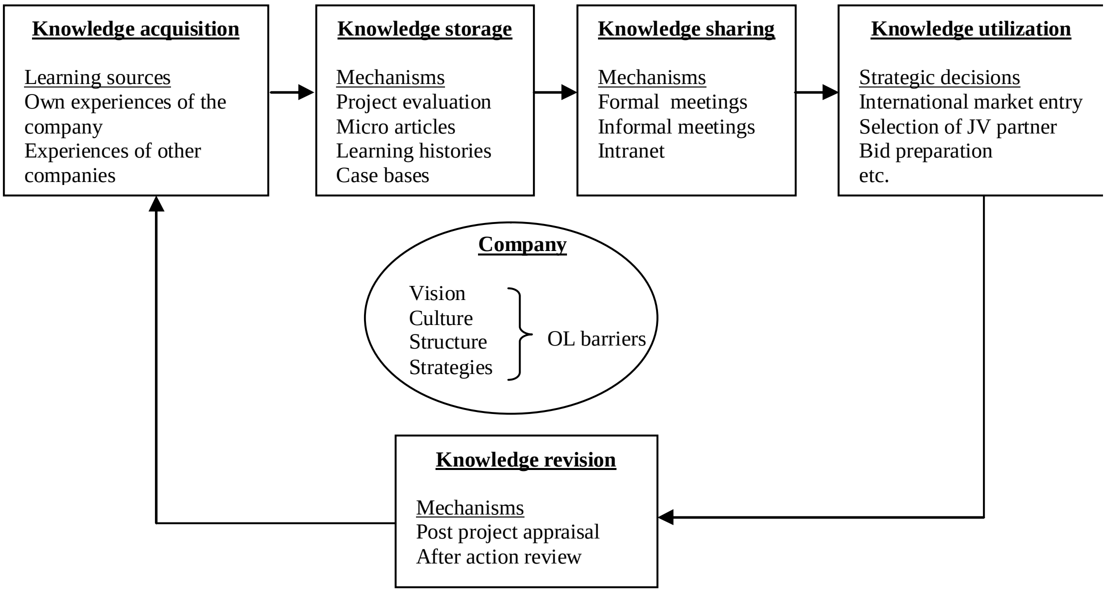

Figure 2 Structure of the interview

1. Learning from own experiences: Lessons learnt from own experiences of the company can be examined under two categories; the knowledge gained from the projects, namely the project memory and the knowledge gained from strategic decisions. These two sources shall be improved as more projects are carried out and more strategic decisions are made. Since the unit of work performed in the construction industry is project, companies mainly learn from the projects they have undertaken and parties involved in these projects. Knowledge may well be acquired as a result of "unrealised projects" where the experiences related with bidding, business development, financial management activities etc. are of paramount importance. Companies do not only learn from the completed projects but also from the ones that companies intend to perform but are not awarded. In this respect companies are asked to state which kind of data they collect and how they store information within their organizations.

2. Learning from other companies' experiences: Construction companies may learn from success/failure stories of their competitors or if they establish long-term or short-term (project-based) partnerships with other companies such as clients, contractors, suppliers etc., they may learn from their practices, expertise and perceptions. Also, relevant expertise of companies operating in sectors other than construction may be transferred to the construction business.

3. Learning from external resources: External learning sources are the parties, which are not directly involved in the projects that construction companies perform, or not among the parties they cooperate or compete with. The company managers are given a list of possible external learning resources such as universities, consultancy firms, governmental or foreign bodies that are not clients, etc. and they are asked to state from which resources they learn.

4. Organizational memory: While individual knowledge is an important part of OM, it is always at risk of being lost. Knowledge acquired through the learning sources have two types, namely explicit (codified) and tacit. Explicit knowledge can be accessed by company members easily since it becomes a corporate asset by being stored in computers in the form of electronic repositories or it is documented in paper form. The tacit knowledge is hidden in the beliefs, perceptions, norms and actions of individuals and requires to be transferred to explicit knowledge in order to be stored. Under this heading, there exist questions regarding the contribution of different learning sources to the company's memory and the percent distribution of knowledge types according to how they are accumulated in the company.

5. Utilization of OM in strategic decision-making: Due to the unique nature of each construction process, inherent uncertainties and incomplete scope definition, it is almost impossible to have all the needed information at the time of decision-making and mostly decision problems are solved by expert judgment. Entering an international market, entering a new market related/unrelated to construction sector, selection of JV partners, preparation of bids and restructuring of the company are among some of the critical strategic decisions made by companies. To facilitate decision-making, DSS, which combine analytical methods with expert opinion, are proposed to be utilized. In this study, it is argued that OM is a valuable asset that must be built and exploited in order to give more reliable decisions at the corporate level and enhancing the codified component of the memory will aid strategic decision-making with a DSS. The research sample is asked to evaluate the importance/effectiveness and utilization level of OM and DSS during decision-making.

6. Organizational learning competence: A company is assumed to have high OL competence if it is good at benefiting from knowledge acquisition sources, if it has knowledge storage mechanisms, if this knowledge is shared and interpreted by the company members, if the end product of these knowledge management activities, namely the OM can be effectively utilized in decision-making process and if the company can continuously revise its OM. Companies are evaluated in terms of the learning practices performed within their organizations.

7. Organizational learning barriers: Although OL is accepted to be necessary and critical concept for the survival of the companies, due to some reasons, OM creation is not at the desired level in most firms. In literature some authors mention the existence of some enablers and barriers to capture and diffuse knowledge such as structure effects, cultural context, the climate for change, skills and capabilities, technological mechanisms and objectives. To find out the dominant barriers to OL, the company managers are asked to list why they are not fully performing the requirements of OL and the causes of deficiencies to structure the OM.

4. Research Findings

Important conclusions can be derived from the answers of the respondent companies, which are extensively discussed in Ozorhon et al. [9]. The most significant point is that although some perceptions and attitudes are common to all companies, some may change due to the differences in cultures, strategies, structures, ages of companies and the markets they are operating in.

Findings of this study reveal that construction companies are rather good at creation of project memory. Experiences gained by the company as a result of previously realized construction projects constitute the major component of OM. The experiences of other companies have a limited contribution to OM, although all respondents agree that learning from failure and success stories of other companies is of paramount importance for construction companies. This kind of information usually resides in the brains of experts, but it is rarely stored in databases and institutionalized.

Companies think that the role of OM in strategic decision-making is limited. Intuition and experience usually play a far more significant role when giving bidding decisions, entering a new market or making new investments. All respondents agree on the importance and use of the codified component of OM in order to build mathematical models especially in bid preparation. Companies do not utilize DSS to aid them in decision-making in spite of the fact that they believe it would be beneficial to have such programs. However, answers of the respondents demonstrate that especially for international market entry decisions, assistance of a computer program would be very beneficial.

When the knowledge management activities are considered, in general, companies seem to be most successful at acquiring and revising knowledge. Knowledge sharing is the most important activity, which is followed by the utilisation of knowledge in decision-making however, these activities are not usually performed as successful as they are regarded to be important.

Some OL barriers related with the nature of the construction industry and service/product exist as well as company-related factors such as cultural barriers. Although perceptions about validity of learning barriers change significantly from one company to another, high employee turnover in construction and corporate management/leadership style seem to be common problems that plug the way of OL in construction companies.

5. CBR as an Organizational Learning Tool

In the experience-based construction industry, previously acquired knowledge is critical to solve similar problems that can be encountered in the future. Although the output of construction is a unique project, construction processes show similar characteristics. As CBR is an analogical learning technique, it seems to be a suitable approach to solve construction problems, which are generally solved through past experience and knowledge of expert people.

CBR is “the process of solving new problems by adapting solutions that were used to solve old problems” [10]. Indeed, CBR uses the principles of human reasoning as it learns from the past situations. With this feature, CBR can be applied in problems that can be solved through previous experiences. CBR solves problems through a process that involves some basic steps as retrieving relevant cases from the case memory, selecting a set of best cases, deriving a solution, evaluating the solution and storing the newly solved case in the case memory [11].

Due to the project based nature of the construction industry and high employee turnover rates, knowledge becomes hard to capture and store. Thus, construction companies should build case libraries that will enhance OL and create OM. These case libraries enlarge OM by institutionalizing the individual knowledge. On the other hand, CBR-based models enable this knowledge to be shared and utilized in the strategic decision-making process. So, development of CBR-based strategic DSS is proposed to increase the OL capability of the companies.

6. CBR-INT

International market selection is a complex decision as numerous factors related with the country, market and project have to be considered and there is no mathematical formulation that can easily associate these factors together with company specific factors with the attractiveness of a project and probability of getting the job given the competitive conditions. There are models developed by many researchers on this subject using different techniques such as cross impact analysis [12], analytical hierarchy process [13] and neural networks [14]. Case-based reasoning (CBR), which exploits past experiences to bring solutions to new situations, has been identified as a promising tool.

The system, as an enabler of OL, is generated under a software package namely, ESTEEM that adopts CBR principles to solve the problems. Experiences of Turkish contractors are used to demonstrate how experiences of competitors may be utilized to facilitate decision-making in a construction company. The model, CBR-INT is developed by using 215 real international project data; 200 cases are used for training the program and 15 cases are used for testing purposes. As input information, 16 features related with the project, market and the country are identified and by the help of CBR-INT, as important indicators, the attractiveness value of an international project and the competitiveness value of a company for that project can be predicted (Figure 3).

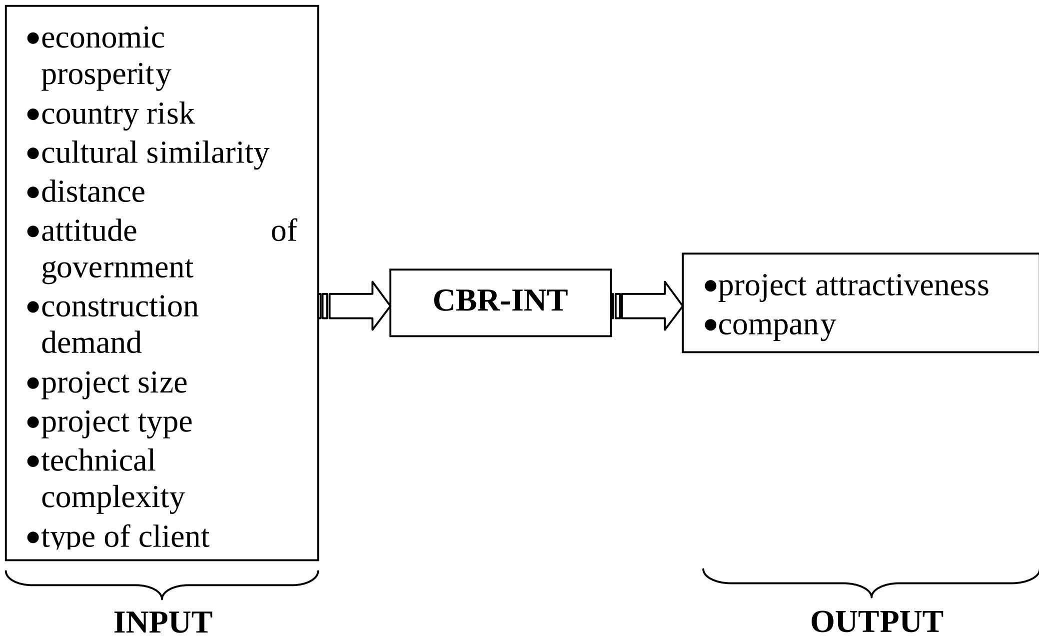

Figure 3 Modeling of CBR-INT

The system adopts both manual and weight generation methods for similarity assessment and retrieves similar cases in the order of their similarity scores to the target case. Adaptation is carried out with different manual methods that will help final prediction. After trying several adaptation models, the best one is selected based on the performance values. The reliability of the best model is found to be around 90%. The case library can be enriched by the incorporation of the latest cases and a larger case library can be used for the retrieval step for the solution of the next problem.

An experienced and large company in Turkey was asked to provide the data of a real international project in order to test the applicability and performance of CBR-INT. The target case was an infrastructure project that requires high experience and where there exists very high competition. The user, business development manager, was requested to specify the values of input parameters; then CBR-INT is run to predict the attractiveness and competitiveness values. Figure 4 presents the retrieved cases list on which similarity scores, case names and corresponding values appear.

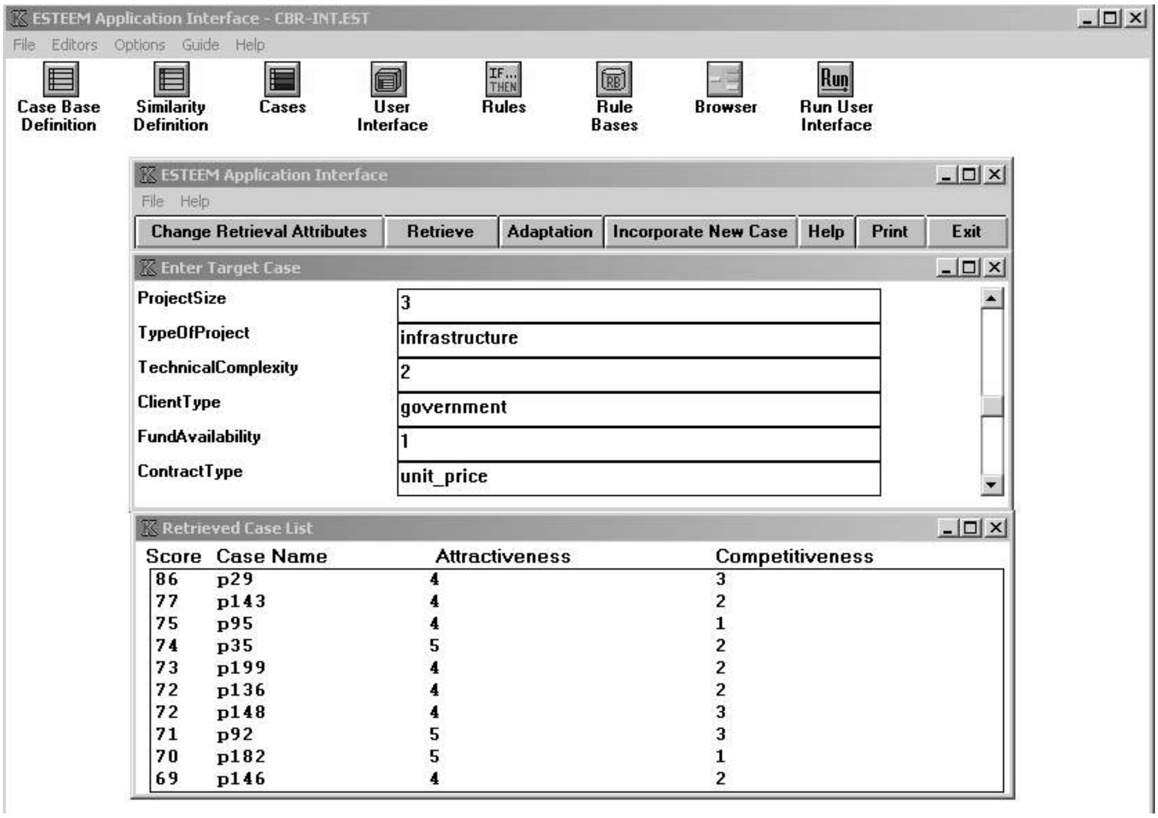

Figure 4 An application of CBR-INT: Retrieval of similar cases

At the end of the application, the project seemed to be highly attractive but the competitiveness value of the company was medium. This situation was expected because the company was meeting the requirements to perform the job but the threat of the competitors was almost impossible to avoid. When the results of the system and the real decision given by the business development manager are compared, it is observed that the model had produced exactly the same conclusions as an expert would do. The manager also was highly satisfied with the performance of the system as it is easy to use and it increases confidence about given decisions.

7. Conclusions

One of the main concerns of this study is to find out how construction companies create OM and how they utilize this asset during strategic decision-making. In the context of this paper, the framework representing the OM formation and utilization is presented; the interview study prepared using this framework is discussed; some of the research findings are summarized and a DSS, which was developed to aid construction companies in international market entry decisions is introduced.

Answers of the respondents denote that construction companies learn from several sources; they are very good at acquiring and storing knowledge but they cannot share knowledge among employees widely. Almost all respondent companies learn mainly from their own experiences;

learning from other companies' experiences and external resources have less contribution to the OM within the companies.

When the knowledge management activities are reviewed, it is seen that companies are most successful at acquiring and revising knowledge. However, they believe that knowledge sharing and utilization of knowledge in decision-making are the most important two activities, which should be carried out in the construction companies, but they are rather weak in these activities. One of the main barriers of OL is the high employee turnover rate that prevents companies embed knowledge within the organization. The other important factor is the firm infrastructure and culture that determine the effectiveness of the learning environment.

One of the most significant points is that the role of OM in strategic decision-making is limited for the construction companies. Company managers usually do not refer to codified knowledge in OM or utilize DSS; rather, they make strategic decisions based on their intuition, experience and expertise. Construction companies especially need a decision support tool for international market entry as found from the interview study. In order to meet the requirements of the industry, a CBR-based DSS is developed.

CBR has become a promising technique in the construction management field due to its ability to reason from the past that well suits to the construction problems. Since in construction industry, decisions are made through experience, construction problems cannot be modeled by strict rules; CBR is a promising technique to aid decision-making in construction business.

The proposed system namely, CBR-INT, is used to predict project attractiveness and company competitiveness when giving bid/no bid decisions in international markets. The reliability of CBR-INT is proved to be high for both prediction of attractiveness and competitiveness and its applicability is shown by a real case taken from the Turkish construction industry. CBR-INT is an example that demonstrates how DSS may increase the OL competence of companies since it requires the acquisition of several data, interpretation of data, transferring it into information, storing in a database and utilization of knowledge at the decision-making stage. CBR is proved to be a promising technique which may increase utilization rate of OM during decision-making and CBR-based DSS may facilitate OL in construction companies.

Use of Feedback System in Traditional Contractual Approach

Rajendra P. Adhikari
Nepal Engineering College, Nepal (email: adhikari_rajendra@hotmail.com)

Abstract

There is a separation between design and construction functions in a construction process and is even more in traditional approach. Thus, to exploit construction knowledge and experience in order to learn from the past to improve constructability of the design, some change seems to be required in the current practice. Early involvement of the constructor in the design process is also viewed as a contributing factor for more efficiency and productivity. Since experience is considered as a valuable asset in the area of construction, this paper discusses the concept of learning organization, a feed back system developed for traditional contractual approach to improve constructability and comments and suggestions made by professional engineers on the practical applicability of the feedback system.

Keywords: Learning organization, constructability, feedback system, traditional contractual approach.

1. Introduction

1.1 Background

One of the major drawbacks of the division of design and construction in most of the contracts is said to be that those who do not have sufficient construction experience carryout designs. Many construction problems are said to have resulted from the division of design and construction process. In the absence of learning from past experience, similar types of problems in similar types of constructions will be repeated.

Therefore, experience is considered as a valuable asset in the area of construction. The analysis of organizational learning showed that there are two levels of learning-lower and higher level takes place in an organization (or in a process). So far as the construction process is concerned, it is different from those types of organizations (or processes) where under a single umbrella different major activities take place or different departments function. In construction process, there is two major phases function under two different settings and the phases more or less follow one after the other. A designer (design firm) carries out design function and a contractor (construction company) carries out construction function. This is more apparent in traditional contractual approach.

The underlying principles of organizational learning will help organizations, wherever they are, in acquiring and transferring experience and knowledge and in modifying their behaviors accordingly. In construction, the separation of design and construction process is criticized for many problems encountered during construction. The importance of organizational learning, thus, is that it encourages to look beyond owns organizational walls for ideas and support. Nima et al rightly say, “ Now the construction industry has a great need to implement constructability due to the size and complexity of projects and to the fragmentation of the construction field into specialized roles and expertise.” [1] The objective of this paper is to propose the feedback system for traditional contractual approach for implementation.

1.2 Methodology

The concept of learning organization and constructability were discussed in the classroom with the students of M. Sc. in Construction Management in the year 2003 and 2004. After discussions, they were provided with the open questionnaire along with the feedback model. The contents of the comments obtained from the respondents were analyzed and discussed in this paper. Among 60 questionnaires distributed 49 (81.66 %) returned back. The design and construction experience of the respondents are shown in table 1.

Table 1: Design and Construction Experience of the Respondents

Experience (Years)	**Design Experience (Number)**	**Construction Experience (Number)**
< 5	31	13
6 – 10	6	17
11 – 15	9	12
> 16	3	7
Total	**49**	**49**

2. Learning Organization

Cangelosi and Dill made a pioneering study of organizational learning in 1965. [2] Since then, many writers have contributed in this area by their influential writings. However, after the publication of The Fifth Discipline, The Art and Practice of Learning Organization written by P. M. Senge in 1990, this concept has been widely accepted. However, no theory or model of organizational learning has been widely accepted.

The earliest definition of organizational learning was that of Herbert Simon who defined organizational learning as the growing insight and restructuring of organizational problems by individuals reflected in the structural elements and outcomes of the organization itself. [3] In this definition, Simon has insisted on growing insight, structural elements and outcomes of the organization. Chris Argyris viewed organizational learning as a process of detecting and correcting error. [4] Error, according to him, is any feature of knowledge or knowing that inhibits learning. He emphasized on organizational response to changes both in the internal and external environment.

Friedlander added the importance of past experience in the process of learning. [5] According to him, system should be geared in such a way that organization made authentic contact with the past. Role of past experience in learning as an agent for change was supported by Robbins who described learning as any relatively permanent change in behavior that occurs as a result of experience. [6] Levitt and March also highlighted the link between past experience and learning. [7] In the same way, Stata said that organizational learning occurs through shared insights, knowledge, and mental models and builds on past knowledge and experience for which he called "memory"[8].

Peter Senge, who popularized the notion of learning organizations, have defined it as an "organizations where people continually expand their capacity to create the results they truly desire, where collective aspiration is set free, and where people are continually learning how to learn together."[9] Highlighting the usage of acquired information Pareek has defined organizational learning as the process of acquiring, retaining, and using inputs for its development. [10]

From the definitions put forwarded by the scholars, most of them are found viewing organizational learning as a process of acquiring and using those acquired knowledge in the form of "learning" (from past experience) in order to improve the performance. This basic and fundamental ground of learning organization is also seems equally important to the construction industry, because, experience is considered as a valuable asset in construction. The fragmented nature of construction process will also be benefited from the discussions of learning organization because notion of learning organization, in general, sought for integration of the whole processes for operating under single system.

2.1 Levels of Organizational Learning

It is observed that learning in organization takes place in two levels and generally referred to as higher level learning and lower level learning. Lower-level learning, in general, occurs within a prescribed activity or behavior. Argyris and Schon referred to lower level learning as "single loop learning". [11] They further described that single loop learning occurs when errors are detected and corrected within a given set of rules.

Lower level learning in construction process is found established in current practices. Figure 1 shows the lower as well as the higher level learning in construction process. [12]

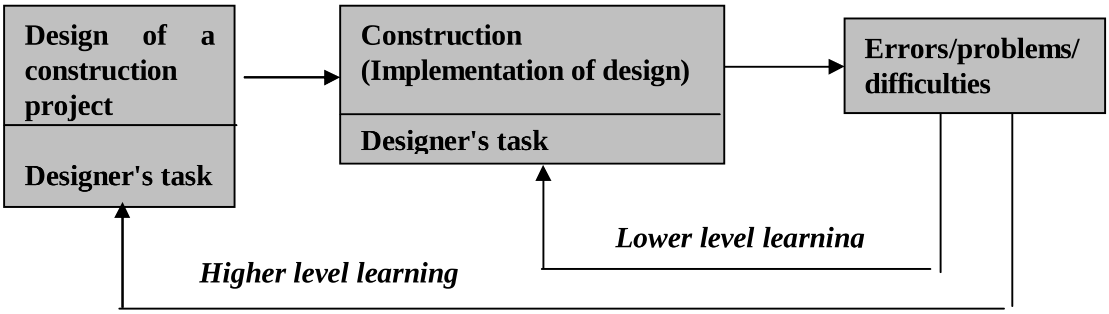

Figure 1: Levels of learning in construction process

It is also observed that higher level learning in construction process is essential to learn form past experience and to improve constructability of design.

2.2 Constructability

As described in the Constructability and Constructability White Paper, constructability is the capability of being constructed. [13] The Construction Industry Institute (CII) has defined constructability as the optimum use of construction knowledge and experience in planning, engineering, procurement and field operations to achieve overall objectives. [14] The Project Management Specialization of the University of Calgary, Canada has tried to define constructability as determining the most effective construction method prior to detailed design. [15]

From the above definitions, it is observed that the basic concept underlying in all definitions of constructability is that the appreciation of construction knowledge and experience into planning and design of a project will be beneficial.

3. Feedback System [16]

Retaining the fundamental features of the traditional approach for design and construction of a project, feedback system has been proposed so that the system can be adopted easily in practice without much disturbing the existing practice and also hoped that the professional without resistance can easily adopt the concept. It is to be mentioned here that along with the soci-economic development of the country, existing practice always required to be improved. In this regard improvement has been viewed as a continuous process. Figure 2 shows the proposed feedback system. In the existing phases of a construction process, some additions have been made to provide the feedback system for designers so that the constructability of design can be improved.

3.1 Pre-bid and Constructability (PAC) Review meeting

Pre-bid and constructability review meeting is one of the major additions in the existing phases of a construction project. In most of the large contracts, after publication of notice for tender and before bidding, a meeting called “pre-bid” meeting is arranged for the bidders (contractors) to orient them about the project. Here, it is proposed to arrange the pre-bid meeting as an equally important phase of a construction process in the form of “Pre-bid and Constructability Review (PAC) Meeting”. This meeting takes place after preliminary design and will be participated by the designer(s), probable bidders (or, pre-qualified bidders), and constructability participant (sometimes may be more than one depending upon the nature and size of the project). In this meeting contractors are provided brief of the project and the design philosophy; and the contractors are also asked to comment on the overall design, drawings, and specifications based on their construction knowledge and experience. Similarly, a constructability participant also provides his/her input to improve the constructability of the design based on his past knowledge and experience. This PAC meeting helps injecting constructor’s site know how into design and also the designer’s have the opportunity of understanding the possible consequences of his/her design during construction. “Combining the effort among designers and builders at the initial stage of design, in a co-operative manner, should reduce problems during the construction phase. Reducing problems during the construction phase reduces a project’s final completion cost. The co-operative combining of skills and experience in a conscious effort to reduce potential construction problems has been referred to as constructability.”[17] Ritz also agreed on that the design is reviewed for the application of the best construction technology to minimize field costs. [18]

Contractors’ pre-qualification (PQ), which is in practice, helps in identifying the real probable bidders (contractors). If PQ of contractors is not possible, only yearly short-listing of contractors by the functional departments also help identifying probable bidders. To invite appropriate contractors in PAC meeting, Contractors’ Associations involvement and help could also be taken.

It is to be mentioned here that the constructability participant may include one or more than one participants depending upon the nature and size of the project and that the constructability participant may not necessarily be a person who is required to be paid highly.

3.2 Finalization of Design

Finalization of design is the other phase added to incorporate the comments and suggestions obtained from PAC meeting. All the contract documents including the design are to be finalized at this stage.

3.3 Detail Project Review and a "Lessons Learned" File

After completion of the project a detail project review is proposed. This review examines in detail strengths and weaknesses of the project implementation and maintains a data file of constructability "lessons learned". This file is proposed to be kept by the owner (if the owner is a public department), the consulting firm (a designer) and the construction firm (a contractor) so that it can be retrieved for use in future constructability analysis. This detail review will also be an important feedback for both the consulting company and the contracting company. "A simple format to report valuable "lessons learned" is essential to any constructability program. Two or three paragraphs are usually sufficient to describe the reasoning and methodology of a constructability application and its results."[19]

One possible option for the improvement of the constructability is to appoint the same designers (consulting firm) for construction supervision, which was involved in the design. This helps providing real feedback to the designer so that constructability of the design can be improved. However, individual learning does not guarantee organizational learning as well as involving same consultant for both design and construction supervision, in all cases, may not be appropriate.

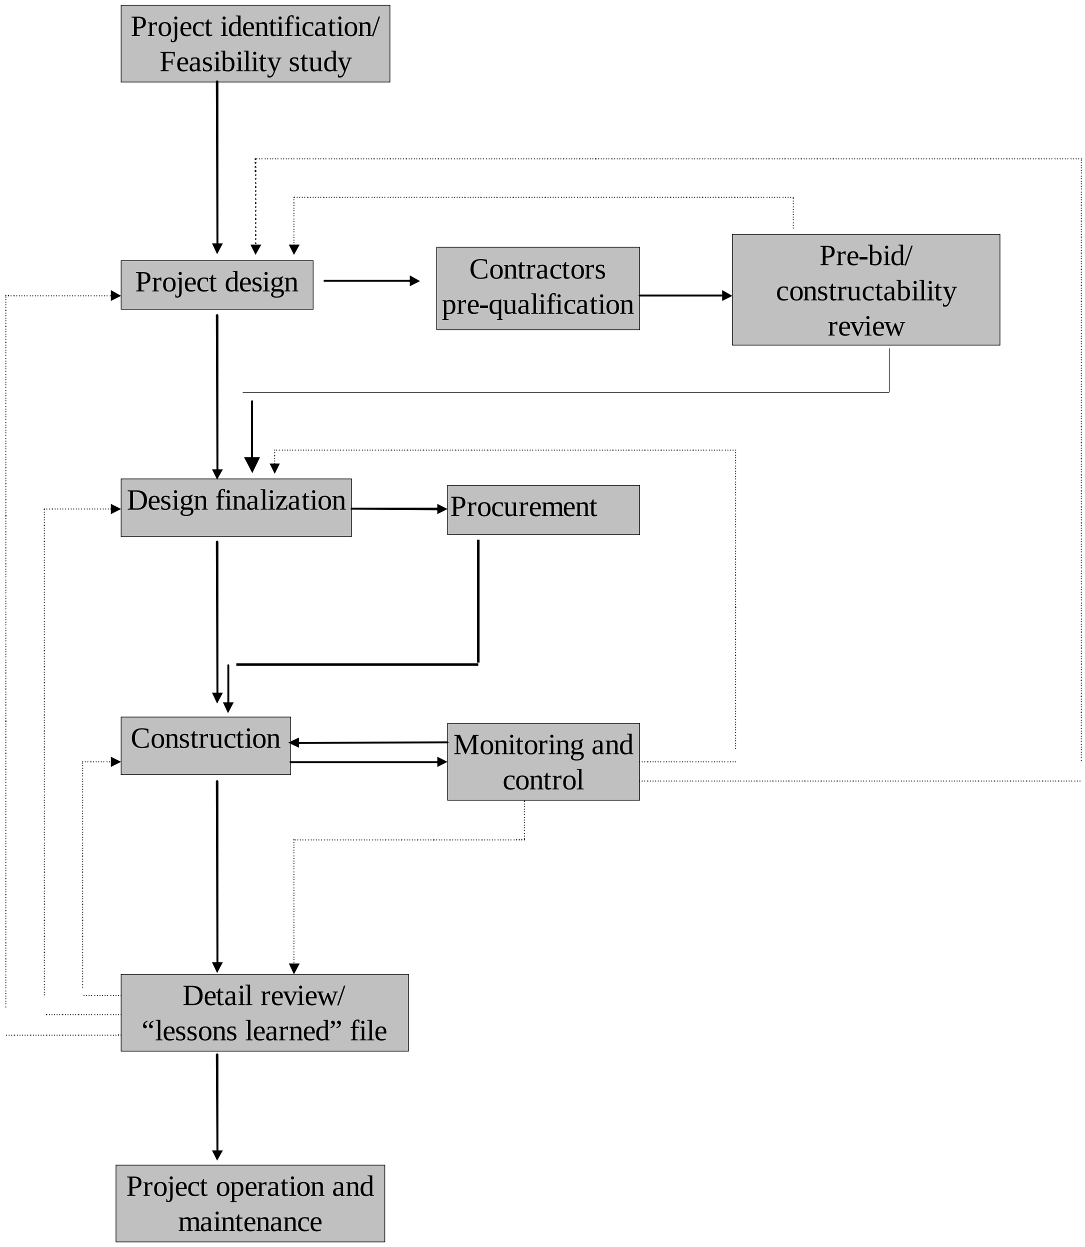

Figure 2: Feedback systems for traditional contractual approach [20]

4. Content Analysis

This section provides discussions based on the information provided by the respondents.

4.1 Applicability of the Model

In the question regarding applicability of the model the comments received were as follows:

i. The model is very effective

ii. The model is not suitable for small projects, and

iii. All the constructability participants may not be interested in attending the PAC review meeting

4.2 Impact on Time

This has been the general comment regarding impact on time – incorporation of pre-bid and constructability review meeting and finalization of design will consume more time. The respondents were of opinion that the constructability review helps in reducing the construction period. However, according to the respondents, design finalization may take time. Therefore, care should be given (a) in the selection of appropriate constructability review participant and (b) in creating the environment in which designer's should not try to defend his/her ego.

4.3 Improvement in Constructability of Design

All the respondents confirmed that this model would bring improvement in constructability of design.

4.4 Problems and Difficulties in the Model

As per the respondents' views, followings may be the problems/difficulties associated with the model:

i. All pre-qualified or short-listed contractors may not be interested in studying and commenting the design.

ii. Constructability review meeting may become a formality only due to lack of incentive to the contractor(s) participating in the constructability meeting.

It seems here that separate study should be conducted to design the incentive schemes for the contractor(s) to confirm their active and creative participation in the PAC review meeting.

4.5 What Should Be Done to Implement the Model?

The respondents said that for implementation, the model should be incorporated in the bidding document and information should be given through notice inviting tenders.

5. Conclusion

Traditional contractual approach is widely in use particularly for public construction works. Main drawbacks of this approach is the separation of design and construction process and because of this separation, separate designer and constructor involved in design and construction of a project respectively. Realizing this fact, a feedback system has been developed and proposed. For effective implementation of this model, the model is proposed to incorporate in the bidding document and information of this should be given through notice inviting tenders and the future research may be directed towards designing incentive schemes to the contractors participating in the PAC review meeting for their active and creative participation.

Siniša Matić
Faculty of Civil Engineering, University of Zagreb, Croatia, (e-mail: simatic@grad.hr)

Abstract

The paper presents the results of research carried out in 1989 and 2003. Based on answers obtained from respondents, the plan and programme of international postgraduate course entitled "Business Management in Construction Industry" was formulated, as initiated by the Faculty of Civil Engineering, University of Zagreb. The plan and programme of studies are presented, and the interdisciplinary nature of the studies is explained. Preconditions for enrolment of the first generation of students were created thanks to EU financial assistance through the TEMPUS programme.

Keywords: Construction industry, business management, manager, management, survey, graduate studies

1. Introduction

Croatian civil engineers have headed large-scale projects that require special managerial abilities for many years. Although without any formal managerial training, they manage companies and projects with the goal of achieving excellent business results through the direct control of labour and of the flow of considerable financial assets.

At the Symposium of Construction Organisation in Cavtat in 1989 we presented the results of a survey [1] designed to show the most important knowledge and abilities that the good construction manager must possess, in the opinion of the respondents (civil engineers who graduated from the Faculty of Civil Engineering at Zagreb University in the period 1955-1985).

An analysis of the answers gave a rank list from which we single out the 10 most important knowledge and abilities/skills needed by the successful construction manager at that time:

1. command of the technical knowledge and professional skills,

2. responsibility towards the company and towards work,

3. ability to organise and coordinate work,

4. ability to establish good interpersonal relations,
5. ability to contract work,
6. ability to ensure quality work,
7. ability to forecast,
8. knowledge of economic business analysis,
9. ability of personnel management,
10. ability of cost control.

The respondents considered it by far the most important for the construction manager at that time to be in complete command of technical knowledge and professional skills. They firmly expressed the view that to be a good construction manager a person must in the first place be a good engineer. It is interesting, however, that they placed the ability to control expenses last of the 10 most necessary abilities.

On the other hand H. Fayol [3], the father of modern management theory, speaking generally about the knowledge necessary for managerial work, as early as 1949, established that there is a fundamental difference in the necessary scope of professional/technical and general (economic, sociological, managerial and other) knowledge for various job positions in the management hierarchy. (Table1)

Table 1. Correlation between technical and other knowledge at the work place

Work place	Technical knowledge needed	Other knowledge needed
1. Worker	85 %	15%
2. Skilled worker	60 %	40 %
3. Technical manager	30 %	70 %
4. General manager	10 %	90 %

This shows that the participation of "general knowledge" grows as we climb up the managerial ladder. Every manager well knows that the higher his position in the managerial structure, the less he has "to do" with solving professional problems and the more time and energy he spends in solving "all the other" problems in the work of the company.

Many years have passed since our first survey. The social and economic system has changed, most companies are now privately owned, and it was to be expected that views about the necessary knowledge and abilities for managers had changed as well. The very different conditions and work processes did in fact change the attitude to the knowledge and abilities/skills needed by managers. Many more people now realise that additional training is necessary for managers and it has become usual for experts, people with university degrees, to go to “schools for managers”.

In Europe and other developed countries, engineers have been systematically trained in management for years, being aware that educating and training engineers in business management and project management in construction is of great importance for the success of both - projects and companies.

At the Faculty of Civil Engineering at Zagreb University we have for many years been thinking about the need to organise a managerial course specially “designed” and adapted to the specific needs of construction. However, before making the final decision and definitely launching the new project, we wanted to find out how much the views of engineers have really changed about the need to gain new, additional managerial knowledge, so we carried out a new survey in 2003. (Appendix 1)

2. Research Results

We can perhaps most simply define the concept of manager by saying what the person who runs the company or the project must do. For example, the manager:

- is responsible for the successful realisation of many tasks, which demands the coordination of a large number of factors and people,
- focuses on the entire company but also on people individually,
- often makes decisions without complete information and under conditions of uncertainty,
- guides the work of others so as to achieve the planned goals of the company,
- depends on the work results of others,
- his/hers own work results are assessed according to the company’s business results.

Therefore most important task facing the management of every company is obviously to tailor work conditions so that the company can achieve its planned goals. For the company this usually means to ensure conditions for a safe and “normal” life on the increasingly demanding and merciless market. A good manager can save a bad company, whereas an incompetent manager can ruin a good company. This has happened many times.

Bearing in mind all the above, we wanted to define the most important knowledge and abilities needed by the “perfect manager” today, on the basis of the experiences of actual managers.

We sent our questionnaire to about one hundred e-mail addresses to find out what knowledge and abilities/skills the “perfect manager” needs today. Within one month, which was the time at our disposal, we received 55 answers (the questionnaire was sent to managers of various professions who had graduated from the faculties of economics, civil engineering, electrical engineering, mechanical engineering and naval architecture, mining, geology and petroleum engineering, philosophy, natural sciences and mathematics, veterinary medicine, architecture etc.).

We must say that our results are not completely scientific because the sample of respondents was not representative. The questionnaire included only those who are Internet users. However, we received interesting results which we will show in the continuation of this paper.

An analysis of the answers [3] gave a rank list of the most important knowledge and abilities/skills needed by the successful manager.

The results showed that today’s respondents consider knowledge in management science (by this we mean: making business decisions, organisational behaviour, designing organisation, managing human potentials, business strategy, negotiating etc.) first and foremost for the success of managers. Of the 55 respondents, 96% consider this kind of knowledge very important (41) or important (11), which places it in first place of our rank list of necessary knowledge:

1. knowledge in management science,
2. knowledge in project management,
3. knowledge in economics,
4. knowledge of foreign languages,
5. Knowledge in specific professional fields.

Knowledge about project management methods (planning methods, resource management, risk analysis etc.) was ranked second by 91% of the respondents. They placed knowledge in economics third, which includes accounting, marketing, funding, international economic relations etc.

It is interesting that has been a change in the order of the most important kinds of knowledge, although the results from 1989 and from 2003 cannot be compared completely, there.

In 1989 command of professional knowledge was ranked first among the most important knowledge and abilities, while today only 11 respondents consider professional knowledge very important, and 30 consider it important, so this kind of knowledge has fallen to fifth place on the rank list.

The reason for this may be changed social and economic conditions, and also the fact that this questionnaire included managers who had graduated from other faculties, not only civil engineers.

It is also interesting that today 85% of the respondents consider it very important for the "perfect manager" to know foreign languages. In the earlier survey, knowledge of foreign languages was 13^{th} on the list of the most important knowledge and abilities.

We also asked respondents about the necessary "abilities/skills" that the good manager must successfully master.

All the respondents (55 or 100%) consider that the "perfect manager"

- must be capable of making decisions,
- must know how to coordinate tasks and people,
- must have organisational skills ,
- must be responsible.

If we observe the category of *very important* only, then decision-making skills come first again because 81% of the respondents consider them very important. Furthermore, 41 respondents or 74% consider coordinating tasks and people very important.

In comparison with the 1989 survey, the ranking of important skills has not changed as much as the ranking of knowledge because then too responsibility and organisation and coordination skills were very highly placed on the list.

These results did not come as a great surprise because we surveyed managers, people who are very well aware of the kind of problems and challenges they meet in their everyday work.

On the basis of the results which, we must honestly admit, only fortified our conviction that we were on the right path, we continued with our efforts to launch our international postgraduate programme *MBA in Construction.*

3. MBA in Construction Course Programme

Specialisation in business management, also known as MBA (Master of Business Administration), is today the most highly respected qualification in the business world. It is a form of additional highest education in management, because the programme provides knowledge and skills that enable course participants to master business processes more easily, and to adapt to globalisation processes more quickly and painlessly. The traditional MBA programme approaches business management as an independent discipline that can be applied to all industries.

In the last ten years or so many business schools and graduate MBA study courses have been opened in Croatia. Nevertheless, we find that studies which train “general managers” cannot be easily “used” for construction managers because they do not take account of the specific characteristics of the construction process.

Construction differs fundamentally from all other industries, because in the usual industrial process the product changes its place and the factors of production (people and machinery) are static. In construction it is the opposite – the product (the facility under construction) is static and does not change its place, when the “production process” is finished it stays where it was made, while the factors of production (people and machinery) move on to the next location – to the “next product”.

This is why we launched the project of multidisciplinary and interdisciplinary MBA studies for construction managers (civil engineers, architects and kindred technical professions).

MBA in Construction is a programme that focuses on construction with the purpose of providing present and future construction managers with knowledge in various scientific and professional fields, necessary for understanding and mastering complex management processes.

Civil engineers are trained as managers in only three universities in Europe, at MBA in Construction and Real Estate by Distance Learning, The University of Reading, and Executive MBA Construction Project Management, University of Leeds, in Great Britain, and IT Based Construction Management at the Istanbul Technical University in Turkey.

Comparing their curriculum with ours we found no significant differences and our programme is completely comparable with European trends, which was confirmed when the EU assigned us financial support through the TEMPUS programme for the first generation of students enrolled in February 2003. Teaching was organised in cycles of five workdays a month for four months during a term at the Faculty of Civil Engineering in Zagreb and at the Centre of Advanced Academic Studies, in Dubrovnik.

The MBA in Construction programme is a project of Zagreb University (Faculty of Civil Engineering and Faculty of Economics), in cooperation with partner institutions from Great Britain and Germany.

In June 2003 the Zagreb University Senate approved this programme making it one of the few graduate business management programmes that has University evaluation and is recognised as an international university postgraduate course.

Thanks to TEMPUS support, teachers from British universities (Dundee University, Reading University and Salford University) and from the Technische Universität München take part in almost every subject. The programme carries a total of 120 ECTS credits in three semesters of teaching and a master's thesis, as shown below.

Table 2. The MBA in Construction course programme according the ECTS credit system

1. Semester	**Lectures (hours)**	**Seminars (hours)**	**ECTS credits**
101 Business Statistics	40		7
102 Organisational Design	40		7
103 Organizational Behaviour	40		7
104 Marketing Strategy in Construction	30		6
105 Business Ethics	20		
192 Optional course - seminar		20	3
Total ECTS credits			**30**
2. Semester			
201 Managerial Accounting	40		7
202 Construction Project Planning and Control	25		4
203 Financial Management	35		6
204 Human Resource Management	35		6

The subjects can be classed in three groups:

- general business management (making business decisions, organisational behaviour and organisation design, business strategy, negotiating and business protocol, business ethics)

- economic subjects (business statistics, marketing strategy, international marketing, accountancy for business management, financial management)

- construction subjects (project planning and control, project management, legal aspects of project management)

We must add that the group of general and economic subjects are also taught by teachers whose basic training is in civil engineering, which ensures a multidisciplinary and interdisciplinary approach.

Cooperation among professionals of different profiles from Croatia and European countries provides course members with the most recent professional and scientific knowledge in the field of business management. The study lasts for two years (three terms of lectures and one term for writing the final paper), a total of about 475 hours of teaching, practical work and seminars.

The success of this graduate programme will serve as a basis for forming and opening the Centre of Excellence in Construction Management, with the purpose of developing and advancing the construction potentials necessary for economic and political development and the stability of the country.

4. Conclusion

Croatian builders have proved their construction knowledge, skill and abilities not only in former Yugoslavia but in many countries worldwide, working in different economic and political environments. Now, when our country is becoming part of the European market, the need for the additional schooling of engineers has become obvious, especially in business management in construction, which includes project management.

We consider it useful to bring to mind [6] some “universal truths” about managers, which are also true of managers in construction:

- Managers are only people and have all the human weaknesses: they may look at a problem without seeing it, listen to collaborators without hearing them; they may think about a problem and not do anything, or do things without thinking about the possible consequences first.

- Managers are created not born.

- The “art of management” must be learned, and what is the most important, it can be learned.

For someone to be a good manager or project manager it is not enough to be “talented” for the job or to want to do it. These are no more than good motivation for a person to embark on the tedious course of acquiring the variety of knowledge and skills without which he or she cannot expect to do demanding and responsible managerial work successfully.

Lessons from the Field - Case Studies

Power, Knowledge and Practice: Embedding New Management Initiatives in Construction Firms

Abstract

Understanding the implementation of innovative management initiatives in construction firms requires an appreciation of the situated nature of organizational learning and the effects of organizing by project on the diffusion of new management knowledge and its embedding in practice. Drawing upon two case studies of the introduction of new management practices in construction firms, this paper highlights two key influences on the nature and extent of change. First, the extent to which new management practices interfere or dovetail with existing project management practice; second, the extent to which they represent a shift in power/knowledge within the organization.

Keywords: Communities of practice, power, knowledge, innovation, learning

1. Introduction

Given the extent of change expected in management practice in the construction sector in recent years, it is surprising that more attention has not been directed towards examining factors influencing change within the construction firm. This is particularly so, given the problems identified by those commentating on prospects for innovation within the sector [1, 2], coupled with results from research that suggest that implementing new management knowledge in construction firms is by no means a straightforward matter [3]. Arguably, the emphasis, until now, has been much more upon examining the *content* of change, as opposed to fully appreciating the effects of *context* and *process* [4].

Recent research, however, has started to question many of the assumptions that underpin broader claims made about change within the sector [5, 6]. As part of this questioning, it helps to understand better the ways in which new management initiatives are diffused, taken up and embedded in management practice. Recent theory and research in the field of knowledge and learning has emphasized the situated nature of organizational learning and the difficulties in transferring knowledge from one context to another [7, 8]. To assume that new management initiatives can be properly understood without an appreciation of the effects of context and implementation process is to ignore the impact of complex organizational circumstances on the translation of new management ideas into practice [9].

The main theme addressed in this paper is that understanding organizational change and learning in the construction firm requires recognition of the constant, complex and dynamic interplay between new and existing management practices within the firm [10, 11]. Project-based working practices have their own logic of action and constitutive knowledge base that define the conditions in which new knowledge and learning is being embedded. These conditions are, in turn, the product of ongoing interactions between discourse and action that are continually being reproduced and adjusted on the basis of experience [12].

This paper aims to contribute to understanding the processes involved in the implementation of new management initiatives by reporting findings from research conducted in the UK (supported by EPSRC grant reference GR/M73286). A comparative analysis is conducted of two case studies to provide an insight into processes of change and to examine the ways in which project-based working shaped new initiatives as they were diffused throughout the firm. The analysis of the cases reveals two major dimensions that influenced the extent to which new management practices were accepted and embedded across projects: whether they interfered with existing project management practice; and whether they corresponded to a shift in power/knowledge within the organization [13].

2. Organizational Change in Construction Firms

Recent work in the field of organizational knowledge and learning has increasingly adopted a practice-based or situated perspective, in which learning and knowledge are embedded in everyday practice [7, 8]. In contrast to a more cognitive-based approach to learning, which emphasizes individualized learning and the abstraction of knowledge from context [14], the situated learning perspective emphasizes social processes and the importance of the context of practice within which learning and knowledge diffusion occur. Consequently, the diffusion of new management initiatives cannot easily be understood without reference to the social context in which it occurs, as well as to existing practices that the new knowledge and learning relate to [8]. However, despite the attention paid to understanding the diffusion of knowledge and learning across complex organizational forms [10, 15], there remain a number of major omissions in the way in which knowledge diffusion and learning processes within communities or networks of practice have been explored.

The first major omission concerns the effects of variation in organizational context and, in particular, the effects of project organization [16]. The form of organization is likely to have a significant impact upon knowledge diffusion and learning processes. Project-based organizations, in particular, represent an especially challenging setting for organizational change, knowledge diffusion and learning, since they often require the development of dedicated modes of organization and management practices that may not align neatly with more routine organizational processes [17]. The dispersed nature of project-based working in construction creates a highly decentralized and de-coupled system of working [18]. This has implications not only for the development of a strong and coherent alternative body of knowledge that is manifested in commonly adopted project management practice. It also has implications for the creation of distinct domains of control and influence within the organization, based on differentiation by project [16].

The second major omission relates to the relative lack of consideration of the effects of power on organizational learning processes [19]. The introduction of new management practices not only confronts existing management practices and routines in a very direct and practical way [12] but, in doing so, potentially challenges and sets out to replace ways of working and relating within the organization that constitute particular configurations of power/knowledge [13]. In other words, the shift towards a new mode of organizing or working practice is likely to involve an attempt to institute a new 'normalized' mode of working that inevitably advantages some individuals/groups while disadvantaging others – in terms of their expertise and therefore control over technical and/or managerial processes [19]. Indeed, achieving such a power/knowledge shift is often a very explicit aim of introducing new management initiatives [20].

Consequently, attempting to understand change in the construction management context brings to the fore the difficulties associated with attempting to embed new knowledge and learning in a context where there already exists a strong project orientation, where existing organizational mechanisms may be temporary and far from all-embracing; and where existing knowledge may be deeply embedded in dispersed managerial practices. Taken together, these points suggest that there is much to be gained from exploring organizational change in the construction context from a perspective that emphasizes the socially situated and contested nature of knowledge and how the particular organizational context affects processes of embedding (or attempting to embed) new management knowledge.

3. Research Methods

In order to undertake this task, research was undertaken in a number of case study construction firms in the UK. The research consisted of several case studies, two of which are reported here. Further information about the other cases can be found elsewhere [16, 21]. In each case study company, one managerial initiative aimed at having a significant impact across the organization was selected. The initiatives chosen varied considerably and included the new risk management system and new estimating process studied here.

The research was interview-based, with data from the interviews being supplemented with documentation, including internal company reports and presentations. Managers selected for interview were those directly involved with and affected by the initiative and included senior managers, project managers working on sites and professionals (e.g. engineers, estimators). Interviews lasted about an hour and all were tape-recorded and transcribed. Open ended questions were asked about the person's background, their understanding of the initiative, the wider commercial and corporate context, the implementation process used, changes to working practices, and overall effects and outcomes.

Data were collected over two years by having key people interviewed more than once in order to track developments and examine more closely emerging themes. This real time investigation, combined with retrospective accounts, allowed some longitudinal examination of the process of introducing change to working practices. The orientation to data collection and analysis was exploratory, intended to generate insights into how new knowledge associated with the initiatives was being interpreted and acted upon by those that the initiatives were designed to effect.

4. Case Study 1: Betta Process

Betta Process is a medium sized firm, specializing in the building of food, chemical, petrochemical, materials handling and nuclear processing plants. It employs around 250 permanent staff, 70% of which are professional engineers. In 1999, the company underwent internal restructuring, which led to a rebalancing of the power structure in favour of the project management axis of the company's matrix organization. The responsibilities of engineers became limited to maintaining/improving technical skills, while resources were now managed centrally. Project managers became responsible for employees' performance evaluation, which was directly linked to remuneration. At the same time, some 'cultural change' was already apparent as people started to identify themselves more with projects than with departments.

At the end of 2001, a new Risk Management System (RMS) was launched. Market pressures and a recent shift to fixed price projects had resulted in dissatisfaction with how risk was being managed. The new system aimed at bringing more precision and accountability, through introducing highly structured and quantified analysis provided by a software-based tool. The RMS was used at the bidding stage of the projects as well as for project management. The scope of the initiative was restricted at first to 'big' projects. One reason for this was that it was too time-consuming to apply the RMS to smaller projects, as it became a risk liability itself.

The new Risk Management System at Betta Process was designed to provide a more systematic risk assessment. It affected existing project management practice directly, since project managers now had to perform new, additional procedures. As one of the senior managers explained,

> Probably, for the people that are actually using [the system] it does not make a whole load of difference. They have a job to do that they did not have to do before. They have to sit down on a monthly basis and punch numbers into the system. What it has done is made a lot of difference at management level as to the degree of confidence they have in the assessment of the financial health of a particular project.

In addition, it also directly affected the degree of financial control exercised by project managers. As a senior manager explained,

> One of the less attractive features of the thing, from the project managers' point of view, is that it gives the project manager far less scope on his project for being able to control his budget because if he identifies a risk as being passed the funds will disappear.

However, in order to use the new system, project managers still had to rely heavily on their expert knowledge. Although the tool itself was well documented and formalized, its use remained extremely subjective and depended on the experience of the estimator or project manager. As one project manager put it,

> It tells you how to use the system just like your car manual will tell you how to operate the car. It does not tell you how to drive the car. And what to do when that pedestrian steps out in front of you.

At a later stage of implementation, the experience-based component of risk assessment was recognized by senior management as being more important than the calculations performed by the system. The tool was "de-sophisticated" to reflect this. Risk categories were simplified and project managers were allowed greater flexibility in interpretation and use.

The introduction of the initiative did not imply any great shift in power or influence in the organization. Project managers' knowledge continued to be highly valued as a crucial component in risk assessment. Even though the new system brought more transparency to project managers' practices, their prevailing concern was how to learn to use the new system. Training had only consisted of one session, in which a 'dummy' project was used to demonstrate the system's functionality. Besides that, people were supposed to be "able to understand what was needed" and expected to learn how to use the tool by applying it. As one project manager recalled,

> The problem with this is you have to apply it. You have got to do it and you have to do it more than once. Each time you do it you get better. So you have to understand the limitations of the system to make sure that you get the right inputs.

The new Risk Management System was applied to two major 'pilot' projects, which allowed project managers to change the way they managed projects. By the time of the completion of this research, the new RMS was considered successful and had started to be applied more widely across the organization.

5. Case Study 2: Delta Oil & Gas

Delta Oil & Gas is an international business with a £65m turnover and 300 employees, including a high proportion of highly qualified engineers, designers, and project managers. They work mainly for large 'blue chip' clients such as Shell and BP and operate in an environment in which oil and gas price movements are cyclical and volatile. A downturn in 1998 affected the company so much that it was forced to engage in significant restructuring and downsizing and was only now fully recovering.

In this context, it was felt that a new approach to estimating was needed. The overheads associated with bidding for jobs were mostly attributed to the amount of man-hours spent by engineers on estimating. The new approach would rely instead on computer-based tools rather than engineers' direct input. The objective was not only to simplify the estimating process, but also to change the role of engineers and how they were used in the company – transferring the ownership and responsibility for estimating to estimators. This approach would also mean greater involvement of project managers in estimating and more interaction between them and estimators during project implementation.

The backdrop to the change was what was seen as the strong departmental culture within the organization, particularly in engineering, which was seen by other groups as responsible for overspending and working in isolation. According to one project manager:

> Engineers are engineers. They want to design the best thing in the world, don't they? That is all they really want to do. It does not matter how much it costs, or how long it takes. […] A lot of them just do their little bit of work in isolation, that is all they ever do. They don't look at the big picture, certainly time and programme.

With the introduction of a new estimating process, project managers welcomed their greater involvement with estimating and the greater shared responsibility between them and estimators. This did not affect their project management function very much. However, it did allow them to have greater influence on the outcomes of the estimating process. It also proved to be useful in dealing with clients, as project managers would have greater knowledge of the financial side of the projects.

Not surprisingly, the changes were perceived very differently by the engineers, who found that the new way of working and their reduced involvement in estimating went against their existing norms and practices. As one engineer commented,

> I have never worked that way. … I am sitting there and I have not been given a copy of the invitation to tender … I think, 'What on earth am I meant to be doing here?' … I think, well, why I am only getting selected documents? I have got to know what's going on. I need a complete set or need open access to a full set of documents.

The new way of working also involved less recognition of the engineering function in the organization. As an engineering manager commented,

> During the compilation of any estimate, [we're] being constantly asked questions by [the estimator or project manager]. How do you do this? What would you do here? How much would you allow for this? How would you arrive at the figure to do that? But when an estimate is tabled it is 'This is my work'. Hence, my resentment.

Although responsibility and control were passed more to estimators and project managers, engineers continued to be the gatekeepers of the knowledge and information needed. Most of the formal communication protocols, such as sharing of detailed information from meeting minutes during bidding, were eliminated by the new estimating procedures. Estimators and project managers had to rely on informal means of communication by "scribbling notes themselves" and engaging in "sweet talk" with engineers to be able to complete the estimates.

Project managers found learning estimating skills even harder. Not only were engineers unwilling to surrender their expertise and influence in the company, but project managers relied critically upon the knowledge of estimators. As one project manager remarked,

> The estimators have intimate knowledge … They understand the functions and the basis [and] you could only interrogate that basis to the extent of your knowledge. Once it had gone beyond that, the estimator could tell you anything he liked because you didn't know any different.

Consequently, even though the new approach to estimating did not significantly influence project managers' everyday practices, it did nevertheless continue to leave them dependent on significant others for knowledge and information relevant to how they did their work and, despite their efforts to develop expertise and skills in this area, did cause them difficulties in attempting to develop their own knowledge base.

6. Case Analysis and Emergent Themes

Of course, a variety of factors – amongst others, the approach to introducing change, the support of senior management and the availability of resources – were important in influencing overall how these two initiatives were implemented and how successful they were. However, as the context and implementation of the particular initiatives being explored across the cases became better understood, it became clear that the variety and distribution of existing management practices, and the degree to which change initiatives were seen to interfere or dovetail with these practices, had an important bearing upon the ways in which new organizational knowledge was accepted and embedded within the firm.

Taking such a situated perspective, two key dimensions emerged strongly from the data. First, the more that the change initiative interfered directly with project management practice (and was intended to do so), the more important became established ways of working and frames of reference used by project managers, as these provided more immediate templates, sources of meaning and legitimacy than the wider company initiative. Second, the degree to which the introduction of the initiatives disrupted existing power/knowledge relations within the organization influenced whether managers reconstituted their knowledge by changing their practices or, alternatively, subverted or resisted the new initiatives.

The positioning of the cases with respect to these two dimensions is depicted in Figure 1 below. At Betta Process, the introduction of the new RMS can be interpreted as having a relatively low degree of disruption to the knowledge/power balance in the organization concerned, but a very high level of impact upon existing project management practice. Despite being a more structured system, it continued to rely for its implementation on the expertise of project managers. This, combined with the willingness of senior managers to defer to their project managers' expertise, allowed them significant latitude in deciding how to use and apply the tool. Before the introduction of the RMS there were no well-defined routines established across projects about how to assess risk. Although the new system implied significant changes to how projects were being managed, the willingness and ability of project managers to learn new skills facilitated the enactment of this newly introduced system and contributed towards its embedding across projects.

		Disruption of knowledge/power balance	
		Low	High
Interference with PM practices	Low		Delta Oil & Gas New Estimating Process
	High	Betta Process Risk Management System	

Figure 1: The Case Studies

At Delta Oil & Gas, the new estimating approach very clearly signified a power/knowledge shift, involving an enhancement of the project management function at the expense in particular of the engineers. In introducing a different sort of 'normalized' working practice across the firm which subordinated engineers' interests and expertise to those of project managers and estimators, the new process very much represented a shift in power/knowledge within the firm and a challenge to existing professional identities [13]. Moreover, by getting involved with and attempting to learn estimating skills, project managers were able to refine their role and identity further as those with more autonomy and expertise to control their projects and deal with customers. Estimating activity was not central to everyday project management practice. However, participation in this activity could make project managers more knowledgeable about the financial side of the projects and, consequently, provide them with greater control over their job.

7. Concluding Discussion

This paper has attempted to examine some of the key problems in implementing new management practices in project organizations, when the practices concerned are expected to affect project management work. Using an approach informed by a situated learning perspective [7], this paper draws upon two case studies of the introduction of new management initiatives in UK construction firms. The analysis of the cases highlights the importance of understanding existing management practices and how they align with new ones being introduced; as well as the degree to which the adoption of new practices disrupts power relations within organizations.

The findings demonstrate that the distributed work practices common to construction firms who base their activity around projects have an important bearing on the shaping and embedding of new management practice, since they directly influence the ways in which broader organizational initiatives are interpreted, legitimated, modified and incorporated within practice. Locally established project management routines, in particular, provide a useful means of re-interpreting and making sense of new practices so that they conform to existing and preferred local norms and values. Furthermore, distributed power domains and group identities based on the control by groups over a particular expert knowledge base, influence change processes quite markedly within such organizations.

These findings not only reinforces the notion that conflict is essential in understanding the learning dynamics associated with the embedding of new knowledge across projects, but also demonstrates how power dynamics can work themselves out, through the creation of new normalized modes of working that differentially influence the expertise, influence and identity of diverse expert groups. More generally, the findings lend support to the idea that the introduction of new management initiatives is often hampered by a failure to understand existing underlying routines [12]. And that project basing poses particular constraints on attempts to diffuse new knowledge and learning because of the dispersed systems of practice that arise in such circumstances [10]. To the extent that the exercise of power and control is integral to understanding learning processes within organizations and wider communities of practice [19], then project-based organization such as found in construction poses particular challenges for the diffusion and implementation of new management ideas.

Project Based Innovation and Partnering in the Swedish Construction Sector

Anna Kadefors
Service management, Chalmers University of Technology
SE-412 96 Göteborg, SWEDEN, (email: annkad@mot.chalmers.se)

Abstract

Although diffusion of innovation in general is slow in construction, single projects may show significant levels of innovation. Partnering is often related to innovation and has been an important aspect of construction sector reform initiatives. In Sweden, there is a strong but declining tradition of standardization by regulation in construction, and partnering has not been promoted by the government. This paper analyses the relation between project-based innovation and partnering in a Swedish context. It is concluded that although the driver for partnering is more often cost-reduction than innovation, partnering can bring about innovations. These often concern processes and systems, which can be important enablers in a long term perspective. More partnering projects are needed to bring attention to those systems, and thus increase the potential for innovation.

Keywords: Innovation, partnering, Sweden

1. Introduction

Often when innovation in construction is discussed, the low pace of innovation and limited learning between projects is emphasized and analysed [1]. Clearly, many projects are carried out according to a standardized process, using mainly standardized components and measures. In recent years however, following the development of the CoPS paradigm specifically developed to address the conditions for innovation in the context of large, unique, complex projects, the role of project based innovation in construction has gained more attention [2]. Several authors have observed that although diffusion of innovation in general is slow, single projects may show significant levels of innovation [3,4,5]. Many of these examples are found in large prestige projects, but there are projects that are more innovative than others also in the domain of more everyday residential and office buildings. Indeed, the degree of innovation seems to vary considerably also within a project category.

Partnering, or more collaborative relationships between project participants, is often related to innovation. In the UK, partnering has been an important aspect of construction sector reform initiatives proposed by the Latham review as well as those following the Egan report. Winch [6] saw partnering as a key to innovation because of the opportunities for introducing gain-sharing mechanisms to encourage project actors to engage in client-focused innovation.

This paper investigates project-based innovation in Swedish partnering projects. A main case study of a project with explicit aims to increase innovation is used to discuss the measures employed by the actors to encourage innovation and the drivers involved. To discuss the role of partnering in relation to innovation, the main study is supplemented by three additional case studies of partnering projects. Important questions are: To what extent is partnering motivated by concerns for innovation? What processes and mechanisms are put in place to support partnering and how do these relate to innovation? What kinds of innovations are likely to occur?

First, however, a background to the Swedish situation is outlined, highlighting the need for an historic perspective and understanding of the institutional context.

2. A Swedish Background

In an industry that is based on temporary multi-organizations but were the products carry a great deal of similarities, the potential for efficiency to a great extent lies in standardizing both the physical and organizational components, and the rules of interaction between the organizations involved [7]. Sweden has a particularly strong tradition when it comes to such industry level standardization. In the period between World War II and the 1980’s, governmental regulation in the building sector continuously grew. Building codes increased in detail, which, in combination with subsidies tied to different aspects of dwellings brought a standardization especially of residential buildings. The concept “subsidies architecture” was coined, as designs were developed to maximize subsidies rather than optimize for user needs, and superior quality was rare.

In the late 1980’s and early 1990’s, government increasingly loosened its control over the construction sector. A new legislation was introduced, explicitly stating that the client is responsible for the quality of the building, and not the local authorities issuing building permits. In steps, the detailed codes, where possible, were replaced by performance requirements. As a part of a major effort to cut back public expenses the subsidies were significantly reduced in the early 1990’s, leading to a sharp cut in residential construction. Demand continued to be low until the next boom in the late 1990’s. Then, construction volumes grew due to commercial buildings and tenant-owner housing, but the previously so important sector of multifamily dwellings for rent remained very limited (but has increased in volume in 2004-2005).

In the previous system, knowledge of the codes and the subsidies became more important to the industry than professional knowledge concerning space planning, architecture or technical systems. The new system seems to call for a higher level of professional competence, but change has been hampered by a lengthy recession followed by a short but intense boom in 1998-2000 when, especially in the Stockholm area, cost considerations were of less importance. Thus, circumstances more favorable to sensible innovative practices have only existed for a couple of years, and it is hard to know if any changes have taken place in practice.

Contrary to many other countries, for example the UK and Denmark, the Swedish government has not pointed out partnering as the preferred procurement route for government sector clients or in any other way promoted partnering. Sweden, however, has a tradition of more collaborative construction relations and low visible costs for conflict resolution. Also, the Swedish construction market is dominated by three large contractors. This may explain why the Swedish discussion and government initiatives have focused on the need for increased competition. The interest in partnering has increased but it is only in 2004 that the Road and Rail authorities, as the first government sector clients, have declared a commitment to developing and using partnering principles, and there are no authoritative guidelines on the subject. Measures and principles tend to be developed by the parties themselves, sometimes inspired by foreign models, but often rather informal, not requiring much extra resources.

3. Methodology

The main case study concerned the new Stockholm office of White arkitekter, one of Sweden's major architectural firms, designed and commissioned by the company itself. This project had an explicit focus on innovation, and was carried out in a partnering environment. The finished building has won several prestigious Swedish awards within architecture, construction and concrete design. The case study started towards the end of the construction phase and was finished at about the same time as the project itself. A total of 14 people were interviewed, representing the project management, tenant, client and architect functions within White; technical consultants; the main contractor's project manager, site manager and purchasing agent; building services contractors and a cladding manufacturer.

The other case studies were studied in a previous research project focusing partnering and collaboration, and were chosen on the basis of their partnering content. Thus, these inform more generally on the role of innovation in partnering projects. These case studies were carried out in 2001. In each project between four and eight interviews were conducted, depending on project size and complexity. Both client and contractor representatives were interviewed in all projects, and the architect was interviewed in two of them.

First, the main case study will be described and then the other four will be briefly introduced. Discussion and conclusions follow.

4. The New Office Building of White Arkitekter

4.1 Background and Aims

In 2002, one of Sweden's major architectural companies was located in an ancient building in the Old Town, in facilities which were pleasant but too small. Also, the technical systems did not fulfil the requirements of a modern computer-based design office. White had been investigating different location alternatives for some time, and had found that a new building would not be more expensive than refurbishing the existing premises or renting larger and more modern facilities in the centre of Stockholm. Also, a new building had other advantages: it gave the company an opportunity to create a best practice case were they could demonstrate the capacity and competence of their firm. As the company has a project management unit, best practice aspects would concern organization and management as well as architecture.

Compared to many other countries, such as the UK, Denmark and Norway, Swedish architects have less influence and responsibility. Since the 1960's, it has been common that the client, in traditional contracts, appoint the architect and other members of the design team to carry out the design but that all contacts with contractors and the construction site are then handled by the client's project management team. Thus, architects and engineers often have little knowledge of constructability aspects. Also, there is a general rule that the contractor is entitled to replace specified components, qualities and trademarks with other "equivalent" products. As aesthetic aspects are difficult to specify in objectively verifiable terms architects in particular are frustrated with this rule, claiming that contractors take advantage of this opportunity to replace carefully selected designs and products with cheaper ones of lower aesthetic and functional quality. People at White were of the opinion that the construction process would benefit from a closer contact between the design team and the contractors, so that price-quality trade-offs could be decided in a discussion with all relevant competences present.

White was also critical to the low level of innovation in the Swedish construction industry, and thought that clients were much too risk-averse in their choice of architectural design as well as technical systems. They claimed that more cost-efficient and fit for purpose solutions could often be found if other alternatives than the standard ones where considered. In particular, design of building services systems could be significantly improved and better integrated with the load bearing frame. However, as HVAC engineering firms are mostly asked to provide standard off-the-shelf solutions they have little incentives to develop innovative or even best practice design competence. Also, the building frame is decided at a much earlier stage in the process than the HVAC-systems which makes integration problematic.

Thus, White had many objectives in assuming a client role when acquiring new premises. In sum, these were to:

- get facilities adapted to their business needs
- show that the firm had a high competence concerning architectural design as well as project management
- show that a better architectural quality does not necessarily lead to higher costs, but that the architect has to have a stronger influence in the project
- show that design consultants bring value in the construction phase
- show that encouraging innovative thinking in the design of technical systems can improve building performance at a lower cost

- propose a quality- and innovation-orientated model for project organization and management

The only problem was that the partner-owned architectural company neither wished to take the long-term risk of owning a building nor deal with everyday facilities management issues. Thus, they had to find a property owner who was interested in buying and owning the completed building, renting 2/3 of the building area to White for period of 10 years.

4.2 Strategy and Model

White had the ambition that the building should be an example of integrated design, where the building services systems are integrated with the structural frame and the physical systems are exposed and form a part of the design. To achieve this, a design contest for HVAC engineers was carried out. This procedure is common for encouraging creativity in architectural design, but is generally not used in engineering. However, the three companies asked were positive, and they developed three different and unconventional (although not totally new) solutions in a rather short time. White was satisfied with the result, and chose a design where pipes where placed inside the concrete slab and sea water was used both for heating and cooling by means of a heat exchanger (the building would be located just by the waterside). Thus, the concrete frame was exposed which conformed to the aesthetic aims. As most electric conduits and piping for ventilation would also be visible, the quality of workmanship would have a direct influence on the architectural expression.

Normally when clients want to have control over both building quality and costs, they prefer a highly specified traditional contract with a fixed price agreement. White initially considered this alternative, but found that it would not grant them enough control over all building details. Instead, a partnering approach was chosen, and a contractor was engaged at an early stage. The contractor participated in the design process and a target cost was set, but there was no gain-sharing mechanism. The client and the contractor agreed that a target cost-incentive fee arrangement would seriously hamper collaboration and be a source of distrust. Thus, the client had to trust the contractor to engage in economizing without economic incentives, but could be confident that the contractor’s suggestions were motivated by a concern for the project. The subcontractors, by contrast, were procured by traditional means on a fixed price basis, and in most cases the company with the lowest tender was appointed. However, only trusted subcontractors were invited to tender.

The partnering model was informal in the sense that no teambuilding exercises or workshops were held. There were no systems for continuous evaluation other than the ordinary ones. Still, there was more project communication and shorter communication channels. A project group was formed including the main decision-makers, which met regularly during the whole project and discussed all decisions of great aesthetic, functional or economic importance. The design phase was carried out in a traditional manner, with the only difference that the contractor participated. New to the consultants was that specific meetings were held for selected systems, were different manufacturers were invited to present their products to the client and consultants. Also, the partnering arrangement allowed the client and the design team to participate in subcontractor procurement, so that they could discuss problems and the requirements concerning quality of workmanship before the contract was signed. During the construction phase, there was close contact between the consultants and the contractors.

4.3 Process and Results

During the first part of the project, most things went better than anyone had dared to hope. The important and costly pre-cast frame and cladding system were procured at a lower cost than previewed. Everyone was excited, and White decided to use money now available to upgrade some designs that had been subject to savings in early stages. However, later in the process, when it came to purchasing of components such as interior wall cladding, staircases and other visible products, prices turned out to be much higher than estimated. The architect had designed non-standard solutions, but as the basic material itself was low-cost and designs simple he thought that these were cheap. But as it turned out, the manufacturers were not very interested in supplying customized products and came up with very high prices. And by then it was too late to find other suppliers or cut back other expenses. So in the end, the cost exceeded budget by 4%, but included quality upgrading representing 7%.

Concerning innovation, the most innovative solutions came up in the design contest. The integrated design concept, however, had further effects. Normally in office buildings there is a sub-ceiling with sound absorbers, but this would compromise the whole design concept. Instead, the architect contacted a Danish acoustics consultant who made computer simulations of how the t-shaped elements of the concrete ceiling would affect the diffusion of the sound waves. It was found that the requirements would most likely be fulfilled without any absorbents at all. Thus, White could keep to their design goals by challenging conventional knowledge.

The collaboration with the building contractor was not strongly innovation focused and brought mainly constructability improvements, although in one case this lead to a significant design change. White was very satisfied with the contractor's contribution to the project, and there were no feelings that the commitment to keeping costs down was lacking. In fact, also the subcontractors were very engaged despite the fixed price/low bid procurement. The reason, they said, was the direct contact with the client in the procurement phase, and also that their tender prices were realistic. The collaboration between the consultants and the contractors as well as the quality of workmanship was excellent. The only problem was that there was too much communication. The craftsmen tended to check very small details with the architect, who willingly answered. The project manager found it a difficult balancing act to encourage contractors to come up with ideas, but still be able to turn down some suggestions without a loss in motivation. The architect, in hindsight, thought that it would have been possible to be more restrictive if there had been a greater consciousness of the problem.

The project goals were more than fulfilled, as the finished building has won the single most prestigious Swedish award within architecture, as well as the contractors' award and an award for the concrete design.

5. Three Partnering Projects

5.1 MedicHus

MedicHus is a municipal agency responsible for old people's homes in Göteborg, Sweden. In the end of the 1990's, the agency started a project to refurbish a series of 16 homes using traditional procurement routes. The interest from contractors in MedicHus' projects was low, manifested by tenders more than 50% over the client's estimate. After a couple of projects, MedicHus decided that they had to find a different approach and started by asking local contractors for advice. The result was a model where the main contractor would be selected mainly on the basis of competence, and MedicHus specified a general standard for the old people's homes and made a detailed estimation of the project costs. In their tenders, the contractors were required to comment the cost estimate, and a target cost was agreed. Gains were then to be shared between the client and the contractor. No explicit teambuilding efforts were undertaken, but the contractor was given sufficient time for planning and procurement of subcontractors before construction started and great care was taken in selecting the right people on both sides. Collaborative relations then came about spontaneously during project planning, where the client staff and contractor staff worked closely together. Each project was procured individually. The first project was completed on half the time needed for a traditional project, and at about 15% below the target cost.

5.2 KappAhl

KappAhl, a clothing company with their own retail stores, needed a new head office. The building would house the design department, why architectural aspects were important. A distinguished architectural firm and technical consultants prepared drawings for a traditional contract. However, costs were found to be too high and a project management consultant was engaged to revise the project. The brief was reworked and floor space was significantly reduced. For time reasons it was decided to use a rather detailed design-build contract, but the architect would continue to work for the client. A contractor was appointed, partly based on their price and partly because they came up with several ideas for improvements. The project management consultant suggested a target cost-incentive fee mechanism for a number of well defined areas (e g a special flooring and façade glazing). Open books were used, and a group including the client, the project manager, the architect and the contractor met regularly to discuss the incentive areas.

During the project, several complications came up. Following a company acquisition more office space was needed, and the building had to be redesigned when the construction had already started. Also, the first incentive discussions were difficult because the architect did not accept the contractor’s proposed alternative for façade glazing system, which in addition turned out to be much more expensive than predicted. However, the collaborative arrangement allowed the project manager and the contractor to meet jointly with the glazing manufacturer and together negotiate a lower price. In the end, the problems strengthened mutual trust. The other incentive discussions were constructive and the project was considered very successful. The deadline was met, the quality was high, the costs were under (the already low) budget and all parties were very happy with the teamwork.

5.3 The Central Hospital of Karlstad

In the late 1990’s many buildings at the Central Hospital of Karlstad were in bad need of refurbishment. The facilities management function expected about 30 projects, and it was decided to develop a partnering model to handle this large construction more efficiently. The agreement was based on plans that 20,000 sqm were to be refurbished during a period of almost three years. A design-build contractor was procured, mainly based on their competence and attitude. Initially, several joint workshops were held for teambuilding and for establishing project goals and routines. The economic agreement consisted of a fixed price part that should cover central administration, profit, insurances, etc. for the entire program, and a cost reimbursable part covering the direct costs for wages, material etc. for each specific project. The design-build contractor had an increased liability: 5 years product warranty and 10 years performance liability for indoor climate. It was stated that the contractor should define technical solutions together with the consultants and the hospital staff. In each project a pre-study was carried out and priced, and a formal contract was written.

The project faced heavy time constraints and important changes in project contents right from the beginning, and early in the process the client project manager was replaced. The first project exceeded budget and the client-contractor relationship deteriorated somewhat and at least temporarily resembled that of a traditional project. No follow-up workshops were held. Despite these conflicts and tensions, all participants were positive to the new way of working. The design team and the contractors worked more closely together than in conventional design-build projects, and new visualization tools for showing contractors and users how technical equipment would be placed in a room were developed jointly. Construction work was of a higher quality and contractor-user relations were improved. However, it was difficult for the contractors to stand up against the requirements of chief physicians and they found their roles in project definition unclear. The new procurement concept and 10-year climate guarantee required many systems to be developed, especially for sub-contractors and facilities management.

6. Case Summary and Discussion

6.1 Innovation

Of the projects, only the White case was explicitly orientated towards innovation. The most important measures chosen to bring about new solutions in this case were the design contest for building service consultants, choosing top consultants and allocating more resources to the design phase. These measures proved effective, and the project included much more unconventional solutions than usual. Still, all these measures could have been used in a traditional contracting environment, while the closer collaboration with the contractor mainly was about ensuring that the architect could influence all project decisions, cost control, and improved constructability.

However, it became clear that also this kind of process and relationship innovations, in combination with a closer contact between consultants and contractors, required new processes. First, it was obvious that the traditional purchasing process is not suitable in a project with a significant share of non-standard solutions. To manage risk of low supplier competition requires, first, that also seemingly simple non-standard designs are identified and investigated at an early stage and, second, a broader knowledge among both consultants and contractors of possible suppliers (also foreign) to shorten search times.

The other cases showed similar tendencies that contractor collaboration focused mainly on cost control, cost savings and constructability. Regarding innovation aspects, many important areas of innovation came up not as an answer to client requirements or cost consideration but to organizational and process needs. The changed purchasing environment was one example, and in the Karlstad case the FM-unit needed new data bases and improved control systems to be able to distinguish system performance from management performance in relation to the increased performance liability. The visualization system was also a need stemming from a closer and more long-term relation between consultants, contractors and users. In the White project the increased consultant-contractor interaction called for new management skills. Thus, the driver for partnering are often be cost-based, but partnering itself then calls for process and system innovations.

6.2 Collaboration Aspects

Despite the general Swedish collaborative mentality and the tradition of informal co-operation, the participants found that the initiatives to increase collaboration in the case study projects made a difference. Inter-organizational teamwork was perceived as significantly better than in “ordinary” projects. In the White, MedicHus and KappAhl projects, the client side was sensitive to the needs of the other parties and made efforts to facilitate their work. There was an emphasis on listening to and respecting other parties’ opinions, a culture that was perceived as rare by those involved. Especially contractors felt more appreciated and found their work more meaningful. All projects reported better quality of workmanship. The overall attitude towards partnering was strongly positive and all of those interviewed wanted to develop partnering further. In two cases, there were incentives (gainsharing mechanisms) and in two there were no incentives. However, the White case demonstrates a strong contractor commitment without any incentives, and the interviews indicate that emotional rewards and intrinsic motivation are very important.

6.3 Formalization

In all cases except Karlstad, the level of formalization was low when it came to collaborative initiatives. Great care was taken in choosing the right people, but no teambuilding initiatives took place and there were no routines for regular joint project evaluations and conflict resolution. In the Karlstad project, workshops were held to promote teambuilding and to establish routines for project work and economic evaluation. However, when problems appeared and a new client project manager took over, there were no more structured initiatives for repairing relations or for joint reflection. It seems likely that these problems, as well as the problems of finding the proper level of consultant-contractor communication in the White project, could have been at least partly sorted out if there had been collaborative and pre-planned evaluations.

7. Conclusions

It was only the White case that there was an explicit aim to find new solutions, and the driver was partly a desire to participate in an ideal project, and partly to create a demonstration project to market the company. This intentional innovation was handled by traditional methods: design contests and more resources given to design. In all projects, reasons for partnering were primarily related to reduced conflict, cost and quality control and smooth project execution. The new relations, however, called for new processes, systems and management skills. These needs often came as a surprise, because beforehand the client's main worry was whether they could trust the contractor, not how a successful trust relationship should best be managed.

Some of the needs were handled within the projects, but some were left open, maybe to be picked up in the next project of the same kind. Thus, to increase the potential for project-based innovation in collaborative projects, there has to be more of this kind of projects. Then the parties will develop knowledge, skills and systems to fit a collaborative environment. And when there is less focus on trust, innovation can be expected to come up as an important management area. Thus, Swedish government might be advised to more actively promote partnering and develop guidelines that will help the parties to build up systems supporting project-based innovation.

Team ‘Working’ & Project Performance in the UK Construction Industry

Stuart Tennant
Bell College of Technology, Hamilton, Scotland (email: s.tennant@bell.ac.uk)
D. Langford
University of Strathclyde, Glasgow, Scotland (email: d.langford@strath.ac.uk)

Abstract

This research programme is currently investigating the relationship between construction site teams and project performance. Much has been written about the benefits of team working and over the last decade management thinking has shifted the typical team paradigm away from a traditional operational application towards an increasingly strategic perspective. The employment of team working within the construction industry is extensive and therefore any development on the management of teams and team working applications may have a far-reaching significance for the sector.

The company case-study investigates the relationship between two ever-present variables in most construction projects: teams and performance. The team study identifies three contextual categories that comprise of seven key characteristics prominent in most group / team environments. The individual team variable ratings are calculated using an attitude statement questionnaire that has been issued to all permanent construction site team members. The questionnaire addresses all seven key variables; each variable has five attitude statements with five possible answers. The individual responses are collated, averaged and presented collectively as a team percentage rating by means of a radar chart. Project performance is evaluated using seven key performance indicators. The KPI’s have been selected to create a balanced performance measure of project ‘well-being’, incorporating the four distinct perspectives advocated in Kaplan and Norton’s Balanced Scorecard concept. The project performance data is gathered from three primary sources: the client or client’s representative, the team leader and construction site team members with specific reference to the seven key performance indicators adopted from recognised construction industry KPI’s and similarly presented on a radar chart.

Analyses of the results quantify the perceptible strength of relationship between team working and project performance. Results also identify individual strengths and weaknesses. In particular team characteristics that may contribute to project quality for the client and promote continuous team improvement for the contractor. Further detailed investigation and data collection has the potential for future development of a diagnostic toolkit that may unlock team working capability. If construction teams are to be better managed then the interaction between site team working, performance and the environment requires to be better understood.

Keywords: Teams, Performance, Key Performance Indicators, Construction Management.

1. Introduction

Team theory is a resilient management theme; the notion of team theory has a long history and in the second half of the twentieth century its theoretical and practical contribution to work place management has been the subject of numerous studies. In a time of ever-changing management fads, corporate interest in teams and team related philosophies has remained steadfast. Some commentators argue that the need for team working in the present corporate climate is even more pressing that in previous times, “developments in modern manufacturing methods and service excellence have put greater emphasis on team working”, [1]. Today, global industries ranging from aerospace and car manufacturing to financial services and the public sector have embraced team ideals in the search for improved efficiency and overall company performance. It is interesting to note that there is a discreet difference in today’s team philosophies with that of previous years. The traditional team working research perspective of the founding behavioural scientists was, in essence, benevolent in its concern, “the principle managerial and social science concerns have been with morale, [2]. While contemporary application of team management theories focus primarily on the needs of the business, “considerations of performance have obviously contributed to the growth in importance of team working during the 1990’s”, [3]. This viewpoint is endorsed by Marchington [4], stating that “more recently, there have been few doubts that the attractiveness of the team concept has rather more to do with gaining competitive advantage through advances in productivity and quality – which may be enhanced by teams, than with any altruistic motive”. The current wave of management thinking has shifted the traditional team paradigm. The rationale for the adoption of team working in the twenty first century is to achieve competitive gains and efficient organisations via effective management of human resources. “The objectives, in other words, are strategic rather than operational”, [5].

2. Teams and Project Performance

2.1 Teams

Team is a common, everyday expression yet an exact definition remains elusive. Dictionary descriptions tend to communicate an overtly casual application of the team ideal, out with any specific context and over-simplifying the team dynamic. Management interpretation of team virtues supplement the familiar interpretations by acknowledging group activity and introducing the need for a commonly shared objective. Katzenbach and Smith [6] suggest that the team definition would be better articulated as a “discipline that real teams share”, stating that “a team is a small number of people with complementary skills who are committed to a common purpose, set of performance goals, and approach for which they hold themselves mutually accountable”. Unfortunately, the liberal use of team vocabulary with everyday management rhetoric may in effect dilute the true collective nature of team orientated operations and “carries with it the danger that team working will lose all meaning”, [7]. “As terminological precision is so elusive, it is perhaps more appropriate to focus attention on how aspects of organisational context influence the different forms of team working adopted”, [8]. A failure to recognise corporate limitations may inhibit team performance. Examples of unsuccessful team working have highlighted the role organisations play in the formation and support of collaborative effort. Lack of attention with regard to existing company policy, procedures and customs may hinder the team effort. Jasmine Tata [9], recognised the significance of corporate environments stating that “work teams do not exist in a vacuum, but are part of a larger organisational system with distinct cultural and structural characteristics”. In other words, the introduction of team working philosophies may contradict existing company practice. Companies should endeavour to establish a degree of compatibility between existing working procedure and those associated with a team-based orientation. Organisational context will shape the team dynamic and as such will redefine the generic meaning of the team within an organisational specific setting. Industry customs and beliefs may also influence the exactness of the team definition. It may therefore be argued that a standard team definition is malleable enough to reflect the various contextual attributes that all teams invariably possess. The application of teams within the construction sector is extensive where, “construction is arguably the largest collectivist activity” [10], of all the UK sectors. Over the past decade, construction company awareness of team working practices has reflected the growing corporate management interest in team related theory. Construction project teams require a multi-functional, inter-disciplinary representation, engaging a cross-section of industry professionals responsible for carrying out duties particular to their area of expertise. This type of team arrangement is representative of a cross-functional or matrix team formation. The appeal of high performance cross-functional teams (HPX_fT) in construction is likely to be commercially motivated, “the pay-off must be financial in the first instance and will only come when team working results in each business firm represented receiving the profit it expected”, [11].

2.2 Performance Management

For Katzenbach and Smith [12], the definitive characteristic that distinguished a group, taskforce, alliance or any other socially inclusive working party from a team is – performance. Historically, organisational performance has focused first and foremost on the financial criteria of company profit. This restricted outlook to corporate performance has over the years, received numerous criticisms for “emphasising economy and efficiency and neglecting measures of customer satisfaction and quality”, [13]. This parochial outlook fulfils a buildability criterion with respect to economies and efficiencies of production but is of limited consequence for the end user, consumer and/or customer with interests in effectiveness and ethics. A contemporary perception of performance management may be expressed as a holistic concept, widening the focus of performance measurement techniques to include traditional as well as contemporary performance dimensions. In response to this need to diversify whilst at the same time encapsulates a range of performance measurements that would better represent corporate well-being, Kaplan and Norton developed the ‘Balanced Scorecard’ concept. The assertion of the balanced scorecard was to construct a set of four inter-related criteria that would give senior managers a fast and comprehensive information model that would be representative of corporate strategy, objectives and competitive demands. The balanced scorecard supplements the financial outlook of corporate performance with three other business viewpoints; customer perspective, internal business perspective and an innovation and learning perspective. The four perspectives create a more ‘rounded’ approach to company performance appraisal, acknowledging the importance of the various stakeholders. Kaplan and Norton [14], stress that the balance scorecard presents a cross-functional shortlist of key indicators for present and future performance. Whereas, financial information on its own is backward looking, reflecting on previous performance without predicting future achievements.

2.3 Performance Management of Teams

Research has indicated that although performance management is widely accepted as a prerequisite of corporate well-being, little has been done to assimilate and customise ‘individualistic’ performance management principles to meet the demands of a team orientated ‘collectivism’ environment. “One of the interesting findings of our research was that…relatively few organisations made specific arrangements for team performance management”, [15]. This comment concurs with Staniforth’s [16] observations relating to staff appraisal policy, where he states, “there is little evidence to suggest that anything other than ‘individual appraisal’ is done”, raising the question, “do we really appraise team work, or just individuals who work in teams”. Staniforth concludes by observing “many UK organisations do not yet appear to have broken the shackles of an individualistic approach to work”.

3. Methodology

3.1 Overview

The research methodology employs two independent techniques for data collection. The team rating is obtained via a team attitude statement questionnaire distributed to all participating construction site team members. Project performance is calculated by identifying key project performance data requirements and benchmarking the results using selected key performance indicators, advocated by Constructing Excellence, [17].

3.2 The Team Questionnaire

The team questionnaire is derived from the initial team literature search and reflects the recurring themes that punctuate team related discussion. Three broad categories are identified that provide a balance to the individual variable(s) that would be used for the evaluation of the construction team rating. Team Compatibility and Diversity is used as a heading to embrace four distinct variables associated within this theme; 1/ Interdependency, 2/ Membership Diversity, 3/ Team Dynamic and 4/ Trust. This category relates to a personal and management awareness of working together and the application of personality inventories developed to assemble individuals who will compliment the functioning of the group in both a professional and behavioural perspective. The second category identified was Organisational Context; this section recognises the potential influence company systems may have on the outcome of team working practices. This category consists of two variables entitled 5/ Corporate Intent and 6/ Policy, Procedures and Customs. The third category ‘Industry Context’ was introduced to represent the established convention that construction is a ‘team game’ and as such may have a subliminal impact on employees working within this environment. Industry context has one variable, 7/ Culture. The team questionnaire has eight sections; one for each of the seven variables identified and an eighth section related to general information that will contribute to project performance measurement. The questionnaire seven team sections employ a rating system whereby the respondent is offered a choice of five possible responses and asked to select the one that best reflects their judgement. The five options are: ‘Completely True’, ‘Mostly True’, ‘Partly True’, ‘Slightly True’ and ‘Never True’. The given response is then translated to a score of 5 – to – 1 respectively (Likert Scale), calculated as a percentage and plotted on the appropriate axis of the ‘Team Rating Radar Chart’. An average construction site team rating is calculated from the seven individual variables.

3.3 Project Performance Toolkit

The project performance toolkit is a customised suite of seven industry recognised key performance indicators (KPI) that provide an all-inclusive snapshot of project performance. In an attempt to capture a more ‘rounded’ examination of project performance Kaplan and Norton’s balanced scorecard concept was utilised as a template for KPI selection. This required addressing the four specific perspectives of contemporary performance measurement, 1/ the financial perspective, 2/ the customer perspective, 3/ the internal perspective and 4/ the innovation & learning perspective. A number of secondary issues that would facilitate the administration of the performance toolkit were also taken in to consideration such as: holistic measurement; KPI adaptability; data and source availability; validity and reproducibility. The performance indicators selected all come from the current (2004) key performance indicators endorsed by Constructing Excellence. The seven selected indicators comprise of four KPI’s from the ‘All Construction’ suite and three KPI’s from the ‘Respect for People’ suite of KPI’s. They are:

Key Performance Indicator (KPI)		Balanced Scorecard Perspective
1/ Predictability	– Construction Cost	(Financial)
2/ Predictability	– Construction Time	(Financial)
3/ Client Satisfaction	– Service	(Customer)
4/ Client Satisfaction	– Product	(Customer)
5/ Employee Satisfaction		(Internal)
6/ Working Hours		(Internal)
7/ Training		(Training & Innovation)

The project data is pooled from three different sources: Predictability – Construction Cost & Predictability – Construction Time is provided by the construction site team leader, typically the project manager. The client or client’s representative is given a short questionnaire to complete regarding service and product satisfaction. Information regarding employee satisfaction, working hours and training is all provided by the construction site team participants, section eight of the team questionnaire. The collated project responses can then be calculated and converted in to benchmark percentages using the appropriate KPI data sheets. The information is then plotted on the appropriate axis of the project performance radar chart with an average project performance calculated from the seven individual results.

4. Case-Study

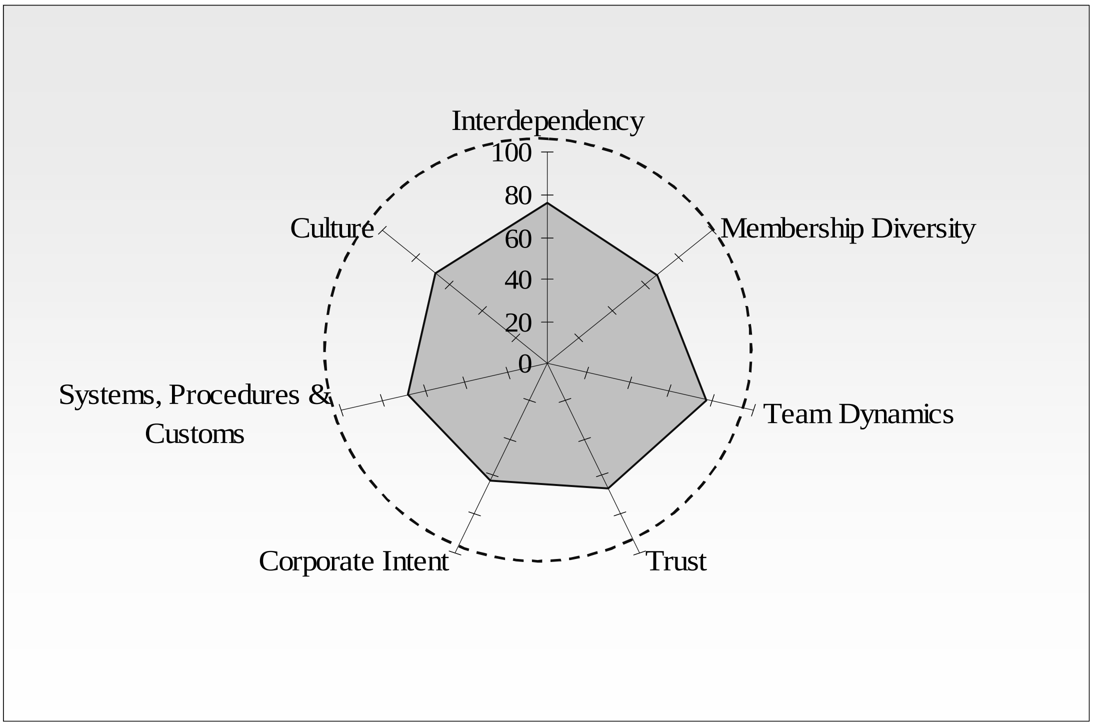
4.1 Overview

The following case-study was carried out between August and September 2004 with the help and cooperation of a major UK contracting organisation with a combined corporate turnover in excess of £1.47 billion. The Scottish regional office provides contracting services across the central belt and is a division of the largest business sector within the group, contributing to an annual sector turnover of £787.6 million. Five construction projects within the Scottish region where selected as suitable for this case-study. The projects varied in valuation, ranged from £2.9m to £9.2m. There was also a cross representation of procurement routes, clients (private and public) and building type. Project 1/ is a £9.2 million conversion project of a city centre, category 'A' listed building. Project 2/ is a new build children's hospice. The £6.3 million development will provide respite care and accommodation for family members, an education suite, day facilities and play areas. Project 3/ is a £8.5 million contract involving a combination of new build and refurbishment work. The refurbishment is a swimming pool with the development of a new adjoining arts centre. Project 4/ is a £2.9 million environmentally friendly, bespoke community building comprising of offices, café and crèche facilities. Project 5/ is another local community project, a state-of-the-art building comprising library, IT facilities, fitness suite and cafe with a contract value of £3 million.

4.2 Results

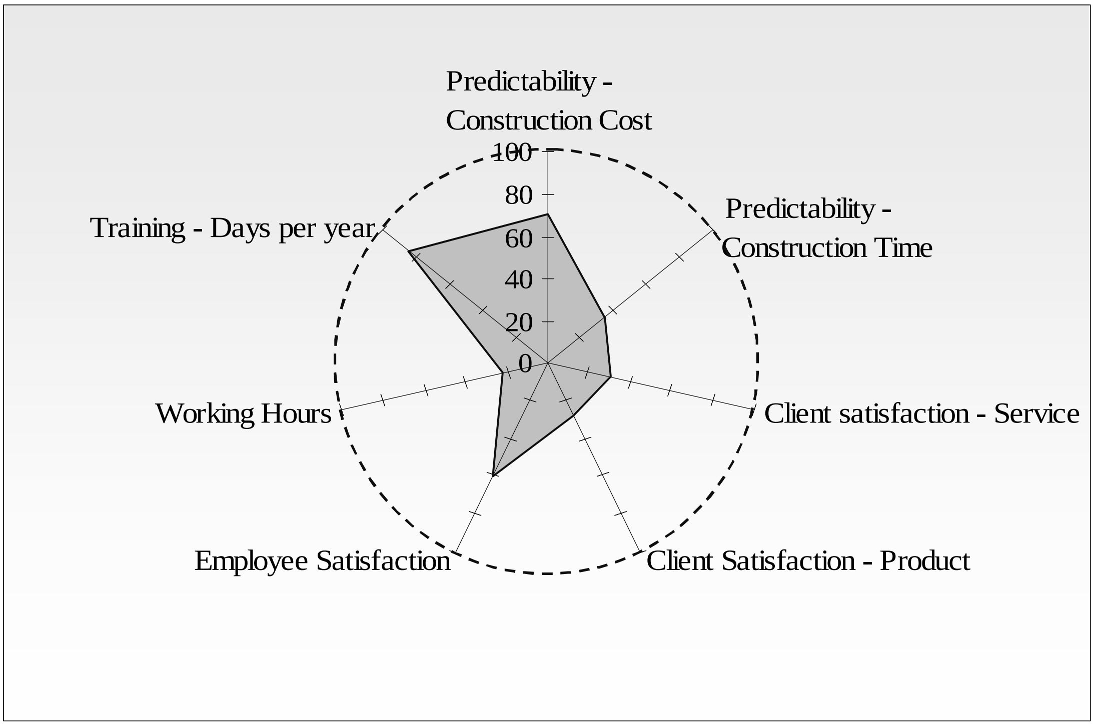
Table 1/ illustrates the individual project results along with a company average for both the 'Team Rating' and corresponding 'Project Performance'.

Project No.:	Team Rating	Project Performance
Project 1/	72% (rank 2nd.)	54% (rank 2nd.)
Project 2/	68% (rank 4th.)	47% (rank 3rd.)
Project 3/	62% (rank 5th.)	29% (rank 5th.)
Project 4/	70% (rank 3rd.)	42% (rank 4th.)
Project 5/	74% (rank 1st.)	61% (rank 1st.)
Company Average:	**69%**	**47%**



Ave. Team Rating = 69%
Standard Deviation = 5.4

Fig. 1: Team Rating Radar Chart (Company Average)



Ave. Project Performance = 47%
Standard Deviation = 24.1

Fig. 2: Project Performance Radar Chart (Company Average)

Note: The results are presented using a radar Chart format. In general, the nearer the plotted line is to the outer perimeter of the radar chart, the higher the overall rating / performance.

Table 2/ is a breakdown of the seven-team variable averages from the five construction projects participating in the case-study:

Team Variable	Team Category	Score
1/ Interdependency	(Group Diversity & Compatibility)	- 76%
2/ Membership Diversity	(Group Diversity & Compatibility)	- 67%
3/ Team Dynamics	(Group Diversity & Compatibility)	- 77%
4/ Trust	(Group Diversity & Compatibility)	- 66%
5/ Corporate Intent	(Organisational Context)	- 62%
6/ Systems, Policies & Customs	(Organisational Context)	- 68%
7/ Culture	(Industry Context)	- 68%

Table 3/ is a breakdown of the seven project KPI average score from the five construction projects participating in the case-study:

Indicator		Perspective	Company Score
1/ Predictability - Construction Cost	(%)	(Financial)	0%
2/ Predictability - Construction Time	(%)	(Financial)	+11%
3/ Client Satisfaction – Service	(out of ten)	(Customer)	7.2
4/ Client Satisfaction – Product	(out of ten)	(Customer)	7.2
5/ Employee Satisfaction	(out of ten)	(Internal)	6.9
6/ Working Hours	(per week)	(Internal)	48.5
7/ Training Days	(per year)	(Innovation & Learning)	3.8

Table 4/ transfers the project KPI average score in to KPI Construction Industry Benchmarks percentage:

Key Performance Indicator	Perspective	Benchmark Score
1/ Predictability - Construction Cost	(Financial)	- 70%
2/ Predictability - Construction Time	(Financial)	- 34%
3/ Client Satisfaction - Service	(Customer)	- 31%
4/ Client Satisfaction - Product	(Customer)	- 28%
5/ Employee Satisfaction	(Internal)	- 60%
6/ Working Hours	(Internal)	- 22%
7/ Training - Days per year	(Innovation & Learning)	- 84%

Note: The project performance results are all from the relevant Headline Construction Performance Benchmark for 2004. KPI 1/ to 4/ is taken from the All Construction suite and KPI 5/ to 7/ is taken from the Respect for People suite.

5. Analysis

A number of important issues need to be clarified prior to the interpretation of the results. At present the case-study company does not employ the current Key Performance Indicators (KPI's) developed by the DTi. In the application of performance management is it fundamental that the participants are fully aware of the standard against which they will be measured, this information permits the targeting of resources in to areas that will contribute to the final evaluation of the project. At the time of the study, all five case-study participants where unaware of the measures against which the site performance was being evaluated for this study. Therefore, due to likely deviations between current company performance measures and those used for the purpose of the research it would be unreasonable to interpret project outcomes' in terms of good or bad. They may be used in comparison with other sites and/or as a starting point for future company benchmarking initiatives. With regard to the KPI Benchmark scores it is important to be aware that initial scores that appear better than average may translate to KPI Benchmark percentages that are in general terms poorer, simply because construction industry standards within that particular sphere are, in relative terms, high. For example, a Client Satisfaction (Product) score of 7 out of 10 may be viewed as above average, i.e. 70%. Translated in to the KPI benchmark a score of 7 equates to a benchmark result of 20%. Meaning that 20% of projects are achieving equal or lower performance and 80% are achieving a higher performance.

5.1 Team / Project Relationship

Three statistical techniques where carried out to ascertain an empirical link between the two project variables. A student's two-tailed t-test of the research hypothesis; H_o = 'construction site teams influence project performance' was accepted with a 95% confidence limit, signifying that the association between the two variables is significant. This result is corroborated by a Pearson's correlation coefficient of +0.95. Again, this figure demonstrates a very strong link between the two principle project variables. The coefficient of determination (RSQ) of Pearsons correlation indicates that the level of association may be as high as 90%. Although the project performance may vary for many reasons, it would appear that in this study 90% of the variation in project performance can be attributable to differences in the team rating. Note, due to the very small sample size further case-studies are required and more rigorous statistical analysis undertaken to develop confidence in the patent cause and effect relationship of team working and project performance. At present, the initial findings suggest a significant level of association.

5.2 Company Results

Within the Team Performance there are two notable highs. Interdependency and Team Dynamics both from the Group Diversity & Compatibility category scored 76% and 77% respectively. This relates to team awareness for the need to work together, acknowledging that success is dependent on a collaborative effort. Team dynamic relates to team size and frequency of communication, formal and informal between team members. Due to the small team compositions, for example the largest participating team size was five members, it may have been predicted that the variable(s) associated with degree of understanding and interaction would score highly. The notable weakness is Corporate Intent with a company average of 62% (Organisational Context). This variable measures an employees' consciousness of team working philosophies as an integral character of company strategy. It may be that team working is taken as customary for the construction industry environment, for example Culture recorded an average of 68% and therefore corporate team training may be overlooked as an explicit business practice for improving company results. The relationship between average team ratings and corporate intent are an exact match with their respective ranking, highest to lowest producing a Pearson product moment of correlation coefficient of +0.95.

Table 5 illustrates the relationship between average team ratings and associated values for the variable 'Corporate Intent' (Organisational Context).

Project No.:	Team Rating	Corporate Intent Variable
Project 1/	72% (rank 2nd.)	64% (rank 2nd.)
Project 2/	68% (rank 4th.)	56% (rank 4th.)
Project 3/	62% (rank 5th.)	52% (rank 5th.)
Project 4/	70% (rank 3rd.)	62% (rank 3rd.)
Project 5/	74% (rank 1st.)	77% (rank 1st.)

Other possible influences could be the high labour turnover and/or recently employed team members. Analysis of the team member questionnaire(s) highlighted a number of recently employed members. The average length of service for site team participants is fifteen months with three of the projects averaging less than twelve months. The project with the highest average team rating had an above average employment statistic of eighteen months. At the lower end of the team ratings, project 2/ and project 3/ had below average figures of four and nine months, ranked 4th and 5th respectively. Another variable very much associated with team awareness at a tactical level is 'trust', recording an average company rating of 66%. It is widely recognised that trust evolves over time spent working in a co-dependent environment. Casual observation of the average project team rating and values attributed to the trust variable demonstrate a similar pattern of lowermost trust values associated with a poorer team rating average, (see table 6).

Table 6/ illustrates the relationship between average team ratings and associated values for the variable 'Trust' (Group Compatibility and Diversity).

Project No.:	Team Rating	Trust Variable
Project 1/	72% (rank 2nd.)	70% (rank 2nd.)
Project 2/	68% (rank 4th.)	63% (rank 4th.)
Project 3/	62% (rank 5th.)	53% (rank 5th.)
Project 4/	70% (rank 3rd.)	73% (rank 1st.)
Project 5/	74% (rank 1st.)	69% (rank 3rd.)

A Pearson product moment of correlation coefficient of +0.90 suggests that the levels of trust within the broad team dynamic may be a core variable, influencing the overall perception of team working and perceived personal well-being between the participants. Again, an itinerant workforce with transient team formations may suppress the development of trust between the team members, inhibiting the transition of group work to team work or team work to high performance teams. Company averages for Project Performance highlight a number of interesting points. The most noteworthy strong point across all the projects studied was 'Training – days per year.' A KPI of 84% was recorded indicating that only 16% of UK construction companies perform better. The lowest KPI score was 22% for 'Working Hours', suggesting that 78% of construction company employees have shorter working weeks. The company average working week for site-based staff employees is 48.5 hours per week. This was consistent across all the projects studied. This may be due to site and/or programme circumstances but other reasons could exist and may be worth investigating in an effort to improve the work – life balance. An interesting detail from analysis of the KPI's is the lower than expected benchmark scores for 'Client Satisfaction – Service and Product'. Both recorded a respectable company average of 7.2 out of 10 from the Client / Client Representative Questionnaire, this translates to KPI scores of 31% and 28% respectively. The result is a potentially motivating outcome because small gains in client perspective would convert to significant improvements in KPI scores. For example, a gain of 0.8 points (7.2 to 8.0) would mean an increase of 24% and 27% to a KPI of 55% for both service and product.

6. Conclusions

From the results of this construction company case-study it may be concluded that enhanced levels of team working significantly influences project performance. The positive correlation in itself is not necessarily unforeseen but the potency of the relationship between the two variables is surprising. The significance of the case-study results encourages the development of a construction team - performance diagnostic toolkit that would 1/ encourages companies to benchmark their project performance, 2/ evaluate performance against current levels of team efficiency and 3/ help align HRM policies to compliment a team orientated environment. By targeting the weaker team variables highlighted by the diagnostic toolkit, High Performance Cross-Functional Team (HPX_fT) working may become a more realistic and achievable objective. In addition, the toolkit also highlights organisational strengths and weaknesses as well as distinct project team - performance issues that can be addresses in the movement for best practice and construction excellence. In short, the research programme demonstrates that if realised, the team 'works'.

Acknowledgements

The author would like to thank the construction company for their co-operation and in particular, the Contracts Manager, the five Project Managers and their site team(s) for participating in this research project. Their time and contribution is greatly appreciated.

Sharing Knowledge across Professional Boundaries: A Case Study in a Government Department

Patrick S.W. Fong
Department of Building & Real Estate, Hong Kong Polytechnic University
(email: bspafong@polyu.edu.hk)
Fiona L.C. Lo
Davis Langdon & Seah Hong Kong Ltd. (email: 01265279d@polyu.edu.hk)

Abstract

Today, knowledge is an important asset in most organizations, enabling them to cope with the changing environment and increase their efficiency. Through inter-disciplinary knowledge sharing, organizations can utilize the competence and knowledge of their staff. This is also true for different construction professionals working on the same project, but knowledge sharing across professional boundaries does not come naturally.

Recognizing the need for research into this area, this study explored inter-disciplinary sharing practices in the Architectural Services Department (ArchSD) of the Government of the Hong Kong Special Administrative Region. A survey was conducted to find out the frequency, channels and types of knowledge shared across professional disciplines. Findings indicate that professionals do share frequently with other professionals in terms of project, procedural, and operational and maintenance knowledge through a variety of channels. Email, informal discussions and formal project meetings are the most popular of these. Sharing knowledge helps professionals to make decisions and solve problems in their daily professional work.

Keywords: Knowledge sharing, professional boundaries, public sector, inter-disciplinary

1. Introduction

For years, competition has been the great motivator of our economic system. However, facing the increasingly competitive market and the tremendous amount of information made available, organizations' competitiveness may decrease if the knowledge bases of their employees cannot be fully utilized.

In construction projects, professionals from different disciplines work together to achieve the objective of completing a successful project. The interdisciplinary nature of the work involves frequent communication and sharing among different project participants. The vast amount of information and knowledge required in projects needs proper communication and cooperation among various professionals.

Inter-disciplinary knowledge sharing can be a solution to our fragmented project-based construction industry. Through proper sharing, knowledge and experience is transferred among professionals of different disciplines. By using knowledge sharing channels such as the Internet, e-mail, intranet, documents or face-to-face meetings, information and knowledge is made available to individuals within a department, a project team or even within an entire organization.

In previous research, there has been a lack of studies on inter-disciplinary knowledge sharing in the public sector. The Architectural Services Department (ArchSD) of the Hong Kong Special Administrative Region (HKSAR) is chosen as the research case because of its relatively large organization size and the fact that it comprises construction professionals from different disciplines.

This research has the following three objectives:

- To identify the frequency of and need for inter-disciplinary knowledge sharing.
- To investigate current knowledge sharing channels and their effectiveness within ArchSD.
- To analyze the types of knowledge shared among various professionals within ArchSD.

2. Inter-disciplinary Knowledge Sharing

Knowledge sharing is a mechanism installed to encourage the sharing of expertise throughout an organization [1]. Knowledge begins with the individual, with new brilliant ideas or fruitful experience. It then comes to the central activity of making personal knowledge available by sharing it with others. This takes place continuously and among professionals of the same and/or different disciplines.

When knowledge is shared across the professional boundaries between different professionals, this type of sharing is identified as ‘inter-disciplinary knowledge sharing’. Professionals can share their own disciplinary knowledge, general knowledge or past project experience. With this kind of knowledge sharing, professionals can solve problems more effectively and readily with others, as Kjellin and Stenfors [2] and Traunmuller and Wimmer [3] suggest. Both tacit and explicit knowledge can be shared in inter-disciplinary knowledge sharing. However, explicit knowledge can be retrieved and transmitted more easily than tacit knowledge [1].

As listed in Table 1, different sharing channels are developed to gather, organize, distribute and share knowledge among professionals throughout an organization. Traditional sharing channels used are documentary records, meetings and direct discussion. In the last decade, with the development of information technology, some new channels such as email and database have been developing rapidly, and it is believed that they will play a major role in the future.

Table 1: Knowledge sharing channels

Knowledge Sharing Channels	
▪ **Documentary**	Memoranda and letters
	Project records
	Internal newsletter and circulars
▪ **Direct discussion**	Formal project meetings
	Informal discussions
	Talks and seminars
▪ **Technological**	Database
	Email
	Internet
	Intranet
	Teleconferencing

Everybody has knowledge useful to somebody else within an organization. Inter-disciplinary knowledge sharing helps individual professionals specialized in certain disciplines to exchange relevant knowledge and experience with specialists of other domains. Huysman [4] indicates that sharing supports the goals in mind of acquiring knowledge, reusing knowledge and developing new knowledge. Effective sharing channels can reduce areas and time people spend on looking for relevant information and knowledge. Thus, individuals' productivity is enhanced.

Knowledge sharing also benefits entire organizations by enhancing the efficiency and effectiveness of the work performed. With knowledge sharing, the problems of an organization in re-learning lessons, repeating mistakes, reinventing solutions or recreating knowledge that already existed in the mind of another professional, as suggested by Seeley [5], will be solved. So, the better the organization can recognize its employees' expertise, the better it is at making decisions and maintaining competitiveness, no matter whether in the public or private sector [6].

Although all construction projects have unique features, some typical problems are frequently repeated. For example, poor logistics co-ordination has led to time and material wastage. And criticism of a design's buildability, poor project management and contractual disputes are common [7]. If knowledge sharing is promoted in the construction industry, problems in one project would be the teachers for the next one. Knowledge sharing is thus an effective and proactive way to prevent problems from happening again. This helps to solve the problem of un-recycled knowledge mentioned by Awad and Ghaziri [1].

3. Case Organization

The Architectural Services Department was established in April 1986 to provide a comprehensive range of multi-disciplinary professional and technical services to the HKSAR Government and quasi-government organizations. Its mission is to provide services in a professional manner. There are six branches under the ArchSD: the Project Management Branch, the Architectural Branch, the Building Services Branch, the Structural Engineering Branch, the Quantity Surveying Branch and the Property Services Branch.

The ArchSD is responsible for the design and construction of government buildings and facilities, as well as those of subvented organizations like the Hospital Authority. It also provides associated professional services related to engineering, planning, landscaping, and the maintenance and repair of buildings. Within ArchSD, there are about 2000 posts that are composed of directorate, professional, technical, site and general staff. Professionals from various disciplines work together to provide for the comprehensive functioning of the department's services. The variety of services of the ArchSD also requires professionals to cooperate and coordinate intra-disciplinarily and inter-disciplinarily. In this way, the department's mission of providing services in a professional manner can be achieved.

4. Research Methodology

4.1 Sample and Data Collection

In this study, quantitative analysis is adopted as the objective of the study is to investigate knowledge sharing practices among different professionals in ArchSD. Feedback from a number of respondents from different disciplines is required in order to draw up a clear and broad view of the overall situation. A questionnaire survey was implemented due to the following reasons:

- Easier to reach a larger number of respondents,
- More convenient for respondents to fill in compared with lengthy face-to-face interviews,
- No interview bias,
- Less chance of feeling embarrassed, as some questions are personal.

The purpose of the questionnaire survey was to find out the current inter-disciplinary knowledge sharing practice in the ArchSD, with special emphasis on the sharing channels. A 6-point scale was used as the weighting order for questions concerning the tendency and attitudes of respondents.

4.2 Questionnaire Administration

The target population was selected by random sampling of the staff list of the Government of the Hong Kong Special Administrative Region. According to the job functions in the Architectural Services Department, 50 professionals were randomly drawn from each of the five disciplines, namely architectural (Arch), building services engineering (BSE), maintenance surveying (MS), quantity surveying (QS) and structural engineering (SE). A total of 250 questionnaires were sent with stamped return envelopes to stimulate an acceptable response rate.

4.3 Response Rate

The number of responses and corresponding response rate are listed in Table 2 according to the job function classification. Out of the 250 questionnaires sent to the ArchSD, 95 valid questionnaires were returned (response rate = 38%). According to Black et al. [8], typical response rates in research in the construction industry are around 30%. Thus the response rate in this research is satisfactory and acceptable.

5. Data Analysis

Data were analyzed using descriptive statistics such as percentages and frequencies to present the sample characteristics such as job function and work experience in the ArchSD. Further descriptive statistics of mean and standard deviation (SD) were used to present the preferences and tendency of respondents in terms of their main attitude towards knowledge sharing practices and channels.

5.1 Respondents' Background

Table 2 shows the distribution of respondents according to their job functions. About 30% of the respondents were in the maintenance surveying profession, while quantity surveying professionals only accounted for 15.8%. Architecture, building services and structural engineering professionals have the same percentage: 17.9% of all survey respondents.

Table 2: Response rate according to job function

Job Function	No. Forwarded	No. of Responses (Valid)	Response Rate	% of Overall Responses
Architecture	50	17	34%	17.9%
Building Services Engineering	50	17	34%	17.9%
Maintenance Surveying	50	29	58%	30.5%
Quantity Surveying	50	15	30%	15.8%
Structural Engineering	50	17	34%	17.9%
Total	250	95	38%	100.0%

From Table 3, over 85% respondents had 6 years' experience or more, while professionals with over 10 years' experience accounted for 55.8%. Due to the reduction in new recruitment in the ArchSD in recent years, no respondents had 3 years' experience or less. This means that the survey findings tend to reflect the attitudes of experienced professionals.

Table 3: Distribution of work experience of respondents

Work Experience in ArchSD	Frequency	Percentage
Less than 3 years	0	0%
3 - 6 years	14	14.7%
6 - 10 years	28	29.5%
More than 10 years	53	55.8%
Total	95	100.0%

5.2 Frequency of and Need for Inter-disciplinary Knowledge Sharing

As Table 4 reveals, the mean scores of inter-disciplinary sharing frequency are all above 4, showing that inter-disciplinary knowledge sharing is quite common in the ArchSD. The highest mean score was for sharing with architects, which is not surprising as they are responsible for the design and are in charge of the whole construction process. Different professionals need to refer to the architects to clarify and interpret drawings and answer queries. The high sharing frequency with architects and building services engineers also reflects the complexity of their tasks, which require frequent coordination.

The mean score is the lowest with the maintenance surveying profession. This result is consistent with real life, in which their work nature requires less sharing with other professions. This is because of their job function, which deals mostly with alterations and maintenance. Their involvement in projects is more independent and requires less sharing with other colleagues during the project lifecycle. Nevertheless, they still need to collaborate with other project team members in order to carry out their jobs properly.

Table 4: Percentage and mean of sharing frequency with different disciplines

Sharing Frequency with	6	5	4	3	2	1	Mean	SD
Arch	23.25%	26.75%	24.41%	16.28%	8.14%	1.16%	4.37	1.29
BSE	20.96%	30.12%	16.31%	22.12%	8.15%	2.33%	4.27	1.36
MS	29.71%	19.31%	19.31%	4.46%	12.34%	14.86%	4.06	1.82
QS	15.73%	29.27%	26.83%	10.97%	9.81%	7.38%	4.17	1.37
SE	17.65%	21.18%	35.29%	11.77%	9.41%	4.70%	4.12	1.36

(6 = Always; 1= Seldom)

The sharing need shows a similar distribution pattern as the sharing frequency, with the mean above 4 (Table 5). The highest mean score is obtained from sharing with architects, indicating how important it is for architects to communicate with and provide information to other professionals.

Table 5: Percentage and mean of need to share with different disciplines

Need of Sharing with	6	5	4	3	2	1	Mean	SD
Arch	21.94%	28.05%	30.49%	12.20%	6.09%	1.22%	4.44	1.21
BSE	20.73%	29.27%	23.17%	18.29%	7.32%	1.22%	4.34	1.27
MS	28.36%	17.91%	23.88%	14.93%	8.96%	5.97%	4.24	1.53
QS	14.29%	22.08%	36.36%	11.69%	11.69%	3.90%	4.14	1.32
SE	15.66%	22.89%	32.53%	13.26%	14.46%	1.20%	4.08	1.30

(6 = Very High; 1 = Very Low)

5.3 Frequency of Sharing Channels Used

As Table 6 shows, email is the most popular and frequently used channel in knowledge sharing in the ArchSD (mean = 4.80), which is unsurprising as it is fast and user-friendly. However, the use of other information technology is not common. The Internet (mean = 3.80), databases (mean = 3.00) and teleconferencing (mean = 1.99) are rarely used in the ArchSD. This shows that the advantages of information technology as a 'knowledge enabler' in sharing, as suggested by Awad and Ghaziri [1], are not fully utilized in the ArchSD.

The high ranking of informal discussion (mean = 4.68) and formal meetings (mean = 4.58) shows that channels involving direct communication and interaction are also popular in the ArchSD, in both formal and informal ways. Meetings provide a good opportunity for different professionals to share knowledge, receive feedback and observe non-verbal clues from project members. However, the frequency of formal meetings is highly dependent upon an individual project's or organization's requirements. Even though professionals find them effective, individuals cannot control the frequency of meetings.

Table 6: Frequency of using different sharing channels

Frequency	6	5	4	3	2	1	Mean	SD	Rank
Database	4.54%	14.77%	23.87%	12.50%	21.59%	22.72%	3.00	1.55	10
Email	30.85%	38.29%	20.21%	3.19%	5.32%	2.13%	4.80	1.20	1
Formal project meeting	18.28%	35.49%	34.41%	9.67%	2.16%	0.00%	4.58	0.97	3
Informal discussion	23.16%	36.84%	30.53%	4.21%	5.26%	0.00%	4.68	1.04	2

(6 = Always; 1 = Never)

5.4 Effectiveness of Sharing Channels

Similar to the frequency distribution of channels, informal discussion, formal meetings and email are the top three most effective sharing channels used by the respondents (Table 7).

During meetings, professionals can share knowledge effectively by expressing opinions and ideas to the team directly. This helps in the collective evaluating and redesigning of new knowledge to the team. Some formal meetings such as project review meetings and project briefing sessions can generate new ideas and provide lessons learned to project participants, which can achieve the aim of knowledge sharing. Informal discussion allows people to discuss issues in a more informal and relaxed environment compared with formal project meetings, as taking minutes can have a “backfire” effect on open sharing. Email as a communication channel does not provide a rich source of interaction, and the meaning of an email can easily be misinterpreted by its receivers as it lacks non-verbal clues.

Table 7: Effectiveness of using different sharing channels

Effectiveness	6	5	4	3	2	1	Mean	SD	Rank
Database	4.76%	25.01%	23.81%	11.91%	14.28%	20.23%	3.33	1.59	11
Email	23.92%	46.74%	18.48%	5.43%	3.26%	2.17%	4.76	1.11	2
Formal project meeting	23.08%	37.36%	27.47%	10.99%	1.10%	0.00%	4.70	0.98	3
Informal discussion	23.66%	45.16%	18.27%	10.76%	2.16%	0.00%	4.77	1.00	1
Internet	8.34%	22.62%	17.86%	15.47%	13.10%	22.62%	3.30	1.68	12
Intranet	14.44%	32.23%	26.67%	5.55%	8.89%	12.22%	4.01	1.56	7
Internal newsletter and circulars	10.22%	20.46%	31.82%	19.32%	7.96%	10.22%	3.75	1.42	10
Internal training courses	7.61%	31.53%	34.78%	13.04%	5.43%	7.61%	4.00	1.29	8
Other meetings	17.20%	32.26%	33.33%	11.83%	2.16%	3.23%	4.40	1.16	4
Memoranda and letters	19.56%	27.17%	31.52%	15.22%	4.35%	2.18%	4.36	1.21	5
Talks and seminars	8.69%	31.56%	29.33%	22.82%	4.34%	3.26%	4.08	1.17	6
Teleconferencing	6.25%	7.51%	11.25%	11.25%	11.25%	52.51%	2.29	1.65	13
Others	33.39%	16.61%	16.61%	0.00%	0.00%	33.39%	3.83	2.32	9

(6 = Most Effective; 1 = Least Effective)

As Table 8 reveals, the ranking of the effectiveness of different channels is similar to the ranking of their frequency of use. This suggests that the use of sharing channels is quite successful in the ArchSD, as the frequently used channels are also the effective ones. Actually, the frequency and effectiveness are closely related. Channels such as databases and teleconferencing are not classified as effective, as they are rarely used.

Table 8: Ranking of frequency and effectiveness of different sharing channels

Sharing Channels	Frequency Ranking	Effectiveness Ranking
Database	10	11
Email	1	2
Formal project meeting	3	3
Informal discussion	2	1
Internet	12	12
Intranet	6	7
Internal newsletter and circulars	8	10
Internal training courses	8	8
Other meetings	5	4
Memoranda and letters	4	5
Talks and seminars	7	6
Teleconferencing	13	13
Others	11	9

5.5 Types of Knowledge Shared

Through the use of different sharing channels, different types of knowledge can be shared (Table 9). It is not surprising that project knowledge is the type most frequently shared among different disciplines (mean = 5.02), while product knowledge scores the lowest mean of 3.73. Procedural knowledge is ranked second, as each organization or department has its own procedures or routines to follow. Operation and maintenance knowledge ranks third, as a properly designed facility also needs to consider future maintenance issues: no facility is maintenance-free. In addition, operation knowledge provides the comfort that people truly desire when a facility is in operation.

Concerning product knowledge, the architectural and maintenance surveying professions rate this much higher than other professions. This is due to their work nature. Architects are involved with the aesthetic issues of a project, and maintenance surveyors work on the compliance with building requirements and maintenance of facilities.

Table 9: Mean scores of different knowledge types shared among disciplines

Types of Knowledge Shared	Job Function					Overall
	Arch	BSE	MS	QS	SE	
Project knowledge	5.18	5.35	5.00	4.93	4.65	5.02
Operation and maintenance knowledge	4.35	4.59	4.97	3.13	3.88	4.18
Procedural knowledge	4.47	5.00	4.79	4.67	3.76	4.54
Process knowledge	4.00	4.53	4.41	3.73	3.76	4.09
Product knowledge	4.29	3.65	4.24	3.07	3.41	3.73

(6 = Always; 1 = Never)

6. Conclusions and Recommendations

The purpose of this research was to study the knowledge sharing of professionals of different disciplines in the Architectural Services Department. In the construction industry, the different professionals have their own expertise. However, they need to share knowledge, experience and information with other project team members in order to perform their jobs properly. Otherwise, the construction industry does not need to call on such a wide spectrum of specialization.

The survey findings indicate that most of the professionals in the ArchSD need knowledge sharing, though such sharing is less practiced with maintenance surveying professionals due to the lower demand for sharing in their work environment. Different types of knowledge, such as operation and maintenance knowledge, procedural knowledge and product knowledge are shared. Among them, project knowledge, including project designs, contractual arrangements, management experience and skills, etc., is the most frequently shared. In addition, project-organizing knowledge is also required, as managing a construction project is a complex business.

To cope with the need for sharing and to enhance the benefits of sharing, different sharing channels are developed. These range from traditional documentary records and meetings to newly developed information technological systems and networks. The findings of this research show that email, formal meetings and informal discussion are the most frequently and effectively used sharing channels. A close relationship between the frequency and effectiveness of sharing channels is noted. Professionals prefer to use traditionally effective channels. Some newly developed channels, such as databases and teleconferencing, are rarely used, and hence are not seen to perform effectively. There is room to develop the use of such new channels. Although the research findings are based on a particular government department, it is believed that similar conclusions can be applied to other types of organizations within the construction industry.

Based on the survey analysis, the following recommendations are made to the Architectural Services Department. They can also be applied to other organizations, subject to careful consideration to suit their own situations.

- It is found that newly developed information technology such as databases and intranets are not extensively utilized in the ArchSD. Developing sharing channels such as setting up project-based intranets, extranets or information platforms is recommended, as they help to cope with the increasing demand for sharing and follow the development of IT in society. In addition, a properly designed intranet enables knowledge to be captured and form part of the organization's memory system, as it enhances information searching and re-use abilities.

- To develop knowledge sharing, emphasis should not be purely on documentation, rules and procedures. Rather, human issues, cultivating a sharing culture and increasing trust among staff are more essential for successful knowledge sharing.

- The department should develop a common consensus with the staff that knowledge sharing cannot be developed overnight. The same rule applies to the benefits that are obtained from knowledge sharing. Resources are spent at first to develop sharing channels and overcome difficulties. However, the final outcome of being an effective and efficient organization utilizing its knowledge base is the best reward. This is especially true in the construction sector, where close cooperation and frequent sharing among different disciplines is an absolute requirement to solve problems in individual projects as well as for the entire industry.

Learning from Experience: New Challenges, Theories, and Practices in Construction

One of the most important outputs of any construction project or process is the valuable experience and corresponding knowledge that is gained. This may be in the form of lessons on as to what to do and what not to do in future projects. It can furthermore lead to a challenge that challenges the very nature of how construction projects and processes are managed.

This book is a collection of how learning from experience has contributed to the identification of new challenges, development of new theories, and management of knowledge in construction. Case studies provide practical insights into the subject matter.

How has project management evolved, what have we learnt, what are future research frontiers, should we be managing projects as if we were managing production, can public institutions stimulate innovation in construction, how do social networks contribute to organisational learning and knowledge sharing, etc., are some of the questions this book provides answers to.

This book is part of a series of scholarly books on *Combining Forces – Advancing Facilities Management & Construction through Innovation*.

Other books in this series include:
-Understanding the Construction Business and Companies in the New Millennium
-Global Perspectives on Management and Economics in the AEC sector
-Systemic Innovation in the Management of Construction Projects and Processes
-Facilities Business and its Management
-Performance Based Building
-ICT in Construction and Facilities Management

ISBN 952-5004-68-6
