These initiatives taken by the Portuguese Government are in line with the efforts made at the international level for the adoption of a more comprehensive framework for the public entities to record their holdings and prepare their financial statements according to the rules of the private sector. This exercise based in recognised national or international standards should lead to greater accountability and more efficient use of resources [1]. This surge in interest for valuing public properties is well explained by Lundstrom and Lind [2] for the case of Sweden - "…partly for ideological reasons, partly for financial reasons, there has been a growing interest in sales of public properties. The public sector has large holdings of real estate (land, special-purpose properties, housing properties and even commercial properties). Sales of real estate could raise considerable revenue…..The cut-back in public administration and public services has also led to vacancies, and an interest in selling properties that are no longer needed for their original purpose" (Lundstrom and Lind, 1996, p 32)[2]. A recent illustration, in the case of Portugal, was the purpose of the Government to sell and lease back a substantial amount of State real estate in order to keep the government accounts in conformity with the Maastricht criterion of budget deficit. However, this action was called off due to a political crisis.

In the first section, the paper presents the classification and the valuation methods used in public sectors assets in Portugal. This is done through a review of the national legislation, viewed within the context of the international regulatory framework on the issue. The next section, and based on previous research, presents the results of a survey on accounting and valuation practices in Portuguese municipalities. Finally, a concluding comment summarises the results of the study.

2. Asset classification and asset valuation in Portugal

The Portuguese legislation prescribes that all public sector assets shall be recorded, but allows that the register might include assets accounted at zero value, while the valuation of other assets may derive from either on the basis of the market value, the salvage value, or the replacement value, among others.

Local government assets, like all public sector assets, are classified according to the following categories:

- **Public domain assets**- as "Assets which, belonging to a collective public right entity, are subject by law to a special juridical regime characterised mainly for being nontradable, in order to preserve the production of their public use…"[3]. This category comprises the following assets: roads, parklands, water supply and sanitary networks, electric power networks and heritage goods.

- **Private domain assets-** as "Assets which, not being considered in public domain, are, in principle, integrated in the ownership regime established in the civil law and are, consequently, subject to the corresponding juridical trade….". [4]. Assets in this category comprise property, plant and equipment, which are not part of the public domain. This category is further divided in *non-disposable private assets,* which are those that are hold and used by the public entity to deliver its statutory services, *and disposable private assets,* which are occupied by the entity but can be transacted at any time.

As stated earlier, the Portuguese legislation stipulates that all type of assets administered by local authorities shall be registered. Thus, apart from the disclosure and classification, the public entity shall value all its assets, both public and private domain goods, in order to elaborate a comprehensive register of all assets to be accounted in the balance sheet and other financial reports. In the case of fixed assets, the POCAL prescribes that this exercise shall also comprise public sector assets in the administrative sphere of the entity, and even those that are in financial leasing regime.

According to the POCAL and CIBE, the production cost or acquisition cost approaches are used as a general rule in the valuation of local authority assets (Figure1). In the cases these valuation methods cannot be applied, or do not provide an accurate picture of the financial and patrimonial situation of the institution, other valuation methods should be used (present value calculated through the discounted cash-flow method, sales comparison method and replacement cost method). If it is not possible at all to value an asset, the notes in the financial statements must indicate which kind of assets is not accounted for, as well as the respective explanation. In this case, namely for historical and cultural goods, they must be recorded and accounted for at zero value, unless they are insured. In the latter situation the insurance value is the basis for the valuation.

The method used in Portugal for quantifying depreciation of public sector assets is the percentage depreciation method, according to the depreciation rates prescribed in the CIBE classifier, according to each type of goods.

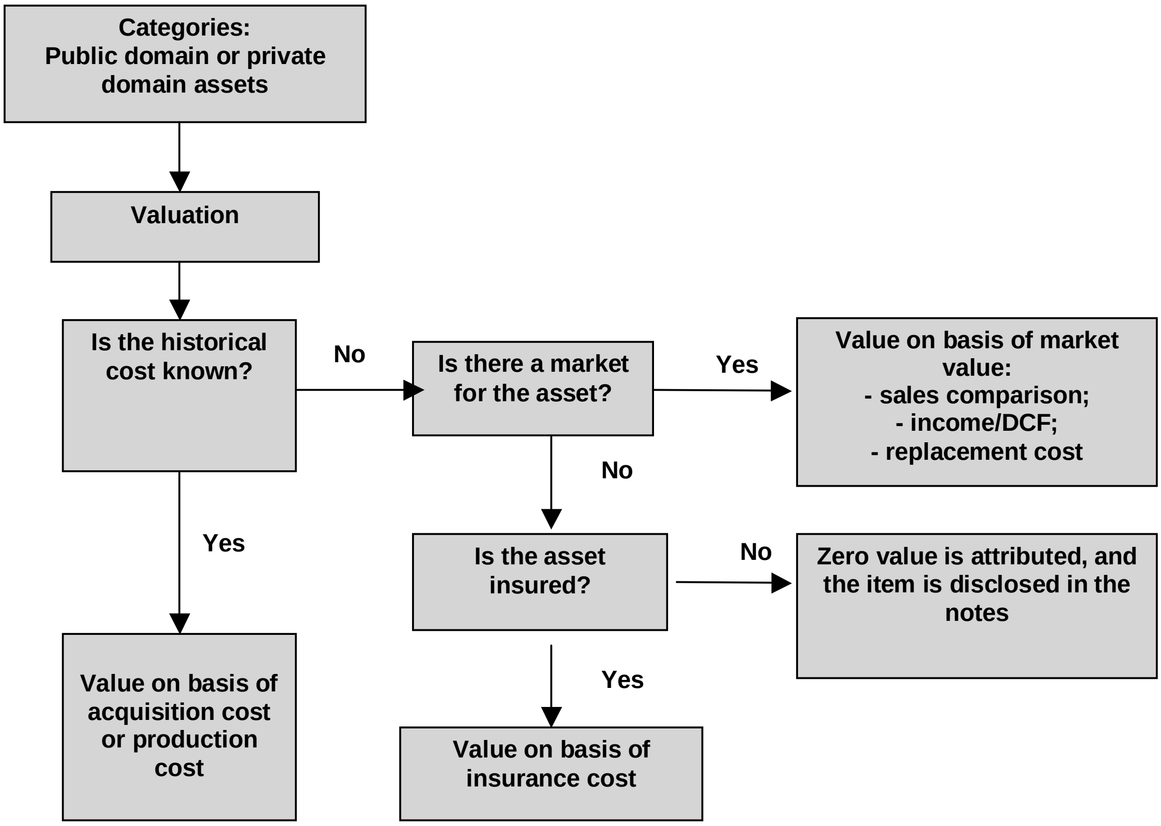

Figure 1: Asset valuation in Portugal

At the international level, the IPSAS (International Public Sector Accounting Standard) 17 [5] prescribes that it is an option for the public sector entities to recognize in their balance the public domain goods that satisfy the recognition criteria of a tangible fixed asset. However, if they do opt for recognition they must follow the disclosure requirements, but not the valuation requirements. According to IPSAS 17 §13 and IAS (International Accounting Standard) 16 §8 [6], a good should be recognised as a fixed asset when two conditions are cumulatively met:

- It is probable that future economic benefits or service potential associated with the asset will flow to the entity; and
- The cost or fair value of the asset to the entity can be measured reliably.

However, the valuation of public sector assets has been subject to many controversies. Several writers [7, 8] have questioned the opportunity and relevance of the register and subsequent valuation of certain types of assets, namely heritage assets, military assets and public goods, which are rarely, if ever, transacted. Furthermore, there are differing points of view and debates, particularly in respect of definition and valuation practices (Pallot, 1997), cited in [9].

In order to place the Portuguese classification and valuation of public sector assets into a comparative perspective, the following categorisation and classification of public sector properties in United Kingdom is presented, according to the RICS *Red Book* (Connellan, 1997, p 216)[10]*:*

- **Non-operational assets**: as "Fixed assets held by a local authority but not directly occupied, used or consumed in the delivery or services. Examples …are investment properties and assets that surplus to requirements…."
- **Operational assets:** as "Fixed assets held and occupied, used or consumed by the local authority in the direct delivery of those services for which is has either a statutory or discretionary responsibility".
- **Community assets**: as "Assets that the local authority intends to hold in perpetuity, that have no determinable useful life, and that may have restrictions on their disposal…"
- **Infrastructure assets**: as "Fixed assets which are inalienable assets, expenditure on which is recoverable only by continued use of asset created. Examples are …highways and footpaths".

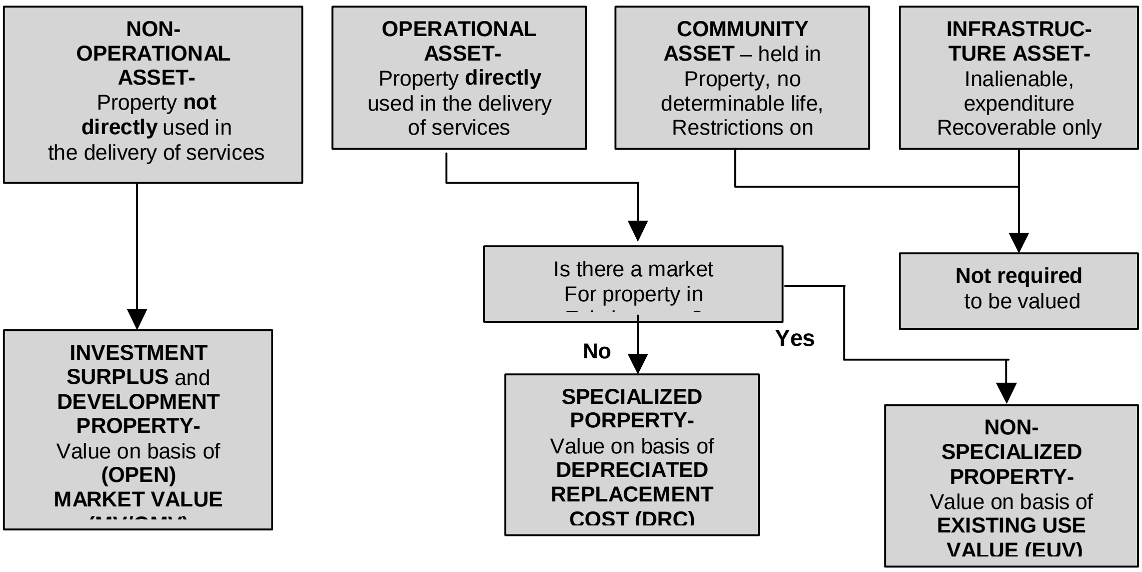

Figure 2: Classification and valuation treatment of assets in UK Source: [10]

Thus, there is no significant difference between the Portuguese and UK classifications of Public sector assets except that the UK categories *infrastructure assets* and *community assets*, taken together, correspond to the Portuguese *public domain assets.* Regarding the valuation practices in the public sector, it can be seen (Figs. 1 and 2) that whereas in Portugal all kind of assets shall be valued, in UK there are some categories (community assets and infrastructure assets), which are not required to be valued.

3. A Survey on the Practice of Local Authority Accounting in Portugal

3.1 Method of Data Collection

As stated before, this section is based on a previous research [11], which was undertaken with twelve local authorities of a district in the north-eastern region of Portugal. The study consisted of structured interviews with representatives of the municipalities (city mayors and/or valuation officers) and was aimed to get acquainted about the way local authorities did register and value their fixed assets, as wells as to get a general view of how they did comply with the new accounting practices. The objective of those face-to-face interviews was to assess the criteria and methods used in each phase of the accounting process (classification, valuation and accounting) and to ascertain the main problems and difficulties they faced in their statutory responsibilities. A summary of the results is provided below.

The results of the initial study shows that, despite local governments are required by law to record their holding of property and other assets since the financial year 2000, nine (75%) of these entities had not undertaken at that time (2002) the register and valuation of none of their assets. The municipalities that had already undertaken the exercise used the valuation criteria prescribed in the POCAL and RICB (Regulation of Cadastre and Register of Local Authority Goods), most often on the basis of the acquisition cost or production cost whenever support documents existed. Other valuation criteria based on the market value approach were also used, namely in roads, public lighting, water treatment and water supply networks. These criteria, depending on the type of goods, are based on the fair value concept and cost replacement value, and are statutorily established by the *Valuation Commissions* whose members are designated by the City Councils. Out of the twelve local authorities analysed, only one had at the time an approved RICP, which limits to a simple transcription of the valuation criteria prescribed in the POCAL, and disregards the situations in which a valuation method should be used in detriment of others.

In order to complement and update the data obtained in the earlier study, a letter was sent in 2004 to the same local government representatives to provide the financial statements of the year 2003, which comprised, among others, the following documents: the annual budget of the entities as well as its execution, the balance sheet at December 31, 2003, and the notes to the balance sheet. Only six (50%) of the local authorities responded to the request.

In the methodology adopted in the study, the data were collected on the basis of the figures and information expressed in the aforesaid documents, namely the expenditure budget control map, the balance sheet and the notes.

3.2 Results of the Survey

Classification and Valuation of Assets

Regarding the classification of assets, the analysis of the data indicates that all municipalities that responded to the request followed the legislation into force. It was, however, emphasised that there were difficulties in distinguishing between private domain and public domain assets, and often in establishing the ownership rights (whether local or central government) over the same assets. Another difficulty concerning all local governments analysed had to do with the lack of records and project designs, namely water and sanitary system designs.

With respect to the valuation of the assets, the data analysed show that 66.67% of the municipalities did not provide the criteria used in the calculation of the fixed assets. Only two, 33.33%, of the municipalities provided in the notes the criteria used in the valuation - the acquisition cost or production cost as a general rule. One of these two entities attributed a zero value to the public domain assets existing until the beginning of 2002, due to varied problems: lack of historical records; difficulty in establishing the ownership of the assets; and the lack of objective valuation criteria pre-established by the competent authorities. The other municipality, in the initial register, used other valuation criteria other than the production cost or acquisition cost for a set of public domain assets, for which information on the acquisition cost was not available. It is assumed that the valuation methods might have been either the replacement value or on the basis of market value approach. The choice of the valuation method was established by an expert commission. With the data available, it was not possible to ascertain the significance of each valuation method in the measurement of total fixed assets of the entities. As an example, for the case of the U K, the following results are presented regarding the valuation methods used in a set of local authorities: Replacement cost – 33%; Sales comparison – 32%; Income/ DCF – 20%; and Other – 15% [1].

For the quantification of depreciation, the valuation officers of the local authorities used the percentage depreciation method, following the prescriptions in the POCAL. As stated earlier, the annual depreciation is calculated on the basis of the depreciation rate defined in the CIBE classifier.

The Clout of Public Domain Assets and Total Fixed Assets

Drawn from the balance sheet of the local authorities, Table 1 presents the share of public domain assets and total fixed assets in the total balance of the entities. It can be seen that the share of the public domain assets varies widely across municipalities - from 4.6 % to 61.6%. This situation is explained by the fact that, as already noted, one municipality accounted at zero value all existing public domain assets in the reference year 2002. In some municipalities, the figures concerning the same category of assets correspond mostly to work in progress.

Table 1- Clout of Public Domain Assets and Fixed Assets in Total Asset

Municipality	***Public Domain Assets/ Total Asset***	***Total Fixed Assets/ Total Asset***	***Total Asset* (€)**
A	22.2%	83.6%	7,751,826
B	4.6%	92.4%	4,249,714
C	26.2%	98.6%	35,350,269
D	22.2%	94.1%	22,801,643
E	33.9%	96.2%	2,292,204
F	61.6%	97.9%	90,438,465

Source: Financial Reports from Local Authorities (2004)

The majority of the municipalities, which have undertaken the valuation of their public domain assets, claimed that there is a lack of trained valuation officers, which would allow them a thorough classification and measurement of their assets. This problem gets worse for the small municipalities are precisely those that present a lesser share of fixed assets in total assets. However, when asked about the importance of the disclosure and valuation of public domain assets, 90% of the interviewees found that that was very important for the majority of the expenditure of the municipalities referred to the production and management of public domain goods.

The picture that emerges from Table 1 (as wells other data from the financial statements) suggests that it is not possible to elaborate a balance sheet that provides an accurate picture of the value of fixed capital of a municipality, so as to allow a comparison between municipalities. In fact, it appears to be a daunting task to draw a comparison between two municipalities, in which one has a total asset valued at € 2,000,000 and the other a total asset of € 35,000,000, when, apparently, the differences between them are not much significant, both in terms of population and territorial dimension, and in terms of the amount of physical infrastructure. In an earlier study, it was pointed out that identical assets were valued trough different methods, for there are no clear rules about when and which methods to be used in each category of assets. This fact was, according tom that study, the main problem for the municipalities to comply with their legal accounting responsibilities [11].

Table 1 also indicates that the value of fixed assets represents, in all but one case, more than 90% of total asset. The share of other components of the total asset is almost residual. If we take into account that some municipalities did not value all of their fixed assets, the clout of this indicator will, in a further accounting exercise, become even higher.

Table2: Share of Capital Expenditure and R & M Expenditure in Total Budget 2003)

Municipality	***Capital Expenditure / Total Budget***	***R & M Expenditure/ Total Budget***
A	55.04%	0.19%
B	39.43%	0.73%
C	49.57%	081%
D	47.92%	0,61%
E	29.03%	0.81%
F	60.53%	0.24%

Source: *Financial Reports from Local Authorities (2004)*

Table 2 presents the share of Capital expenditure and R&M expenditure in the total budget of the municipalities in 2003. It can be seen that the former represented bout 50% of total budget and the share of R& M was insignificant. The latter is explained by the fact that repair and maintenance is treated as current expenditures in line with the Portuguese *National Accounts*. Thus, the expenditure on capital comprises only new construction and equipment and major repairs. Data from the financial reports indicates that construction (building and civil engineering) represents the major part of the capital expenditure of the municipalities. This, added to the fact that most of existing fixed capital is comprised of construction stock, is a significant aspect that reflects the importance of property in the economy of the municipalities.

According to a recent study undertaken by a CIB (International Council for Research and Innovation in Building and Construction) project group, after allowing for cyclical fluctuations, the general trend in construction activity in very developed countries is for construction activity to be in a relative decline [12]. The study also reveals that a noticeable feature of the activity of the industry in these countries has been the change in the *new build: repair and maintenance* mix over the last few decades. Repair and maintenance now accounts for almost a half of the industry’s activity, as stock management has become a relatively much more important aspect, particularly in post-industrial economies. Although the share of R& M in total construction is about 7% (this figure is certainly underreported), it is assumed that the development pattern of the construction industry in Portugal will follow in the medium to long term the general pattern of the highly industrial countries [13]. As fair as local authorities are concerned, there has been a trend in shifting responsibilities from central to local government with respect to the management of infrastructural assets. The repair and management of this huge stock will become a central aspect in the activities of the municipalities.

4. Conclusion

This paper has presented an analysis on the criteria and methods of classification and valuation of public sector assets in Portugal, with a particular focus on local authorities. The results of the study have shown that despite the municipalities are required by law to record and value their holdings of property and other fixed assets since the financial year 2000, some of the entities analysed in the study did not comply with their legal responsibilities. The entities that did undertook the exercise emphasised definitions problems in what concern the distinction between public and private domain goods, and lack of a comprehensive framework to the valuation practice in the public sector. Though the latter aspect is also an international concern, the problem is aggravated in Portugal due to a lack of clear rules for the classification and valuation of public assets.

The analysis has also shown that building (both public domain and private domain buildings) and civil engineering infrastructures have a significant impact on the economy of the municipalities, both in terms of existing capital stock and in terms of annual capital expenditure. Taking into account that the trend is the increase in the repair and management of existing in stock to the detriment of new build, this aspect may have implications for the management of the activities of local authorities, and certainly for all public policy in the years to come.

The sample analysed in this study is very small and may not provide a true picture of the valuation and accounting practices in Portuguese local authorities. Anecdotic evidence, however, suggests that, allowing for <major metropolitan areas, some patterns that were outlined still hold for the majority of the local authorities. Of course, the sample should be broadened and the underlying issues should merit a more thorough investigation. This is the subject for further development.

Global Perspectives on Management and Economics in the AEC Sector

Global business can have a wide variety of appearances from temporary projects to carefully established new business operations. In addition, rapid manoeuvres of capital investments between countries and companies are creating new challenges and, of course, opportunities. Globalization and global aspects are increasingly affecting management and economics in the AEC sector. This book is bringing together results from research and development around the world on managerial and economical issues.

Can building economics become instrumental in reforming construction and its relationship with facilities management? Life cycle economics, competitiveness, economic efficiency, new valuation approaches and integration of various values are topics of importance at the moment. These demonstrates aspects of significance covered by this book.

This book is part of a series of scholarly books on *Combining Forces – Advancing Facilities Management & Construction through Innovation*.

Other books in this series include:
-Understanding the Construction Business and Companies in the New Millennium
-Systemic Innovation in the Management of Construction Projects and Processes
-Facilities Business and its Management
-Performance Based Building
-ICT in Construction and Facilities Management
-Learning from Experience – New Challenges, Theories, and Practices in Construction

Preface

In an industry that is dominated by one-of-a-kind projects involving competence sharing between different organisational entities, and thin profit margins, a key challenge in the new global economy is to ensure delivery of projects that are on time, within the cost limits, of high levels of quality, sustainable, and provide value to the customer. All this, while ensuring that contractors remain profitable without raising project costs. This calls for systemic innovation in the management of construction projects and processes that takes into consideration all relevant aspects and stakeholders of the complete product and service lifecycle [1, 2 and 3].

The Project Management Body of Knowledge (PMBOK) [4] provides one perspective to the effective management of projects and processes. Understanding the unique characteristics of the construction industry, a special construction extension to the PMBOK was released [5]. It is primarily based on a set of guidelines for different functional areas for the management of processes within projects. Concerns have however been raised about its completeness and applicability[1]. In fact, Koskela and Howell [6] challenged the validity of the underlying theory of project management. If not more, this at least presents the impetus to explore project management from a different set of perspectives. As an example, one could consider management of processes and projects from the perspective of information flows and contract networks (figure 1) within inter-enterprise project environments such as construction [7]. This simple illustration is an indicator of some of the underlying problems in the management of processes and projects within the construction sector.

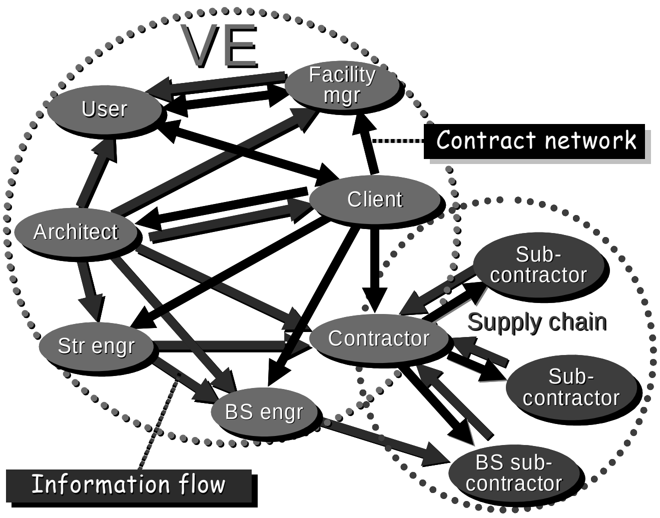

Figure 1: Information flows and contract networks within construction projects

The challenge of systemic innovation in the management of construction projects and processes has been taken up in this book. Contributions and experiences from Australia, Brazil, China, Croatia, Finland, Norway, Saudi Arabia, Sweden, Taiwan, The Netherlands, United Kingdom, and USA unveil how systemic innovation is being used to manage projects, product processes and control, productivity and performance improvement, product delivery systems and contractual practices, and risk management.

Acknowledgements

This book would not have been possible had it not been for the untiring efforts of Dr. Kalle Kähkönen, Chief Research Scientist, VTT – Technical Research Centre of Finland, in championing the scholarly book series on *Combining Forces – Advancing Facilities Management and Construction through Innovation*. A special note of appreciation is extended to all contributing authors for their willingness and enthusiasm in sharing their research and experiences from practice.

Abstract

More than £ 1 billion of public funding has been spent by the Arts Council of England (ACE) Lottery Fund on the arts, mainly on building constructions. However, it is evident that many of these projects were completed over the budgeted amount and scheduled time. Among various phases in the procurement, the briefing process has been considered critical to successful construction and yet problematic in its effectiveness. Whilst the briefing process in construction projects has been generally claimed to 'limit' the client in further stages, the briefing process for the Arts is required to translate the spatial needs of the so-called 'artistic vision' into a building. Thus, the briefing process in the Arts project is expected to accommodate the needs and requirements of the Arts clients that may be unique and dynamically change over time. The research aims to elucidate the most appropriate briefing process or processes that delivers a 'better' environment for the Arts. The methodology applied in this investigation is literature synthesis followed by case study. Case historical analyses of six case studies will be performed with one of the cases as a pilot case. In further phases, in-depths interviews to the key persons of the six cases will be conducted to complement the case historical analyses. Findings from the literature synthesis of generic briefing and the proposed research methodology are brought together in this paper and major issues highlighted.

Keywords: Arts projects, briefing, client needs and requirements

1. Introduction

A distinctive characteristic of most of the Arts buildings is the many sources of funds there may be for a single project, acquired from a broad base of funding sources. These sources of funds may affect the phasing of the building programme or incorporation of special facilities [1]. Various sources of funding are available for the Arts. The funding is for promoting the Arts, subsidising Arts productions, supporting Arts projects, as well as capital projects [2]. In addition to one-off grants from local and central government, tourist authority, European Union, Development Corporation, and Regional Arts Boards, there are loans from local governments, banks and financial institutions [1]. However, local governments' funding is typically through providing buildings and revenue support to Arts organisations. Private sector is another source of funding [2]. Government's funding the Arts has been channelled through several non-governmental organizations [1, 2], the largest of which is the Arts Council.

More than £ 1 billion has been spent by the Arts Council of England (ACE) Lottery Fund on the Arts building construction. However, a significant proportion has been considered problematic. The National Audit Office (NAO) reports many of the reviewed projects were experiencing cost overruns and delays [3, 4]. The CIB (1997) [5] has published a set of documents designed to improve the quality, effectiveness and efficiency of construction projects with particular emphasis on the briefing process since the outcome of any project is considered relying on the quality of the briefing. Kelly et al. (1993) [6] recommended a thorough briefing in order to develop a building with better value for money. Whilst the best value for money is considered achieved when quality is maximised for a given cost, cost minimised for a given quality or some optimal compromise between the two [7], it has been generally accepted that quality is defined in term of punctual deliver of the completed facility, functional utility, social and legal acceptability and aesthetics [6]. Hence, the success of the briefing process can be associated with the success of the project deliveries. Despite the fact that the briefing process has been extensively researched, building for the Arts are considered complex and unique due to the strict requirement to meet exacting technical requirements and also necessity to respond to various and sometimes conflicting demands of artists and performers, managerial staff, funding organizations, and the general public [1, 2]. Hence, an alternative approach may be required to apply the generic concept of briefing 'good practices' into the performing of Arts building projects.

In light of this, the research is set to investigate the most appropriate briefing practices to enable a 'better' environment in order to deliver excellent buildings for the performing Arts. This is to be achieved by investigating and analysing selected buildings for the performing Arts (i.e. case studies) that have been briefed, designed and procured in the relatively recent past. The use of case study method allows the research to retain the holistic and meaningful characteristics of real-life events [8]. In-depths interviews to the key persons of the studied cases will be conducted to complement the case historical analysis. The outcome is expected to provide valuable new insights and guidance for the Arts community to engage in a capital project to receive the best value for money in providing spaces for the performing Arts.

2. Construction Briefing

The common understanding of the briefing process in the UK (also known as architectural programming in the USA terminology) is generally about capturing information and ideas from Clients. This process results in the development of the brief and is followed by understanding the captured information and ideas, proposing and explaining to the Client all the alternatives and issues related to their requirements (e.g. risks and constrains), justifying and getting approval of the Client for certain alternative or scheme, followed by the translation to the designers' language to form the base for further stages. Despite this common understanding, various formal definitions of the briefing process exist [5, 9, 10, 11, 12]. Complementing the definitions, researchers have also provided their own explanations in understanding the process. Kamara et al. (1999) [13] defined the briefing process as the process of formulating and developing the brief. Barrett and Stanley (1999) [14] perceived briefing process as a process of innovation in which ideas are created and implemented and continued to inform all the technical work throughout the project. In the field of building design management, Grey *et al*. (1994) [15] regarded the briefing process as providing a clear means for proceeding and communicating the design tasks and objectives across the interfaces between one stage and the next. Hyams (2001) [16] described briefing as a process that is distinct and yet integral to the design process, avoiding wilfulness and giving client they have decided, need and want. From the various definitions and views on briefing discussed, three central themes were observed to enable further discussion, namely the role of the parties in the briefing process, the extent of the briefing process in regards to the construction stages, and the objective of the briefing process.

2.1 The Role of the Parties

The briefing process has been considered as a team effort between the participants from both the client group and the consultant team [17]. Further break down of the parties were provided by various research [16, 18, 19] into four general groups, namely the *Clients*, the *Building Users*, the *Regulatory Agencies* (including public interest parties), and the *Consultants*. However, the term *Client* reflects a singular term often intended to encapsulate a complex consortium of stakeholders whose opinions and factual requirements need to be consolidated into a singular consensus view [20]. Hence, in the subsequent discussion, the term *Client* is considered encompassing both the client organisations and the *Building Users* (i.e. end users).

Various definitions and views of the briefing process prescribed the role of the parties, particularly the Client and the Consultant. BSRIA (1990) [11] regards briefing as a process by which the designer receives all information to form the basis for detailed design involving the extraction of information from clients regarding their requirements and expectations. CIB (1997) [5] explicitly mentioned that the Clients should inform other of their needs, aspiration and desires, either formally or informally implying that the Client is responsible to make clear the requirements to the consulting team. This stand is supported by BRE (1987) [18], describing clearly that the Client is responsible for the briefing process by the means of preparing and providing enough information. Sports Council (1994) [21] prescribed the Client's body to be responsible in determining what is and its local community need or want. The purpose of briefing process is for the Clients to communicate their needs and objectives in initiating the project [22]. Clients must clearly express project objectives in terms of building requirements, costs and time budgets [23]. The findings from a study by Cherns and Bryant (1984) [24] have demonstrated the importance of this Client's role in a briefing process.

In contrast to the views above, British Standards (1995) [25] views the briefing process as a process of identifying and analysing the needs, aims and constraints of the client. RIBA (1967) [9] prescribed that the briefing process is intended to prepare general outlines and plan future action by setting up the Client organisation for briefing and also to provide the Client with an appraisal and recommendations. These views shifted the responsibility from the Client to the Consultant. The Consultant is no longer perceived as a passive party relying on the Client to provide information, but rather as an active party to identify, capture, and analyse the Client's requirements and needs. Several researchers were even promoting further analysis of the Client's business processes in order to improve the briefing process and to understand the way in which any proposed built solution would impact upon these business processes [6, 26, 27].

Various other views present a reconciliation of these two views. Murray (1996) [28] asserted that the Client has direct responsibility for the project development in the briefing process with a 'symbiotic' relationship (i.e. a reciprocal interaction) to achieve more effective briefing. CIRIA (1995) [12] views the briefing process as a collaborative and evolutionary process between the Clients and their advisors. BSRIA (1998) [11] perceived the briefing process as an iterative process involving regular feedback from the Client, advisers design team, and end users. Thus, briefing is a collective process involving both the Client's and the Consultant's contributions. The allocation of responsibility bearing on the briefing process is associated with the experience of the Client. Gameson (1996) [29] asserted that the level of briefing interaction between the Client and the Consultants varies considerably depending on two factors, one of which is the Client's previous experience of building construction. The experience of the Clients has been reported to influence the potential of having changes on the pre-construction and construction periods [30, 31]. The more experienced the Client is, the less necessary for the Consultant to identify, capture, and analyse the Clients' requirements and needs.

2.2 The Extent of the Briefing Process

Kelly et al. (1993) [6] and CIB (1997) [5] recommend two stages of the briefing process, known as the strategic briefing and the project briefing. The strategic briefing comprises a strategic review of the Client's organisational needs and further specified as an independent stage to set up the project strategy for the Client's business needs and objectives prior to any formal design and construction action. The latter is more tactical in nature and is primarily concerned with issues of performance specification. A detailed chart of briefing process has also been provided by CIB (1997) [5]. In this chart, the strategic briefing is subdivided into two key stages (i.e. *Getting Started* and *Defining the Project*). Each stage is defined as a set of necessary activities in order to produce a strategic brief or project execution plan. Gray *et al*. (1994) [15] asserted that the briefing stage should provide a clear means for proceeding and communicating the design tasks and objectives across the interfaces between one stage and the next. These views are inline with the view from RIBA (1967) [9] mentioning that the briefing process encompasses the inception and the feasibility phases of their *Architect's Plan of Works*.

However, RIBA (1973) [10] expanded this view on briefing process later on to include the outline proposal and scheme design phases of the *Architect's Plan of Works* and freeze the content of the brief for the subsequent phases. Whilst accepting many criticisms for freezing the brief after the scheme design phase, this expansion of the briefing process demonstrated a significant shift from viewing the briefing process as a 'one-off' event to the one that encompass other phases in the construction process. The briefing process is now considered to encompass both the strategic and project briefing. This shift of paradigm can be addressed to the limitation of the 'one-off' view which is not allowing options to be kept open to reflect the changing circumstances during the development of the project [32]. Atkin and Flanagan (1995) [26] proposed an eight-stages briefing process which overlaps the briefing process with the design process. Furthermore, CIRIA (1995) [12] considers the briefing process as a process after the feasibility stage that encompass programme for the design and construction work, and control procedure to guide the progress of the project within the time and budget. British Standards (1995) [25] considers a brief as a working document which specifies at any point in time the needs and aims, resources of the Client and user, the context of the project and any appropriate design requirements. Barrett and Stanley (1999) [14] considered briefing process as a process that starts early and continues to inform all the technical work throughout the project.

In the facility management, Preiser (1993) [33] identified the importance of developing a database of previous projects to learn from successes and failures in building performance to future buildings, thus promoting the importance of the Post Occupancy Evaluation (POE). In line with this, the function of briefing is extended further to the post project stage involving a constant feedback loop [5, 32, 34, 35]. Briefing is regarded as a continuous and cyclical process in order to evaluate the project and feedback to new projects (includes the POE process). Nutt (1993) [35] proposes a *total briefing cycle* in the facility management. The focus of this approach is on extending briefing into a cycle feedback information system, in which the brief is regarded as a periodic modification and improvement of facilities for a long-term consideration. The concept of POE is employed into *a total cycle* of the briefing process. Reinforcing the *total cycle* view of the briefing process, Blyth and Worthington (2001) [32] proposed a framework associated with a series of activities to identify various types of briefs that recorded the entire project development. The briefs are then guiding the development of the design process in sequence including POE. The shift from viewing the briefing process as a part of an early stage into an integrated part of the entire construction and management process encompassing the POE has been considered as the current trend [36].

2.3 The Objective of the Briefing Process

Generally, the objective of the briefing process is to develop the brief which encompasses the Client needs and requirements to enable the designer fulfilling those needs and requirements. Several views [37, 38, 39] have stimulated an ethos shift from merely fulfilling the needs and requirements specified in the briefing into pursuing for the Client's satisfaction. Clients are most likely to be satisfied when the final product matches or exceeds their expectations [40]. Research on the construction process has suggested the significant role of briefing in delivering client satisfaction [41] underpinned by the underlying assumption that an improved briefing process can deliver a better product to the Client [42]. Driven by this redefined objective (i.e. to satisfy the Client), further research emerged resulting in various frameworks and interesting findings. The Innovative Manufacturing Initiative/IMI (a joint research council activity funded by Engineering and Physical Sciences Research Council/EPSRC, Economic and Social Research Council/ESRC and Biotechnology and Biological Sciences Research Council/BBSRC) targeted the construction sector with a number of programmes. One of these programmes is the Link IDAC (Integration in Design and Construction) programme, co-funded by the Department of Environment Transport and Regions (DETR). Many of the projects are concerned with briefing and design or general information capture from the Client in construction such as *Managing the brief as a process of innovation* (Link IDAC 88) by the University of Salford, *Design information methodology and tools for the management of detailed building design* (Link IDAC 100) by the Loughborough University, *A client's project definition tool* (Link IDAC 11) by the University of Reading, *Decision making tools for controlled innovation in construction* (Link IDAC 82) by the Cranfield University, *Building a high value construction environment* (Link IDAC 229) by the London School of economics and the Leeds Metropolitan University, *The proposed requirements/conceptual design project* (Link IDAC 5/044) by the Loughborough University and the Strathclyde University, *The proposed IMI Process Protocol* - Level 2 project by the University of Salford and the Loughborough University, and *Learning from Experience: Applying Systematic Feedback to Improve the Briefing Process in Construction (LEAF)* by the University of Sheffield.

Leaman (2002) [43] proposes a detailed matrix (known as 'targeted briefing') method to conduct the briefing service to the Client. This method assumes that the Client's requirement can be identified thoroughly by fulfilling targeted headings of the brief format. Various other researchers prescribed models based on the matrix framework [34, 44, 45, 46]. This matrix framework has been generally considered an advancement of the more traditional checklists as proposed by Salisbury (1998) [47] or Hyams (2001) [16]. Moreover, Kamara *et al*. (2002) [48] proposes the *Client Requirements Processing Model* (CRPM) focusing on a solution-neutral formulation of client requirements. Another research by Fisher *et al* (2000) [49] proposed the *Client Project Definition Tool* (CPDT) with a focus on capturing user requirements for buildings. These models represent the implementation of methods applied in manufacturing industries for reconciling costumer's need and business objectives in the product development into construction briefing process, widely known as the Quality Function Deployment (QFD).

3. Evaluation of Briefing in Arts Construction Projects: the Research Methodology

This research project aims to assess the briefing process in the performing Arts construction projects. The measurable objectives of the research is to investigate and analyse thoroughly how selected buildings for the performing arts have been briefed, designed and procured in the relatively recent past. This is expected to lead to the identification and the development of the successful ‘good practice’ (applicable to all stakeholders) exploiting the particular skills and abilities in the Arts for creating and communicating ideas and 'visions'. This is to be followed by a broad dissemination of the new understanding in ways which are intelligible and engaging, exploiting media familiar to the Arts community in the use of the moving image, performance, narrative and scenario building in addition to more conventional outputs.

In order to achieve the aims and objectives of the research, the generic overview of briefing process in the construction projects has been reviewed. In-line with this, subsequent phase discusses the evaluation of the briefing process in the Arts construction projects. As a starting point, the evaluation of the briefing process in the Arts construction projects can be viewed from three different perspectives explained in the previous section, namely the role of the parties, the extent of the briefing process, and the objective of the briefing process. As highlighted earlier, the study intends to investigate and analyse selected buildings for the performing Arts that have been briefed, designed and procured in the relatively recent past. Hence, the selected strategy is multiple case study and grounded theory methodology in order to ensure an in-depth interaction between the researchers and the participants of the briefing process and formulation of an interpretation of the encounters. The richness of descriptions will be organized to develop a new understanding of briefing for the arts buildings.

Grounded theory is a general methodology to develop theory that is grounded in systematically gathered and analysed data aiming to develop theory through continuous interplay between analysis and data collection [50, 51, 52]. Theories emerging from grounded theory methodology are always traceable to their original data source, and are always fluid due to the emphasis on interaction among participants, temporality and process. This faithfulness of theory to the actual data offers usefulness in practice [50]. In acknowledging the multiple perspectives of a diverse range of existing theories, it is considered important to combine the theory emerging from the grounded theory methodology with the existing ones, while keeping the connection with the actual data [14]. Case studies are empirical inquiries investigating phenomena in their natural settings [8]. In a multiple case study strategy, the cases are studied in their real-life contexts with reliance on multiple sources of evidence and with a purpose to generalise to theory, which is emphasized in the research design phase [52]. Case studies are essential for description [53, 54] and therefore useful with grounded theory. The multiple case study aims to identify patterns using replication logic within and among cases, which can be either similar (literal replication) or contrary but for predictable reasons (theoretical replication). Consequently, one of the strategies is replication seeking, in which repeating patterns (either similar or contrary) are presented. The other strategy is pattern matching, in which findings are compared across cases or to a theoretical proposition to reveal patterns [8].

Two techniques of data collection are intended for use in this research, namely interviews and archival research. These two techniques are expected to inform each other at different stages of the study. Interview was set as the primary method of data collection, since individuals are considered the valuable sources of particular information. Interviews allow both parties to explore the meaning of the questions and answers involved. The interviewees were targeted and selected from different stakeholder groups to provide multiple perspectives and in-depth understanding of different issues in the briefing process. Archival research involves locating and assessing primary data or information in archives pertinent to the topic of the study [55]. In this study, the major archives resource is the documentation from the design teams. Another source considered is the building management, such as the management boards' files.

Being the interplay phase between analysis and data collection, coding for analysis is integrated to data collection procedure. One option of establishing coding frames is to follow the sequence of open coding, axial coding and selective coding [56]. Open coding involves organising the data into categories and sub-categories. Axial coding puts the data back together in a new way through establishing the relationships between these categories and sub-categories [57]. Selective coding involves conceptualising the relationships among categories for theory building [52]. Selective coding also includes comparing the potential theoretical frameworks emerging from analysis to the existing theories in the literature [14].

Following the finalisation of the cases and respondents selection, the broad framework for interview questions are prepared based on the literature review and pre-pilot interviews. The pre-pilot interviews are conducted prior to the pilot case with respondents involved in briefing and design processes for a performing arts building other than the cases selected for this case studies and aims is to complement and clarify the topics identified in the literature review. The pilot case is intended to provide guidance in evaluating the interview questions, the types of archives to investigate, and the coding frame at this stage of analysis. The pilot case will be started after clarifying the broad framework for interview questions. Upon completion of interviews and archival research of the pilot case, initial stage (open coding) of the analysis will be carried out. In this phase literature will be revisited to provide important insights in preparing the coding frame. The three perspectives identified (i.e. the role of the parties, the extent of the briefing process, and the objective of the briefing process) are intended to assist in understanding of the briefing processes in the performing Arts construction projects. For the remaining five cases, similar analysis procedure follows. At the cross-case analysis stage (axial coding), the coding frames of each case will be compared. The final theory building will be based on pattern matching among the cases and revisiting the literature to compare the emerging theoretical frameworks to the existing ones in the literature (selective coding). Within the scheme of multiple case study strategy, performing arts buildings are selected to ensure variety (theoretical sampling) and accessibility of the resources (purposive sampling). The variety criteria of the selected cases are based on the type of the client, number of spaces in the project, type of the project (new-build or refurbishment), funding source, budget size, audience type, and program type. The selection of cases also considers the completion (within the last five years) and the accessibility to archives and interviewees. At the present stage, six cases have been identified and targeted in order to fulfil the desired criteria. The selected case studies include two arts centres, three theatres, and one drama studio. The case studies represents both newly-built and refurbishments. The initial budget size of the cases ranges from £ 4.8 millions to £106 million. At the moment of preparing this paper, many of the interviewee targets from the selected cases have been contacted and requested for cooperation.

In order to summarise the research methodology designed to evaluate the briefing process in the performing Arts building projects discussed above, a diagram is provided in the Figure 1.

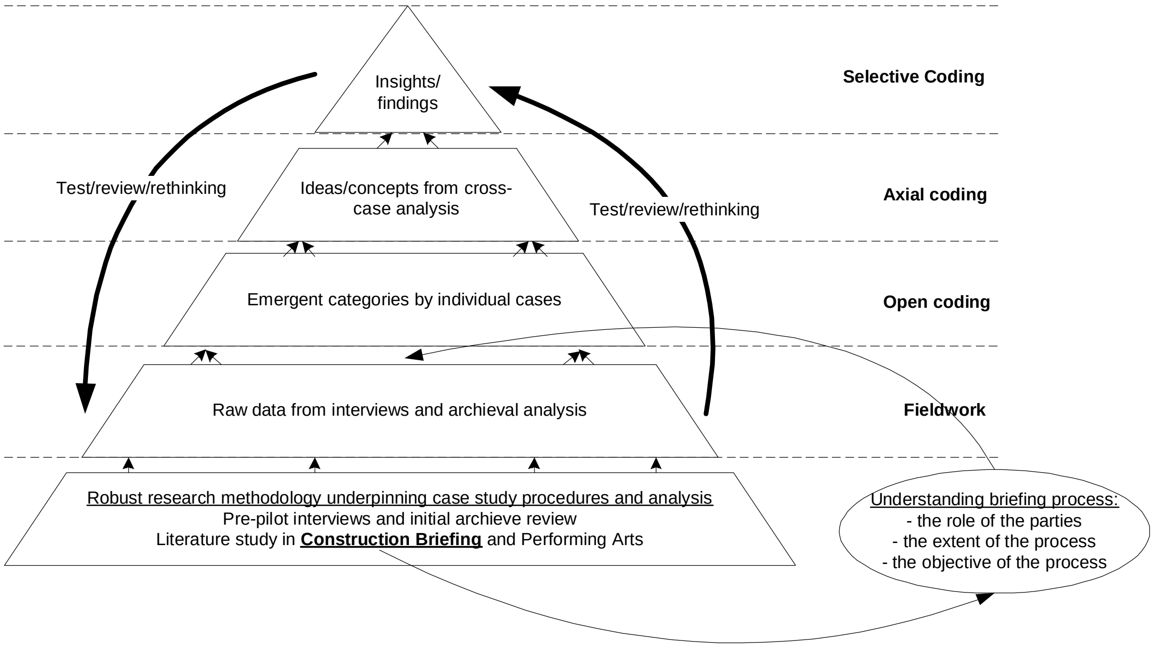

Figure 1. Research methodology to evaluate briefing process in performing Arts construction projects (adapted from Barrett and Stanley (1996) [14]).

4. Conclusion and Further Research

This paper has explained an on-going research project aimed to assess role of the briefing process in providing a 'better' environment for the performing Arts projects. The measurable objectives of the research is to investigate and analyse thoroughly how selected buildings for the performing arts have been briefed, designed and procured in the relatively recent past. This is expected to lead to the identification and the development of the successful 'good practice' (applicable to all stakeholders) exploiting the particular skills and abilities in the Arts for creating and communicating ideas and 'visions'. This is to be followed by a broad dissemination of the new understanding in ways which are intelligible and engaging, exploiting media familiar to the Arts community in the use of the moving image, performance, narrative and scenario building in addition to more conventional outputs.

The briefing process has been reviewed in detail in this paper. Various views on the briefing process have been presented by providing in-depth discussion on emerging three central themes, namely the role of the parties in briefing process, the extent of the briefing process, and the objective of briefing process. In discussing the role of the parties in briefing process, different opinions on allocating the responsibility of the briefing process became evident. The allocation of responsibility of such a process was then found influenced by the experience of the Clients. The more experience the Clients, the higher their own ability to ensure that the Consultants understand their needs and requirements and the Consultants are then responsible to accommodate the needs and requirements into their design. The discussion on the extent of the briefing process revealed differences on the implementation of the briefing process on the construction stages. Some views consider the briefing process as a 'one-off' event that performed in the pre-project stage, typically prior to the design phase to establish a 'frozen' brief. However, the review of the literature has also revealed the shift from this view into the one that consider the expansion of the briefing process into the whole life cycle of the project. In discussing the objective of the briefing process, the shift of working ethos from merely fulfilling the Clients' needs and requirements into the one that embrace the Client's satisfaction was identified. Various research were attempting to achieve such redefined objective including the implementation of methods applied in manufacturing industries for reconciling costumer's need and business objectives in the product development into construction briefing process.

Furthermore, the research methodology has also been explained in detail. The use of multiple case study strategy enables the study of each building's briefing process in detail. Interviews are expected to enhance the thoroughness of the study by providing access to exploring actual experiences of participants whilst archival review is considered to offer precise and detailed descriptions of conducts among stakeholders during the briefing process. The use of grounded theory methodology has also been considered crucial for identifying successful 'good practice' since the emphasis of the methodology is on the interplay between data and analysis in developing theories. Six cases have been identified and targeted in order to fulfil the set criteria. Further phases involve finalising the interview questions (to be tested with a pre-pilot interview) prior to performing the interviews and data analysis of the selected six case studies.

Project Diagnostics – Assessing the Condition of Projects and Identifying Poor Health

John Tsoukas
Arup Project Management, Brisbane Australia (email: john.tsoukas@arup.com.au)

Abstract

In many cases, construction projects do not achieve the objectives that the project participants set for them. If participants could better understand how their project is performing overall, at various stages of its delivery, then the opportunities to achieve project success would almost certainly be greater.

This paper documents a method of assessing the status of a project, at a point in its design or construction phase, or after completion. The status is assessed in terms of up to seven (7) key success factors. Any evidence of less than adequate performance in these performance areas is scrutinised to seek out the root causes of why this situation is happening. Using these identified root causes of under performance, general suggestions can then be made as to how to return the project to good health.

A software package that assists in assessing the status of the project has been developed. The package is currently being calibrated before commercial release.

Keywords: Diagnostics, project status, project performance indicators, root causes

1. Project Diagnostics

1.1 The Gestation for Project Diagnostics

Many projects fail to meet predetermined objectives. This failure is a major issue adversely affecting the construction industry, and more generally, the community. From the need to better understand how to judge the prognosis for a particular project (in terms of its likely performance), the idea of developing a "diagnostic kit" arose.

Project Diagnostics is a research initiative of the Australian Cooperative Centre for Construction Innovation (CRC CI). Arup Pty Ltd (Arup) is a founding member of the CRC CI, and lead this research project. This project was undertaken by a team with industry, government, and academic expertise.

1.2 The Human Health Analogy

Humphreys, Mian, Sidwell, (1) identified parallels between construction project health and human physical health, and proposed that in many ways the “health” of a construction project is analogous to human health. Human health can broadly be thought of as the condition of the body. When physical health is poor, performance or quality of life can be compromised. Poor physical health often has associated symptoms that can be used to help pinpoint the cause of ill health quickly and accurately.

Once the cause has been identified, a remedy can be implemented to assist the return to good health. If symptoms are left unchecked, they can develop into critical situations. In many ways the ‘health’ of a construction project is analogous to human physical health:

- State of health influences performance
- Symptoms can be used as a starting point to quickly assess health
- Symptoms of poor health are not always present or obvious
- State of health can be assessed by measuring key areas and comparing these values to established norms
- Health changes temporarily
- Remedies can often be prescribed to return to good health
- Correct and timely diagnosis can avoid small problems becoming large.

Project health is synonymous with project performance. If a particular project aspect is not performing as expected it would be perceived as unhealthy, or failing. On the other hand, if it is fulfilling expectations, it would be perceived as healthy or successful. The requirement for rapid, accurate diagnosis leads to the concept of an initial broad health checking mechanism, which could guide further more detailed investigations. More detailed appraisals identify the more fundamental factors contributing to poor health.

1.3 Industry Need

Research during the latter part of 2002 indicated that a reasonably comprehensive tool to assist in the assessment of the state of the existing health of construction projects was not generally available. Ready access to such a tool would significantly enhance the opportunity for an under performing project to be appraised - and then corrected, in a focused and systematic way.

Project Diagnostics has developed such an assessment tool to aid understanding of the current condition of a project. The assessment identifies performance against industry benchmarks for the key success factors. Further analysis of any underperforming areas is carried out – enabling the probable root causes of poor performance to be captured. This diagnosis can then provide a prognosis for the success of the project, or otherwise. The diagnostic toolkit can then point the way to remedial actions that could be taken.

These activities are highly relevant to industry. If project participants are able to confidently compare how a project is currently performing against industry norms, then targeted action can be taken to improve performance, as necessary. The diagnostic toolkit can be then applied again at subsequent stages of the project, to continue to monitor the effectiveness of remedial action taken.

2. Methodology

2.1 Project Methodology

The Project Diagnostics methodology is shown in Figure 1. The following steps outline the methodology and should be read in conjunction with this figure.

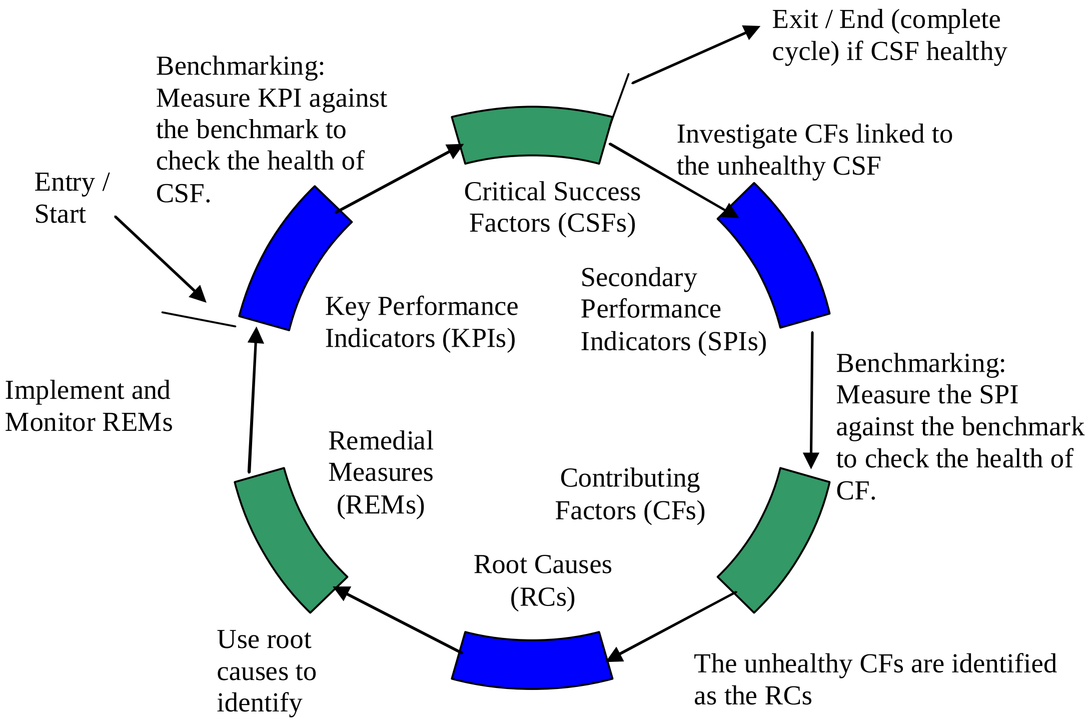

Figure 1: Project diagnostics methodology

2.2 Critical Success Factors (CSFs)

Research carried out in the last decade provides many sources of success and failure measures, totalling more than 120 different relevant measures. The measures have been split among different stages of a project. In order to make these extensive lists more manageable to work with, and to help analyse the interactions, they are represented by seven main measures of success. These are termed Critical Success Factors (CSFs).

The factors used for the assessment of current health of the construction project are:

- Cost
- Time
- Quality
- Relationships
- Safety
- Environment
- Stakeholder value

As is the case with human physical health, these measures are critical areas that can facilitate a broad evaluation of project health; they need to be investigated in order to ascertain project health.

2.3 Key Performance Indicators (KPIs)

The seven CSF themes represent critical areas of construction project health. In order to use these CSFs as indicators, they need to be properly assessed. This task was achieved by developing an associated series of Key Performance Indicators (KPIs) for each CSF.

The KPIs are used to measure the degree of acceptability of CSFs. Their value is compared to benchmarks, to check status. The aggregation of CSF status information provides an indication of the project health. This process involves collecting data from the project under scrutiny, calculating the KPIs, and comparing them with benchmarks.

The use of KPIs to assess the performance of the main CSF themes allows the model to be applicable to most (if not all) of the project stages and a majority of the procurement methods. To facilitate the KPIs application to assess the performance of the CSFs, they were calibrated using benchmarks from Australia (Coles 2003, (2)), UK (CBPP 2003 (3)) and USA (CII 2003 (4)). Calibration makes the model applicable to a project regardless of generally how the performance target was arrived at.

After careful scrutiny, a total of 33 KPIs were chosen. As an example, the KPIs for the "Cost" CSF follow:

Table 1: KPIs for Cost

CSF	Key Perf Indicators	Explanation of Indicator
Cost	CPI (Cost Performance Indicator)	CPI = BCWP / ACWP Where: BCWP = budgeted cost of work actually performed. ACWP = actual cost of work actually performed. CPI ≥ 0.85 indicates a healthy project. CPI < 0.85 indicates an unhealthy project. The benchmark is based on an average value of cost overrun of 15% from survey of 375 general building projects in the Giles Royal Commission (1992) into the productivity of building industry in NSW. This indicator provides a snapshot of the project cost at a particular point in time. The source for gathering ACWP would be the progress claims of the consultant/contractor showing the approved amount at that point of time. This will be compared with the BCWP at that time - can be sourced from the contractor/consultant cost plan. The budgeted cost should include approved variations.
	PJCI (Projected Cost Indicator)	PJCI = BAC / EAC Where: BAC = budgeted cost at completion. EAC = actual cost at completion (i.e. actual cost to date plus updated estimate of work remaining). PJCI ≥ 0.85 indicates a healthy project. PJCI< 0.85 indicates an unhealthy project. The rationale behind the above benchmark is the same as the CPI. This purpose of this indicator is to check the health of a project at completion based on the forecast from the particular point in time chosen for the snapshot for CPI. In order to check the health of a project as far as cost is concerned, the CPI & PJCI are considered together in terms of the following conditions: CPI < 0.85 & PJCI < 0.85 indicates an unhealthy project. CPI < 0.85 & PJCI ≥ 0.85 indicates an unhealthy project. CPI ≥ 0.85 & PJCI < 0.85 indicates a healthy project. CPI ≥ 0.85 & PJCI ≥ 0.85 indicates a healthy project. The CPI and PJCI are applicable to all stages of a project from planning to hand over.

It was necessary to validate the robustness of these KPIs by testing them on actual projects. Table 2 provides an explanation of how the indicator was used in testing.

Table 2: Example Cost Performance Indicator (CPI)

CSF	Indicator	Explanation of Indicator
Cost	CPI	Definition: CPI = BCWP / ACWP Where: BCWP = budgeted cost of work actually performed ACWP = actual cost of work actually performed Benchmark: CPI ≥ 0.85 indicates a healthy project CPI < 0.85 indicates an unhealthy project This provides a snapshot of cost performance on the day of health check.

For all relevant CSFs (up to seven), the results are then analysed and the overall health of the project is able to be assessed. If the results indicate a healthy project the cycle ends. Otherwise, the use of the toolkit proceeds to the next step.

2.4 Contributing Factors (CFs)

CSFs that were found to indicate project performance as being less than industry benchmark levels were used as the focus of a more detailed investigation. Factors leading to poor levels of performance against benchmarks were assessed; these factors are called the Contributing Factors (CFs). There is a direct relationship between CFs and the root causes of poor project performance.

A list of Contributing Factors associated with each CSF was developed in consultation with industry through pilot studies. Pilot interviews were conducted on projects identified by the industry partners from the research team. These interviews were conducted using a structured questionnaire. The respondents included clients, consultants, contractors and sub contractors. A total of 28 interviews were conducted. The questionnaire was designed to allow identification of CFs and to allow them to be ranked in terms of relative importance using a numeric scale. This list of CFs was augmented with CFs identified from a literature survey.

The CFs were further validated using a Delphi type approach using industry partners as specialists.

The overall ranking of the identified CFs for each unhealthy CSF from the pilot questionnaire was calculated, using a statistical frequency analysis.

Table 3 shows the rank and importance index for CFs for “Cost” as an example. The indexes are ranked in descending order.

Table 3: Rank and Index of Contributing Factors

CSF	Contributing Factors (CFs)	Index	Rank
Cost Overrun	Variations	14.7	1
	Inaccurate cost estimate	6.0	2
	Rework	3.3	3
	Lack of client decision making	2.7	4
	Competitive nature of market	2.3	5
	Poor quality of design and documentation	2.3	5
	Approvals	2.0	7
	Contractor / Sub-contractor work efficiency	2.0	7
	To manage project simultaneously a large component of work was done in another city branch office	2.0	7
	Poor workmanship	1.3	10
	Work sequencing with other trades	1.3	10
	Audit testing	1.0	12
	Change of management	1.0	12
	Emissions and under measures in documentation	1.0	12
	Lack of completeness of contract documents	1.0	12
	Limited resources	1.0	12
	Lack of architect higher management interest	0.7	17
	Productivity of workforce due to traveling involved due to remote location of project	0.7	17
	Relationship workshop	0.7	17
	High quality product required	0.3	20
	Higher management direct involvement	0.3	20
	Programming issues causing pressure on contractors	0.3	20

The importance index and rank for each CSF was found by calculating the average index for the rank 1 to 4 of contributing factors within each CSF. Table 4 shows the index and rank of the overall CSFs.

Table 4: Rank and Index of CSFs

CSFs	Index	Rank
Cost	6.68	1
Time	3.86	4
Quality of documentation - increase in RFI	3.20	8
Quality of construction - increase in rework	4.65	2
Safety	3.60	5
Relationships	4.15	3
Environment	3.40	7
Stakeholder value	3.43	6

As mainly successful projects were evaluated in pilot studies, the list of CFs was not considered comprehensive. Augmentation with CFs identified from a literature survey occurred. The CFs were further validated using a Delphi type approach using industry partners as specialists. Thes team members added CFs to the list obtained from pilot studies so as to achieve a comprehensive list. A second round of feedback on CFs was instituted with the research team. Finally they were discussed in a workshop attended by the same specialists to get a final list, based on the consensus of these specialists.

2.5 Secondary Performance Indicators (SPIs)

Like CSFs, the CFs needed to be assessed to pinpoint the areas most likely to be causing poor project health. This task was accomplished with a series of Secondary Performance Indicators (SPIs) for each CF. A number of key criteria, similar to those used for selecting KPIs, were also used for choosing SPIs. A sample of “Cost” SPIs follows:

Table 5: Example showing "Cost" SPIs

CSFs	Contributing Factors	Secondary Performance Indicators
Cost Overrun	Inaccurate estimating of cost	To measure the reliability of cost estimates, actual design or construction cost is needed and estimated design or construction cost; and using the formula: Performance Percentage Predictability = (Actual design or construction cost – Estimated design or construction cost) / Estimated design or construction cost and plotting this value on the Predictability - Cost curve indicates the performance level.
	Consultant / contractor lack of appropriate experience	Profile is an indicator - has consultant or contractor successfully completed a similar project in terms of size, locational restrictions, complexity etc. This indicator however needs benchmarking.
	Inflation	Magnitude has direct impact on cost estimates.
	Lack of trust in contractors and consultants by client	The policy adopted by the client may lead to teams' protecting their own position, resulting in loss of focus or reduced productivity.
	Adoption of inappropriate contract type	An inappropriate contract type (eg, Fixed, or Cost Plus, when scope is not well defined), can lead of cost overruns.

Potential SPIs associated with each CF were identified from the literature. As with the KPIs, these SPIs needed to be benchmarked. Benchmarks were identified through a literature review of research material from the UK, the USA and Australia. In addition, results from four projects of the project team members were used to validate the results. The results weer further reviewed in a workshop with industry research partners.

2.6 Root Cause Identification

Knowledge of the particular CFs failing to meet the target (benchmarked) values, provide the necessary insight to confidently identify root causes of poor performance. For example, if the relevant "Cost" CF was the use of an inappropriate contract type (as highlighted by the SPI), then the relevant root cause becomes almost self evident. In some cases, the CF and its root cause are quite similar. In other cases, such as the relevant "Cost" CF being inaccurate cost estimating, then the specific root cause needs further review; is the inaccurate cost estimating due to poor project scoping, or inadequate resources, or lack of skills, or some other basic cause? It is here that the experience of the project participants, and/or external professionals, comes into play.

Once the root causes were acknowledged, remedial measures associated with each of them were able to be identified: based on lessons learnt from the industry partners, through case studies, and from another literature search.

Correct and timely identification of contributing factors along with accurate assessment of SPIs, generally allowed an effective remedy to be prescribed, through insight into root causes of concern. The role of the subsequent remedies is to return the project to good health. Recognising the potential effect early and taking the proactive steps necessary to avoid unwanted consequences, can achieve this.

2.7 Remedial Activity

The practical nature of construction suggests that a suitable approach for development of a suite of remedies for a range of health problems would be based on the experiences of the project participants, but focused on the specific results of the CF/ SPI analyses.

A combination of the Project Diagnostics specifics, and a broad industry understanding is a powerful project improvement tool. In some cases, it may be appropriate to introduce independent industry professionals to assist the project team in this process.

One of the limitations of using lessons learnt is that remedies tend to be dependent on personal experience. This means that remedies for a given contributing factor or identified root cause, may vary from person to person – and potentially in conflicting ways. The approach for this model will be to develop a set of remedies that have proved historically to be workable and can achieve results.

However, it needs to be understood that each project is unique, with its own set of issues and most appropriate ways of restoring it to good health.

For this reason, remedies nominated in Project Diagnostics can be generic remedies only – and should only be seen as such, until and unless the particular project dynamics are clearly understood.

It is possible that single or multiple remedial measures will be associated with each of the contributing factors for the specific unhealthy CSF. The implementation of the measures may require the coordination of multiple project participants or stakeholders. Once implemented, time may be required time to restore the project to good health.

As necessary, the KPIs for relevant CSFs are able to be measured again later, to check if the cause of poor performance has been remedied. The cycle can iterate until the project health is considered to be satisfactory.

3. Software Development

3.1 Toolkit

The aim of Project Diagnostics was to develop a Toolkit that enables the user to:

- Investigate the health of a construction project
- Identify the root causes of poor health
- Give an indication of remedial measures which could be implemented to improve project performance and outcomes.

This toolkit has both the potential to be used as required when clients or other project participants feel that a project is not performing according to their expectations; and at regular intervals as a 'health check' during the delivery of the project.

The toolkit is designed to have integrated benefits that include identifying areas of poor project health, pointing to the probable root causes and suggesting possible remedial measures. It is envisaged that the use of the toolkit will be very cost effective for clients and stakeholders as compared with the costs associated with the adverse impacts of failing projects. These include cost and time overruns, inadequate build quality, poor project relationships, loss of reputation, public clamour and legal disputation.

The software development is well advanced. As at January 2005, commercial arrangements for the finalisation of the software toolkit are being finalised.

3.2 Validation

Further validation of the KPIs, CFs and SPIs, and linkages to case studies are required, before the package is ready for commercial release. To date, four case studies during the later stages of development of the toolkit have been used to validate the model and refine the parameters used. Ten pilot projects were used earlier in the initial development of the approach used in the software.

Comprehensive validation of the software package is intended to be complete by early 2006. The package will then be available for commercial use. Expectations are high for the benefits that Project Diagnostics will bring to the entire industry.

4. Conclusions

Project Diagnostics aims to bring the benefits of industry knowledge and experience, built up over many years, to project participants. By assessing the state of critical success factors for construction projects, at various stages of progress, it is possible to gain a confident view as to the likely prognosis for success of the project.

The software toolkit automates this assessment. The toolkit facilitates the identification of areas of project under performance. Use of the toolkit will assist in setting appropriate remedial measures, to facilitate the restoration of the project to good health.

Acknowledgements

Thanks are owed to the Project Diagnostics Project Team, comprising Arup, CSIRO, Department of Main Roads (Qld), Department of Public Works (Qld), John Holland Constructions Pty Ltd, and Queensland University of Technology. The research described here was carried out by the Australian Cooperative Research Centre for Construction Innovation whose significant role in sponsoring and guiding this project, is also gratefully acknowledged.

Abstract

For the past three years, Florida Department of Transportation (FDOT) construction contracts have run approximately 23,000 days over original contract time each year. These extended days comprised 28%, 23%, and 25% of the original contract days, respectively. During the same period, the cost of the projects averaged $124 million per year over the original contract amount. Even though the increase did not result entirely from the extended days, it is reasonable to assume that the project cost increase is related to the time extensions in some way.

The data for this paper were obtained from the FDOT database. FDOT posts “Construction Cost and Time” Quarterly Reports on their website, with available data including project location, duration, cost, contract type, and delay days.

FDOT categorizes delay days as either weather days, time extensions, or supplemental agreement days, depending on the circumstances. The time extension (TE) heading and supplemental agreement days (SA) heading both are broken down into 12 sub-headings of circumstances, which can cause delay. These 12 sub-categories are the same for both SA and TE. The twelve categories of extended days (TE and SA) and weather days are analyzed in this paper as causes for delay in highway construction projects.

The goal of this paper is to analyze the factors that influence contract duration for highway construction. Also of interest is the relationship between delay and cost increases, so a regression model was developed showing that relationship. Using the results of this analysis, a comparison between regions of the state representing urban and rural areas, and a comparison between contract types (unit cost, lump sum, and others) were made so that parameters could be set for estimating more reasonable schedules for future projects depending on project regions and contract types. Finally the most prevalent causes for delay in highway construction projects are identified.

Keywords: Delay, weather days, time extension, supplemental agreement, project cost changes, regression model, lump sum.

1. Introduction

There is a growing need for rehabilitation and reconstruction to sustain the U.S. highway system. However, while desperately needed, the construction causes many problems, such as inconvenience and delays for road users and economic loss for communities. Shorter construction durations usually produce better results in terms of safety for the public and construction workers because the public is exposed to the work zone for shorter periods of time. Other advantages of shorter construction durations are lower road user costs due to minimizing traffic delay and lower overhead costs for both the contractor and public owner (agency).

In reality, however, it is very difficult for a construction project to be constructed both "on time," and "within budget." Delay is one of the most common problems in the construction industry. FDOT had 22,835 delay days in fiscal year 2001/2002 (28.4% of the original contract duration), and, although they decreased to 22,634 days (22.6% of the original contract) in fiscal year 2002/2003, the delay days increased in 2003/2004 to 23,919 days (25.2%).

Over the last three years, FDOT has averaged spending $124 million per year more than initially planned for construction projects. FDOT paid $1,240 million to the contractors in fiscal year 2001/2002, for projects originally contracted at $1,104 million. The amount paid also increased from an original $1,399 million to $1,522 million in fiscal year 2002/2003 and from an original $1,387 million to $1,501 million in fiscal year 2003/2004. By analyzing the factors affecting construction duration for transportation construction projects, reliable parameters can be set up concerning the relationship between delay days and project cost changes, with variability depending on region, contract type, and district characteristics.

The subject of construction delays has been analyzed previously by many researchers, but most of the studies have been conducted using survey results. Very little information was found which described research using delay analysis that included delay days from actual transportation projects.

2. Literature Search

The problem with project delays is not a new one. Contractors are obligated to complete construction projects within a time period specified under the contract, so time is one of the most important aspects of a construction project. However, unexpected delays and problems routinely occur, that affect time and cost. Therefore, many studies related to the influence of delays on construction projects and various statistical analyses have been conducted.

From more than 4,000 projects constructed over twenty-seven years (1959-1986), research showed that surprisingly few projects were actually completed within their budget and on schedule [1]. As far as the impact of delay on project performance, U.S. and international research reveal that many nuclear power plant projects in the U.S. experienced an increase in project cost and duration [2]. Arditi et al. reported that the percentage of projects successfully completed on schedule in Turkey ranged from 8% to 15% [3]. Some extreme examples were reported such as a hospital construction project that was completed after a delay of 6 years, amounting to 233% of the original construction duration.

Many previous studies have discussed causes for delays. In studying large building projects in Saudi Arabia, Assaf et al. outlined 56 causes and grouped them into 9 major categories [4]. As a means of delay factor identification, a survey was used and results of that survey indicated that the delay factors categorized as “financial” were ranked the highest (most delay), whereas those delay factors categorized as “environmental” was ranked the lowest by all three groups of respondents - contractors, A/E, and owners. Baldwin and Manthei stated that the major causes of delays in building projects in the United States were weather, labor supply, and subcontractors [5]. These results were also obtained from a survey given to engineers, architects, and contractors.

Majid and McCaffer classified the main causes of non-excusable delays and then identified the factors contributing to those causes using the Ishikawa, or fish bone, diagram [6]. To determine the ranking of the factors, they used previously published reports. For the first three major factors contributing to causes of non-excusable delay, late delivery, damaged materials, and poor planning are identified.

Some studies have discussed the issues relating to delay analysis. Bubshait and Cunningham compared three delay measurement processes, which are as-planned schedule delay analysis, as-built schedule delay analysis, and modified as-built schedule delay analysis. They then showed that one procedure might be more reliable than others in certain circumstances [7]. Computer-aided construction delay analysis for preparing claims was studied by Alkass et al. [8]. They presented an integrated computer-based system (CDCA) as an improved method of analyzing delays and preparing claims. Shi et al. presented a construction delay computation method at the activity level [9].

Many previous studies have discussed subjects relating to delays. When the studies dealt with causes or reasons, conclusions were mostly based on survey results from the respondents and data that were based on the literature review. As noted earlier, no major study has been done to explain causes for delays in transportation construction projects using actual delay data from construction projects.

3. Data Gathering

Data for this paper were taken from Construction Cost and Time Quarterly Reports of the Florida Department of Transportation (FDOT) for the duration between fiscal year 2001/2002 and fiscal year 2003/2004; however, the report for fiscal year 2001/2002 was posted as an entire year instead of each quarter on the Internet. Therefore, when the data were analyzed to see if there was a trend of factors affecting delay by time, the entire 2001/2002 report was used instead of a quarterly report.

In the Quarterly Reports, data is shown for projects that had been completed through that particular quarter within that particular fiscal year, cumulatively. Table 1 shows the number of completed projects for each district by fiscal year. A total of 1,205 projects completed between fiscal year 2001/2002 and 2003/2004 were used for the analysis. Obtainable data from these 1,205 projects included the district in which each project was performed, original contract days, delay days, original contract amount, final contract amount, and contract type.

Table 1: Number of Projects Completed

District	Number of projects completed			
	2001/2002	**2002/2003**	**2003/2004**	**Total**
1	52	46	49	147
2	66	90	68	224
3	54	114	79	247
4	39	46	54	139
5	50	59	52	161
6	24	37	40	101
7	28	60	40	128
8	10	23	25	58
Sum	323	475	407	1205

The term "delay days" means all days over and beyond the original contract days; it does not necessarily mean that projects are behind schedule. The delay days can be divided into three categories according to circumstances surrounding the delay: weather days, TE, and SA days. The TE and SA days are also divided into 12 sub-categories according to the reason for the added time. These 12 sub-categories are the same for SA and TE. For this research, weather days and 12 reasons for extended days were considered as factors causing delays (total of 13 factors). In the Construction Cost and Time Quarterly Reports, these 13 delay factors are expressed in the form of number of delay days based on original contract days.

Interviews were conducted as part of the data verification process after analyzing the data from the quarterly reports. Weather archives were also collected in order to verify whether the weather days granted to the contractors coincided with inclement weather as documented by the weather service.

3.1 Identification of Delay Factors

SA Days are those days that were granted as part of a Supplemental Agreement. A Supplemental Agreement is a legal document that amends a FDOT contract in some way. TE days are simply days granted the contractors by FDOT according to FDOT procedures under circumstances that do not require a SA. Weather Days are days that are granted by letter because weather prevented the contractor from working on critical work items on a specific day. Weather Days do not include any damage to the project caused by weather.

Since days granted for weather are not actually added to the contract, the total TE and SA days are the total number of days added to the contract; therefore, the difference between TE and SA days is just in the mechanism by which extended days are granted.

The twelve reasons (sub-categories) for delays granted by either SA or TE are changed conditions, plans modifications, specification modification, value engineering, partnering, CEI action/inaction, minor changes, defective materials, weather-related damage, claims, utility delays, and invalid reason codes.

"CEI" is the term used for a consulting firm that performs construction engineering and inspection (CEI) services. CEI action/inaction means that contract change was brought about by some action of the CEI. It could have been a decision to change something or a lack of decision where the contractor requested some action.

Weather-related Damage means days granted as either a TE or by SA because some damage was caused by weather where the contractor had to redo some of the work.

4. Data Analysis

First, factors that influence contract duration were identified as described. The number of delay days that contractors were granted was then obtained and sorted according to which of the 13 factors caused each delay for each quarter from fiscal year 2001/2002 to fiscal year 2003/2004, and the following analyses were done.

1. Factor Distribution
2. Comparison of delays by geographic region, district, demographics, and contract types.
3. Cost vs. Delay Analysis.
4. Regression Analysis of the relationship between delay days and project cost changes.

4.1 Factor Distribution

Delay distribution by fiscal year (representing time) and district (representing location) reveals whether or not a specific type of grant for delay days, such as Weather Days, plays a significant role in the total number of delay days granted.

Figure 1 shows the delay distribution by fiscal year according to grant type. In fiscal year 2001/2002, 63% of all delay days were either SA days or TE, and 37% were Weather Days, whereas in fiscal year 2002/2003, 52% of all delay days were SA or TE and 48% were Weather Days. In fiscal year 2003/2004, delay distribution is also 48% Weather Days and 52% either TE or SA Days. One possible explanation is that according to the weather service there were 12% more rain days in fiscal year 2002/2003 than in 2001/2002 (281 days versus 251 days).

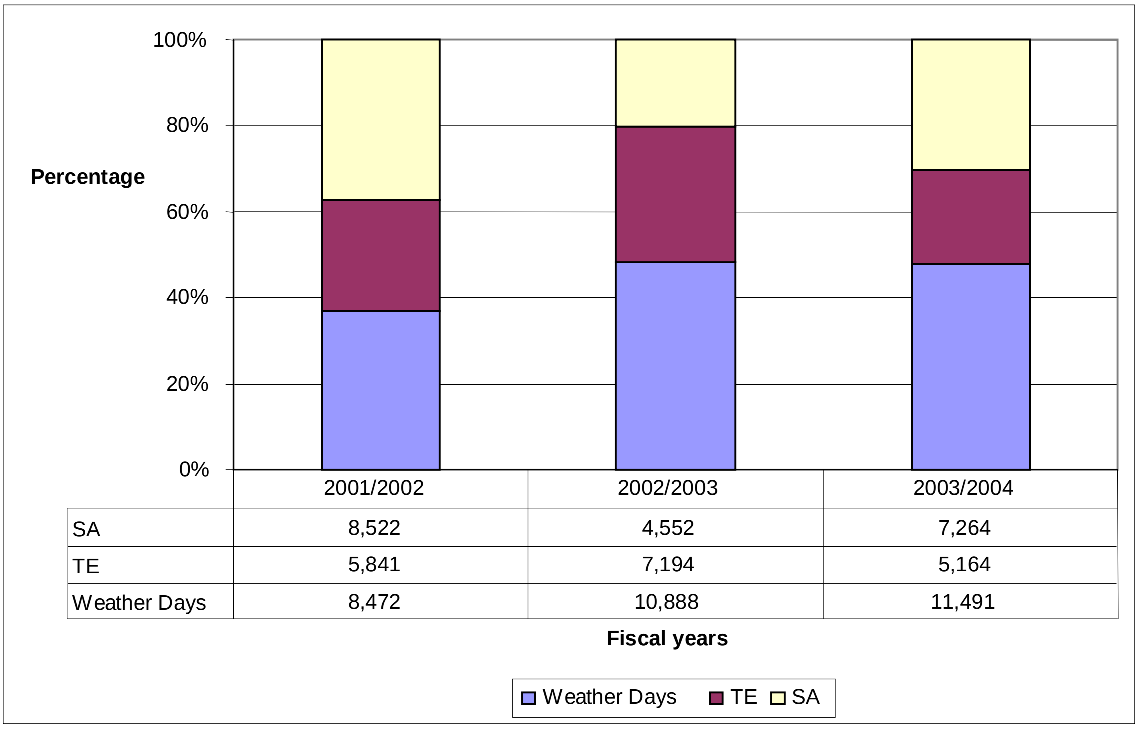

Figure 1: Statewide Delay Distribution by Each Fiscal Year

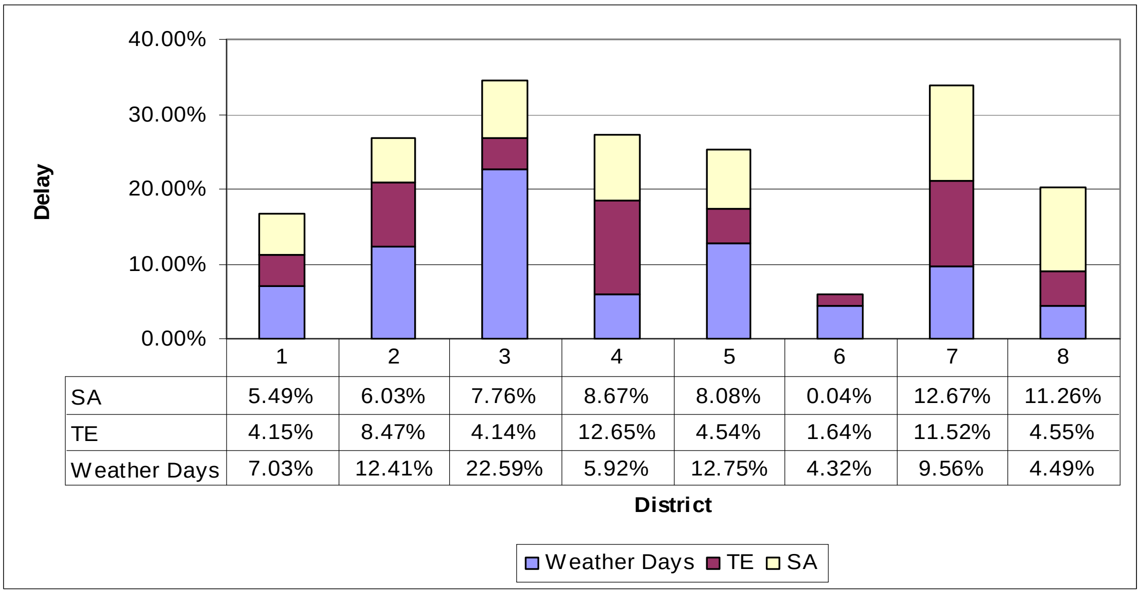
The weather archives at the National Climate Data Center under the National Oceanic and Atmospheric Administration (NOAA) classified rain days as either >0.1" rain days, >0.5" rain days, or >1.0" rain days. The research team concluded that >0.5" rain days would generally seriously affect construction projects. To determine the number of rain days in each district, major cities in each district were randomly selected, and the number of rain days in each city was sought. The average rain days among these cities, then, represented the number of rain days in each district, so 281 rain days in fiscal year 2002/2003 means that the sum of each district's average number of rain days from July 2002 to June 2003 is 281days.

According to the delay distribution results during the three years, the proportion of Weather Days and TE/SA Days looks quite consistent.

Delay distribution by district for the three years is presented in Figure 2. District 3 has significantly more Weather Days than any other district in Florida. Weather Days will be discussed later in detail.



District	1	2	3	4	5	6	7	8
SA	5.49%	6.03%	7.76%	8.67%	8.08%	0.04%	12.67%	11.26%
TE	4.15%	8.47%	4.14%	12.65%	4.54%	1.64%	11.52%	4.55%
Weather Days	7.03%	12.41%	22.59%	5.92%	12.75%	4.32%	9.56%	4.49%

Figure 2: Delay Distribution by Districts (2001/2002 – 2003/2004 Total)

Weather days, plans modifications, and changed conditions comprised 44%, 22%, and 20% of the total delay days, respectively. So, these 3 factors comprised approximately 86% of the total delay days while the other 10 factors accounted for only 14% of the delay days. Among the 10 less significant factors, CEI action/inaction and utility delays were responsible for 6% and 4% of the total delay days, respectively. Delay days due to factors such as specification modification, V.E., partnering, defective materials, claims, and invalid reason were very small, with each factor accounting for less than 1% of the total delay days.

4.2 Comparisons

4.2.1 By Region

As noted earlier, District 3 had significantly more weather delay days than any other district. This district is in northwest Florida, and encompasses the "big bend" and "panhandle" areas. The district has a long coastline, so there is a possibility that District 3 had more rain days than other districts. To verify this, weather archives from NOAA were checked. Table 2 shows that District 3 had more rain than the average in other districts in terms of precipitation and more rain days (>0.5"). The difference in precipitation, however, was just 10 inches over 3 years, and the difference in rain days was just 11 days over 3 years. This difference does not explain the wide gap in weather delays.

Conjecture is that perhaps District 3 has a more lenient policy regarding the granting of weather days than other districts, but this cannot be verified by any form of documentation.

Table 2: Weather Comparison (2001/2002 – 2003/2004)

	District 3	Others (Avg.)
Precipitation	164.44	153.69
Rain Days (>0.1")	199	204
Rain Days (>0.5")	105	94

4.2.2 District Characteristics

Because there were more weather days in District 3 than expected, the research team suspected that granting extended days might be affected by district characteristics. Excepting District 8, which is a turnpike district with no real geographic identity, the research team classified Florida's districts into three categories. Districts 4, 6, and 7 were categorized as "urban" areas. District 3 was categorized as a rural area, and District 1, District 2, and District 5 were categorized as areas with both characteristics, or "mixed."

Figure 3 indicates that not only did District 3 (Rural) have more weather days than the other two groups (Urban and Mixed) but delay composition rates also increased gradually from the rural group to the urban group. It is inferred that the more crowded districts are less likely to grant delay days for weather. In addition, even though the difference is not significant, the sum of TE and SA in each group gradually increased from the rural group to the urban group, which is consistent with the general belief that urban projects are more complicated because of their confined working conditions and therefore more susceptible to the 12 areas of potential delays under the TE and SA headings.

	Rural(3)	Urban(4,6,7)	Others(1,2,5)
Weather Days	22.59%	6.50%	10.91%
TE	4.14%	9.16%	6.06%
SA	7.76%	7.33%	6.46%

Figure:. Delay by District Characteristics (2001/2002 – 2003/2004 Total)

4.2.3 By Contract Type

The total number of delay days in District 2 was relatively small, and it was learned that a significant number of days were given back to FDOT through SAs. Further analysis was done to determine why District 2 had a negative number under the heading "SA days."

Among the number of SA days going back to FDOT, which meant time savings, a disproportionate number came from lump sum contracts. District 2 had more lump sum contracts than any other district in Florida in terms of number of contracts and total contracted amount. Most FDOT lump sum contracts in District 2 were completed on schedule. To reveal why lump sum contracts had such good results in terms of the schedule, interviews were held with FDOT personnel in District 2.

It was found that many of the lump sum contracts in District 2 were landscaping projects. Unlike other districts, District 2 has a policy that landscaping work be pulled out of roadway construction projects and given separate contracts.

Conventionally, the contractors are given two growing seasons in a contract that includes landscaping to make sure that plants are well established since production rates for plants can't be determined at the time of planting. Separating the landscaping from the rest of the contract allowed District 2 to eliminate this extra time by having contractors put a warranty on the landscaping plants. Warranty bonds now guarantee that contractors will water the plants after contract time expires, so that time can be given back to FDOT. Burn-in periods for traffic signal contracts are now being handled the same way [10] in this district.

In order to have the best probability for successful lump sum contracts, plans must be better than those of unit price contracts [10]. The fact that there are fewer conflicts concerning quantities begins with the assumption that plans and specifications are clear enough to avoid quantity arguments. If plans and specifications are not good enough, then more conflicts between contractors and the CEI will arise and lead to an adversarial relationship between them, which hinders the success of any project.

As for the process of selecting the contract type, in District 2, resident engineers chose whether they want a lump sum contract or a unit price contract on a specific project. Once it is decided, resident engineers meet with design engineers to formulate a plan that conforms to that particular contract type.

4.3 Relationship between Time and Cost

Intuitively, highway projects that have no, or lower, time extensions have lower overall costs than those with higher time extensions. Figure 4 shows this to be the case. Projects that have higher time extensions are shown to cost, on average, more than projects that have no, or lower, time extensions. In Figure 4, plotted dots represent the number of delay days and the difference between initial cost and final cost for the quarter's projects.

In order to ensure that there was a statistical relationship between extended project duration and project cost, and to further analyze the details of that relationship, statistical analysis was performed, using multiple linear regression.

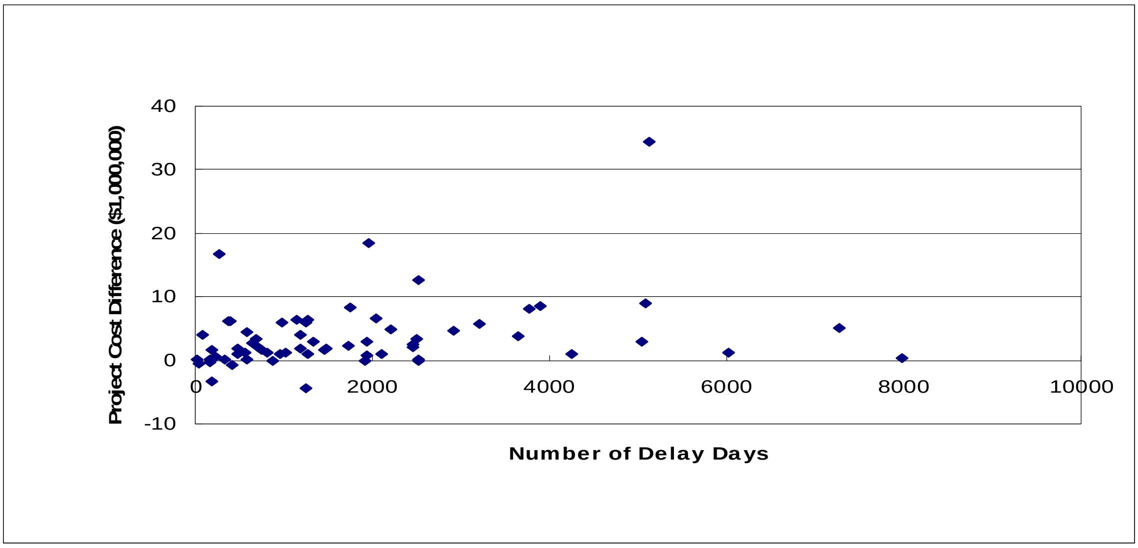


Figure 4: Delay Days vs. Project Cost Changes by Quarter/District

4.3.1 Regression Model

Regression analyses were performed to determine the statistical relationship between a response and the variables. In this analysis, the response was the project cost difference, and the variables were delay factors such as weather days and these factors found under the SA and TE headings such as changed conditions, plans modifications, and specification modification.

Several assumptions are required for the regression model. The regression model is expressed in the form of EQUATION (1).

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \ldots + \beta_p x_{ip} + \varepsilon_i, \quad i = 1,2,\ldots,n \qquad (1)$$

And, the assumptions of the model are:

- y_i is regarded as the response that corresponds to the levels of the explanatory variables $x1, x2, \ldots, x_p$ at the ith observation.
- $\beta_0, \beta_1, \ldots, \beta_p$ are assumed to be the coefficients in the linear relationship. If there is a single factor ($p = 1$) for the equation, β_0 will be the intercept, and β_1 will be the slope of the straight line defined.
- $\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n$ are assumed to be errors which make a scatter pattern around the linear relationship at each of the n observations. These errors are mutually independent, are normally distributed, and have a zero mean and variance, σ^2, under the assumption of the regression model.

The method of least squares was used for both its mathematical simplicity and its ability to provide explicit expressions for estimates of the coefficients in the regression model. The research team assumed that since each variable is a distinct and separate factor in the FDOT system, no interactions between the variables would be considered.

Sixty-four data sets were used, derived from eight quarterly reports, with each report containing eight districts in Florida. From the data sets, all 13 delay factors were chosen for the regression analysis at the first stage; however, a factor (partnering) was removed from the first regression equation because there was no time alteration to any contract over this time period attributed to partnering.

The results for the regression analysis at the first stage revealed that at the 90% confidence level, only two of the 13 factors (plans modifications and minor changes) were statistically significant.

Tables 3 and 4 show the regression and the ANOVA statistics for the final equation. From Table 3, it is interesting to note that when all of the insignificant factors from the first stage were eliminated, only the delay days due to "plans modifications" continued to have a significant relationship with the project cost changes. Even though there were many delays due to weather days, the relationship between weather days and project cost changes was not statistically significant. The weather days might affect the contractor's cost, but they don't seem to impact the owner's cost.

In Table 4, the P-value indicates that the regression as a whole is very significant for a significance level of less than 1%. The coefficient of determination, R^2, indicates that over 60% of the variation in the variables is explained by the regression model, shown in EQUATION (2).

Project Cost Difference ($100k) = 4.23 + 0.204 Plans Modification Delay Days (2)

Table 3: Regression on Delays

Variables	Coefficients	Standard Error Coefficients	t-ratio	P-value
Constant	4.230	5.323	0.79	0.43
Plans Modifications	0.204	0.020	10.30	0.00

Table 4: ANOVA Statistics for Regression on Delays

Source	Degree of Freedom	Sum of Squares	Mean Square	P
Regression	1	123,522	123,522	0.00
Residual Error	62	72,199	1,165	
Total	63	195,721		
R^2	63.1%			
R^2 (adj.)	62.5%			

The adjusted coefficient of determination R2 (adj.) is a rescaling of R2 by degrees of freedom so that it involves a ratio of mean squares rather than sums of squares. This removes the impact of degrees of freedom. Unlike R2, R2 (adj.) need not always increase as variables are added to the model. The value of R2 (adj.) tends to stabilize around some upper limit as variables are added [11].

Figure 5 indicates how the regression equation fits the data. When the values derived from the regression equation are put on the y-axis and the values of actual project cost changes are placed on x-axis, the scattered dots show a linear trend. In this drawing, the ideal estimates will lie on the 1:1 line, which shows that the derived value is exactly equal to the observed value of actual project cost change.

Even though the regression equation proved significant for project cost changes, the assumptions of the regression model should be checked to see if they are satisfied. Homogeneous variances and normal distribution of experimental errors are among the most important assumptions. Residual plots are carried out to provide visual evaluations of the analysis of the constant variance assumptions, which assumes each data point is equally reliable [12].

The residuals e_i measure the discrepancy between the data y_i and the estimated or fitted model $\hat{y}_i$. If the constant variance assumption is satisfied, then residuals will follow a distribution with a zero mean and variance, σ^2. In addition, the residuals should be plotted randomly, having 95% of the residual points within a 2σ horizontal band around zero.

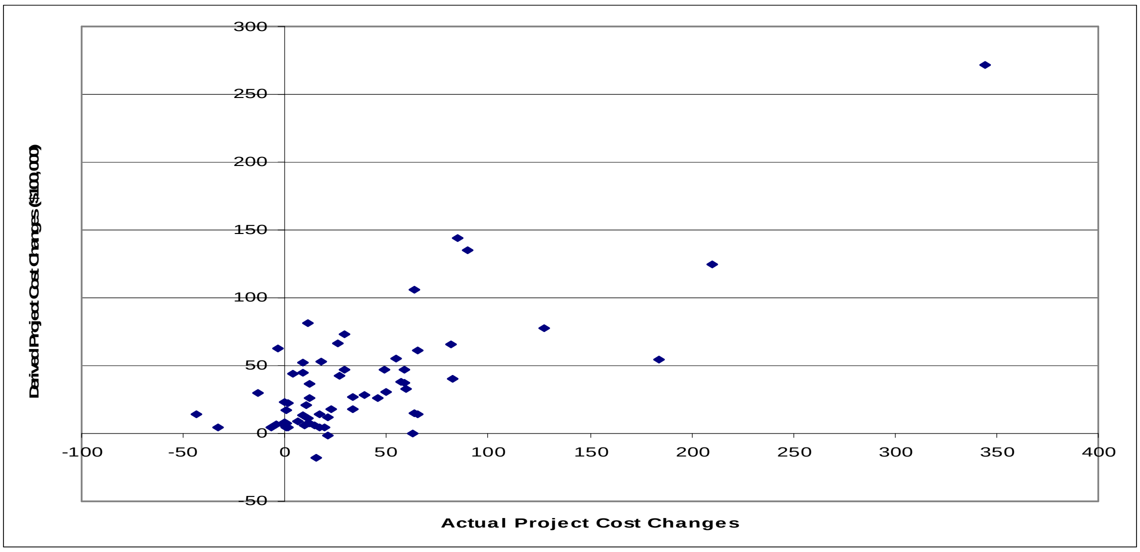

Figure 5: Actual Project Cost Change against Fitted Project Cost Change for Linear Regression Model

In Figure 6, when the residuals from the regression model are plotted against fitted values of the regression equation, any evidence for a nonrandom pattern can be detected. Further, it can be determined from Table 4 that most of the residuals should exist between the ranges of $\pm 2\sqrt{1,165}$, or ±68.26 since the mean square of the residual error in the ANOVA is an estimator for σ^2, which is 1,165. From Figure 6, it is proved that most of the residuals are between the anticipated ranges; showing approximately two points are located outside this range, or 3% of the total observations. Therefore, it can be concluded that the constant variance assumption is satisfied. One of the purposes of deriving a regression equation in this research was to assist in predicting project cost changes in highway construction projects using actual delay days. With the resulting $R2$ value of 63.1%, it can be said that actual project cost changes can be estimated using the actual delay days under each category.

5. Conclusion

This paper presents an analysis of factors influencing contract duration for highway construction and multiple regression analysis of the causes of delay in transportation projects. Delay distribution was quite consistent, and the composition rates among the grant type of delay days (Weather, TE, and SA) did not change much unless there were noticeable changes in rain days.

The granted weather days were compared to actual weather reports at the National Climate Data Center. Even though both documented precipitation and the number of weather days granted in District 3 were greater than the other districts, the difference in weather days granted was significantly greater than the difference in documented precipitation.

Weather days were the number one reason for delays on highway construction project. Plans modifications and changed conditions were also major reasons for delays.

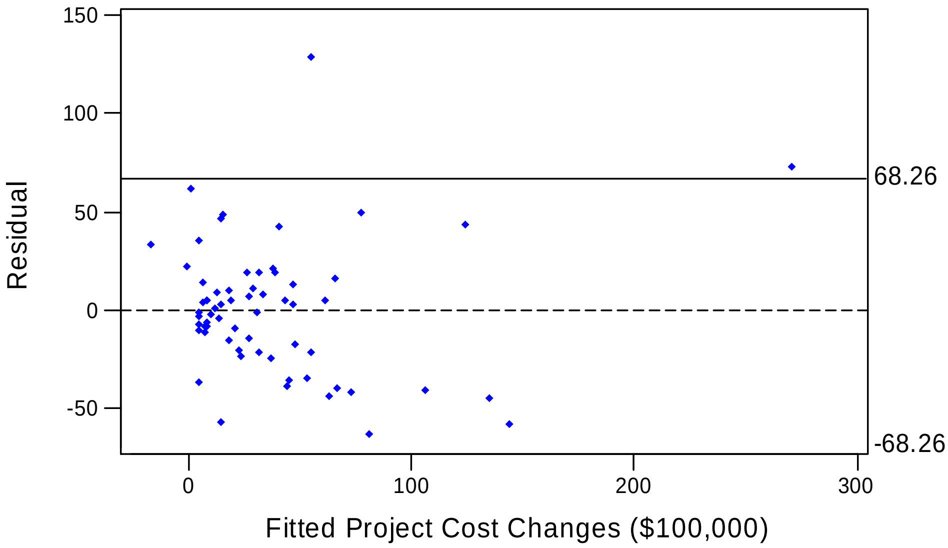

Figure 6: Residual Plot for Linear Regression Model on Project Cost Changes

The composition of the total delay days varied from district to district. The more rural the district, the more weather days were granted on average; and the more urban the district, the more TE and SA days were granted. TE and SA days are made up of changed conditions, plans modifications, specification modification, value engineering, partnering, CEI action/inaction, minor changes, defective materials, weather-related damage, claims, utility delays, and invalid reason codes.

Contract type also had an influence on project duration. In this research, the lump sum contract was noted to have played a positive role in projects having shorter project durations. One reason for lump sum contracts having shorter durations was that landscaping projects were contracted using lump sum contracts with warranty bonds separately from roadway construction projects. With the warranty bond and motivated contractors, the lump sum contract was, then, successful, and FDOT received many days back from contractors through SAs.

Regression analysis was performed, and multiple linear regression determined the statistical relationship between project cost differences and project delay. In this analysis, the regression model for project cost changes has provided a regression equation that satisfies over 60% of the variance. Among the 13 delay factors analyzed as part of the first stage, only delay days due to plans modification had a significant relationship with the project cost changes.

Benchmarking Project Management in the United Kingdom: Developing the Measuring Instrument

Chris Fortune
School of the Built Environment, Heriot Watt University, United Kingdom
(email: C.J.Fortune@sbe.hw.ac.uk)
Mel Lees
Research Institute for the Built and Human Environment, University of Salford,
United Kingdom (email: m.a.lees@salford.ac.uk)

Abstract

The paper is an output from the research being undertaken by the Task Group in Project Management, which is part the activities of CIB W65. The objective of the research is to benchmark the activities of practising project managers against the Project Management Institute – Body of Knowledge. The methodological approach is a survey of practitioners. This paper reports on the development and piloting of the survey questionnaire that was designed with input from the Task Group in Project Management. The resulting questionnaire is presented and discussed in a UK context. The results show that the questionnaire will form a suitable basis on which to survey current practice. It will allow the assessment of the extent to which practitioners in the UK have the skills to undertake the various project management activities, how much of their time they commit to them, and how valuable they consider their outputs.

Keywords: Body of knowledge, project management, skills, value

1. Introduction

This paper sets out the findings of the development stage of the benchmarking study in project management. It is designed to inform a debate in the CIB W65 Task Group in Project Management on how to proceed with data collection on role of the project manager in the United Kingdom (UK) as the first study in a collection of national studies. The paper sets out a review of project management standards and justifies the choice of the Project Management Institute – Body of Knowledge (PMBOK) as the basic structure for data collection in the benchmarking process. The rationale for the development of a data collection tool is explained and the findings of a pilot of a questionnaire are discussed and reported.

2. Literature Review

The problems and difficulties of the UK construction industry in terms of it delivering satisfactory service levels to its clients have been well documented by various government reports over the years (Simon[1], Emmerson [2], Latham [3] and Egan [4]). In summary, such problems may be classified as not managing project budgets, timescales and/or quality standards. In general, research suggests that the overall track record of British organisations in managing projects leave much to be desired. BS6079 [5] acknowledged such poor levels of performance prevail when it commented "the delivery of projects on time within pre-determined cost and to the requisite standard within set constraints of established safety and quality criteria are less frequent than they should be".

In essence, these concerns are related to the product of the construction management process. It can be argued that to only focus practice based research on the resolution of such symptoms of construction project management problems is misplaced, as attention also needs to be given to a wider agenda related to the processes (or causes) which produce such symptoms of professional service dissatisfaction. Support for this view can be drawn from the work reported by Hibberd and Djebarni [6]. This study with UK construction industry clients and their consultants ranked for importance the factors that they considered being issues in the delivery of construction projects. This survey revealed that although product or goal related factors such as time (3%), cost (6%) and quality / design faults (16%) were issues that were considered to be problematic there were others. The other factors rated by the respondents to that survey that were more related to the processes used to provide construction project management services such as, change requirements (25%), teamwork (25%), communications (18%), and project team responsibility / roles (5%). The general issues related to the management processes that UK based construction industry consultants use to deliver their services address matters such as what services, how are they structured, when are they delivered and to what quality levels are they provided. For the purposes of this work those concerns have been put into context by addressing matters related to construction project management functions and standards, activities and timescales and quality service level benchmarking. Each are now considered below.

2.1 UK National Project Management Standards and Functions

In the UK, there are two main methodologies, namely, Prince 2 and BS6079 that can be used as the basis of a strategic project plan document. The Prince 2 system can claim to be the *de facto* standard for the UK government and local authority usage. The Prince 2 and the PMBOK cover many of the same topics and both represent best practice. Waterman [7] identified the main sections of the Prince2 system as being, project start-up or initiation, planning, directing or executing, controlling and closeout.

The establishment and revision of the BS6079 [5] standard also aimed to help management address the issues highlighted above. The standard has been developed from a perceived need of central UK government and as a document it is divided into five sections, namely, (i) general matters, (ii) corporate aspects of project management, (iii) project and company organisational structures, (iv) project management processes, (v) project life cycles. Coe [8] has already undertaken small-scale quantitative research studies into the usefulness of BS6079 in practice. In the study it was found that only 40% of respondents were even aware of the existence of BS6079 in its original form. Similarly, concluded that BS 6079 does not yet appear to be taken seriously by the UK construction industry.

2.2 International Project Management Standards

Formal planning and management programmes have developed greatly since the 1950s when the US defence industry introduced the PERT network. From such early developments there has been a continual drive to develop project management standards and certification on a world-wide basis. Many countries and many sectors of industry either have or are attempting to produce their own individual standards so as to formalise their project management techniques. The internet based PMforum hosts a world wide listing of regional, national and international professional project management organisations. It lists on its web pages a total of 35 separate national project management associations from across Europe, Asia, and the Americas - see www.pmforum.org. This proliferation of standards and approaches is presently being addressed by the Global Standards working party and its brief is to establish a global standard that can be used to establish professional competence. Some of the most widely known and used international project management standards are now set out for consideration,

The Project Management Institute (PMI) set out in their Body of Knowledge (PMBOK) what they claim is the necessary guidance on the processes and knowledge required by practitioners involved in managing single projects. Its main sections cover the management of risk, management of people, and the management of time. This standard is seen as being the industry standard that can be applied on a global basis to promote the project management profession. However, as indicated above other standards available include the following,

The Engineering Advancement Association of Japan (ENAA) has produced its own Project Management Body of Knowledge. The Japanese have looked to see how project management can help innovation and improve business value. The standard was initiated by the Japanese Project management Forum (JPMF). The project management book of knowledge concentrates on the management of projects rather than the management of differing systems that make up individual projects. The four main sections of the ENAA BoK are objectives, strategy, value, management and finance. It is interesting to note that this BoK places emphasis on the management of finances and it also covers the management of programmes which is an area that the PMBOK has been criticised for overlooking. This Japanese standard has been heavily influenced by the government and it has been tailored to its needs.

In Germany, there are the DIN standards and the PM-Kanon standards that are most used in relation to project management standards.   The DIN standards that are applicable are DIN 69900, 69903 and 69905. These standards relate specifically to the definition of terms and processes used in project management. The standards also give local and national compliance requirements that are similar to the UK British Standards. These standards are essentially national in application and are not seen as having any influence or relevance outside Germany.

The Cost/Schedule Performance Management Schedule was developed in Canada. This standard was developed specifically for major crown and other government projects. In the guidance note it is made clear that this standard is not intended for use on projects which are related to the production of commercial services. Canada is further developing a separate project performance management standard. This is being produced by a joint industry / government working group and its aim is to produce a more straight forward document / standard. The working group have taken on board the development of other standards such as those operating in Australia and the US Department of Defence. In time this will give this revised standard a wider than just national relevance to Canada

There are two main standards in Australia which relate to project management. One standard, AS4360, refers to managing risk in Australian public service. This standard is the one used by the Australian National Audit office to audit projects and programmes undertaken on behalf of the Australian government. The second is the Australian National Competency Standard for Project Management. This is a national standard sponsored by Australian Institute of Project Management. This standard was developed with the aim of promoting the profession and being used as the basis for the certification of professional standards. The PM BoK was used as the initial baseline for the standard and as a result the standard is good in the assessment of an individual's competence but it is limited in its use to the Australian context. Indeed, Turner et al [9] commented that in keeping with other standards "this standard does not prescribe how project management competence should be developed".

The Association of Project Managers Body of Knowledge was developed in 1986 primarily to address all aspects of education and training of project managers in the UK. It is not seen as a standard to be used for the implementation of project management services. Rather it is seen as a mechanism to structure certificated training. The APM and other nationally based standards are based on the PMI body of knowledge that is becoming accepted as the global standard. The standards and guides indicated above detail the functions or the 'what' that constitutes the potential range of services that construction project management needs to address. The next issue to consider in order to begin to establish common approaches to construction project management are the process by which such services are delivered.

2.3 Project Management Activities

During the construction project lifecycle it is self evident that project management activity should be centred on ensuring that the project achieves its recognised success factors. Previous work by Morris and Hough [10], Nicholas [11], Keeling [12] have between them all developed comprehensive lists of issues that construction project managers need to address in order to ensure their management activities are best directed towards the achievement of project success. In summary the principal features advanced in the literature revolve around the conventional issues of project management activity being focused on the management of time, cost and quality during the construction or implementation stage of the project delivery lifecycle. However, Winch [13] notes that such a focus on conventional project success criteria provides a narrow view of what project lifecycle activities actually need to be addressed. Winch [13] suggests that such a view is limited in that it takes as given solutions to the problems during briefing and design and it ignores the differing interests of all project stakeholders. Winch suggests that project management services that focus on such narrow conventional criteria is an approach that is product or goal orientated rather than one that takes cognisance of the processes by which such goals can be achieved.

Burke [14] suggests that project management activities that focus on the processes by which the project life cycle is fully implemented need to address issues that can be grouped under the following headings, namely, the concept and initiation phase, the design and development phase, the implementation and construction phase, and the commissioning and hand-over stage. Given this wider perspective it follows that the time project managers allocate to the differing phases of project delivery should be distributed across the project lifecycle and not exclusively focused on the project's construction or implementation phase.

2.4 Benchmarking

Benchmarking is the term applied to the method of comparing best practices amongst peers or competitor organisations to identify, and adopt best practices that can help a particular organisation to improve the level of its services to its clients. Keeling [12] identifies the concept of benchmarking to be an established mechanism used by project management organisations to ensure that they learn from the experience of themselves and similar business organisations. However, work by Somerville and Stocks [15] indicated that the prevailing 'blame culture' together with the fragmented nature of the UK construction industry may well combine to frustrate the same characteristic of competitive benchmarking to become as established in the UK construction industry.

3. The Project Management Process

3.1 The PMI Body of Knowledge

The Project Management Institute established its first Project Management Body of Knowledge in 1976 on the premise that there were many management practices that were common to all projects and that codification of this "Body of Knowledge" would be helpful not just to practising project management staff but to teachers and certifiers of project management professionalism. It was not until 1981, however, that PMI's Ethics, Standards and Accreditation Committee submitted its recommendations for a BoK to the PMI Board of Directors. These were published in the August 1983 issue of the Project Management Quarterly, and this subsequently formed the basis for PMI's initial accreditation and certification programmes. A revised document was published in the August 1986 issue of the Project Management Journal and approved by the PMI board in August 1987 as the "Project Management Body of Knowledge". Further work by PMI's

Standards Committee resulted in a revised document titled "A Guide to the Project Management Body of Knowledge". This was done to emphasise that even though the document defines the PMBOK as all those topics, subject areas, and intellectual processes which are involved in the application of sound management principles to projects – a claim which this paper will question – it will never be able to contain the entire PMBOK which is out there in the universe of project management. A further revised and updated version was published in 1996. Trademarking of the term PMBOK was recently sought by PMI. Currently, the structure of the PMI's PMBOK™ document consists of "generally accepted project management practices" represented by 37 component processes. It also includes a description of what the PMI defines as the "project management framework": definitions of key terms, a description of pertinent general management skills, and an introduction to the concept of a project management process model (Morris, [16])

3.2 The Construction Extension to the PMI Body of Knowledge

In 2000, PMI issued its Construction Extension to the PMBOK. In the introduction to the extension, the PMI states that the extension "supplements, modifies, reinforces and expands the profession's *de facto* global standard in an easy-to-use format for practitioners in the construction industry" (PMI, [17]). The extension introduces four additional activity areas – project safety management, project environmental management, project financial management, and project claims management. The activity areas of the PMBOK and the Construction Extension are shown in fig. 1.

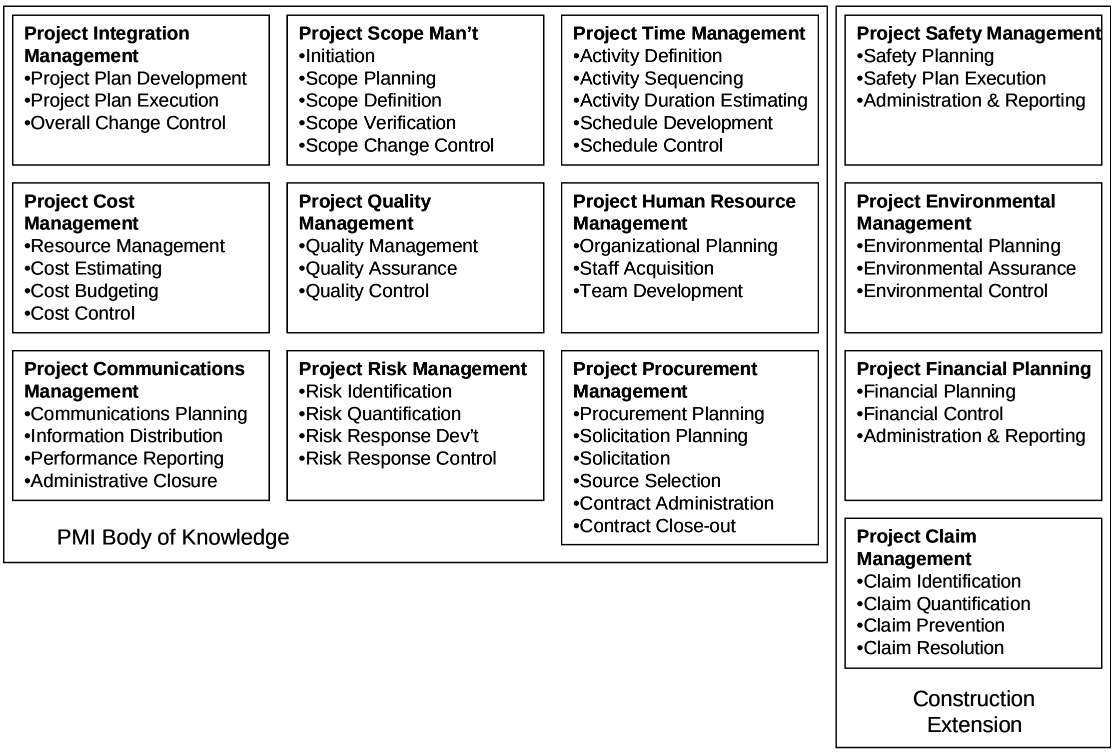

Figure 1 The PMBOK activity areas and the construction extension

4. The Benchmarking Process

4.1 The Task Group in Project Management

The Task Group in Project Management was set up under the CIB W65 Organisation and Management of Construction in 2002. The objectives for the task group include an international benchmarking exercise on the role of project management. The argument for this was articulated in the proposal:

> The globalisation of construction, particularly for large infrastructure projects, creates situations where companies from across the world come together in a unique partnership to solve a particular problem, often working under the direction of a single, project management consultant. Those postgraduate programmes for project management that recruit in a global market are recruiting well and from counties all over the world. There is little or no evidence to suggest that the elevation of the importance and significance of the project manager is confined to the United Kingdom, it is a global phenomenon.

This benchmarking study has two components:

1. A quantitative study designed to examine the role of project managers in construction projects in different countries. This part will attempt to gather data as widely as possible.
2. A qualitative investigation into the factors affecting the differences between countries.

This paper presents the findings of the development of a measuring instrument for part 1 of the study.

4.2 Developing the Measurement Instrument

The measuring instrument has been developed following workshops held alongside CIB symposia in Singapore and Toronto. The PMBOK provides the structure for the benchmarking process. It gives a total of 13 activity areas that are sub-divided into 43 sub-activities (see fig 1).

The starting point is what is meant by role? A dictionary definition would be: 'the actions and activities assigned to or required or expected of a person or group'. This is an important issue in this context and goes to the heart of the investigation. Role descriptors are usually ascribed to individuals or groups of individuals and any examination of 'role' must, therefore, focus on the individual within the process. For this study, the focus is on the role of the project manager in the management of construction projects.

It must be recognised that the term project manager is generic and that the function of the project manager may be undertaken by a separate consultant with the title of project manager, or by any other actor engaged in the construction process, or indeed a combination of these. If it is the role of project manager that is to be benchmarked, rather than the named persons duties, it is important that data is collected on who is performing the duties of project manager?

The next issue is about the investment made by the project manager in discharging their obligations. Here data can be collected on the relative use of manager's effort, in the form of time, across the activities in the PMBOK. This follows on from the study reported by Fortune and Lees [18]. Data also needs to be collected on the perception of value added by each of the activities. This will allow for the alignment between effort and value to be assessed.

Finally, it is important to capture data about the respondents, to establish whether there are trends that affect their execution of the role. Here it is proposed to examine the level of experience, appropriateness of formal education and training and discipline background of the respondent.

The framework for the measuring instrument is summarised in figure 2.

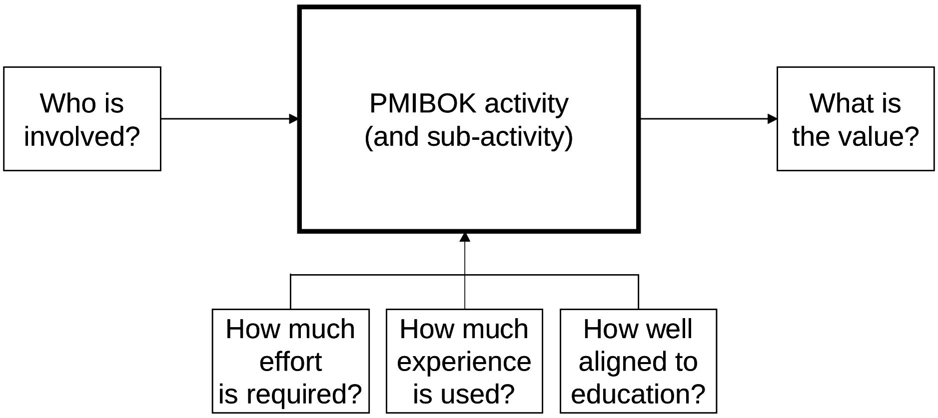

Figure 2 – Rationale for the development of the measuring instrument

4.3 Validating the Questionnaire

For the purposes of this development process a paper questionnaire was prepared in accordance with the principles established in fig 2. The questionnaire in its first form runs to several pages and there is insufficient space here to reproduce the whole questionnaire. However, fig 3 shows the typical arrangement of the questionnaire and also shows an example of how it was completed.

In the pilot study, the questionnaire was given to five practitioners to complete along with a supplementary set of questions that asked questions about their experiences of filling it in. These questions covered ease of understanding, time taken to complete and appropriateness of questions.

The respondents found the questionnaire relatively easy to understand, although there was some confusion over how to respond to the question on the proportion of their time spent on different activities. The main problem here was a lack of certainty over what constituted 100% of their effort. Was it the amount of time spent as a consultant or was it only the amount of time spent as a project manager? Confusion on this matter led to a lack of clarity in the data collected.

The time taken to complete the questionnaire was considered to be too long and likely to have a detrimental affect on the response rate. This matter will need to be discussed by the Task Group before a final decision on how to proceed can be taken. The options would appear to be either to make the sample of respondents a smaller, solicited sample that only includes those who have agreed to respond, or to improve the efficiency of the data collection by making the questionnaire a web-based data entry form. The latter has certain attractions as it would remove the confines of A4 paper sheets and allow a greater level of instruction on how to complete the form.

The general view of the respondents was that they felt the questions were appropriate, but they did not feel qualified to comment on this as they were not fully aware of the purpose of the research.

7. Project Cost Management	What proportion of your time as project manager is given to this activity?	How do you rate the [see below] (where 0 = low and 5 = high) – circle as appropriate: The value-added by your engagement with this process	Your value of your experience to this process	The value of your education to this process	Which of the following ***actors*** has **primary responsibility** for the process? 7.4 Cost Control – controlling changes to the project budget.	10%	0 1 2 3 4 5	0 1 2 3 4 5	0 1 2 3 4 5	☑	☐	☐	☐	☐	☐	☐	☐

Figure 3 – Example a completed part of the questionnaire

Overall, the pilot demonstrated that the questionnaire design is a reasonably robust and reliable basis on which to develop the measuring instrument. Further work is required in refining the tool before it used to collect data in the UK as the first part of the benchmarking process. A workshop is to be held in Helsinki to move the development to the next stage.

5. Conclusions

The main finding of this part of the study is that the basis on which the measuring instrument is designed is reasonable and robust. However, further refinement is required before the data collection can be undertaken in a full study. This refinement needs to be informed by the debate in the next workshop meeting of the Task Group, which is to take place in Helsinki in June 2005.

Process Oriented Integrated Management System - Development and Implementation

Jarkko Muurimäki
Skanska Talonrakennus Oy (e-mail: jarkko.muurimaki@skanska.fi)
Kaisa Kekki
Skanska Oy (e-mail: kaisa.kekki@skanska.fi)

Abstract

The management system of Skanska Talonrakennus Oy is an integrated system, which addresses the following aspects: quality, environment, occupational health and industrial safety. The system describes the best practices applied to planning, implementation and improvement of activities as well as the responsibilities of different individuals. The indicators of the management system are intended to support continuous improvement of operations.

Upgrading of the management system was started because the previous functional management system had some significant inherent shortcomings. The old system was not sufficiently customer-oriented, did not support cooperation between the various units and functions, and did not help conceptualize the whole. In addition, the system, maintained in hard copy folders was onerous to update, and reporting of indicators required much work and was not illustrative.

The goals set for the new process-based system were not so much standard-oriented as business-oriented and their purpose was to support the strategic goals of the company. The method chosen was tightly scheduled teamwork led by the process owners and supervised through the different phases by an external expert, Mr. Kai Laamanen. Definition of customer-oriented goals proved to be a good way to help understand customers' expectations and challenge the existing management practices that were the result of the functional system.

The digital management system has proved to be a good concept at the construction sites and offices of Skanska Talonrakennus. The extensive material is logically organized in the system, and documents of the reference material are easy to find. At the same time, the digital system has significantly accelerated the development of the entire management system of Skanska Talonrakennus. Reporting and analyzing of indicators has reached an entirely new level thanks to the software. The reports are illustrative, they are produced on real time and decision-making concerning needed actions on their basis has become more dynamic.

Implementation of the process concept throughout the organization is not yet completed. In 2005, resources will be dedicated especially to training, reference material of the system, and reporting on safety findings. Judged on the basis of the positive first experiences, the reform of the management system has been a significant step in the right direction. In the future, the new system will be a good support for achieving the strategic goals of Skanska Talonrakennus.

Keywords: Management system, process, implementation, improvement

1. Need for Development of the Management System

1.1 Role of Skanska Talonrakennus Oy's Management System

The management system of Skanska Talonrakennus is an integrated system which addresses the following angles: quality, environment, occupational health and industrial safety. The system is certified in respect of all of the above-mentioned areas.

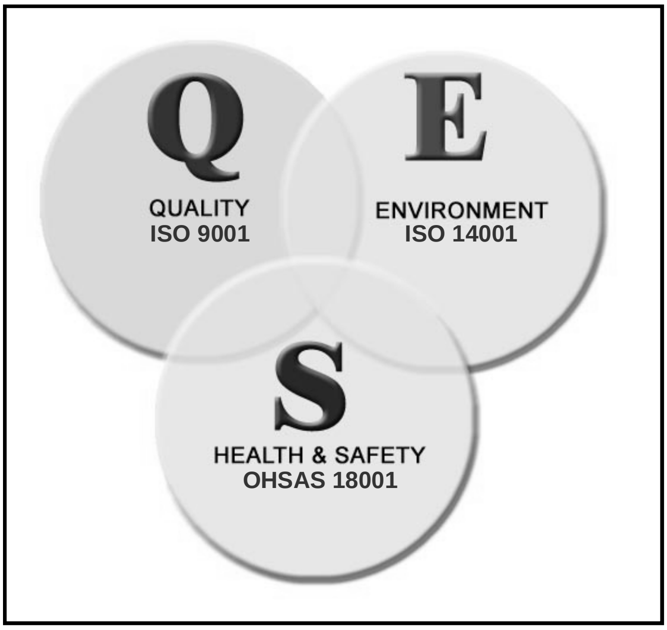

Figure 1. The three components of the integrated management system: quality, environment and health & safety.

The management system plays a significant role in the daily work of all Skanska employees both at the construction sites and offices of the company. The system describes the best practices of the company for planning, implementation and improvement of activities as well as the responsibilities of different individuals. Every Skanska employee has the duty to follow the management system in his/her individual duties.

The indicators of the management system support continuous improvement of operations. Financial, qualitative, environmental and safety performance capacities are measured by several different indicators. Further actions and development projects are determined on the basis of the measuring results.

This article describes the project for reforming the management system, its premises, goals and implementation as well as the characteristics of the new system.

1.2 Problems Associated with the Functional System

Until 2002, the structure of the management system was functional. The management practices were described as entities consisting of different functions. For example planning supervision, bidding calculation and production were such functions. The function procedures were described by means of written procedure descriptions and internal functional process charts. The system also included a large amount of reference materials, such as model plans, forms checklists and model documents. The system was quite viable and was generally considered to have no other defects except its heaviness and the extensive volume of its material.

However, this functional structure had several shortcomings. Firstly, the system contained no description of the customers' activities. The matters described in the system were based on Skanska's internal needs, not on the customer's expectations and requirements. It was impossible to understand the customer's role by means of the system, and customers' expectations were not very significant in the system improvement process.

The functional way of describing the system did not support cooperation between the different corporate units and functions; instead cooperation depended on the active commitment and skills of individuals. In addition, transmission of information between different functions was given relatively little attention.

A third significant question was the conceptualization of the whole. In the functional system, each function had its set goals which could, however, be conflicting with the goals of other functions, the goals of the entire company and those of customers. Employees also had difficulties in conceptualizing the operation of the entire company and their own role in it.

1.3 Problems with the Paper-based System

Previously the functional system was recorded in hard copy folders. About 1,500 Skanska employees in Finland had their individual system folders. Implementation of improvements was difficult, because even the smallest change required duplication of at least 1,500 hard copies of the document and their distribution to different parts of Finland. For this reason, the system was updated only once or twice a year. Small instant improvements were not carried out.

In the manual system, compilation and reporting of the measuring results was tedious work. It required an estimated work contribution of 20 people every six months to collect data on the qualitative, environmental and safety indicators. In addition to hard work, the reporting thus also lagged behind the real situation, and the clarity of the reports was only passable, and it was not easy to identify problems and improvement targets.

2. Goals Set for the Reform of the Management System

2.1 Goals of the New Management System

The management of Skanska Talonrakennus considered the success of the project for reform of the management system as critically important due to the dominant role of the system. The goals defined for the new system were not so much standards-oriented as supportive of the strategic goals of the company. Another goal was to create a system that would serve as the framework for planning of all activities and development in Skanska. Process approach provides a good basis for 3D modeling and standardization of construction projects where Skanska has allocated significant resources in recent years.

An important aspect is that the true objective of the system reform was to achieve the benefits offered by the process approach. The reform turned out to be a large project where the operations of the company were described in an entirely new way. The change of processes required by the new standards could have been achieved by a much easier updating of the system by just calling the existing functions processes and the persons responsible for the functions process owners. But such a flimsy reform would not have generated any new benefits, and the activities and their evaluation would have continued largely unchanged.

The goals defined for the new management system were:

- Our customers are more satisfied.
- We manage the risks.
- Our implementation costs are reduced and our productivity improves.
- The quality of our operations and products improves.
- We deliver the projects on schedule with zero defects.
- Control of our environmental and safety matters improves.
- Our cooperation network together with us does its best to achieve the above-mentioned goals.

2.2 Goals of the Reform Project

A challenging target schedule was set for the reform of the management system. The work was started in April 2002 and the system was to be ready for use and for training of personnel in April 2003. External audits in accordance with changed standards ISO 9001:2000 and OHSAS 18001 were performed in June 2003. In this connection, the environmental standard (ISO 14001 remained unchanged. In addition, the working method of the reform project was to utilize the best skills and knowledge of personnel and support widespread commitment to the goals.

3. Project for Reform of the Management System Step by Step

3.1 Theory Applied

Skanska Talonrakennus had no previous experience from a process modeling and development work of the type of this project. There was, however, ongoing cooperation with Kai Laamanen, a leading Finnish process expert, for instance connected with self-assessments. He was a natural choice as our cooperation partner for this development project, because he was already familiar with Skanska's operations and his process expertise was widely recognized.

It was agreed with Laamanen that he would train Skanska personnel in process management, and would then serve as instructor in the project, supervising and commenting on the different work phases. The three project phases presented in this chapter follow the model for building of process system, presented in Laamanen's book "Manage your business as a network of processes". The terminology used is from Laamanen's book " Terms and concepts in business process management". [1], [2]

The basic theory of process approach is that there is a certain chain of processes used by the organization to generate value to the customer. This generation of value must be managed in the organization and the operative result of the organization is generated in this process. [1]

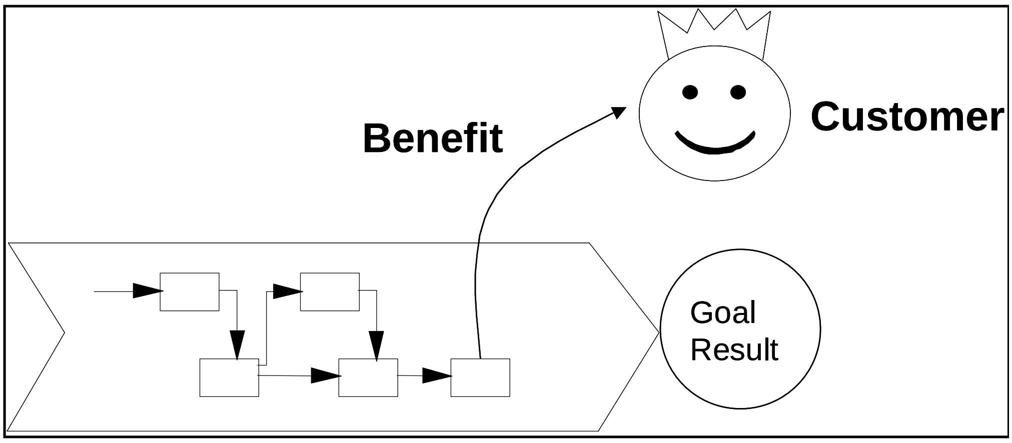

Figure 2. Value generation and target-setting.

3.2 Work Method

In March 2002, a schedule with intermediate goals was created for the project for reform of the management system. The working method came to be such that all persons who participated in the reform project held a joint meeting of a day or half a day at the beginning of all the project phases described in the following chapters. The status of the work and the guidelines for the following phase were reviewed under Laamanen's guidance. Small teams established for each process continued working between the meetings. Each small team had a chairman, and the chairmen were later also appointed as process owners.

APRIL – MAY 2002
Process training to process owners and quality managers
JUNE – AUGUST 2002
Definition of customer's operations
SEPTEMBER 2002
Definition of the inputs, phases and products of all processes
OCTOBER – NOVEMBER 2002
Appointment of process owners. Writing of process descriptions
DECEMBER 2002 – MARCH 2003
Modeling of processes; linking of reference material by means of QPR ProcessGuide
APRIL 2003
Training of Skanska personnel
MAY 2003
First meetings of process development teams
JUNE 2003
External audits

Process owners, key persons and quality managers did the work (50 persons)

Figure 3 .Schedule of the project for reform of the management system.

3.3 Training of Key Persons

Knowledge and skills were seen as key success factors for the project. Training events were organized in April and May for about 35 Skanska employees. Basics of process approach and measuring of indicators were the training themes. The persons who participated in the training were mostly members of senior management and quality managers. These persons and 15 other Skanska experts subsequently participated in every phase of the reform project described in this document.

3.4 Definition of Customer's Operations

Definition of the customer's operations consisted the first phase in the creation of the new process-based management system. Families who buy houses, clients who want to build residential projects, companies investing in commercial and office premises (e.g. insurance companies) and users of commercial premises are customers of Skanska Talonrakennus.

The customer's operations were initially described on a summary level. Six main phases of the customer's operations which illustrate the operations of all the above-mentioned customers in relation to Skanska were described on this level,. The customer's operations were defined during June – August.

3.5 Identification of Processes

The core processes of Skanska Talonrakennus were identified in August 2002 on the basis of the customer's main processes. The role of these core processes is to supply the best possible service to the main phases of the customer's operations efficiently and profitably. The number of these identified processes was five.

Also the most important support processes were identified. Support processes are internal processes of the company that create the preconditions for the function and results of the core processes. The number of these identified support processes was eight.

The above-mentioned core and support processes are Skanska Talonrakennus Oy's key processes and they play a major role in achieving the performance targets of the company. This is why their adequate description and continuous improvement are important. Several support functions whose development in this connection was not considered critically important were excluded from the management system. The customer's operations and Skanska's key processes are presented in the process chart on the highest level of the management system.

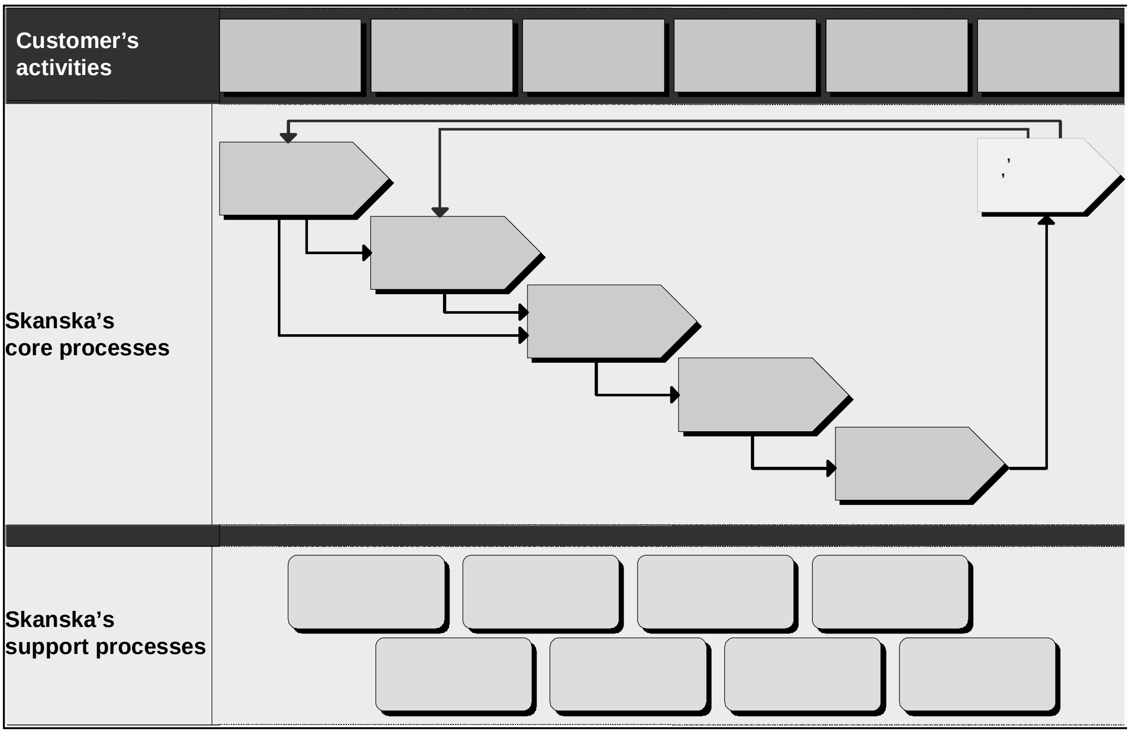

Figure 4. Structure of Skanska Talonrakennus Oy's process chart.

3.6 Setting of Process Boundaries

The boundaries of all processes in the management system were defined in September 2002. This was done by defining the inputs, phases and products of each process and also what happens before and after each process. These boundaries helped get a picture of the process contents and especially of the integrity of the core process, ensuring that the products of the previous core process are inputs of the next one. This also ensures that the processes really go from customer to customer and begin with planning (anticipation) and end in evaluation (learning).

3.7 Appointment of Process Owners and Writing of Process Descriptions

At the beginning of October 2002, an owner was appointed for each process. The owners are typically members of senior management who are in a prominent and influential position. Their first duty was to form a development team for the process, representing extensively all the units and the best know-how within Skanska. The first task of the process development team was to write a verbal four-page description of the process. To facilitate this writing work, all members of the team were given standard headings and questions that should be answered. The process description includes among other things:

- Purpose of the process
- Critical success factors of the process
- Main process phases
- Process indicators
- Process improvement
- Central roles functioning in the process.

In other words, the process chart is part of the process description. The process description is necessary to understand the operations and the critical factors that impact them (e.g. importance of cooperation). This supports operations, management and improvement. The purpose of management is to help people understand their own roles and the critical factors in the functioning of the organization.

3.8 Creation of Process Charts and Linking of Reference Material

The period from December 2002 to March 2002 was used to prepare the process charts by means of the QPR software, and to link the reference material to these charts. Certain basic rules were applied to the preparation work, e.g.

- The maximum permitted number of boxes (= functions in a chart) is 20, in other words only matters critical for success are described
- The charts start from the customer and end to the customer
- The customer is on the top line
- The following lines include Skanska’s different roles, or task definitions
- The functional text must describe activities and be a sentence

- The charts describe who performs the tasks in reality, not only who is ultimately responsible for the matters. [4]

Drawing of the process charts led to extremely fruitful discussions in the process development teams. The straight-forward way of presentation forced the teams to put the processes of the company and the relating functions in an accurate order of priority. Sometimes the description progressed easily in a spirit of good cooperation, while at times there were lengthy discussions about the priorities of doing things and who should do them.

The reference material: instructions used in daily operations, forms, checklists, etc., were linked to the process charts. As a result, more detailed relating material can be accessed from each function box of the process to make implementation easier.

3.9 Training of Personnel and Introduction of the System

The training events organized for all staff in April 2003 were quite straightforward. The first hour of the events was used to review the ideas and goals of process management as well as the changes in the structure of the management system. During the second hour, the participants practiced the use of the management system software in a computer class. After one hour of practice and final test everybody could use at least the basic functions of the system, such as roaming between process charts and retrieval of data. In connection with the training events, the hard copy system folders were collected from personnel and the fully digital system was taken into use.

The quick introduction of the system was supported by the following aspects:

- The basics of the process approach are accurate and straight-forward and aim at efficiency, and are therefore meaningful for business
- The goal of the system was simplicity of content and user interface
- Only the basics were taught during the first training round to ensure that the big organization did not need to absorb too many things at once
- General improvement of computer skills to ensure that users did not find the digital system as frightening or difficult to conceptualize
- Strong role of the management and other key persons in implementation and marketing; in other words, there was no uncertainty about the importance of the matter.

3.10 First Meetings of the Process Development Teams

The first meetings of the process development teams were held in May 2003. At that time, people had one month of experience in the use of the system. After this, the development teams have convened regularly and decided on improvements on the system.

3.11 External Audits

SFS performed the external certification audit of the system in June 2003. In the audit, the new process model was found to be good, and the auditor made very few comments about it.

3.12 Improvement of Measuring Indicators; Further Development

Continuous improvement of the system has continued energetically even after its introduction. Improvement of the measuring indicators has been a special priority during 2003 – 2004. The content of the indicators has been reviewed and improved from the angle of process efficiency and strategies. Reporting and analyzing have taken a significant leap forward following the introduction of the measuring software.

4. Digital Management System

4.1 Requirements

The environment where the management system and its computer applications are used is challenging. Skanska Talonrakennus has about 200 construction sites in different parts of Finland. The sites may be in tightly inhabited population centers and in city centers, or in very sparsely populated areas. The system must function right from the beginning of the site with the available telecommunication connections which can be of a varying quality.

The system must be easy to use, modern and attractive. Both process modeling and the use of the material of the management system must be simple and logical.

Since the management system is continuously used in 200 projects and many support processes, the system must be reliable. We cannot afford interruptions in its use.

4.2 Piloting

On the basis of a brief comparison, the process and score card software supplied by QPR Software Oy seemed to be the most attractive alternative. As the matter concerned the development of a system covering the entire personnel, we wanted to make sure before the investment decision that the characteristics of the software that would be purchased should meet the requirements of usability and information technology.

To ensure suitability, the software was pilot tested before acquisition. We agreed with the software vendor about a pilot project in which all parties participated to supervise fulfillment of their specific requirements. The software was tested at some sites and Skanska offices in different parts of Finland. Skanska's data administration unit tested its suitability for the existing IT environment, and the management evaluated the benefits of the software in its meeting.

Piloting confirmed the suitability of QPR, and there have been no surprises in this respect during the two years of use.

4.3 Use of the Digital Management System; Benefits in Production

The digital management system has proved to be a good concept at the construction sites and offices of Skanska Talonrakennus. The extensive material is logically organized in the system, and the documents of the reference material are easy to find. A basic user needs to know only a few functions, which makes the use of the system more meaningful and efficient. Another benefit for the users is that now the definitely most up-to-date and currently valid system material can be found in one single place on Skanska Intranet.

The digital system has significantly accelerated the development of Skanska Talonrakennus Oy's management system. Small improvements to the reference material are a virtually continuous process, because it takes very little effort to immediately make the updates available to the entire organization.

A new level has been reached in the handling of the measuring indicators thanks to the software. Reporting on quality, environmental and safety indicators used to be tedious, outdated and non-conceptual. Today, after the indicator system has been created, data can be entered in the system on real time, and the most recent information about the performance ability of the company is continuously available by means of the selected indicators.

The way of presenting the measured results is also illustrative and invites discussion. Green light indicates a performance that meets or exceeds targets, yellow is passable, and red is poor. Analysis of process indicators and decisions concerning further steps have become a natural element of management and all significant meetings in Skanska Talonrakennus.

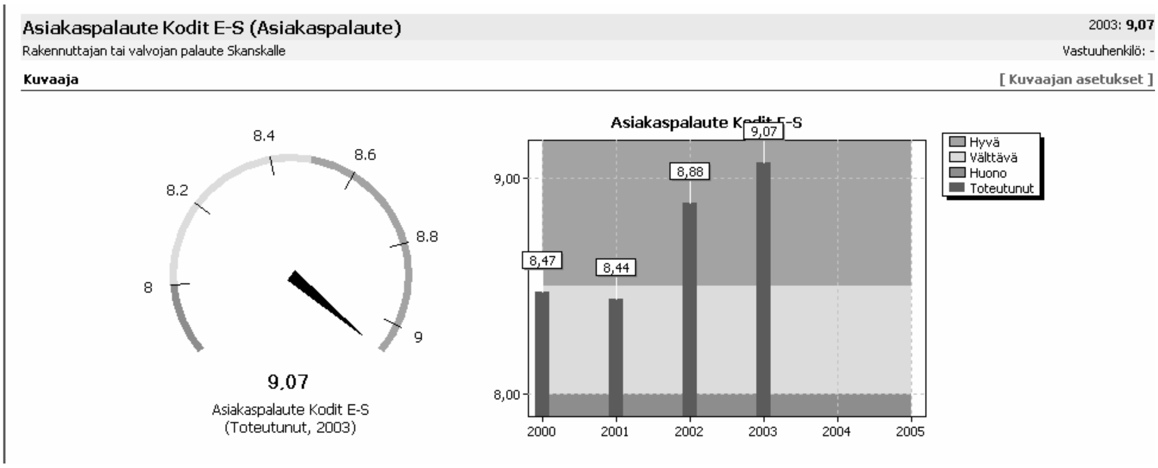

Figure 5. View of the indicators.

5. Critical Factors for the Reform of the Management System

Reform of the management system of Skanska Talonrakennus was an interesting project where many critical aspects and goals were implemented successfully. On the other hand, there is also still room for learning and improvement.

Since we had to deal with a matter new to the organization and even theoretically challenging, there was a risk that the work of fifteen process development teams would lose miss their guiding principles, and the result would be heterogeneous. The implementation of the selected phase-based process theory was, however, quite disciplined, and the result was a logical system.

Customer-oriented definition of processes proved to be a good way to learn understanding the customer’s expectations and call to question the conventional practices of the company, which were the result of the functional system. Reception among customers has naturally been very good for an management system of this type.

Appointments of people were successful. Process owners remained active throughout the project. Another essential factor were the intermediate goals set for the project at intervals of roughly two months, and the owners complied with these goals. Their enthusiasm about the process approach and their good position in the organization facilitated the introduction of the system significantly. The duty of the process owners also in the future is to improve the system to ensure that it generates value to customers as efficiently as possible. As the implementers also managed to create a relatively simple, modern system that makes work more efficient, its use was also preferred compared to the old system.

Measuring indicators were extremely successful in improving the quality of reporting. However, their content still requires a lot of improvement. Most of the indicators measure more the outcome than the true efficiency of the process. There are also some indicators in the measuring system whose real useful exploitation has not yet been confirmed.

Although the entire personnel was trained to adopt the process approach and the new management system, training has not yet been sufficient. Training on process contents needs to be increased. Also basic system training must be continued even to other employees, not only newly recruited personnel, because the using skills differ between the regional units. The level of skills is better in units where personnel has had the possibility to practice on their own the basic characteristics of the system in computer classes than in units where training was given in the form of lectures.

6. Conclusions

According to the experiences of Skanska Talonrakennus, process approach is a good way to model, manage and improve project-oriented construction operations. Provided that the process model is kept sufficiently simple, it supports prioritization of activities and development of critical success factors. The process-based management system helps understand the ensemble of all operations.

In the initiation phase of the project it was estimated that taking the process approach through an organization of this size would require five years of work. Now we are about halfway through that time, and a lot still remains to be done. For instance continuous improvement of processes has only begun, and the heritage of functional approach still shows even in planning of operations.

In 2005, resources will be allocated particularly to training events and reference material of the system. Some of the reference material is relatively heterogeneous and outdated, copied from the previous system. Improvement of the usability of reference documents is going on.

This year we will also introduce a new system tool for collecting and analyzing of safety findings. All findings relating to industrial safety at the sites of Skanska Talonrakennus will be recorded in the system. The idea is to have a good system that will activate the entire personnel into improving industrial safety.

Extension of the system to strategic planning, definition of individual user profiles and integration to other Skanska systems are some of the potential development targets.

The quality of the new management system can for the time being be evaluated mainly on the basis of employees’ comments and changed management practices. On the basis of their positive nature we have reason to believe that the reform of the management system has been a significant step in the right direction, and that the new system will from now on provide good support to Skanska Talonrakennus in achieving its strategic goals.

Project Management as a Synergic Competence for a Construction Corporation

Jani Kiistala
YIT Corporation (email: jani.kiistala@yit.fi)

Abstract

Corporate synergy and construction project management (CPM) as a synergic competence are discussed as the two challenges in the context of managing a multi-service corporation in construction. First, a main contractor (as an internal client) and a sub-contractor are trying to meet their own project goals separately. In turn, the goals of two units are seen as the common one in the eyes of corporate management. Herein, the latter can enhance profitable synergy through both (a) hard values such as the scale of economies in procurement contracts and (b) soft values such as shared client relationships, joint development teams, and shared know-how. Ultimately, corporate management gives the guidelines for solving this internal partnering dilemma, i.e. ensuring the competitive price/cost and high productivity in each project. Second, CPM is herein perceived as one of the synergic core competences of a construction corporation. Thus, corporate management guides the advancement of CPM skills, common language and sense of responsibility among key personnel across all the related businesses and units.

Keywords: Construction, cooperation, internal partnering, project management, synergy

1. Introduction

Herein, **the management of a construction corporation** is approached, in particular, in terms of solving the two internal problems that are typical in corporate settings. **The two-fold aim** of this paper is to address (a) the first problem involving conflicts between achieving the real corporate synergy and attaining the project-specific objectives of the two units at the same time, and (b) the second problem which is inherent in enhancing construction project management (CPM) skills as a synergic core competence through all the related businesses and units.

The paper is structured as follows. First, a dilemma of synergic corporate management versus project management responsibility is dealt in light of some relevant literature. Second, the importance of CPM as one of a construction corporation's synergic competences is highlighted. Third, the dual problem is elaborated with reporting on the initial results of one case study. The case firm is one of the largest corporations in Finland, YIT Corporation. In particular, the actual efforts to solve the synergy problem and the CPM competence problem are discussed. Finally, some promising ways for solving the two problems as part of effective corporate management are emphasized.

2. Project Responsibility versus Corporation Synergy

2.1 Converging Goals of Primary Project Stakeholders

In principle, clients (owners) may set very individual goals for their construction projects. However, it is herein assumed that **(profitable) project stakeholders** have many converging goals such as the finishing of the project on schedule and within budget as well as a project is performed without quality deviations and violations against safety regulations. Owners set various goals for their building projects concerning the effectiveness of the procurement process and the performance and the quality of the built spaces and systems. When strategic thinking in real estate evolves, attention will increasingly be paid to creating value-added services for users. The new sources of revenues and the solutions that improve the overall profitability will be sought instead of only minimizing the acquisition costs. At the same time, the scope of a contractor’s duties is expanding as well as long-term partnering and cooperation models are gaining ground. Operational models where both the risks for the investment object in question and the rewards of its successful implementation are shared spur the parties to closer cooperation and innovativeness. Incentive contracts are, after all, designed to line up a contractor’s goals with those of a client by making a contractor’s benefits partly dependent on the results that are important for a client. In this way, a client’s goals become the leading idea driving the implementation of an entire project. [1]

In construction corporations, there are several businesses and units that together create an extensive construction service provider. When one of a corporation’s main contracting units is selecting a subcontractor, a natural choice would be the use of in-house services and supplies. In this internal case, both an external client and corporate management expect flexible and profitable cooperation between a corporation’s units that are engaged in an external client’s project. Typically, an external client and an internal client are both expecting to get high quality and functionality at the targeted (minimum) cost (Figure 1).

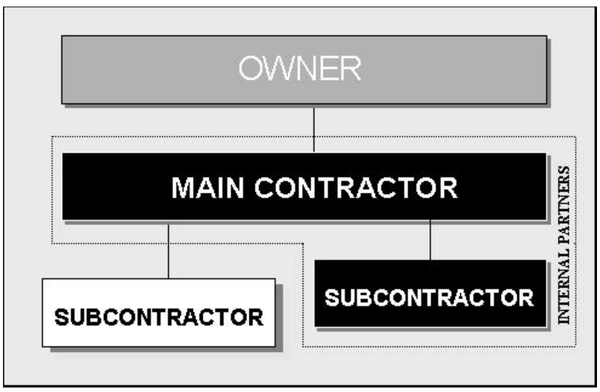

Figure 1: Converging project goals of the external and internal clients of an internal subcontractor (in the case of a construction corporation).

2.2 Procurement Dilemma

In many EU countries, the most common competitive bidding methods (related contracts that eliminate flexibility) and payment rules do still prevent from attaining any higher or broader goals beyond the project-level ones. This practice is coupled with one key task of a project manager, i.e. to finish his/her project within budget and, preferably, to maximize profits. Even in the focal corporate setting, a project manager is usually authorized to procure freely in order to attain the project goals and, thus, a corporate profit is beyond his/her direct concern. A cost-focused project manager drifts to select subcontractors and suppliers through a traditional competitive bidding, which means that an internal unit has to compete with external competitors. In addition, an internal unit is struggling both to fulfill the contract(ed wishes) of its client(s) and to meet its own financial goals, typically, by optimizing the resource uses and implementing everything within the necessities only. Thus, it seems that traditional project management and procurement behavior are together one of the root causes for a procurement dilemma, i.e. diverging project goals and contractual disagreements occur frequently also inside construction corporations.

2.3 Appropriate Internal Procurement

Appropriate procurement is dealt with **in the case of an internal client** as follows. It is assumed that an external client will first select one unit of the focal construction corporation as the main contractor. In turn, this main contractor faces a dilemma of using one or several “sister” units according to the corporation’s procurement policy. How is this internal client to choose the unit that is appropriate, competent, and trustworthy? Herein, only a few of Winch’s principles of resource-base selection are briefly applied to appropriate internal procurement. Typically, service contracts assigned in the early phases of a project, principally associated with design, face higher uncertainty than those assigned later, principally associated with execution on site. It is argued that also internal clients can consider **the four ways of procuring construction services** as follows [2] (Figure 2):

- An internal capability is maintained. This option involves a traditional choice of make or buy. In construction corporations, a true in-house service is regarded as a cost centre only.
- An internal subcontractor or supplier is appointed. In conditions where there is not enough information to allow the preparation of tender documents, the appointment of the internal party based on a list of references for having previously completed similar projects is a viable option. Appointment may also be used when the requirement to mobilize the resources for execution on site is urgent. Internal partnering may become very similar to appointment.
- Concours like procurement can be considered, in particular, concerning design services. The essence of a concours is that competition is based around the quality of a solution offered to a client’s problem, rather than its price.

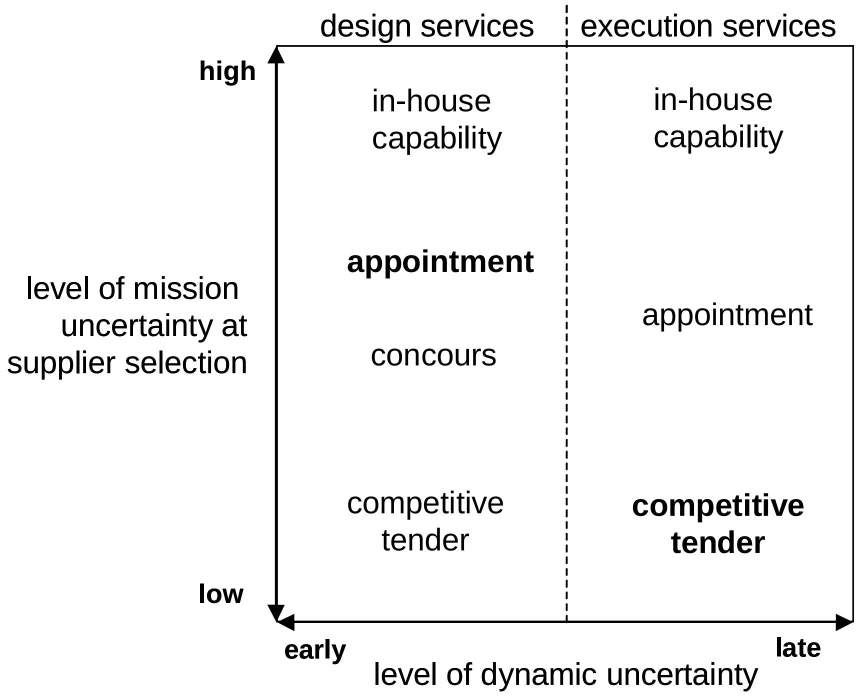

Figure 2: Alternative supplier selection methods (methods in bold are the most common per phase) [2 p. 102]

- Competitive tendering is a plausible basic option for selecting internal subcontractors or suppliers in corporate settings. It is distinguished by the formalization of both the selection process and the criteria upon which the final decision is made. However, competitive tendering often colludes with the idea of corporate synergy.

In broad terms, **the appropriate form** of resource base selection is a function of the level of uncertainty in the specification of the resources required at the time of selection. In particular, the level of mission uncertainty and the phase in the project life cycle are taken into account. [2] In addition, corporate management deals with an economic trend (high, boom – low, depression). During the low economy, it is more in the overall interest of a corporation that internal client-ship works. During the times of boom, it is evident that many possibilities exist to gain higher profits by procuring from supply and service markets.

2.4 Transfer Pricing

In a large construction corporation, management cannot monitor and control all the operation parameters of every unit. For this reason, corporations are organized as a set of divisions. Corporate management aims at coordinating divisions in ways that maximize the total profit. However, each division is still fairly autonomous and its head may have a freedom to take all the actions perceived necessary. Therefore, corporate management meets **a difficulty in evaluating and comparing division-specific performance**. In order to evaluate the performance of each division, several methods may be used for trying to measure the contribution of each division to the total profit of the corporation. One common way is to set transfer prices for internal services, goods, and outputs which are transferred from one division to another. The alternative **transfer pricing methods** are as follows. [3]

The market price is used as a transfer price, if there is a market for an intermediate service price. Often a transfer price is the market price minus the selling expenses. In **a dual price method**, the price that the selling division receives is not equal to the price that the buying division pays - and is usually higher. This mechanism generates a deficit, which corporate management sets off by an optimal transfer price and, hence, the optimal transaction volume, which in turn yields higher performance than other methods. Indeed, this method requires corporate management to be involved in a complex process of price-setting. **Negotiated transfer price** is reached between the relevant division managers. The advantage is that it preserves the divisions' autonomy. Its problem is the sensitivity of the outcome to the managers' negotiation skills. **Resale price** is used when a corporation purchases goods from internal units and resells them to external parties without any value additions being made. The arm's length price is calculated by deducting the gross profit from the resale price on the goods sold.

The cost plus method can be employed when there is a transfer of semi-finished goods between internal units, joint facilities are arranged, or services are provided. A cost base for both a comparable company and the one under review must be carefully analysed to ensure that the costs to be marked up are consistently defined.

Under **the profit split method,** the combined profits, which are the total profits from the controlled transactions, will be apportioned between the internal units based upon the relative value of the functions performed by each of the parties in the controlled transactions. Where two or more transactions are interrelated, it may not be possible to evaluate them on a separate basis. This method seeks to eliminate the effect of special conditions on profits by determining the division of profits that independent parties would have expected to realize from engaging in the transactions. The method can be used when there are no comparable transactions between independent parties. Under **the transactional net margin method**, the profit levels of similar firms serve as a guide to help determine the arm's length price to be applied to the transactions between two or more internal units. This method looks at the net profit margin relative to an appropriate base (e.g. costs or sales) that a tax-payer makes from a controlled transaction. [4]

In general, the use of transfer pricing is an effective way to allocate resources. In construction, transfer pricing seems to be used seldom. Herein, transfer prices are seen as a viable tool when the overall solution is sought for a procurement dilemma within construction corporations.

2.5 Corporation Synergy and Internal Partnering

The basic idea of **corporation synergy** can be described by an equation of 1 + 1 > 2. A construction corporation should be more profitable and effective than each of its divisions alone. It seems that **internal partnering** is one of viable ways of achieving corporate synergy. [5] Or, if you are not partnering internally - communicating with your colleagues, your members and customers; working as an integrated client team - then it is unlikely that you will successfully partner with external organisations. [6] There are many advantages to be exploited but cooperation cannot be taken for granted. In particular, internal partnering forced by corporate management is leading nowhere. Herein, a set of alternative ways of achieving corporate synergy is compiled. This initial list consists of ways coupled with **hard values,** i.e. benefits that are (fairly) easy to measure as follows (Table 1, the left column):

- Vertical integration consists of benefits available from managing contractual business relationships between internal units, with the goal of improving capacity utilisation, price realisation, and market access.
- Economies of scale can be achieved in several construction processes or functions both through increased project volume and internally benchmarked learning.
- Combined new business creation can be based on the utilization of know-how within several related units and the extraction of activities from these units and the establishment of a new unit as well as internal joint ventures or alliances.
- Shared tangible resources may involve achieving benefits through economies of scale and the elimination of duplicated efforts when physical assets and resources are shared, e.g. two or more business divisions are using the same manufacturing facility or research laboratory.
- In procurement, the pooled negotiation power of the corporation comprises the cost or quality benefits that can be gained typically from the bigger scale. It can also be extended to achieve many benefits through joint negotiations in various transactions with other stakeholders such as customers, governments, and universities.
- Coordinated strategies enable to reach for benefits that arise when the strategies of two or more businesses are aligned. For example, internal competition is avoided or reduced between units (e.g. allocated markets). Similarly, the competitive reactions of two units are coordinated against shared competitors (e.g. multi-point competition). [7]

In practice, the value of many operational synergic benefits is difficult to measure. The potential of **these soft values** is inherent in trust, avoidance of litigation, common values and rules, and the use of the outcomes of shared development projects (Table 1, the right column). Typically, shared know-how covers the benefits associated with the sharing of knowledge and core competences across the business portfolio. It may involve the sharing of best practice in certain business processes, the leveraging of expertise in functional areas, or the pooling of knowledge upon how to succeed in specific geographical regions. The know-how may be written up in manuals, policies, and procedures. In many cases, know-how is less formally documented, i.e. it is a dilemma of sharing the implicit, tacit ways that skilled managers master.

On the other hand, **an equation of 1 + 1 < 2** is not unknown. In construction corporations, there are typically internal obstacles that more or less prevent corporate management from mobilizing the huge potential of internal synergy and partnering. In practice, when internal units are unable to operate as a single project team, the resultant performance is probably lower than the level they would achieve under a contractual relationship between independent parties. Typically, the economies of scale are seldom achieved fully. In many cases, internal divisions are too autonomous. In other words, each division is simply focusing on the minimization of its costs and the maximization of its profit. [5]

Table 1: Alternative ways of synergic performance within a construction corporation.

MEANS FOR SYNERGY	
Hard values –benefits are easy to measure	Soft values –benefits are difficult to measure
• Corporate management • Economies of scale • Combined new business development • Synergic software • Shared human resources • Marketing (e.g. corporate brand) • Shared space (e.g. office building) • Procurement (incl. also personnel related procurement) - company telephone subscriptions - vehicle leasing policy - etc.	• Cooperative leadership • Organization • Joint training programs • Personnel rewarding methods • Shared customer relationships • Joint development teams • Shared know-how • Shared company values and policy • Trust • Avoidance of litigation

3. Construction Project Management (CPM) as a Core Competence

3.1 CPM as One of Corporate Competences

Herein, the management of a construction corporation with **a capacity to remain balanced** through the conflicting demands of the daily operations of the units is seen as a significant achievement. However, the strategic use of core competences does not end at the boundaries of the focal corporation. Rather, a corporation that uses core competences as an avenue to focus on growth opportunities must also focus on the external market. In targeted markets, the strategic focus transfers from keeping the corporate units directed toward a balanced system to retaining a cohesive focus in relationships with external clients. At the first level of this external focus is each external client. Paralleling a focus on internal activities, an external focus on clients is needed to pursue individual clients or projects that fit within a corporation's strengths. Retaining this client focus is a central component of a core competence concept. [8]

Construction project management (CPM) consists of a management system and personnel's individual skills. The key is to place individual competencies into a proper pattern that builds the corporation into a set of dynamic units that are capable of moving beyond their current focus and limits. [8]

3.2 Characteristics of an Effective Project Manager

Traditionally, **CPM** is emphasized in terms of management systems. CPM focuses on planning, controlling, and other management functions. Luckily, the effects of human actions in project processes are being guided more and more. Even in projects with technical challenges, a technical competence is not the factor that makes the difference between effective and bad project managers. It is vital that a project manager is capable of interacting and communicating while managing project processes and tasks. Herein, **the five key characteristics** of an effective project manager are put forth as follows: (1) do explain complicated things simply, (2) do not panic in difficult situations but stay calm and find a step-by-step way forward with the CPM team, (3) do face up the problems, find out causes, and make proposals to remove them, (4) do let people know what is happening all the time, and (5) do keep in mind the big picture of the project environment while performing the project processes and tasks. The criteria for a project manager's success involve factors having to do with both a manager's characteristics and project results. The former are clearly split between the two aspects of management: production-orientation and people-orientation. [9]

3.3 Problematic Variation of CPM Skills between Internal Divisions

In general, **everyday CPM problems** on construction sites are well-known: too little time is spent on CPM both in planning and execution. This is resulting in difficulties in holding project schedule and budget. One barrier for fluent cooperation between contractors involved in the same project is a lack of common language, policies, and CPM skills. Communication and information sharing between the project manager of the main contract and the ones responsible for the subcontracts is vital. When CPM information is not shared effectively, a large number of problems are emerging on sites. Herein, it is argued that **the variation of CPM skills** is large also within construction corporations, between international divisions, in part due to variations in educational background and corporate culture. On the one hand, divisions assuming a role of a main (principal) contractor in projects are well equipped with CPM competences. On the other hand, divisions acting as subcontractors seem to possess more technical competences (e.g. HEVAC) and less CPM competences. A lack of CPM skills causes problems in coordinating schedules, communicating between project actors, and actually leading specialty works.

4. Case YIT

4.1 YIT – Finnish Multi-Service Corporation

YIT is the leading Finnish-owned construction corporation which is also engaged in extensive international operations. YIT offers technical infrastructure investment and upkeep services for the property and construction sector, industry, and telecommunications. In all these sectors, YIT's services cover the entire life cycle of investment objects (projects). **YIT Corporation** is managed along its four businesses: building systems, construction services, services for industry, and data network services. The corporate organization consists of four subsidiaries, respectively. In tens of projects, **the subsidiaries** of YIT are acting together through contractual relationships. Typically, Construction Services Oy operates as a main contractor and Building Systems Oy (with HEVAC services) as a specialty subcontractor. In addition, the role of Data Networks Services Oy is growing in internal contracting in the future.

YIT is **a project-driven organization**, i.e. various projects (contracts) are the most important sources of revenues. (Construction) project management is thus seen as a core competence for YIT. Each project involves several contractors in these project-driven businesses. Each contractor is dependent on each other's schedules and milestones. So it is assumed herein that effective cooperation between contractors requires the same kind of (C)PM skills (Figure 3).

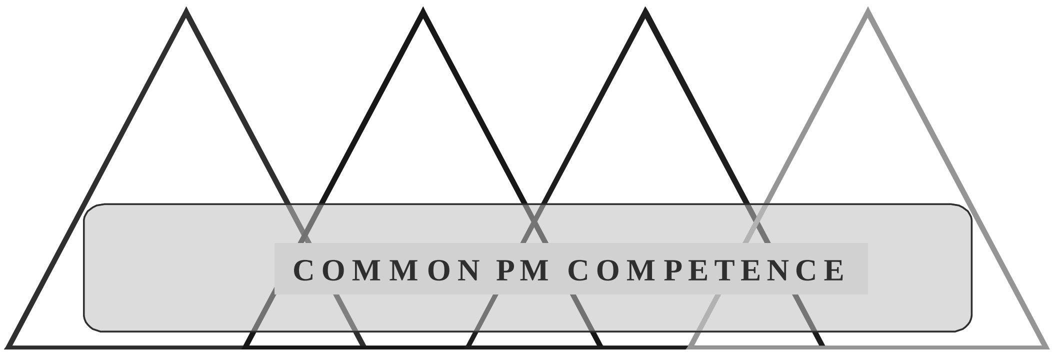

Figure 3: YIT's four businesses with their distinct spearhead competences and (C)PM competence as a common core competence of corporation

4.2 Questionnaire Survey on CPM Training Needs

Within YIT, **the questionnaire survey data** is being collected on a regular basis to get better understanding of the need of CPM training in the future. A questionnaire has certain advantages compared to an interview, e.g. hundreds of people can be reached at a relatively low cost. Respondents are given a possibility to answer anonymously. CPM is divided into 17 areas based on the literature and the accumulated experience within YIT. The CPM areas are considered as rational internal training modules (Table 2).

Herein, it is reported on the results of the recent surveys among the personnel who participated in YIT's internal CPM training during the last quarter of 2004 and the first quarter of 2005. The 149 respondents include project managers, project administrators, cost estimators, and middle managers in both the corporate offices and the regional offices in Finland. The questionnaire included one major question: **In what kind of CPM training are you willing to participate in the future?** Overall, the results are a bit surprising, i.e. 65 % of project personnel desire for deeper knowledge on project cost management, nearly 50 % time management and scheduling, and nearly 40 % contractual matters. Thereafter, project planning, design and engineering management, and project handover process are also highly scored (Figure 4).

In terms of **YIT's three businesses**, 46 % of the respondents belong to Construction Services (CS), 39 % Building Systems (BS), and 15 % Data Network Services (DNS), (Figure 5). Within both the CS and BS, the CPM interest of the personnel is fairly high. The two distributions are surprisingly near each other despite a few differences (e.g. design and engineering management). Broadly, the high needs for CPM training seem to indicate that some past conflicts of joint projects may have been caused by a lack of proper CPM culture. The lower rates of the CPM interest within DNS may be due to the different nature of this third business.

Table 2: Seventeen modules of CPM training within YIT.

1. Project Time Management and Scheduling	10. Management of Life-Cycle Issues
2. Project Cost Management	11. Design and Engineering Management
3. Contract Management	12. Environmental Management
4. Risk Management	13. Cost estimating and bidding/tendering
5. Procurement and Logistics Management	14. Customer Relations Management
6. Project Planning	15. Project Handover Process
7. Internationalization and Language Skills	16. Safety and Health Care
8. Site Management and Quality Management	17. Leadership training
9. Project Data Management and eService records	

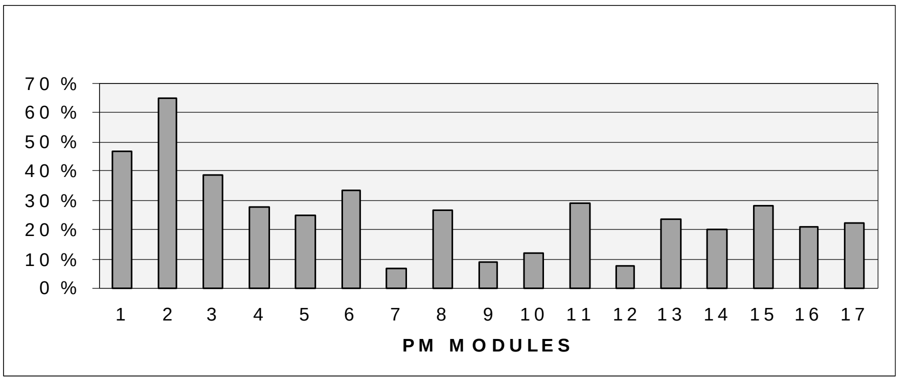

Figure 4: Total rate of interest in CPM training modules within YIT around a turn of 2004/05.

5. Conclusions

In this paper, the two issues within effective corporate management are addressed, namely, managing a corporate synergy despite many barriers and enhancing CPM skills up to a synergic core competence of a construction corporation. In principle, corporate management should thrive on **corporate synergy** especially when economy is down. In turn, corporate management may allow the outreaching for higher profits during booming periods. The corporate goal is to grow the synergic businesses, not only to share the contracted total profit. In the case of YIT, a potential of corporate synergy is high due to the relatedness of its four businesses. However, this kind of business portfolio is vulnerable to a risk of two businesses going down at the same time at least in one of YIT's primary markets.

In concepts of **partnering**, cooperation and the search of common goals are praised. In practice, real project life is more complicated than these concepts let us assume. "Project (wo)man" operates fundamentally with her/his own interests and this tendency needs to be taken into account when planning internal partnering and synergic joint projects. For example, project goal-setting can be done jointly by the internal project managers. No single project manager (team) should be left alone with less (when her/his/their colleagues are gaining more) without the compensation in one form or another. At the end of the day, other ways of seeking after higher profits through corporate synergy, i.e. ways that are not directly related to projects may remain obscure in the minds of CPM teams.

For construction corporations, **some conditions of effective internal partnering** are suggested as follows. Every partner (unit) acts on a truly profitable basis. Market price seems to be the only encouraging pricing method. Negotiated price is also possible. The competitiveness of each unit needs to be measured also against the direct external competition in terms such as quality/price ratio on an annual basis. An "open book" cost model and a flexible, open frame contract are used to create and maintain trust. Some elements of internal competition are preserved. Through a chain of projects, cost efficiency, time-saving scheduling, and team spirit should be advanced. In addition, the internal partners need to act as the seamless front in the eyes of primary external clients (owners). In the case of YIT, the principal contractor and the HEVAC contractor are obviously aiming at the flawless contract fulfilment with each external client. In the future, these subsidiaries could analyse a potential of the resale price method and the one of the profit-split method.

Finally, **CPM** is herein advocated as one of core competences within construction corporations. In practice, the effectiveness is highly dependent on personnel's CPM skills. Also the enhancement of high, balanced CPM skills across the corporation is one of the conditions for profitable synergy. [10] In the case of YIT, the survey results indicate that the personnel are aware of their needs for higher CPM skills. Obviously, one of the ways to advance CPM as a synergic core competence involves the hands-on training and learning by accomplishing more demanding CPM tasks under professional guidance.

Abstract

The effective control of a construction project budget from project inception to completion and occupation is one of the primary tasks of any organisation employed to deliver construction project management services irrespective of the projects actual global location. This paper sets out the key issues and problems involved in the delivery of this service to construction industry clients in the UK.

The main features of a project cost management system are identified in the paper before it addresses the principal problem areas of initial cost budget or baseline setting and project cost performance management. The literature reviewed identifies the potential project management tools that can be used to contribute to the management of each of the principal problem areas. The paper reports evidence collected from previous data collection exercises with practitioners based in the UK that allows current practice to be illustrated. The data on project performance measurement reported in the paper have been collected by mailed survey from one hundred and fifty two organisations involved in delivering project management services in the UK in 2004. The survey achieved a 42% response rate and its results raises questions about the claimed benefits of a bespoke project cost performance management tool termed as earned value analysis. The paper concludes by considering the direction of future construction related project cost management education and the role that can be played by professional institutions to promote change in practice.

Keywords: project management, cost budgeting, cost performance, tools in-use

1. Introduction

The UK construction industry, like others around the world, has a reputation for delivering its projects over budget. The latest high-profile example of this phenomenon is the new Scottish parliament building that, when completed, was nearly ten times over its originally forecasted budget. The Fraser Report [1] on the public inquiry into the project highlighted, amongst other issues, that a poor quality feasibility stage budget estimate and a poor level of cost control provided by the construction organisations involved were to blame for general dissatisfaction with the project. Other high profile instances of such poor performance were identified by Jackson [2] and include projects such as the British Library, Portcullis House, and the Welsh Assembly building. Jackson [2] reports repeated survey work by HM Treasury (1995), the Construction Clients Forum (1997) and the DETR (2000) that have shown clients to be generally dissatisfied with the service provided by practitioners involved in the provision of building project budget stage cost advice and subsequent construction phase cost performance management processes. Therefore the issue of poor project cost management is an ongoing problem for the construction industry and its clients. It is now timely to investigate the processes involved in this business advice function and determine the current state of the art in terms of cost control tools in-use so as to ensure clients' are better able to achieve value for money from their inter-actions with the UK construction industry.

This paper is structured to provide a review of relevant previously published material before it goes on to present the results of data collection exercises with UK based organisations that have enabled a snap-shot of current practice to be established. The paper concludes by considering the direction of future construction related project cost management education and research and the role that can be played in the development of this business service in the UK by professional institutions.

2. Context

Green and Simister [3] cite Hammer and Champy's (1993) definition of a business process as being, "a set of activities that, taken together produce a result of value to the customer". Currently, the processes used in the construction industry to deliver its clients' projects are being subjected to a period of re-design and accelerated change to ensure that they deliver greater value for money. Increasingly the assessment of value-for-money is being considered from a broader perspective that includes social, environmental, and economic features [4]. Winch and Carr [5] maintain that this the generation and communication of reliable early stage project budget estimates and the implementation of effective project cost control measures that are related to the construction and commissioning of building assets are sub-processes within their standardised project related process map. As such it has been asserted that industry would benefit from their further development and as a result of actually using the output of research. Similarly, the generic design and construction process protocol developed by Kagioglou *et al* [6] also indicates that such business activities would be considered as a sub-process within their model, namely the feasibility stage of a project's pre-construction cycle and the project's construction cycle. It can be seen that effective construction project cost management processes are a fundamental component in any project's value appraisal system.

Kerzner [7] and Lock [8] amongst others, identify the principal components of a construction project's cost management process as being; the establishment of a realistic budget, the determination of a system of work authorisation and release, the collection and analysis of timely performance cost data across the project lifecycle, the establishment of effective cost change management systems, and the creation of meaningful cost account and variance reporting mechanisms. This broad analysis has a strong relationship to the main components of a cost control process set out by the Project Management Institute (PMI). The PMI indicates in its body of knowledge (BoK) that its cost management processes are concerned with creating what it terms as being a project cost baseline as well as managing changes to the cost baseline. For instance the PMI [9] indicates that the main features of such a project cost control system need to address cost inputs, the tools and techniques used to assess performance and the cost reporting mechanisms used to provide timorous information to decision makers. There seems to be broad agreement on the principal components of an effective project cost management process. As a result this paper addresses two features of any cost management system namely, the building project baseline budget estimating processes and then secondly, the tools and techniques used to assess the cost performance of the project during its production phase.

2.1 The Building Project Baseline Budget Estimating Process

Skitmore *et al* [10] considered pre-tender budget price estimates which within the construction industry form the project cost baseline position and asserted that the 'dominating presence of uncertainty in the construction process militated against the production of accurate estimates by numerical analysis alone'. As a result building project budget estimating must involve a mixture of calculation and judgement. In order to develop an understanding of how building project budget estimates may have their quality enhanced it is necessary to identify the processes involved. Bowen [11] developed a communications based theory of building project price forecasting. That model was based on the Shannon and Weaver's linear or process model of communications and it indicated a major divide in the process between the phases of forecast formulation and forecast transmission. The formulation phase of this theoretical process was divided into iterative cycles of investigation and application. There remains a need to fully investigate the construction project budget estimating process as a means of addressing the performance gap of practitioners that can result in the incidences of inadequate business services indicated above in terms of poor quality project cost advice. What is acknowledged is that an essential part the building project budget price advice process is the selection and use of the most appropriate tools or models.

Repeated surveys by Fortune and Hinks [12] and Fortune and Cox [13] have established the 'state of the art' in terms of building budget estimating models in actual use in the UK. In general these large-scale empirical studies have found that there were over twenty models currently in-use. The results of the surveys show that in general terms the paradigm shift towards the newer non-traditional models, called for by academics such as Brandon [14], has not been generally achieved. What can be seen is that the results of successive waves of the prevailing engineering or product or tool centred research that has been funded by government grant has not been found to be useful in practice. Examples of such an engineering or product-related research paradigm are the knowledge-based models, the regression models, the whole life cost models, the fuzzy logic and neural network models, which have been developed over a period by academe for the industry to use. The repeated surveys show consistent evidence of low levels of usage of such models and the continued overwhelming use of manual, deterministic models that have been found to formulate inadequate cost advice over a period of time. Latterly there has been much research effort directed to the development of models or tools that can take account of the sustainable impact of proposed projects. The survey work reported in Fortune and [13] again reveals that such tools have not yet been adopted for widespread use in practice. Given the slow rate at which changes in practice can be achieved in the construction industry then it is too soon to suggest that these new models that address the assessment of sustainable impact of projects have been abandoned by practice. However, the same cannot be said for the paradigm change called for by Brandon in 1982. The results of the research reported above indicate that such a paradigm change has now been abandoned by practice and as such this finding will have implications for the education and training of future professionals.

2.2 Construction Phase Cost Performance Tools In-use

Lock [8] considers that the emphasis given to project management cost control is unique in the UK construction industry due to the existence of quantity surveyors and detailed bills of quantities. As a result the standard tools suspected as being in use in the construction industry to manage the construction phase project cost performance management process included milestone monitoring, variance analysis, valuation analysis and standard s-curves. Milestone monitoring uses predefined stages or phase completion of projects as the trigger mechanism for contract payments to be made. Lock [8] indicates that the data required to set up the milestone approach to construction project cost control are the project schedule or programme and the budgeted cost of the activities required to be completed to achieve the milestone. A potential drawback to the use of this approach to production cost control is the re-active and delayed nature of information availability. The cost information generated by this technique takes no account of the actual work achieved on site and assumes one hundred per cent efficiency of site operations. However, Abdomerovic *et al* [15] do acknowledge that the great advantage of using this approach is its simplicity and resource efficiency in operation.

The use of variance analysis as an approach to construction phase project cost performance management acknowledges that changes are endemic on construction projects. Ronald [16] asserts that this approach can be used to highlight the inefficiencies caused by such changes in terms of their cost consequences on the project's baseline budget figure. Pilcher [17] argues that this technique is well suited to construction project production phase cost control due to the prevalence of bills of quantities but nonetheless it is generally accepted that such a system is itself costly to set up and does not focus on overall project costs. The valuation analysis approach was asserted by Walker and Wilkie [18] as being the most popular in-use. This approach calls for the practitioner to carry out valuations of the work executed on the project at the end of a given period. Such an approach provides data for the contractor to use in benchmarking performance against payments received for each of the resource centres required for project production, namely. labour, materials, plant, and sub-contractors. However, Pilcher [17] points out that the approach can lead to inaccurate data and that often contentious items are excluded from timorous payment although resource has been expended in their execution. In addition this approach does not facilitate the forecasting of overall project costs. This is a claimed advantage of the S-curve approach to providing construction phase project cost performance management. This approach provides data against the formation of standard cost curves for the project. Such curves are usually s-shaped and are derived from data from previous similar projects. Control can be achieved by plotting actual expenditure against budgeted costs on a periodic basis. Galley [19] pointed out that the main flaw with this approach was that the s-curves produced could indicate performance gaps but on their own it is not possible to say whether the project is behind or ahead of the planned schedule.

Wake [20] asserted that earned value analysis was an approach that was developed to overcome the combined problems of the conventional approaches to project cost management during the production phase of projects. Support for this position comes from the PMI which indicates that the main tools available to project managers looking to control project cost performance in general include tools such as performance reviews, variance analysis, trend analysis and earned value analysis. Of the tools indicated by the PMI BoK [9] as being generally available it was asserted that it was *"earned value analysis (EVA) in its various forms is the most commonly used method of project performance measurement"*. EVA is based on the combined work breakdown structure (WBS) and the organisational breakdown structure (OBS) for the project being constructed being drawn together so as to develop a task responsibility matrix (TRM). Winch [21] determines that such an analysis can facilitate what he terms as a cost control cube to be formed and that such an approach provides a disciplined framework for the organising, planning, budgeting, measurement monitoring, and reporting of a project's performance.

Fleming and Kopplemann [22] asserted that if EVA was to be implemented efficiently then it was best employed from the earliest stages of the project's development. If this was the case with the use of EVA on construction projects in the UK then it would be necessary for consultant quantity surveyors and other built environment professionals to develop appropriate skills to ensure its application. However, Baker [23] identified that many such practitioners see EVA as being a complex process, which is shrouded in terms, acronyms and formulae that can be intimidating to the uninitiated. On the other hand sources such as Webster [24] asserts that the use of EVA provides a uniform measure for reporting progress on a project and a consistent method of cost performance analysis. The benefits of using EVA as a tool for the measurement of project production cost performance was also given emphasis by its inclusion within the BS6079 and the PMI BoK [9]. Such sources maintained that the use of EVA would allow a more disciplined approach to planning and risk management, as well as providing good programme visibility, and encouragement to the objective and quantitative performance measurement on projects. It was asserted that such an approach would enable timely indications of problems to be developed which would facilitate a more reliable prediction of programme cost schedules.

As this paper is concerned with establishing the tools currently used in practice to manage construction phase cost performance it was now resolved to conduct a questionnaire survey amongst construction project management organisations in the UK. It was determined that the questionnaire should gain measures to determine the current usage of the tools indicated as being available to practice in the literature reviewed above. Accordingly a sample of one hundred and fifty two organisations drawn from both consultant and contractor based construction project management organisations was constructed from the 2003 yearbooks of the Association of Project Managers (APM) and the project management faculty of the RICS. The questionnaire was administered by surface mail and good practice ensured the questionnaire was appropriately piloted before dispatch. Similarly good practice required a covering letter and a stamped addressed return envelope to be included and each form had its own unique reference number that facilitated follow-up in the case of non-response. As a result the survey attracted a response rate of 43% which was considered adequate enough to provide meaningful data.

3. Questionnaire Survey – Results, Analysis and Discussion

Responses were evenly divided between those organisations that classified themselves as being a contractor based organisation and those organisations that classified themselves as being a consultant organisation and these classifications were later used as the principal variables to analyse the data. The first question in the questionnaire asked the respondents to confirm their involvement with construction project management. The results of the question showed that none of the respondents to the survey indicated that that they had no involvement in construction project cost management. This was essentially a checking question that provided data that confirmed the appropriateness of the sample and an indication of the validity of the results. Respondents were then asked to indicate the usual point in a project's lifecycle that they were engaged to provide their project cost management services. The results of the survey have been summarised below in Figure 1. It can be seen that generally respondent organisations start to provide their project cost management services during the pre-construction phase of a project's delivery cycle.

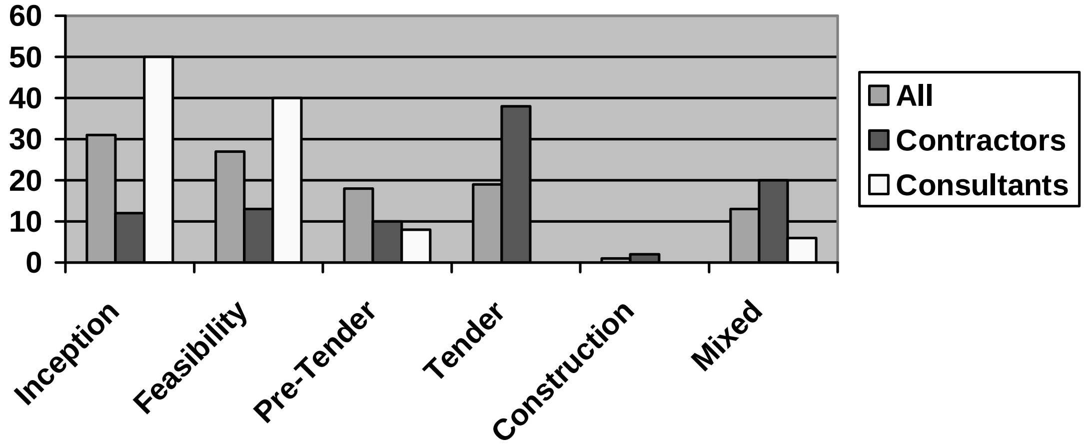

Figure 1: Project Cost management services and the project lifecycle

Figure1 shows that there is difference in approach between consultant and contractor based organisations that responded to the survey. It can be seen that contractor based organisations are more likely to start to provide project cost management services to their clients at the tender and construction phases of a project's lifecycle which would reflect the prevailing procurement pattern in the UK. As the changes in the operational practices of the UK construction industry alter following the calls for change made in recent UK government reports then it is likely that project cost management services will be delivered from project inception to completion and occupation. This change in practice should help UK construction industry clients to achieve better value for money from their business investment decisions.

Respondents to the survey were then asked to indicate the project cost control system they were using in practice. Figure 2 provides a summary of the results obtained and it shows that in general the most popular method is the conventional monthly valuation analysis (70%). The other techniques such as milestone monitoring, variance analysis, s-curves and earned value analysis were used by an approximately similar sized minority of the respondents to the survey (15%).

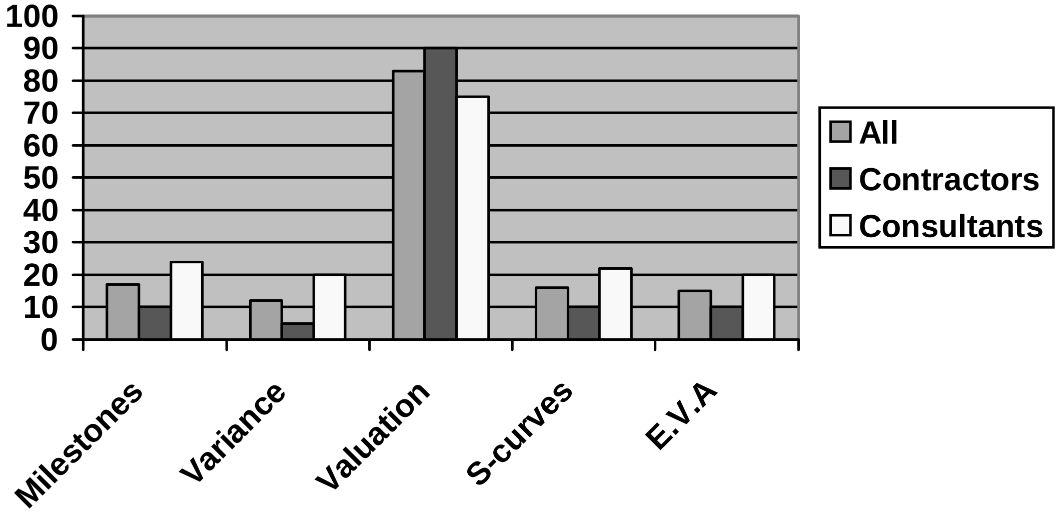

Figure 2: Types of cost control system in-use

This result indicates that the conventional approach to project cost control is still in widespread use despite the claimed advantages of the new wave tools such as earned value analysis. The literature reviewed above indicated that of the newer techniques that were available it was earned value analysis that offered the most to project mangers involved with the provision of cost performance management services. The next question in the questionnaire explored the reasons why the respondents to the survey were not making use of earned value analysis as a cost performance measurement tool. Firstly the respondents were asked to indicate whether they were actually aware of the existence of earned value analysis as a tool to use in project cost control. Figure 3 indicates that the majority of respondents (73%) claimed that they had no awareness of earned value analysis. It can be seen that there was some difference between the consultant (80%) and contractor (65%) organisational types responding to the survey.

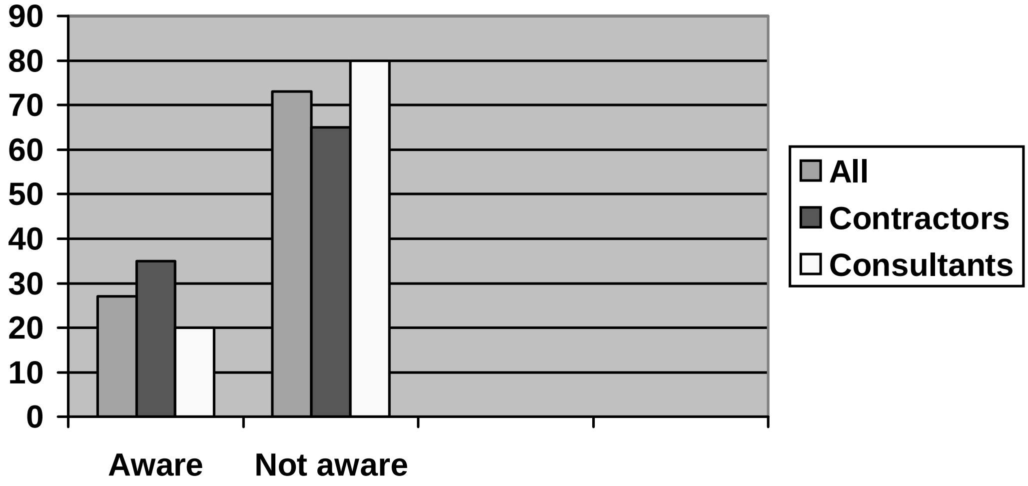

Figure 3: Level of awareness of EVA as a cost control too

This result indicated that contractor based respondents are more likely to be aware of EVA but as revealed above a concern must be that such organisations do not enter the project lifecycle under the tender and construction phases of a project's lifecycle. This late entry to the project was acknowledged to be a real disadvantage in terms of using EVA to its optimum effect. This result also confirmed the finding of earlier work undertaken by Brandon [25] which asserted that earned value analysis was little used in the UK construction industry due a lack of commercial awareness of its potential benefits. This was surprising to Brandon [25] as he pointed out that earned value analysis was indicated as being the preferred tool for project cost control in key documents such as BS6079. However, an earlier survey reported by Fortune and Lees [26] found that in the UK the majority of project managers did not adopt BS 6079 as the co-ordinating vehicle for their project documentation.

The respondents that indicated that they had made use of EVA as a technique to control project cost performance were then asked to give their assessment of the technique in-use in terms of the accuracy of the data it generated and the usefulness of the information it provided. Figure 4 shows that only 31% of respondents that had used EVA found that it was able to generate more accurate data than the other more conventional methods of cost control.

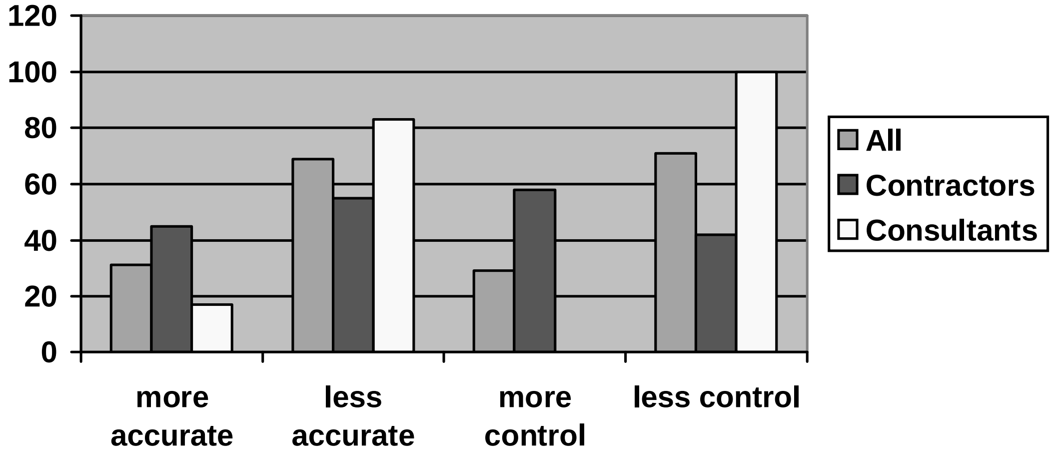

Figure 4: Capability of EVA to generate more accurate data and exercise budgetary control

The results show that there was some difference of opinion between the respondents to this question that were located in consultant and contractor based organisations. It can be seen that only 15% of respondents in consultant and 45% of respondents in contractor based organisations agreed that EVA was capable of generating better budgetary control for their projects. This difference in response was further tested using chi square test and it was found that the difference was not statistically significant. Nonetheless the overall result of this question is in direct contradiction of the finding found in the work of Fleming and Kopplemann (2001) who asserted that the use of such a tool enabled practitioners to generate more accurate data for use in project cost control. Figure 4 also shows that only 24% of respondents that had made use of EVA considered that the technique enabled them to exercise greater levels of project cost control than the other more conventional tools that they had previously used. The results of this question call into question the claims of Wilkens [27] that EVA was a tool that was better than other techniques at keeping projects within established budgets. The results shown in Fig 4 provide clear evidence that practitioners on the ground have not found that newer project cost control techniques such as EVA provide real improvement over their tried and trusted techniques. In such circumstances it is not surprising that EVA is not in widespread use in providing construction project cost management services to UK based clients.

The respondents to the survey that indicated that they had not yet used EVA as a tool for project cost management were asked to indicate the reasons why they had not as yet adopted the method as a tool for use. Figure 6 shows that of the reasons listed, namely cost to set up and maintain, high satisfaction levels with existing tools, and unfamiliarity with the technique. Of the options listed it was found that general unfamiliarity with the approach was the main reason for its non-adoption (58%) and that 30% of this type of respondent felt that their more conventional cost control technique was providing satisfactory levels of service.

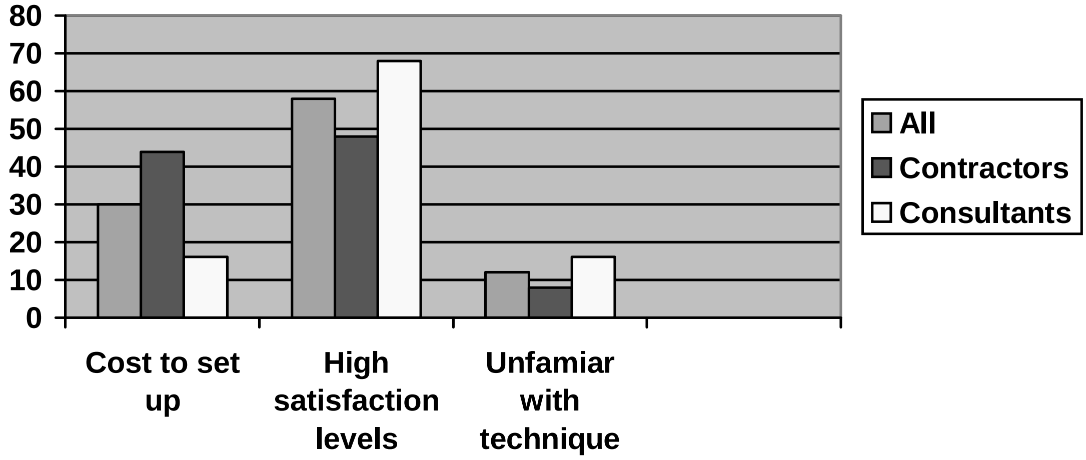

Figure 5: Reasons for non-use of EVA as a cost performance tool

Such results confirm the general level of response generated in response to earlier questions in the survey and provide a measure of internal consistency within the questionnaire which generates confidence in the survey' results.

4. Conclusions

The survey work reported in this paper indicates that the newer tools and techniques advocated by academe for use in UK construction industry for the delivery of project cost management services have so far been rejected. This finding applies equally to the tools used to generate the initial project budget and the tools used to provide data for effective construction phase project cost control. The paper focused on these two key aspects of project cost control as being central features that construction related project managers needed to get right to ensure the effective delivery of project cost management services. The finding in relation to the tools used to set the initial budget for the project is of concern given that academe has been calling for a move away from the conventional tools in-use for over twenty years. Such continued non-use of tools such as regression analysis, probabilistic models, neural models, and neuro fuzzy models raises questions about the effectiveness of previous research paradigms in this topic area. The non-use of sustainable assessment models for projects and the newer construction phase cost control tools such as milestone payments and earned value analysis do not as yet raise the same questions. In terms of the widespread non-use of sustainability models and EVA it is probably to soon to conclude that they have been rejected for use by practice. Rather it points out the time lag that can exist between academe and practice in terms of performance advancement. Nonetheless the survey rejects the findings of other non-construction focused investigations and helps make the case for the approaches adopted in construction related project cost management services to be seen as being non-generic in nature. The lack of awareness of the newer project cost performance tools such as EVA calls into question the effectiveness of the curricula driving courses of formal and informal education. Such lack of awareness also flags up to the relevant professional institutions the need for greater emphasis to be given to this topic in terms of CPD type training programmes.

Production Processes and Control

Introducing Last Planner™: Finnish Experiences

Anssi Koskenvesa

Lauri Koskela
The University of Salford (email:L.J.Koskela@salford.ac.uk)

Abstract

The Last Planner method1 represents a radically different manner of controlling production in construction. Even if its benefits are widely observed, it is also a common observation that the introduction of the Last Planner method to a site, into a company or into a country is not an easy and uncomplicated task. This paper reports on the experiences and lessons gained during the introduction of the Last Planner to Finland. A simplified explanation of Last Planner is presented. The experiences and lessons gained are contrasted with those presented in prior literature.

Keywords: Last Planner System, production control, implementation

1. Introduction

During the last few years, Last Planner has been implemented systematically in a number of contracting companies in different countries. The results have been most encouraging in regard to productivity, duration and safety. The Last Planner method represents a radically different manner of controlling production in construction. Even if its benefits are widely observed, it is also a common observation that the introduction of the Last Planner method to a site, into a company or into a country is not an easy and uncomplicated task.

The authors undertook to implement and disseminate this method in Finland since 2003. The goal of this paper is to report of the experiences gained.

The paper is structured as follows. First, the salient characteristics of Last Planner are recapitulated. Then, the first Finnish pilot project is presented, and after that, the learning gained in the subsequent projects. Then, the Finnish manual on Last Planner is briefly described. Next, the simplified explanation of Last Planner is discussed. After considering the present status and prospects of Last Planner in Finland, the concluding remarks are presented.

2. The Last Planner System of Production Control

Last Planner, developed in the United States in the 1990's [1] [2] [3] is a method for production planning and control on construction sites. Last Planner addresses short term planning and control of operations. The goal is to ensure, through different procedures and tools, that all the preconditions of a task exist when it is started, that the task can be executed without disturbances, and that it is completed according to the plan. The share of tasks completed as planned is monitored on a weekly basis. The reasons for lack of completion are investigated. By influencing the reasons found, an increase of the degree of realization of weekly plans is sought. One further element of the Last Planner method is rolling look-ahead planning, in which the preconditions for tasks are made ready for the next 4-6 weeks. The goal is to maintain a sufficient backlog of ready tasks.

Last Planner production control is based on a new theoretical foundation [7]. Production is conceptualized as flow, leading to an emphasis on reduction of uncertainty and on stemming the penalties of uncertainty. The primary concern of weekly planning is not merely, which tasks should be started according to higher-level plans, but also, which tasks can be started regarding their preconditions. The execution of weekly plans is seen to be based on a conversation, where the responsible person commits himself to the completion of a task as planned. Control is positioned as a starting-point for continuous improvement.

3. The First Pilot Project

The first Finnish pilot project in introducing Last Planner took place in the year 2003. Four major construction companies, YIT Rakennus Oy, Skanska Talonrakennus Oy, NCC Rakennus Oy and Rakennusosakeyhtiö Hartela, each with one project and site took part in the training and testing project. Testing and training lasted for six months on each site.

How did the project go ahead? A detailed theoretical explanation was prepared and it was initially used in training. However, a simplified way of explaining and justifying the Last Planner method for construction professionals was also developed and it turned out to be more effective in training. The training time could be reduced, and justification of the method to managers was made easier.

Training started with a one day teaching and discussion session. About twenty persons involved in site management took part in learning the basic principles of Last Planner and discussing the practices which were to be tested. We also wanted to learn what were the major reasons for difficulties of production planning by making the participants to choose among the following reasons:

- Managing concentrates in control (monitoring) and forgets “making ready” the pre-requisites and resources required to do the work.

- Planning isn’t systematic, but instead it depends only on the ability, skills and motivation of the managers in charge.
- Planning is considered to be same as drawing a schedule.
- The capability of the planning system is not measured.
- When targets and plans are not met, the reasons are not sought and analyzed.

All of the possible answers above were chosen. This shows clearly that the problems of production planning are wide. Solving them requires understanding of the theories, too. In this regard, our one day of training was just a start.

In our site testing we concentrated in

- Making weekly plans, where tasks don’t have any constraints and the pre-requisites are taken care of.
- Getting participants to make commitments in the weekly plans.
- Checking the PPC (percent plan complete).
- Arising interest and starting systematic look-ahead planning, where the pre-requisites for the tasks to be done in the next couple of weeks are realised.
- Finding the reasons and explanations why the weekly goals were not met and also trying to learn from the past to prevent similar difficulties recurring in the future.

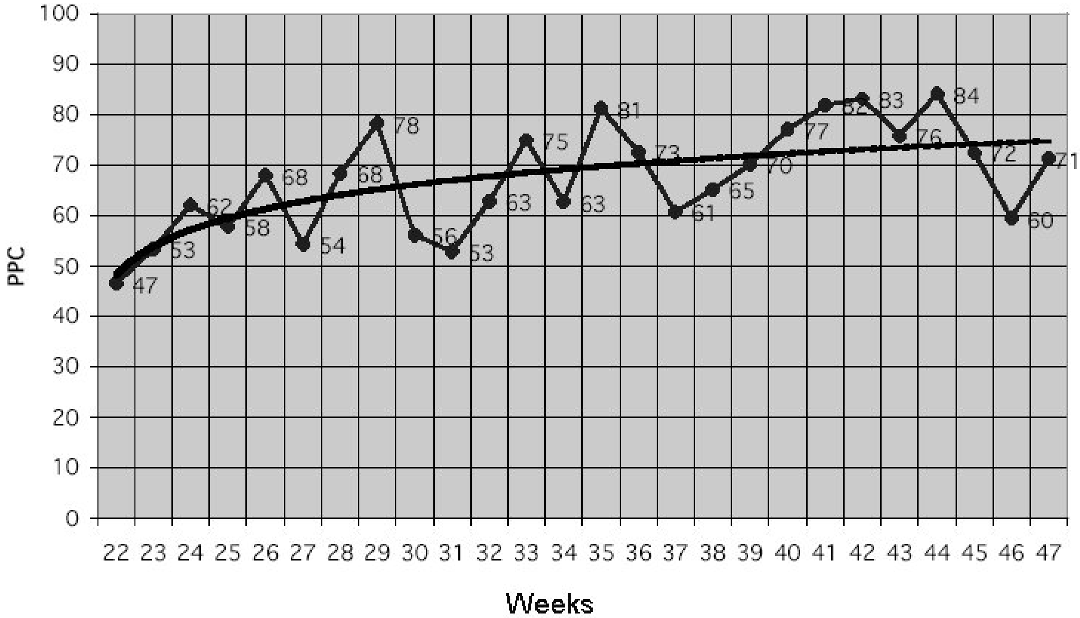

Figure 1. The development of the PPC as an average on all four test construction sites in Finland [8].

The results of the introduction of Last Planner on four domestic construction sites are parallel to those abroad. The PPC got better rising from the average of 47 % to over 80 % before our second day of teaching (Figure 1). After having a day of feedback and benchmarking the intensity of planning and following the Last Planner method probably somewhat dropped.

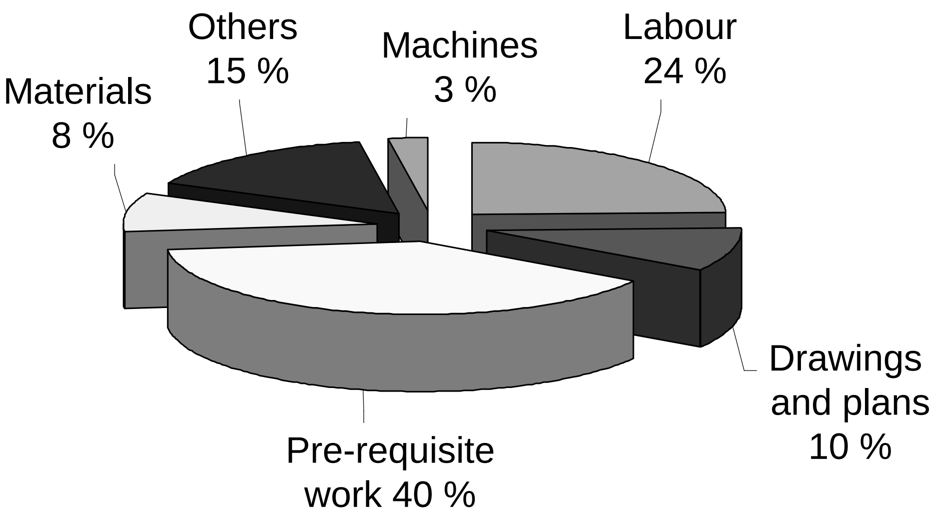

Figure 2 The reasons for non-completion of tasks in weekly plans in the Finnish experiment [8].

The reasons for non-completion of weekly tasks were not those expected. The two biggest groups of reason were pre-requisite work and the labour (See Figure 2). Our test showed that maybe too easily we are looking someone from the outside to blame. Drawings and plans are often said to be the reason for delays and changes. In our test only ten percent of weekly plan failures were due to drawings and plans.

The quality and degree of realization of weekly plans clearly increased. The site personnel considered the method useful especially regarding that the quality level of task ready-making increased and that getting tasks completed in one pass became easier. The quality and quantity of tasks could be controlled, when tasks were clearly defined. This made it easy to measure the productivity of a particular task and its variation. The amount of ad hoc work decreased. The weekly planning sessions made coordination between tasks, workgroups and contractors easier. Also, having reasons for lack of task completion was experienced useful, and it was seen to contribute to the elimination of problems.

Taking the positive results of the experimentation and the foreign cases into account, the implementation of the Last Planner method was recommended in short term production control on construction sites in Finland.

4. Subsequent Pilot Projects

After the first experiment and the report [8] written about it, interest to Last Planner arose among the construction firms. Similar experiments as in the pilot project were conducted in a couple of firms. Some firms made experiments on their own. In the following, related observations and findings are presented.

Phase planning was tested in a middle-sized reconstruction firm. They wanted to get the HVAC-contractors to make commitment to a tight schedule. This was established by making the participants and performers to know each other and collaborate in dividing the building in to parts which can be the basis for phase planning. After that schedules were made in co-operation and committing to one another. A tight four month plan was made to be the basis. Even a great number of changes, as in reconstruction so often, didn’t mess up the phase plan because the promises and commitments were so clear and the tasks due to changes were fitted in with the motivation of keeping the due dates.

The problem with planning ahead seems often to be caused by a failure to plan ahead. Very often the tasks just seem to come from nowhere and we have to start them without all necessary prerequisites. This produces problems in quality, safety and productivity. Although for some managers in Finland it seems to be hard to believe that it is more efficient to wait and make things ready than to just go ahead, lookahead – planning became reality in several projects when a simple worksheet was taken into use (see Figure 3).

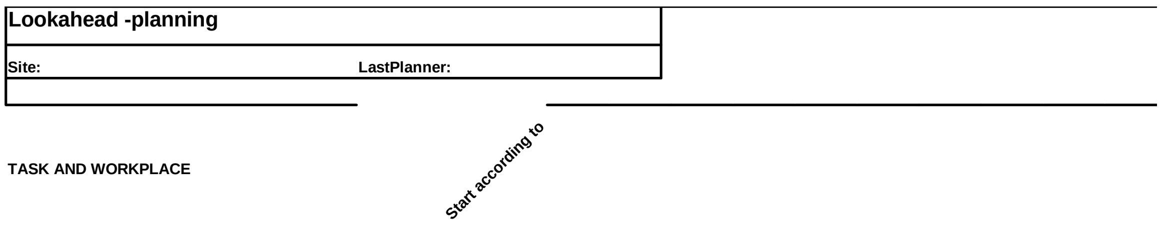

Figure 3. Lookahead –planning spreadsheet on one Finnish construction site.

A belief in the almighty power of the master schedule sits very tightly in the Finnish construction. Master schedules are mainly produced by special scheduling programs on computers. Maybe the colourful, nice looking schedules seem to be something to trust in. In one reconstruction project there were more than 1400 master schedule tasks. So many tasks but very little actual information on task contents, people who are to do the work, with what equipment and even less on commitments. The reality in this project was that the master schedule was of no use.

One key instrument on Finnish construction sites is task planning. It is a systematic way to plan one task from all the production aspects. For example time, cost, quality, safety and pre-requisites are taken into account. Tasks are prepared as whole from beginning to end. Still there is the continuous need for look-ahead planning.

The success in planning and controlling production comes from reliable commitments to the client, phase planning done together, task planning by each subcontractor, rolling lookahead planning and weekly plans into which participants have committed (Figure 4).

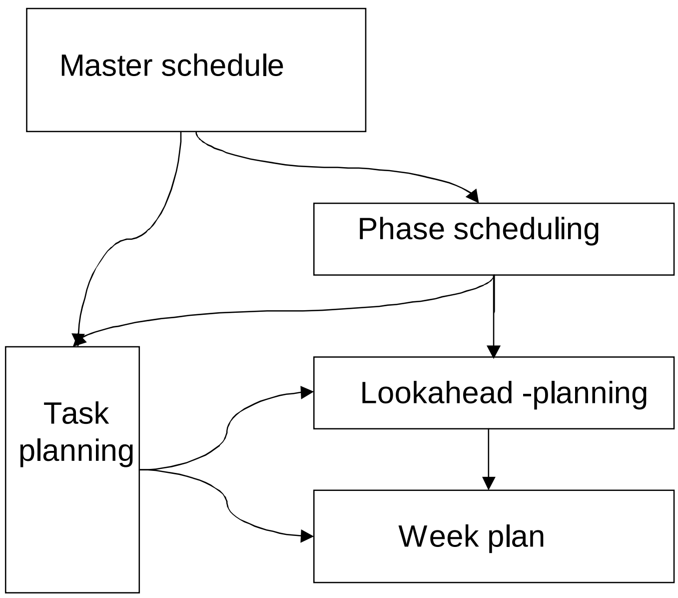

Figure 4. Overall picture of the Last Planner stimulated production planning and control, which is being implemented at the moment in Finland [8].

In view of the first, successful pilot project, the Confederation of Finnish Construction Industries organized a project for creating a manual of Last Planner, to be used both in company training and college and university education. The outline of the resulting manual [9] is presented in Table 1.

Table 1.The outline of the Finnish Last Planner manual.

Introduction
Guideline for using and reading this manual
Last Planner production control: why and what?
What is the goal of LP?
The totality of the LP production control
Methods and practices of LP production control
Phase planning
    Why? Basic procedure
    Advanced practice
    Examples and observations
Look ahead planning (this heading and all below in this section have the same subtitles as above)
Weekly planning: making ready
Weekly planning: conversation and commitment
Weekly planning: checking task completion
Weekly planning: finding reasons for non-completions
Continuous improvement
Introduction of the Last Planner production control
Implementation on site when LP is new for all parties
Implementation in a company
Training effort needed
Information technology as a support to LP
Interfacing Last Planner to existing production control system of the company
Higher level plans
Task planning
Further information
References, links etc.

In the manual, the method is structured into seven parts, and the rationale, basic procedure, advanced practice as well as related examples and observations for each part, connected to the overall explanation of the method, are presented. Also the implementation issues are discussed.

5. Explaining Last Planner

In the introduction of Last Planner, there are two challenging moments of explanation and persuasion. First, the method must be sold to the management of the contracting company, so that pilot test can be launched. Second, the method must be explained to the site personnel participating in the pilot test. To some extent, the method can be sold referring to good results abroad. However, inevitably the question emerges: Why is Last Planner more effective than the conventional method? Thus the problem is as follows: How can Last Planner be shortly explained in a plausible way to an experienced professional of site construction? The authors came to think that the explanation must be anchored in the everyday experiences of these professionals.

The observations of Jaafari [5] on productivity in a construction task were taken as a starting point:

> While the size of samples is not large enough to yield conclusive results, the general pattern remained similar. Productivity showed a gradual build-up at the start (often associated with unavailability of specific tools or materials at the time required, or lack of foreman instruction, or absence of key craftsmen). Steady progress in productivity continued unless interrupted externally, then followed by unexplained drag at the end, or often unfinished 10-15 % for a variety of reasons such as urgent start elsewhere, technical problems, or breakdown of tools.

Indeed, for every person experienced in site construction, it is evident that there are problems related to *starting a task*. After they have been solved, new problems *during the task* emerge. And finally, there are problems related to *completing the task*. However, these problems are assumed away in task planning, where a constant productivity is usually assumed (Fig. 5). This is reinforced by the habit of representing tasks as neat, well-defined rectangular boxes. However, if we consider productivity (or output), tasks cannot be considered as rectangular boxes – rather, the productivity increases slowly to its maximum, decreases through interruptions and typically there is a tail end to be completed later, often just before handover (Fig. 6).

In view of this, the simplified explanation[2] of Last Planner is as follows: *The Last Planner System endeavors to recreate the neat rectangular form of a task output, starting sharply,, reaching the sustainable and stable output level immediately, maintaining it to the end, and thus finishing the task as planned, without any tail end.* For so doing, Last Planner utilizes its seven features, the contributions of which can be allocated to the solution of these three problems (Fig. 7).

[2] Note that this explanation is parallel to the argument that Last Planner is primarily addressing the waste of *making-do* [7] but avoids the use of difficult operations management terminology.

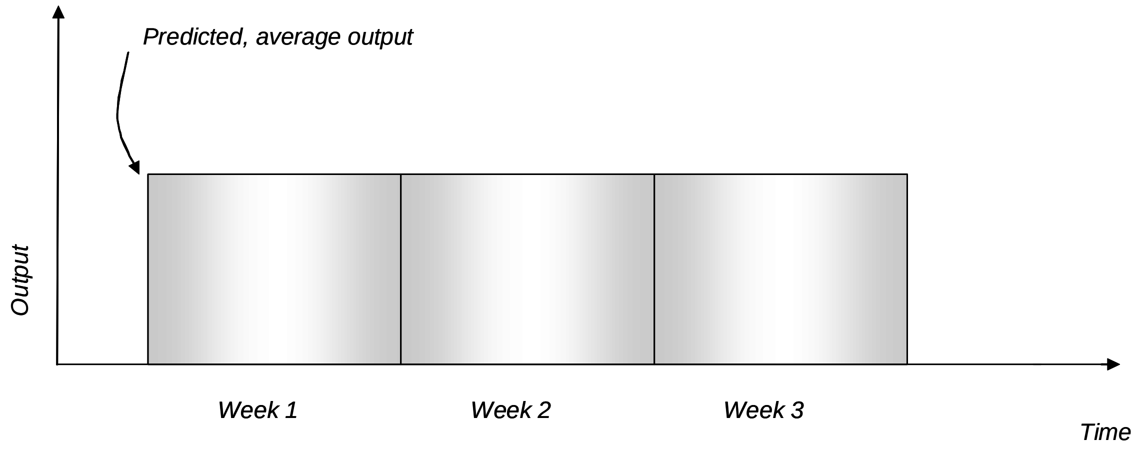

Figure 5.Task output as assumed.

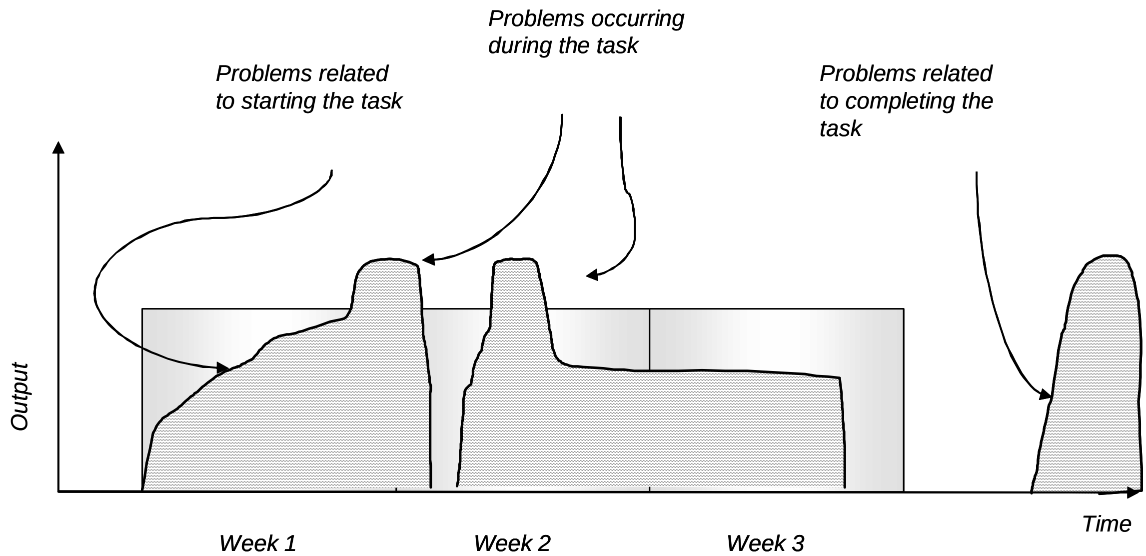

Figure 6. Task output in reality (illustrative example).

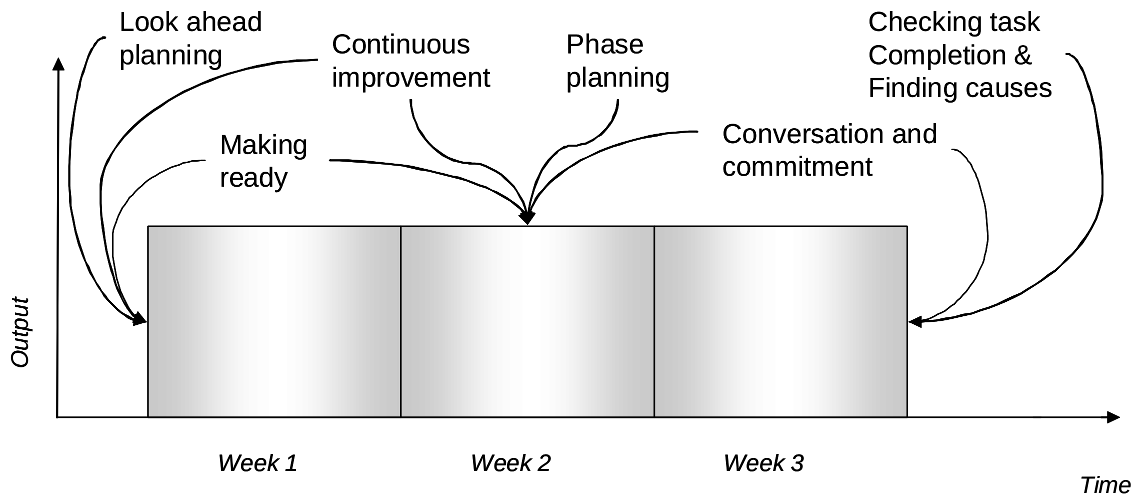

Figure. 7. Using the features of Last Planner for ensuring a sharp start, constant uninterrupted progress and planned completion of the task (only the primary mechanisms indicated).

The problems related to starting a task are addressed in three ways. In *lookahead planning*, there is a focused effort towards eliminating constraints for starting tasks: prerequisites are pulled (rather than pushed). Secondly, the *ready making* function ensures that only tasks with all prerequisites available are actually started. Thirdly, *continuous improvement* will for its part contribute to the reduction of starting problems on longer term.

Regarding problems during the task, there are three mechanisms. First, *phase planning*, carried out in collaboration between different teams and subcontractors, ensures that the best order of tasks is determined, and thus the risk of unforeseen interference between tasks is diminished. Second, *ready making* is focused on weekly tasks, and thus the prerequisites of longer tasks are checked weekly, rather than only at the start of the task. Third, all the weekly tasks are covered in the weekly planning (*conversation and commitment*), and thus in principle there should not be unplanned tasks emerging during the week, causing interruption or interference to planned tasks. However, in practice, there often is unplanned work to be carried out, but as plan reliability progressively increases along with use of the Last Planner, its amount will decrease.

When it comes to problems related to completing the task, first, all features mentioned above in relation to the two first problems help to avoid these completion problems. For example, a problem related to starting (say, shortage of materials) or a problem emerging during the task (say, necessity to move the gang temporarily to another work) may halt the task for the rest of the week. Second, task completion is specifically addressed by the planning conversation resulting in *commitment* to realize tasks as planned. Thirdly, *checking of task completion* as well as *finding reasons for non-completions* emphasize the need to realize and complete tasks as planned.

Next, the benefits of Last Planner can be explained. The elimination or at least alleviation of these three problems leads to direct benefits in terms of productivity, safety, quality and duration:

- Productivity. Each task can be sharply started, when all prerequisites are at hand. Interruptions and interferences are minimized. There are fewer tail ends, requiring a revisit by the gang.

- Safety. In comparison to the prior situation, a bigger share of tasks can be carried out as planned (including safety issues) and within regular conditions.

- Quality. A bigger share of tasks can be carried out as planned, in regular conditions, in one pass.

- Duration. Plan predictability increases along with the elimination and alleviation of the mentioned three problems. Thus, the time buffer between consecutive tasks can be shortened, with leads to a shorter total duration.

6. The Present Status and Prospects of Last Planner in Finland

At the moment, Last Planner seems to have firmly settled down in Finland. It is used by several individual construction managers, and there are pilot projects underway in two major contracting companies. There is training and facilitation available to companies through a Last Planner trainer certified by the Lean Construction Institute. There is a manual for Last Planner, published by the Confederation of Finnish Construction Industries.

However, it would be wrong to assume that the production planning paradigm has already changed in the country. The diffusion has been more bottom-up than in other countries – there has not yet been a locomotive company implementing Last Planner systematically and widely in its activities. Likewise, the curricula in universities and technical colleges tend to stress the conventional production planning mode, even if Last Planner has been point wise introduced.

One explanation to the inertia observed is that many key professionals seem to passionately subscribe to the conventional production control methodology. For them, the rejection of the master schedule as the primary tool for controlling a project is not something that could be accepted easily. Also, the temptation of automating the preparation and monitoring of the master schedule through IT tools has been irresistible to many.

7. Conclusions

The Finnish experiences on the introduction of Last Planner are to a great part similar to those gained in other countries, but to a certain degree there are novel emphases. There is similarity especially in the observation that Last Planner is a powerful method, which has already been demonstrated in pilot implementations and provides clear benefits (compare [4]). Other significant observations, some novel, others adding to prior evidence, emerging in the framework of Finnish experiences include the following:

- *Theory-based approach*. A simplified way of explaining and justifying the Last Planner method for construction professionals was developed. The training time could be reduced, and justification of the method to managers was made easier. Also, the introduction of the Last Planner into the national educational and training system seems to require that a detailed theoretical justification, especially in comparison to the traditional way of production control, can be presented.

- *Incremental introduction*. The method was structured into seven parts, and a logical order for their progressive introduction on site was developed. A rationale for each part, connected to the overall explanation of the method, was developed.

- *Need-based facilitation*. A method of facilitation emerged where the intensity of facilitation progressively decreases according to the advances and learning made on site.

- *User acceptability*. The user acceptability of the method emerged as a critical feature. The users of the method must themselves realize the superiority of the new method, if a successful implementation is targeted.

- *Contextual tailoring*. The method has been tailored in operational details to match the existing production control methodology of the company.

Case Studies of Using Flowline for Production Planning and Control

Abstract

Flowline, or Line-of-Balance, has recently gained attention in Lean Construction literature because of its capacity for facilitating control of production flow and planning of continuous work. In the broader technical literature, previous work has concentrated on the analytic properties of flowline, such as learning curves, and is generally silent on how the method should be used to improve productivity. This is because internationally the technique has received relatively little application. However, in Finland, flowline has been used as the principal scheduling method since 1980s.

This paper takes a practical approach and describes the use of flowline based planning and control in two real case projects. One of the projects is a large residential construction project in Sydney, Australia. The other project is a Finnish retail park construction project. These pilot projects were done at the same time and the projects were able to learn from the experiences of the other. The cases highlight the differences between the Finnish way of planning a schedule with buffers between activities with synchronized production rates and the Australian way of driving a schedule with a tightly constrained CPM schedule.

A methodology using flowline as a visual planning tool but using familiar CPM logic as the underlying engine was appropriate in the Australian case. In this methodology the objective is to improve site control by including information about location and to be able to plan continuous work for subcontractors and to visualize the effects of planning decisions. The result is much clearer communication to the trade contractors about the timing and location of their work, improved control systems and better work flow. The Finnish project team was already familiar with the basic use of flowline so the more advanced risk management based approach was used. The risk management based approach includes using quantities estimated by location as the starting point and optimizes the crews so that the risk of schedule disturbances is minimized. The planning happens on two levels: the master schedule has less detail and the task plans are detailed plans of individual tasks which are done by persons responsible for the work when all the necessary information about implementation is available. The results from the Finnish case include a methodology for effectively controlling production flow and how to include the subcontractors in the process.

Comparison of the two different strategies reveals important knowledge about the role of custom in scheduling, and reveals potential barriers to adopting innovative approaches.

Keywords: Flowline, line of balance, scheduling, implementation

1. Introduction

1.1 Flowline and its Applications

There are two main methodologies for scheduling work: activity-based scheduling and location-based scheduling. These two methodologies in turn have many methods and techniques, often designed to achieve the same purposes in different ways [1].

The dominant scheduling technique is activity-based scheduling and it was first developed in the 1950s [2]. The technique relies on the construction of a logical network of activities in three visual forms; activity on the arrow, activity on the node and logical dependency constraints [3], with four levels of complexity; deterministic (for example: CPM), probabilistic (for example PERT) generalized activity networks [3] and arguably the more recent critical-chain method [4].

A familiar to many, but relatively little used, alternative scheduling technique is that of location-based scheduling, more frequently known as repetitive scheduling. Originally developed by the Good Year Company in the 1940s and expanded by the US Navy in the 1950s [5], the suite of techniques has found strong support in continuous production systems (more typical in engineering construction) but only limited support in commercial construction. Finland is a notable exception to this, as the technique is the dominant method in the Finnish construction industry. Harris & Ioannou [6] summarize the various names (and sources) given to the variations in the method, including 'Line-of-balance', 'Construction planning technique', 'Vertical Production Method', 'Time-Location Matrix model', 'Time Space Scheduling method', 'Disturbance scheduling' and 'Horizontal and vertical logic scheduling for multistory projects'. Interestingly they do not identify perhaps the most evocative term, that of 'Flow-Line' [7]. Harris & Ioannou [6] also identify the terms used in engineering construction such as highways, pipelines and tunnels, as 'Time versus distance diagrams' (TD charts), 'Linear balance charts', 'Velocity diagrams' and 'Linear scheduling'. [8] also identify 'Horizontal and vertical scheduling', and 'Multiple repetitive construction process'–but aims these at the specific case of vertical replication repeated in multiple buildings.

All these methods involve repetitive activities and for this Harris and Ioannou suggest a new generic term 'Repetitive scheduling method (RSM)'. However the methods also strongly suggest location or place, and thus the use of the term 'Location-based scheduling' proposed by Kenley [1].

1.2 Background

Activity-based scheduling dominates most of the world's construction industries. This is certainly the case in the Australian industrial context. Little needs to be said to describe the common methods for planning projects, as they will be familiar to most. Essentially they are driven by software such as Primavera (the most commonly used package), Microsoft Project and equivalent CPM tools.

The education system in Australia generated students with a deep understanding of the underlying mechanisms of CPM planning until the mid 1980s. These students were also generally exposed to alternative manual methods such as Flowline [7]. Students of Walter Mohr [7] were more exposed than many. The advent of powerful software on micro-computers subsequently lead to a reliance on packages for the teaching of planning. It is fair to say that nowadays, construction management courses teach the use of software, paying only a cursory interest in the underlying principles and methods. A consequence of this is a lowering of planning skills, except in the use of software, and a reliance on common approaches. Accordingly, it would be extremely rare to see application of location-based scheduling in Australia, indeed few people would have the skills to understand the method.

Furthermore, location-based scheduling is best driven by location-based measurement (BOQ). The standard method of measurement in the Australian industry does not allow for location-based measurement. The industry has also substantially moved away from measurement of commercial building projects, particularly those procured using Design and Construct methods, and many commercial contractors simply do not have adequate measurements to support location-based techniques properly.

In contrast, location-based planning methods have been used widely in Finnish construction since the 1980s. The methods were brought to Finland and adapted to commercial construction by professors Kankainen and Kiiras from Helsinki University of Technology [9], [10]. In research tests it was established that the use of modified flowline planning increased productivity and decreased waiting hours for own workers and for subcontractors [11].

Finland suffered from severe economic recession during 1990s during which many construction companies went bankrupt and the value of real estate plummeted. During the recession, training of construction management professionals and construction engineers practically stopped because jobs were not available. This has resulted in a lack of skilled engineers in the field when the economy began to recover. During the recession the flowline scheduling skills were forgotten and the industry reverted back to using gantt charts which could be easily drawn by using computers. The only available flowline software was a drawing tool and wasn't suitable for complex planning.

New research efforts to improve the scheduling skills of the industry were started at the end of 1990s by professor Kankainen's research group. The results included tools such as task planning [12], project control charts, checklists to assess schedule's feasibility [11] and new contracts to support location-based control. The research results were used in a software development project to design a new software able to be used as a planning and control tool. The features of the software DynaProject™ have been described [13].

Because of popularity of the location-based graphical methods, Finnish construction companies had never really adopted CPM –based methods. Activities which are linked by precedence logic are rare in Finnish schedules. The schedule is used as a visual planning tool and the planners check for logic errors by examining lines which cross in the flowline diagram.

It is clear, therefore, that a comparison between the Australian industry and the Finnish industry, the methods and practices of planning, would cast valuable light on the culture of planning in both countries. In this paper, the experience of planning using location-based scheduling techniques on a specific project case study from each country is discussed; allowing comparisons to be made and conclusions drawn about the differences in the culture of planning in each country.

2. Case 1: Residential Construction Project in Sydney

2.1 Description of the Project

Victoria Park stage 302 is a residential complex in inner Sydney. It comprises four residential towers of varying heights, joined through a common podium. The largest tower was fifteen floors, the next nine, then eight and four. There were approximately 300 apartments in total. The schedule was from May 2004 to June 2005.

2.2 Available Starting Data

Walter Construction Group was totally new to flowline based production control systems. All their systems revolved around CPM and Primavera. As this was a trial to develop more efficient management systems, both CPM schedules and flowline schedules were developed.

There was no quantity take-off done corresponding to the physical locations of the building. Nor was there any available database of production rates. This is common within the Australian industry, where sub-contract packages are generally allocated a number of days of work for each task, in precedence logic, and no attempt is made to ensure continuity of work flow.

2.3 Scheduling Process

Because of the poor starting data, it was difficult to schedule the project using location-based methods. It was necessary to take the CPM schedule and artificially apply it to a location-based methodology. This presented the first significant barrier to implementation: the automatic systems designed into the software could not be used and the inability to use quantities and productivity data exposed the shortcomings of CPM only systems which are not sensitive to designed productivity changes.

The CPM schedule was never fully completed due to the complexity and scale of the projects. Therefore, the CPM schedule calculated a typical floor in detail, then replicated this for each floor. This is understandable, as with 300 apartments and with approximately 50 activities to schedule, it would be necessary to schedule around 15,000 activities. In contrast, the location-based methodology required only 50 activities, with the approximation of quantity in each of 300 locations. A simple trick was employed to achieve this: The unit of quantity measured was a standard shift, with the number of days of work being the actual measurement. This rough approximation allowed reproduction of the CPM schedule, but exposed the problem of manipulating the productivity to improve the schedule (and indeed the problem of a culture of fixed durations existent within the industry – a topic for future research).

One important lesson is that this sort of power leads to extremely rich and complex schedules. The loss of dominance of the critical path, replaced by dominance of work-flow, results in project models with large quantities of information – all very powerful for managing the project. To illustrate the complexity, a small section of the finishes schedule for one part of one building is displayed in figure 1.

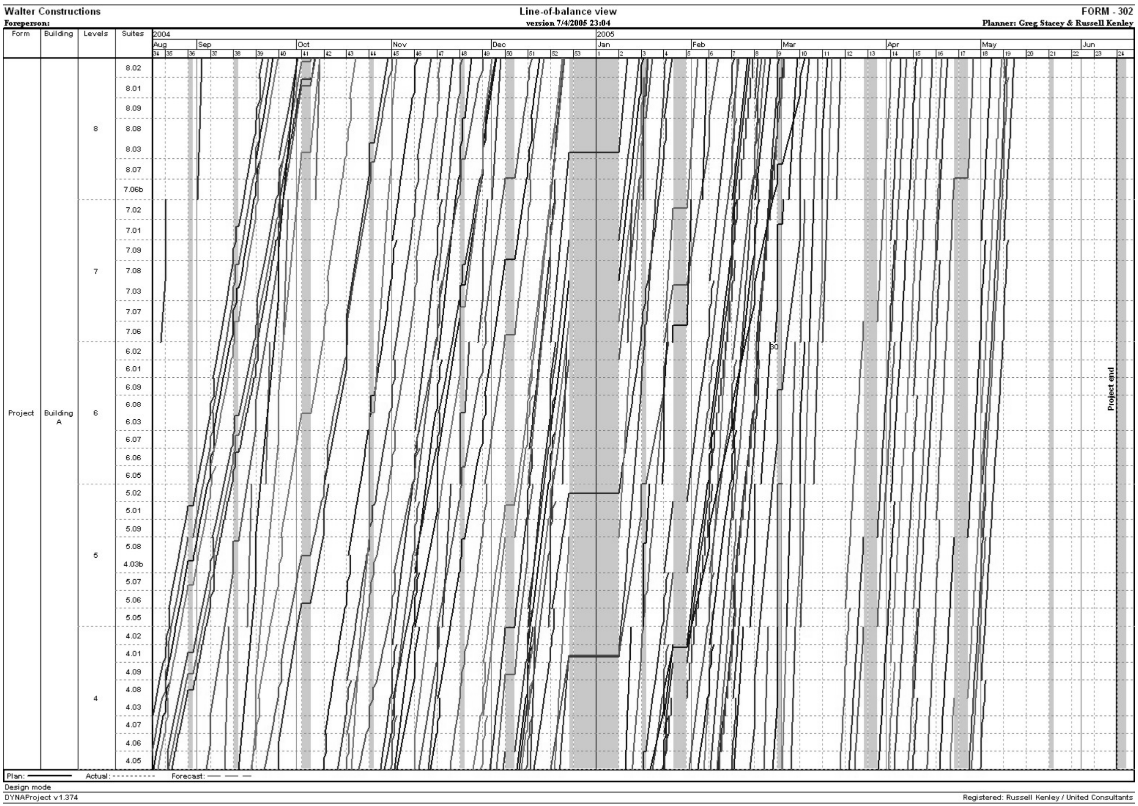

Figure 1: Section of finishes schedule for Victoria Park.

The initial schedule resulted in a duration far in excess of the required duration. In order to simulate alteration of work-crew productivity (the normal method), activities were resourced with work-crews with $1/10^{th}$ productivity – and a base multiple of 10 units. Thus 20 units would double productivity and 5 would halve the productivity.

After manipulation, a schedule was developed which conformed to the duration requirements, but which ensured that each work-crew was able to work continuously, without interruption, from start to end of the project. In the words of one site manager on a later project, "Do you mean to say that we can not only finish on time, but also have continuous work?"

In contrast to the finnish methods described below, the contractor wanted to continue their use of scheduling in extreme detail. This may be termed micro-management [1] and scheduling to such detail was considered most unusual by our Finnish colleagues. Their risk management approach results in less detail and simpler schedules. The detailed approach dictated by a CPM culture results in much more detailed schedules, more complex models but powerful management tools when used correctly.

2.4 Control Process

The project schedule was completed prior to commencement of the finishes work on-site. The planned control process was to work with the sub-contractors to ensure their productivity rates matched with the plan. Once this was done, each work-crew would be able to work continuously, systematically and without interruption – this greatly enhancing their financial performance and that of the project.

The reality was very different. A competing process was being employed on the project in the design stage and unfortunately spilled over into the site-work phase. This process, called *Project Blue* [14] involved intensive focus on team work and integration – very valuable aims. However, the methodology for site work was strictly CPM – and followed the original CPM planning method. A typical floor was worked out according to the original plan and trades were told to "pass work on" to following trades. Unfortunately, this method fails due to the conflict between a typical floor schedule and the need to flow resources through multiple floors and buildings. The result was largely chaos, work out of sequence and a loss of control. Such performance was largely accepted however, because this is unfortunately normal practice on any Australian project.

The result of this conflict is that the location-based control system was never implemented. The company subsequently reviewed the project and determined that on future projects the method would be implemented rigorously and not be sabotaged. A special project team was initiated to follow this through.

Unfortunately, it must be reported that, due to the failure of the German parent company, Walter Construction Group failed in February 2005 and this implementation project has now stopped.

2.5 Lessons

This project highlighted that CPM scheduling done in the traditional way presents major problems for site management which are generally managed by the site staff though working out of sequence, discontinuous work and work interruptions.

In contrast, a location-based approach such as flowline has the capacity to deliver more efficient site work. However, successful implementation requires significant cultural change before it can be successful. Even with senior management support, the project management team must support the innovation.

3. Case 2: Business Park Project in Helsinki

3.1 Description of the Project

Opus business park is a 14 500 m2 office building in eastern Helsinki. It is composed of two sections, which can be built independently of each other and of parking hall below the main building. Both sections have six floors. The total schedule is from August 2004 to December 2005.

3.2 Available Starting Data

NCC Construction has devoted a lot of resources to implement flowline based production control systems [15]. The quantity take-off is done corresponding to the physical locations of the building. In this example, all the quantities had been distributed to sections and floors so that they could be directly utilized in flowline planning. Labour consumption information has also been standardized within the company allowing for a very fast planning of first drafts of the schedule. Also the building services quantities are estimated based on project characteristics and size. The productivity and quantity databases include information about subcontracted work. The main principle is that subcontracted work should be planned as if it were done with own resources because otherwise effective control is impossible.

3.3 Scheduling Process

Because of good starting data, it was possible to create many different alternative schedules in a short period of time. Two main alternatives were examined:

- Completely continuous schedule
- Work continuous in sections but a break between two sections

Completely continuous schedule would have had the same end date as partially continuous schedule but both sections would have been finished at approximately the same time. Partially continuous schedule achieved much of the same benefit but enabled the first section to be finished earlier thus reducing the risk of exceeding the total duration. The project team decided to implement the partially continuous alternative and take the break between sections into account in contracts with subcontractors.

It was not possible to change the sequence of sections because the parking hall had to be handed over before the second section could be started. This was because the second section was used as a temporary parking lot for customers of the neighboring supermarket. If the second section could have been built first, the project duration would have decreased by one month.

In the final schedule the production rates have been synchronized and a buffer has been planned between the most important activities. All task durations are based on quantities, resources and productivity data from earlier projects or from Finnish productivity database, which has been created as a joint effort of the industry [16]. The final master schedule is shown in figure 2 (only the space-critical activities shown).

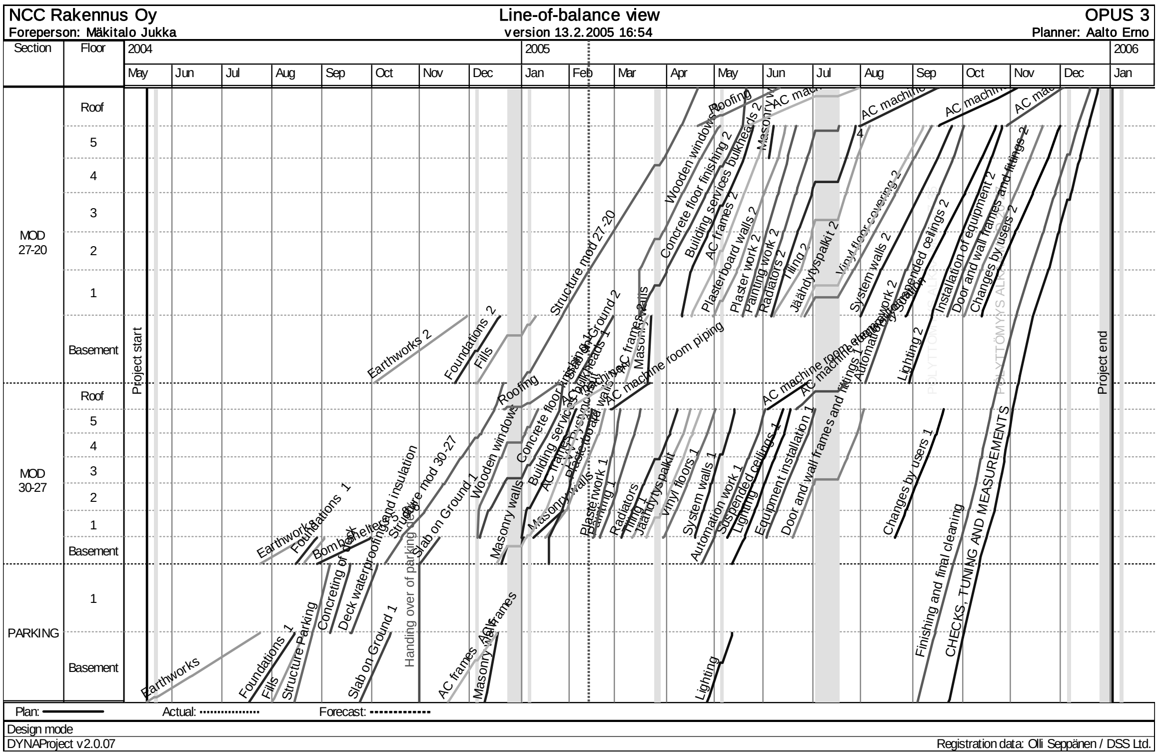

Figure 2: Master schedule of OPUS project – only the space-critical activities are shown

3.4 Weekly Control Process

The weekly control process was based on task planning method [17]. The schedule of upcoming master schedule tasks was exploded into more accurate level and the quantities were updated. This process started in the beginning of the project so by planning just one task accurately each week it was possible to always be well ahead of production. While the master schedule looks at production flow at "macro" level, the task schedules schedule continuous work for each worker and assure that the same worker won't be in two locations at the same time. Task schedules are constrained by the master schedule so that task schedule must finish all subactivities in a location before the next master schedule task begins in that location. Task schedules are updated weekly to always correspond with the current situation but the master schedule is never updated. This is because updating the master schedule has been shown to fool the site management into false sense of safety. In reality updating the schedule shifts the problems towards the end of project and leads to hurry in the end of project [11].

Every week on Tuesday, the actuals from the last week were compared with the weekly assignments derived from all of the task schedules. The data was collected from site by using the control chart, a matrix of locations and tasks which shows with color codes the status of each location [13]. The reliability of task plans was measured by calculating the percentage of planned assignments completed (PPC) during the week. This measure is the same as in the Last Planner™ system of production control (e.g. [18]) but the assignments are the result of flowline-based task planning process.

All existing task schedules were updated next to take changed circumstances and actual production into account. Actual production rates were used in task schedule updates to make schedules more accurate and to show increased resource needs. The master schedule sets the boundaries for planning so the problems couldn't be pushed farther than the end of master schedule task in a location. All the updating was done using best possible information. The aim was to make best possible forecasts for the rest of the task while preserving continuous production for as many workers as possible. Most effort was expended on updating the next week's plan because the next week's task schedules were commitments by the planners.

If there was sufficient information on a master schedule task which was about to begin in the next few weeks, new task schedule was planned. The first draft of the task schedule used accurate quantities taken from current drawings and estimated production rates. It was planned by the site engineer. Before beginning of production, the task schedule went through multiple rounds of comments by the subcontractor, the superintendent and procurement people.

After updating the task schedules the status of master schedule was evaluated based on computer-calculated forecasts. [19] If the delay of a task endangered the continuous flow of another task, control actions were planned by updating the task schedules to minimize the risk of interference. Actual situation and resource availability of the subcontractor as well as the cost effects of acceleration were evaluated to arrive at the best solution. If interference couldn't be avoided, task planning was used to estimate the optimal time to continue production for the disturbed trade.

The resulting set of task schedules were up-to-date, took into account the availability of resources and were based on actual circumstances. From these task schedules the production objectives for the next week were established. These objectives were communicated to the subcontractors and superintendents. Their success was evaluated in the next Tuesday's schedule update by calculating the PPC.

This weekly control process took two to four hours time from the project engineer and one of the authors (OS). In addition, the project engineer used time in communicating the plan, assessing the circumstances and getting the actual data from site.

3.5 Results

The project was still on way during the writing of this paper. The structure of the first section and the parking hall were finished and the interior works of the first section were on way. In spite of many deviations from the plan, the project was overall on schedule. Main problems included earthworks and structure. Structure had too tight a schedule in the master schedule, a fact taken into account in risk analysis. Because of the buffers between structure and interior work, the delay of structure didn’t have an impact on the interior works and their flow wasn’t disturbed. However, the structure of the second section started late because it was using the same tower crane. Control actions are needed in the immediate future, or there will be interference in the second section. Figure 3 shows actuals (dotted lines) and forecasts (dashed lines) on top of the original schedule (solid lines). Master schedule hasn’t been updated and can still be used to control production. The results indicate that the master schedule was on sufficiently rough level of detail that it could accurately forecast how the project would be carried out.

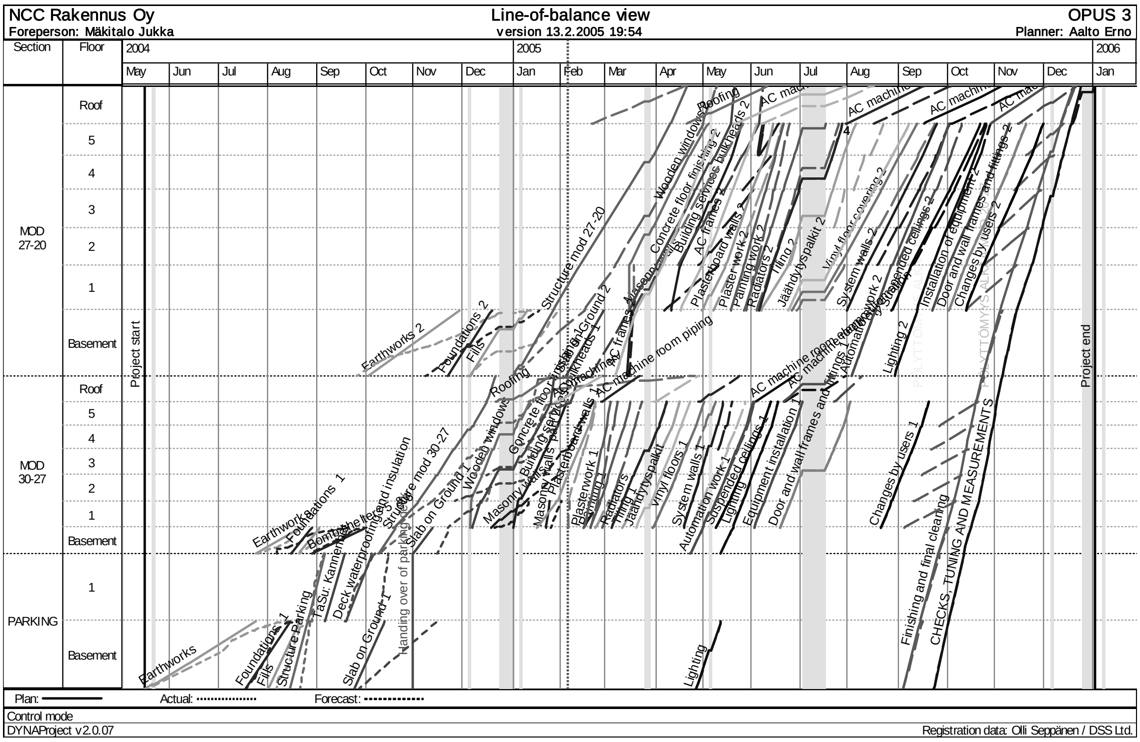

Figure 3: Master schedule of the Opus project planned lines (solid), actuals (dotted lines) and forecasts (dashed lines)

Systematic weekly control process improved the project team’s feeling of control. Measuring the percentage of weekly assignments completed (PPC) was found to motivate the team to take planning more seriously and to strive for best possible results. This showed in an increase of the PPC from 50 % level to near 80 % level during the initial stages of the project. Improvement in PPC correlated with the catch up of the schedule.

Combining task planning with master schedule based schedule forecasts worked well because if the site set too relaxed weekly targets, the master schedule forecasts alarmed that there will be problems in the future. If the site set too tight, unrealistic objectives, the PPC value plummeted. Catch up can be planned to be incremental by updating the task plans. By combining the systems, the site can set realistic objectives, commit to them and maintain control of the overall schedule.

4. Discussion

There are very significant cultural differences between the methods, despite the fact that the same software tool was being employed. Indeed, it was realised that neither group could really understand the schedules generated by the other.

The Australian planners, while they liked the idea of the risk management schedules and the rapid construction of schedules from quantities and templates, could not accept their validity in their context and insisted on their detailed CPM-like, micromanaged, flowline schedules. They didn't understand the concept of buffers, preferring instead a fixed lag (delay) between activities in the network.

The Finnish planners, in contrast, had never seen such large and complex models, and were fascinated by the complexity, but equally could not justify the approach, fearing that such precision and detail without buffers in time or location, would lead to problems in implementation.

This illustrates that the risk management approach and the CPM approach provide two completely different planning systems. Improving our understanding these differences, now identified, will be an important research project for the future.

5. Conclusion

Flowline, as a technique, and DYNAProject™ as a software tool, have demonstrated their capacity to be used in completely different ways according to the underlying planning culture. This project demonstrated that flowline can provide a powerful planning and control tool for projects, with two completely different methodologies available.

Abstract

The efficiency and the effectiveness of construction processes have previously often been discussed and criticised. Obviously the final goal of parties within a construction project is the completion of the project. However it is not necessarily a goal in itself to organise the process as fast and efficient as possible. Most practitioners in construction consider that ‘quality versus time versus cost’ is a zero sum game, and hence, whenever there is a choice among the three, usually quality is often the first to be sacrificed. The core of this problem lies within the classical project delivery methods not aiming to bring together the different interests of the value demanding and the value supplying parties, and not shielding the process against negative effects from outside the project. Most project delivery methods are set up in such a way that an increase of profit for one party often means a loss of profit for the other party.

The concept of dynamic control aims at bringing together the different interests of the value demanding and value supplying parties within the building process. It aims at the improvement of added value for demanding parties as well as profit levels of supplying parties, and thus the total benefit of built facilities, i.e. the sum of added value for clients and profits for suppliers. However contracting practices and procurement strategies need to support this positive mechanism and build-in positive incentives for parties to join in a collective effort to search for the optimal solution and overall benefit.

In this paper the concept of dynamic control is combined with alliance contracting principles and delivery method. It is argued that alliance contracting is a beneficial procurement strategy to achieve the goals of dynamic control, i.e. achievement of joint benefit through a collective process of progressive development of value and costs, and thus added value for demanding parties and profit for supplying parties. This results in a basic alliance framework for dynamic control and project delivery, illustrated with practical solutions and methods.

Keywords: Construction, dynamic control, incentives, procurement strategies, project alliance, supply chain.

1. Introduction

The efficiency and the effectiveness of construction processes have previously often been discussed and criticised. The characteristics of construction, such as fragmented demand and supply chains, the complexity of projects and long lead times are basic causes, often leading to cost and time overruns, delivery of less value than agreed, and dissatisfied clients and users [15].

The concept of dynamic control aims at bringing together the different interests of the value demanding and value supplying parties within the building process. It aims at the improvement of added value for demanding parties as well as profit levels of supplying parties, and thus the total benefit of built facilities, i.e. the sum of added value for clients and profits for suppliers. However contracting practices and procurement strategies need to support this positive mechanism and build-in positive incentives for parties to join in a collective effort to search for the optimal solution and overall benefit.

In this paper the concept of dynamic control [9, 10, 11, 12, 13, 14, 15] is combined with alliance contracting principles and delivery method. It is argued that alliance contracting is a beneficial procurement strategy to achieve the goals of dynamic control, i.e. achievement of joint benefit through a collective process of progressive development of value and costs, and thus added value for demanding parties and profit for supplying parties. This results in a basic alliance framework for dynamic control and project delivery, illustrated with practical solutions and methods. The illustrated solutions are derived from three cases that were examined in three MSc. theses delivered at Delft University of Technology [7, 20, 26].

2. Value Engineering and Value Management

Crum [8] defined value engineering as a disciplined procedure directed towards the achievement of necessary functions for minimum cost without detriment to quality, reliability, performance and delivery. Heller [17] defined it as a shift from finding the lowest cost way to produce the product finding the lowest cost way to perform the desired value.

Kelly and Male [19] observed value engineering as a subset of value management. Value management can be structured across the life cycle in three phases: value planning (definition, development), value engineering (design implementation) and value review (operation, end of asset) [23]. The process is integrated through systemic planning and feedback across the entire process. Through a value management and teamwork approach value criteria and benefits of all stakeholders must be assured in a lifecycle perspective. It is argued that the cost savings potential of value management decreases along the life cycle and must therefore be applied from the early phases of construction projects (i.e. design) [22].

Project delivery methods should therefore give room to value management in the earliest stages of the project. Not only by integrating the value demanding and supplying parties in the early phases of a project, but also by making both parties aim for the same goals in the project by raising the difference in interest. Only then will the different parties within a project work together on the same goals. This is the creation of as much as possible added value, within the set boundaries of cost and time.

3. Interests and Goals in Construction

The value demanding parties have different interests then the value supplying parties within a project. The value demanding parties' interest is to gain as much as possible added value (benefit) for the lowest price possible. The value supplying parties' interests on the other hand is to gain as much as possible profit (difference between price and costs) from the project (see figure 1).

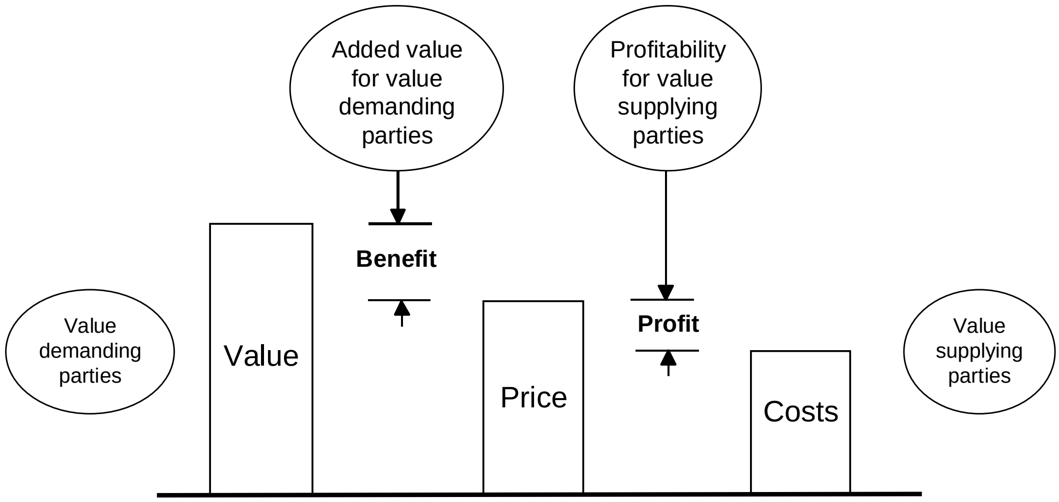

Figure 1: Goals of value demanding and supplying parties in construction projects [15].

The classical project delivery methods do not address this problem. Thus keeping the different parties having different interests within a project.

The interests of both parties have to be aligned to be able to form an integrated team that aims for the same goals. This means that the amount of profit of the value supplying parties has to depend on created added value that is delivered to the value demanding parties.

De Ridder and Vrijhoef [15] have proposed this idea also in their Value-Price-Cost leverage model for the integrated control of value, price and costs of construction projects. The ultimate objective of this idea is to optimize the total benefit of the built facilities through the lifecycle. This paper looks at how this idea is integrated into the project alliance delivery method.

4. Dynamic Control

Previously De Ridder [9, 10, 11, 12] has introduced the concept of dynamic control. The concept is based on the paradigm shift from a discrete process of fixed prices on fixed contract moments between the different phases in the life cycle (static control), towards a continuous process of establishing and monitoring the VPC balance through the life cycle, and acting in case of changing demands or circumstances (dynamic control). In short, dynamic control aims at the improvement of added value as well as profit levels, and thus the total benefit of built facilities, i.e. the sum of added value for clients and profits for suppliers

In order to maximize the benefit, two basic strategies can be distinguished (Figure 2). The first strategy is to add extra value against a small amount of extra costs. The second strategy is to accept a bit less value against substantial less cost. In terms of quality, Bogenstätter [6] approaches these strategies by proposing 'more quality for the same money' and 'same quality for less money'.

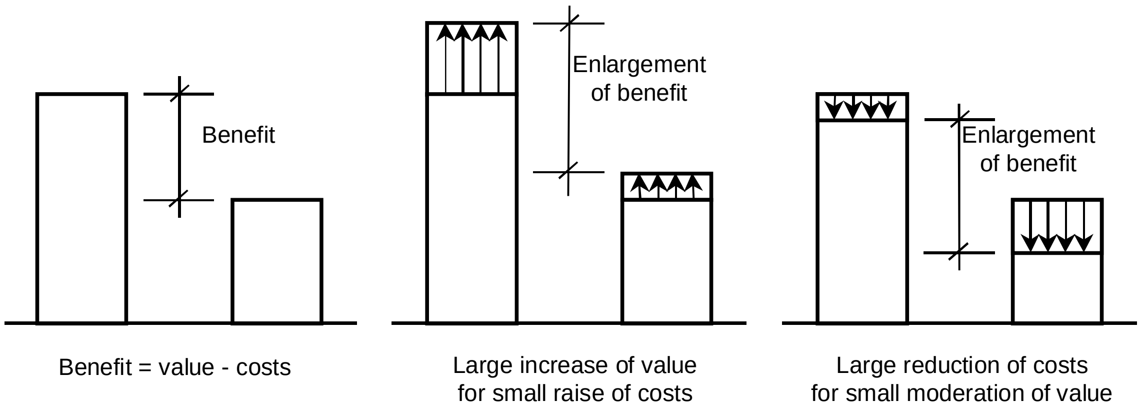

Figure 2: Two basic strategies for the maximizing benefit [15].

The coupling between value, price and costs is essential for dynamic control. The coupling is two directional. This means that value, price and costs must be balanced in the most beneficial way for the all involved parties, thus for value demanding parties as well as value supplying parties.

The two respective couplings between value, price and costs are represented by the brief (value-price) and the working concept (costs-price). The two couplings are the basis of the dynamic control concept. The brief (program) balances the desired value and the price the demanding parties are willing to pay for the built facility. This balancing is a continuous process, and takes place in all stages of design and construction, however on an increasing concrete level. The concept represents the coupling between price and costs. In the design, the supplying parties work out a concept that meets a maximum cost level based on the demanded value and the desired price. Balancing price and costs is also a continuous process, in which additional costs, risks and uncertainties influence the balance between price and costs, and determining the ultimate price, that is often higher than expected.

Demanding parties and supplying parties each have a different focus on the balance they want to optimise. The interests are basically opposite. Demanding parties want to maximize the difference between value and price. Supplying parties want to maximize the difference between costs and price. As a consequence, the interaction between demanding and supplying parties should be focused on integrated balance of the value, price and costs, and maximizing the total benefit through the integrated development of the brief (design program) and the concept. The price is the "lever". Due to the dynamics of the process, this calls for a convergent process of continuous price forming, ultimately leading to a realistic price level in between the emerging desired value and an optimal cost level.

5. Project Alliance: An Applied Dynamic Control Method

5.1 Basic Concept

The concept of dynamic control has been applied in several project alliance projects [20]. It is done by the coupling of the term value of the value demanding parties with the possible profit of the value supplying parties. This is done is such a way that when value rises, the possible profit rises and when the value declines, the profit declines (see table 1).

Table 1: The coupling of the delivered value with the profit of the value supplying parties

Delivered Value (performance)	**Profit**
Good	Good
Normal	Normal
Bad	Bad

By the coupling, the value supplying parties shift from a price-cost (profit) mindset to a value-profit-cost mindset, because the final profit is directly dependent of the delivered value.

In a project alliance the partners bear a portion of the total risk, profit and losses. This way the partners are stimulated to collaborate in order to achieve maximum profit in relation to the delivered value. This contributes to the philosophy of partnering, which says that performance in terms of cost, time, quality, buildability, fitness for purpose and whole range of other criteria, can be dramatically improved if participants adopt more collaborative ways of working [2, 3, 4].

5.2 Condition One: Define Value

The first condition in being able to couple the delivered value with the final profit is by defining the term value. The term value will be different for every value demanding party. Globally the term value for the value demanding parties can be defined as the balance between time, price and quality [24].

5.3 Step Two: Setup a Benchmark And Set Incentives

The following step is to define the minimum quality level (process and/or product), the maximum price level and maximum time the project may take and setup a benchmark to measure these levels. Through the benchmarks the value is quantifiable, thus the profit can be made dependent from the measured levels. In a project alliance this is done through the so-called Risk/Reward schedule. The Risk/Reward schedule puts incentives on the measured levels of quality, price and time (for example see figure 3).

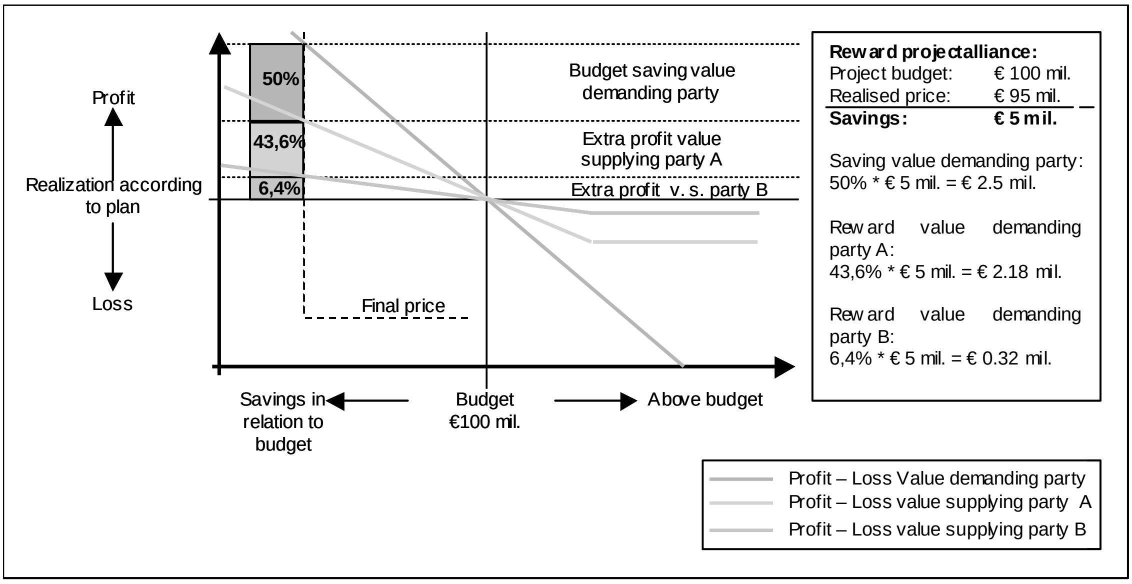

Figure 3: Example of incentive put on the realised price of a project (Risk/Reward-price) [7]

The Risk/Reward schedule (the three incentive schemes placed on time, cost and quality) should be balanced in such a way that the profit of the value supplying parties starts hitting zero as soon as the expectable minimum balance between quality, cost en time is in sight. The following example (figure 4) shows a project in which the quality level of the project is leading. When the quality of the project is low, even when the project is delivered on time and far under the budget, there will be no profit. This way the quality level is secured. There will only be a profit when the quality that is delivered is on the minimum adaptable level and the project is on time and within budget.

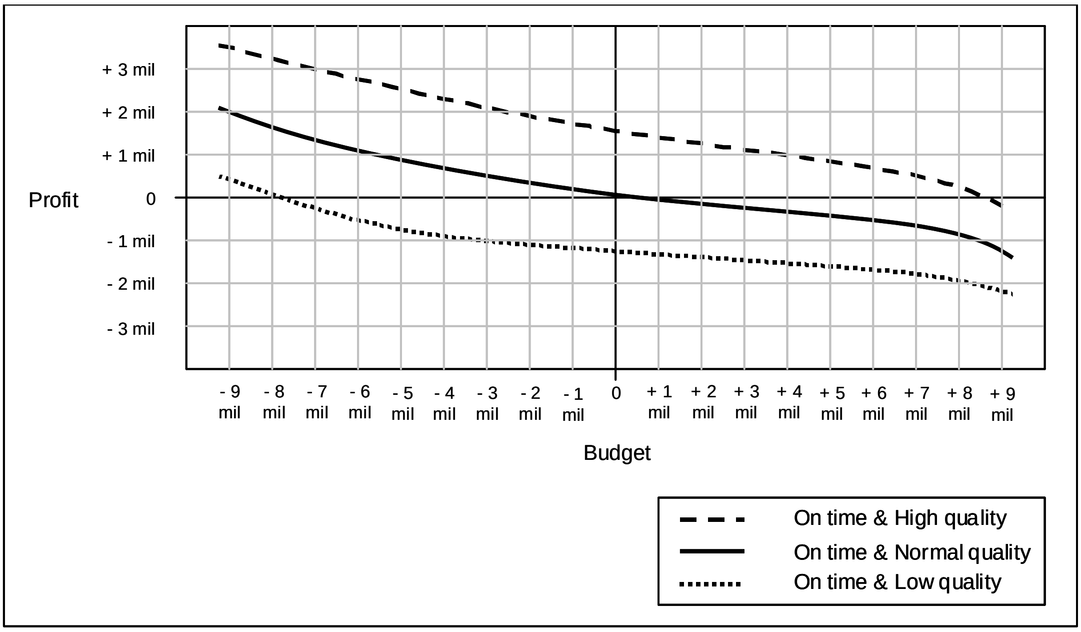

Figure 4:Example of profit coupled with the balance of quality, price and time, where the quality is leading [20]

There are however other aspects that need reckoning. In order to develop collaboration between the partners, only relying on incentives is too simplistic. Open communications, supporting policies, systems and practices are needed to stimulate and maintain collaboration [5,20,26].

5.4 Step Three: Open up the Building Process for Dialogue

The third condition is to open up the building process. Where normally the value demanding parties define the wanted value before starting the dialogue with the value supplying parties, it is now necessary to open up this phase to the value supplying parties. This is done because the value demanding parties are not yet certain about the product that has to be delivered [25]. This can be done for instance by putting the development phase after the selection phase of the project (see figure 5). This way possible optimisations and value enhancing ideas from the supplying parties can be integrated into the design, the phase where the cost for changes are low and the possible influence is high [22]. This means that the method of selection cannot be based on the evaluation of the bid or lowest price. It means the selection should be based on the qualities of the value supplying parties and their possible input into the project.

A direct consequence of the selection based on the qualities of the value supplying party is that the project has to be shielded for the selection of the wrong value supplying party. Selection based on the quality of a party can result into the selection of the wrong party, because this selection methodology is much less developed to date, than the lowest price criteria. The following steps should be incorporated [20] (see figure 5).

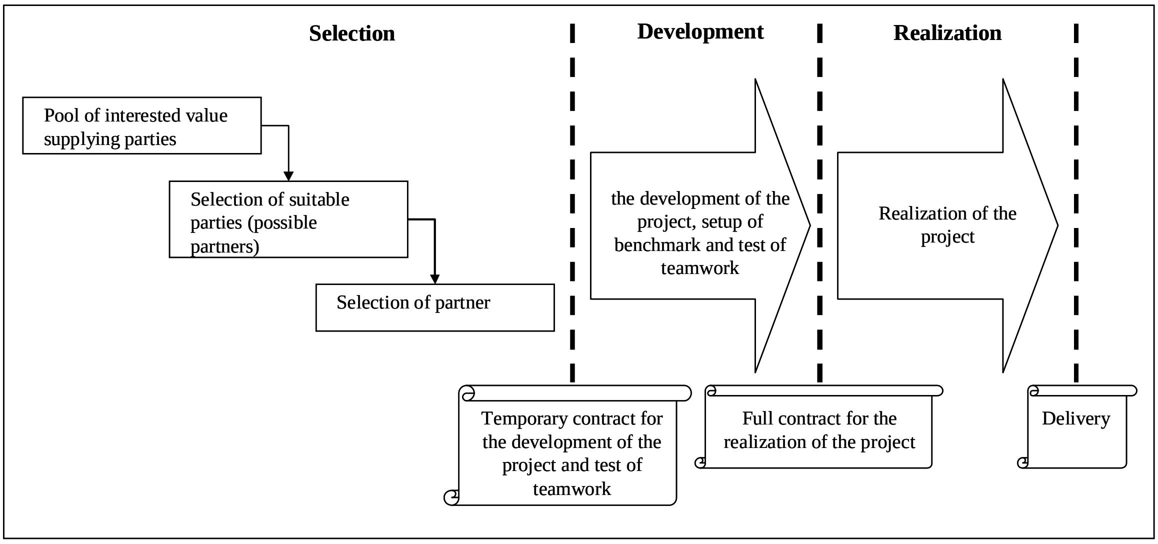

Figure 5: Steps in the tendering process of a project alliance

Figure 5 shows the tendering process for a project alliance. In this process the development phase has been placed behind the selection process. As a result the value supplying parties (including the contractor) will be contracted before the full scope of the project is visible. This is the reason why a temporary contract is installed. Under this contract the partners (including the value demanding parties) develop the project and the benchmarks (for the Risk/Reward-scheme). If the development phase is satisfying for the value demanding parties, the temporary contract can be converted into a full contract for the realization of the project.

6. Demand and Supply Chain Integration In One Organisation

A project alliance can be seen as a delivery method that integrates the demand and supply chain. Client, contractor, architect, consultant and even subcontractor can form a joint venture for the duration of the project [20]. For the duration of the project, the members form a temporary organisation that operates independently from the organizations that gave birth to it. The goal of the organisation is to deliver the project on time, within budget and with an acceptable level of quality, guided by the Risk/Reward scheme. The alliance members, including the client, make all decisions in relation to the project. In case of a dispute the members are kept to solving this internally. This can be done through multiple alternative dispute resolution methods [21].

The main contractors role during the process of construction is mainly focussed at facilitating and coordinating the production process. Subcontractors carry out most of the production nowadays [1]. Most subcontractors are contracted by the main contractor through traditional contracts, which means that the subcontractors are only asked to deliver as certain amount of production and not to utilise their specific knowledge for the benefit of the project. In project alliances it is possible to utilise this specific knowledge by integrating the subcontractor into the alliance [20]. By making the subcontractor part of the alliance, the subcontractors' profit will also be part of the Risk/Reward scheme, thus stimulating the subcontractor to collaborate with the alliance partners to deliver more overall value to the client [20]. This way specific knowledge of the subcontractor, which can have a decisive role in the project, can be integrated into the project.

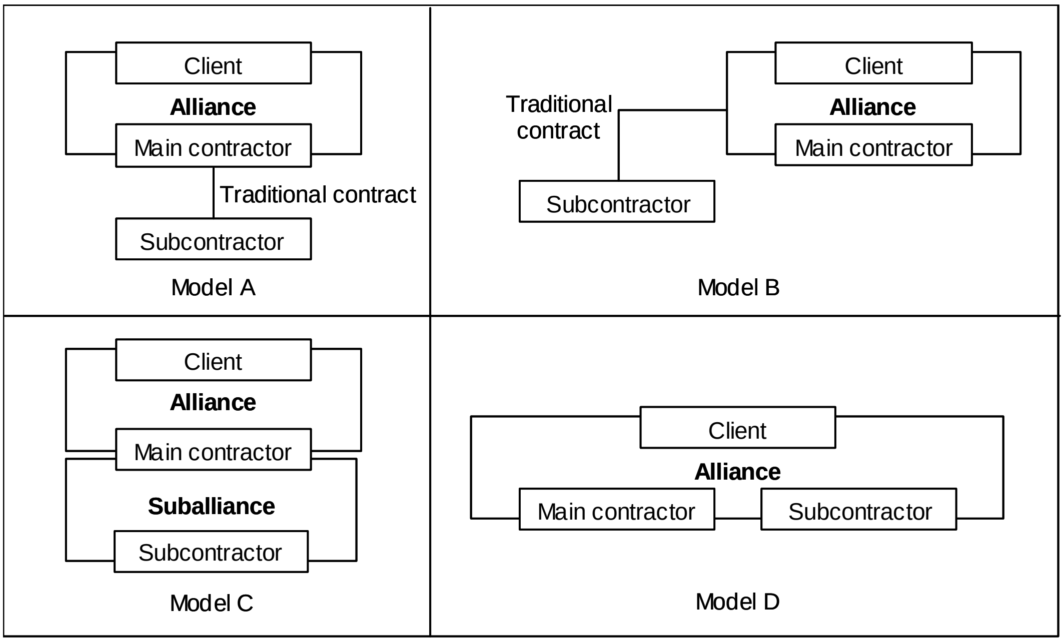

Figure 6: The position of the subcontractor in relation to the alliance [Based on 7, 20]

The position of the subcontractor in respect to the alliance can be realised multiple ways, these are [7] (see figure 6):

A. Subcontractor outside the alliance and under the responsibility of the main contractor (traditional contract);

B. Subcontractor outside the alliance and under the responsibility of the alliance (traditional contract);

C. Subcontractor as part of the alliance through a sub-alliance between the contractor and subcontractor;

D. Subcontractor as a full member of the alliance.

Model A and B represent the more traditional position a subcontractor can have in the building process. Models C and D represent possible ways to integrate the subcontractor into the alliance. In model C the subcontractor remains under the control of the main contractor, but will share in the possible risks, losses and profits of the alliance made on a particular part of the project (for instance the steel construction) for which the subcontractor is contracted. When the subcontractor is responsible for a large portion of the total work or the subcontractors' work can be seen as a critical part of the project, model D can be an option. In model D the subcontractor is part of the alliance as a full partner, this way the subcontractor will share in the full risks, losses and profits of the alliance. This will stimulate the subcontractor even more to work closely together with other partners in the alliance in order to deliver maximum value and thus receive maximum profit.

Models C and D can also be applied for the integration of suppliers and consultants with the alliance. This integration makes dynamic control of the supply chain reach far further than just the contractor.

7. Discussion and Conclusion

The project alliance delivery method can be seen as a first direction to achieve dynamic control of a project's value. It is done by the coupling of the value of a project with profit of the value supplying parties through the so-called Risk/Reward scheme.

The Risk/Reward scheme puts an incentive on the value of the value demanding parties. The incentive should be placed in such a way that there will be no profit for the value supplying parties as this value reaches minimum acceptable levels. Extra profit can be gained by supplying extra value to the value demanding parties. This way the Risk/Reward mechanism supports the concept of dynamic control, because the value supplying parties will always search for solutions that will optimize their profit and thus stimulate the delivery of extra value.

One of the more important steps that have to be taken in order to make project alliances (and dynamic control) possible is to open up the development stage of a project. During the development stage value demanding and supplying parties should be able to work together on maximising the possible outcome of the project. This means that the development phase should be placed after the selection phase and that the selection should be based on the quality a value supplying party could deliver into the project.

In a project alliance demand and supply chain are integrated to the extent that they form one organisation for the duration of the project. The goal of the organisation is to deliver the project on time, within budget and with an acceptable level of quality, guided by the Risk/Reward scheme.

Subcontractors, suppliers and consultants can play a decisive role in the success of a project. In order to fully utilise their specific knowledge for the benefit of the project they should be made part of the alliance. In this way the subcontractors', suppliers' or consultant's profits are made dependent of the success, thus stimulating full dedication. Subcontractors, suppliers and consultants can made part of the alliance by the means of a sub-alliance or by making this party a full member of the alliance. By doing this dynamic control further into the supply chain is made possible.

Project alliances should be seen as a starting point from which we can further develop the dynamic control of construction projects. In order to develop dynamic control into the lifecycle of a building, further research is necessary. The first direction given is that dynamic control can only be fostered by procurement methodologies that leave room for value being developed in a dialogue between value demanding and value supplying parties. Selection methodologies will need to address other issues like fit for project, alliance thinking, collaboration, creativity, past performance and so on. In order to be able to select a contractor (or other party involved in the project) that is able to deliver maximum value for the value demanding party. Performance based procurement [18] for instance aims at selecting high performance contractors who deliver value against competitive prices.

Integrated project delivery asks for high performers who are able and willing to collaborate with the client in order to deliver maximum value to the client and optimise the possible profits. This could be further stimulated by having the alliance deliver multiple projects instead of one. This implies the formation of a strategic alliance [16]. By having multiple projects being developed by the same alliance, the partners will be more willing to keep good relations between each other. Further, the learning effects of the first project could be stored into the alliance and utilised for the benefit of the following (similar) project. Not only will the organisation of the alliance will become better structured and adjusted, mistakes made in the first project will be prevented in the following projects.

This concept should be further developed over the lifecycle of a project. Data about the lifecycle costs and performance of a building should be gathered and used by the construction of the following similar project. When this is done within a strategic alliance, the possible benefits during construction period and the lifecycle can be utilised fully to the benefit of the value demanding parties.

Procurement Methods are Not Set-up for Lowest Cost!

Jan A Elfving
Helsinki University of Technology (email: jan.elfving@hut.fi)

Abstract

This paper argues that general contractors' procurement methods in the Finnish construction industry are generally focusing only on a small part of cost, namely, on the seller's margin of the product price. The margin is often only a few percentages in some cases it may be up to 15% of the product price. The rest and the major part of the product price consist of labour and material costs, and overhead. The general assumption is that the market forces suppliers constantly to reduce labour, material, and overhead cost in order to stay competitive hence it is enough if buyers of building products such as contactors and owners have means to identify the lowest market price. However, evidence demonstrates that in many cases buyers of construction products can significantly impact on suppliers' labour and material cost; and moreover, on the process cost. Still, current procurement methods are lacking systematic methods to address other costs than margins.

This paper proposes a framework for buyers based on Transformation-Flow-Value theory and lean methods to reduce both process and product cost during the procurement phase. Here the supplier and buyer aim in collaboration to reduce waste from the supply chain installed. Waste is a non-value adding activity such as, inventories of goods awaiting for further processing or consumption, unnecessary production, unnecessary transport of goods, defect products, design of goods and services that fail to meet user’s needs, and make-do. With help of examples in procuring wood-framed windows and pre-fabricated concrete elements, it is demonstrated that certain waste can only be reduced through supplier-buyer collaboration. The savings from the reduced waste can be significantly larger than what can be reached in traditional procurement through competitive bidding based on nominally complete plans and specifications.

Keywords: Procurement, market price, supply chain, lean construction

1. Introduction

In construction, procured material and labour can be up to 70% of project cost [1, 2]. In Finland, the large general contractors source mainly with help of annual purchasing agreements, where unit prices are set for a pre-determined time period; or through the spot market, where products and services are bought based on the prevailing availability and lowest cost. However, in both cases, when the supplier is selected, the product price is the decisive factor and the transaction cost and the cost of waste are not considered. The transaction cost consists of the cost of specifying the details of procurement contracts, the cost of discovering what prices should be, the cost of negotiating the procurement contract, and the cost of monitoring the fulfilment of contract [3]. Several studies has shown that the transaction cost can be significant, 10% or more, of the product price, e.g., [4, 5, 6, 7]

Waste is a non-value adding activity [8] such as, inventories of goods awaiting for further processing or consumption, unnecessary production, unnecessary transport of goods, defect products, design of goods and services that fail to meet user's needs, and make-do. In mid 90s, the Swedish construction company, Skanska, studied how much non-value adding cost where embedded in various material deliveries in the Swedish construction industry. In the study it was found that a large part of the cost is waste, e.g., if gypsum board cost 100 the non-value adding part of the delivery cost is 140 (Figure 1), hence the actual price of gypsum board as it reaches its final consumption on site is 240 [9].

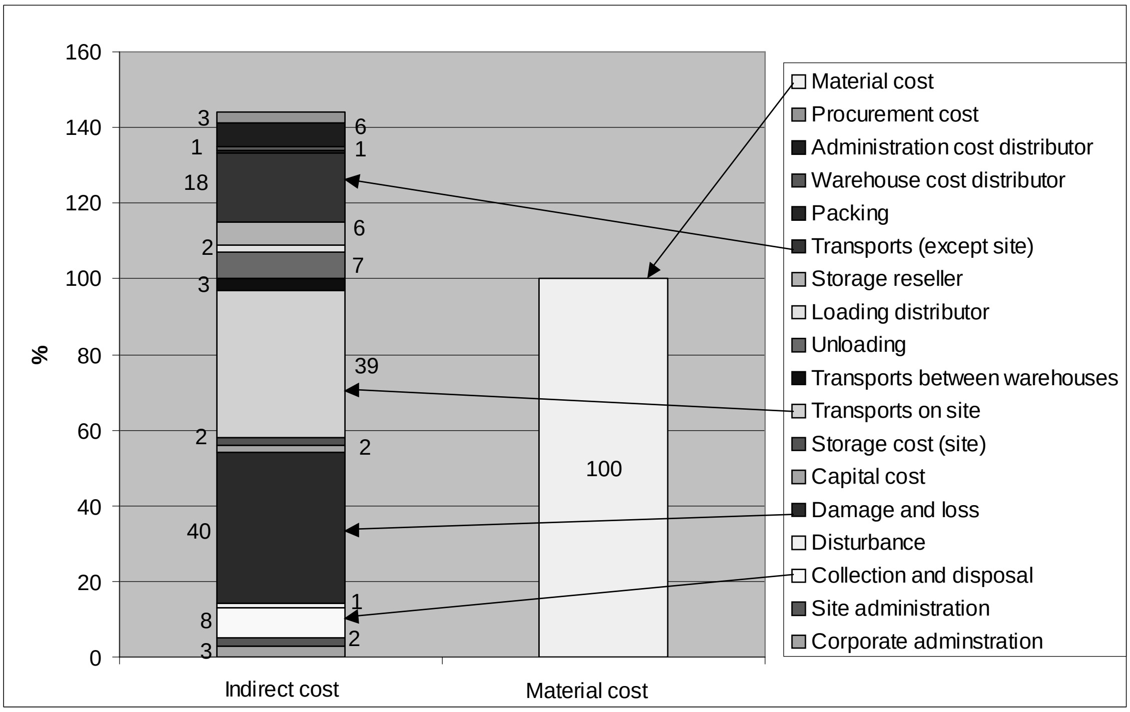

Figure 1: Indirect and direct cost for gypsum board [9]

In construction, one reason why the transaction cost and waste are poorly considered is that they are tedious to capture thus their value tend to be underestimated. Also, even if there is a sense of the magnitude of the costs; there is a lack of means to address them. The purpose of this paper is to present a framework that captures the transaction cost and waste during the procurement phase.

Next, a brief description of the key concepts, some case examples, followed by a description of the framework. Finally, the paper ends by discussion and conclusion of the preliminary findings.

2. Theory

2.1 Lean Construction

Lean construction was sparked by two main motives. First, the construction industry had long been criticized for lacking a production theory, which by several scholars, e.g., [10, 11], have been considered as the reason for poor performance of the industry. Second, the extraordinary achievements in "lean manufacturing" inspired scholars in the construction industry to rethink lean production methods and tools to project-based production, such as construction. Even if the term lean manufacturing was coined in 80s the underlying theory of lean manufacturing was not explicitly explained until Koskela [12] studied production theories in-depth. He identified at least three different conceptualizations of production that have been used, namely; transformation, flow, and value (TFV). Further, he argued that all three conceptualizations are necessary and should be used simultaneously. These concepts form the theoretical foundation of the TFV theory. According to the TFV theory, the design, control, and improvement of production should be conducted as an integration of transformation, flow, and value concepts and not as alternative concepts [12].

The concept of transformation is based on the idea that production is conversion of inputs to outputs and the goal is to make the transformation as efficient as possible. Although this concept has dominated the construction industry, it has severe shortcomings. It does not aim to reduce wasted resources and does not focus explicitly on customer requirements [12]. The flow concept recognizes that production consists of inspection, waiting, transportation as well as transformation [12]. The first three factors are non-value-added; hence, they should be eliminated. Ohno [13] and Shingo [8], who termed non-value-added tasks "waste". Ohno [13] and Shingo [8] observed that by merely eliminating waste from the production system, significant productivity improvements were achieved. The goal of the value concept is to generate best possible value to the customer, based on his requirements [12]. Value is not the same as quality. Quality is an assessment of how well customer needs are met, whereas value can be understood to also include the sacrifice to meet the needs [15] (Table 1).

Table 1: Summary of TFV theory [16]

	Transformation concept	**Flow concept**	**Value concept**
Conceptualization of production	As a transformation of inputs to outputs	As a flow of material composed of transformation, inspection, moving, and waiting	As a process where value for customer is created through fulfillment of his requirements
Main principle	Getting production realized efficiently	Elimination of non-value-added activities	Elimination of value loss
Methods and practices	Work-breakdown structure, MRP, organizational responsibility chart	Continues flow, pull, production control, continues improvement	Methods for requirement capture, quality function deployment
Practical contribution	Taking care of what has to be done	Making sure that unnecessary things are done as little as possible	Taking care that customer requirements are met in best possible manner

2.2 Procurement Based on Transformation (T)

Procurement is a process that defines what, when and how much to purchase and ensures that what is required is received timely according to the specifications [17]. Project Management Institute's PMBoK [18] identifies as the major process in procurement: procurement planning, solicitation planning, solicitation, source selection, contract administration, and contact close-out (Table 2). PMBoK's description of procurement is a based on transactional contracting. In construction the contracts are typically transactional contracts [19], where contracts are short and limited, and past or future relations between the parties are not considered [20]. PMBoK's description of procurement is a good example of the application of the transformation concept, where the focus is to transform inputs to outputs, without explicitly considering on reducing process waste and customer requirement (primary focus on contract requirements). The contract and its follow-up are the key outputs.

Table 2: PMBoK's procurement processes

Major process	Description
Procurement planning	Determine what to procure and when.
Solicitation planning	Documenting product requirement and identifying potential sources.
Solicitation	Obtaining quotation, bids, offers and proposals as appropriate.
Source selection	Choosing from among potential sellers.
Contract administration	Ensuring that seller's performance meets contractual requirements.
Contact close-out	Completion and settlement of the contract, including resolution of any open items.

2.3 Procurement Based on TFV

Procurement may generate significant amount of waste. If procurement is performed according to PMBoK, it forces upstream players to commit early to design solutions and to pursue large design batches. The design cycle time becomes long thus the probability of changes increases and the change-order process is typically tedious and disputes are common [7]. From a supply chain approach, where the product detailing, procurement, manufacturing, shipping, and site installation of the product is included (Figure 2), most of the time is pure waiting, and re-designing and re-work are common [7, 21]. The design is driven by the need for contract documents not actual site conditions. Also, it is rare that detailing, manufacturing, and site installation are performed in the same sequence and batch sizes (e.g., [22]).

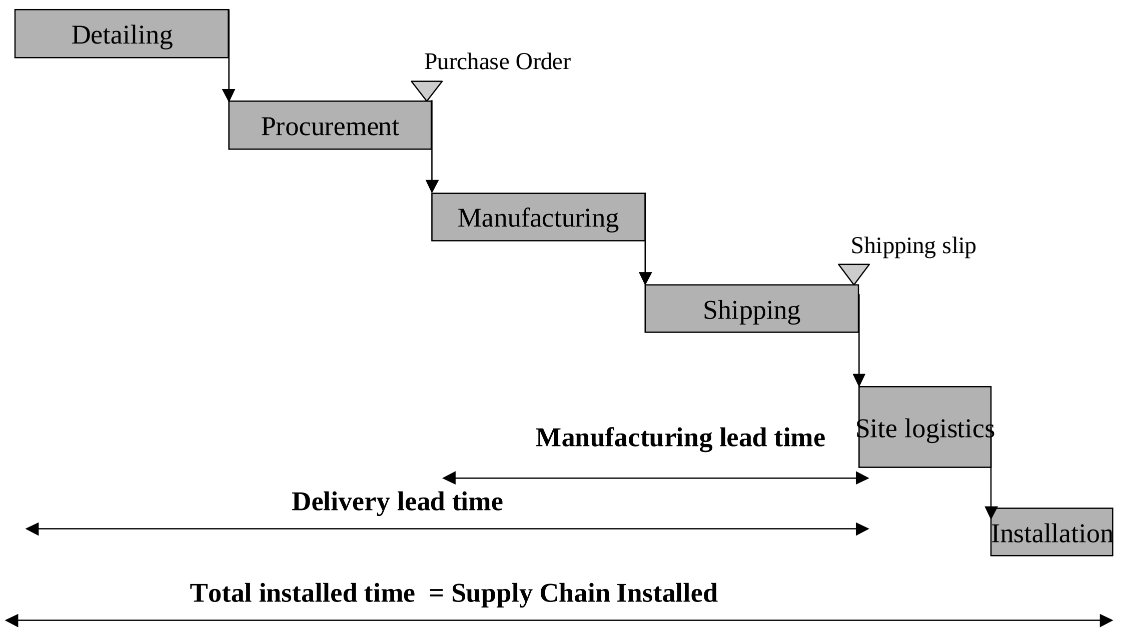

Figure 2: Phases of supply chain

This does not mean that the transformation approach is not needed rather than there has been too much focus on the transformation and too little focus on the flow and value concept. From a flow approach the procurement should be conducted so that it reduces process waste. In waste reduction, the main principles are to reduce variability and overall lead time [12]. From a value approach the procurement should be conducted so that the customer requirements are fulfilled. The nature of project-based production is iterative; where as the process progresses more information and knowledge become available. Consequently, project stakeholders' requirements sharpen and may even change. Therefore, it is of value not only to fulfil the initial requirements but also be able to fulfil by minimum waste customer requirements that result from the "organic growth" or change-orders. In summary, in procurement based on TFV, all three concepts are included, and the main emphasis would be on flow and value (Table 3).

Table 3: Procurement based on TFV

Approach	Description
Transformation	Procurement is able to efficiently turn product specification and delivery requirements to products that are ready to install.
Flow	Procurement generates minimum waste in supply chain.
Value	Procurement is able to maximize customer value throughout the project including the organic phase.

3. Case examples: Procurement based on T

The two case examples are randomly chosen without a special intention to find worst or best cases rather they are cases that probably every practitioner can assimilate to.

3.1 Wood-framed Windows

The company A has procured wood-framed windows from company B. The focus is on product price; hence, the process cost is forgotten. As a result, plenty of waste in the process is generated, which can be picked-up from the correspondence between the two companies:

- Building permit April 2004 (master schedule and project completion date set)
- 27.5.2004, company A informs company B windows needed beginning of September, 2004 (Company B makes capacity reservations at the plant)
- 12.8.2004, company A informs company B windows needed beginning of December, 2004 (Company B re-schedule capacity)

- 2.11.2004, company A informs company B windows needed beginning of December, 2004

- 3.12.2004, 200 windows ready by company B.

- 11.12.2004, company A informs company B windows needed beginning of January, 2005 (Company B runs out of storage space)

- 14.12.2004, windows are delivered to logistic centre

- 11.01.2004, company A informs company B windows needed mid February, 2005

- 19.01.2004, window installer expects installation starts, mid March, 2005

The original schedule was 27 weeks wrong and the windows waited 19 weeks in "logistic centre". The supply chain installed was 84 weeks and manufacturing lead time 4 week. The process cost was significant but never addressed.

3.2 Pre-fabricated Concrete Walls

This project was on a strong schedule pressure and the structural and the MEP engineers were working significant overtime and in an irrational engineering sequence to meet the milestones set during the procurement by company C (contractor) and company D (supplier). As result, there were expensive design details, particularly caused by lack of time during detailing; and waste, particularly waiting (Figure 3, Figure 4). Interestingly, some pre-fabricated elements that waited (element details and ready elements) 100 days or more; and still, there was a rush! This is another example where procurement was based on T and product price but the process cost was ignored. The design paid a price but also company C, the buyer, because of the expensive design solutions and indirectly for the capital tied in ready products waiting to be installed.

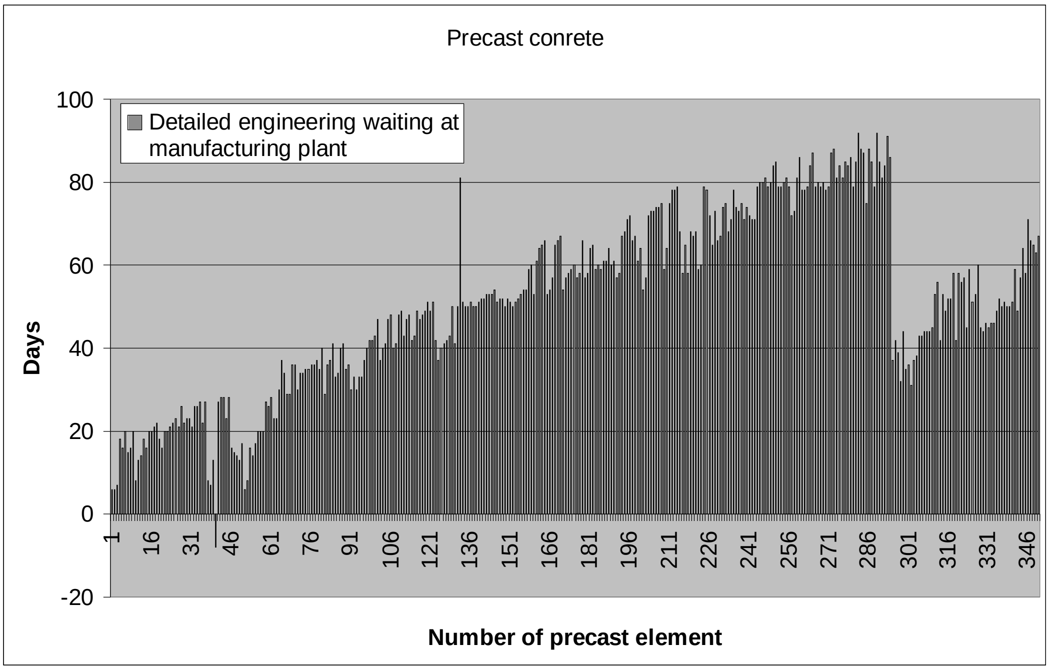

Figure 3: Waiting of detailing at manufacturing shop

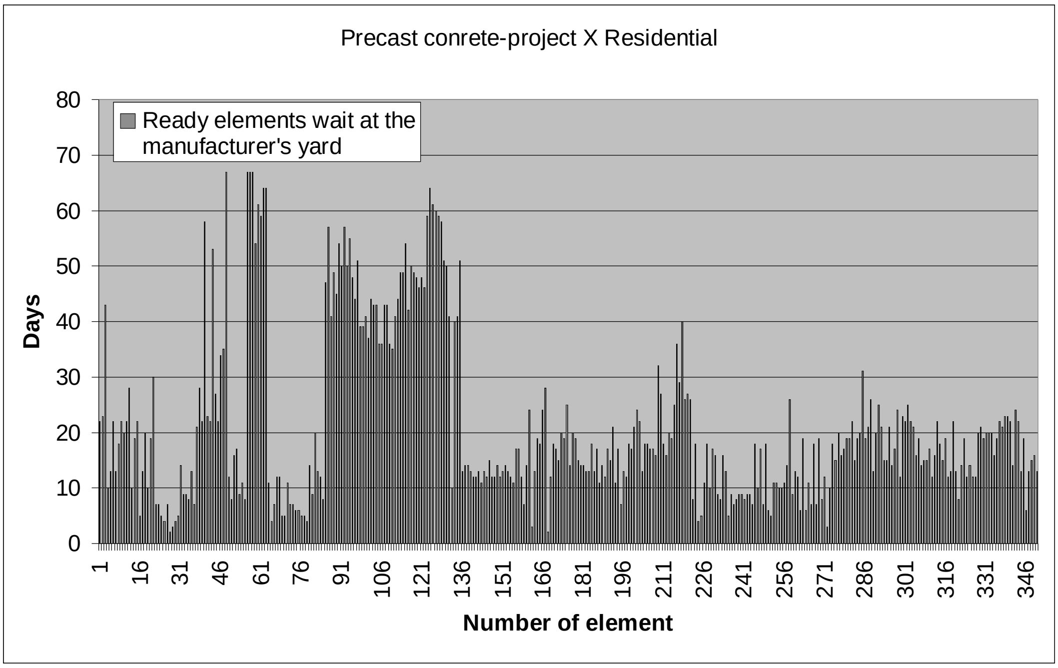

Figure 4: Waiting of ready elements at the manufacturer's yard

4. Framework for "Lowest Cost" Procurement

This section provides an alternative to procurement based on T. The alternative aims to consider TFV simultaneously in procurement. The cost scope of the framework is either Total Installed Cost (TIC) or Total Cost of Ownership (TCO), depending on how much contractors and suppliers are able to influence customer requirements[1]. In TIC, the cost of installing the equipment to its final location in the building is considered along with purchase price, logistics cost, and transaction cost (e.g., the time and effort needed to exchange data between the buyer and the supplier during design, detailing, on-site assembly, and start-up). TCO is the broadest definition of cost. It includes transaction costs product purchase price, shipping cost, operation and maintenance cost, and disposal costs [21]. The framework of the "lowest cost" procurement is described in Figure 5. Essential is that the procurement process is designed, controlled, and continuously improved.

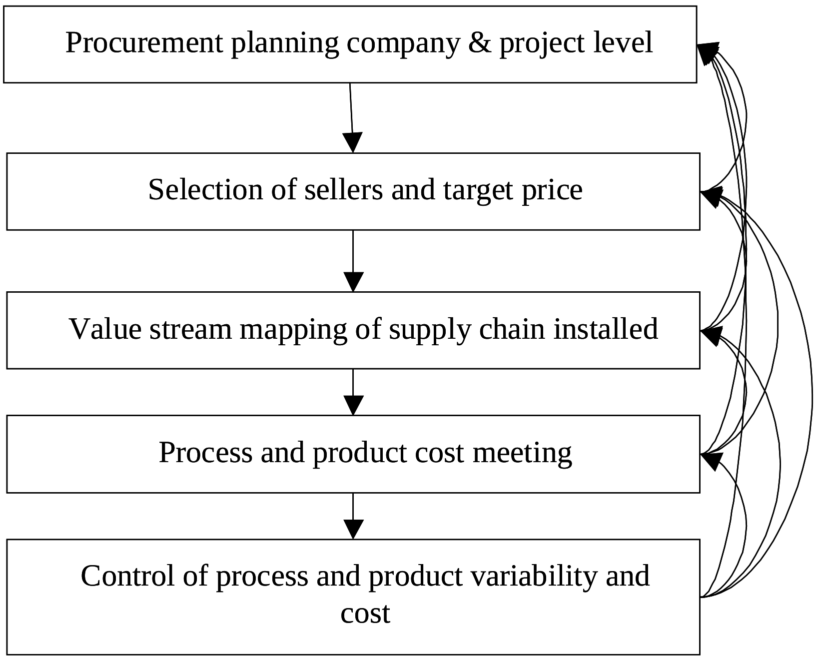

Figure 5: Framework for "lowest cost purchasing"

4.1 Procurement Planning Company and Project Level

The procurement planning is separated between company and project level so that innovation and volume can properly be addressed. On company level, procurement planning is conducted on those items, where multiple projects will benefit, e.g., where product innovation and close co-

[1] In some instances the building code, municipal, and owner may have defined specification prior to contractor or supplier involvement; therefore, TCO may not always be fully applicable.

operation between supplier and contractor are needed, and where purchasing power of multiple projects can be applied. Project level planning addresses project specific needs, what is needed and when.

4.2 Selection on Sellers and Target Price

The selection of suppliers is based on supplier reliability and TIC or TCO. The reliability is described in sub-section 4.5. The target price of a product or service is set in prior to the value stream mapping. The target price is based on past projects, or in some cases, a supplier is consulted.

4.3 Value-stream Mapping of Supply Chain Installed

In value-stream mapping each task from specifying the product to installation (Figure 2) is in detailed mapped out (see [7] for detailed value stream mapping). The mapping provides a tangible opportunity to address flow and value issues. In mapping important characteristics are the visualization of hand-offs between organizations by clearly separating organizations from each other and the use of a minimal amount of symbols for clarity. Besides tasks and their inter-dependencies, inputs and outputs, also time is mapped out. The time mapping includes the lead time of the supply chain installed and each tasks duration.

4.4 Process and Product Cost Meeting

After the target price is set and the value stream mapping is completed, both product and process costs can be estimated. The process cost is calculated from the labour hours consumed in the process excluding manufacturing or installation hours. Based on the estimated process and product cost process participants will meet to find ways to reduce both product and process costs. Besides the contractor and supplier the meeting often requires a representative of the particular engineering discipline and/or architect depending on the purchased item.

4.5 Control of Process and Product Variability And Cost

In order to continuously improve the procurement and to lower TIC the actual procurement process and installed product is measured and compared to the planned. The root causes of variability is captured and used to control variability in future procurement initiatives.

5. Discussions

The author is currently working with an architect, a contractor and a window-frame manufacturer and installer according to the proposed framework. Currently the team has advanced to the forth stage, process and product cost meeting. So far, the contractor has chosen wood-framed windows to be a company level purchase item, where innovation and consolidating company wide volumes are considered beneficial. The seller has been identified and target prices have been set based on historic data. The value stream mapping has been completed. So far, with help of object-oriented product libraries, the information flow between parties has significantly improved as well as the task durations for the stakeholder, e.g., the architect needs only a third of the labour hours required before for the detailing, and the procurement needs only a tenth of the labour hours required before in purchasing. Currently the team is working on finding means to reduce more waste and product cost (manufacturing). The team has identified major opportunities in reducing waste thus increasing the productivity in the site installation. A major issue is to share real-time production schedules between the stakeholders and to increase reliability. This requires close co-operation among the manufacturer, installer, and contractor. The major challenge has been the slow pace of change. Even if there are good ideas that the team has found, the implementation of these ideas to multiple organizations is tedious. Also, although success is achieved in one project it still does not mean that other project teams will change their current practice.

6. Conclusions

In the Finnish construction industry, it is not typical that transaction and process cost (waste) are considered during the procurement phase. One of the reasons is that procurement is based on the transformation concept. As a result, there seem to be a significant opportunity to reduce procurement cost that goes far beyond in just cutting suppliers' margins. A framework was proposed to address also the flow and value concepts during the procurement phase. Key parts of the framework are value stream mapping and control of variability. Although the framework has been only partially tested and the framework may still change as it is applied, the preliminary results have been encouraging. There has already been significant reduction in transaction cost. Currently, the target is to reduce waste and product cost of the wood-framed windows. This may require moving from transactional contracts to relational contracts.

In addition to wood-framed windows, the author is applying the proposed framework for the MEP and site prep supply chains. However, these studies are still in an early phase. Future research is needed to better understand how flow and value concepts can be used during the procurement phase. Also, more data needs to be collected about transaction cost and waste caused by procurement. It is time to fundamentally re-think the procurement in the construction industry, and continuously work for lower cost, and not just hunt for "low" spot market prices.

Barriers and Opportunities for Offsite in the UK

Chris I. Goodier
Department of Civil & Building Engineering, Loughborough University
(email: c.i.goodier@lboro.ac.uk)
Alistair G. F. Gibb
Department of Civil & Building Engineering, Loughborough University Leics., UK, (email: a.g.gibb@lboro.ac.uk)

Abstract

The UK still falls behind most equivalent economies in terms of the take-up of industrialisation in construction and techniques such as offsite construction. Interest in the UK in industrialisation and offsite has recently been increasing however, partly attributable to the increased demand for housing, and pressure by Government and industry to improve the performance of the UK construction industry, particularly its efficiency, quality, value and safety. This paper discusses the views of the UK construction industry on offsite. This work has been conducted by Loughborough University as part of a DTI and UK industry funded research programme on offsite technologies and prefabrication called prOSPa (*promoting Off-Site Production applications*).

This paper presents results from a recently completed questionnaire survey on offsite and prefabrication in the UK. A preliminary survey was used to guide and inform the development of a main survey involving three different questionnaires in order to target the three main groups of stakeholders involved with offsite - suppliers/manufacturers, contractors and designers/clients.

More than 90% of the respondents had used some type of offsite or prefabrication in at least one of their projects. Demand for offsite is clearly increasing in the UK and nearly three quarters of the suppliers surveyed thought that take-up of offsite by industry was increasing in their sector. The biggest advantages of offsite compared with traditional construction were thought to be the decreased construction time on site and increased quality. The belief that using offsite is more expensive is clearly the main barrier to its increased use.

Keywords: Offsite, offsite production (OSP), survey, questionnaire, prefabrication, industrialisation

1. Introduction and Background

This paper investigates the views of the UK construction industry on offsite production and technologies. It provides an indication of the opinions of the different sectors within the industry, including clients, designers and contractors, as well as the suppliers of offsite systems and components. Due to the fragmented nature of the UK construction industry it is not practical to assess the views of every organisation in every sector and so this study aims to provide a snapshot of the UK construction industry's views on offsite at the current time.

This paper is based upon research carried out by Loughborough University as part of the DTI and industry funded prOSPa research programme, which commenced in July 2003. The prOSPa consortium is composed of Co-Construct members (BSRIA, CIRIA, The Concrete Society, SCI and TRADA Technology) and Loughborough University. The programme aimed to promote appropriate applications of offsite and thus help improve the performance of the UK construction industry.

Although interest in offsite has been increasing in this country in recent years, the UK still falls behind most equivalent economies in terms of the take-up of modern methods of construction (MMC) such as offsite. This increased recent interest in offsite in the UK is partly attributable to the increased demand for housing and to pressure by Government and industry to improve the performance of the UK construction industry, particularly its efficiency, quality, value and safety.

There is almost a consensus amongst major developers over the need for more prefabrication in the future, in contrast to the actual amount employed, and it is the public sector client groups that are currently leading the way in the introduction of radical new systems [1].

For this study, offsite is defined as the manufacture and pre-assembly of components, elements or modules before installation into their final location [2]. Many terms have been used in the past to define and describe offsite, and many of these are still used today, including Off-Site Production (OSP), Off-Site Fabrication (OSF), Off-Site Manufacturing (OSM), Off-Site Construction (OSC), pre-assembly and prefabrication. This plethora of terms can at first be confusing for both the non-expert and expert alike, and so for this study we used offsite.

2. Methodology

The data for this study was obtained from four main sources of data:

1. a detailed review of existing recent surveys and publications on the subject;
2. a preliminary questionnaire survey of six organisations;
3. a main questionnaire survey of 75 UK construction organisations, including clients, designers, contractors and offsite suppliers and manufacturers;
4. a workshop held on the 6th July, 2004 by the prOSPa Programme Steering Committee to debate and refine the main findings of the survey.

Three different questionnaires were used for the main survey, one for clients and designers, one for offsite suppliers and manufactures and one for contractors. Although the majority of the questions were the same, a proportion of the questions were specifically targeted at the different industry sectors. 75 main survey questionnaires were completed and returned, including 39 from clients and designers, 13 from contractors and 23 from offsite suppliers and manufacturers. The types of organisation who participated in the main survey are shown in Table 1.

Table 1. Type of organisation.

Organisation type	% of respondents
Client / end user	27
Specialist supplier	24
Other	24
Main contractor	19
Architect / Designer	13
Specialist consultant / designer	12
Project / Construction Managers	8
M&E consultant / designer	4
Maintenance contractor / FM	1

Note: Some respondents selected more than one category.

The main '*Other*' types of organisation listed by respondents included multi-discipline consultants, modular building manufacturers and specialist sub-contractors.

Several other studies from the last three years have examined different aspects of the offsite industry in the UK and the results of these reports have also been included within this study where relevant [1, 3, 4, 5].

3. Results

3.1 Respondents Experience of Offsite

The overwhelming majority of the respondents from all the sectors had used some type of offsite in at least one of their projects (Table 2). A very small proportion of the client/designers had not used offsite before and 8% of the contractors surveyed were not sure if they had or not.

Table 2. Percentage of respondents who have used offsite on any of their projects.

	% of respondents	
	Clients/designers	**Contractors**
Yes	97	92
No	3	0
Maybe	0	8

Figure 1 shows the type of offsite product or system which is most commonly considered for construction projects by the clients and designers, and contractors in this study. Most of the types of offsite were used by more than half of the clients and designers surveyed, with framing systems, volumetric modular buildings, cladding systems and bath/toilet/kitchen pods all being used by approximately 70% of the respondents. More than half of the contractors surveyed had also used most of the types of offsite listed, with the exception of volumetric modular buildings and building services, which had been used by less than half of the contractors surveyed.

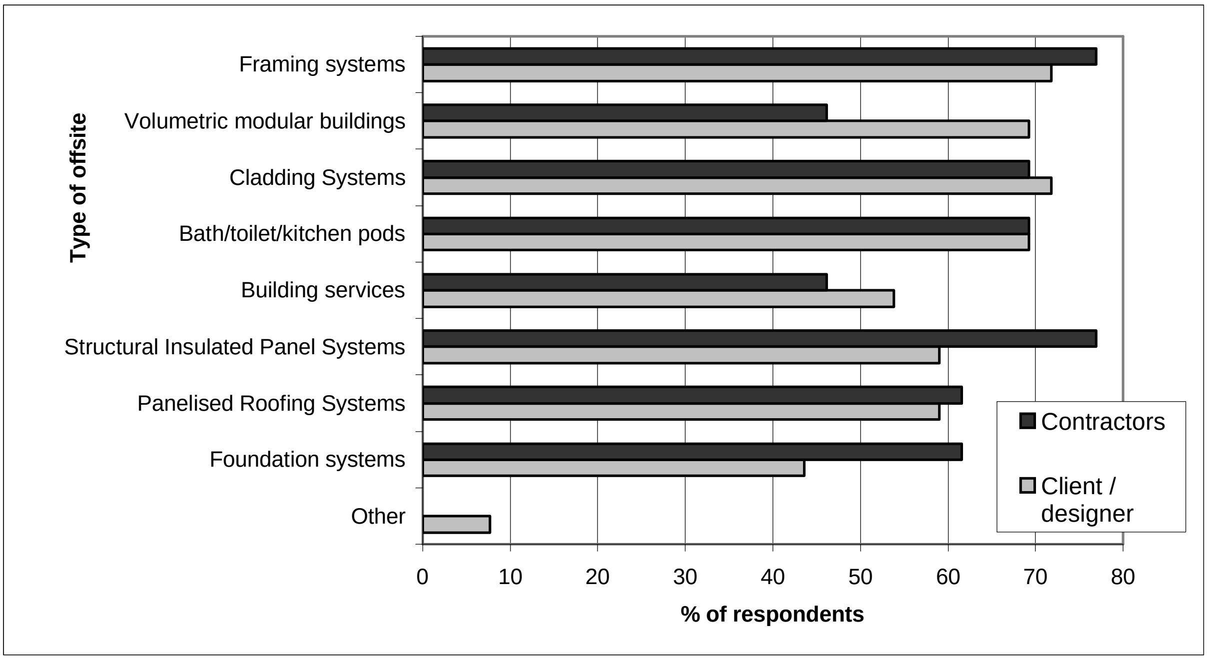

Figure 1. Type of offsite most commonly considered for projects.

3.2 Advantages, Barriers, Drivers and Take-up of Offsite

The majority of clients and designers surveyed (73%) claimed that they were sufficiently aware of the relative advantages and disadvantages of offsite over traditional construction, compared with just over half (54%) of the contractors surveyed. However, less than a third (30%) of the suppliers questioned thought that their customers were aware of the relative advantages and disadvantages of offsite over traditional construction.

This difference in awareness and knowledge of offsite is a frequent source of frustration for suppliers, with customers believing that they are aware of the relative advantages and disadvantages but suppliers knowing, or believing, that they are not. Some suppliers believe that there is an extraordinary lack of understanding in all sectors of the construction industry for the full benefits that offsite can bring and that the general understanding of offsite to some people just means volumetric modular boxes, usually grey. Many customers in the industry routinely use products and methods such as precast concrete without appreciating that this is a form of offsite. Conversely, some contractors complain that suppliers are not always fully aware of how tendering works in traditional construction, what the price means in contractual terms, and the importance of early notification if anything is done in the design development that will cause costs to rise.

The biggest advantage of offsite compared with traditional construction is thought to be the decreased construction time on site. This was stated by about 90% of respondents, including clients, designers and contractors (Table 4). Unsurprisingly, this factor is of particular benefit to contractors, with 69% ranking this as their number 1 advantage. Increased quality also ranked highly by all respondents. A more consistent product and reduced snagging and defects were also seen as advantages by the majority of respondents, although more so by the clients/designers than by contractors. Of the remaining possible advantages, a higher percentage of the client and designer respondents selected each of the possible advantages compared with the contractors who responded. This probably reflects the higher proportion of clients and designers compared with contractors who said that they were aware of the potential advantages of offsite.

Table 3. Advantages of offsite.

Advantages	Clients/designers		Contractors	
	% of respondents	% as 1st choice	% of respondents	% as 1st choice
Decreased construction time	87	38	92	69
Increased quality	79	28	77	15
More consistent product	77	18	54	0
Reduced snagging & defects	79	8	69	0
Increased value	51	5	23	0
Increased sustainability	49	3	31	0
Reduced initial cost	44	3	15	8
Reduced whole life cost	41	0	15	0
Increased flexibility	33	0	15	0
Greater customisation options	33	3	0	0
Increased component life	28	0	15	0
Other	18	15	8	8

Much research has been conducted into the barriers, both perceived and real, that are hindering the increased uptake of offsite in the UK construction industry. The study by Robert Gordon University [1] was based upon the premise that house buyers are so strongly influenced by negative perceptions of post-war ‘pre-fab’ that they will resist any innovations in house construction which affect what a ‘traditional’ house looks like.

The main barriers found in this survey stopping clients/designers and contractors from using more offsite are presented in Table 4.

Table 4. Main barriers hindering the increased use of offsite.

Barriers	Clients/designers		Contractors	
	% of respondents	% as 1st choice	% of respondents	% as 1st choice
More expensive	67	54	77	38
Longer lead-in times	46	8	62	8
Client resistance	38	13	31	23
Lack of guidance and information	33	5	46	0
Increased risk	36	0	15	0
Little codes & standards available	33	3	23	0
Other	31	18	15	8
Negative image	28	0	46	8
Not locally available	18	5	15	0
No personal experience of use	18	3	38	15
Obtaining finance	18	3	8	0
Insufficient worker skills	21	0	23	0
Reduced quality	13	0	15	0
Restrictive regulations	13	0	31	0

The belief that using offsite is more expensive than traditional construction is clearly the main barrier to the increased use of offsite in the UK, even though a large proportion of the respondents thought that one of the advantages of using offsite was both a reduced initial cost and a reduced whole life cost (Table 4). Suppliers often argue however, that offsite is not more expensive as costs are not compared in the right manner in order to take into account advantages such as reduced on-site construction time and economies of scale [3]. This issue is also addressed by the IMMPREST (*Interactive Method for Measuring PRE-assembly and STandardisation benefit in construction*) tool developed by Loughborough University, which seeks to provide a framework for comparing solutions in a holistic manner. Other advantages such as increased quality and reduced snagging are rarely included in costings and many projects are still judged purely on first or initial cost, either intentionally or unintentionally.

Longer lead-in times were also a significant barrier to clients, designers and contractors. This was a barrier to a higher proportion of contractors however, presumably because the use of offsite could delay the beginning of the project on site.

Who usually drives the idea of using offsite for a particular project depends upon who you speak to, as can be seen in Figure 2. Clients and designers think that it is the client who usually drives the use of offsite on a project, together with the contractor, designer and architect. Contractors however, feel that it is more themselves and the architect who are the drivers. Suppliers on the other hand, think they themselves are one of the drivers, together with the client and the contractor and that the designer and architect are less so.

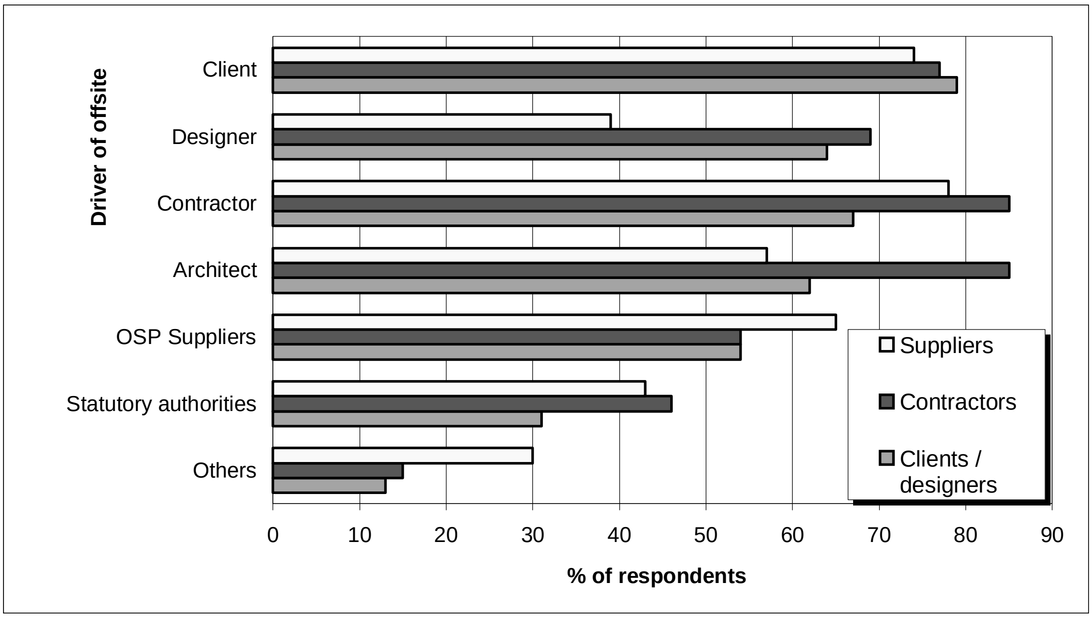

Figure 2. Main driver of offsite on a project.

3.3 Supply and Demand of Offsite

Nearly three quarters of the suppliers surveyed thought that take-up of offsite by industry was increasing in their sector, and only one respondent thought that it definitely was not. This agrees with other reports, which predict growth of 9.7% per annum (by value) by 2010 [4].

The main barriers stopping clients/designers and contractors from using more offsite were discussed earlier and presented in Table 5. Suppliers were therefore asked what means they used in order to overcome their clients' resistance to the use of offsite. The main method used was the provision of examples and case studies of previous successful uses of offsite (Table 9). The other main methods included client experience and increased partnership and marketing, all different ways of informing, educating and/or convincing the client of the possibilities and advantages of offsite. Reductions in price were only used by about a quarter of the suppliers in this survey, even though the increased expense of offsite was the main barrier to use quoted by clients/designers and contractors (Table 5). The majority of suppliers presumably sold the use of offsite on other factors such as speed of construction, quality and value rather than cost.

Table 5. Overcoming clients resistance to offsite.

Means of overcoming resistance	% of respondents
Provision of examples / case studies	68
Client experience	55
Increased partnership arrangements	55
Increased marketing / information	50
Price reductions	27
Other	23

3.4 Refurbishment

The suppliers in this survey were asked what percentage of their work was attributed to new build and how much to major refurbishment and maintenance. All of the suppliers were involved in new build, with almost 60% of the respondents being involved in new build *only*. About 40% of the respondents also supplied products for major refurbishment but only one supplier surveyed supplied products for maintenance.

When asked if the suppliers thought that there *was* a market for offsite in refurbishment in the UK, only about one third said definitely yes (Figure 4). Interestingly, this proportion was less than the number actually currently supplying products for this market. More than half of the suppliers surveyed were not sure if there was a market for this in the UK or not. This could be due to these suppliers waiting to see how the market for refurbishment develops before deciding what to do.

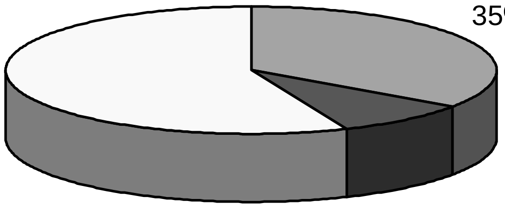

Figure 3. Proportion of offsite suppliers who thought that there was a market for offsite in refurbishment in the UK.

In recent years however, nearly half of all construction expenditure in the UK has been spent on refurbishment and repair compared with new construction. Furthermore, in the house building sector this proportion rises to approximately two thirds [6]. Refurbishment and repair is therefore a potentially large market for offsite in the UK into which it has already made some progress, but for which there is potential for significantly more. Not all of this market is suitable or practical for the application of offsite however, as a significant proportion can be classified as domestic DIY, but potential still exists for further expansion within this sector.

3.5 Labour and Skills

The UK construction industry has a historically low level of training compared with other countries and it is estimated that between 70 and 80% of the workforce in construction in the UK has no formal qualifications [7]. A large proportion of the workforce are labourers, many of them self-employed, and their skill-base is narrow and their training is limited. There is also an estimated annual turnover of between 65000 and 75000 people per annum in the UK construction industry [8].

Electricians, joiners and bricklayers were the three skills generally cited the most by all the sectors questioned as being in short supply and contributing to the increased demand for offsite products (Table 12). Contractors seem to be feeling the effects of the skills shortage as plumbers were the only trade which they felt was not increasing the demand for offsite to a significant degree. Conversely, the majority of suppliers thought that the lack of concreters, steel erectors and steel fixers contributed little to the increased demand for offsite. The other main skill mentioned by respondents which was not on the list was plasterers, which also seem in particularly short supply.

Table 6. Skill shortages contributing to the increased demand for offsite.

Skill	% of respondents		
	Client/designer	**Supplier**	**Contractors**
Electricians	65	38	67
Joiners	59	76	83
Bricklayers	44	71	58
Steel-fixers	35	19	42
Steel-erectors	32	10	33
Other	29	48	42
Concreters	26	10	50
Plumbers	12	33	8

It would seem at first that, with this general lack of skills, the UK construction industry would be perfectly placed for the increased use of offsite. Clarke [9] reports however, that a skilled workforce is required to enable innovations such as offsite to be applied. Workers here in the UK are generally not provided with an initial broad-based training after which they specialise. Instead, they are usually trained for just one role which consequently makes adapting and multi-skilling difficult, which is what is required for an increased uptake in offsite.

All respondents were asked what steps they thought could be taken by manufacturers, trade bodies and/or the Government to encourage people to enter careers in offsite in order to reduce the skills deficit. More written responses were received to this question than any other in this survey, reflecting both the importance and the far-reaching consequences of the skills deficit.

The two subjects that were mentioned most frequently were training and education and raising the awareness of offsite. Respondents mentioned that investment was needed in training and education at all levels, from school leavers through to university courses. The lack of, and need for, modern apprenticeship schemes was mentioned up by several respondents, as was the need for NVQ's in offsite and multi-skilling. Government training grants were suggested by several respondents, both for offsite manufacturers and for training colleges. Partnerships between local colleges and offsite suppliers were also discussed, as was the inclusion of offsite topics in University courses for building professionals. Raising the awareness and increasing the perception of offsite, particularly to clients and the general public, was mentioned by several respondents in order to relieve the technology of its poor historical 'pre-fab' image. This could be done by promoting and marketing the benefits and advantages of offsite more widely, both by individual companies and by the Government, and by highlighting good practice.

4. Conclusions

This paper has presented some of the views of the UK construction industry on offsite production and technologies. It provides an indication of the opinions of the different sectors within the industry, including clients, designers and contractors, as well as the suppliers of offsite systems and components.

More than 90% of the respondents from all the sectors surveyed had used some type of offsite in at least one of their projects. Nearly three quarters of the clients and designers claimed that they were sufficiently aware of the relative advantages and disadvantages of offsite over traditional construction, compared with just over half of the contractors surveyed. However, less than a third of the suppliers questioned thought that their customers were aware of the relative advantages and disadvantages of offsite over traditional construction.

The biggest advantage of offsite compared with traditional construction is thought to be the decreased construction time on site, together with increased quality, a more consistent product and reduced snagging and defects. The belief that using offsite is more expensive when compared with traditional construction is clearly the main barrier to the increased use of offsite in the UK, even though a large proportion of the respondents also thought that two of the advantages of using offsite were both a reduced initial cost and a reduced whole life cost.

Who usually drives the idea of using offsite for a particular project generally depends upon whom you ask.

Nearly three quarters of the suppliers surveyed thought that take-up of offsite by industry was increasing in their sector. The preferred method used by suppliers to overcome the resistance of their client to the use of offsite was the provision of examples and case studies of previous successful uses of offsite.

All of the suppliers questioned were involved in new build, with nearly 60% of the respondents being involved in new build *only*. Approximately 40% of the respondents also supplied products for major refurbishment but only one supplier surveyed supplied products for maintenance. When asked if the suppliers thought that there *was* a market for offsite in refurbishment in the UK, only about one third said definitely yes.

Electricians, joiners and bricklayers were the three skills generally cited the most by all the sectors questioned as being in short supply and contributing to the increased demand for offsite products. The two main methods suggested to encourage people to enter careers in offsite in order to reduce the skills deficit were training and education and raising the awareness of offsite.

Serviceable Foundation with Truss Structure

S.P.G. (Faas) Moonen

Abstract

A new foundation method for housing is initially developed to be preparatory to tomorrow's industrial building requiring a basis that is accurate within some millimetres. However when studying possible alternatives it was also found that the process of making a foundation could become much more efficient by changing the sequence of activities. This paper describes a pilot project to test possibilities of the new foundation method in real building practice. It was observed that this fully prefabricated foundation required less material, less building time and less organisation effort. Another major improvement is obtained by simultaneous pouring of concrete for ground floor and foundation beams. These aspects make this foundation method already advantageous in today's building, where improved accuracy is reduced to a side issue.

Keywords: accurate-foundation, efficient-foundation, reduced costs, integrated design

1. The Need for a New Foundation Method

1.1 Preparatory to Industrial-produced Large-size Building Parts

Industrial produced components will become more and more important in modern building. Accordingly it is expected that house building will tend towards the use of large-seized components (prefabricated full wall-parts) and high exactness (feasible by manufactured products). In construction however, benefits of accurate large-seize wall elements can only be fully utilized if the foundation provides a similar exactness as the applied wall-elements. Current foundation methods don't provide this required accuracy without labour-intensive adaptations. With this in view a new foundation method is developed providing high accuracy (of overall +/- 2 mm) and befitting present-day chances in construction.

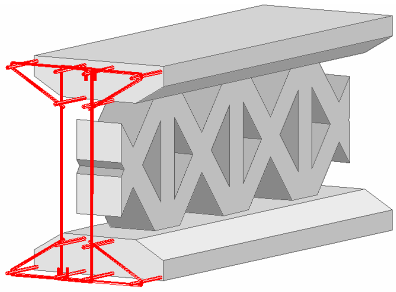

Figure 1: Outline of proposed foundation beam.

1.2 The Roman Already Knew How to Make Foundations

The way we make foundations today show many similarities with the mediaeval way of making foundations. As a matter of fact the principle itself probably goes back as far as ancient Romans since the foundation of villas and “insulae” (3-7 storied housing blocks) constructed in about 100 A.D. have “opus caementicium” beams with a kind of masonry on top to support ground floor and wall. This principle still serves as a model for present-day foundation in housing. Of course there have been numerous improvements, mainly in the last decennia, but these are primary alternatives for concrete beam or formwork, not regarding the composition itself. The original principle is designed for work done by hand and hardly changed by contemporary possibilities. As a consequence today’s foundation work is fragmented and inefficient but this is hardly noticed in building practice due to common habituation to the arisen situation.

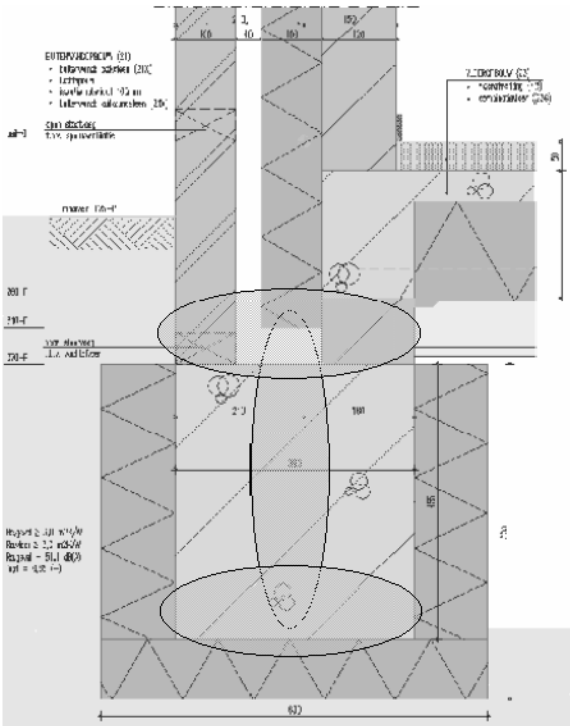

Figure 2:cross-section that is needed to meet demands of prescribed depth/width

1.3 A New Foundation as an Alternative for Inefficient Practice

Although it is obvious that the sight of a traditional foundation site displays a traditional scene with many fragmented activities few studies are known regarding alternative foundation methods. This is not explained by excellent performance of the traditional set-up as a study in 2001 observed at least 20 separate activities that have to be organised by a building company to make a “simple” strip foundation and about 25 separate activities for a regular foundation on piles [2]. With this in view the newly developed foundation method for housing was not only focussed on accuracy but also on improving efficiency. This became possible by applying fully prefabricated parts (of integrated formwork and reinforcement) and because the sequence of pouring concrete and refilling soil was swapped to get the required accuracy. This foundation principle is explained hereafter. The major improvement regarding efficiency is in excavating (excavator that dig and refill at once and thus completes all work in one activity), in omitting labour-intensive bricklaying and in reducing pouring of concrete (ground floor poured at the same time as foundation beam). Furthermore building organisation is simplified as the foundation is developed to be contracted out to a subcontractor resulting in only one activity for the building company to organise (instead of 20-25 in a traditional setting). This does not mean that difficulties are passed on to a subcontractor since the subcontractor can finish all work on site with two persons in running actions and with only four activities to organise (as sending for a plumber and ordering a truck mixer).

1.4 Inefficient Use of Material

Figure 2 shows a model regarding the effective cross-section of foundations. On top a width of 400 mm is required (to support brickwork wall and ground floor). The depth requires some 650 mm in the Netherlands to get a frost-free support. The base width depends on the foundation type: about 400 mm for a foundation on piles and 400-1200 mm for a strip foundation. The remaining I-shaped beam is almost equal strong and stiff compared to a common used rectangular beam but saves about 30% concrete.

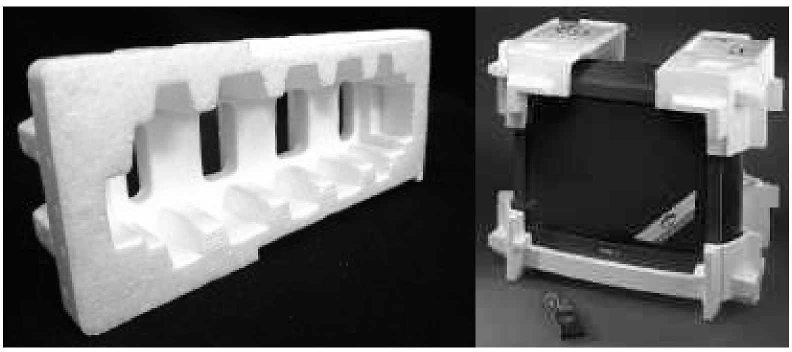

Figure 3: The idea of shells (figure 4) is picked up from packaging where EPS enables a complex form at very little expense (if mass-produced)

The detail in the background of figure 2 shows a permanent formwork made of rigid insulation material (expanded polystyrene-EPS some 100-120 mm in width) that is common used in the Netherlands. Here the thickness of EPS is governed by temporary loads of liquid mortar pressure. After hardening the EPS formwork is still useful as thermal insulation to reduce temperature drop nearby the skirting (a lower temperature might cause internal condensation). However the thickness of the permanent formwork required to resist the temporary loading is far too excessive for a later insulation use.

2. Three-dimensional Shells Used as Permanent Formwork

This paper describes a new foundation method with a typical feature of a swapped sequence of pouring concrete and refilling soil. For this purpose a permanent formwork is developed that is largely defined to resist temporary loading of refilled soil. The load of refilled soil mainly applies horizontal on both sides of the formwork. The easiest way is to link both sides of the formwork, and simply balance horizontal loads.

Linking both sides of a formwork is achieved by applying the principle of a truss structure (figure 1) to the I-shaped beam in figure 2. Forming a concrete beam as truss brings repeated spots in between diagonals, verticals and horizontals where connectors can be located to link both sides of the formwork. Just one step further is to apply three-dimensional shells with bulges in between diagonals, verticals and horizontals where both sides of a formwork can meet (figure 4). Implementing this truss structure is combined in this study with possibilities of shaping an EPS-shell in a mould. Figure 3 shows examples of three-dimensional foam elements used as packing material of a television set made of expanded polystyrene (EPS). Each element is shaped in a mould and in large numbers produced at very little expense. In packaging elements of EPS even can be very large up to (lxbxd) 2000x1200x450 mm^3 in a variety of possible shapes.

Because areas in between members of the truss (where horizontal load of refilled soil is balanced) are of reasonable size it is possible to leave openings in the EPS form (figure 4). These openings can be used to pass sewage pipes (and other pipes that have to be conducted through a foundation beam) at intervals of 0,3 m without specific adjustments during prefabrication.

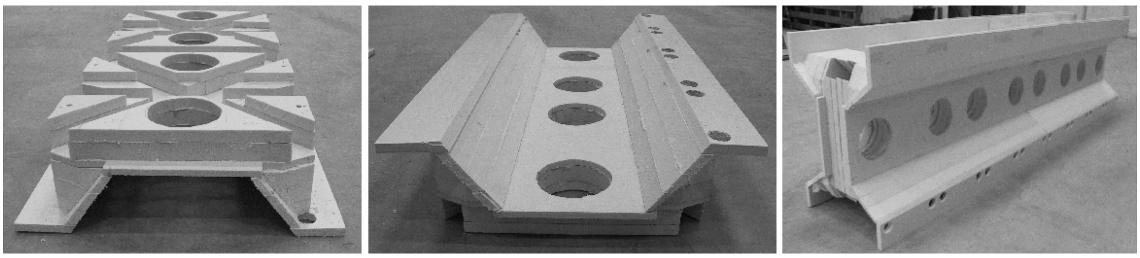

Figure 4:Three-dimensional shell as side panel of formwork. Left: seen from the inside. Middle: seen from the outside. Right: Two shells combined enabling prefabricated formwork

The three-dimensional shell (figure 4) is developed with various aspects at the back of mind:

- to save concrete by applying I-shaped beams with a truss structure put in place of the web;
- to save EPS by reducing thickness and by openings (advantageous since material costs of EPS is of the same order as material costs for concrete) ;
- to develop a standard shell fit for mass-production;
- to make solid prefabricated components out of the standard shells (put mirror wise in a row with large faces of contact);
- to have prefabricated reinforcement slot into the shells (with suitable concrete cover);
- to have openings at intervals in prefabricated formwork, enabling (sewage) pipes to be conducted through at numerous locations without special provisions (maximum Ø125 mm);
- to balance temporary loads of soil on both sides of the formwork (to save EPS, to minimize groundwork and to start with a well supported form when creating an accurate foundation);
- to have openings that can let through liquid mortar (and also have openings for compacting so the concept does not solely depend on self compacting concrete);
- to have minimum labour on site.

Another three-dimensional EPS-form is developed to be used as edge form of concrete mortar poured on top of the ground floor. This form (figure 5 and 6) will be put on top of two EPS-shells. There are two longitudinal notches on both sides to create a good-glued connection to the side of two EPS-shells that are put vertical. By means of covering rigid EPS-shells by rigid EPS-edge forms and by glued connections the prefabricated formwork becomes quite solid (if coinciding overlap of endings are avoided).

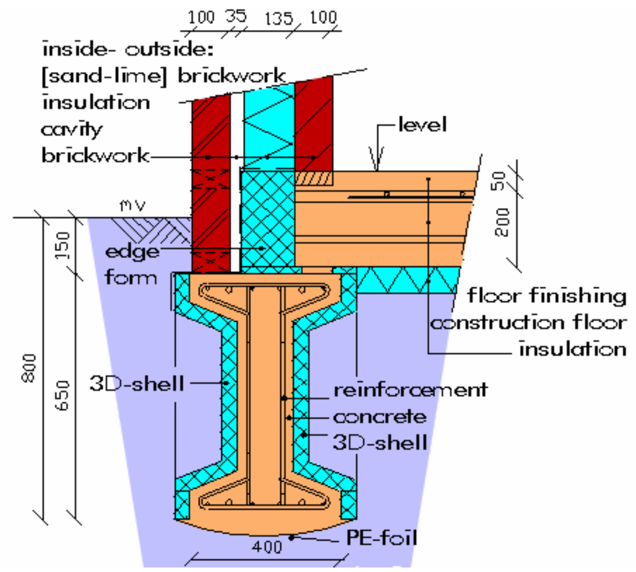

Figure 5: Detail of brickwork wall. 3D-shells, reinforcement and edge form are prefabricated. Concrete is poured on top of the floor and runs through openings of the EPS-edge form.

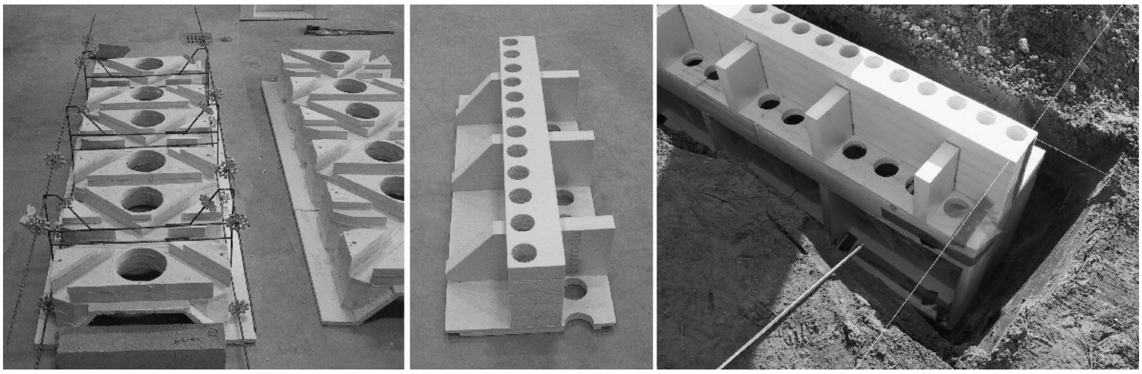

Figure 6. Left: three-dimensional shells put in a row with reinforcement put in. The formwork is closed and fixed by other shells and than turned a quarter. Another form (shown in the middle) is put on top. Middle: three-dimensional form used as edge formwork for ground floor. Right: prefabricated formwork brought to a building site and put into an excavated trench.

Although the edge form is primarily needed for pouring a ground floor (figure 10) it will also serve as cavity insulation after mortar is cured. In this respect the EPS-edge form connects the insulation underneath the ground floor with insulation in the cavity wall making a closed insulation layer (except for the small openings explained hereafter).

A third function of the EPS-edge form is to simplify progress of work for pouring a foundation beam. For this reason some openings are left in the lowest part (middle in figure 6) to let liquid mortar trough. With these openings it is possible to pour concrete mortar on the ground floor (figure 10) to fill the formwork of the foundation beam. In this way the ground floor acts as buffer when ground floor and concrete beam are poured simultaneously. And the row of openings in the top part of the EPS-edge form (as can be seen in the middle of figure 6) is meant to let through a vibrating needle for compacting mortar (as can be seen in the middle of figure 10). The vibrating needle can reach mortar at the underside of the foundation beam through verticals of the truss. Since the position of an EPS-edge form is not subjected to positions of three-dimensional shells the location of an opening and a vertical may change. For this reason a row of openings is provided so one of the openings is always located above a vertical. The practical test proved that these provisions are well applicable to get a good compacting. But the practical test also revealed that the openings turned out convenient because it provided a good visual check of the progress of filling the foundation beam.

Figure 7: The excavator makes trenches, puts formwork in and refills in running actions.

Figure 8:Left: the excavator is used to put in the prefabricated formwork. Middle: Formwork with refilled soil. Right: Next the ground floor is prepared, here a PS-combination type is used.

In developing the EPS-edge form special attention was paid to resist the effect of communicating vessels since the level of concrete mortar on the inside (floor) was some 250 mm above the level of the foundation (see also figure 5). In particular regarding the high specific gravity of mortar the different level was well considered. In the test seepage of mortar is barred by a proper glued connection of edge form to three-dimensional shell. Also the weight of mortar itself that rests upon the EPS-edge form helps to keep a closed formwork. The practical test (figure 10 and 11) showed that mortar pressure did not affect the form since seepage was not observed.

3. Practical Test

Students have carried out a small pilot project on the campus of Eindhoven University of Technology to study practical applicability of the developed foundation concept. All three-dimensional forms were made out of stacked Styrofoam sheets of 20-50 mm in width. There were two different types of EPS-shells and so also two different types of truss compositions made and tested. For the reason that the three-dimensional shape of the shell in figure 4 and 6 (resulting in the truss shown in the middle and right in figure 11) was rather complex to make out of stacked sheets the number of shells was reduced. As a result the length of this foundation beam is reduced to 1,8 metre. The main subject of research regarding this foundation beam is to test concrete filling of the quite small verticals, diagonals and under chord of the truss by practical experience.

The other type of truss (left in figure 11) was less difficult to compose out of stacked sheets so the length of this foundation beam is made 4,2 metre. In between the two foundation beams there is a small ground floor (PS-combination floor) with a span of 1,5 metre. Figure 6 shows prefabrication of formwork and putting in reinforcement. These photos do not show plastic foil that is attached to the underside of the shells (drawn in figure 5) to separate mortar from soil when pouring.

Figure 7 and 8 shows activities on site that took about 2 hours. The activities on site started with preparation of the site for building by a mini-excavator. After that the mini-excavator made a trench. Then the prefabricated formwork was picked up by the mini-excavator and placed into the trench. The prefabricated formwork had special provisions for exact positioning. The description of this falls outside the scope of this paper. When the formwork is positioned the mini-excavator immediately refills soil to fix the formwork.

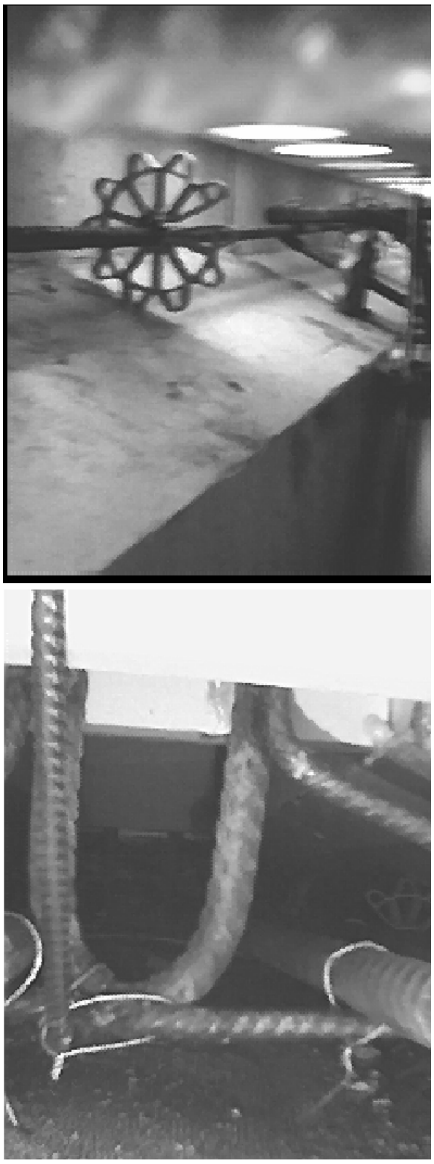

Figure 9: photo’s inside a foundation beam (after refilling soil and before pouring mortar). Above: part of top flange of I-shaped beam. Below: part of bottom flange.

The second formwork is handled in like manner followed by placing the elements for the ground floor. The next step could have been pouring concrete, but since this was a pilot project the procedure was stopped to allow inspection and documentation. Inspection of the hollow section of the formwork was carried out several days later by a small video camera that was inserted through the openings in the EPS-edge form (figure 9). These video recordings showed no signs of pushed in insulation (for instance by loading of refilled soil). All reinforcement was still in its place with sufficient cover and also the bottom reinforcement was far-off from the subsoil. The PE-foil functioned well as separator of soil and mortar. Also all displacements of the formwork were measured to study the accuracy of this foundation method.

The next day concrete mortar was poured. This took about ½ an hour and is shown in figure 10. The concrete mortar directly ran out a truck mixer on top of the ground floor. A vibrating needle and shovel was used to displace mortar to all sides to flow into the hollow section of the formwork. It was observed that mortar flew well and could be well compacted by the vibrating needle via openings in the EPS-edge form.

Figure 10:Left: Mortar is poured on top of the floor. Middle: Mortar flows into the foundation with openings that make compaction possible. Right: Finished floor and foundation.

Three days later the foundation was dismantled. Both foundation beams were dug out and brought to the laboratory (figure 11). After removing all insulation covering it was found that both forms were completely filled with mortar and irregularities were not observed. The foundation beam of 4,2 metre in length will be tested in the laboratory in near future.

Figure 11: (Left:) the foundation beam is dismantled afterwards. (Middle:) and EPS-formwork is removed. (Right:) showing a completely filled beam with I-shape and truss structure.

4. Further Continuation

Since the small-scale test indicated serviceability in real practice, a patent is applied regarding working procedure and developed forms. The next study to carry out regards building economics. Based on observations and time registrations of the pilot project a comparison will be made to find the range of possible savings as regard to traditional foundation methods. A second study regards the development of strip foundations and also of specialities. Also optimising the prefabricated reinforcement will be further developed.

It is expected that the shape of all three-dimensional forms will be adjusted by the outcome of these studies. Next aluminium moulds shall be developed to enable large-scale manufacturing of

EPS-shell and edge form. After that more practical test can be performed to study new possibilities of this foundation method.

5. Conclusions

The practical serviceability of a new foundation method for housing is demonstrated by a small pilot project resulting in savings of concrete (some 30%) and less labour on site (some 50%). All requisites are standard elements manufactured beforehand (so this foundation method is prepared for prospective mass-production) and assembled as prefabricated formwork based on specific project requirements (so also irregular lay-outs can be realised). On site all activities can be carried out in running actions by a team of two persons (excavation worker and excavator machinist). This enables foundation work to be contracted out. The result is a more efficient organisation of foundation work.

Using the ground floor as buffer when pouring concrete mortar makes progress of work easier. Furthermore this enables simultaneous pouring of foundation beam and ground floor.

The pilot project shows promising applicability of the foundation method. Yet further study and practical tests are required.

Productivity and Performance Improvement

Is Performance-Based Procurement a Solution to Construction Performance?

Abstract

There are two ways to analyze the problem of construction nonperformance (not on time, not meeting the quality expectations of the owner, and not having cost increase change orders). The first is a project-specific approach, which assumes that the problems are being caused by the uniqueness of each project. This approach stresses: finding solutions in better trained personnel and craftspeople, more standards, construction management, and inspection. The other is a process approach, which assumes that the problems are being caused by the process. Performance-based procurement uses the process approach. It hypothesizes that the current price-based design-bid-build procurement process is inefficient, supports an adversarial environment, is devoid of performance information, is highly inefficient, maximizes management and inspection instead of quality control, and treats highly differential construction products and services as commodities. The Performance Information Procurement System (PIPS) was created to resolve these issues causing construction nonperformance. The results of 380 tests of construction procurement will be assessed in terms of performance. Using case studies from a variety of large clients, the results of performance will be analyzed in terms of on-time, on budget, and meeting customer expectations. Lessons will be drawn on the cost of performance, the minimization of client management and inspection, and the creation of a "win-win" relationship of best value for the owner while concurrently maximizing the contractor profit.

Keywords: Performance results, performance based procurement, construction delivery process, Six Sigma process application

1. Introduction - Construction Industry Performance

For the past twenty years, the construction industry has attempted to improve its construction performance (finishing on-time, minimizing change orders, and meeting customer's expectations). In both the United States and in the United Kingdom, overall performance has hovered between the 60% - 70% range for owner satisfaction [5, 16, 20]. The performance issues can be summarized by the following numbers:

1. 33% of projects in the US end over budget.
2. 53% of clients in the US do not want to have a relationship with the contractor at the end of construction.
3. Only 68% of clients in the UK would give a 8/10 rating or better on satisfaction.
4. Only 45% of clients in the UK stated that the costs were on target
5. Only 62% of clients in the UK stated that the projects were completed on time.

The construction industry has tried various solutions to improve construction performance. These have included continuous improvement, partnering, business process re-engineering, just-in-time construction, lean construction, prefabricated systems, and long-term partnerships. Although each solution may have improved construction operations, the general problems of nonperformance have persisted.

1.1 Influence of the Worldwide Competitive Price Pressures

The construction industry is guided by two major factors: competition and performance (Figure 1) [11]. In Figure 1, Quadrant III represents the construction industry structure before the advent of the worldwide, highly competitive marketplace. Clients or building owners selected performing designers and contractors. Terms were negotiated, and the construction was completed. Hiring was based on performance before price. These designers and contractors had highly skilled personnel and craftspeople that did their own quality control.

With the worldwide competitive marketplace, clients sought to procure a better value. The intention was to keep high quality, but increase the competition (moving from Quadrant III to II). However, the inability to identify and measure the difference of performance resulted in the awards being price based. Instead of moving from Quadrant III to II, the majority of clients moved to Quadrant I.

Quadrant I is a price-based, commodity environment. A price-based environment is only optimal when the products and services are true commodities. Commodities are described using minimum standards and requirements. The best value is the lowest price. Procuring construction as a commodity forces the contractors to provide the given acceptable performance at the lowest price. The client's representative (architect/engineer) uses minimum standards to reduce the risk of receiving a lower quality product. Figure 2 shows an example of four contractors, each with different levels of performance ability for a particular project. The specifications (input based specs (USA), not output based specifications as are common in the UK) put forward in the contract documents dictate a specific level of performance quality. To reduce costs and the chance of a successful bid, the contractors with a greater level of ability for the given project (quality, speed, expertise) lower their performance to the level of the specification. Thus, the contractors (and manufacturers providing the construction products/materials) use the minimum expectation as a maximum level (in order to maximize their profits and likelihood of a successful bid). By awarding to the lowest bidder, performance is guaranteed at only the lowest possible level, which maximizes the client's risk of nonperformance by a contractor. The resulting difference commonly causes an adversarial relationship (Figure 3) where the owner see the stated specifications as a minimum level of quality while contractors (and suppliers, manufacturers, etc.) see it as a maximum level of quality [9].

Figure 1. Construction Industry Stability

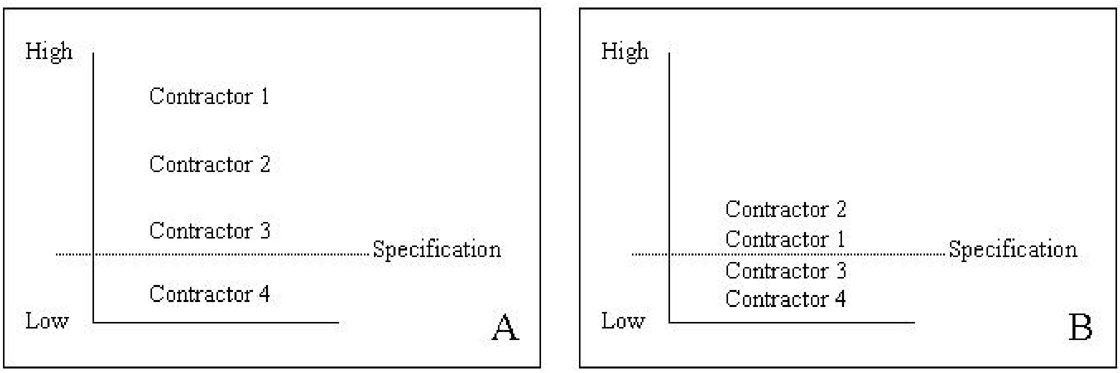

Figure 2. Impact of Minimum Standards on Performance

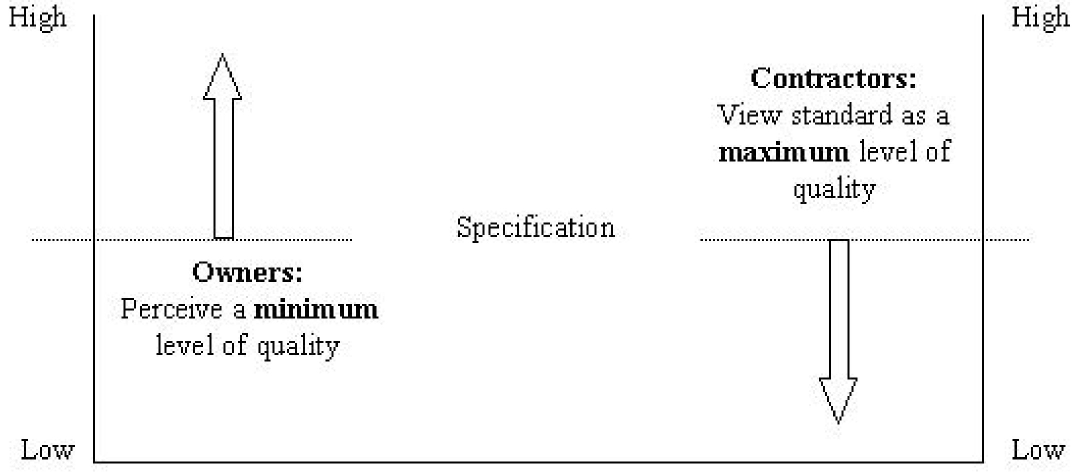

Figure 3. Owners vs Contractors: Difference in Objectives

1.2 Project Specific Approach: Construction Management and Expertise

The industry has tried to solve the adversarial, high risk environment by hiring experts who uses their expertise to differentiate every type of construction, set technical standards in each specialty; create means, methods, and material specifications; prequalify contractors; and manage, control, and inspect the contractor using technical expertise, thereby theoretically eliminating as must risk as possible. Ironically, their chief weapon, the minimum standards are a major source of risk [11]. Offering a higher performance (in a price based, Quadrant I environment) is a noncompetitive practice. This concept helps explain some of the bankruptcies of experienced construction businesses that have been in the industry for over ten years [3].

When standards are used, it forces the client to inspect in terms of means, methods, and materials (MMM). Minimum standards have no correlation to performance [2, 6, 13, 14, 21]. Standards and specifications also allow contractors who do not have experience to bid the project. The award to the low bidding, inexperienced low bidder may actually result in a higher project cost. This environment, with it poor performance results, threatens the sustainability of low-bid construction. The risk can also be identified by the high costs to sureties in both the bonding and insurance payouts [18, 15, 3]. Due to these factors, the authors hypothesize that performance has no direct correlation with awarded price. Therefore, if price does not affect specified performance, high performing contractors do not require external management and inspection. High performance contractors will quality control their own work. They minimize the performance risk with expertise and quality control.

The authors propose that by moving to a Quadrant II, performance based environment, the efficiency of the construction process will increase, minimizing performance issues. By hiring experienced personnel and contractors (which need less control, less management, and less inspection), the contractors will maximize their profit, and the owner will get best value. The authors are proposing that the effort to minimize construction performance issues using a project specific approach (Quadrant I) has proven to be inefficient and ineffective. A process based solution (Quadrant II) is required.

2. Process Based Solution: PIPS

To investigate process based performance procurement in comparison to current low-bid practices, the Performance Information Procurement System (PIPS) was designed in 1991 and has since been tested, modified, and retested 380 times over the past ten years. It is a Six Sigma based process that defines the process, measures the critical elements and the level of risk, analyzes the process using fuzzy logic, forces improvement, and controls deviation through process control (fundamentally Six Sigma's DMAIC (Define, Measure, Analyze, Improve, Control)).

The ten year, $4.2M research effort has involved the procurement of $230M of construction, and has resulted in over 80-refereed conference and journal papers. The fundamental hypothesis (construction nonperformance is a process based problem) has not been altered over the ten years, even though steps in the process has been improved through trial and error.

2.1 Research Hypothesis

Research Hypothesis:

1. Construction performance is mainly a process issue.
2. The critical element is identifying and competing performing contractors.
3. Management/control by the owner should be minimized [4].
4. An efficient environment will lower cost, deliver best value for the owner, and maximize the contractor's profit.
5. Risk should be minimized by contractors rather than clients.
6. Prequalification is only used when the process is price based.

Under the above hypothesis, PIPS was formed and is composed of five major filters of procurement (contractor selection) that seek to test the hypothesis. These major components or filters of performance based procurement are:

1. *Identification of past performance*. Past performance includes frequency of on time completion, minimal change orders, and high customer satisfaction of critical project performance elements (general contractor, site superintendent, project manager, and mechanical, electrical, waterproofing and other critical subcontractors).

2. *Project specific capability*. This is defined as the capability to identify, prioritize, and minimize the risk of the project in the non-technical terms of cost, time, and quality expectation.

3. *Competition based on performance (past performance and ability to minimize risk) and price*. The prioritization is done using a multi-criteria decision making model, which minimizes risk of nonperformance by giving credit to the identified critical past performance elements (recorded values of filters one and two). This model does not penalize values which are near the mode, but penalizes values that are below the mode. The processing of values forces contractors to provide their best value, and compete with every other best value, resulting in a two step best value process.

4. *Pre-award phase*. The best value contractor (as identified by the multi-criteria decision making model) must minimize the risks identified by all competitors. They must coordinate the requirements between critical elements, clarify or seek clarification on the project. The contractor will then sign a contract that includes their risk minimization plan, the intent of the owner, and all clarifications.

5. *Construction*. The contractor is forced to manage the project in terms of risk. The contractor passes risk information (affecting cost, time, and quality expectation) to the client's representative.

6. *Measurement of performance*. The project will be rated after completion. All critical elements of the general contractor's team will receive the same performance rating. The rating becomes up to 50% of the critical element's future performance rating.

3. Testing – Application of PIPS

Testing of PIPS was accomplished via its application on real projects for contractor procurement. Testing has been conducted over a ten year period in the public and private sectors for the following clients: Intel, Motorola, Boeing, Burr-Brown, International Rectifier, Honeywell, State of Wyoming, US Army Medical Command, Federal Aviation Administration, State of Utah, United Airlines, State of Hawaii, University of Hawaii, State of Georgia, Wyoming National Guard, Dallas Independent School District, Denver Hospital Group, Harvard University, and the US Coast Guard.

Over 380 tests and $230M of construction projects were procured using the PIPS system. The overall performance results of PIPS tests were:

1. No evidence that the first cost of the performance-based awards was more expensive than the costs of the low bid award. The Civil Engineering Unit of Oakland, CA of the US Coast Guard (USCG) concluded, via a cost analysis of PIPS awarded projects and non-PIPS awarded projects for the USCG, that PIPS represents a savings as large as 19% for a project's life cycle costs compared to low-bid or non-PIPS procurement [17].

2. PIPS showed 98% performance, where performance is given as projects that were delivered on time, with no contractor generated cost change orders after the pre-award phase, and

high customer satisfaction. This is in comparison to the documented performance of 60 – 70 percent performance of construction in both the United States and the United Kingdom.

3. Increased performance of contractors over time or in comparison with their performance in the low bid environment.

4. Contractors performing to a higher level in the PIPS environment than in the low bid environment. This includes perceived higher performance of the same contractors in the PIPS environment than in the low bid environment.

5. Construction management minimized up to 80%.

6. Minimized means, methods, and material details in design specifications.

7. Risk of designers was minimized due to the two levels of constructability review (business level review in the risk identification filter and detailed constructability review in the pre-award phase by the best value contractor).

The first repeat user of PIPS was the FAA Western Region (50 storm damage repair projects ($4M)) and the FAA provided no technical specification to the contractor. PIPS allowed the FAA engineering requirements group to increase the amount of work procured by 300 percent. Projects included building repairs, road repairs, and electrical and mechanical systems repairs. All the projects were finished on time, without change orders, while satisfying the clients.

United Airlines (UAL) was the next repeat user of PIPS (results shown in Table 1, where the owner rated certain items on a scale of 1-10 with 10 being the highest (most favorable)). As in the FAA projects, technical specifications were minimized. The process was tested on roofing, painting, waterproofing, flooring, abatement, and renovation/remodeling projects. The speed, efficiency, and minimized effort of PIPS decreased the overhead of construction delivery allowing more of the funding to go into construction.

Table 1: United Airlines Performance Based Results

NO	Criteria	Results
1	Total number of projects	32
2	Award Cost	$ 12,750,000
3	Low-Bid System of contracting. (Owner scale rated 1-10, 10 is max)	3
4	Performance Based System of contracting. (Owner scale rated 1-10, 10 is max)	9
5	Percent satisfied with PIPS	100%
6	Overall quality of construction using PIPS (Owner scale rated 1-10, 10 is max)	9
7	Percent of users that would hire the contractor again	100%
8	Percent of projects that finished on time	100%
9	Percent of projects that finished within budget	100%
10	Percent of projects with no change orders	100%

The State of Utah projects were the first large multi-million dollar projects (6 projects, $80M budget, the largest being $53M Olympic Village, Phase II). Due to the State's requirements, the projects had to be run without the most critical component of PIPS, the pre-award phase. Even though the capability of the process was limited, PBSRG ran the modified process to determine if PIPS could be used successfully on large projects with multiple subcontractors. The results were the best results (Table 2) at the State of Utah in ten years [1]. Without the pre-award phase, the contractors were not forced to find mistakes in the design documents before construction award. In the only project that was not completed on time or without change orders, the user stated that architect missed too many items for the contractor to cover [7]. The results reinforced the importance of the pre-award phase. The largest project, the $53M 2002 Olympic Village Housing project was awarded to the low bidder.

Table 2: State of Utah Project Results

NO	Criteria	Results
1	Total number of projects	5
2	Award Cost	$ 80,506,376
3	Budget	$ 85,770,000
4	Percent Under Budget	7% Under Budget
5	Low-Bid System of contracting. (Owner scale rated 1-10, 10 is max)	4
6	Performance Based System of contracting. (Owner scale rated 1-10, 10 is max)	9
7	Percent satisfied with PIPS	90%
8	Overall quality of construction using PIPS	9.2
9	Percent of users that would hire the contractor again	100%
10	Percent of projects that finished on time	80%
11	Percent of projects that finished within budget	80%
12	Percent of projects with no change orders	100%
13	Number of companies that were surveyed on past performance	357

The State of Hawaii ran the most projects (over 150) for the longest period of time (4 years) of the ten year test cycle. The test results were captured in the State's internal audit. The process eventually ended due to a change in political party and the appointment of a new comptroller who wanted to return to the traditional, technical based project approach. It is interesting to note that the State has been unsuccessful in finding a process that duplicates the results of PIPS. Their current inability to identify or use performance information, and the inability to document the performance of construction projects supports the authors' hypothesis that the owner does not know the value of construction in the priced based environment. The analysis of performance in the Hawaii tests were done in several ways:

1. Of the 55 roofing clients, 100% stated that the PIPS contractors' performance was excellent, 100% stated that they preferred PIPS over low-bid award, and 96% were satisfied with the quality of work [19].

2. Out of 20 inspectors, 100% were satisfied with the PIPS work, 94% stated that the PIPS contractors were more willing to perform, and 95% stated that PIPS required less work for their staff [12].

3. A transaction cost analysis was performed on the roofing PIPS projects and low-bid projects. The analysis concluded that PIPS resulted in over 13% savings in the first cost in comparison to low bid [19]. This did not take into account the increase in quality.

4. A comparison of 96 PIPS roofing projects documented that [19]: 98% of the roofs were completed on time, the contractors produced approximately twice as much work per day, and stopped the practice of the State repairing its roofs during the warranty period.

A project run at the State of Georgia was very significant since it allowed a clear comparison of the first cost of running PIPS versus the cost of low-bid on the exact same project. The procurement of the $45M construction of an environmental wet laboratory was bid twice using both processes [8]. The first round of bids was done using the PIPS process. The bid was rejected due to the perceived high cost. It was later identified that the project was over-designed. The project was redesigned cutting $4.5M from the project. It was re-bid and awarded using the low-bid process. The project was still over budget ($46.6M) and completed at $48.8M and late by 50% of the initial construction time. The project was finally completed with over $2.2 Million in change orders and approximately one year behind schedule. The State of Georgia ran a second, similar project using PIPS. After awarding to the best performer, they proceeded to manage and control the contractor as though it was a low bid contract. The client was impressed with the contractor but discouraged by the bureaucratic control by the State.

The Dallas Independent School District (DISD) implemented PIPS on nine roofing projects. The implementation illustrated several key concepts, including:

1. Contractors that DISD thought were very low performing (due to past low-bid work), were capable of performing very highly under PIPS.

2. Contractors and manufacturers did not know the performance of their roofs.

3. Contractors and manufacturers immediately began responding to problems that DISD had been requesting to be fixed for over two years.

Table 3 summarizes the results of the PIPS implementation at DISD [10]. The projects were completed on time, and 13 percent under budget. Once again, the first costs were lower for higher performance than the low bid prices.

Table 3: Dallas Independent School District Project Results

NO	Criteria	Results
1	Total number of projects	9
2	Award Cost	$ 4,205,208
3	Budget	$ 4,824,357
4	Percent Under Budget	-13%
5	Percent satisfied with PIPS	100%
6	Percent of projects that finished on time	100%
7	Percent of project that finished within budget	100%
8	Average user rating of low bid (Owner scale rated 1-10, 10 is max)	1
9	Average user rating of PIPS (Owner scale rated 1-10, 10 is max)	10

4. Conclusion and Recommendation

The process based approach of PIPS, based upon the nearly 400 projects run using the performance based system, seems to be far more effective in minimizing construction performance issues than the project specific, low-bid approach. The success of the PIPS system shows that the Quadrant I, technically oriented, price based construction delivery process may be the primary cause of construction nonperformance. PIPS is fundamentally a Six Sigma application that defines the process, measures performance at the right time by the right party, automated the analysis process using fuzzy logic, forced continuous improvement without management and control, and minimized deviation through the process control (DMAIC.)

What do Construction Workers do? Direct Observations in Housing Projects

Jesper Strandberg
Peab AB, Sollentuna, Sweden (email: jesper.strandberg@peab.se)
Per-Erik Josephson
Building Economics and Management, Chalmers University of Technology, Gothenburg, Sweden (email: per-erik.josephson@bem.chalmers.se)

Abstract

Industrialization is currently seen as one of the most important developments in the Swedish construction. All large construction companies have initiated processes for more prefabrication, especially in housing. The reason is to develop more lean processes as a way to increase the productivity and the profitability. In order to learn more about how productive and efficient their production processes really are, the Swedish construction company Peab has introduced short studies on how the time of construction workers is used on site. Full-time observers follow different work activities in housing projects and register what randomly chosen workers do every second minute. The purpose of this paper is to illustrate one aspect on how efficient the production is, by presenting how construction workers' time is used on construction sites. The results from the case project, which is presented in this paper, indicate that less than 20% of the workers time is spent on direct value adding activities for specific activities and that approximately 20% of the time is direct waste of time.

Keywords: Industrialization, productivity, construction workers, housing, work sampling

1. Introduction

The Swedish construction industry is often viewed as conservative and producing buildings on high costs. At the same time, the general opinion is that the industry is under hard competition and that the profit margins are low. In order to improve the productivity, the major construction companies make significant investments in developing the production towards more industrialized processes, especially in housing where repetition is obvious.

Peab is, next Skanska and NCC, the largest Scandinavian company in the field of construction and civil engineering. The group runs construction and civil engineering operations primarily in Sweden, but also in Norway and Finland. The group net sales are SEK 20 billion with about 10,000 employees. In order to learn more about how productive and efficient their production processes really are, Peab has introduced short studies on how the time of construction workers is used on site. Another reason for collecting empirical data from the construction sites is that Peab several times has realized that most employees don't accept improvement programs or specific projects aimed for improving certain processes. Empirical evidence would be helpful to initiate discussions about how to improve the processes.

The aim of this paper is to increase practitioners as well as researchers attention on the potentials to increase the productivity in construction. It is done by presenting empirical data from one housing project. The more specific aim is to identify what construction workers do in housing projects, especially (a) to identify the efficiency defined as the percentage of time spent on direct value adding work, but also (b) to identify the waste defined as the percentage of time lost.

The results indicate that the time spent on adding direct value into the building is surprisingly low. There are strong arguments for paying more attention on developing more industrialized processes in order to increase the efficiency and reduce the waste.

2. Labour Productivity

Construction workers in Sweden are, in an international perspective, well educated. Most of them have studied nine-year compulsory school and then three-year upper secondary school education. The workers have an open and fairly independent role on site. It's common that they get fairly much information about the project and that they take some part in planning and work preparations. There is a trend to include more managerial roles into the workers' tasks. Since the 1980's, most construction workers are employed with conditional tenure.

Considering construction workers, there has been a number of work sampling studies in the U.S. for the last 30 years. Allmon et al. [1] summarize the trends in U.S construction labor productivity for the period 1970-1998. A research group at University of Texas at Austin studied 72 projects during this period. The annual direct work mean values for these projects varied from 41 to 61%. This is in line with Oglesby et al. [2], who predict that direct work falls within 40-60% in most construction projects.

The activities of workers in these studies are typically divided into three categories, according to Allmon et al. [1]. Direct work includes productivity actions, picking up tools at the area where the work is taking place, measurement on the area where the work is taking place, holding materials in place, inspecting for proper fit, putting on safety equipment, and all cleanup. Supportive work includes supervision, planning or instruction, all travel, carrying or handling materials or tools, and walking empty-handed to get materials or tools. Delay includes waiting for another trade to finish work, standing, sitting or any non-action, personal time, and late starts or early quits. Inspired by popular literature and oral presentations about the Japanese car manufacturer Toyota, we believe that this structure is rather passive and must be developed further in order to strive for world-class productivity. Direct work should for example be divided in direct value adding work and indirect work.

Several authors discuss factors influencing the productivity. Allmon et al. [1] mention project uniqueness, technology, management, labor organization, real wage trends and construction training. Moselhi et al [3] study change orders impact on labor productivity. Ng et al. [4] take another approach and look at demotivating factors; rework, overcrowded work areas, crew interfacing, tool availability, inspection delays, material availability and foremen incompetence. According to Kaming et al. [5] bricklayers, carpenters and steel fixers in Nigeria rank lack of material, rework, absenteeism, interference and lack of tools as the major productivity problems.

3. Methodology

The approach we have chosen for the study, work sampling studies, could be criticized in several ways. Allmon et al [1] argues, for example, that work sampling only gives information about time spent on activities and therefore gives indirect information about productivity. However, they mean that direct work time does not necessarily correlate with unit rate productivity. The level of labor skill and the standard of equipment may for example influences the productivity without necessarily influence the volume of direct work. An advantage with the approach is that it is less controversial than other approaches such as output per time.

The study is limited to one housing project, which was used also for some other studies within Peab. Of that reason, the personnel on site were used to development work and various types of studies. However, an introductory discussion with the site managers and the construction workers were carried through in order to guarantee that they realized the aim with the study; to identify what the workers do as a consequence of the organization, the plans and the production systems, not how fast they work.

The data collection was performed as direct observations by one of the authors. Before the studies started he used a random table to systematically decide in which order the workers would be followed and for how many observations. During the observations he tried to stand and walk in such way that he influenced the work and the workers as little as possible. He experienced that they quickly accepted him as a part of a natural working situation.

The registrations were done exactly every second minute from 6.45 in the morning when the work started until 4.00 pm when the work finished. But if the work of some reasons began earlier in the morning or finished later in the afternoon he extended the observations to also include these periods.

Three building elements were chosen of practical reasons. These were studied during one week each during 2004.

The authors developed a code structure based on experiences from similar previous studies and on which activities were performed during the study, see Table 1. Every observation included six questions.

- Which date the observation was made, example yy-mm-dd.

- What time the observation was made, example hh-mm.

- Which construction worker to observ.

- Which building element the specific worker worked with. A detailed code structure was used.

- Which activity the specific worker performed. Six main groups of general activities were identified depending on if it was value adding work, preparations for value adding work or just lost time.

- Comments were made now and then in order to clarify what the workers did and also to note various reflections made during the study.

Microsoft Excel was used to analyze the data. A summary of the each week of study was presented for the workers followed by a discussion on what could be improved.

4. Results

4.1 Case: Area Folkparken

The case project is initiated and developed by Peab. The budget is SEK 64 million. The site is situated in Haninge, approximately 20 km south of Stockholm. The product is a house with external galleries and is designed to manage heavy traffic noise from one side. The gross floor area 5,159 m^2 and the gross building volume is 14,703 m^2. The project includes 82 tenant-owned flats with 1-2 rooms each. The building, which is divided in three parts with different numbers of storeys, has the form of an “S” in order to be experienced as more slender and better harmonize with the environment. The form of the building was one reason to that the distances on the site were quite long. The closest distance from the production site to the workers facilities was 70 m, to the site office 110 m, and to the stock of material 30 m. The distance between the north and south end of the building was 90 m. Peab’s site organization was in the beginning of the project one site manager, one site clerk, and one foreman.

Three elements of the building were studied:

- Load-bearing structure. The structure is in prefabricated concrete, which consists of a floor structure and load-bearing walls. The assembling of the structure was performed by six workers and supported by one manager.

- Roof. The roof is tin plated with low gradient. The roof trusses are wooden and prefabricated. The roof work, excluding tin plate, was done by Peab’s personnel. The number of workers varied from three to six. One manager supported the work.

- Exterial walls. The wall, which is not load-bearing, consists of a prefabricated wooden structure. It is internally covered by plaster and externally covered by mineral wool and plaster. The work was done by two to four workers and supported by one manager.

4.2 Results

In total, 4,979 observations were done during fifteen days of study, Table 1. However, the number of observations corresponds to almost 22 full working days, i.e. eight hours long days. The reason is that two teams of workers were studied in parallel for some days, and some working days were ten hours. Direct value adding work was on average less than 20% of the total time. Note that this group includes some corrections of defects. Indirect work, material handling and work planning is needed to be able to perform direct value adding work. These groups of activities corresponded to 45.4% of the workers time. 25.5% were spent on indirect work, which includes all kind of preparations in a few meters distance from the working spot. Indirect work included mainly handling of material and equipment, but also work with temporary constructions. 13.9% of the workers' time were spent on material handling, which includes transportation of material on the construction site. There are common that construction workers take part in the planning of the production on Swedish sites. In this case was 6.0% of the time spent on work planning. Waiting and unexploited time corresponded to as much as 33.4% of the workers' time. Almost 20% of the time was used to move between working spots and also moving before and after breaks.

Table 1: How construction workers use their time in load-bearing structure, roof and facade.

Activity / Element of building	*Load-bearing structure*	*Roof*	*Façade*	*All*

Total	100.0	100.0	100.0	100.0

5. Discussion of Results

We found that the direct value adding work was 19.5% of the construction workers time in this case. However, 2.0% of their time was spent on corrections of defects. Of that reason, the direct value adding work would be 17.5% of the time. This is surprisingly low percentage compared to the American studies, which reported 40 to 60% [1,2]. On the other hand, in this case we have followed the definitions of value adding work fairly hard. For example, if the worker picked up nails from the floor exactly when the registration was made we registered losses, even if it only took a few seconds to do it.

Looking at these figures we could argue that the efficiency was very low in this case. But we could also take the discussion a few steps further in order to carry the matters to an extreme for the company. During the time of the study approximately 6% of the employed workers were on sick-leave. If we include these workers we could argue that the direct value adding work for the company's construction workers are 16.4%! In the next step we could include the managers, who supported the workers. For the three building elements, there was approximately 1.0 manager per 4.5 workers. If we also include the managers on site we could argue that the efficiency is as little as 13.4% of the total time spent on site, Table 2.

Table 2: Direct value adding work from three perspectives

Direct value adding work	*(% of total time)*
Construction workers on the site	17.5
All construction workers employed by the company	16.4
All construction workers employed by the company + supporting managers on site	13.4

The wasted time is at least 19.1%, Table 3. Then we include correction of defects, all waiting except moving between working spots, and all unexploited time. The major areas of waste were moving in connections to breaks, waiting because of lack of work or instructions and correcting defects. The volume of wasted time is significantly higher than what has been reported in defects studies [e.g. 6]. Still, the volume could be higher if we analyze the reasons for moving between working spots, which corresponded to 16.3% of the workers time. Some of the preparations, i.e. indirect work, material handling and work planning, could also be consequences of problems occurred.

Table 3: Activities performed by construction workers divided into direct value adding work, preparations, moving between working spots and waste.

Activity	*% of total time*
Direct value adding work, excluding corrections	17.5
Preparations	45.4
Moving between working spots	16.3
Waste	19.1
Other	1.7
All	100.0

A great number of studies claim that a typical day for managers in general and also for site managers include numerous interruptions and change of activities [e.g. 6,7]. This study indicates that also construction workers seem to have very divided days. Figure 1 shows a typical eight-hour day at the site for a construction worker, excluding breaks for coffee and lunch. In this case the worker have changed activity at least 156 times during the day.

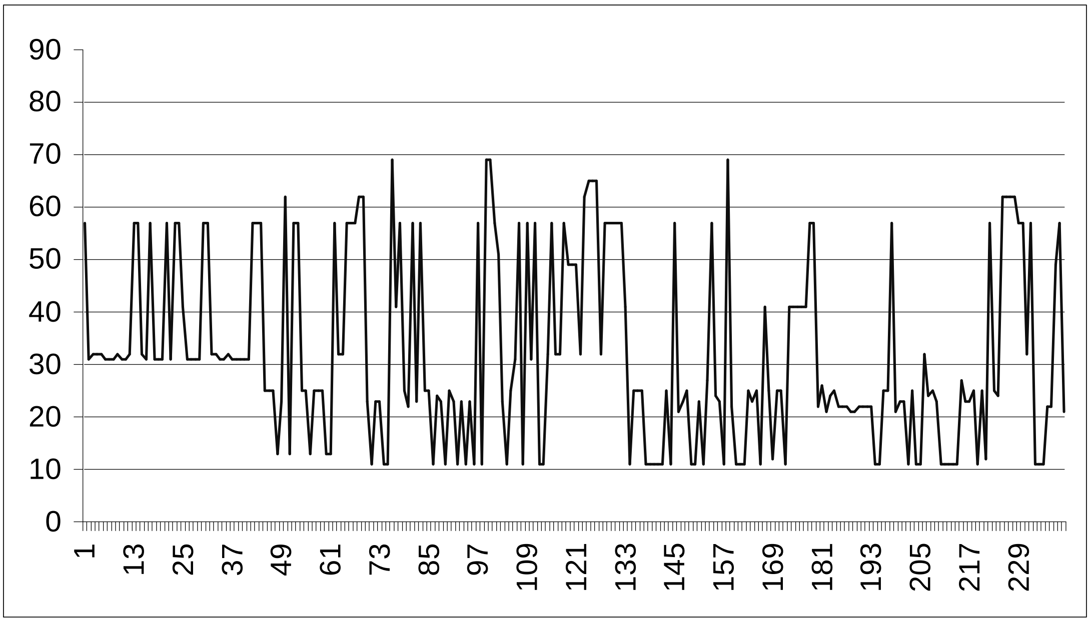

Figure 1: A typical eight-hour day at the site for a construction worker. The horizontal scale presents the number of minutes from start. The vertical scale presents the code for activities (see Table 1).

6. Conclusions and Recommendations

The aim of this paper is to identify how construction workers' time is used on construction sites, by making direct observations on site. The results form a strong argument for managers to pay far more attention on production processes than what is common today.

We have found that the efficiency is surprisingly low. Less than 20% of the workers time is spent on direct value adding activities. The obvious wasted time is approximately 20%, but will probably increase if we look closer at the indirect work and the handling of material and equipment. The typical day at work is divided and includes many different activities. The case considers a single housing project. However, the personnel within the project perceive it as quite normal. The results presented here should of that reason be considered as a typical example. There is a risk that the observer has influenced the team during the studies. We believe, however, that this influence is minimal. The main reason is that the study has been for such a long time that the individuals get used to people around.

The definitions of what is direct value adding activity, indirect work etc, has been quite hard in order to get as true picture as possible. We have experienced that practitioners tend to perceive indirect work and material handling as value adding. With influences from popular literature and a number of oral presentations about companies with more industrialized processes, especially Toyota, we have, however, decided to adhere to our original definitions.

The results indicate that further empirical data is needed in this area, as well as further analysis of the data, in order to better understand how much is wasted time, what kind of waste it is and what waste can be reduced or eliminated with existing production system as well as with other production systems.

The results have been an alarm for Peab. They have decided to also in future projects use the tool they have developed for work sampling studies about what construction workers really do. The approach is to make observations for a week and then analyze the data and go back to the site and discuss the results with the workers. On project level, the aim is to get the workers aware of the current situation and to get them create ideas of how to improve the situation. On firm level, the aim is to learn more about existing waste and how it can reduced.

Abstract

To forecast labor productivity indexes is a very important task to be performed, by the construction managers, in order to compose reliable building construction budgets and schedules. To do so, the main information sources have been the estimating manuals. These type of manuals are normally available in several countries, both developed and developing ones. The data, in such manuals, usually represent mean values for regional contractors performance. Although very easy to use, this approach, in the opinion of the authors, cannot be considered appropriate to the present context of Construction; the very competitive environment demands more accurate indexes to support managers' decisions.

Some recently developed researches, in Brazil, demonstrate the importance of considering a range of values to represent labor productivity unit rates instead of adopting a mean value for a broad scope of situations. The choice of a value from the proposed range would be based on the job's features.

Keywords: Labor productivity, productivity forecast, formwork, estimating manuals.

1. Introduction

The construction companies seldom measure the real productivity in their sites. So it is a current practice in Brazil to utilize productivity indexes gathered from estimating manuals to make budgets and schedules (Figure 1 shows the steps of a traditional budgeting process). These budgets and schedules are based on the physical resources consumption, which is composed by the labor, material and equipment consumption. This paper focus on labor consumption forecast for formwork job. Labor is the physical resource more difficult to manage and which demand have the highest variability. On the other hand, formwork is a labor-intensive task and often represents an event in the critical step of the project [1].

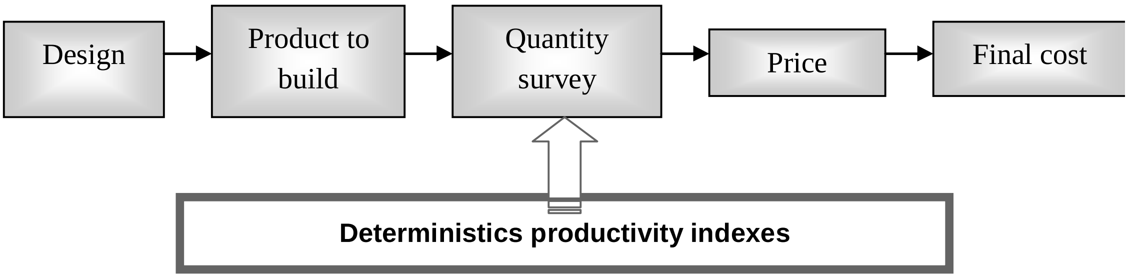

Figure 1: Traditional budgeting process

Two of the more important Brazilian estimating manuals, TCPO 2000 [2] and SBC [3], consider deterministic productivity indexes, as showed by the example in the Table 1.

Table 1: Productivity values formwork job taken from the main Brazilian estimating manuals for

Unit Rate (UR)	TCPO 2000	SBC		
	For whole formwork job	*For slabs*	*For beams*	*For columns*
Carpenter	1,35 Mh/m²	0,928 Wh/m²	1,268 Wh/m²	1,361 Wh/m²
Helper	1,35 Wh/m²	1,443 Wh/m²	1,773 Wh/m²	1,907 Wh/m²

*Wh/m² - Workhour per square meter of formwork

Authors as [4], do not indicate deterministic values on productivity forecasting. [5] emphasize that the simplicity on using deterministic approaches can be associate to a lost of precision on predicted productivities. [6] say that the costumers are not satisfied with the manuals values once they do not expose the job contend and context involved.

The high variability on productivity figures find representative of Brazilian building sites - that can reach 100%, according [7] e [8] - associated with the habit of using deterministic values and with an environment highly competitive generate a big insecurity on construction companies to forecast production costs. So, this paper intends to explore ideas linked to improve productivity forecasts to help the decision makers in the construction companies.

2. New Approaches to Forecast Productivity in Use in Brazil

The new approaches to forecast productivity discussed in this paper are based in the models prescribed on the literature (mainly on the Factors Model [9]) and on a productivity data base that have been collected since 1996 by the researches of the Department of Construction of University of São Paulo. The researches have been working on several different ways to of organizing productivity data to help the forecasting process. This paper discusses two of them: parametric equations developed by means of regression analysis and productivity range values associated to a list of factors that influence them.

The use of parametric equations was presented on [1]. Other research, as [11], added confidence to the statistical analysis. This paper deals with more recent parametric equations, as showed in 2.1 and productivity ranges on 2.2.

2.1 Parametric Equations

The unit rate for column, beam, slab and stair can be calculated by the following expression:

- ***bUR forecast - column***

$$bUR_{column} = 1.885 + 0.131BLE - (4.67SAR + 0.274BPL + 0.11TIE + 0.27LTI) + STR_{column} \quad (1)$$

Where:
UR = Productivity Unit Rate
bUR = Baseline for the skilled team
BLE = 0 when column leveling is based on each panel leveling; and =1 when column leveling is based on template leveling;
SAR: median cross-section area (in m^2);
BPL = 1 when column plumbing is based on studs plumbing; and =0 when column plumbing is based on whole panel plumbing;
TIE = 0 for removable ties; and = 1 for incorporated ties;
LTI = 1 for predominantly external ties; = 0 for predominantly internal ties;
STRcolumn = part of bUR referring to the column forms stripping. The proposed values for "STR" vary as showed by Table 2. One should choose higher whenever expects more difficulties in stripping the panels.

Table 2– "STRcolum" values variation range.

Minimum (wh/m^2)	Median (wh/m^2)	Maximum (wh/m^2)
0.13	0.14	0.30

- ***bUR forecast - beam***

The unit rate can be calculated by the following expression:

$$bUR_{beam} = 2.43 - 0.558BL + 0.267TU + STR_{beam} \quad (2)$$

Where:
BL = median beams length;
TU = 0 for when no tie is used; and = 1 for ties utilization;
STRbeam = part of bUR referring to disassemble beam forms. The proposed values for "STR" vary as showed by Table 2. One should choose higher whenever expects more difficulties in stripping the panels. The proposed values for "STR" vary as showed by Table 3. One should choose higher whenever expects more difficulties in stripping the panels.

Table 3– "STRbeam" values variation range.

Minimum (wh/m^2)	Median (wh/m^2)	Maximum (wh/m^2)
0.10	1.18	2.60

- ***bUR forecast - slab***

Floor structures with close slabs and beams raise difficulties in pulling down the formwork, inducing poor productivities (higher UR's). Table 4 presents some bUR values for slab formwork in conventional structures, where slabs rely on beams, and in plain slab structures, where slabs rely directly on columns.

Table 4 – bURslab values variation range.

Floors	**bUR_{slab}** (wh/m^2)	
Conventional structure (slabs with beams)	Minimum	0.40
	Maximum	0.96
	Median	0.69
Plain slab	Median	0.33

- ***bUR forecast – stairs***

bUR_{stairs} forecast can be based on the Table 5 information.

Table 5 – bURstair values variation range.

Stairs formwork	**bUR_{stair}** (wh/m^2)	
During the floor production	Minimum	1.78
	Maximum	2.64
	Median	1.93
After the floor production	Median	1.00

- ***bUR forecast – whole structure***

The $bUR_{whole\ structure}$ is calculated by the expression 3:

$$bUR = \frac{(bUR_{column} xA_{column} + bUR_{beam} xA_{beam} + bUR_{slab} xA_{slab} + bUR_{stair} xA_{stair})}{A_{column} + A_{beam} + A_{slab} + A_{stair}} \qquad (3)$$

Where:

bUR= baseline for the skilled team

A= area (m^2 of structure).

2.2 Productivity Range

Labor productivity figures are presented by mean of a “ruler”, having the minimum and maximum values of the database at the extremes and the medium value pointed out in the between. The “ruler” comes with the indication of the factors driving the expected rate towards right (unfavorable ones) or left (favorable ones), as shows the Figure 2.

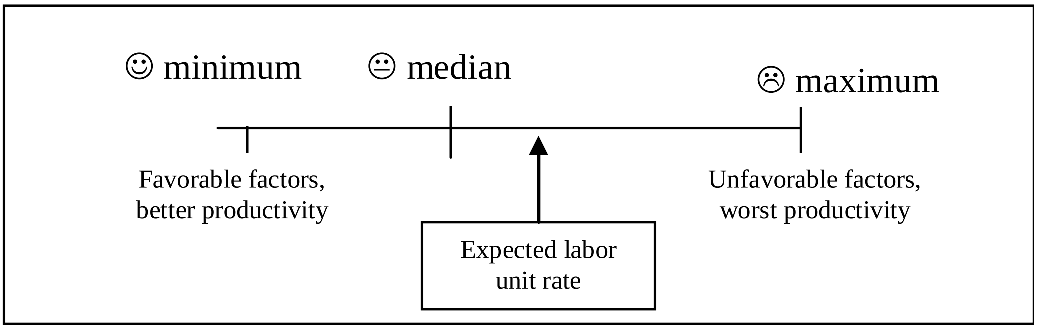

Figure 2: Concept of variable productivity range, Fonte: SOUZA et al.(2003)

In the Figures from 3 to 6 are presented labor productivity indexes range to carpenters of formwork job. The job envolves 4 tasks: column formwork (Figure 3), beam formwork (Figure 4), slab formwork (Figure 5) and stair formwork (Figure 6).

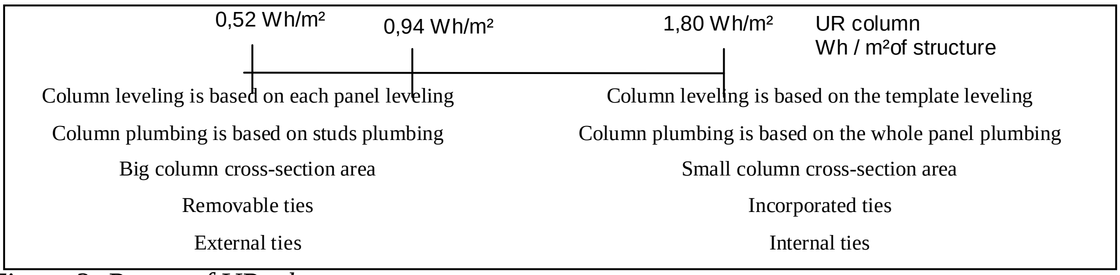

Figure 3: Range of URcolumn

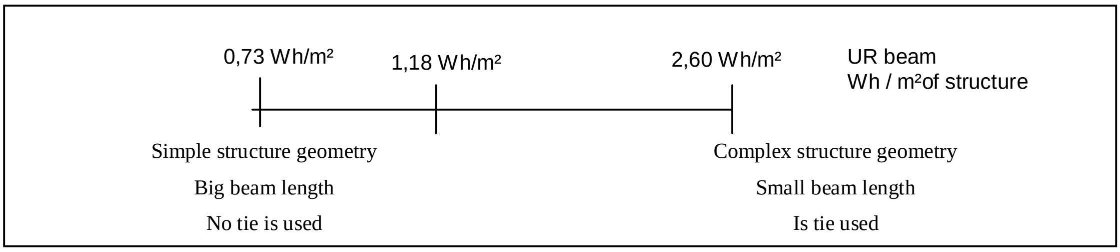

Figure 4: Range of URbeam

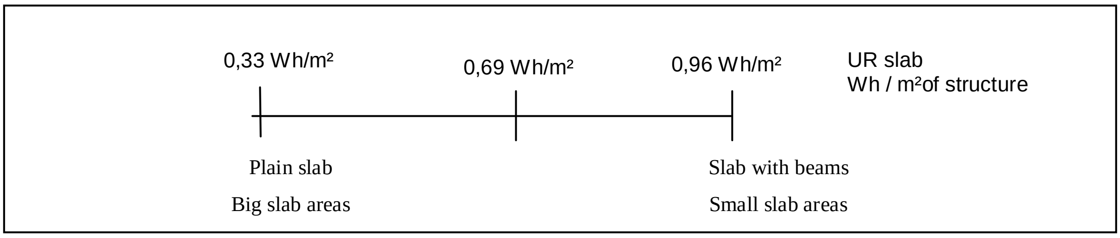

Figure 5: Range of URslab

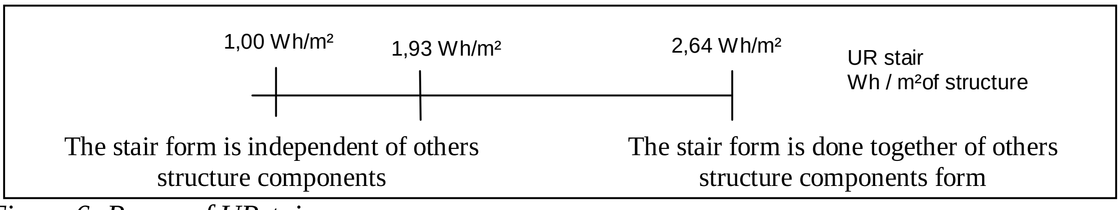

Figure 6: Range of URstair

Observe on Figure 3 that the median value is 80% superior to minimum and the maximum value is about 90% superior that median; this demonstrates the fault that we can do when the median value is chosen in situations in which one of the extremes were expected.

Any value within the range is accepted as possible value for productivity, although the expectations for the best or worst results involve other subjective factors.

In order to know the UR for all structure formwork, it should be done using the Equation 3. It will be necessary to chose on ranges what productivity better adequate to your build (minimum, median or maximum) and to know the dates of quantity extracted from projects.

3. Evaluating the Applicability of New Forecasting Approaches

The new approaches were tested following the steps of Figure 7.

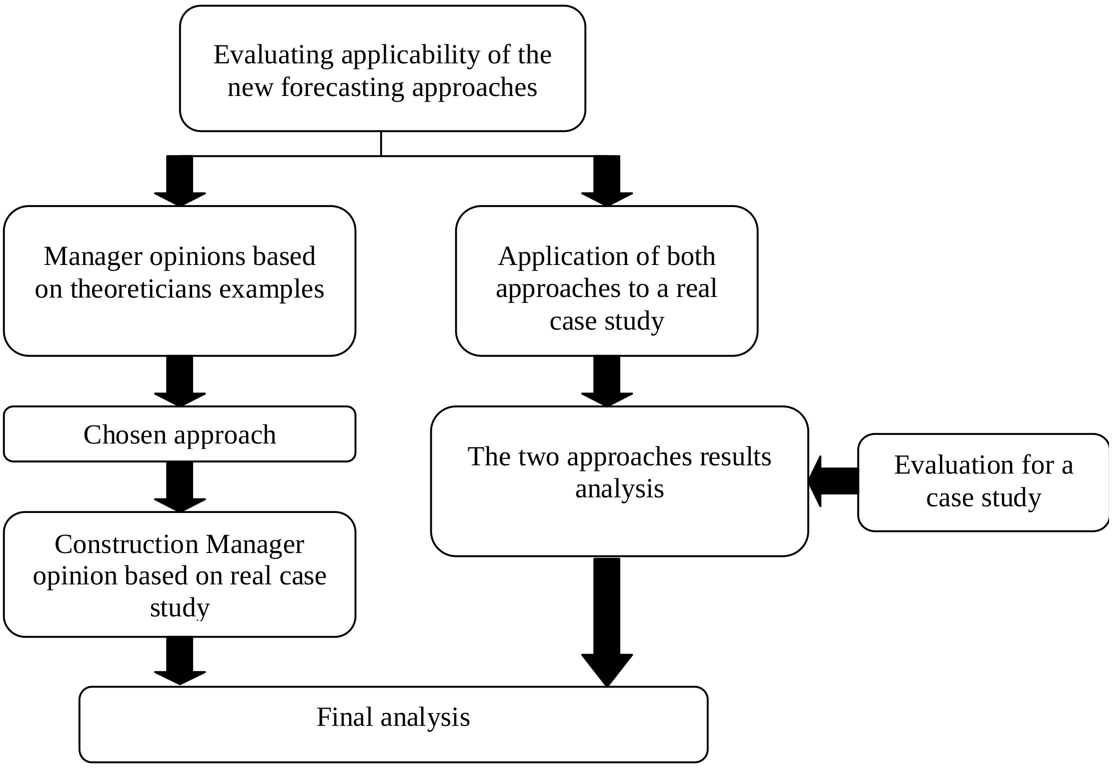

Figure 7: Methodology used to test the applicability of new forecasting approaches.

The test of applicability of two forecast approaches were has two ways:

a) First step - the approaches were submitted to construction managers to see what of them they feel more promising. These professionals were participating of a course about productivity concepts. They appreciate both approaches because they can have more dominion above the forecasts. Although they can apply the equations, they choose the ranges because they feel more comfortable on using it. After that, the ranges were presented to a construction manager that have never been in contact with productivity concepts or forecast. It was observed that he not feel secure as well in relation to factors relevancy as to analyze the productivity separately per components (column, beam, slab and stair). The manager have the feeling about total productivity that is necessary to get per type floor, this is due the labor contract model, which considers a fixed price per floor.

b) Second step – the authors did a forecast to a real build (that one in which the manager was questioned in the first step) utilizing as the range as the equation.

Productivity Range Forecast

It was chosen the follow values for the productivity:

- URcolumn: 0,94 Wh/m² (median value)
- URbeam: 0,73Wh/m² (minimum value)
- URslab: 0,69 Wh/m² (median value)
- URstair: 2,64 Wh/m² (maximum value)

The build had more favorable factors than unfavorable, however, to get more security on forecast, the median was chosen to column and slab. Only in the case of stair that the worst situation was chosen to be coherent with the factor, that was unfavorable. Based in these values and on survey of project quantities, applied on Equation 3, it were obtained the productivity forecast (0,80 Wh/m²).

Parametric Equation Forecast

It was given heights to the characteristics of build as indicated on 2.1 heading. The heights are presented on 3rd column on Table 6. Utilizing these heights into the Equations 1 and 2 plus the values chosen on Table 4 and 5, referent to structure components, it were obtained the results for column, beam slab and stair, which are presented on column 4th. These values were applied on Equation 3 to get the total productivity for whole structure, whose the result is presented on 7th column. The 5th column present the values chosen in the productivity range approach. The Table 6 shows yet, the Brazilian estimating manuals (SBC e TCPO 2000) values, on columns 6, 9 and 10.

In order to know the real productivity involved on formwork job in the floor, it were collected the quantity of hours worked for de formwork crew, which were composed only by carpenters (583 Wh/type floor; UR = 0,84 Wh/m²). This value is presented on 11th column on Table 6.

Table 6– Productivity dates for the real build.

Structure component	Build characteristics		Forecasted UR for the structure components (Wh/m^2)			Forecasted total UR (Wh/m^2)				Real UR (Wh/m^2)
			Equation	Range	SBC	Equation	Range	SBC	Tcpo 2000	
Column (200,5 m^2)	BLE	0	1,16	0,94	1,36	0,79	0,80	1,13	1,35	0,84
	SAR	0,12								
	BPL	1								
	TIE	0								
	LTI	0								
	STR	0,14								
Beam (153,3 m^2)	BL	3.81	0,40	0,73	1,27					
	TU	0								
	STR	0,10								
Laje (328,5 m^2)			0,69 (mediana)	0,69	0,93					
Escada (9 m^2)			1,93 (mediana)	2,64	0,93					
1st	*2nd*	*3rd*	*4th*	*5th*	*6th*	*7th*	*8th*	*9th*	*10th*	*11th*

Observes, therefore, that the forecasted productivity values obtained as for the equation as for the range (about 0,80 Wh/m^2) got a great forecast, because they are near to the real productivity (0,84 Wh/m^2) reached by the crew on the site building, while the estimate manual values are more distant to real productivity.

4. Final Considerations

The research with construction manager opinions not shows resistance on using of range. On the other hand, the position of construction manager interviewed presented critical, probably justified by the lost of training or sensitization about the subject and due to a form of labor contraction.

In the results analysis, although of, theoretically, the range presents a minor precision on forecast, because is a simplification on equations, it provides to a bigger easiness of application and the value gotten in this in case were satisfactory due to be near to the really it happened in the site build. On the other hand, the range eliminates some cited problems related to the traditional position (only presenting the average value).

Recently, one of the most important Brazilian estimating manuals included, beyond the traditional approach, the alternative approach of productivity ranges. The responsible believes that it can provide a better understanding for both, construction managers and designers, about the factors that influence productivity labor.

Once providing better understanding of labor productivity, the authors believe the “productivity range approach” can help improving cost and schedule forecasting in the Construction Industry.

Acknowledgements

The authors want to acknowledge the construction managers from São Paulo Construction Companies that are participating of productivity courses promoted by Department of Construction of University of São Paulo. In special way, the company Tarjab Ltda., that allowed visits in its site building to perform this research.

The authors want also to acknowledge the institutions CAPES and FAPESP, which have always been supporting our efforts to develop construction research.

Abstract

Numerous independent studies have shown that there is significant room for improvement on construction sites, particularly in relation to productivity, quality, health and safety, and innovation. At the new Royal Bank of Scotland (RBS) headquarters in Edinburgh, the client and the construction management team set out to produce a construction project that would be considered an example of best practice in the above categories, and create a stimulating and rewarding working environment for the whole construction team. BSRIA, an independent construction consultancy, helped achieve these objectives by delivering comprehensive and interactive training, monitoring and analysing key activities of the construction process, and compiling an evolving and evidence-based lessons-learned database for feeding back valuable knowledge into the project. The outcome was a construction project that has generated construction cost savings of 9.33% and a construction time reduction of 33.3% when compared to projects performing at conventional UK construction industry levels. This success was complemented by an outstanding health and safety record.

Keywords: Costs, Health and Safety, Performance, Productivity, Site Management

1. Introduction

1.1 The Construction Industry

The construction industry is the largest industrial cluster in the world. In the European Union (EU-15) construction accounts for an annual turnover of € 955 billion[1] and direct employment of 11.8 million people[2], or 11% of the total gross domestic product (GDP)[1,3] and 10.4% of all employment[2], respectively.

In addition to its importance as an industrial sector, the construction industry profoundly affects the overheads of all other industrial, commercial, educational, healthcare, recreational, communication and transport activities and makes a huge contribution to the quality of professional and private life across the world. It is evident, therefore, that business performance and the daily lives of the world's population can be improved with better health and safety, quality, environmental, social and productivity performance within the construction industry.

Although the construction industry does produce some very accomplished work, independent research (and various performance statistics) conclusively shows that there is significant room for improvement in project performance. Some of these areas for improvement are summarised below:

- Over the last ten years, BSRIA has conducted detailed research into site processes and construction productivity in some EU countries and in North America. The research has shown that approximately 50% of all site labour resource is wasted due to a combination of delays and variability in installation performance [4].

- In the UK, widely-used Key Performance Indicator (KPI) data showed that, in 2004, only 60% of UK construction projects were delivered on time, only 49% of UK construction projects were delivered on budget, and only 68% of UK construction projects scored 8/10 for defects at handover [5].

- Health and Safety Executive statistics for 2004 reveal that there were 4,001 major injuries and 8,162 over-three-day injuries on UK construction sites [6]. Seventy people were killed on UK construction projects in 2004 (30% of all worker fatalities occurred in the construction industry), which is equivalent to a rate of 3.55 deaths per 100,000 workers [6].

- Recent statistical data has indicated that average worker fatality rates for EU-15 countries are approximately 1.6 times higher than the UK figures [7]. In addition, the deaths-per-100,000 workers rate for construction in the USA is 11.4, which is more than triple the UK rate [8].

1.2 The RBS Gogarburn Construction Project

The RBS Gogarburn project involves the construction of a new worldwide headquarters for the Royal Bank of Scotland (RBS) in Edinburgh, Scotland. It has been designed to accommodate 3,250 people, with parking for 1,650 cars. The main part of the project comprises the construction of seven, three-storey office buildings and a 500-seat staff restaurant. These are linked by a 300 metre-long enclosed street, which contains assorted retail outlets and informal social spaces. A basement runs the full length of the development. It provides parking for cars and bays for bicycles, and contains storage, kitchen, mailroom and plantroom areas. In total, the main development, shown in Figure 1 below, extends to around 65,300m^2.

Figure 1: The main building at RBS Gogarburn

The site also features separate conference, nursery, leisure and sport facilities on site, which account for an additional 8,000m^2 of floor space to the project.

The total development budget for the project is £335 million. The construction costs are £229 million, of which around 10.5% has been spent on site organisation and 12.1% has been spent on preliminaries. Groundworks commenced in November 2002 and practical completion is scheduled in February 2005, creating a construction programme of approximately 27 months.

In line with the high ambitions for a headquarters project, the project team was also looking to create a construction project that demonstrated best practice in productivity, quality, and health and safety performance.

2. Delivering Performance Improvement at RBS Gogarburn

At RBS Gogarburn, the project team acknowledged that the creation of a stable, highly productive, safe and quality-focused environment would require an investment in both the development of the people who would work on the project, and in an initiative that employed evidence as a key mechanism for delivering performance improvement. BSRIA was invited by the project management company Mace and the client Royal Bank of Scotland to assist with the delivery of these two elements.

2.1 The “Moving Forward” Training Course

A key objective of the RBS Gogarburn project team was to create an effective and efficient workforce capable of safely delivering best practice levels of construction site productivity and an excellent finished product. In order to achieve this objective, the traditional, high quality building skills that the workforce possessed, needed to be complemented with improved competence in areas such as work preparation, meeting the needs of others, housekeeping, innovative ways of working and learning from experience.

In order to embed these new areas of competence in the project workforce, BSRIA designed, in close collaboration with the rest of the project team, a five-module, half-day, interactive, site-based training course called: “Moving Forward”. A colour, pocket-sized project handbook contained key project health and safety information and a two-page summary of each course module, together with tear-out pages featuring work preparation checklists and feedback forms that could be used by the project team.

The five, 25-minute modules were designed for delivery to everyone working on the project, from director through to apprentice and from architect through to scaffold erector. The content of the five course modules is summarised below.

- Module 1: Knowledge and Learning – *Outlined the key objectives of the project team, provided an overview of a simple review and improvement methodology, highlighted the role of the individual in making improvement happen and showed examples of where evidence-based review and improvement had been successful.*
- Module 2: The Changing Construction Site – *Contrasted the relatively unchanged, 5,000 year-old, construction methodology based upon lots of people taking lots of time to put lots of components together on site, with industries that have introduced paradigm shifts in their production processes. Introduced the concept of the modern construction process, which blends the best of traditional practices with new products and innovative ways of working. Provided examples of construction project teams that have made this change*
- Module 3: The Working Day – *Examined how the build process on site is typically composed, together with the inputs, resources and outputs that are required for successful task delivery. Showed how a typical working day is composed through the concept of productive and non-productive time.*
- Module 4: Work Area Control – *Introduced 14 characteristics of work area control, which together enable the workforce to build high quality products in a safe and highly productive manner.*
- Module 5: Tools you can use – *Reviewed the key elements of the four preceding modules in conjunction with the accompanying project handbook. Provided an*

overview of the continuous improvement activities taking place on the project, together with the lessons-learned database in operation on the project.

2.2 Evidence-based Review and Improvement

Clear evidence in the form of performance statistics and independently-configured lessons-learned were selected as key drivers for the continuous improvement process at RBS Gogarburn. In order to collect this evidence, BSRIA conducted detailed monitoring exercises on activities that were either principal consumers of time and cost, or that dominated the critical path of project delivery.

A crucial component of the activity monitoring was the measurement of what percentage of the working day was lost to delays across all key work packages. BSRIA used its 10 years of expertise in this field to pre-define the 14 delay types employed in this process.

In conjunction with this performance measurement, good practice or areas for improvement were identified during the monitoring activity, and a process of root-cause analysis was undertaken to identify the causal reasons and appropriate corrective actions. In addition to conventional written representation of this information, digital video clips and digital photographs were also extensively employed.

The evidence produced by the above activities was fed into a wide range of performance improvement mechanisms, such as a single-page feedback forms with embedded charts or photographs, multimedia de-brief sessions for specific elements of the project team, input to project meetings, and content for plasma screens and notice boards located around the site. In addition, all the evidence produced was stored in a lessons-learned database located on the project intranet, which was structured by work package and by file type.

3. Results

3.1 Knowledge and Learning

During a 21-month period, 976 people from 85 different companies have attended the BSRIA "Moving Forward" training course. This is the largest initiative of this kind ever undertaken on a UK construction project.

A project lessons-learned database, structured according the work package descriptions already in use on the project, has been populated with the following evidence:

- 221 single-page, colour feedback forms on a diverse range of issues, such as site logistics, interface details, housekeeping, installation productivity, delays, health and safety and quality management
- 407 video clips of key activities on site
- 2,220 high resolution photographs that capture the construction process and show key project details

All the above files have been named using a standard protocol based upon the use of a primary and secondary keyword, the work package number and name to which it relates, a date and a identifier for the file type. *E.g. Protection-curtain wall-3200-external cladding-10 Nov 04-V.* This approach has facilitated easy storage and retrieval of the evidence.

3.2 Cost and Time Performance

At the time of writing of this report, the RBS Gogarburn project is 96% complete and one month away from practical completion. The project will be delivered below the original budget and four weeks ahead of the original completion date.

A key contributory factor to this impressive cost and time performance has been that the project team has managed to increase the amount of productive time during each working day, when compared to conventional UK performance. Over a 21-month study period, each person working within the observed construction teams at RBS Gogarburn lost an average of 20% of each working day to delays. Although there is room for improvement in this level of performance, this figure is significantly lower than the average UK construction industry benchmark of 40%, which was established by BSRIA during its detailed research between 1994 and 2002 [4,10]

Site personnel costs on the RBS Gogarburn project were an average of 28% of the total construction costs. This figure corresponds closely with other reference sources that have examined the configuration of costs on construction projects [9].

The effect that the improvements in productive time have had on time and cost certainty on the project is illustrated in Figure 2 and Figure 3 below. The analysis shows that if the project had experienced delays at conventional UK construction industry levels of 40% of the working day:

- The construction cost would have increased from £229 million to £250.4 million, or by 9.33%
- The construction programme would have increased from 27 months to 36 months, or by 33.3%

Actual construction cost performance on the RBS Gogarburn project with productive time equal to 80% of the working day	
Construction cost	**£229**
Non-labour cost at 72% of the construction cost	£164.9
Labour cost at 28% of the construction cost	£64.1
The amount of the labour cost converted into productive time (*80% of the working day)* This figure is therefore the cost of the actual manpower required to build the project.	£51.3
The amount of the labour cost consumed by delays (*20% of the working day)* This figure is represents the cost of the manpower that was paid for, but which did not contribute to the building of the project.	£12.8

Theoretical construction cost performance on the RBS Gogarburn project with productive time equal to 60% of the working day	
The cost of the manpower, or productive time, required to build the project. *(This figure is the same as in the table above because the quantity of built product is the same)*	£51.3
The amount of the labour cost consumed by delays*. (40% of the working day)* This figure is represents the cost of the manpower that was paid for, but which did not contribute to the building of the project. *(The cost of this element is significantly higher than the corresponding figure in the above table. This is because the productive time component of £51.3 in this table represents only 60% of the working day, as opposed to 80% of the working day in the calculation used in the above table)*	£34.2
Labour cost required for the delivery of the project.	£85.5
Non-labour cost required for the delivery of the project. *(This figure is the same as in the table above because the quantity of built product is the same)*	£164.9
Construction cost	**£250.4**

Figure 2: An analysis of construction cost performance on the RBS Gogarburn project (All figures are in £ millions)

Actual construction time performance on the RBS Gogarburn project with productive time equal to 80% of the working day	
Construction programme duration	**27 months**
The amount of the construction programme converted into productive time (*80% of the working day)* This figure represents the actual productive time required to build the project.	21.6 months
The amount of the construction programme consumed by delays (*20% of the working day)*	5.4 months

Theoretical construction time performance on the RBS Gogarburn project with productive time equal to 60% of the working day	
The amount of the construction programme required to build the project. *(This figure is the same as in the table above because the quantity of built product is the same)*	21.6 months
The amount of the construction programme consumed by delays. *(This element is significantly higher than the corresponding figure in the above table. This is because the productive time component of 21.6 months in this table represents only 60% of the time required, as opposed to 80% of the time required in the calculation used in the above table)*	14.4 months
Construction programme duration	**36 months**

Figure 3: An analysis of construction time performance on the RBS Gogarburn project

3.3 Health and Safety

Over five million man-hours have been worked on the RBS Gogarburn project since construction activity commenced. Three reportable injuries have occurred during this period. This level of health and safety performance is more than ten times better than the current average level of performance for the UK construction industry [6,11].

The level of health and safety performance generated on the RBS Gogarburn construction project demonstrates that the combination of a well-trained, motivated and responsible workforce, excellent site organisation and the provision of appropriate plant, tools and equipment does generate a reduced incidence rate of reportable injuries.

The achievement of the project team was recognised in January 2005 when a film crew, commissioned by the Health and Safety Executive, interviewed 20 workers at the RBS Gogarburn construction project. These individuals were asked to provide feedback about working on a project where a great emphasis had been put on best practice health and safety performance. The edited version of the video was shown at the Construction Health and Safety Summit 2005 – a major conference on health and safety in construction held in London in February 2005, which was attended by senior executives and trade union officials from the construction industry, as well as senior representatives from UK governmental departments.

3.4 Quality

A study of the causes of defects recorded on the project prior to practical completion revealed that 54% of all defects on the project were attributable to outstanding works, 20% were attributable to the quality of workmanship, 13% were attributable to the precision workmanship, 12% were attributable to damage of finished work, and 1% was attributable to either material or functional faults.

A analysis of the time taken for the clearance of individual defects from the project management system employed on the project also highlighted that there was not enough commitment from the specialist trade contractors to providing dedicated teams who assumed responsibility for finishing the project in a defect-free manner.

The above evidence was fed back to the organisations working on the project and this helped the project focus on the key factors that were inhibiting the delivery of a defect-free project at handover to the client. Consequently, the project team has been able to work towards project completion in a much more controlled manner than normal UK construction projects that have not had this level of understanding.

4. Conclusions

- The global construction industry has significant room for improvement in its cost, time, quality, and health and safety performance.

- If properly trained and motivated, the construction workforce is capable of delivering improvements in cost, time, quality, health and safety performance. Site-based training of the workforce should be more widely adopted by construction project teams. It should focus on complementing workers' traditional technical skills with improved competence in work preparation, meeting the needs of others, housekeeping, innovative ways of working and learning from experience.

- Evidence-based review and improvement is an effective mechanism for improving performance on construction projects. This approach enables teams to identify, review and improve the things that really matter, and should be more widely adopted by construction project teams.

- Performance improvement on construction sites generates significant economic benefits for all parties involved. Improved working conditions also create considerable social benefits for the workforce.

- Performance improvement in the construction industry will generate benefits for all other industrial, commercial, educational, healthcare, recreational communication and transport businesses.

Scientific Benchmarking of Building Projects – Model and Preliminary Result

Thorbjørn Ingvaldsen
NBI – Norwegian Building Research Institute (email: thi@byggforsk.no)

Abstract

The Norwegian construction industry needs a benchmarking tool suitable for both common and individual use. The R&D project "Productivity in Norwegian construction industry" uses a scientific method, the Data Envelopment Analysis (DEA), for this purpose. The challenge has been to identify and collect data and supplementary facts for the analysis. The study is carried out at the project level. The data collection tool, i. e. a questionnaire with guidelines, has been designed with focus on the project as a whole. Likewise, much effort must be put on identification of the most important parameters. The contractor's point of view is chosen and the sampling for the investigation must consist of fairly similar types of projects. A pilot study on the production of blocks of flats is carried out. The preliminary benchmarking result is suggestive and encourages the R&D project team in the commissioning of the pilot study and start of new investigations.

Keywords: Productivity analyses, efficiency analyses, benchmarking, statistics in construction, cost control

1. The R&D Project

1.1 Overview

Productivity in Norwegian construction industry is a five-year (October 2001- September 2006) research project with an estimated effort of 200 person-months. The main goal is to develop a tool for scientific benchmarking of building projects. The project is based on cooperation between two research environments; the Department of building process studies of NBI and the Frisch centre / Department of Economics at the University of Oslo. The economists support the project with know-how of applying benchmarking using the non-parametric, multivariate method for efficiency analysis referred to as DEA (Data envelopment analysis [2]). Further development of this method is a separate part of the project; see paper by Dag Fjeld Edvardsen, NBI [1].

1.2 Background

In the period 1995 – 2000 the Norwegian construction industry experienced a severe decline in productivity. Observing this in the context of similar figures for the average of all industries in Norway leaves an alarming impression. See figure 1.

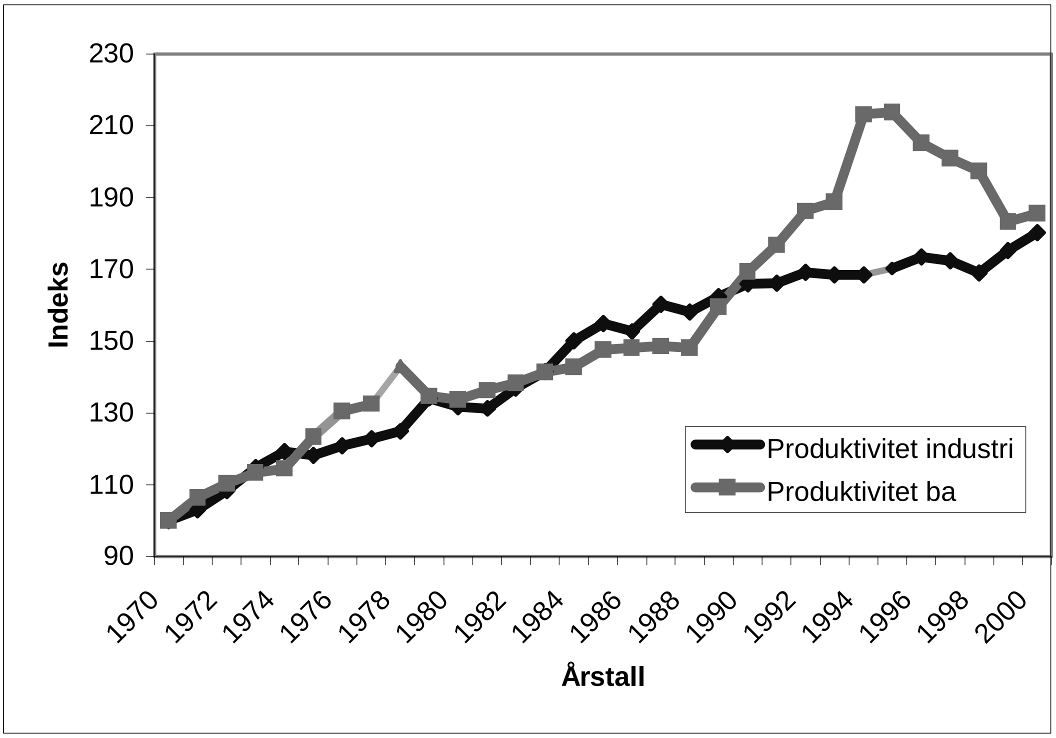

Figure 1: Development in labour productivity (grey) in construction industry vs. all industry (black) 1970-2000. Index 1970=100. Source: Norwegian national accounts

The dramatic (right) part of the curve has been given de-dramatizing explanations like

- the construction industry is very sensitive for change in business cycles

- the labor productivity figure, from national account, is not suitable as a basis for discussion of the productive efficiency in an industry like construction.

Nevertheless, the unpleasant development of productivity and the recognition of national account figures as non-suitable for productivity studies in construction industry, gave birth to the R&D project presented here.

1.3 Industrial Need

The construction industry is important for any industrialized nation. In most European countries it has a 5 – 15% share of the gross national product (GNP). The importance is strengthened by the fact that the construction industry has a strong impact on all other sectors in the economy.

To keep their "competitive edge", construction companies, as all other companies, has to establish and support their individual, continuously running improvement programs. The *ideal* concept for improvement work is an systematic, scientific approach, including productivity measurement and statistic analyses, as recommended in the ISO 9001:1994 Quality systems. In the Norwegian construction industry this is not very often observed. It is more usual, if there is any improvement program at all, that it is a "gut-feeling"-based approach with low attention to data and statistics.

Few productivity studies have been carried out in the past in the construction industry. The main experience is that data collection is difficult and that low quantity of data causes low quality of the results. Consequently the industry does not know much about itself through statistics. A few national account based studies indicate that the efficiency fluctuates with the business cycles. That is about all. There is a lack of knowledge about how to measure productivity/efficiency and how to identify influencing factors. The aim of the ongoing R&D project is to change this unsatisfying state of art.

2. Productivity and Efficiency in Construction Projects

2.1 Measuring Productivity

This paper gives a summary of the early phase work of the R&D project. The aim was (is) to develop a model for measuring productivity of building projects, on which a final benchmarking can be carried out. Productivity is defined as the ratio

$$\textbf{Productivity} = \frac{\textbf{Product} \text{ (e. g. figure(s) giving precise quantitative measures of the delivered product)}}{\textbf{Resources} \text{ (e. g. figure(s) giving precise quantitative measures of resources used)}}$$

In construction industry, the tradition has been – and still is – to pay the workers ("blue collars") based on *labour productivity* (piece work contracts). Between the worker's union(s) and the contractors' trade union federation(s) normative references are established for all types of operations in the construction process. For given parts of a project, e.g. the floor construction, one can calculate the labour productivity as:

$$\textbf{Productivity of floor production} = \frac{\textbf{Floor area} \text{ (f.ex. 1000 m}^2\text{)}}{\textbf{Hours} \text{ (f.ex. 500 hrs.)}}$$

For sub-contractors with floor constructions produced on-site as the main product, this number will be of high interest for every contract they carry out. (In the denser parts of Norway, such organizing/specializing of the building process is normal). Even for this type of company, the floor production differs from project to project. Span and thickness of the floor construction differs, and so does the specification of the concrete, the required finish, the number of block-outs, embeddings, etc.

When it comes to production of a complete building, the challenge of measuring productivity is increased: First of all, not all activities in the building process are as easy to single out as the production of floor slabs. Normally 10 – 30% of the tasks will be handled in other ways than through a piece work contract. Furthermore, most buildings are one-of-a-kind projects, making systemizing and use of productivity data resource consuming and difficult. With the increased number of sub-contractors in an ordinary project, the productivity data will be spread on different companies. Finally, the ability to produce a building with a minimum of resources (with highest possible efficiency), seems to depend on how much time is “leaking out” *between* all specified activities, different professions and/or contracts in the project.

Measuring productivity has different challenges. One of them is how to separate the productivity from the profit, see figure 2.

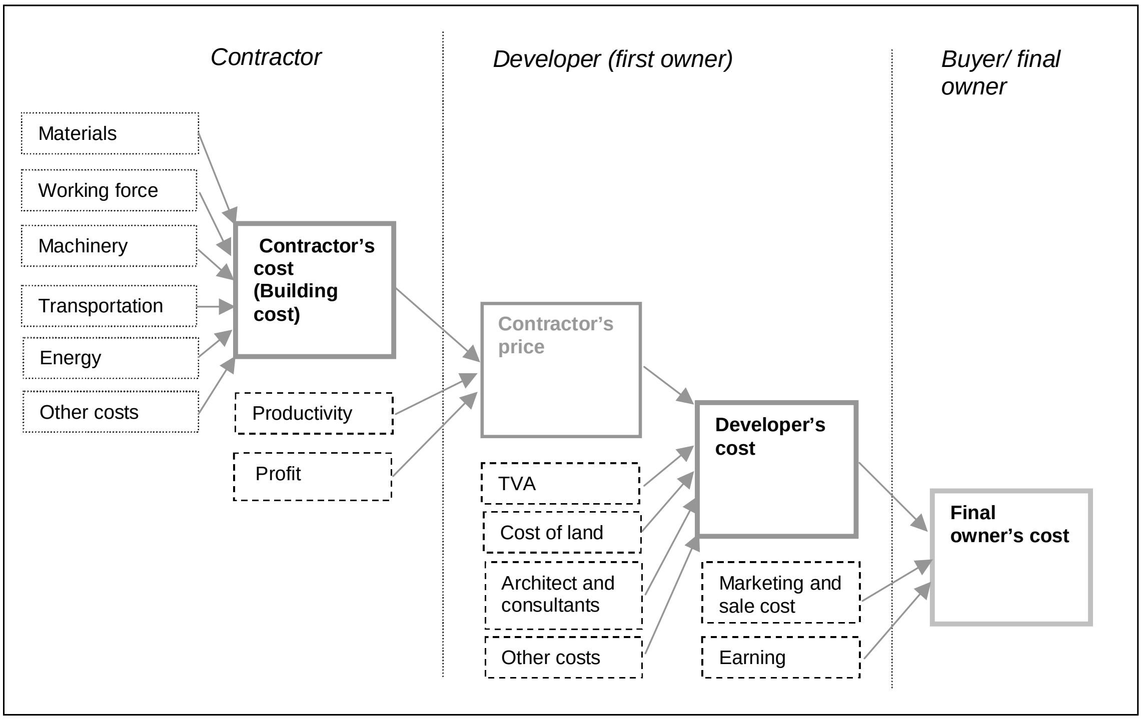

Figure 2: Building – the value chain. Source: Eurostat 1996

In figure 2, *productivity* is illustrated as an individual item, separate for the cost and the profit. In the contractors' books, the phenomena of productivity will show up as a part of the profit figure. If the productivity has been better than anticipated, this will become visible as a higher profit figure than calculated. If the productivity is lower than planned, the profit will become lower than calculated. (Other relations can also have a similar influence on profit. This makes the detection of "through productivity" even more difficult. - *The productivity box* in figure 2 can be read as an emphasizing of the fact that productivity is a specific aspect of the production that should be identified).

2.2 Comparing Productivity

From improvement point of view the productivity number has limited interest. The interesting part is to learn how well one producing unit is performing compared to other units, to it's own earlier performance(s) or to some normative number. When comparing productivity, each producing organization in a sample will come out with it's own "E-score" (the efficiency score), see figure 3.

$$E_n = \frac{P_n}{P_{Ref}}$$

Figure 3: Efficiency ("relatively productivity") for a unit (n) with reference to the unit (Ref)

The DEA method uses economic theory to rank a group of producing units from the most efficient one(s) (E-score 1.0) to the least efficient ones with scores from 1.0 and downwards. The main principle of the method is that each unit in the master sample is compared to the one(s) with highest E-score (1.0), i.e. the units that have demonstrated *best practice.* The theory is complex and can be studied in relevant literature, see for instance [2]. The basic condition for carrying out a proper benchmarking by this method is that the products are comparable ("Apples compared with apples"). Crucial is also that collected data are consistent and of satisfactory quality. Discussion of these aspects of the research process is presented in 3.1.

An interesting part of the early phase work was the discussion of details with respect to *point of view*, i.e. if we should establish our investigation with the owner's point of view or the contractor's point of view. The contractor's point of view was chosen, mostly because the fact that the word *productivity* in a historic perspective is connected to *physical production*. (See also figure 2, where the "productivity box" is connected to the contractor. On the other hand, the owners also conduct their business with different skill and success, and it would be of great interest to study the productivity based on the cost figures of the owner).

To reduce “market disturbances” we asked the contractors for their cost *without* profit. The fact that the contractors’ cost numbers contain the profit of their *sub-contractors* can produce “noise of second order”, but we regarded this as a minor problem.

Conclusion of the preparatory activities:

1) A tool for productivity measurement in the construction industry has to focus on *the project as a whole*.
2) The challenge is to identify the most important parameters for the nominator (product) and the denominator (resources) in the productivity formula, see above.
3) The resource data shall be collected from the *contractors’ project accounts*
4) The main sample must consist of fairly similar types of projects

2.3 The Pilot Study

To succeed with the modeling work, it was necessary to focus on one certain type of construction project. It was, for several reasons, natural to choose blocks of flats for the pilot study.

One of the benefits of DEA is the fact that the analysis is not dependent on a representative (large) number of items in the sampling [1]. Traditionally, a homogenous set of approximately one hundred items is regarded as satisfactory for a qualifying analysis. Based on this, we planned a data collection operation with the goal of getting 120 units, thus keeping the necessary number of qualified projects after excluding “bad data” items.

Blocks of flats-projects were defined as

- buildings with at least three floors
- buildings that can, but does not need to, have cellars (lower ground floor)
- projects that include common stair(s) and lift(s)
- buildings where the area of flats exceed 50% of total main function area. This means that part of the project can host other functions, like stores, institutional service function etc.
- projects that are one single block of flats or more than one (many)

Preferred type was defined as blocks with apartments of two, three, four or more rooms, principally planned for sale in the market. But other types, like studios, student housing, buildings with a share of social service department, were also accepted.

As many contractors as possible, situated all over Norway, should be invited to participate with information. Each reported project would have to be completed, physically and with respect to the project accounts.

A questionnaire was prepared to the collection of data and other project information. It was divided into four parts, one for each type of information, see figure 4.

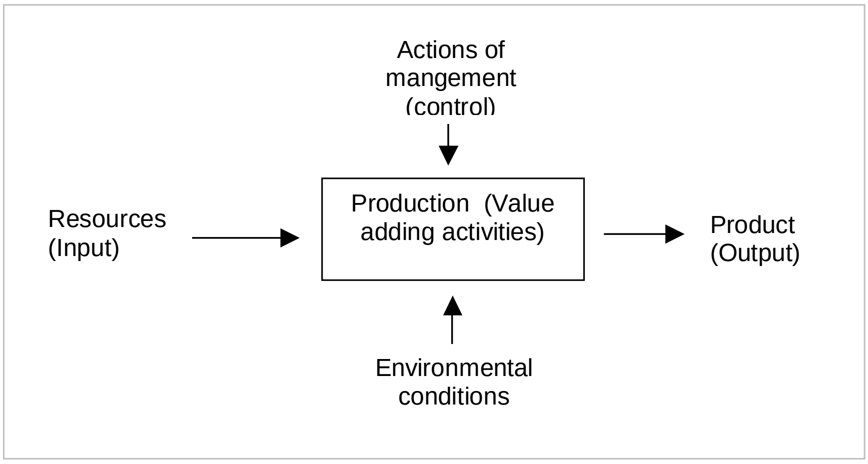

Figure 4: Efficiency analysis – the four main groups of information

The efficiency ranking of the group of building projects is based on calculations of data from the two groups Resources and Product See discussion of the productivity ratio in 2.1 (above). The other two groups of information are the *explanatory variables*, which are used in step two of the analysis, where regression technique is carried out to identify correlations between efficiency and the different variables. The Resources and Product parts of the questionnaire are commented in the following two chapters. The two parts covering explanatory variables are discussed (shortly) in 3.3. (An additional part asks for ID of the project and some rough characteristics. This firs page of the questionnaire is not given further comments in this paper).

The questionnaire is prepared for communication between the R&D project and each actual building project's manager. The ideal way of data collection, i.e. to invite the participants so enter the R&D project's homepage (www.byggforsk.no/productivity) and fill out the questionnaire, was abandoned after testing the probability of broad response this way. Conclusion was to open different ways of answering, giving each project manager the freedom to use the one preferred by him – or her. (The main sampling includes approx. 3 % female project mangers, unfortunately too few to test hypothesis "Efficiency and *female management*"). Approx. 40 % returned the questionnaire as attachment to e-mail. Another 30 % answered by post after having filled in information by pen. The last 30 % was also a paper copy, filled in by the R&D project representative during meetings with the building project manager that wished "1:1-information" before doing the answering job, which was estimated to take 3 – 6 hours. For more about data collection experience see section 3.1.

2.4 Resources

In productivity measurement theory [2] resources normally are grouped as follows:

Working time; f. ex. man hours. (B15 + B16 + B23 + B24)

Materials; raw materials and manufactured components for enclosure. (B22)

Energy; heating, enlightening, running of producing machinery, etc. (B13)

Capital; rent of machinery and equipment supporting the production) (B11)

To carry out the efficiency study, we needed these types of data for each building project. The Norwegian Standard NS 3453 *Project cost structure* (chart of account for building projects), includes all four of these resource groups. This gave input to the design of the part B of the questionnaire. See figure 5 and the numbering in brackets above. Unfortunately the NS 3453 structure does not correspond directly with the contractors' calculation sheets and charts of accounts. Each company has it's own structure, mainly following the construction process from ground work and concrete structure to technical installation and interior finishing work. (Curiously enough, the difference between the different charts of accounts is small. It seems mostly to be a result of habit and traditions. It should ease future data collection, if all companies and projects had taken the same charts of account into use).

As long as the contributors' charts of accounts were different, the R&D project was in a state of (strong) uncertainty regarding how good each project's information about use of resources could match any structure in the questionnaire. Consequently we designed the questionnaire to take care of both a "worst case" and "best case" responding situation.

Worst case: Low degree of detailing in many project accounts. The anticipation was that even if this would be the situation, all of the project managers most certainly would know the *B-40 figure* for his own project and give the R&D project this minimum of information necessary to feed the DEA model, see figure 4.

Best case: Highly detailed account in most every project. The expectation was that all cells in the break-down-column (Level 2) would be filled with the actual cost figure for each project, thus giving us high freedom to develop the optimal model.

B- Resources (Inputs)				

To get updated on the principles of this study, take a quick look at the first chapter of the Guidelines

		Level of information 1 Main figures (in 1000 NOK)	*Level of information 2* Brake down costs	*Level of information 3*
B-10	**Common costs (establ. + running the site).....**			
B-11	Rent of machinery, production tools etc.			
B-12	Waste; rent of containers, transportation etc.			
B-13	Cost of el. energy for running the site			
B-14	*Salary, production mangement/staff*			Number of workin hours
B-15	*Wages + worked houres, own empoyees*			
B16	*Cost of workers hired through personell support companies*			
B-17	Other costs (reg. establishing and running the site)			
B-20	**The building**			
B-21	Sub-contractors			
B-22	Costs of materials (for own producton)			Number of workin hours
B-23	*Wages + worked houres, own empoyees*			
B-24	*Cost of workers hired through personell support companies*			
B-25	Other costs (if any)			
B-30	**Technical installations……**			
B-31	HVAC			
B-32	Electricity			
B-33	Low voltage installations (Theleph., ….)			
B-34	Lifts			
B-35	Other installations (if any)			
B-40	**Acc. Cost of building, see Norw. Stand. 3453 …..**			
B-51	*Outdoor works (green surroundings, etc.)*			
B-50	*Acc. Cost of enterprise, see Norw. Stand. 3453 ……*			
B-61	*Costs of detailed planning (after general permission)*			
B-60	*Turn key cost", see Norw. Stand. 3453 ……*			

B-70	Check of the quality of the filling in:	Mark a positive answer (Yes) with a X
1	All figures are cost figures, i.e. NOT including our own gross margin and profit	
2	The figures are NOT including VTA	
		In 1000 NOK
3	B-40 includes following costs regarding non-conformancy work, either already paid out or expected to be paid during the "warranty period"	

Figure 5: Questionnaire – Part 2 Resources used in the building process

We also had a “Very best case”, which was all “man hours-cells” filled in with figures for each project (Level 3 in figure 5). This information would improve our platform even more, as we then would reduce the need for deflating the costs (index problem).

2.4 The Product

The most common way to quantify the product (the result of a building process) is by the gross floor area. Through this simplified way of quantifying the product, and with cost as quantification of the resources, the productivity factor of a project will be

$$\textbf{Productivity of floor production} = \frac{\textbf{Floor area} \text{ (f.ex. 1000 m}^2\text{)}}{\textbf{Hours} \text{ (f.ex. 500 hrs.)}}$$

In Norway this ratio is often used as an indicator of productivity or cost efficiency (Square meters/NOK - or more usual the inverse; NOK/square meter). As an indicator it might be suitable, at least among experienced builders. As measurement unit it is too rough, since important aspects of the product, like differences in standard ("quality"), important environmental conditions like ground, etc. is disregarded.

The great benefit of the DEA is the ability to take more than two aspects into consideration when measuring productivity. In short, the method, and the high computer capacity of today, gives us the opportunity to carry out numeric calculations of productivity with many independent variables, that is 4 - 8 when the data set consists of approx. one hundred items.

Part C in the questionnaire was designed in a similar way as shown in figure 5, though consisting of two A4 pages, due to the many aspects needed to define and quantify the actual product. Table 1 contains the factors asked for in the part C of the questionnaire.

Table 1: Product definition factors for blocks of flats

Quantifying factors for blocks of flats	Comments
1 The block(s) in general	
- number of blocks	
- number of floors (total, incl. basement(s))	
- number of basement(s)	
- number of lifts	
- number of indoor stairs/staircases	
- number of flats with open fireplaces	for gas or wood
2 The Block(s) – areas	
- gros area (BTA)	
- open air area (OPA)	galleries, balconies, terraces
- total areas of flats	(BOA and/or “BRA-Sale”)
- heated area for other main function than living	F. ex. stores at ground floor
- area for parking and tchn. func. in basement(s)	Data control question
3 Standard of construction (“qualities”)	
- standard of specified parts of the flats	7 different parts are quantified
- standard of the exterior and common areas	4 different parts are quantified
4 Non conformance to specification	
- degree of non-conformance at hand over	Degree of remarks in the protocols
- cost of repair during the guarantee period	In Norway this is 5 years by law
5 Energy for heating	
type of energy delivered	main source of heating
type of heating systems in the flats	main system of heating

3. Efficiency Analysis

3.1 The Data Set

During the period from June 2003 to January 2005 data from 138 completed blocks of flats projects were collected. The collecting process lasted longer than expected. Different circumstances can explain this, but it should be stressed that the R&D project is a model development project and not an ordinary collection of data for statistically processing in an existing tool.

The many projects were all built in the period 2000 – 2005. Based on the filtration criteria, see 2.3, nine projects were excluded, thus leaving an early main sampling of 129 projects. Suppliers were 37 contractors/ 65 profit centers (regional offices, departments) throughout Norway. The size of the projects varied from 7 mnok to 450 mnok with arithmetic middle of 77 mnok, respectively 6 to 618 dwelling units with arithmetic middle of 75 units.

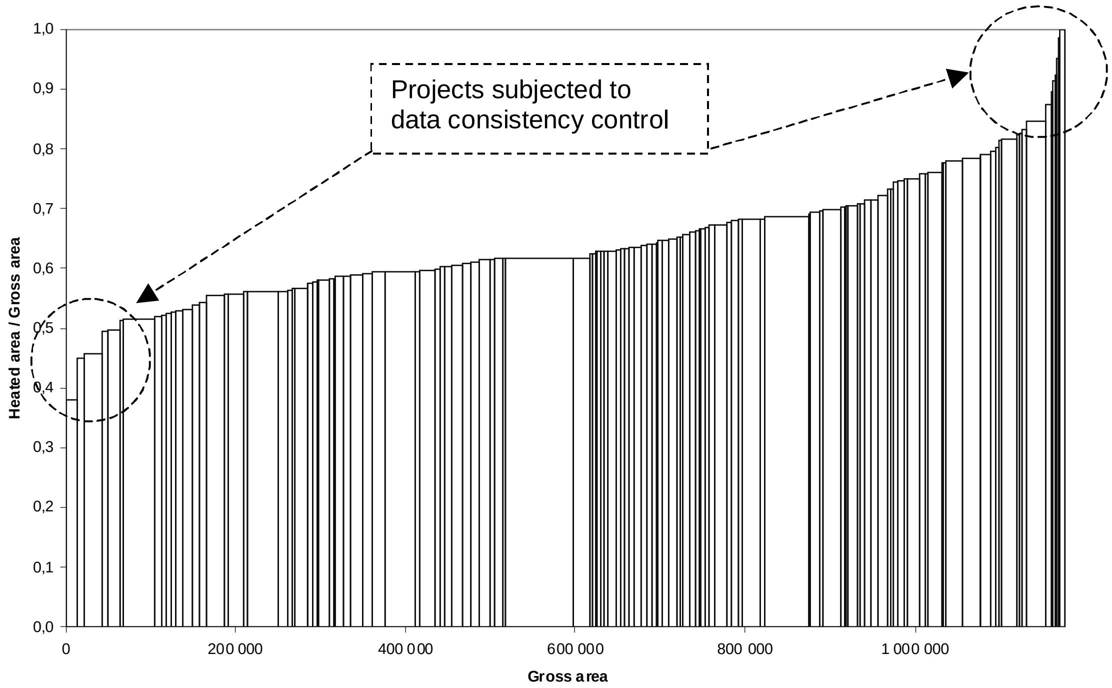

Figure 6: Example of data consistency control.

The quality of the present set of data differs, even if much effort has been put into control of data during the collecting phase. Checking the data set is still an ongoing activity. At the time of writing, 12 different data consistency controls have been carried out, and a similar number will follow. Figure 6 shows the ratio “Heated area”/Gross area. The “tails” (see dotted circles) of the diagram calls for special attention. The values (area numbers) behind the extreme low, respective high, columns are hopefully correct, but by controlling these once again we can discover miscopies, slips or errors or have even higher confidence to the data set.

3.2 Preliminary Efficiency Benchmarking Result

Based on the partly checked data set a preliminary result of the efficiency analysis can be presented, see Figure 7. The result is based on a DEA model with seven variables, operated by project colleague Dag Fjeld Edvardsen of NBI.

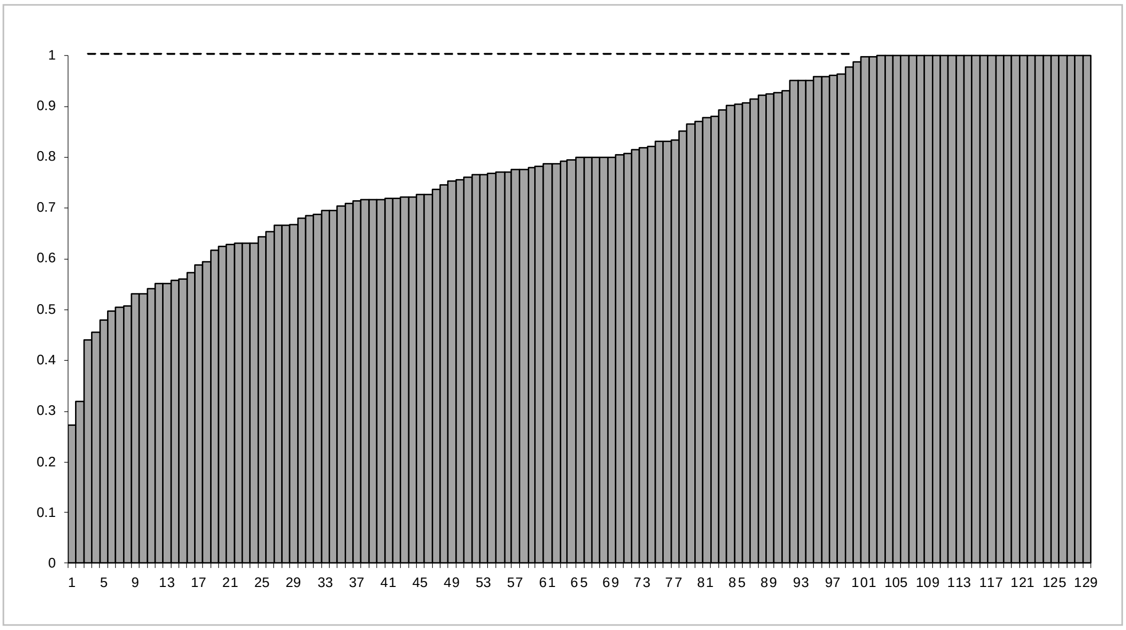

Figure 7: Preliminary efficiency scores for 129 projects (blocks of flats)

Each column in figure 7 represents one project. (In the final version each column will be given a width corresponding to the project's size (cost of construction, B-40). The figure shows considerable differences in efficiency. To the right is 27 projects with E-score = 1,0. These represent *best practice*. The rest of the projects are compared to a convex combination of these. The total improvement potential is indicated by the integral over the curve (the white triangle between curve and dotted line at level 1.0).

It is interesting to observe the improvement potential, especially if the 129 projects are part of the same economy. In our case there are 37 different companies behind the result. A group of five major companies have contributed with more than 10 projects each. For these, and in fact for all with more than a few project in the lot, the results are of specific value. The identities of the projects are anonymous, but each company can know the ranking of their own projects. Based on this a company will have valuable information of own performance and a basis for individual improvement initiatives.

3.3 Why are the Most Efficient Projects Most Efficient?

The projects representing best practice is of course of specific value. Together with data regarding resources and product, the questionnaire was used to collect information of *Environmental condition* and *Actions of the project management*, see figure 4. Approximately 500 questions about the two types of *explanatory factors* are answered by the project mangers and prepared for the step 2 of the efficiency analysis. By regression technique we are searching for explanatory factors that correlates with high efficiency, respectively with low efficiency. – After this huge numeric operation, and after having assured the quality of the research results by case studies of a few projects from the two extreme categories, we hopefully will have identified certain Environmental condition and Actions of the project manger that characterize each of the two groups. In he near future we hope to report also these Step 2 results.

4. Conclusions

The construction industry needs adequate tools to carry out benchmarking as basis for organizational learning and company development. Based on the DEA method and statistical analysis, NBI has carried out a pilot study where the main challenge has been identification and collection of necessary data and supplying facts. A questionnaire has been designed and answered by 138 project managers of assumed comparable projects of blocks of flats. The data consistency check and preliminary efficiency analysis make us believe that the method can be taken into use for continuously benchmarking of production of blocks of flats. We also believe that the model can be adjusted to suite other types of construction project. A simplified and refined questionnaire is the aim of the R&D project, used on a new set of data during 2005-06.

Abstract

This research is an empirical study of human resource management (HRM) for the motivation of masons in the Sri Lankan construction industry (SLCI). The structured interview was chosen as a main research instrument for data collection. 90 masons and 30 supervisors were randomly selected from 10 construction sites within the SLCI.

The study's findings show that the supervisors and masons in the construction industry (CI) in Sri Lanka are aware of the supposed advantages of staffing, employee development and the rewards of a HRM approach. However, these characteristics have yet to play a significant role in the motivation of Sri Lankan supervisors and masons. A contextually sensitive application of these three strategies has the potential to improve motivation of the Sri Lankan construction workforce.

Keywords: Motivation of Masons, human resource management, Sri Lanka

1. Introduction

The management of present day construction projects is becoming increasingly complex and challenging due to many factors. To meet this challenge it is of the utmost importance to provide efficient management throughout projects. This research is an empirical study of human resource management (HRM) in the Sri Lankan Construction Industry (SLCI). The research focuses on the particular roles that staffing, employee development and rewards have in the motivation of masons in the SLCI. The study as a whole contributes to the wider debate on worker motivation.

2. Statement of the Problem and Significance of the Study

The construction industry (CI) is one of the most important industries in almost every country [1]. The crucial importance of the CI to a sustained development effort in a developing country cannot be overemphasised. Although construction is not an end in itself, it is the means for the achievement of the desired end, which is the development of new production capacity in the economy. In developing countries, productivity in construction has remained at a relatively low level compared to other major industries [2]. Therefore the effect of productivity on a nation's economy is highly significant. Improved productivity in the CI can have an important role in promoting national competitiveness and a satisfactory growth rate.

The Sri Lanka State Engineering Corporation, Sri Lanka Building Department, Sri Lanka Port Authority (SLPA) and Sri Lanka Labour Department have experienced that most of their projects are affected by low productivity and motivation [3, 4]. Most projects have also suffered from serious setbacks and even termination of contracts. In the SLCI, it is believed that productivity is low when compared to other developing countries and to the Asian sub-continent in particular [5]. One of the factors contributing to such low productivity is that of employees' motivation [6, 7, 8, 9]. However, in the ancient and colonial eras, the SLCI was properly organised, well motivated and highly productive [10, 11], although no evidence of the methods they used to manage and motivate construction employees still exists. It could be argued that without sufficient motivation of employees, such success could never have been achieved. Therefore motivation of Sri Lankan workers is one of the appropriate approaches to achieve higher productivity in SLCI. There is a large body of conceptual and empirical evidence concerned with the application of motivation theory to the CI [12, 13, 14, 6, 15, 16, 8, 9]. Unfortunately, there has not been so much empirical research on applying HRM strategies to the CI. No research about motivation was conducted for SLCI. The literature on motivational studies has flaws and weaknesses and is outdated [17, 18].

3. Motivational Theories vs. HRM Concepts

Motivational theories are also based on the functionalist paradigm, are not multi focused and do not give a real representation of how workers in construction are motivated. Most of them deal with intrinsic properties which are not sufficiently socially constructive for any credence to be given to them. The motivational theories, which take a functionalist view, offer only one perspective on the social construct. What is needed, therefore, are other methods of researching motivation in construction which embrace some of the salient points mentioned in social research theories [19]. Both the social as well as the scientific nature must be included in any study of construction worker motivation.

HRM is a socially constructed concept as opposed to the functionalist and traditionalist views of the motivational theories. Therefore, future studies of motivation of construction workers, in particular Sri Lankan construction workers, should embrace these modern, more pragmatic views of the social construct that are found within human resource management [20, 21, 22].

However, the traditional motivational theories used by previous researchers are dated: the researchers still talk in terms of managerial issues and personnel administration. These theories do not incorporate the different facets of human complexity and the evolving dynamic construction environment. They do not in any way play a significant role in shaping the self-identity of workers even though they have existed for a very long time. The main theme of this research is that motivation of workers cannot be separated from the context of the socio-economic environment. The extent to which perception of the workplace can be changed by HRM discourse is questionable in the case of construction employees' motivation. However, from this perspective, HRM plays an active role in understanding and constructing the social reality of the workplace and motivation of employees.

More crucial is the need to be aware of the strong links between the conceptual literature that has sprung up on HRM and the outdated empirical research that has been carried out on motivation. Themes such as staffing processes, employee development processes and rewards systems have to be understood. On the other hand, in Sri Lanka, Western management and HRM approaches have been employed in construction projects over the past few decades, without an assessment of the appropriateness of such approaches.

This has raised some crucial problems. The workers in the CI in Sri Lanka are aware of the supposed advantages of the HRM approach. The discourse of HRM in the SLCI has played a role in the motivation of the Sri Lankan workers. Effective and efficient application of HRM to Sri Lankan workers would improve their motivation.

4. Methodology

Research data were collected by means of a survey of masons in 10 construction sites in Sri Lanka. The data-gathering techniques were:

Interviews (one-to-one)
Interview sessions were the main research instrument in the study. 120 structured interview sessions were conducted and fully tape recorded. The interviews were conducted in Sinhala, which is the lingua franca of the Sri Lankan operatives.

Observation
10 observation sessions were conducted in 10 work sites within the SLCI. Structured observation schedule was used for each observation session. The findings of the observations were triangulated with finding from the interview sessions. Both techniques were pilot tested prior to the main research work.

5. Research Results and Discussion

5.1 Staffing Processes

Staffing encompasses the human resource activities designed to secure the right employees in the right place at the right time [23]. Management professionals in the construction industries making a decision to recruit employees must consider whether to rely on the external or internal labour market [24]. Among Sri Lankan construction firms, those with outstanding and average performance seem to be less informed about recruitment and selection processes.

5.1.1 Existing Staffing Processes in the SLCI

This research shows that the most common staffing procedures for supervisors and masons in the SLCI are as follows: advertising the vacancy, calling job applicants, conducting interviews, direct recruitment through personal contacts, friendship or any other form of relationship. Advertising the vacancy is more prevalent than other existing staffing procedures.

Direct recruitment through personal contacts, friendship or any other relationship sometimes causes favouritism and employment of unsuitable workers. However, there are some advantages to this system. Recommendations from a reliable source can guarantee the trustworthiness of employees.

Other methods for recruiting employees are not common in the SLCI. These include: direct recruitment, conducting a practical test of applicants' knowledge, conducting a theory test of applicants' knowledge, giving effective pre-work training, and using a registered list or recruitment agency. Although direct recruitment as a result of political influence is not common in the SLCI as a whole, it does play some part in direct labour recruitment. Direct recruitment due to political influence is detrimental to the company and results in similar difficulties to those discussed earlier in relation to direct recruitment through personal contacts, friendship or any other relationship.

The theory test of an applicant's knowledge is not especially suitable for masons and not prevalent in the SLCI. One reason is that most masons are not taught the rudiments of masonry theoretically. They start off as an apprentice to another mason, or as labourer who shows some interest in masonry work. Only 7% of supervisors and none of the masons mentioned the theory test method. In general, masons are not as well educated as supervisors – thus some Sri Lankan masons cannot understand the theory test. The practical test is more suitable for the recruitment of masons, because their job is completely practical, unlike that of supervisors. 62% of masons and none of the supervisors specified a practical test. Recruiting employees through an agency system does not exist in the SLCI. This is due to the availability of cheap labour. An employment agency system has not taken root in Sri Lanka.

5.1.2 Characteristics of Staffing Processes in the SLCI

The research results show that the existing characteristics of staffing processes in the SLCI, which have a response rate of more than 50%, are as follows:

- There are appropriate and adequate job design and analysis procedures (mainly concerned with how to recruit, how to select, how to train, how to develop, how to downsize, how to administer wages etc.)
- The organisation has clear staffing procedures
- There are recruitment plans to avoid unexpected staff (labour) shortages
- Staffing is designed to secure the right employee at the right place and at the right time

- The recruitment and selection processes are concerned with identifying, attracting and choosing suitable people to meet an organisation's HR requirements.

The above characteristics are perceived as being very important to the SLCI. There is a general willingness to include them in company practices. Unfortunately, only the first characteristic is currently functional. The reasons for the malfunction of the other characteristics can be identified as follows: financial and facility problems, the difficulty of introducing new methods, the difficulty of giving up old procedures, insufficient time because of a busy schedule, the difficulty of changing how the institution is perceived, management deficiencies and superiors' lack of interest in management procedures. A small number of employees cited other influences (e.g. political). However, effective management can help to prevent the above problems from arising.

5.2 Employee Development Processes

Employee development processes have become an integral part of most construction industries (25, 26). In general, both new and existing workers will require more training and employee development, especially in developing countries. The findings show that the employee development and training process is a highly valued function, but not adequately distributed amongst supervisors and masons in the SLCI. Only 12% of the respondents stated that they had satisfactory access to employee development processes. This is the result of the reluctance of employers to invest in employees due to uncertainties in the SLCI.

5.2.1 Existing Employee Development Processes in the SLCI

The survey results regarding employee development processes in the SLCI reveal that the following processes are both widespread and popular:

- On the job training by specially appointed people
- On the job training provided by senior employees
- Induction training at the beginning of employment
- A short duration training programme.

Most construction firms in the private sector offer only introduction training as an employee development process. Some private firms do not even offer this limited option due to their busy day-to-day schedule. This means some employees are starting work without any induction being offered by their employer. This can obviously result in poor quality work and low productivity, because company procedures are not well understood. On the job training by senior employees can sometimes prove detrimental to a company because of favouritism, or the passing down of work-related weaknesses from senior employees to trainees. On the job training by specialists can overcome the above disadvantages.

There are other methods (e.g. a firm's own training programme, frequent conferences) which are not common in the SLCI. Although uncommon when considered as a whole, considerable variation in response can be seen if the responses of the various groups are considered separately (e.g. masons only or supervisors only).

Most employee development processes in the SLCI are available to supervisors to a much greater extent than they are to masons. The supervisor's role involves more responsibility and is thus of more importance to the firm. Consequently, only 36% of masons but all of the supervisors have short introductory training programmes. Similarly, only 26% masons compared to 80% of supervisors experience their firm's own paid training sessions. It should be noted that some training sessions that are conducted for masons can prove to be very challenging due to the low literacy level of most masons within the SLCI.

5.2.2 Characteristics for Employee Development Processes in the SLCI

The characteristics of most employee development processes are that they are scanty and not fully functional. This can be clearly seen from the fact that in the survey, when asked to identify the existing and functional characteristics of employee development in the SLCI, the respondents only cited one characteristic with a response rate of more than 50%:

The management may decide to orient their training and development activities towards short-term or long-term objectives.

In reality, this characteristic cannot be said to be functioning adequately in the SLCI.

The findings show that all characteristics investigated in employee development processes in the SLCI are clearly perceived to be important but that there are significant obstacles to their successful implementation (e.g. financial and facility problems, lack of time due to a busy schedule).

5.3 Reward Systems

Another key feature of modern approaches to HRM, within the construction industry and elsewhere, is reward systems [26]. Generally, the structure of the reward package is related to the job, as well as to the expectations of the employee and the labour market. Reward packages consist of either a salary component or an incentive component, and can also be categorised as money related or non-money related [27, 24]. However, most Sri Lankan construction firms suffer from serious financial problems and are busy with day-to-day workloads. These firms still have poorly distributed reward systems. The superficial view is that most of the small private sector firms in Sri Lanka are often bankrupt and terminate contracts without having a chance to reap the benefits of reward systems. The study findings show that the majority of construction firms in Sri Lanka have some kind of reward system, but that these are inefficient.

5.3.1 Existing Reward Systems in the SLCI

Certain reward and incentive systems are currently in existence in the SLCI. The following are all being implemented with varying degrees of efficiency: a satisfactory salary is earned; a good reputation is achieved, good employer/employee relationships are achieved; satisfactory facilities are provided (e.g. housing, accommodation, etc.); satisfactory welfare facilities are provided; a satisfactory bonus is offered; overtime is offered; social activities are organised; appropriate quality training is offered; permanent jobs are offered; praise is given; rewards and certificates are given; performance appraisal programmes are conducted; and promotions are given. However, from the above list, only the following elicited a response rate of more than 50%:

- Overtime is offered
- A good reputation is achieved
- Praise is given
- Satisfactory facilities are provided (e.g. housing, accommodation, etc.)
- Social activities are organised
- Rewards and certificates are given
- A good employer/employee relationship is achieved
- A satisfactory salary is earned
- Permanent jobs are offered

Overtime is currently the most prevalent and popular reward system in the SLCI. Considering the high amount of absenteeism and the insufficient number of employees, management has to cover the day-to-day workload by giving overtime to existing workers. This explains the high incidence of overtime in the SLCI. However, management has to manage and plan the workload. It also has to take into account employees' work capacity and allocate overtime accordingly, otherwise productivity and motivation will be negatively affected.

Unemployment is a severe problem especially in developing countries and this situation is clearly true for SL. The opportunity to have a job is a significant motivation for Sri Lankan employees. It must also be remembered that the benefits and salary provided by employment within the SLCI are much higher than in other industries. Hence having a job in the SLCI is also a means of achieving a good personal reputation.

Expressing warm approval, respect and gratitude for high-quality work is also considered to be a reward system in SL. This reward can be easily provided and achieved. However, praise given to unsuitable employees can also negatively affect the motivation of others. Management has to be aware of this because the problem of favouritism is also widespread in the SLCI. Bearing in mind the economy and living conditions of the country, the provision of satisfactory facilities (e.g. housing, accommodation, etc.) is a reward valued highly by Sri Lankans.

Considering supervisors and masons separately, it can be seen that there are more beneficial reward systems available to supervisors than masons. 100% of supervisors and only 36% of masons have permanent jobs. 77% of supervisors and 53% of masons are satisfied with the social activities organised by their firms. Furthermore, the results show that there is only an 11% overall prospect of promotion in the SLCI. This is extremely low. The responses of supervisors and masons differ: 67% of supervisors and only 24% of masons stated that their firms have a clear promotion scheme. Offering training opportunities or facilities as a type of reward is more freely available to supervisors than masons.

Masons appear to be more satisfied with their salaries than supervisors, even though the supervisors' salaries are higher than those of the masons. According to the qualification, social status and comparison with other industries, masons are more satisfied with their salaries.

5.3.2 Characteristics of Reward Systems in the SLCI

The following characteristics are currently in existence within the reward system in the SLCI: the organisation has an efficient reward and incentive system; a reasonable performance appraisal programme exists in the organisation; money-related rewards are important; non-money-related rewards are important; group-related rewards are important; individual related rewards are important. There are incentives not linked to performance such as holiday pay, sick pay, long-service allowances, pension funds etc; there are incentives partially tied to performance such as profit sharing; incentives directly tied to performance; and the organisation keeps its payment structure up to date.

However, an examination of all the responses reveals that only a small number of characteristics can be said to be in existence to any significant degree. The following elicited a response rate of more than 50%:

- The organisation has an efficient reward and incentive system
- The organisation keeps its payment structure up to date
- Non-money related rewards are important
- Incentive is directly linked to performance
- Group-related rewards are important.

Although the respondents stated that all of the reward system characteristics were important to their firms and that they are willing to have them, the above characteristics are not functional due to financial problems as well as the inadequate resources and facilities available within the SLCI.

To summarise, the findings show that most supervisors and masons are aware of the supposed advantages of modern HRM approaches (i.e. staffing, employee development and rewards). They realise that these approaches can have significant positive effects on employee motivation, although they have yet to play a role in the motivation of the Sri Lankan supervisors and masons. Furthermore, supervisors and masons are aware of the motivation benefits, which can result from the implementation of the approaches. 95% of the respondents cited the motivational benefits (e.g. institutional and employee productivity is increased).

6. Conclusion

The study concludes that supervisors and masons in the construction industry in Sri Lanka are aware of the advantages of staffing, employee development and rewards in HRM; a contextual application of staffing, employee development and rewards for Sri Lankan masons would improve their motivation. The findings also show that the discourse of staffing, employee development and rewards in Sri Lankan construction industry have not played a role in their motivation.

Measuring Productivity on Project Level

Antti Lakka
VTT – Technical Research Centre of Finland (email: Antti.Lakka@vtt.fi)

Abstract

This paper presents a research project which developed a method and indicators for construction site productivity assessment as well as tested them on apartment-block sites. Productivity indicators were complemented by others representing explanatory factors, their purpose being to help identify best practices. Dependencies were studied, for instance, with the BayMiner data mining tool. The research is part of a joint venture of five Nordic countries implemented in 2001-2004.

Keywords: Productivity, efficiency, benchmarking, construction, data mining

1. Introduction

1.1 Overview

The Norwegian Building Research Institute, the Icelandic Research Institute, the Swedish National Testing and Research Institute, the Danish Building Research Institute and VTT have completed a three-year productivity study on the Nordic construction sector. Each country conducted a subproject focussing on itself. The findings were shared through the joint Nordic project. This paper describes the Finnish portion of the productivity study.

The main interest of a company in conducting productivity studies is to identify the factors which impact productivity. Knowing these factors makes it possible to improve internal processes. By collecting information from several projects, companies can identify the best practices for high productivity, and transfer them from one project to another. If the key factors for high productivity can be identified, productivity measurement can be an important development tool for a company.

The objective of this work has been to develop a methodology for measuring productivity on the project level and to conduct a benchmarking analysis.

1.2 Measuring Productivity in Construction

One focus of productivity research is the analysis of company-level productivity and analysis of the productivity development of various processes and work phases. Companies make use of productivity monitoring and indicators in developing their operations and technologies. Statistics Finland monitors productivity development on the national economic level, and the results are used in evaluating industries and their development needs.

In 1996 the construction industry and Statistics Finland conducted the *building construction productivity indicators* study. It defined productivity indicators for the entire building construction industry and its sectors. The study suggested measuring the productivity of the industry on three different levels. Annual development is monitored on the industry level by an index type indicator that does not depict the level of productivity but changes in it. Another level of measurement consists of value-added-based indicators for subsectors that show the absolute level of productivity. The third level involves monitoring labour productivity by product group- and building type-specific indicators which are by nature physical productivity indicators. [1] Statistics Finland launched the highest level monitoring suggested. However, sector organisations have not yet begun monitoring productivity on the other two suggested levels.

Companies are not in the habit of publishing their in-house productivity studies, but Helsinki University of Technology has persistently researched the performance of companies with them [2]. VTT has developed methods for determining the efficiency of the site process as part of the *Site process re-engineering in building construction* project in 2002-2004 [7]. The indicators of productivity measurement were studied in 1992-93 [13]. VTT has also examined the monitoring of productivity in infrastructure production. The project produced productivity indicators for the infrastructure sector and launched monitoring to test the developed indicators [12].

1.3 Implementation

The study investigated ongoing productivity research in construction in cooperation with Nordic research partners. In addition to Nordic research, it reviewed the English KPI (key performance indicators) method which was also tested by the Norwegians in an actual construction project. The Finnish subproject consisted of the following phases:

1. Definition of preliminary productivity indicators
2. Development of data collection models
3. Comprehensive data collection
4. Adjustment of productivity indicators and analysis of material
5. Reporting

Comprehensive data collection was implemented in the form of a questionnaire study targeted at the contact persons of participating companies using a multiple-choice Internet form. The response material was analysed by both the traditional normative statistical approach and so-called data mining based on the Bays Network. Reporting consisted of a public research report and a confidential report to each partner company.

2. Methodology

2.1 Approach

The evaluation of the performance of a complex process can be approached in two ways. One involves developing an indicator-type integrated gauge consisting of individual gauges that measure different features of the process as comprehensively as possible. The industry-specific overall productivity indicator can be considered one: it measures the combined performance of various subprocesses by a money-based indicator of added value and combines them into a single indicator.

Another approach to gauging a complex process is to use individual physical meters that provide the best possible description from the viewpoint of the performance of the entire process, while they actually only assess a single feature of the process. Gauges can also target the process preceding the process in question, the one following it, the use of process resources, or process control. For instance, process resource consumption can be used to evaluate also the performance of the process itself. This approach has been applied, for instance, to the assessment of the quality of the operations of a construction company.

The study approached productivity measurement by applying the principles of complex process measurement. Practical input-output parameters were defined in accordance with the concept of productivity: their ratio depicts productivity. To determine the factors that affect productivity, the impact of various control and environmental factors on productivity was analysed. (Fig. 1)

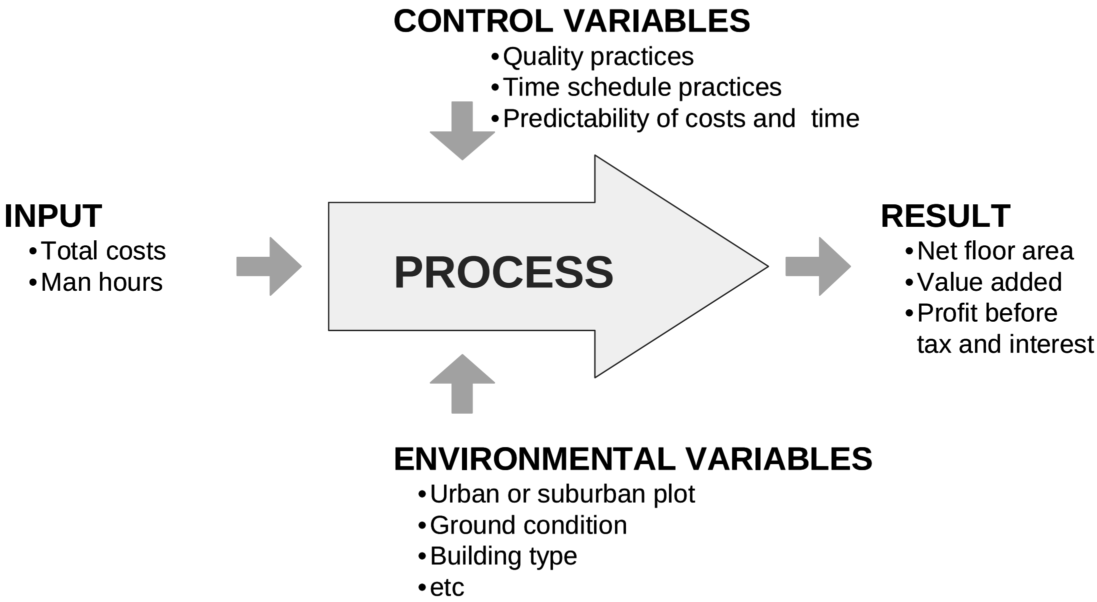

Figure 1. Productivity measurement by the input-output ratio. Control and environmental factors can help discover procedures and factors that explain good and poor productivity.

2.2 Explanatory Factors

For the purposes of this study explanatory factors were divided into control and environmental factors. Control factors are linked to things that the construction company itself can impact. The control factors examined in the study include, for instance, the quality procedures employed in the construction project, how intermediate scheduling goals were reached, what share of the costs had been realised at handover, and the degree of subcontracting.

The construction company cannot affect environmental factors itself. These include things like whether the building is located in an urban centre or a suburb and the foundation engineering conditions. Factors like the distribution of dwellings within the building and distribution of dwelling sizes were also considered environmental factors even though some of the projects were self-developed projects. It is naturally unthinkable that a builder would just construct large dwellings in a suburb pursuing higher productivity when demand focuses on small units in the central area.

2.3 The DEA Method

Data envelopment analysis (DEA) is used to rate the efficiency of organisational units against the best unit. Basically, the method tells what percentage of the inputs used by a unit would have been required for a certain output, had the unit operated as efficiently as the best compared units.

The method is suitable in instances where the evaluated organisational units produce a similar product. In Finland the construction products industry has tested the method at least in rating the productivity of facade element production. There the input was labour input in hours and the output the square metres area of produced elements. In other Nordic countries the method has also been applied to the measurement and comparison of the productivity of building construction. In building construction the benchmark project must be as comparable as possible.

In the DEA method the material is reviewed using a so-called Salter diagram or a so-called scatter diagram. In the scatter diagram resource consumption (input) is represented by the x-axis and the output produced by the organisational units by the y-axis. The surveyed organisational units are represented by dots in the diagram. A broken line drawn through the best organisational units indicates the realistic target level that all organisations could reach if their productivity was as high as that of the best units (Fig. 2).

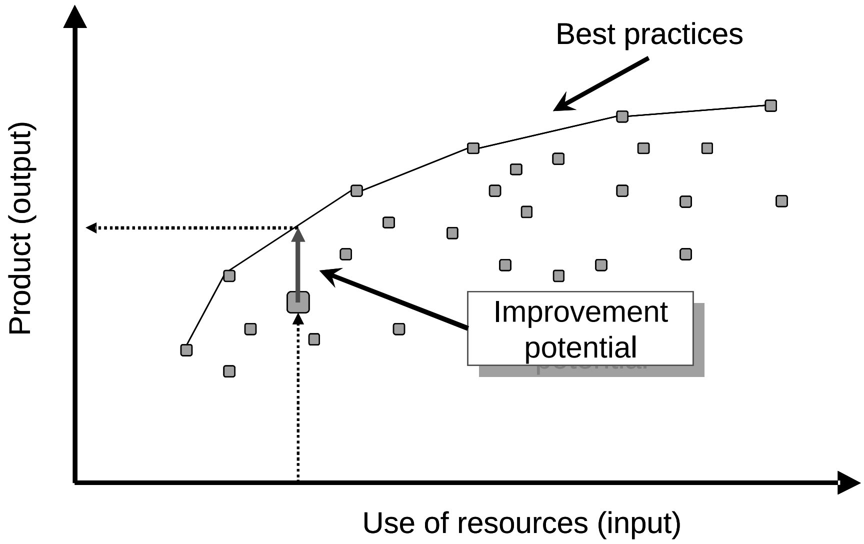

Figure 2. Scatter diagram. A broken line drawn through the best organisational units indicates the attainable improvement potential.

2.4 Bayes Network

The challenge of productivity research is to determine which practices actually are so-called best practices and place the project either in the good or bad category. Since we cannot tell beforehand which practices are good, it is worthwhile collecting as much data as possible on several potential explanatory factors. This leads to complicated analysis of causal relations.

In complicated reasoning tasks the lack of human knowledge can be replaced by calculation models, so-called computational intelligence, where part of the calculation model is based on collected measurement data on the subject. An expert may have a conception of the operation of the target process, but not enough knowledge about all causal relations. To produce a model capable of predicting the future, the missing parts are complemented by so-called computational intelligence [9].

Bayes Networks are decision-making systems based on probability calculation and, above all, so-called Bayesian decision-making. Probability distributions are assumed for all elements of modeling: the parameters applied to the model architecture and the data used for the purpose. The system then selects the most probable model and parameters considering the measured data.

Construction of a model based on the Bayes Network is possible using complex algorithms and requires high computing power. The advancement of IT has, however, made it possible to calculate efficient algorithms, and applications built on Bayes Networks have also seen commercial use.

Bayes Information Technology Oy has developed an efficient data mining tool based on the application of the Bayes Network for statistical processing of material. The BayMiner software is used via the Internet as a so-called ASP service. The BayMiner software is also suitable for analysing research problem setting, i.e. determining which control and environmental factors explain the construction project's ending up among good or bad ones (Fig. 3) [10].

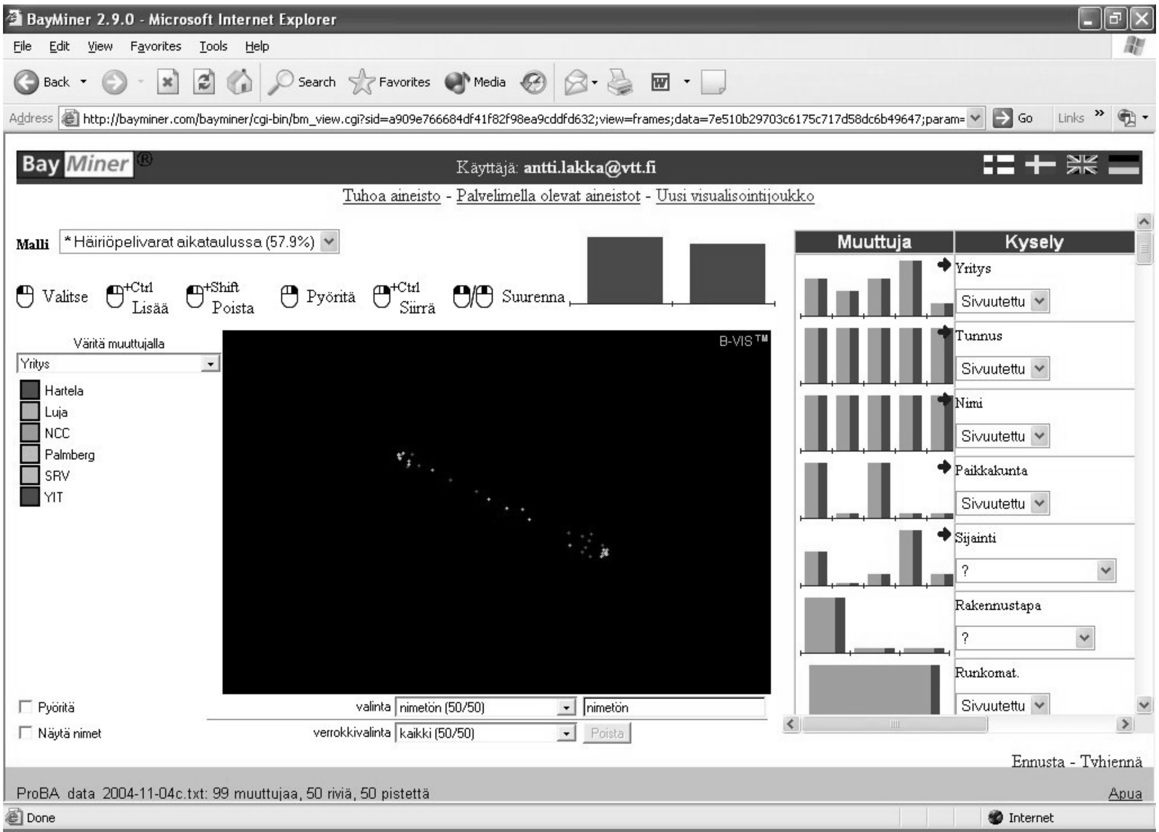

Figure 3. User interface of BayMiner data mining tool. The software was developed by Bayes Information Technology Oy.

3. Comparative Study

3.1 Sample

Apartment-block sites were selected as the subject of productivity comparison: they were thought to be sufficiently alike to allow site-level productivity comparison. The subject was limited to new construction, and comparison targeted the site phase of the project. Cost items external to the site were excluded such as the acquisition cost of the plot and profit margin. Confining the survey to realised costs limited usable productivity indicators to physical ones. For instance, a value-added-based productivity indicator based on the value added to the company per person-year was thus excluded.

Sample size was 50. Data on some was deficient and consequently comparisons were based on a reduced sample. The typical sample size for surveying explanatory factors was 43.

3.2 Productivity Comparison

A productivity indicator that treats different types of apartment-block construction as impartially as possible was sought to allow distinguishing "good" building projects from "bad". The goal was a practical gauge that provides a reliable indication of the productivity of compared projects for which input data is available from projects of various construction companies. The input of the selected productivity indicator consisted of the consumption of resources on site in monetary terms, i.e. realised site costs in euros. The selected output was the volume of site production in net floor area.

In Fig. 4 the sample of the comparative study is plotted in a so-called scatter diagram. A broken line was drawn to connect the points representing the best performing projects to indicate the highest attainable productivity. For instance, one building project used about €3.5 million in resources to produce a net floor area of 2,200 m^2. The best project, on the other hand, used the same amount of resources to produce nearly 3,500 m^2 of net floor area.

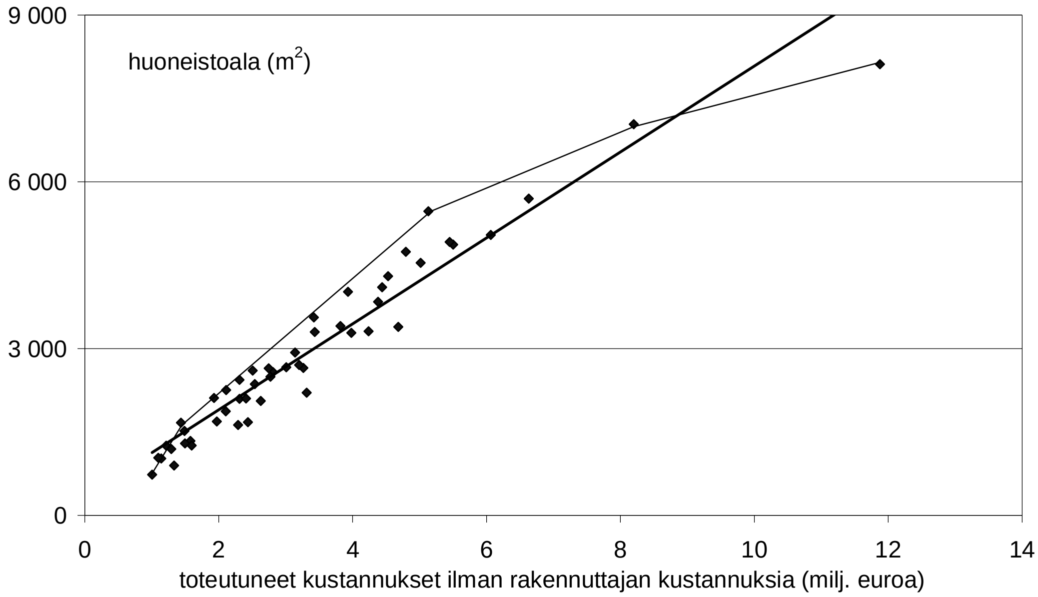

Fig. 4. Scatter diagram: output of building project [net floor area] in relation to used resources [realised construction costs]. Sample N=50 apartment-block projects.

In the comparison of projects special attention was given to the comparability of input data. For example, the content of different sets of area data in the sector has been defined quite well on the national level and can be considered comparable. On the other hand, the comparability of cost data is less certain.

In the study an attempt was made to secure the comparability of subjects by excluding the client's costs and by concentrating on site costs. The results of a productivity comparison are also impacted by the quality level of buildings since the quality level of units built wasting resources may be higher which also raises their sale price.

In addition to finding productivity indicators, the study also tried to define other key indicators which would allow dividing the sample projects into good and bad ones. Such an indicator is the predictability of costs represented by the ratio of realised costs to planned costs.

One indicator that proved good during the study is the ratio of realised profit margin to planned profit margin. The major advantage of that indicator is its neutrality towards different projects whose target margins may differ widely. The indicator based on a change in profit margin was not, however, tested in practice during this study.

3.3 Factors Affecting the Success of a Building Project

So-called best practices may underlie the success of good projects measured by different indicators. Indicators are also susceptible to various environmental factors which the site cannot impact even if they are known to have an advantageous or adverse effect on the result of the productivity indicator. The relationship between explanatory factors and productivity was studied using BayMiner data mining tools.

The explanatory factors used in the study could not, however, identify good procedures. The reason is that the selected explanatory factors were too common. For instance, using applied quality procedures as the explanatory factor could not provide additional information about good projects since nearly all apartment-block projects apply the same quality procedures. The situation would be different if quality procedures were just being launched and different projects applied different procedures. The scheduling practices used in the studied material were also in line with the prevailing good production practice, and there were no differences between projects in that area.

The analysis of environmental factors revealed that the best projects based on the selected productivity indicator were all outside the metropolitan area. The explanatory factors were the parking and foundation engineering solutions which increased costs per useful area. There may also be other factors that raise or lower costs which were not detected on the basis of the studied material.

4. Conclusions

4.1 Methodology

The developed research method was found to be, on the whole, usable in measuring site-level productivity. It is important that the productivity indicator is complemented with other performance indicators since it is difficult to establish a single site-level productivity indicator that is descriptive enough. It was also discovered that the data mining tool based on the Bayes Network is suitable for analysing explanatory factors in a site-level productivity survey.

The research found that indicators that explain and complement actual productivity indicators should be quite accurate – preferably ones that depict site processes. It would be good to select the measured processes serving as the explanatory factor from among recently launched site processes since differences still exist between them. In an ideal case someone has made an educated guess in advance about the impact of a certain factor on the project turning out good or bad. Then, the method used in the study could verify the accuracy of the prediction and thereby confirm the procedure as a good one.

4.2 Productivity Indicator

The productivity of a construction company or project can best be measured by a value-added-based productivity indicator. The indicator output is the monetary value added to the company or project. The indicator input consists of the labour input within the company or into the project, measured, for instance, in person-years.

Physical productivity indicators are most suitable site productivity indicators. The output may be produced useful area, and the input construction costs or own labour input on site in person-years. The problem with physical productivity indicators is that they are not comparable between highly different construction projects.

4.3 Suggestion for a Site Performance Indicator

It is suggested that site performance be assessed based on a profit-predictability figure indicating the ratio of realised profit to target profit. Profit predictability is a comprehensive indicator of the success of site operations. Its significant advantage is its neutrality vis-à-vis different projects whose target profits may vary widely.

Project Delivery Systems and Contractual Practices

Experience on a PPP-based High Speed Road Maintenance Project in Hong Kong

Abstract

There is a growing trend for governments worldwide to explore new routes for procuring infrastructure facilities, such as various forms of Public-Private Partnerships (PPP), due to restricted fiscal budgets and an increasing demand for infrastructure facilities. Many practitioners and researchers believe that PPP can harness flexibility, encourage innovation, enhance productivity, allow better risk allocation, increase value–for-money, and improve cost-effectiveness by involving the private sector in the provision of public services. A Work Department of the HKSAR Government (the Department) has recently introduced the concept of PPP into their road maintenance programmes – the High Speed Road Maintenance Contract. The project is an interesting challenge to relevant public authority as the form of contract, project organisation, risk allocation and points of responsibility are totally novel. Most of the infrastructure projects using PPP approach are of much larger scale and are in the form of PFI so that the private sector is responsible for financing, constructing and maintaining the road network. The experience gained from this project, and especially its success would improve our understanding on whether PPP is suitable for similar road maintenance projects around the world. Before investigation of the success level of the new project, it is important to study the view and standpoint of the stakeholders on the issue of PPP as the human factor is believed to be a crucial contributor to the success of PPP. The paper begins by outlining the nature of the PPP high speed road maintenance project. As there is potential for the Department to extend the use of PPP approach to other road maintenance projects, a questionnaire survey conducted with other potential stakeholders of future PPP projects of a similar kind are presented to examine the effectiveness of the new PPP contract from their perspective.

Keywords: Public-private partnerships, high speed road maintenance, questionnaire survey

1. Introduction

Public-private partnership (PPP) is becoming an increasingly popular option of project delivery for governments. In view of the restricted fiscal budgets and the growing demand for infrastructure facilities, governments worldwide are striving to explore the use of private sectors' resources and particularly to involve private finance in the construction of facilities for the purpose of providing services. Many practitioners and researchers believe that PPP can harness flexibility, encourage innovation, enhance productivity, allow better risk allocation, increase value-for-money, and improve cost-effectiveness by involving the private sector in the provision of public services. It is also believed that PPP can improve project procurement environments and the relationship between project participants by changing the traditional adversarial scenario to cooperative partnerships [1].

The idea of PPP is not new to Hong Kong. Since the late 1960s, Hong Kong has gained valuable experiences from the successful development of five large-scale tunnel projects using the Build-Own-Transfer (BOT) arrangement [2]. In 2003, the HKSAR Government (the Government) has set up a clear goal in developing the city into a society with "big market, small government" [3]. This new principle of governance is supported by the idea that government should "steer more and row less" and that the role of government should be "proactive market enabler" [4]. In response to that, the Government has begun to explore different options of private sector participation. Several guidelines were published aiming to encourage the use of the private sector in serving the community. The Chief Secretary for Administration, Donald Tsang pointed out in the foreword of the guidelines that it is the responsibility of the Government to make the best use of both the public and private sectors so as to ensure that government activities do not dominate the market and would not absorb more of the gross domestic product than is optimal for economic success. With the help of the private sector, the Government can then focus its limited resources on identified priorities. [5]. In addition to new infrastructure projects, the Government is also being proactive in examining existing activities to determine whether they can be provided by the private sector, and the use of PPP would be explored for both traditional and innovative projects [6]. By moving tasks into the private sector, the Government believed that employment and business opportunities can be developed and expanded in ways that are simply not possible within the public sector [7]. In this paper, the effectiveness of PPP is examined through a pilot PPP maintenance project in Hong Kong.

2. Case Study in Hong Kong

Aligning with the government direction, a Work Department of the HKSAR Government (the Department) has introduced the concept of PPP into their maintenance contracts and a trial project, the High Speed Road Maintenance Contract was started last year based on the PPP approach. Being different from Private Finance Initiatives (PFI) – the most common form of PPP, this project involves no financial investment from the private sector. While many people equate PPP to PFI after its introduction by the British Conservative Government in 1992 [8], PPP actually has a much broader scope. It is defined as a cooperative venture between the public and private sectors for the delivery of a public service through appropriate allocation of resources, risks and rewards [9]. The ultimate objective of PPP is the joint realization of commercial and social benefits between the two parties [10].

2.1 Problems in Traditional Term Contract

The traditional high speed road maintenance project is in the form of a term contract. Staff from the Department are responsible for general road inspection to identify defects on the road which require work to be carried out. Work orders are then issued by the Department to the contractor for carrying out the corresponding maintenance work. There is full time supervision on the contractor to ensure the quality of work. Upon completion of the work order, the amount of work done by the contractor is measured and payment is given to the contractor according to the agreed rates stated in the contract. The traditional system of the maintenance project is considered as insufficient, since the amount of maintenance work to be carried out is budget driven instead of as-need. In addition, it is time consuming and tedious to deal with the large amount of work orders. A great amount of resources is also required for carrying out the measurement, estimation, accounting work as well as inspection and full time supervision. There is no room for innovation in the traditional term contract as the method of work is specified in the contract and little flexibility is allowed. Maintenance work is also considered to be inefficient in the traditional term contract. Long and complicated procedures are required to be gone through from the time of defect identification or receiving complaints to issuance of work order.

2.2 The MOM Contract

As a result of the deficiency in the traditional system of road maintenance and in response to the Government announced policy, the Department has taken a step towards PPP. It aims to improve the efficiency, performance and cost-effectiveness of high speed road maintenance project through involving private sector resources and enhancing cooperation between the two parties. To test the successfulness of PPP in high speed road maintenance project, a new project based on the PPP approach was started in 2004 by the Department using the western network of the high speed roads as a trial. By drawing upon the experience learnt from the trial project, other high speed road maintenance projects may also adopt a PPP approach on completion of its existing term contract.

The new high speed road PPP contract has taken the form of a Management, Operation and Maintenance (MOM) Contract and is a performance-based maintenance contract. In this project, the contractor is responsible for providing scheduled road maintenance services including road inspection, planning, design and supervision for repair and minor improvements of roads and highway structures, as well as for handling complaints from the public during the 4 years contract period. The management and maintenance works required to be carried out by the contractor are grouped under 3 main work orders which were issued at the beginning of the contract period. The major work items in the work orders are highlighted in Table 1 below.

Table 1: Major work items covered in the three work orders issued at the beginning of the contract

Work Order 1	**Work Order 2**	**Work Order 3**
1. Provide network manager 2. Maintain road markings and road studs 3. Maintain road drainage system 4. Conduct routine maintenance inspections for slope and undertake maintenance works	1. Conduct road safety inspection and undertake general road maintenance works 2. Conduct road detailed inspection and undertake general road maintenance works 3. Conduct structural inspection and undertake structural maintenance works	1. Maintain vegetation 2. Sweeping road by mechanical sweeper 3. Picking up litter 4. Cleansing traffic signs and the like 5. Cleansing carriageway 6. Maintain road network in hygienic condition 7. Operate calls receiving centre 8. Provide electronic maintenance management system

However, only 65% of routine maintenance works are covered under the PPP part. The rest of the non-scheduled, unplanned works are carried out according to the traditional work orders system. The contractor is entitled to a lump sum payment for the PPP component. Monthly audits would be carried out by the client's representative to determine the level of payment that the contractor can receive according to the predefined performance yardsticks. Samples are selected for audit is carried out on a random basis and 24 hours' notice would be given to the contractor before the audit. In addition to monthly audit, with no advance notice given to the contractor, the Department's staff would also continuously carry out road defects inspection on the road network. Default notice would be issued to the contractor on identification of any defects and a fixed sum of money would be deducted from the contractor. It is believed that the performance-based payment system can allow greater flexibility, encourage innovation, enhance efficiency and improve cost-effectiveness of work by allowing concurrent engineering of functions, use of new materials and techniques [11]. The performance standard of the contractor is measured by a set of benchmarks in different areas of works as specified in the contract. For example for road markings, a continuous road marking line with more than a certain percentage loss of paint in any given section length would be counted as a defect. The lump sum payment entitled by the contractor would be adjusted according to the number of defects discovered by the client's representative in the audits. Table 2 illustrates the differences between PPP and traditional approach in the high speed road maintenance contract.

Table 2: Comparison between PPP and traditional term contract

	Traditional	**PPP**
Form of contract	Maintenance term contract	Management, operation & maintenance contract
Terms of payment	Schedule of rates	Lump sum
Payment mechanism	Work-based (payment according to amount of work done)	Performance-based (reduction of monthly sum if performance standard not reached)
Specification	Method specification	Performance specification
Quality control	Full time supervision	Inspections & monthly audits
Road defects inspection	By staff of the Department	By the contractor
Time to carry out maintenance work	On receiving work order from the client	Immediately after identification of defects
Duties of client	Estimation, measurement, issuance of work orders, road inspections, full time supervision, programming of maintenance works	Audits and ad hoc Inspections
Duties of contractor	Maintenance work according to work orders	Road inspections, operation of call receiving center and electronic maintenance management center, planning and programming of works, general road maintenance
Documentation	Work orders (by client)	Work programme, report of finished work (by the contractor) Inspection records & site audit checklists (by client)
Types of work covered	All types of maintenance work	Routine & scheduled maintenance works
Relationship	Principal – agent	Peer – peer

2.3 A New Form of PPP

The new maintenance project is a great challenge for the Department as the form of contract, project organization, risk allocation and points of responsibility, etc. are all novel to the Department. No other similar project has ever been carried out before. Most of the overseas maintenance projects using PPP approach are of much larger scale and are in the form of PFI, which means the private sector is responsible for financing and constructing the new roads together with the subsequence maintenance of the road network. For example in Singapore, according to the PPP Handbook for public consultation [12], PPP is a form of “best sourcing” that mainly used in cooperation with the private sector to deliver services that require the development of new physical assets. Some of the staff in the Department also believed that the optimal and ideal form of PPP project should be one which starts from the capital works and continues with the maintenance works. This can encourage the contractor to uplift the construction quality so as to save its future maintenance cost. The contractor can then be paid on the “user pays” principle through the operation of toll roads. However, this kind of PPP in highways schemes may be difficult to be carried out in Hong Kong. It is because the road network in Hong Kong is almost fully developed, and very few new roads will be constructed in the near future. For the renovation of old roads or other road improvement works, it is difficult to convince the contractor to finance the work and be paid back through operating the toll roads without a good business case. Like other BOT-type projects, there would be practical, social and cultural difficulties as it is a radical policy change to charge on a user-pays basis for services that traditionally had been provided free of charge by the government [13].

3. Research Methodology

At the time of the research, the high speed road maintenance project using the PPP approach has only been implemented for less than a year. Therefore, not much data can be collected for evaluating the cost effectiveness of the project and the performance of the contractor under PPP. However, as there is potential for other road maintenance projects to migrate to PPP, views of other staff within the Department as well as other contractors should also be collected to uncover their views on the new PPP approach. It is believed that their opinion would be more objective and without bias as they have not been involved in the PPP project. In addition, since the human factor would also be a crucial criterion for the success of PPP, it is important to study the attitude and perspective of other stakeholders towards the new approach. This may be helpful in developing a PPP culture among the stakeholders within the organizations.

A questionnaire survey had been conducted with some potential stakeholders of future PPP projects to examine the effectiveness of the new PPP contract from their perspective. They include different levels of staff from the Department in various groups of maintenance projects (including both high speed road and local road) as well as contractors who have been involved in traditional term contract. A total of 33 respondents completed the questionnaire, of which 26 were from the Department and 7 were representing the maintenance contractors. The profile of the respondents is shown in Table 3.

Table 3: Designations of respondents

The Department	
Engineer or Technical Officer	12
Inspector of Works	6
Work Supervisor	8
Contractor	
Manager	2
Site Agent	5

The questionnaire consists of 17 statements regarding the cost and effectiveness of the PPP contract. To improve the understanding of the respondents, a brief introduction to the new PPP approach was provided to them as a preamble to the questionnaire. Depending on their level of understanding, questions were explained in greater detail and reasons for their answers were sought through face-to-face or telephone survey.

4. Questionnaire Findings

The results of the questionnaire show that the respondents from the contractor group generally have more positive views on the effectiveness of PPP while the responses from the Department's staff are more diverse. Many of them might have had some reservations in answering the questions. In this paper, only part of the questionnaire findings (in the aspects of time, cost and quality) are presented.

4.1 Effectiveness of Contractor-led Inspection

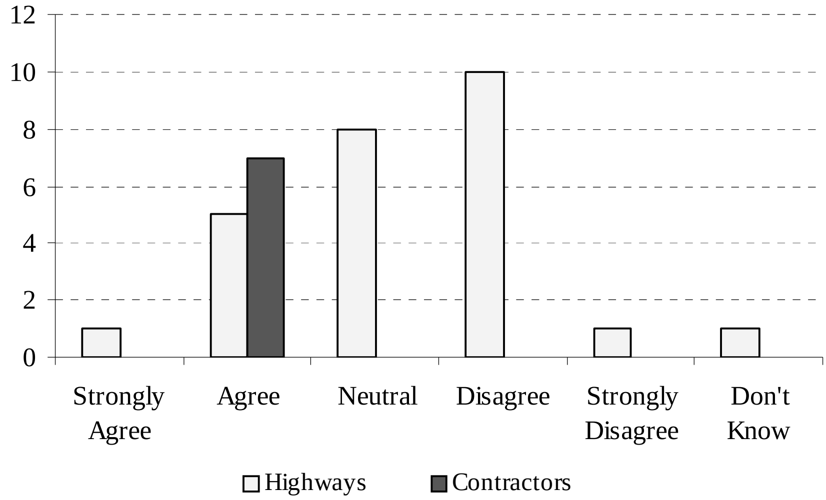

Figure 1: Effectiveness of contractor-led inspection in identifying defects

As shown in Figure 1, all respondents from the contractor group agreed that inspection carried out by the contractor is more effective in identifying defects than that carried out by the client representative. They claimed that the contractor can take the initiative to work and more resources can be devoted for full-time inspection. It was believed that payment reduction on defects discovered is also an important factor driving the contractor to more effective inspection. On the contrary, most respondents from the Department (11 out of 26) disagreed with the statement. They thought that the contractors in Hong Kong do not have self-discipline and supervision is required to monitor their work. There is also large percentage of the Department's staff (8 out of 26) expressing neutral view on the statement. They thought that the effectiveness of inspection depends on many factors including the tender cost, audit requirement, individual initiatives, human resources input, as well as qualification, training and experience of the inspectors. Some staff of the Department agreed that contractor-led inspection would be more effective. They believed that the contractor would have more resources and can have a dedicated team to take charge of inspection, whereas in a traditional term contract, there is not enough staff from the Department for the inspection work and the inspectors are always tied up with other duties at the same time. In addition, any unrectified defects would contribute to payment reduction. Thus the contractor would devote more effort in the inspection work.

4.2 Efficiency of Maintenance Work

Regarding the efficiency of maintenance work, nearly all respondents from the contractor group agreed that work carried out through PPP approach is more efficient than traditional term contracts. It is because work can be carried out directly without waiting for the issuance of work order. The majority of respondents from the Department also agreed with the improved efficiency due to the streamlined procedures and better programming of work. Time can be saved in preparing work orders which are tedious and time consuming to prepare. Some respondents had negative opinions on the efficiency of the work. They believed that the contractor would tend to leave the work until a later stage during Cyclic Lane Closure (CLC), while in the past, staff of the Department can issue work orders to instruct the contractor to finish the urgent work immediately. They thought that there is limited control on the contractor in the PPP contract.

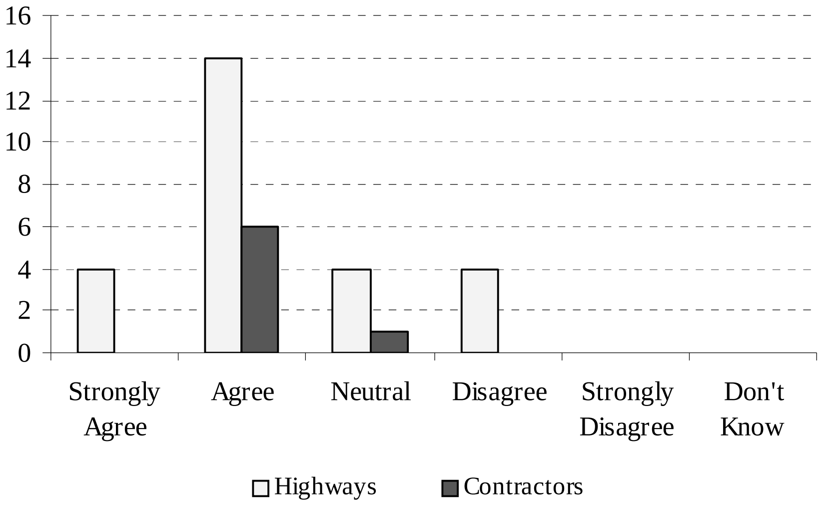

Figure 2: Efficiency of maintenance work carried out through PPP approach when compared with traditional term contracts

4.3 Amount of Documentation

For the amount of documentation, most respondents from the contractor group claimed that the amount of documents the contractor has to deal with has greatly increased. The contractor has to submit their programme and completion report to the client. On the contrary, most respondents from the Department (12 out of 26) agreed that the amount of documentation can be reduced in PPP contract due to the great reduction in amount of work orders. There would no longer be estimation, measurement and checking of work completion. However, some respondents argued that there would be additional documents like default notice, inspection report and audit report resulting in a similar overall amount of documentation.

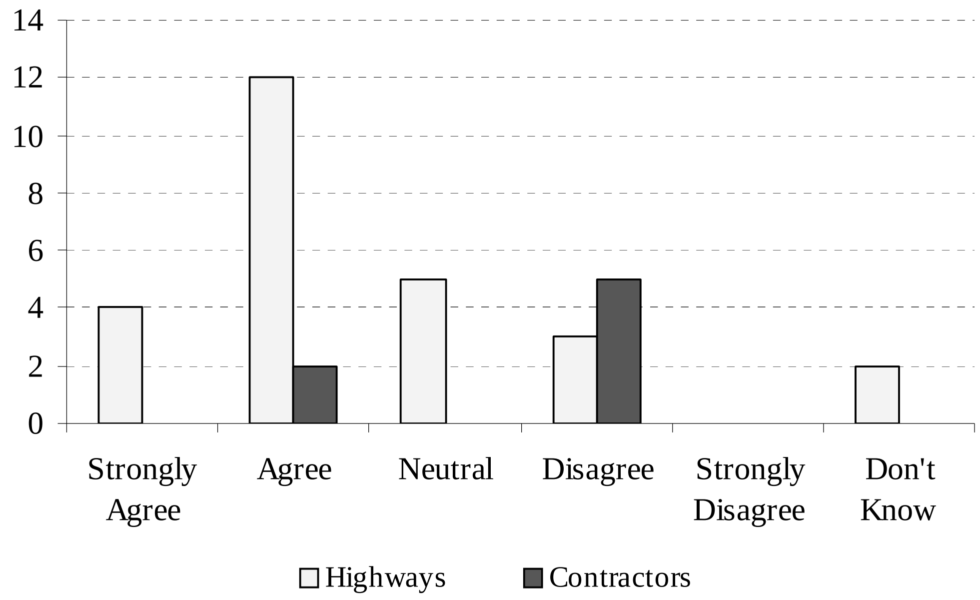

Figure 3: Potential of reducing the amount of documentation

4.4 Amount of Administrative Work

4 out of 7 respondents from the contractors believed that the amount of administrative work would be more than the past as the scope of work of the contractor has increased. Most respondents from the Department believed that the amount of administrative work can be reduced due to streamlined procedures and better communication. They no longer need to prepare or sign work orders for works under the scope of PPP.

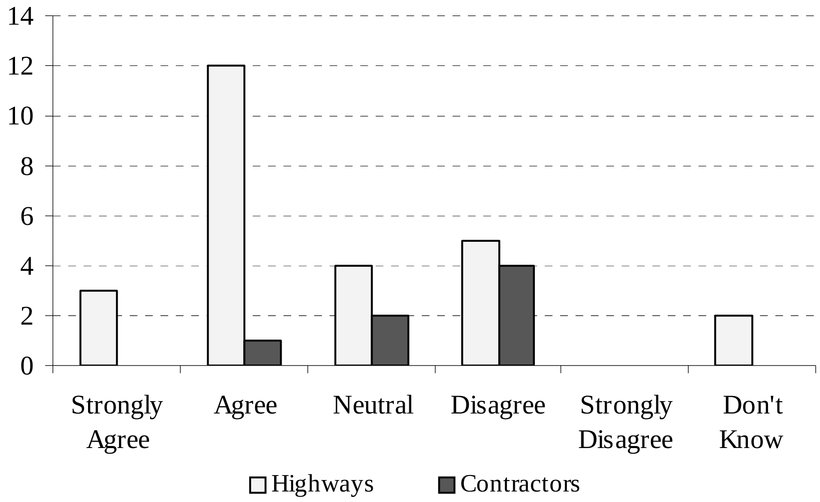

Figure 4: Potential of reducing the amount of administrative work

4.5 Staff Cost of the Department

As shown in Figure 5, most respondents from the two groups also agreed that staff cost of the Department can be reduced. It is because most of the work has been taken up by the contractor, including inspection, coordination and planning. There is no longer full-time supervision on the contractor and thus the number of supervisor can be reduced. Besides, preparation of work orders, estimation, measurement and accounting work can also be reduced. Some respondents argued that staff cost of Department depends on the contractor's performance. It would require more audits if the performance of the contractor is poor.

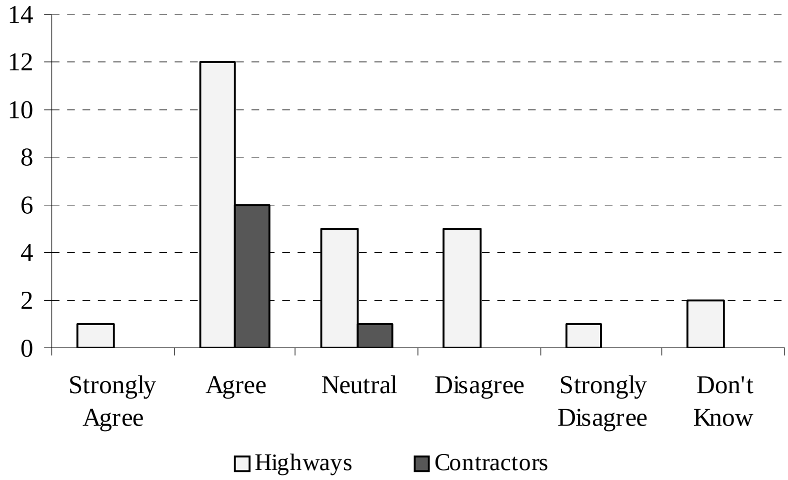

Figure 5: Potential of reducing the staff cost of the Department

4.6 Overall Cost Effectiveness

As shown in Figure 6, many respondents from the contractor group (5 out of 7) and the Department group (11 out of 26) believed that PPP would be more cost effective than a traditional term contract in the long run. Some staff of the Department surveyed postulated that the overall cost effectiveness depends on the tender price, the conditions of contract as well as the contractor's performance. More resources are required if the contractor is not good.

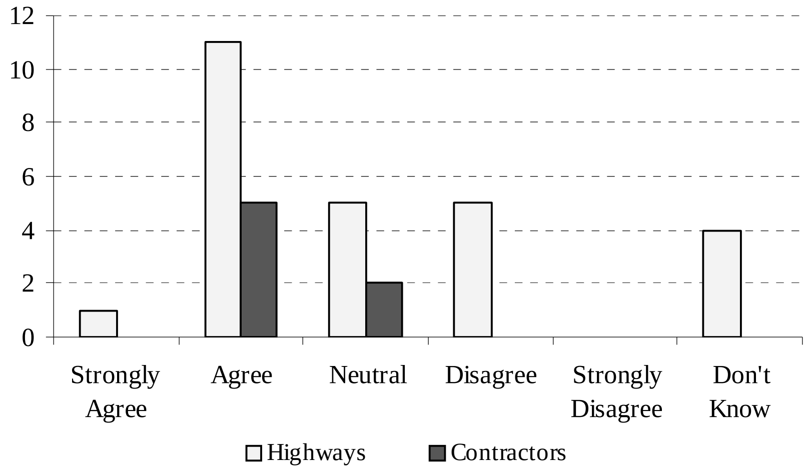

Figure 6: Overall effectiveness of PPP when compared with traditional term contract

5. Conclusion

The idea of PPP has been widely adopted in many countries over the world. It has mainly been used in large-scale capital or infrastructure projects in the form of PFI. The Department of Hong Kong has extended the use of PPP to their maintenance contracts. A new project, the high speed road maintenance contract was launched in 2004 using the PPP approach. It is a form of MOM contract with the contractor being responsible for the management and maintenance of the high speed road as well as operation of the call receiving centre throughout the four years contract period.

To study the potential for future development of PPP in other maintenance projects, a questionnaire survey was conducted to study the perspectives of potential stakeholders of future PPP projects on the effectiveness of the new PPP contract. The results from the survey indicate that most respondents supported the use of the PPP approach and agreed that it would be more cost-effective than the traditional term contract. They believed that the new approach can help by bringing in operational efficiencies, cost savings and better output performance.

DBB, DB or DBM?
Performance of Road Project Delivery Methods

Tiina Koppinen
VTT – Technical Research Centre of Finland (email: Tiina.Koppinen@vtt.fi)
Pertti Lahdenperä
VTT – Technical Research Centre of Finland (email: Perttti.Lahdenpera@vtt.fi)

Abstract

Internationally, road procurement is moving towards more integrated services. At the same time, the number of alternative project delivery methods has increased making selection of the best one difficult. The client must understand the features of the methods in order to select the most effective ones. That is why the presented study compared the performance of Design-Bid-Build (DBB), Construction Management (CM), Design-Build (DB) and Design-Build-Maintain (DBM). Based on the analysis of road procurement, more integrated services give better value for money and are of more help to the client in attaining his goals than more traditional methods. Yet, one should realise that each method has its typical applications, and all methods are not suitable for all purposes.

Keywords: Road procurement, project delivery, performance, comparison, life-cycle

1. Client's Changing Needs as Starting Point

Project delivery methods where the implementer offers more integrated service packages are increasingly used in infrastructure projects worldwide. The client no longer splits up the project to procure different types of services by different contracts. Besides construction, at least technical design and maintenance for a certain time period, often also financing, are covered by a single contract. The change in the modus operandi is the result of clients wanting to focus on their core businesses as managers of infrastructure networks as well as the overall aim of generating added value.

Generally, broader service packages have been assumed to allow optimising the product and implementation as a whole as well as to actuate sector development. Yet, contrary views in favour of traditional methods are also voiced: splitting up the project into small components is believed to increase competition in the markets and ensure the client's decision-making power concerning the details of the project. This together with other presented critique raises the issue of the usability and actual effectiveness of various delivery methods.

2. Performance Assessments as the Goal

The presented study charted the performance of different delivery methods in road procurement from the international viewpoint focussing especially on three areas:

- Examination of the operating principles and present performance level of various methods in actualized road projects.
- Assessment of the development means and potential of delivery methods and their resulting future performance.
- Anticipation of changes in the operating environment, and evaluation of their impact on the usability of different delivery methods.

Since there is special interest towards Design-Bid-Build (DBB), Design-Build (DB) and Design-Build-Maintain (DBM) in Finland, the study was to analyse the performance of these delivery methods and their applicability. As the municipal sector uses Construction Management (CM) it was also included in the comparison to some extent. Different financing solutions and costs as well as (indirect) social impacts were excluded from the study.

3. Charting of International Experiences

The study looked at the experiences gained from different project delivery methods in England, Australia, New Zealand and the United States in addition to Finland. An earlier study [3] found these countries the most innovative, which was presumed to mean that they were best poised to answer questions about new methods. Data were collected by interviewing over 60 persons representing different project parties in these countries and by charting and making use of studies conducted there and in other countries [1]. In the assessment of the merits of the delivery methods, the client's viewpoint was emphasised. The viewpoints of the contractor, designer and end user were also considered in order to ensure the support of all parties for the methods. Only that ascertains the positive future development of the sector.

In the studied countries there is a clear trend towards more integrated services and more risk borne by service providers. DB has gained ground on DBB and even replaced it completely in some countries. It is considered effective in procuring roads since it shortens project duration thereby improving cost certainty. Just about the only problem seen with it is the cooperation between the parties (especially designer/contractor) which various joint enterprise models seem to be able to address.

Various applications of DBM have also been used alongside DB since the 1990s to improve the life-cycle economy of roads. The applications have ranged from fully client-financed roads to pure toll roads. With the former, the enlarged responsibility of the private sector covers only 10-year maintenance whereas in the case of toll roads the project company collects revenue in the form of user fees over a contract period of 30-40 years. DBM has led to effective operation in terms of quality, schedules and costs. Yet, for instance, the used payment bases have also been criticised.

CM has been used hardly at all in road procurement. Finnish experiences of CM indicate some benefits from it although, at the same time, the fact that buying small work packages does not allow the industry to develop drew criticism.

4. Cost Savings through Integrated Services

Each phase of a project (procurement, design, construction and maintenance) involves a certain cost and duration. Costs may be incurred by the client's organisation (procurement, supervision) or industry (tender preparation, design, construction, maintenance, consulting). In the study, the interviewees indicated the actual phase-level, party-specific cost changes of various delivery methods compared to traditional procurement based on projects they have carried out. The costs for comparing different delivery methods were calculated on the basis of relative costs where the starting point was the cost structure of two reference projects. The chosen study period was 30 years, and delivery methods were compared on the basis of the present values of their costs.

The analysis [2] showed that DBB is the slowest and generally leads to the highest total costs in road procurement as shown by Fig. 1. CM speeds up project implementation, but costs about as much as DBB. The duration of a DB project may be slightly longer than in CM due to the longer procurement phase, but shorter than with DBB. On the other hand, the costs are clearly lower than with the CM and DBB. However, DBM is the one that yields the largest savings. In DBM the project takes a little longer than in DB and especially CM.

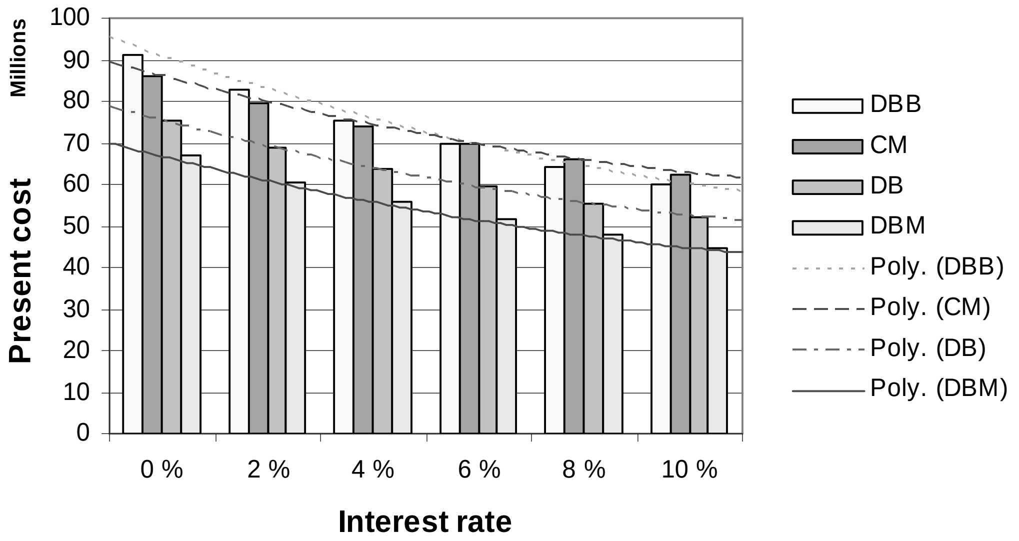

Figure 1. Costs of reference project by different delivery methods and at different discount rates.

The savings from DB and DBM depend on many factors; the most significant one appears to be savings in construction costs. Moreover, the methods also lower a project's supervision, project management and design costs. On the other hand, the savings in maintenance costs appear to have little effect on the present value of total project costs. The present cost is also affected by the discount rate, but – with the exception of relative position of DBB and CM – changes in it do not alter the ranking of the delivery methods. Subsequent assessments were made using relative costs based on a discount rate of 6 per cent.

5. Added Value through Integrated Services

Not only does the cost behaviour of procurement methods vary, their ability to generate value for the client and the other parties also varies. The value criteria generally used were grouped in the study into the value factors of Fig. 2: cost certainty, time certainty, short cycle times, good quality (aesthetics, travelling comfort, minor need of maintenance), safe and environment-friendly implementation, flexibility (ease by which client can effect changes), smooth delivery (effective communication, no disputes or claims), public inconvenience (road availability, minimum user disturbances). The interviewees assessed how well these goals were attained by different delivery methods compared to DBB. The viewpoint was mainly that of the client.

In general, the interviewees found that methods where the contractor is responsible for design (DB and DBM) generate more value. The broader the service package, the better the perceived value generation on average. DBB and CM, on the other hand, were believed to lead to an increased number of interfaces between the parties and possibly to problems, inefficiency and lower value generation. CM was, however, considered superior to DBB in some areas.

Different clients and projects may emphasise value factors quite differently. If flexibility becomes the determining criterion, DBB and CM are the best methods. On the other hand, if the weight of quality and flexibility trebles, the value generation of DBB exceeds that of DB. If again, the weights of flexibility and time certainty increase 2.5-fold, CM generates more value than DB. Yet, as the study focussed on a so-called average project, various value factors were assigned equal weight in drawing conclusions and the illustration of results.

When value generation was studied from the viewpoints of other project parties, contractors and designers were found to have noticed some problems also with the more integrated methods. Contractors perceived high tender costs and cooperation with the designer the biggest problems. Risk allocation and increasing project sizes also provoked discussion. Typically contractors did, however, find that broader service packages lead to efficiency and better possibilities of developing operations. Designers saw problems especially in the implementation of DB where they are often subordinated to the contractor as the limited economic resources of designers seldom give them an equal footing.

Figure 2. Value generation capacity of different procurement methods compared to DBB.

6. Economic Efficiency is the Key

There is a continuous demand on public clients to get more value for tax money. The accrual of costs or value generation in themselves do not prove the excellence of a delivery method in that context. The significant factor is the amount of value the method can generate in relation to its costs. That is why the concept of economic efficiency (EE) was introduced into the study. It indicates the normative ratio of generated value to costs in comparison to DBB.

The conducted analysis and Fig. 3 in the next chapter show that CM's economic efficiency is on a par with DBB. DB improves EE significantly: it generally allows generating more value for the client at lower costs. DBM as much as doubles the benefits of DB and thus gives the best value for money. The total differences are so large that moderate changes in the weights of value factors play no role in the ranking of delivery methods. The overall assessments requested of interviewees concerning the "value for money" of various methods were also in line with the above analysis. The general reasons perceived to contribute to the superiority of DB and DBM included transfer of risk to the private sector, the optimised delivery process and quality as well as utilisation of the management skills of the private sector.

7. Development is the Basis of Future Performance

The study also attempts to provide answers for the long term instead of just evaluating the "historical performance" of delivery methods. Therefore, the interviewees were asked to assess the development potential of different methods. Development potential was divided into more easily assessable sub-factors by main categories as follows: 1) adaptability/regeneration of process, 2) generation/utilisation of information, 3) project team coherence/capacity for cooperation, and 4) means and possibilities of improving workability of delivery method. The first three categories represent general preconditions for development of the activity over the long term. The fourth one covers the concrete means for improving the efficiency of delivery methods presented by interviewees and literature. Based on the assessments of the interviewees and on the critical analysis, it became evident that DBB and CM have little development potential whereas the potential of DB and DBM is significant. The relative development potentials of different delivery methods are indicated by the lengths of the arrows in Fig. 3. However, here the lengths of the arrows are meaningful only in relation to each other, not as exact numeric values.

Future performance is the sum of present performance and development potential. Thus, there are good grounds to assume that the performance gap between DBB and CM on the one hand, and the more integrated DB and DBM on the other, will only widen in the future.

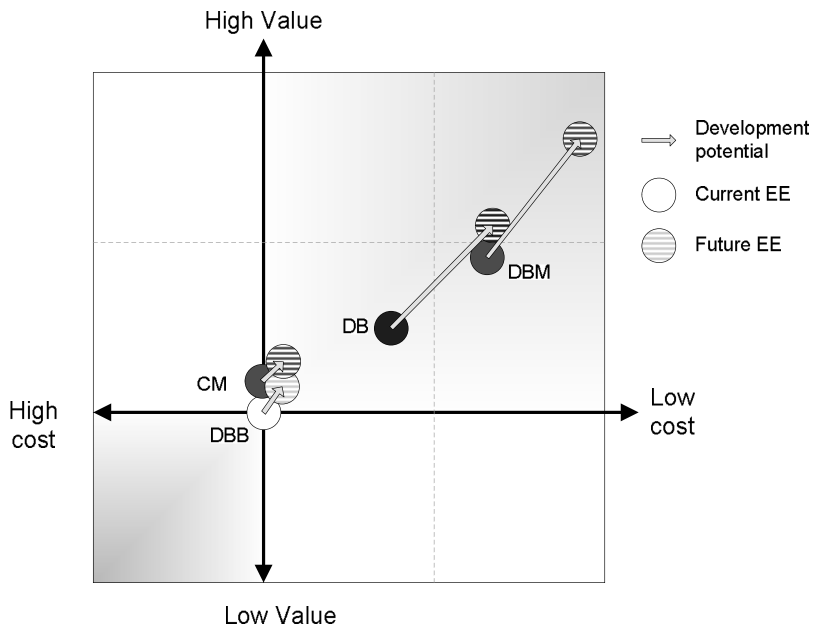

Figure 3. Current economic efficiency of delivery methods and its future development.

Attainment of the full performance capacity of delivery methods naturally requires elimination of the existing factors that limit efficiency. The research report [2] specified the improvement proposals already considered as development potential above. Their aim is to optimise the performance of delivery methods from the viewpoint of all parties (see [1]). In DBB, for instance, the constructability of designs and cost certainty can be improved. In CM, the overlapping of operations can be reduced thereby making project management more effective. In DB, tender costs can be cut, cooperation between suppliers improved, risk allocation optimised, opportunities to innovate increased and quality improved. In DBM, tender costs can be reduced, risk allocation optimised, innovation promoted and flexibility increased.

8. The Future Operating Environment

The future will bring changes also to the operating environment where roads are procured and built. Changes will affect factors guiding procurement (rules, financing, changing traffic environment) as well as the production process – even the end product. In light of the anticipated changes it would appear that more integrated delivery methods will allow us to adapt better to changes than more traditional methods. Yet, there would appear to be no serious hindrances to the use of any of the methods in the future.

9. Application Areas of Different Delivery Methods

The study would seem to indicate that more integrated delivery methods provide better value for money than traditional ones. Each delivery method does, however, have its distinct best applications outside of which its advantages cannot be realised in full. According to Fig. 4, DBB is still suitable for small and simple projects, which offer little room for innovation, or which involve many factors of uncertainty due to parties or issues external to the project. CM, again, is well suited for large and/or tight-scheduled projects involving many constraining factors where the client also must effect changes during implementation or the life cycle.

As project size and degree of freedom increase, DB and DBM become more preferable. Since DBM is suited for larger-than-average projects, DB can be considered appropriate for average projects. DB and DBM projects must not, however, involve factors of uncertainty due to third parties.

10. More Integrated Service Packages for Future Roads

The study clearly indicated that more integrated service packages can provide concrete benefits to all parties compared to DBB. Thus, further development of DB and its adoption as the standard alternative to DBB is recommended. The benefits of DBM are also apparent; it is generally the best solution for large projects.

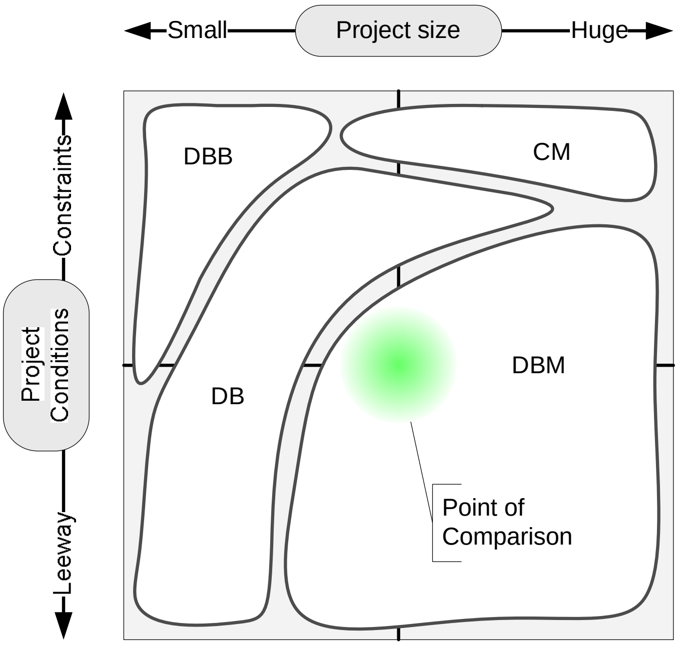

Figure 4. Optimal application areas of various delivery methods.

Changes in procurement must yet occur in steps in order to give industry time to adapt and to allow time for contract standardisation and development of appropriate specifications. Selected delivery methods must also be used continuously to motivate people to acquire the know-how required by new methods which will also make them better. The private sector must at the same time focus on relationship-building and developing cooperation models. Thereby road procurement and implementation can be raised to a new level which furthers the attainment of the client's goals, increases industry's productivity and profitability, and gives society the best possible value for tax money.

It should be kept in mind that the study targeted only road projects. Thus, the results cannot be assumed to be directly applicable to vertical, or even other infrastructure construction, since these often differ from road construction in many ways.

Advanced Design Management as Part of Construction Management (CM)

Juhani Kiiras
Helsinki University of Technology (email: juhani.kiiras@tkk.fi)
Matti Kruus
Indepro Construction Management Consultants Ltd (email: matti.kruus@indepro.fi)

Abstract

Construction management (CM) contracts are increasingly used in large building projects in Finland. It is understandable that opinions on the relevance of CM forms of contracts vary widely. Finnish owners have had mainly positive but also some negative experiences with their CM projects. Typically, many owners are starting their building investments before users are known or users are not yet ready to determine their design requirements. CM contracts make it possible to start new buildings before even room layouts are designed. It has not been easy to change the traditional culture of the sequential design and construction to the concurrent CM culture. The greatest problems lie inherent in the delivery and the contents of the building design documents. The suggested design management model (FINSuke) enables true teamwork between project actors. The results of the initial tests suggest that there are many advantages in CM projects compared to fixed-price projects. For example, it is possible to arrange enough time for designers in the working drawing phase. Designers may now protect the visual and technical solutions without drawing and specifying all the details before the tendering of subcontracts. In addition, it is possible to utilize the solutions of product suppliers. Final designs can be developed in cooperation among a CM manager, designers, and suppliers before the assignment of subcontract agreements. The best performing contractor (or supplier) is then chosen in competitive terms.

Keywords: Buildings, construction management, design management, Finland, project delivery methods

1. Introduction

Herein, a new model (FinSUKE) for managing building design processes as part of construction management (CM) projects is introduced briefly. The FinSUKE model is being developed within the unit of Construction Economics and Management (TKK/CEM) at the Helsinki University of Technology. The FinSUKE study as a whole aims at developing **a new design management system** which will in part ensure the attainment of the project-specific (or building-specific) objectives in terms of performance, quality, costs, and schedule. In part, a few existing concepts such as the basic principles of open building [e.g. 1, 2] have been applied to this model design task.

The design management is herein approached in terms of **planning and controlling** the delivery of the design documents and the procurement concurrently as follows. In general, the two kinds of problems beset conventional engineering, i.e. weak process and weak co-operation [3, 4]. The separation of design and construction has long been presented as **the root problem of construction**. This separation threatens, in particular, the constructability of the building in question. Thus, it is no wonder that great expectations have been attached to the use of design-build contracts, where these two stages are integrated at the outset [3]. However, many empirical findings [5,6] have revealed that the design-build contract alone does not produce significantly better results than conventional procurement methods.

In the manufacturing management literature, push and pull are distinguished as the two primary techniques for managing work flows [7,8]. When the pull technique is used, a site will “shout for” design documents from designers. When the push technique is used, design documents are prepared and submitted to a site according to a design schedule. Herein, experiences have proved that no single model functions well alone. For example, a design schedule cannot be effectively derived from a procurement schedule. This is due to a fact that each of separate bidding packages is only a small, “wrong” piece from the point of view of the design process. In the FinSUKE model, the design management is perceived as **a combination of a push technique and a pull technique** (Figure 1). From the beginning, design management is a push technique until the inspections of the advancement of the design package take place. After each inspection, the remaining management of the work drawings and the specifications is a pull technique which utilized by management at a site.

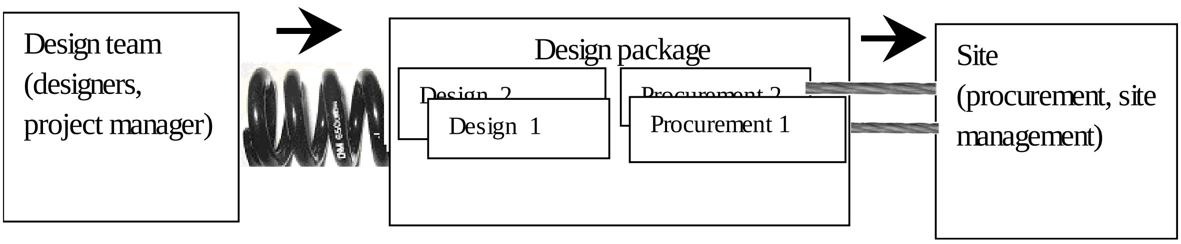

Figure 1: Building design management as a combination of the push and pull techniques.

In many countries, the dominant project delivery methods involve the ones where all the design documents are ready before construction works actually begin. Typically, these practices have been justified by such reasons as pre-managing the complete design process efficiently. On the contrary, the authors counter-argue herein that **the dependencies caused by contract forms and building design must be cut off**. Under CM contracts, the dependencies caused by the contract form are being readily eliminated. But a CM form as a delivery method does not alone guarantee flexible projects. The flexibility has to be carried into subcontracts, especially into building services (M&E) contracts.

From the design management view, **the principles of open building** offer one plausible way to produce highly flexible building (sub)solutions [1, 2]. The cutting of the dependencies not only enables the shortening of the total implementation period, but it has many other advantages. A design team is guided to approach the design of a permanent support with a long life span in a way that differs from the one adopted for the design of an infill part with a short life span. Flexible designs and technical solutions are being enhanced. The principle of cutting dependencies makes also the work of a structural engineer easier because the information such as the loads of the structures and the flues for building services (M&E) are produced on time.

The paper is structured as follows. Next, the founding differences in the use of the contract forms are emphasized in the case of Finland, the UK, and the USA. Thereafter, the three alternative process models of a CM project are introduced. The concept of design packages is introduced as the core of the advanced design management under CM projects.

2. Use of Contract Forms in Finland, the UK, and the US

In Finland, building projects have traditionally been executed under so called **main contract forms**, i.e. general lump sum contracts. A project can be delivered under one main general contract or multiple prime contracts for structural works as well as air conditioning, piping, electrical, automation, and IT installations. When **multiple prime contracts** are used, all the contracts are assigned to the main contractor for coordination only. It is much like the UK nomination system. In Finland, it is normal for owners to hire a professional construction manager (an agent or a representative), who will manage both the design process and the prime contracts. Thus, these main contracts with multiple assigned prime contracts are not considered to be a CM form of contract. In the USA and the UK, construction management with a single general contractor is one of CM forms [9]

In forms of general contracts or main contracts, owners (clients) receive fixed prices and schedules. However, their possibilities to influence processes or to make changes during construction stages are limited. Any change in design involves negotiations between a client and a contractor concerning costs and scheduling. The implied lack of competition infers that changes in the late stages can become expensive.

Chains of competition can be compared in the various forms of contracts as illustrated in Figure 2. In lump sum general contracts, chains of competition are very long. Each building-product purchase must pass 3-4 price competitions. It is very difficult to produce high quality through these kinds of elimination processes. An owner has his or her designers finalize the plans, drawings, and specifications that are used as a basis for arranging competitive bidding among interested general contractors. In turn, a general contractor arranges competitive bidding among second-tier subcontractors, and so on. All these competition stages are based on the cheapest products that meet an owner’s requirements. Designers try to avoid a decrease in quality in these competition chains by specifying increasingly detailed product requirements.

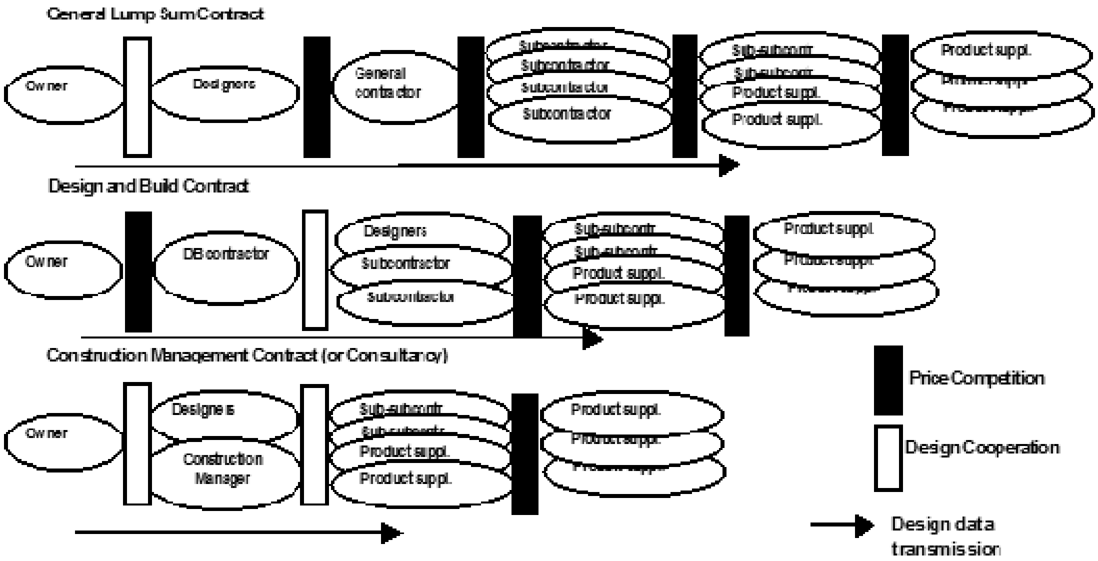

Figure 2: Chains of competition. A comparison of cooperation and price competition in general, design build, and CM forms of contracts [applying 10,11]

Thus, the number of eligible products is reduced and quality/price competition is restricted. All available suitable products and high operational performance cannot be obtained through this low bid chain. Instead, owners are left with many severe low bid problems such as weak quality, chained price competition, decisions made prematurely, and low flexibility for possible design changes [10, 12] When one of the CM forms of contracts is adopted, the improved performance can be part of the selection procedures. In addition, the freedom of suppliers to offer their solutions and assume the responsibility for same can be incorporated into contracts.

The Finnish forms of CM consist of two models as is the case in the USA and the UK, namely, CM consulting (Agency CM or CM for fee) and CM contracting (CM at risk). Construction management is characterized as a form where a professional CM organization leads a project in close cooperation with an owner (client). A construction manager suggests the schedules of the design development packages and those of the procurement packages as well as the related contracts. The relationship between an owner and a construction manager is based on **true cooperation** including open books (cost information). A construction manager acts as an owner's right hand, i.e. their representative who sits at the same side of the table. An owner has the final decision-making power during the course of a project concerning design solutions, trades or works contracts, and suppliers. An owner may make decisions later at more suitable points in time.

The suggested FinSUKE model of design management can be incorporated both into a CM consulting form and a CM contracting form. Likewise, many of its principles are readily applicable to design management contexts where other project delivery methods are used.

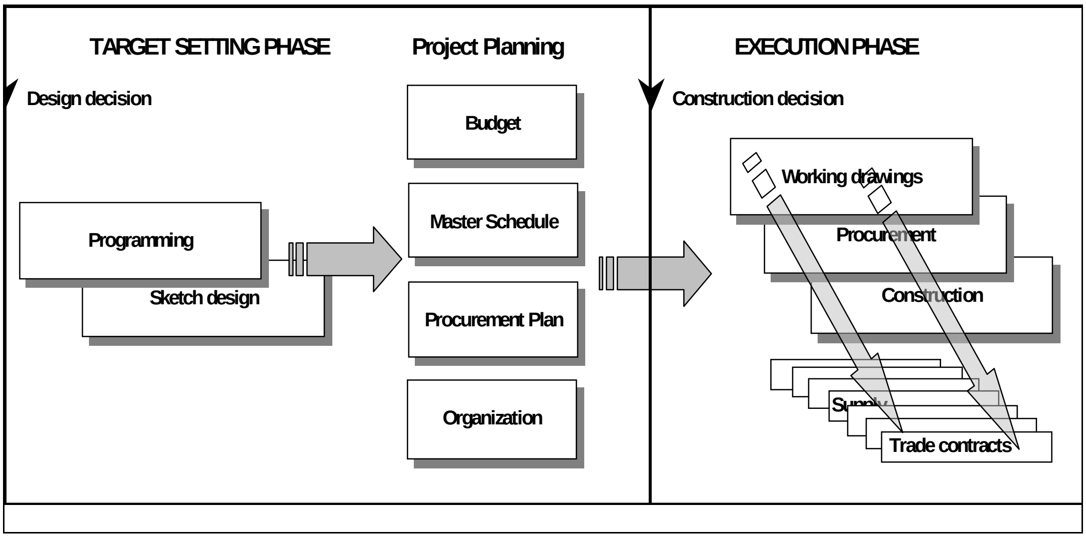

Figure 3: Two-phase model of a construction management (CM) project [12]

3. Three Basic Process Models of a CM Project

In general, a project process is defined to include building design, procurement, and construction works as well as to expose the overlapping of these phases. Herein, **the three alternative basic models** of a project process are illustrated in Figure 4. The critical paths are marked with the shadowed lines. The same (maximum) period of time can be allocated for the actual construction works. **The chain model** is underlying the traditional main contracts, i.e. each sub-process follows fully one another. **The concurrent CM model** involves the time compression based on the two start-ups with the shortest periods that are interrelated, i.e. (a) “Scaling WD1”, which is a period needed to make design documents before the first related procurement, and (b) “Scaling P1”, which is a period needed to make the first procurement before the related building work starts at the site.

The Finnish CM model is designed as a concurrent model, in which the building design, the procurement, and the construction works overlap and particular bidding packages are used as the tools for project management. The durations for making the last working drawings are fairly open to the end.

A physical segmentation adds value also in CM-projects. Using the segmentation it is possible to make design documents ready for one segment while the design of other blocks continues. A segment is usually a vertically sliced entity from a cellar to a roof in new buildings. In addition, the horizontal dimension is applicable in many renovation projects.

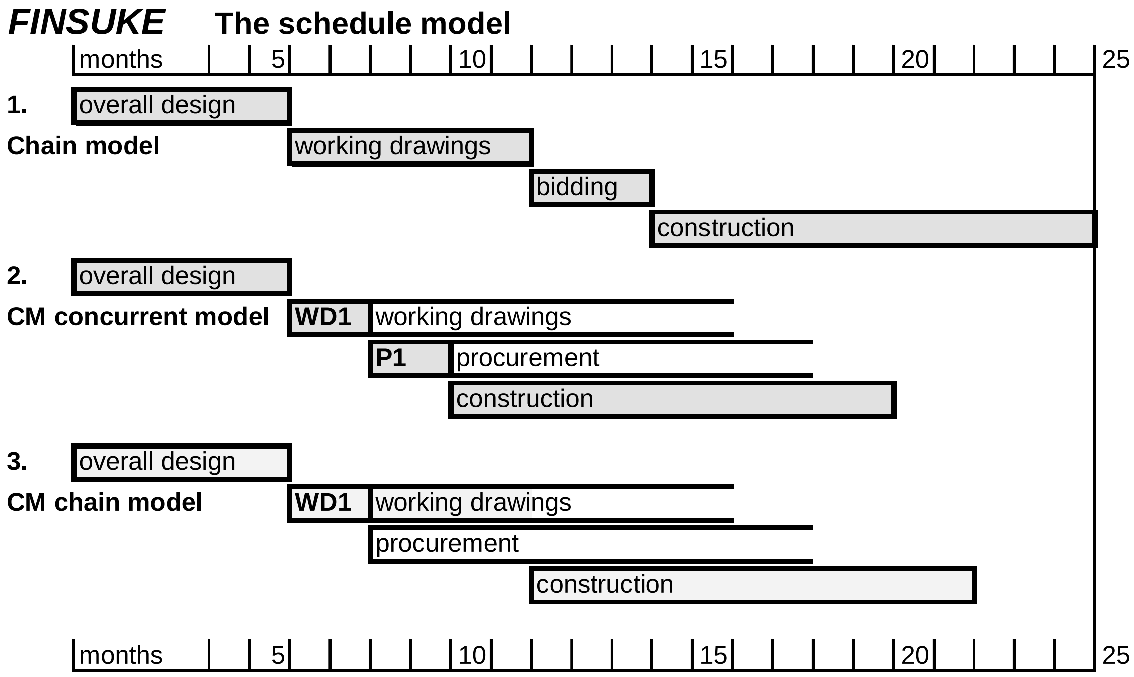

Figure 4: Three alternative project process models illustrated in the case of a typical new building (of 50 000 sqf) in Finland.

4. Design Packages as the Core of FinSUKE model

Under traditional main contract forms, the working drawing phase is often scheduled as one long task (line). Under CM contract forms, the design development is traditionally divided and scheduled based on the project breakdown as **a set of procurement packages**. However, procurement packages are mainly based on trades and so a single procurement package is seldom the most relevant criterion for managing a building design process effectively. Sub-design objects are mostly building elements. Thus, most procurement packages do not contain the complete sets of the enabling sub-designs. This fragmentation of design work causes problems for the delivery of design documents. For example, when only one set of design documents for a procurement package is suddenly needed, the designer must ad hoc solve the related design package as a whole. In the same vein, when the building works are compiled into packages purely by trades, this implies the fixing of many preceding sub-designs too early (concerning e.g. metal works, masonry works).

When the design management is acknowledged as one of the primary, interrelated processes, separate design tasks and documents are compiled into sub-designs based on the concentrations of the primary dependencies among the design tasks themselves. In the suggested FinSUKE model, these sub-designs are managed and called as **design packages**. The model includes a list of standardized design packages with their basic contents.

Table 1.@b@1@e@1 FinSUKE standard design packages, building services (M&E) is not included. Based on Finnish Building 2000 BE classification (translated using UNIFORMAT II) @b@6pr

	Design package		Design package
0	The supplementing design documents	8	Space partitions and doors
1	Excavation works	9	Spacial components
2	Demolition works	10	Other space structures
3	Foundations and slab on grade	11	Interior finishes
4	Elevetors	12	Fittings (to be renoved)
5	Frame	13	Fittings (new)
6	Enclosure	14	Space equipment
7	Roofing	15	Site

In each CM project, **design packages** are determined early as part of a project plan. A CM team compiles and schedules a set of the most effective design packages in cooperation with the designers. The design work is divided on a basis of the standard design packages. Optimally, each project-specific design package includes those parts and works which are procured at the same time and produced accordingly through the preceding design tasks (Figure 5).

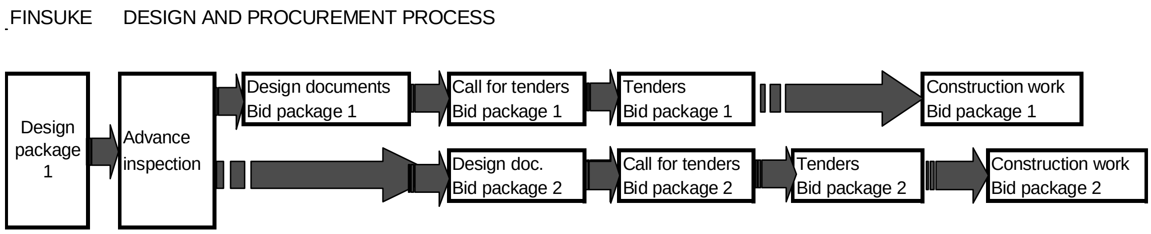

Figure 5. Management of a building design from the design package to its use as a basis for the procurement phase and the construction phase (FinSUKE).

The use of design packages enables **the design team** to achieve many advantages such as:

- To avoid the accumulation of the design work (traditionally scheduled as one task) to the last remaining days through the introduction of design phasing.
- To facilitate effective communication among the designers as well as between the owner and the design team and the procurement team.
- To balance the need and use of design capacity and to enable the flexible increase of the design resources when needed.
- To avoid the preparation of non-constructable sub-designs for single procurement packages.
- To avoid the non-productive preparation of design documents with too small scopes.

- To allow more time, overall, for the attainment of the key objectives of the building design such as functionality, safety, environmental conformance, and aesthetics.

In addition, the use of design packages enables **the procurement team** to achieve several advantages such as:

- To integrate two or more initial design packages to support bigger procurement packages, when this is justified.
- To prepare all the documents of one design package effectively and later to phase the submission of the finished documents according to the related smaller procurement packages.
- To initiate the procurement of a certain package without the need to prepare and submit all the related design documents at the same time.

At the project level, the use of design packages enables **the project management** to achieve the key advantages such as:

- To allow the beginning of the construction work also in the case when all the related design documents are not ready.
- To leave more (enough) time for decision making, especially concerning the final infill of the building.
- To enable the control of the design process and the real-time feedback to the sub-designs.
- To inspect each design package in advance will prevent typical design errors from occurring.

In the FinSUKE model, **a design schedule** is prepared by design packages also in the cases when construction works would not begin before the completion of the design

In the design documents (packages), **a breakdown into the procurement packages** need not to be readily presented . In turn, a CM team determines the contents of each procurement package after the completion of the related design packages. A CM team prepares the tender documents where the contents is specified (often in more detail than in the related design documents) for the procurement. However, some of the traditional trade divisions (e.g. the masonry works for the facade/interior and the steel works) needs to be broken down into parts.

In turn, **a procurement schedule** is prepared by using and integrating the design packages (Figure 6). This is so because the common language is needed in order to ensure the seamless interfaces between the site staff and the designers. Thus, both the design documents and the tender documents are assembled by the design packages.

DRAWINGS	DESIGN PACKAGE	BID PACKAGES
Cut-away drawings Details Balcony Windows and outer doors diagrammatic documents	**6 THE FASADE** Fasades, outer doors, windows Fasade equipments Balcony, canopy	Fasade timber work Fasade claddings Fasade equipments Flashing Windows Outer doors Painting Balconies

Figure 6. Design package as a linkage between design documents and procurement breakdown.

In the FinSUKE model, all the design documents are drafted and finalized up to the working drawings that enable the actual procurement. The exceptions are stated in a project plan.

In CM projects, **the completion degrees of design documents for a procurement package** may vary In each case, the selected procurement strategy determines the required completion degree. Readily, there are (at least) the three alternative procurement strategies as follows:

- Bidding based on working drawings
- Bidding based on tentative design documents
- Bidding based on design requirements.

In the design schedule of a CM project, the allocation of time takes place at a level which allows to present (a) the preparation periods for the design packages, (b) the dates for the pre-inspections of the design packages, (c) the dates for the uses of the design packages, and (d) the dates for the uses of the working drawings for the procurement packages.

5. Conclusions

In traditional building projects in Finland, all the decisions are made in the beginning of the design process. The easy-way-out attempts are being made to fix the final layout of the spaces and to specify the products by dictating these decisions prematurely. After the prolonged project process, the spaces have become readily outdated and, as usual, any changes would turn out to be expensive Normally, designers specify all building products in detail. When a contractor has been buying these detailed products, the prices have risen to too a high level; while other suppliers offer cheaper products which have same or even better properties.

The suggested FinSUKE model is designed in order to change the aforementioned ineffective procedures. The permanent support (shell and core) of the building will be designed first so that it will meet the demands of the modifiable infill. The detailed solutions of the spaces (infill) are finalized according to the space-specific decisions; taking also into account the choices of the tenants. For a procurement phase, design documents can be prepared well to comply with each of the “chosen” products. During the negotiations, a procurement team (i.e. procurers, project manager, and designers) reviews upon how the alternative solutions influence the final outcome. If the other solution is chosen, the original product will be replaced.

Standard design packages fit the construction of new buildings. Instead, the effective adoption of CM forms is more demanding in the case of renovation projects and in building services (M&E) works. For example, the management of M&E design programs is problematic due to sub-wholes based on each of the spaces (or interior areas).

In the FinSUKE model, the design management is theoretically defined as **a combination of a push technique and a pull technique**, i.e. as a push technique up to the completion of the design package and, thereafter, as a pull technique performed by the site management. The site team secures the status of the design documents for 4-6 weeks ahead. A tool like The Last Planner [13] seems to be effective for the pull-based control at site. In addition, **the principles of open building and the principal procurement strategies** are being incorporated into the later versions of the FinSUKE model.

The testing of the design packages and the other FinSUKE tools will continue up to the year 2006. So far, the parts of the model have been mainly tested retrospectively. The testing of FinSUKE model prospectively will also be carried out. In particular, the ways of managing building services (M&E) design process need to be enhanced further.

In Finland, **the scope of design work and design management tasks** are described with standard task lists published by the Building Information Foundation RTS [14]. The standard task lists are prepared for the main contract forms. Such task lists do not at all support the active participation of the designers in the procurement process and the construction process. The TKK/CEM research team is preparing the lists of additional tasks as part of the FinSUKE model.

Finally, the authors do not believe that, in building projects, one can succeed by trying to attain the set objectives by drawing up the more exact descriptions of the tasks of the various project actors and arranging the low-bid competitions for the accomplishment of the detailed tasks. In turn, **the authors recommend performance based methods** for selecting CM consultants, designers, CM contractors, and subcontractors [see 15, 16] .

The suggested FinSUKE model promotes and creates procedures and methods to improve the cooperation among the parties in the construction project. The essential tool to increase the cooperation is a project plan in which the design packages are integrated. Furthermore, the advance inspections of the design packages and the contract negotiations promote cooperation. The constructability is secured at the negotiations during the selection of subcontractors. It is possible to buy product know-how from the suppliers and it is possible to transfer responsibilities for the products to their actual experts – to subcontractors and suppliers. The best performing contractor (or supplier) is then chosen. In CM projects, it is possible to have enough time for this cooperative design development during procurement process.

Advancing Building in Finland through Special Systems Contracting (SSC)

Teppo Salmikivi
University Of Helsinki, Technical Department (email: teppo.salmikivi@helsinki.fi)

Abstract

In Finland, the Special Systems Contracting (SSC) refers to the design, manufacturing, delivery and installing of the building elements by various Specialty Contractors (SCs). A call for SSC tenders includes readily the schematic design documents with the functional and technical requirements. A contractor is responsible for his system element in question and its interfaces with the other building elements as well as the performance of design solutions. Through the SSC, a true know-how and quality competition or a life-cycle delivery competition can be arranged. Essentially, the know-how of both designers and the SCs is fully utilized within the suggested SSC model. Traditional suppliers and subcontractors can adopt herein a new enlarged role with incentives for system development, innovations, and new delivery packages. The penetration of the SSC will create more effective networking within the building industry. In the on-going study, the first retrospective case projects have been analysed. The prospective testing in the actual projects will follow.

Keywords: Special systems contracting (SSC), specialty contractor (SC), design documents, procurement, Finland.

1. Introduction

1.1 Background and Objective

In Finland, the use of the alternative contract forms has been quite stable during the last years. Normally, an owner relies on a general contractor and some technical prime contractors with fixed prices. Finnish designers are accomplishing computer aided design with modern tools. However**,** the use of design documents as part of call for tenders has remained the same. All design documents are completed before calling for tenders and the competition between contractors is based on the efficiency of construction.

In the design and build (DB) method, general contractors can utilize fully their expertise in project management. In turn, the know-how of systems and products among subcontractors can be utilized through the suggested special systems contracting (SSC) model.

The SSC refers to the design, manufacturing, delivery, and installing of the building elements by various specialty contractors (SCs). A call for SSC tenders includes readily the schematic design documents with the functional and technical requirements. A constructor is responsible for his system element in question and its interfaces with the other building elements as well as the performance of design solutions. Through the SSC, a true know-how and quality competition or a life-cycle delivery competition can be arranged. Essentially, the know-how of both designers and the SCs can be fully utilized. On the other hand, the interfaces of separate deliveries are still problematic in the current uses of the SSC in the building sectors in Finland. Likewise, the responsibilities of designers is not yet well-thought out. A lot of know-how and work is required from all the project parties. The negotiations for an agreement as well as the conditions of these agreements are complex. In addition, the future penetration of the SSC seems to involve a risk that number of suppliers and competition among them might decrease.

This paper is based on the ongoing study project for **a new model (FinSUKE)** for managing building design processes as part of construction management (CM) projects in Finland [1, 2]. The FinSUKE model is being developed within the unit of Construction Economics and Management (TKK/CEM) at the Helsinki University of Technology. The study as a whole aims at developing a new design management system, which will in part ensure the attainment of the project-specific (or building-specific) objectives in terms of performance, quality, costs, and schedule [1].

The main objective of this paper is to introduce the initial special systems contracting (SSC) model, which is in part based on the analysis of some retrospective case projects, as follows.

1.2 Specialty Contractors in the USA

Herein, the definition of specialty contractors in the US context [3] is reviewed in order to offer a benchmark for understanding the Finnish SSC approach also outside Finland as follows.

In the US context, specialty contractors (SCs) are generally construction's 'job shops'. SCs allocate their resources to match various 'delivery' dates demanded by multiple projects. Further, specialty contractor management depends on the quality of production management on projects, i.e., their coordination by general contractors. SCs perform the construction work that requires skilled labour from one or at most a few specific trades (e.g. electrical, plumbing, HVAC, roofing, iron work, and concrete) and for which they have acquired special-purpose tools and equipment as well as process know-how. Because of this specialization, their work is limited in scope relative to the work required to complete an entire facility [3].

Further, **subcontractor activity** not only pertains to construction work on site, but, out of necessity, also to work related to design completion. Indeed, it is seldom the case that contract documents, including design drawings and specifications, are unambiguous and sufficiently detailed to be of direct use to specialty contractors. Shop-drawing detailing followed by architect-engineer (AE) approval is often expected of specialty contractors, but this process more often than not reveals incompatibilities in the design documents that are presented to them and vagueness in their scope of work… It must therefore be acknowledged that the involvement of the contractor and subcontractors in the project begins, not with the start of construction, but with completing the design [3].

1.3 Special Systems Contracting in Finland

In Finland, the special systems contracting (SSC) model in building is defined as a contract in which a supplier takes the responsibility for the system design and detailed engineering, manufacturing, and installation of the building element in question including the in-use-performance of the system as defined by the owner (client). The SSC transfers a part of design responsibility to the system contractor and it also combines the product design and production planning [4, 5]. When competition is based on both design solutions, material choices and production efficiency, the SSC model does not discriminate construction techniques and materials. Competition expands from the production know-how to the system know-how and from the details to the wholeness. In competing with solutions, it is possible for system contractors to achieve more innovations and develop their production. In the SSC, it is possible to compete only based on production technologies but competition can include a system and technical solutions, too.

In comparison, special system contractors are responsible for wider scope of work in Finland than traditional specialty contractors in the USA. The latter are mainly interested in the design phase of the products, but Finnish special system contractors are actually responsible for designing their systems, too.

2. Methods and Forms for Special Systems Contracting

2.1 Key Principles in the FinSUKE Development Project

The principles of the FinSUKE model are presented in Kiiras and Kruus [1]. Herein, the key principles are introduced only briefly as follows.

In the FinSUKE model, **building design management** is perceived as a combination of a push technique and a pull technique. From the beginning, design management is a push technique until the inspections of the advancement of the design package take place. After each inspection, the remaining management of work drawings and specifications is a pull technique which is utilized by management at a site. [1]

From the design management view, the principles of open building [6] offer one plausible way to produce highly flexible building solutions. A design team is guided to approach the design of permanent support with a long life span in a way that differs from the one adopted for the design of an infill part with a short life span.

2.2 Special Systems Contracting as Part of a Building Project

The special systems contracting as part of a construction process is shown in Figure 1.

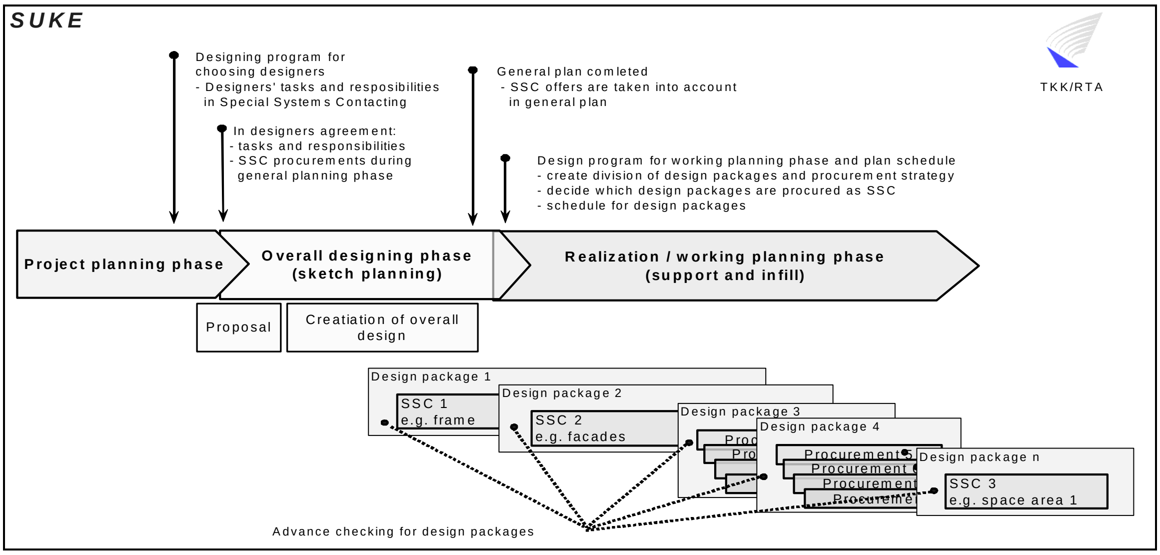

Figure 1. Special systems contracting (SSC) as part of construction process (FinSUKE).

In the beginning of **the overall design phase**, the project management (team) will draw up the design programme for the choice of designers. In the design programme, the designers' tasks for the SSC procurement are defined. The same tasks are presented also in design agreements (i.e. the content, the scope and the schedule of the procurement and the requirements to the accuracy of tender documents).

The design documents for the SSC procurement, which have been completed during the overall design phase, are also taken into account when making an overall design. At the end of the overall design phase, the inspection is performed. Project management draws up the design programme for the working drawings based on the overall design. A project plan shall include a division of design packages and a design schedule and it also identifies readily the particular design packages to be procured through the SSC procedure.

The design documents within the calls for tenders are later taken into account in other design packages. Furthermore, the special system contracts are scheduled in a way that allows, if necessary, the adoption of normal procurements. **A design package** for a special system contract is presented only with requirements and specifications, unless the project management instructs designers otherwise. In the FinSUKE model, only the independent building elements, which are designed as one design package, can be procured as a special system contract. Thus, the model emphasises the shared design and the enlarged responsibility of a contractor. At the same time, the aim is to emphasise the position of the architect and the duty of specialized engineers for checking and combining the separate designs (documents).

2.3 Process of a Single Special System Contract

The main design tasks of a single special system contract are presented in Figure 2.

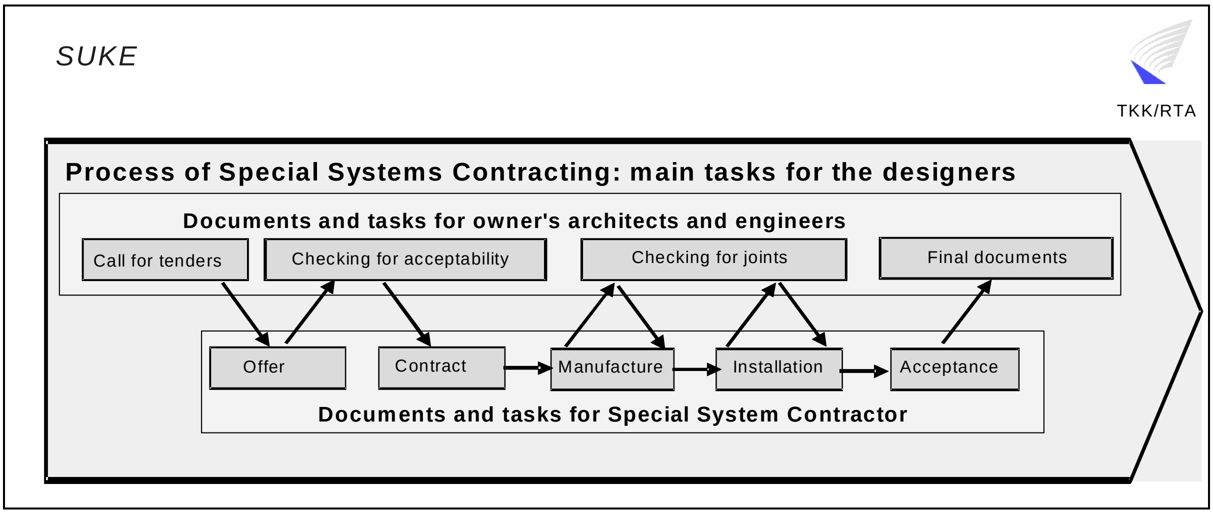

Figure 2. Process description of the special systems contracting (SSC) (FinSUKE).

In the SSC, the main tasks of an owner's architect and engineers are defined as follows:

1. **Create the design documents for the invitation for SSC tenders**
A designer drafts the documents of the call for SSC tenders (the requirements, sketches, instructions etc.) and participates in the preparation of commercial documents. In the preliminary examination of each design package, the definitions and the requirements based on the extensions of the coupled building elements are stated.

2. **Inspect the acceptability of the offered designs**
A designer checks the acceptability of the tender design of each Special System (SS) contractor and performs the comparison of the accepted tender designs.

3. **Participate in the procurement negotiations and the agreement preparation**
An owner's designers participate in the procurement negotiations directing the contractor's design work. A SS contractor's designs are developed into the final level before the signing of the agreement. Thereafter, the solutions of the SS contracts are integrated within an owner's master design and the designs are revised and accepted.

4. **Inspect the production plans of the special system contractor**

An owner's designer checks the compatibility of each SS contractor's production plans. However, a SS contractor has a responsibility for the contents of production plans, but an owner's designer is responsible for the interfaces.

5. **Participate in the inspection of the installation plans in advance**

An owner's designers participate in the inspection of the installation plans before the beginning of the construction work at site. The checking concerns the conformance with the construction and the interfaces.

6. **Check the as-built documents**

As part of the acceptance inspection, an owner's designer checks the final as-built drawings and documents of the system and places the detailed system drawings to the final design documentation of the project.

In the SSC, the responsibilities of building design must be agreed upon early. These significant design responsibilities are taken into account also in the payment schedule for each SS contractor. There are no contractual agreements between SS contractors; their joint participation on a single project is arranged through general contractor-subcontractor agreements. The role of a general contractor is then to manage also all the activities of SS contractors at site.

2.4 Definition of Systems and System Division in the SSC

An abstraction 'system' is determined as an entity, which is independent from other entities, i.e. building elements [4, 5]. The definitions for the term system in the SSC model vary in the literature. At its widest, a system contains the whole building as an individual system. At its smallest, a system includes only, for example, the mounting and planning of a small part of construction work, like concrete reinforcing.

In the FinSUKE model, the SSC is limited to refer only to larger systems where a SS contractor is responsible for the system design, the production planning, and the installation as a functional element of the building in question. The SSC is also limited to refer to entire design packages. A SS contractor's input into the project-specific design of the system element is essential. This differs from the usual CM way of procurement in which a supplier's solutions are included in the final design.

According to the principles of the open building, a building is divided into the systems of the permanent base building (support, shell and core) and the flexible space infills. The flexible space infills are further divided into the interior areas (or departments), the design and the realisation of which are accomplished in accordance with the users' complementary requirements. The fixed spaces are carried out either in connection with the permanent base building or in connection with the flexible spaces (Figure 3).

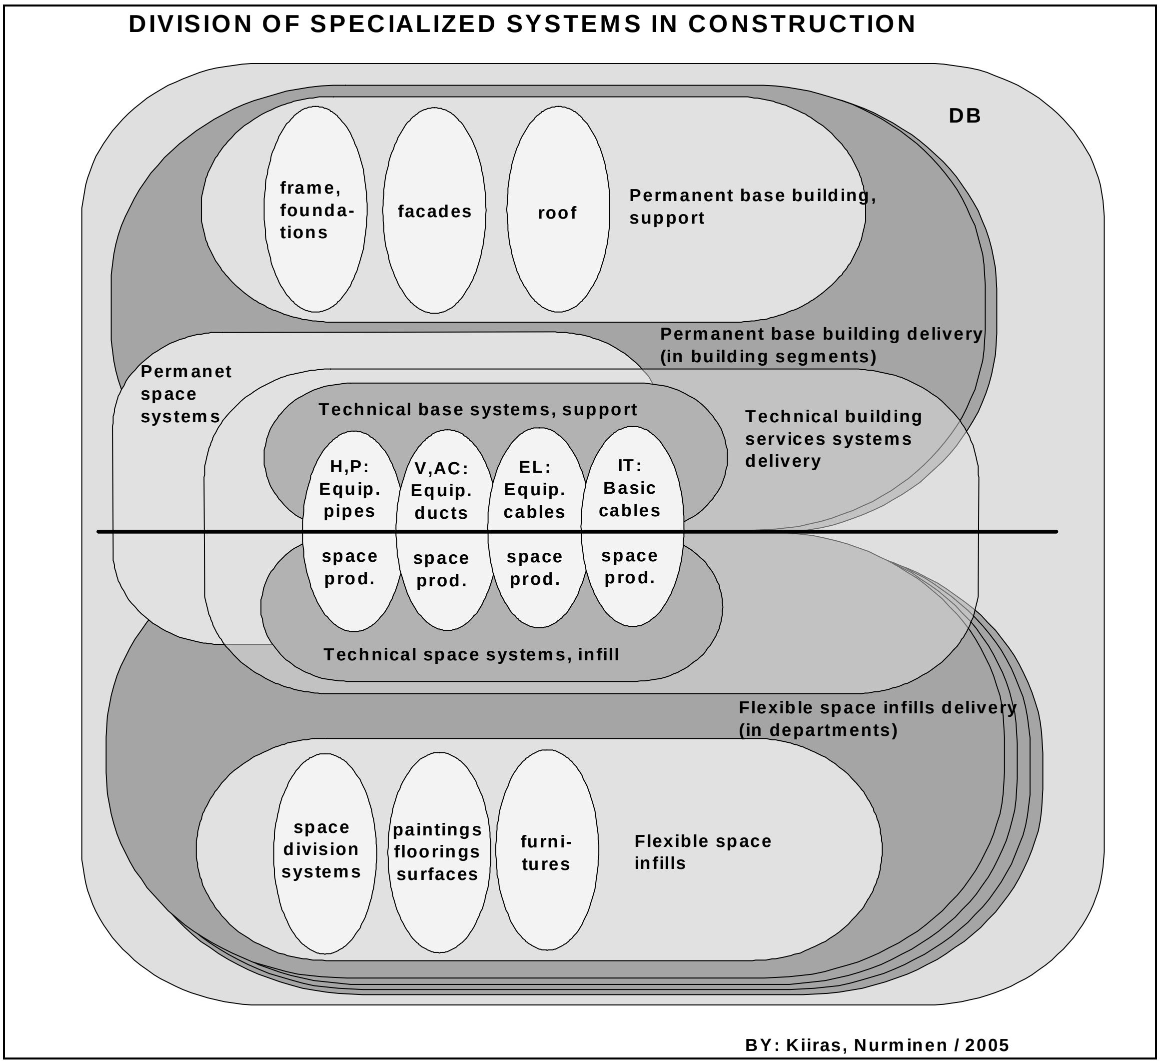

Figure 3. Division of specialized systems in construction (FinSUKE).

Concerning the independence of design and production, the systems are divided **into the five categories:** base building systems, permanent space systems, technical building services systems, flexible space systems and exterior area systems as follows:

- Base building systems (in building segments): ground work and excavations, demolition, foundations and building frame, roof, facades and outer levels,
- Permanent space systems (in building segments): permanent space areas (stairs, entrance halls, auditoriums etc.), space components,
- Technical building services systems: HEVAC systems according to the trades (plumbing, heating, ventilation, cooling, air-conditioning, electricity, information systems etc. separately) **or** technical base systems including central equipment and fixed base system (pipes, ducts and cables) to the border of the interior area (technical core),

- Flexible space systems: separate space areas or departments, HEVAC techniques of the space infills either as their own **or** to be included in the SSC of the space area and
- Exterior area systems: all exterior building area structures, including the HEVAC technical work in the exterior areas.

The SCC of the space infills is carried out by departments, which can be procured as separate units. So the SSC of the space infill contains both the construction and technical design and allows the integration of the production technique with the space parts.

2.5 Design Documents in the SSC Model

In the general FinSUKE model, the three design "as-is" levels are determined for the design documents as part of the call for tenders as follows: 1) final designs according to one solution, 2) "directive" designs or 3) aesthetic, functional and technical requirements. An owner's designers will prepare complete plans according to one solution in design packages, if no other instructions are given [1].

On the basis of the completeness of the design, the invitation for SSC tenders is divided from a level where only the production plans of the system are missing into a level where only needs and requirements are described. According to this "freedom degree" of the design, at the widest each SS contractor is competing on its system and the technical solutions. In addition, the aesthetical, functional and technical requirements as well as the selection criteria are presented in the call for SSC tenders.

In the SSC, a SS contractor's tender design must be at the level of directive design to prove the conformance with the specifications, the quality of the system and the requirements of the regulations. Furthermore, the integration possibilities of the related systems are secured. In each of the SS contractors' agreements, the designs are developed into the level of the final designs.

3. CASE Projects and Research Aims

3.1 Building Projects at the University of Helsinki

The University of Helsinki is the largest university in Finland and its scientific base is wide, 11 schools from medical to law and bioscience. The total amount of the students is about 40 000 and the building area is circa 750 000 m^2. The university and its technical department acts as a client and an owner in building and renovation projects. During the last years, the investments in the construction have been 30-50 million euro yearly.

The CM methods are widely used in the university projects because of the flexibility of the method. In addition, an open building ideology, new construction forms, LCC-competitions, partnership contracts and other new methods are being co-pioneered and tested in the projects and, thereafter, during the facility management carried out by University of Helsinki. In the future, one of the aims is to utilize more SSC methods in building projects.

3.2 Analysis of SSC in Case Pilot Projects

The SSC model has been tested in several case projects and the model (described in section 2) was applied to the actual pilot projects. Herein, the results of the analysis of some case projects at the University of Helsinki are summarized as follows.

Learning centre building at Viikki area (Infocenter, completed 1998)

Test scope: A technical specialty contractor was responsible for the design and the construction of the HVAC system. The energy consumption for the first five years was also a part of the procurement competition. Procurement documents: The invitation for tenders was done by functional and technical requirements. The tenders included directional designs and energy consumption calculations. Results: The new method for call for tenders, own designs from all technical contractors, life cycle costs as competition criteria, and low energy consumption.

Medical laboratory building at Meilahti area (Biomedicum, completed 2000)

Test scope: A contractor was responsible for the design, the manufacture, the delivery and the installation of 20 ventilation plants in engine rooms. The properties and the energy consumption of machines were calculated before the contract and tested after the delivery as the complete units. Procurement documents: The invitation for tenders was done by functional and technical requirements. The tenders included the description on the plant and its properties. Results: Life cycle costs and technical properties as competition criteria, machines tested before installing, high reliability on plants and low energy consumption.

Bioscience laboratory building at Viikki area (Biocentre 3, completed 2001)

Test scope: A general contractor was responsible for the design and the construction of the foundations, the frame, the roof and the facades. A technical specialty contractor was responsible for the design and the construction of the HVAC system and also the energy consumption for the first five years was part of procurement competition. Procurement documents: The invitation for the both tenders was done by the outline drawings completed with the functional and technical requirements. The tenders included the directional plans and in technical system contract also the energy consumption calculations. Results: Five different frame solutions for the same architect's outline drawings, five different HVAC solutions for the same frame drawings, developed building frame system and low energy consumption.

Office and library building at Helsinki City centre (Minerva building, completed 2005)

Test scope: A subcontractor responsible for the design, manufacture, delivery and installation of the steel-framed glass curtain wall. Procurement documents: The invitation for tenders was done by the complete drawings according to one solution. The tenders were asked as the contractor’s own system with the directional plans and the details. No offers were received. The glass wall was divided and procured in smaller trade parts. Results: SS contractors were not interested in such a difficult and small delivery and this influenced also the master construction schedule.

3.3 Research Aims for Prospective Projects

The research underlying this paper is continuing with new prospective projects as an action research method by piloting all the procedures discovered and developed in the former pilot projects. According to the statements in chapter 2, the hypotheses of the case study of the SSC are initially as follows:

- The supplier of the system is responsible for one specific building system,
- A system division corresponds to the design package division of the FinSUKE model.
- The procurement of building area, permanent structures and spaces are separated.
- A building design is divided in the two phases: the overall design and the realisation design (design development and detailed design).
- The documents for call for tenders are based on system requirements.
- Tenders include directive plans and the attention is paid on the following plans.
- The status of an owner's designers is emphasised.
- The guarantee and the service life objectives of each SS contract are determined separately.
- A construction project can be carried out effectively by dividing it into SS contracts.

Some obstacles for the SSC to become common include the indefinite definitions of the design responsibilities as well as the designers' worry of their tasks not being clear. Also a small number of potential suppliers is slowing down the penetration. An attempt is to reduce difficulties by emphasising the significance of the overall design phase, increase the main designers' consolidation obligation, and extend procurement entities.

The future study aims at solving also these problems, which have appeared in the SSC through the advanced design management. Also the hypotheses, the rules, and the methods that have been presented will be tested in future new construction and renovation projects. The performance based procurement and Best Value Procurement [7] will be tested in some case projects, too.

In addition, the international use of similar methods will be reviewed and then compared with this Finnish way of action. With the help of site visits and research co-operation, it is possible to become acquainted with the use of the special contractors in the international field. Thus, both design management and project management will be enhanced with the help of the SSC model.

4. Conclusions

In the suggested Special Systems Contracting (SSC) model, each SS contractor is responsible for the design, the manufacturing, the delivery, and the installation of the separate building elements. Possibilities for quality competitions and competitions for life cycle deliveries and longer guarantees are created. The SSC model makes it possible to manage the project by independent and causally interrelated entities instead of details.

In the FinSUKE model [1], the SSC is limited to refer only to systems, of which the specialty contractor is responsible for the product design, the specific production planning, and the installation of the system to be a functional and independent element of the building. In SSC the project-specific planning work of a system is an essential part of the delivery. According to the principles of the open building [6] the FinSUKE model divides the building into permanent support elements and flexible space elements.

Thus, one of the main aims is to clarify how both the designers' and the suppliers' know-how can be taken into the best use with the effective SSC. In particular, with the simultaneous analysis of design processes in CM projects and the testing in prospective SSC-cases, the instructions for using the SSC model will be developed. The tasks and responsibilities of project actors during the various stages will be clarified.

Abstract

Client control over a construction project is an essential element in the delivery of construction. Construction management is a booming profession in the construction industry. The construction industry also has some stubborn problems to which the industry is trying to find solutions. Some of the problems are poor performance (defective construction, not on time, not on budget, and not meeting the intent of the client), a lack of accountability for problems, a lack of continuous improvement, deteriorating quality of design documents, and a lack of qualified personnel entering the industry. This paper hypothesizes that the problems are being caused by a management/business issue. It uses the example of Ricardo Semler and the transformation of SEMCO, a Brazilian based manufacturing company, from an acceptable company to a very efficient, high performance, successful company by minimizing direction, management, and control. Other successful business practices are used to support the thesis of Semler. The paper proposes that the same approach can be used in the construction industry to minimize the current performance issues. The paper proposes that by minimizing management and subjective decision making by all participants and in all relationships, the construction performance issues can be severely minimized.

Keywords: Minimized control, minimized direction, minimized subjective decision making

1. Introduction

The construction industry is characterized by low performance, sharing of accountability, and the maximization of management [2, 7]. Construction projects are not being completed on time, they are not meeting budget, and they are not meeting the expectations of the owners. Owners cannot identify the source of the problem. Identification of the designer as the problem led to the design-build process where the designer works for the contractor. The inability of the design-build process to meet the client's expectations of performance led to the formulation of the construction manager at risk (CM@Risk) delivery process. There is very little empirical to identify what is causing construction nonperformance [1].

Analysis of the Construction Industry Structure chart (Figure 1) gives some possible clues to why the construction industry has had performance issues. The construction industry has historically been awarded based on low price. The price based environment has the following characteristics:

1. The award is made based on price.
2. Risk is minimized by the client's representative through specifications, management and control.
3. Subjective minimum standards are used for requirements.
4. There is no performance information on contractors and construction systems. Therefore there is no method to identify if a system is an "or equal" to what is specified. This becomes a subjective decision.
5. There are relationships, trust, and maximum information passed between the client's representatives and the contractors. This is a result of subjective decision making of the client's representatives.

There are three major actions that maximize risk. The first is that the client is directing the contractor to bid the lowest possible price or maximize the amount of risk on the project. Note that risk and performance are reciprocal. If the contractor tries to use their expertise to minimize risk, their price will rise, and they will be noncompetitive on the project. The contractors are being directed to not minimize risk using their expertise, but maximize the amount of risk by bidding the lowest possible price.

The second action is that the requirement is based on subjective minimum standards which have no proven correlation with performance. If the requirement is not sufficient, the designer is powerless to rectify it because it is a standard. The third action is that the contractor is being told to do minimal work which is based on subjective standards, and to do things as economically as possible. They are being told that any unforeseen condition is not there responsibility. The contractor is being directed to act in their own best interest, and not in the interest of the client.

The price based environment is creating low performance by giving the low performing contractors the competitive advantage. This creates an adversarial environment by directing the contractor that they have no responsibility to act in behalf of the client. The price based environment then uses subjective minimum standards which have no correlation with performance. The environment is therefore: filled with nonperformers, adversarial, and ambiguous. This environment is inefficient and therefore, nonperforming. It is in this environment that the client is attempting to manage and control the contractor.

2. Hypothesis

Management, control, and inspection are not an efficient way to do business. In the manufacturing sector, lean manufacturing and continuous improvement efforts identified that piecemeal work, incentives, and management, inspection, and control of manufacturing workers and their production lines was inefficient and noncompetitive. This paper proposes that to improve construction performance, clients must minimize management, direction, control, and inspection of the construction contractor. Clients must create an environment that motivates the contractor to do quality control.

3. The Transformation of SEMCO

SEMCO is an example that releasing control can increase efficiency, expertise, and performance. Ricardo Semler, the CEO of Brazil-based manufacturing company SEMCO, implemented a formal structure within his company which shifted control of work to employees who performed the work. This example shows how SEMCO thrived using these practices. It is a potential solution for the construction industry to solve performance issues.

The origins of SEMCO were established in 1954 by Antonio Curt Semler, who patented a centrifuge for separating oils, and started the small machine shop called Semler & Company. Within a short while, the company became a $2 million (gross revenue) a year business. Around 1960, the company formed a partnership with two British marine pump manufacturers which transformed SEMCO into the major supplier of the Brazilian ship building industry. As time progressed, Ricardo Semler, son of Antonio, took charge of the company.

After firing two-thirds of his father's senior managers, and after twenty years of changing SEMCO's business practices, the company now has gone from the founders' peak of $4 million to a $212 million in annual revenue in 2003. In "The Seven-Day Weekend", a book by Ricardo Semler, Ricardo explains that the title "The Seven-Day Weekend" as SEMCOs' way of getting out of control business and back to the companies core competencies [8].

SEMCO's policy was to remain a premium player in each of their markets. SEMCO's products were not the lowest priced products or services. Premium products attract intelligent clients who understand risk and understood the price of minimizing risk. SEMCO moved away from clients who did not understand risk, who therefore were low bidding buyers.

SEMCO strove to put employees in a continuous improvement environment. The key concept that each employee was taught first was to understand is to avoid routine. Once they understand this concept, SEMCO then relinquishes control over the employee. In order to move a business or organization ahead, SEMCO directed the minimizing of management and control. SEMCO allowed workers to align their individual goals with the company goals. SEMCO allowed employees to find the optimal job for themselves in the company. They'll let their new employees to wander around the company until they've found out what it is they want to do. Each employee has a special talent. Many companies throughout the world find out who their least productive employees are and immediately give them the boot. SEMCO treats every individual as a unique person who could help the company in a different way. If an employee isn't performing as they should in a particular area of the company, they're not fired. Instead, they're free to discover for themselves where their talents can be used for the company's benefit. Having employees measure, analyze, and control themselves, and dictate how their strengths and talents can assist the company to be successful. By doing this, managers and workers alike respect each other's differences and it helps to create a less stress-free and productive work environment.

Other practices at SEMCO which showed a release of control include:

1. No formal organizational chart.
2. No rules for office organization or dress code.
3. Removed security checks.
4. Delegated to the lowest level.
5. Workers make their own decisions, operational manuals thrown out.
6. Profit sharing across all employees.
7. Employees help managers make decisions.
8. Memos had to have conclusion as the subject and could only be one page long.

SEMCO's practices identify the following concepts:

1. Only stay in business in the best areas.
2. Minimize the management and control functions.
3. Buy and sell based on value.
4. Force everyone to do quality control.
5. Release control to the workers (contractors in the construction industry).
6. Force everyone to measure themselves.
7. Rely on logic instead of bureaucratic systems.
8. Minimize communication.
9. Make people accountable.

This paper proposes that the same concepts used by Ricardo Semler can be used to minimize the problems in construction. Many of the same principles were also used by Jack Welch in the transformation of GE to a highly successful company [9]. Rudy Guiliani used many of these concepts to transform NYC into a safer city. Deming [4], Ohno [6], and Womack [10], proposed the same concepts in continuous improvement, the statistical control process, just in time, quality control, and lean manufacturing. The authors propose using the SEMCO concepts in the following ways:

1. Clients should only hire the best contractors.
2. Management and control of the contractor by the client, and control of the subcontractors by the general contractor should be minimized.
3. Communication between the client and client representative and the contractor should be minimized.
4. Contractors should quality control their own work.

5. Contractors should be at risk and minimize the risk.
6. Contractors to measure their performance.
7. Anything counterproductive should be minimized.
8. The client's representatives should be accountable for their actions as well as the contractor's personnel.
9. Contractor key personnel should be interviewed and rated as well as the general contractor.

4. Movement to Best Value Environment

In order to implement some of these concepts, the construction delivery environment must be changed. The structure of the current low-bid environment has the following practices which immediately run counter to the proposed concepts:

1. The contractor is directed to maximize instead of minimizing risk.
2. The client's representatives minimize risk through management and inspection.
3. There is not trust, no transfer of risk, and management and control.
4. Clients hire the lowest performing contractor instead of the highest performing.
5. Communication between client and contractor is maximized instead of minimized. The specifications have to be more detailed, more complete, and the contractor is also managed.
6. Contractors cannot quality control their own work. If they do, they will not be competitive, and if they disagree with the client's representative, they will be overridden. Minimum standards do not lead to effective quality control.
7. Contractors are not at risk as long as they listen to the client's representative.
8. There is no performance information of contractors or key personnel.
9. Specifications and subjective decision making override logic.
10. Client's representatives are not accountable. There is no performance information on the client's representatives. The only way to get the client's representative to be responsible is to prove negligence.

Figure 1: Construction Industry Structure (CIS)

The major difference between the Price Based environment and the Best Value environment is that the contractor minimizes the risk instead of the client's representative. Accordingly, the following items must occur:

1. The risk is transferred to the contractor.
2. The contractor uses high performance expectations instead of minimum standards to do their work.
3. The contractors will quality control their own work because they now have the responsibility to minimize the risk.
4. Management and inspection by the client's representative is no longer required. Instead, quality assurance must be practiced.
5. Performance information must be used on all critical components allowing price and performance or best value can be used for the selection process.
6. General conditions which are punitive in nature and are designed for contractors, who are not acting in the best interest of the client, can be eliminated.

5. Obstacles in Changing Environments

Obstacles facing clients in implementing a process that releases control include:

1. What to do with the professionals who have made it their livelihood to manage and control and design processes and standards that are required in this controlling environment.
2. Finding a process which minimizes the risk of the client by selecting the best possible contractor option to minimize the construction risk.
3. How to minimize the relationships that spread risk and override performance information.
4. How to educate their personnel who have been taught the concepts of management, control, and inspection.
5. To change the overall concept that management is the solution to problems.

In the latest Construction Owners Association of America (COAA) identified that 58% would hire construction managers from the beginning of design throughout the construction process. Design-build (DB) and construction management at risk (CM@Risk) were created to minimize construction problems. The differential with the design-bid-build process is merely the transfer of risk. However, DB and CM@Risk can still go awry if the client is represented by a professional who wants to manage and control. Clients have to be educated that the construction delivery process is no different than any other delivery process and can be optimized using business best practices of outsourcing, quality control, just-in-time, and the minimization of management and control.

6. Best Value Procurement

The US Federal Government has identified that the method of procurement of services using the price based, specification, and management and inspection is inefficient, keeps the risk with the government, and does not result in a better price or performance [4]. Several federal agencies (Federal Aviation Administration (FAA), US Army Medical Command (Medcom), US Coast Guard (USCG)) have been testing a best value procurement system, the Performance Information Procurement System (PIPS), developed at Arizona State University. The same procurement system has been tested by the states of Utah, Hawaii, Georgia, and Wyoming. Non-government clients who have tested the process include Harvard University, United Airlines, Motorola, Honeywell, Intel, IBM, and Boeing. The process has the following history [4]:

1. Tested over 10 years (1994-2005) on 400 projects ($260M of construction procurement).
2. 98% performance (on-time, no contractor generated change orders, high customer satisfaction)
3. Consistent results over the ten years.
4. Minimizes construction management, control, and inspection by up to 80% of the price based processes.
5. Biggest resistance was from non-value added functions and nonperforming contractors who felt that their livelihood was being threatened.
6. Being introduced for implementation tests in the Netherlands, and introduced into the UK and Finland education/research groups.

The test results are similar to the SEMCO results. The authors propose that construction is similar to other processes and problems of inefficiency and nonperformance should be solved using the same best practices.

7. Performance Information Procurement System (PIPS)

The PIPS best value process differs from other processes in the following ways [4]:

1. The process minimizes technical decision making in the selection of the best value contractor. There is no technical evaluation.
2. The process using past performance information on all critical entities in a contractor's bid.
3. The contractors are forced to identify, prioritize, and how they will minimize the risk on the project in the competitive bid process.
4. The process is "blind." Value of relationships is minimized.
5. The process uses an artificial intelligence system that compares all the alternatives and identifies the best value.
6. The best value is forced to minimize the risk before they are awarded the project.
7. The contractor, who the best value process identifies as the best performer, looks at the intent of the client, and proposes how they will minimize the risk.
8. The contractor does all documentation during the construction.
9. The contractor takes control of the project and makes the client's representatives, users of the future construction, and procurement personnel responsible to cooperate in a timely manner.
10. The performance of the entire group is rated at the end of construction.

PIPS uses the concepts in the SEMCO transformation. The authors propose that the client, contractor, subcontractors, and client's representatives be viewed as a large company. The results of PIPS are as successful as the SEMCO transformation using the same principles.

A recent survey was taken showing that there are no significant differences between the contractor-performed acceptance data and concomitant highway agency-performed verification data [5]. A consensus of random states took part in the survey. The study proved to show that the performing contractors testing seemed to be more accurate than that of DOT officials. Not only that, but both the DOT and hired contractors felt that the overall construction quality and meeting the schedule was evident by having contractor performed quality control. The only concern, stressed by the DOT, was that the DOT felt they had to have trust in the contractor [5]. The authors propose holding the contractors responsible for the construction, very similar to bonded warranties.

The prevailing practice in construction is still to manage and control the contractors. Of the over 200 construction management education/research programs in the United States, only one unit has an education/research program that assists clients to maximize construction performance by minimizing construction management/inspection.

A concentrated effort is being made to take the education/research to the largest construction programs in each sector of the country. The first prototype was at Central Connecticut State University. The second university will be Colorado State University, and the third will be Florida International University.

8. Conclusion

Ricardo Semler and SEMCO used concepts which minimized management and control to increase their business tenfold. SEMCO had many of the same traditional control mechanisms that are found in today's construction industry. The authors identified the concepts and discovered that the same concepts were already being tested in the construction industry. The same concepts have been proposed by Deming, Taiichi Ohno and James Womack, and Jack Welch in the manufacturing industry. If these concepts are correct, it identifies the major sources of construction nonperformance being the client's inability to identify performing contractors, inability to release control to the contractors, and the inefficiency and nonvalue added functions of construction management. The authors are proposing that the construction industry must move from the price based to the best value environment. Efforts to maximize the performance of construction in the price based environment have been unsuccessful and inefficient. The authors recommend that construction research groups consider changing their focus from optimizing contractor operations in the price based environment to turning the control of construction to contractors, minimizing the use of construction management, and educating construction clients on the potential of the changing from a price based to a best value environment. The authors propose that construction education consider teaching that construction management belongs with the contractor who is awarded a construction project, and should not be a third party or representing the client.

Appraisal of Subcontractor Performance – Criteria and their Importance

S. Thomas Ng
Department of Civil Engineering, The University of Hong Kong (email: tstng@hkucc.hku.hk)
Wai Yin Wan
Water Supplies Department, HKSAR Government (email: wy_wan@wsd.gov.hk)

Abstract

Several influential industry reports have pointed out that a decline in construction quality and productivity could be attributed to the performance of subcontractors who are entrusted to complete majority of the actual works, yet subcontractor performance appraisal is a much neglected subject in construction. A review of the current practice reveals that only some public clients have been keeping track on subcontractor performance based on certain vague criteria. To facilitate subcontractor registration, management and/or selection, an equitable and reliable framework for appraising subcontractor performance would be indispensable. This paper reports the findings of an empirical study conducted in Hong Kong focusing on the criteria for used in subcontractor performance appraisal and their importance. The paper begins by identifying a list of criteria relevant to and suitable for appraising subcontractor performance. Criteria having a high significance to subcontractor performance appraisal are highlighted. Finally, a strategy for scrutinizing the information is proposed to minimize the potential bias induced by the use of qualitative information.

Keywords: Construction subcontractors, performance appraisal, evaluation criteria

1. Introduction

Subcontractors play a significant role in ensuring the success of construction projects, as up to 90% of the total project value are entrusted to various subcontracting firms [1]. Despite that, to survive in a highly competitive market, many lower tier contractors are tempted to recover their desired profit by cutting corners. This could result is a decline in productivity and quality [2]. A general dissatisfaction with the current practices of subcontracting [3] has prompted the introduction of various measures that aim at enhancing the performance of subcontracted works. Examples of these include subcontractor registration schemes [4,5,6] and mandatory disclosure of subcontracting firms at the time of bidding.

Other initiatives include restricting the percentage of work to be subcontracted especially for works of significant importance or where testing, supervisory or performance control is difficult. To promote a non-confrontational relationship, researchers [7] proposed extending the partnering arrangements to cover main contractor and subcontractors so as to help improve the co-ordination and management of subcontracted works effectively. Certain clients now insist on partnering as one of the requirements for contractor selection in their projects [8,9].

While those initiatives may reduce the possibility of recruiting incapable subcontractors, the main contractor and project team seldom measure the performance of subcontractors appointed in a systematic manner [10]. In view of the growth in the size and complexity of subcontracts, there is a need to monitor subcontractor performance more closely [11]. The development of a practical and objective framework for subcontractor appraisal is, therefore, relevant to the current trend and needs of the industry.

The desire to improve the practice of subcontractor performance appraisal has aroused a series of research in Hong Kong. Amongst that, an empirical survey was conducted to examine the importance of criteria for subcontractor appraisal. In this paper, the criteria used by various organizations in appraising subcontractors are first outlined. It is then followed by a brief introduction to the research method. The importance of decision criteria is presented, and the most important subcontractor appraisal criteria are discussed. Finally, a method for evaluating the decision criteria is proposed.

2. Existing Subcontractor Appraisal Models

An extensive literature review and web search unveils the existence of a several established subcontractor performance appraisal models around the globe. These include the models developed by the State of Wisconsin, South Carolina State Government, Los Alamos National Laboratory (LANL), and Fermi National Accelerator Laboratory (FNAL). As the emphases of these models are not the same, there are slight variations in the criteria employed.

2.1 State of Wisconsin's Model

The Wisconsin model [12] is used for appraising the performance of contractors and subcontractors involved in projects commissioned by the State of Wisconsin, USA. The appraisal mainly focuses on (i) schedule; (ii) quality; (iii) cost; (iv) safety; (v) relationship; (vi) communication; and (vii) documentation. These criteria are generic to all contractors and subcontractors, and all criteria carry equal weighting. Compared with other available models, guidelines and procedures provided in this model are by far the most comprehensive. Detailed definitions on the ratings and performance indicators are available, while the guidelines are designed in question form in order to stimulate the thinking of assessors when reviewing the performance of subcontractors.

2.2 South Carolina State Government's Model

The key criteria adopted by the South Carolina State Government for appraising their contractors and subcontractors [13] are very similar to the Wisconsin model. Despite that, this model is rather primitive when compared with that of the State of Wisconsin, as the definitions of the criteria and factors to be considered when completing the report are not clearly specified in the model. Different assessors may, hence, have different interpretations on the criteria and this could affect the objectiveness of the model. A major feature of the South Carolina model is that assessors are required to enter not only the rating but also the weighting for each indicator to reflect its importance. However, weightings are assigned by assessors after discussing with subcontractors, and this could give rise to controversial and biased decisions. The difference in yardsticks renders the comparison among subcontractors difficult if not impossible.

2.3 Los Alamos National Laboratory's Model

The LANL model [14] is designed for measuring the performance of subcontractors who are engaged in the environmental restoration projects of the Laboratory. The criteria adopted in the LANL model include: (i) compliance with planned schedule; (ii) submittal of administrative procedures; (iii) deliverables; (iv) notification of anticipated delays of regulatory deliverables; (v) thoroughness and accuracy of work; (vi) quality program implementation; (vii) compliance with environmental/waste management regulations; (viii) effectiveness/communication; (ix) teamwork; (x) adherence to cost estimate; (xi) adherence to site-specific health and safety plan/health & safety plan/regulations; (xii) occurrence of imminent safety or health incidents or serious safety or health incidents; and (xiii) lower-tier subcontractor safety performance. Comprehensive guidelines and procedures are provided in LANL model. For instance, detailed definition for each criterion and rating is stipulated to avoid possible misinterpretation. While weighting is not considered in this model, assessors have to enter the rating for each criterion to obtain the total score relative to the norm. To increase the transparency of the appraisal process, subcontractors can review and comment on the relevancy and accuracy of the performance report.

2.4 Fermi National Accelerator Laboratory's Model

FNAL is a laboratory specializing in high-energy physics research, and the FNAL model [15] is therefore designed for evaluating the performance of this type of subcontractor. However, the criteria *viz.* (i) business relations; (ii) management of key personnel; (iii) schedule; (iv) cost control; (v) health and safety; and (vi) performance/quality of works, are equally applicable to construction subcontractors. The criteria carry equal weight in the FNAL model. Furthermore, brief definitions on the criteria and ratings are given despite more details on the procedures and definitions of criteria could have been provided to improve the fairness of appraisal.

2.5 Environment, Transport and Works Bureau's Model

Although there is yet to be a subcontractor appraisal model in Hong Kong, a framework for monitoring the performance of main contractors [16] has been developed by the Environment, Transport and Works Bureau (ETWB). The ETWB model examines the: (i) progress; (ii) site safety; (iii) resources; (iv) design; (v) attendance to emergency; (vi) organization; (vii) general obligations; (viii) industry awareness; (ix) workmanship; and (x) environmental pollution control. While these criteria are used for assessing the performance of main contractors, it is worth examining whether they can be applied to subcontractor appraisal.

3. Subcontractor Appraisal Criteria

In order to formulate a common set of performance appraisal criteria for the subsequent study, criteria used in the models described above are summarized in Table 1. Based upon the criteria of the ETWB model, other criteria appeared in the established subcontractor appraisal models including "adherence to cost estimate", "relationship" and "communication" are added.

Table 1: Criteria used in various subcontractor appraisal models

Indicator	*State of Wisconsin*	*South Carolina State Government*	*Los Alamos National Laboratory*	*Fermi National Accelerator Laboratory*	*Environment, Transport and Works Bureau*
Workmanship	✓	✓	✓	✓	✓
Progress	✓	✓	✓	✓	✓
Site safety	✓	✓	✓	✓	✓
Environmental pollution control	✗	✗	✓	✗	✓
Organization	✓	✓	✓	✓	✓
General obligations	✗	✗	✗	✗	✓
Industry awareness	✗	✗	✗	✗	✓
Resources	✗	✗	✗	✗	✓
Design	✗	✗	✗	✓	✓
Attendance to emergency	✗	✗	✗	✗	✓
Attitude to claims	✗	✗	✗	✗	✓
Adherence to cost estimate	✓	✓	✓	✓	✗
Relationship	✓	✓	✓	✓	✗
Communication	✓	✓	✓	✗	✗

Legend: ✓ *= Same or similar indicator is adopted in the assessment model concerned*
✗ *= Same or similar indicator is not adopted in the assessment model concerned*

As shown in Table 1, "workmanship", "progress", "safety" and "organization" are adopted by all models for assessing subcontractor performance. The Wisconsin, South Carolina, LANL and FNAL models, however, do not put particular emphasis on "general obligations", "industry awareness", "resources", "design", "attendance to emergency", and "attitude to claims". Having considered the peculiar situation of Hong Kong, virtually all identified key criteria were considered to have a high potential for use in appraising subcontractors except for "design" and "adherence to cost estimate" (Table 2).

Table 2: Suitability of subcontractor appraisal criteria

Indicator	*Suitability for further study*	*Reason*
Workmanship	✓	This is the common criteria appeared in all reference model.
Progress	✓	This is the common criteria appeared in all reference model.
Site safety	✓	This is the common criteria appeared in all reference model.
Environmental pollution control	✓	As subcontractors are the parties that actually carry out the works, their strict compliance of the relevant contractual requirements or regulations is critical in protecting the environment.
Organisation	✓	This is the common performance indicator appeared in all reference model and hence should be adopted in the questionnaire survey
General obligations	✓	This criteria does not appear in the subcontractor assessment models of the US. The reason behind may be that subcontractors normally concentrate their effort on the works only while compliance of general obligations rests with main contractors. However, this is not the case in Hong Kong situation. The subcontractor has to comply with the general obligations such as the cleanliness of site, care of utilities, etc. in executing the sub-contracted works.
Industry awareness	✓	This criteria does not appear in the subcontractor assessment model of the US. However, in order to encourage the subcontractor in providing more training opportunity for the trainee craftman as well as the care and welfare of workers, this criteria should be included.
Resources	✓	The resources of the subcontractor directly affect the progress of the works and hence should be equally important as or even more important than the resources of the main contractor. If resources are considered as an indictor for the performance of a main contractor, there is no reason why it should not be considered alike in assessing the performance of a subcontractor.
Design	×	The client normally does not require subcontractor to design permanent works in Hong Kong.
Attendance to emergency	✓	This critieria is critical as subcontractors are required to respond to emergency works as needed to avoid possible delays and disruptions.
Attitude to claims	✓	This criteria is important when partnering approach is not adopted. The attitude of the subcontractor in claiming additional cost could affect the final contract sum as well as the administration cost borne by the client.
Adherence to cost estimate	×	In Hong Kong, as the clients normally rely on consultants to prepare the cost estimation, this indicator is less important to subcontractors.
Relationship	✓	It appears that partnering will become a trend for construction projects in Hong Kong, it is worthwhile including this criteria for further consideration.
Communication	✓	Good communication is essential to the success of construction projects.

Legends: ✓ *= The indicator is recommended for further study in the sub-contractor assessment model*
× *= The indicator is not recommended for further study in the sub-contractor assessment model*

4. Research Methodology

A questionnaire survey was conducted to establish which criteria are more important to subcontractor performance appraisal in Hong Kong. Based upon the 12 key criteria as shown in Table 2, a total of 29 sub-criteria were identified for the questionnaire survey. Respondents were requested to express their perception on the importance of the 29 detailed criteria through a 5-level Likert scale, with 1 representing "very low" importance and 5 indicating "very high" importance.

4.1 Sample Frame

Since the criteria are used for appraising subcontractors, it is unrealistic to assume the views of the main contractors would adequately reflect the concerns of subcontractors. On the other hand, as the clients and consultants may play a less predominant role in subcontractor appraisal (as domestic and specialist subcontractors are employed by main contractors instead), the collective views of the clients and consultants should reflect their position as a policy enforcer.

Random samples were drawn from the three stratified sample groups of client/consultant, contractor and subcontractor. In this study, a sample size of 100 was set for each of the three stratified sample groups. A total of 35, 33 and 24 valid replies were received from the client/consultant, contractor and subcontractor groups respectively, representing an overall response rate of 30.7%.

4.2 Method of Analysis

The 'mean score' method [17] was adopted for analysing the collected data. The mean score (MS) for each indicator was computed by the following formula:

$$MS = \frac{\sum(f \times s)}{N} \qquad (1 \le MS \le 5)$$

where s = score given to each criterion by the respondents and ranges from 1 to 5
f = frequency of responses to each rating (1-5) for each criterion
N = total number of responses concerning that criterion

The rank order, in descending order of importance, of the 29 subcontractor performance appraisal criteria was determined by comparing the individual mean score.

5. Results and Discussions

Table 3 summarizes the mean score and ranking of each subcontractor performance appraisal criterion. It is apparent that the most important criteria include: “standard of workmanship”, “action taken to mitigate delay”, “communication”, “identification of and responsiveness to problems”, and “provision and maintenance of work environment”.

Table 3: Importance of subcontractor performance appraisal criteria

Performance Criteria	*Level of Importance*					*Average Score*	*Rank*
	Very low (1)	*Low (2)*	*Moderate (3)*	*High (4)*	*Very high (5)*		
Standard of workmanship	3	0	17	42	30	4.04	1
Action taken to mitigate delay/catch up with programme	2	3	17	45	25	3.96	2
Communication	0	5	21	39	27	3.96	3
Identification of and responsiveness to problems	0	4	24	41	23	3.90	4
Provision and maintenance of work environment	3	3	28	24	34	3.90	5
Coordination of contractors	1	2	24	48	17	3.85	6
Suitability of method and sequence of work	3	1	22	47	19	3.85	7
Standard of materials or equipment supplied	3	3	22	44	20	3.82	8
Adequacy of site supervisory staff	1	5	25	42	19	3.79	9
Compliance with statutory requirements	2	3	26	42	19	3.79	10
Adequacy of labour resources	2	2	24	50	14	3.78	11
Achievement in progress	2	4	25	46	15	3.74	12
Care to general public	2	4	27	42	17	3.74	13
Care of works	1	3	31	42	15	3.73	14
Provision and maintenance of plant	3	4	29	35	21	3.73	15
Coordination with subcontractors	1	5	29	41	16	3.72	16
Adequacy of material resources	2	2	31	43	14	3.71	17
Reasonableness of monetary claims	3	5	32	30	22	3.68	18
Adequacy of planning	0	8	25	47	12	3.68	19
Adequacy of plant resources	0	7	31	39	15	3.67	20
Action taken to remedy non-compliance	1	6	30	40	15	3.67	21
Adequacy of programme	4	1	28	48	11	3.66	22
Reasonableness of extension of time claims	3	6	33	30	20	3.62	23
Compliance with non-environmental enactments	2	4	35	38	13	3.61	24
Standard of temporary works	3	7	28	40	14	3.60	25
Compliance with environmental enactments	1	8	35	34	13	3.55	26
Adequacy of notice for inspection of works	1	4	38	42	7	3.54	27
Adequacy of pollution avoidance measures	1	7	40	28	15	3.51	28
Care and welfare of workers	4	6	46	27	9	3.34	29
Cleanliness of site	2	13	38	32	7	3.32	30
Training of apprentices, graduates and craftsmen	9	7	34	31	11	3.30	31

Standard of workmanship: From the client's perspective, good standard of workmanship can ensure the designed life of the services; minimize the costs on maintenance; and reduce future disruption to the services caused by the repairs. In the ETWB model, poor workmanship results in a "poor" overall performance automatically and the performance report will be rated as "adverse". As subcontractors are the party who perform the construction works, their standard of workmanship is of paramount importance. The contractors and subcontractors consider good standard of workmanship can enhance their goodwill and hence result in greater opportunities to new jobs.

Action taken to mitigate delay/catch up with programme: For public schemes, delay in project completion would inevitably cause social disruption. However, any delay in private developments would mean postponement in sale and hence a financial loss due to extra interest on loan capital. The contractors and subcontractors also see this as an important criterion as liquidated damage and poor performance report will be resulted from any delay project completion.

Communication: Good communication can minimize misunderstanding, develop good relationship and improve productivity of works. While contractors may be in a more suitable position to determine whether subcontractors have any "communication" problem which could affect the project outcomes, communication with the client and the project team is also needed in a multidisciplinary environment. Therefore, it may be a good practice for both the contractor as well as the client/project team to assess this important criterion.

Identification of and responsiveness to problems: Problems may grow if they are not identified and addressed promptly. Being the one who is responsible for the actual work, subcontractor are expected to keep the project participants informed of the potential problems and propose solutions to prevent any possible delays and reworks. The ability of subcontractors in resolving problems is the most obvious means to determine the effectiveness and efficiency of their organization. Obviously, problems cannot be identified early and solved promptly without good communication, supervision and executive authority of the subcontractors.

Provision and maintenance of working environment: In recent years, continuous and considerable effort has been made by the government and the industry to promote site safety via legislation, education and upgrading safety requirements. It appears that all parties including subcontractors acknowledge the importance of site safety now. All construction stakeholders understand that site safety brings about indirect benefits which will eventually contribute to the direct ones by creating a better working environment and reduced risks.

6. Conclusions

In this paper, a list of criteria pertinent to subcontractor performance appraisal has been established. The results of a survey conducted in Hong Kong indicate that "standard of workmanship", "action taken to mitigate delay", "communication", "identification of and responsiveness to problems", and "provision and maintenance of work environment" are the most important criteria for appraising subcontractors. It is necessary to ensure that these criteria are carefully incorporated in the subcontractor performance appraisal model.

Despite that, the most important criteria like the "standard of workmanship" may not be very easy to measure even when guidelines or procedures exist. As a result, expert judgment is inevitable in establishing the benchmark. To improve the fairness and transparency of subcontractor performance appraisal, the evaluation must be founded on unequivocal yardsticks instigated by the objectives and expectations of the client.

In recent years, certain organizations, such as the US Department of Commerce, Canadian Government, etc., has begun to realize the benefits of the Balanced Scorecard and Gap Analysis techniques and apply these methods to various kinds of performance-based appraisal schemes including business, environment, quality, etc. The research team is exploring the full potential of these techniques in promoting the objectiveness and transparency of subcontractor performance appraisal, and the results of analyses will be reported in due course.

Delivery Systems as Service Processes in Building Projects

Pirjo Pernu
YIT Rakennus Oy (email: pirjo.pernu@yit.fi)

Abstract

This paper discusses the challenges in examining project delivery systems as service processes. Delivery systems are categorised in four different ways according to the requirements of clients. Certain clients prefer conventional delivery systems and enter into the main construction contract with or without nominated sub-contractors. Project management and design-build systems have gained a significant market-share, too. This paper focuses on project development systems as there is a demand for developing after-sales services which guarantee a long-term profit for investors. The issues for clients in choosing as well as the issues for service providers in offering total service packages, are briefly described. A case study of a market-financed rental housing project is presented as an example of how after-sales services can be included in the service process of a building project.

Keywords: Project delivery system, building procurement system, service process, client, project development, design-build, construction management, building construction, Finland

1. Introduction

In Finland a great deal of effort has been made to develop the building process [1]. The objective has been to promote the internal effectiveness and international competitiveness of Finnish construction industry. In particular, the employment of a design–build approach has been promoted as a means of encouraging innovations by combining the design and production planning sides [2]. At the same time, the use of construction management approaches has increased. Nevertheless, the traditional systems i.e. the main contracting with nominated sub-contractors, have continued to dominate the market because clients want the ability to influence the design [3].

On the other hand, there are clients who are not interested in how the building project is organised. The trend in the real estate market, now that foreign investors are also entering Finland, is that clients consider a built project as one alternative way of investing among existing real estate or other alternative investment options. The major players are forced to enlarge their service supply both to make sure that users' demands are met and to help investors achieve the expected profits.

Major Finnish construction companies like YIT Rakennus Oy, NCC Finland Oy, Skanska Oy and SRV Viitoset Oy have created their own business park concepts to satisfy the demand of those investors interested in commercial properties. A necessary service element has been to commit at least the main user to the planned working environment. Some insurance companies have also utilised project development systems in rental housing production to spread and lower the investment risk.

New services included in built projects are constantly being explored, for example, to guarantee the rest value of the premises as well as guaranteeing the premises are kept attractive for users. However, the problem seems to be that clients are not convinced that the increased added value is worth paying for. The delivery systems are commonly difficult to demonstrate as clear service processes because the terms used in the field are vague. For example, the largest office building project in Helsinki Kamppi is organised and presented with a construction management approach, but the contractual relationship with the city of Helsinki is based on design-build responsibility.

It is hoped this paper will help to analyse different delivery systems from the service process perspective. The aim is to achieve a holistic view of the services included in building projects and thus to give ideas to develop service management. The objective is to promote the understanding of the overall service business in building projects.

2. Traditional Analysis Methods for Delivery Systems

Project delivery system is defined as a comprehensive process to deliver a built project to the owner [4]. However, the procurement system could be defined as the most appropriate method of procuring according to client choice after the decision to build [5]. The choices to form a building procurement or delivery system is varied and categorising them difficult [5].

Traditionally, procurement methods have been analysed according to the responsibilities, the contractual relationships and, less frequently, the ways of inviting tenders. Besides the design and supply, the responsibilities concern the pricing methods, as well as the preparedness of design documents. The vast variation of alternative options stems from the great number of client decisions.

Together with the task allocation, procurement systems can be described through customer-orientation with the help of information transfer and co-operation [6]. The ability to respond to risks and to reach the set project aims can provide selection criteria for procurement options to promote positive and hinder negative project outcomes [6].

When the service providers offer their own concepts, analysis of differences between the delivery systems play a key role. In the international market the one-point-responsibility seems to be significant for design-builders [7]. In project management methods the co-operation with the client both in design and in procurement stage is emphasized [8]. This form of categorising is flexible as all kinds of demanded services are included in existing delivery systems and new service packages have been created from the basis of old ones.

3. Clients in Building Project Business

3.1 Definition

"Client" in this paper is considered to be an organisation that hires professional services from the Finnish building market such as investors as well as public and private owners, who decide how to procure a building project. "Service" is a tailored solution for the client who participates in the service production process [9]. So it is essential to enter into the client's decision-making and, preferably, before the decision to build new facilities is made. Certain services are assumed to be included in defined delivery systems and certain services are self-evident in all of them.

3.2 Operating Environment

The Finnish construction market is characterised by its small size. There are fewer than ten large construction companies with the ability to take on the economic risk of larger building projects. The other companies are small and medium size firms. Architectural and engineering companies are small firms without the resources to take on at-risk responsibility for project management. Few differently oriented project management consultants are available.

In principal, it has been impossible for the firms to build a competitive advantage based on technological benefit or lower cost in built projects [10]. In other words, it has not been possible to differentiate the core product. Individual successes have been based on convenient site location or personal relations. It seems that functioning core products are available in the field, but because long-term relationships have not become common, there are currently no fully functioning total service offerings.

Issues in the operating environment in the building project market are the following:

- The whole building sector is fragmented and the heterogeneity is challenging to manage.
- The core product is less often the reason for dissatisfaction than the surrounding services. Investing in services has not paid off.
- The running costs of working environments are not reasonable and they are not easily calculable apart from in apartment buildings.
- Premises should be suitable for changing purposes.

- The difficulty is to influence the client's decisions-making by offering attractive ways to organise the projects. Traditionally, what is offered is what is demanded, but in more hi-tech industries the firms have been more innovative and forward-looking.

3.3 Triangle of Investor, User and Service Provider

It is obvious that the competitive edge in offering building project lies in the services. In most cases, the service provider is required to manage the expectations of the owner as well as the users and integrate them (Figure 1). The triangle has to be taken into account when developing the service management strategy for project development.

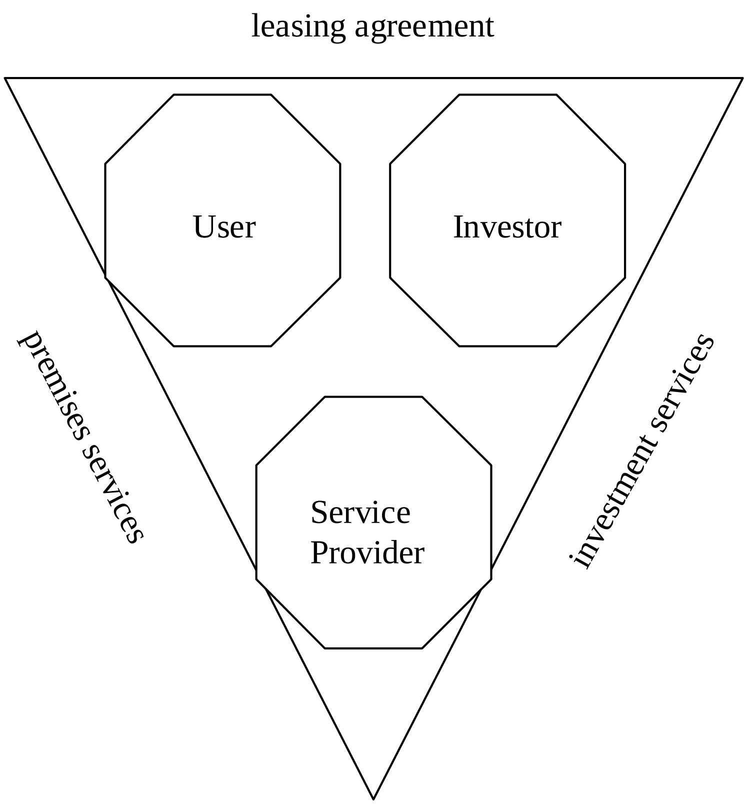

Figure 1: The customerships in project development from the clients' point of view.

3.4 Service Competition

The delivery systems have been categorised in four groups according to the services most of the clients demand from the project implementer. Traditional contracting is for the owners that use separated procurement systems and want to deal with all the organisations involved in the project. Design-build is a system where clients appreciate the one-point-responsibility. In construction management systems clients want to have a greater involvement in the project and the physical construction is carried out by means of packages. Development projects are available for investors to whom building project is just an alternative to invest in. The user is the owner's client and definitely the most important partner for the service provider.

Any quality problems stem from functional quality because all the firms can produce approximately the same technical quality. The trend in the business operations is to include more and more added value to the delivery systems. Formerly the competition concerned the price of materials and labour, but nowadays the operators are in the middle of service competition. In any case, customer satisfaction is hard to achieve and the reason could be that too little attention is paid to the recovery services.

3.5 Service Encounters in Different Delivery Systems

On the following tables, services which clients typically expect with different procurement approaches are listed. The service encounters, that are relevant when evaluating a suitable delivery system, are different on separate organisational levels. On the strategic level the investor decides in which manner the money is invested (Table 1). On the project management level (Table 2) service encounters that help to reach the set project aims are of importance. The key level is the operational one (Table 3) as the user of the premises will pay for the whole process.

Table 1: Service encounters in different delivery systems in strategic level where the demand is for a sound investment. The emphasis is in the after-sales services offered before the project is commenced.

STRATEGIC LEVEL	**Development projects**	**Construction Management**	**Design-Build**	**Traditional Contracting**
Cash flow promises	X			
Leasing responsibility	X			
Financing	X			
Site selection	X			
Life-cycle guarantee	X			
Maintenance	X			
Repairs and replacements	X			
Rebuilding	X			

Table 2: The service encounters offered typically for the managerial level where the demand is for a successful project during design and construction period. The emphasis is on the accomplishment of the contract.

MANAGERIAL LEVEL	**Development projects**	**Construction Management**	**Design-build**	**Traditional Contracting**
Programming	X			
Consultant selection	X	X	X	
Feasibility studies	X	X	X	
Comprehensive responsibility	X		X	
Product modelling	X	X	X	
Power to control design	X	X		
Power to control procurement	X	X		
Cost and value engineering	X	X	X	
Examining alternative design solutions	X	X	X	
Design development and coordination	X	X	X	
Cost control	X	X	X	
Constructability view	X	X	X	
Cooperation with Authorities	X	X	X	
Change order management	X	X	X	X
Construction supervisor	X	X		
Project portal	X	X	X	
Insurances	X	X	X	X
Guarantees	X	X	X	X
Liabilities	X	X	X	X

Table 3: The service encounters offered typically for the operational level where the demand is for working premises when the user operates the building. The emphasis is on maintenance and performance.

OPERATIONAL LEVEL	**Development projects**	**Construction Management**	**Design-build**	**Traditional Contracting**
User Services	X			
Maintenance	X			
Service recovery	X	X	X	X
Project Portal	X	X	X	

Most services are for the management level to achieve and to accomplish the contract. Few services are offered to the users. User services are based on partnering such as occupational health care, catering, telecommunication, fitness services and secretarial services.

3.6 Service Profiles of Delivery Systems

Analyzing the service-orientation of different delivery systems will be useful in describing the roles of the participants in the service process. In figure 2 the service profiles illustrate implementor's service process as well as the clients' participation in the building process. Service profiles can also be one way to roughly compare the delivery systems to each other. The profiles give an image of the significance of the users' participation, too.

Traditional procurement is suitable for clients that are interested merely in the core product i.e. the price of construction. The widest service package is included in project development systems and at the same time the construction stage itself seems to be less important. The one-point responsibility can be an obstacle to clients participation in the design-build service process but at the same time it can save the owner's resources. The project management systems are appropriate for clients who want the power to control the process during the design and construction stages.

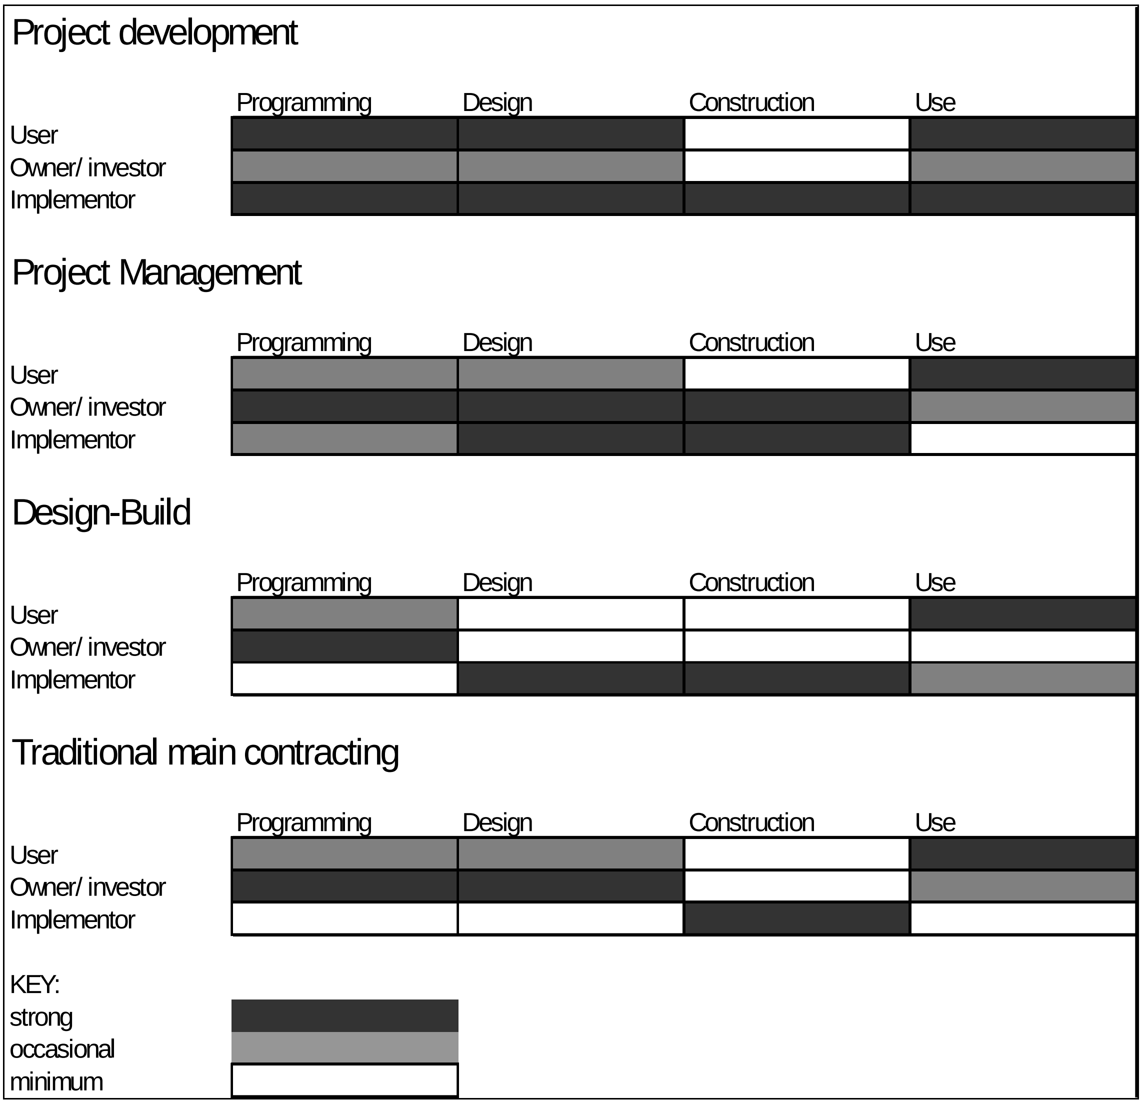

Figure 2: The service profiles of different delivery systems.

4. Guarantee in Rental Housing Projects

4.1 Residential Building Projects

There will be a continuous need for new apartments in the next decade because people are moving from the northern parts of Finland to the greater Helsinki area. The main new housing production is market-financed characterised by the fact that the founding shareholder of a housing company sells the housing shares at the construction stage. Most often the major construction companies are the founding shareholders. Customers as shareholders will form the new board of the housing company after buildings are approved for use.

4.2 Service Package for Residential Real Estate Investors

Market financed housing production is very sensitive to any negative fluctuations in the economic situation especially to changes in interest rates. To prepare for the future risks YIT Rakennus Oy started a product development project to build up a service package for private housing investors. The aim was to offer an agreed profit level by guaranteeing a balance between expenditure and long-term ownership.

According to figure 3, the focus is on the after-sale services instead of site selection, design and construction. To guarantee the agreed profit level, services are provided to take account of both incomes and expenditure. Besides, clients can benefit from the increase in value of the residential property. The idea was to emphasize customer-orientation by keeping the decision-making close to the clients. This means that all the services are options and they can be tailored for each client differently.

The location of the project and the apartment program is the basis for the service provider to commit to the rental revenue and to take responsibility of the renting. Maintenance costs in blocks of flats can be quite accurately estimated and thus the risk of overruns is managed. Certainly, the maintenance serves to keep the property attractive for the tenants.

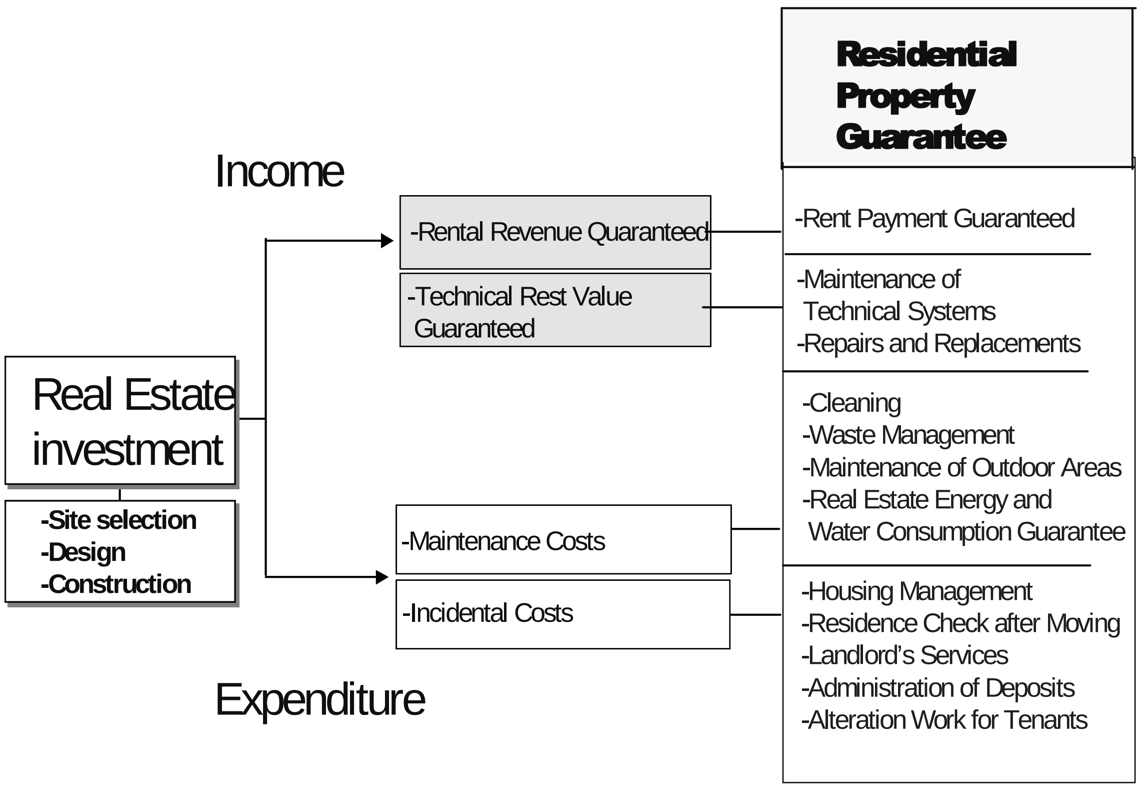

Figure 3: Guaranteed investment in market financed rental housing.

This development work continues. Firstly it has not yet been tested whether the clients appreciate the value of these services and are willing to pay for them. Secondly we must learn how the long-term cost affects our clients. Finally, clients will always remain who are only looking for a core solution and they are not interested in value-adding additional services.

5. Future Service Processes

To develop the future building project delivery systems there is a need for analyzing and comparing the existing, both domestic and international, systems from the service perspective. This kind of study will help clients in decision-making from the earliest stage of a building project. For the operators, perhaps, the results would be of help in service management when the knowledge as well as the weaknesses, the firm has, can be identified. The following benefits may also accrue.

- The ability to describe the service totality to clients will be improved.
- Low price will not be the only decision criterion and clients are willing to pay for the new services.
- It will be easier to market new building projects from the service point of view.
- A core product or the quality of the new facilities is self-evident, but the service quality can vary easily. Quality gaps can be minimised as promises and expectations are more likely to be met.
- There will be expertise to offer all the procurement methods available and to add new options to meet clients' objectives.
- The services as a means of differentiating from the competitors will be encouraged.

6. Conclusions

Service components have become more essential parts of the building procurement than the core product itself. To keep their competitive edge large construction companies will not only offer the facilities, but their complete maintenance, servicing and repairs. Guaranteeing incomes for the future real estate owners will also be necessary.

There will always be a demand for all types of delivery routes. The trend is towards more added value and more sophisticated services. The firms in the field will put effort into differentiating readymade after-sales services that are new to the branch. However, all delivery systems will remain in use because clients' needs, project characteristics and the market situation will vary significantly.

Service concepts will surely become more common in the housing sector, too. Guaranteeing both incomes and expenditures are obligatory services to make the institutional investors invest in residential real estate. In addition to products for investors, purely demand-oriented service encounters, like housing companies for senior citizens including nursing services with reliable partners, will emerge.

To adopt more responsive responsibility for the clients' business, necessitates a vast number of services offered within the delivery systems. Through effective management of these services, success in the market can be achieved.

Developing the Decision-making of Step-in Rights for BOT Projects

Chiu Wei Sung
Dept of Civil Engineering, National Taiwan University (email: d92521027@ntu.edu.tw)
S. Ping Ho
Dept. of Civil Engineering, National Taiwan University (email: spingho@ntu.edu.tw)

Abstract

As economy slows down, the BOT/PFI projects become popular in many countries. BOT procurement is undertaken on a service-based output basis rather than an asset delivery basis. Major studies and efforts focused on financial arrangements or project construction management. No serious research on the public sector's step-in rights related issues nor were relevant significant cases been analyzed. To address the uncertainty nature of BOT projects within operation period, the public sector's action should follow Pareto rule, namely to develop a decision–making process which (1) maximize the efficiency of resource allocation and income distribution as well as (2) minimize the transaction cost. Satisfying these objectives is a challenging task that requires identifying tradeoffs among themselves. This paper presents a case study for examining one of the very first PFI agreements in 1993 and the renegotiation of the deal in 1999.The analysis provides some valuable lessons which could be learned from this particular deal for future BOT/PFI contracts design. Furthermore, the outcome of the study will be interdisciplinary works which provide a new approach to BOT/PFI regulators and contracting parties without discrimination.

Keywords: BOT, decision-making, benchmark approach, contract-designing, option theory

1. Introduction

The outset of the Private Finance Initiative (PFI) in 1992 provided concession-based deals which were generally produced on a limited recourse or project financial basis. For the private sector entity to undertake such a long term commitment, it must have sufficient funding to deliver the contracted-for service as well as to ensure that project may be build and then operated and maintained.

Inevitably, BOT/PFI procurements are for the delivery of what amount to indispensable service to the public. The absolute necessity to deliver these services has led to unusual contractual requirements within public-private concession contracts. Legal issues arise across a very broad area and need to be identified carefully. Early studies indicate that governments will seek step-in rights in a board range of circumstances, such provisions are not only made for the public sector to be able to intervene earlier in the event that the private sector is not delivering service to the performance standard but also alarm lenders and other investors - they will not recover the investment they have made in the project unless the private sector borrowers is delivering services and being paid for such services.

1.1 Scope of This Study

We shall introduce the study conducted by researchers on financial and economic law analysis first, and then we shall adopt modern research on real option models and benchmark approaches, to discuss how they can be related with our research objectives. As to contract design related monitor issues arise within the operation period for example, are whether the establishment of the project was consistent with the public sector's long-term business strategy; how the private sector's problems arose; whether the terms of the original contract aided the resolution of crisis; what options considered to tackle the crisis; what the terms were of the revised agreement made to save the project. We tried to collect the evidence in support of our opinions under each of these issues from examination of the Royal Armouries case. According to the scenario case study, this article shows some strategies for improvement of the decision-making system in order to reduce the risk of BOT/PFI projects within operation period...

The paper is structured as follows:

- part 1 contains overview of BOT/PFI and identifies performance risk within operation period;
- part 2 considers step-in rights and provides methods to formulate the critical time issue;
- part 3 reviews an empirical case and examines decision –making process;
- part 4 discusses optimal contract design and monitoring strategies;
- part 5 conclusions

1.2 Risk Management in Operation

Government is responsible for a wide and diverse range of activities including delivering services to the public such as social welfare benefits; procuring and managing major construction projects; regulating industry and collecting revenue. All of these activities involve some form of risks. The Treasury published *Management of Risk - A Strategic Overview* (2000) [1] which defines risk as" *the uncertainty of outcome, within a range of potential exposures, arising from a combination of the impact and probability of potential events.*" Risk management means the public sector has a corporate and systematic process for evaluating and addressing the impact of risks in a cost effective way and having staff with the appropriate skills to identify and assess the potential for risks to arise.

According to the result of survey by NAO in 2000, the main barriers for risk taking in the public sector side are: asymmetric information, risk averse, lack of expertise, lack of formal systems, processes and procedures, unclear responsibilities, the status and activities of public body's limits and time, funding constraints. Instate of tolerating those barriers, the incentives should be incorporated with concessions.

2. Step-in Rights

Step-in rights entitle the public sector to be able to intervene earlier in the event that the private sector is not delivering service to the agreed performance standard .To the extremely circumstance, such a right can be a trigger for the contract termination before contract duration.

2.1 Optimal Time

How often do departments assess overall risks? NAO report (2000) [1] showed thirty-eight per cent of departments do not routinely assess their overall risks. For the private sector entity to undertake such a long term commitment, a further consideration is that priorities change over time and areas of performance subject to assessment need to be reviewed periodically. It is therefore important to identify core areas whose indicators will be collected on consistent basis over time. Later, we shall introduce two financial methods (1) NPV-at-risk method and (2) option pricing theory to identify the critical time issue.

2.1.1 NPV-at-Risk Method

Ye and Tiong (2000) [2] presented the NPV-at-risk method to analyze the impact of the risks on the value of a BOT project. The basic concept of this method is to simulate the primary variables underlying the net present value of a project, and obtain the distribution and confidence level of the NPV. Myers (1976) pointed out the major limitations of the NPV-at-risk method: '*If NPV is calculated using an appropriate risk adjusted discount, any further adjustment for risk is double-counting. If a risk-free rate of interest is used instead, then one obtains a distribution of what the project's value would be tomorrow if all uncertainty about the project's cash flows were resolved between today and tomorrow. But since uncertainty is not resolved in this way, the meaning of the distribution is unclear*.'

2.1.2 Option Pricing Theory

Traditional methods, such as NPV analysis, fall short in reflecting the characteristics of privatized infrastructure projects and the risks involved. Ho and Liu (2002) [3] examined why the evaluation of BOT investments can be improved by applying real option framework and present an option pricing based model for evaluating the project financial viability. So the critical time (bankruptcy condition) can be modeled as

$$V_t - D_t(K_t)e^{-r_d(T-t)} < O$$

Note：

$D_t(K_t)$ is defined as the total outstanding debt at time T prices estimated at time t.

$D_t(K_t)e^{-r_d(T-t)}$ is the total estimated debt at time t prices obtained by discounting $D_t(K_t)$ at the loan interest rate r_d for the period $T - t$.

In order to account appropriately for the asymmetric payoffs under the bankruptcy risk, Equation above suggests that if the project value estimated at t is less than the estimated required total debt at time t prices, the lending bank will force the bankruptcy of the BOT firm to prevent further loss. This quantitative model considers the project characteristics explicitly and evaluates the project from the perspectives of the private sector and of the public sector when the project is under bankruptcy risk. Therefore, the critical time would be pointed out. In that case, the public sector shall have a strong theoretical reason to trigger step-in rights by all means before bankruptcy. Interested readers may refer to Ho and Liu (2002) [3] for details regarding the formulation the BOT-Option Value model.

2.2 Performance Measurement System

In order to trigger step-in rights without discrimination, BOT/PFI contract should contain a reasonable system to measure the private's performance against specified criteria. We introduce two different approaches to explore this issue.

2.2.1 Value for Money

Value for money (VFM) means to achieve the optimum combination of whole life cost and quality to meet customer requirements. Within a VFM framework, evaluation is commonly directed at the following:

- Economy – how much money is spent;

- Efficiency – the relationship between the inputs into activities and the direct outputs from those activities;

- Effectiveness – the relationship between efficiency and outcomes. Outcomes are the ultimate impact of activities and are intended to relate to aims and objectives.

To identify VFM, the illustration between conventional procurement and PFI is showed below (See Figure 1).

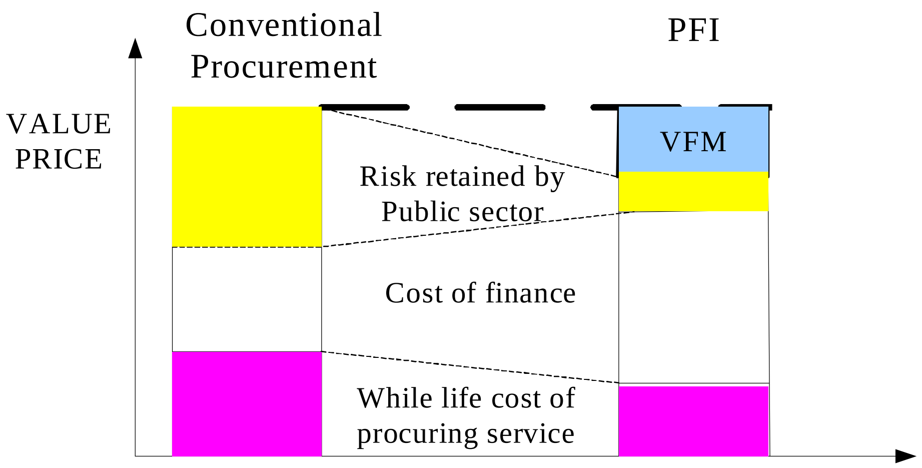

Figure 1. VFM

However achieving cost reductions (or containing costs) does not always represent *good management* – for example if there is a disproportionate, detrimental impact on outputs and outcomes. The transaction cost shall be appraised by including searching cost, bargaining cost and enforcement cost. That is why it is also necessary to evaluate efficiency and effectiveness. Performance Indicators (PIs), for instance, can be used effectively as management tools within an organization to improve the quality, efficiency and effectiveness of museum activities.

2.2.2 Benchmark Approach

Appeals Court Judge Richard Posner, the modern economic law pioneer, pointed out that decisions (judgments) require a benchmark for comparison which implies wealth maximization. Without question PFI's objective shall match the end - wealth maximization. UK experience provided the Public Sector Comparator (PSC) as a benchmark now and it means a benchmark against which VFM is assessed (see Figure 1). The PSC is typically a cost estimate based on the assumption that assets are acquired through conventional funding and that the procurer retains significant managerial responsibility and exposure to risk. The PSC had an inherently high level of uncertainty attached to it, as a result of the difficulty of forecasting not only the demands over 20 years or more, but also the associated running costs and potential income realizable from the project. Risks were modeled in the comparator by using Monte-Carlo simulation and the final output of the final PSC was expressed as a range. The risks modeled in the PSC covered uncertainties in predicting future income in areas such as tickets sand sales and uncertainties in future costs such as ongoing maintenance payments.

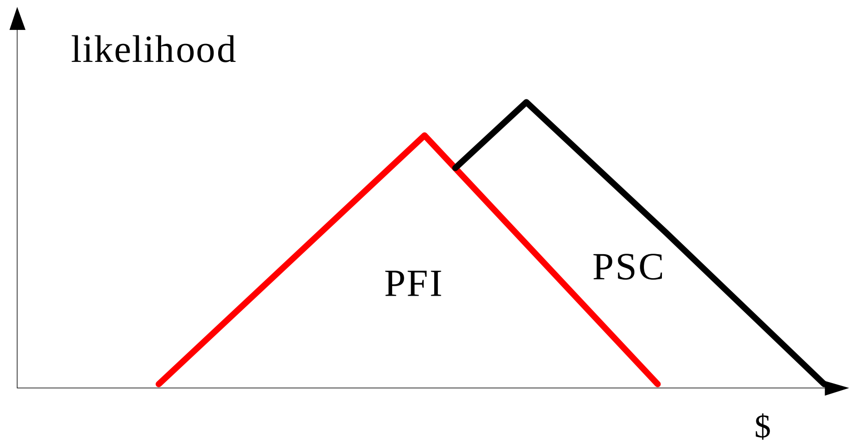

Figure 2 *The Public Sector Comparator (PSC)*

In order to evaluate success, it is necessary to have in mind benchmarks of measuring quality. A key element in this is the perception of value by users. The survey of expenditure may be useful for the private sector to carry out preliminary benchmarking on the relative proportion of expenditure they incur on different types of activity. This may in turn facilitate the gathering and interpretation of benchmarking information.

3. Case Study

The Royal Armouries originally entered into a PFI contract with Royal Armouries (International) plc ("RAI") in December 1993(see Figure 3). Under this contract RAI were to build a new museum which would allow the Royal Armouries to display a greater proportion of its collection. The Royal Armouries agreed to contribute £20 million to the £43 million cost of construction, with RAI meeting over £14 million and Leeds City Council and Leeds Development Corporation £8.5 million.

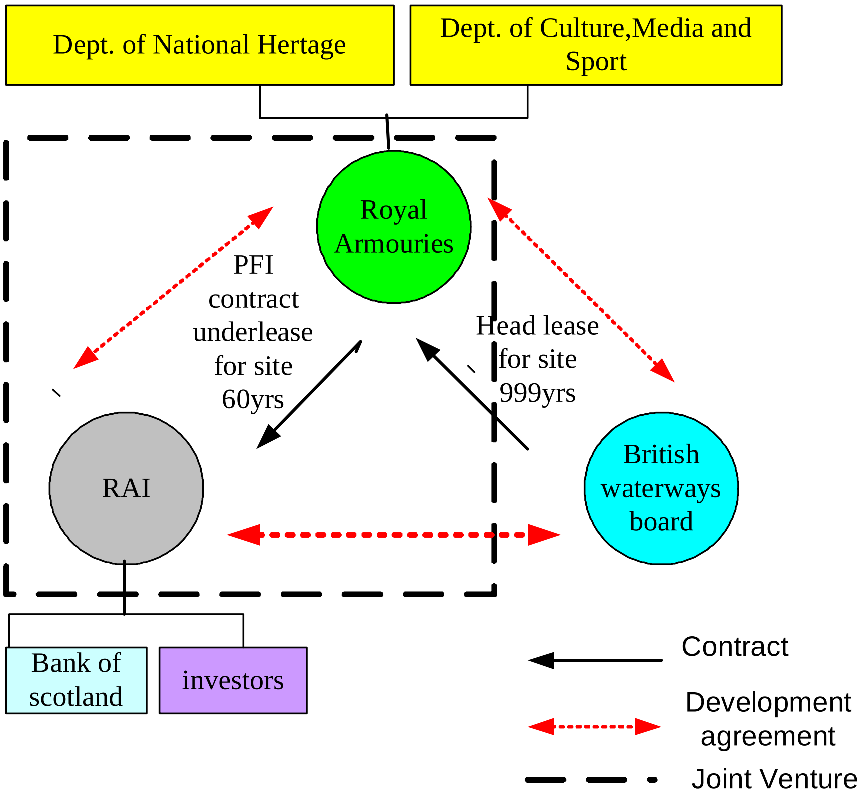

Figure 3 Original PFI Relationship Frameworks in 1993

Once construction was complete, RAI was to operate the new museum for 60 years. (see Figure 4) In return RAI would retain all the income the museum generated from visits by the public. The new museum opened in March 1996; however, visitor numbers were so low that it never made enough money to meet its operating costs and the costs of servicing RAI's debts.

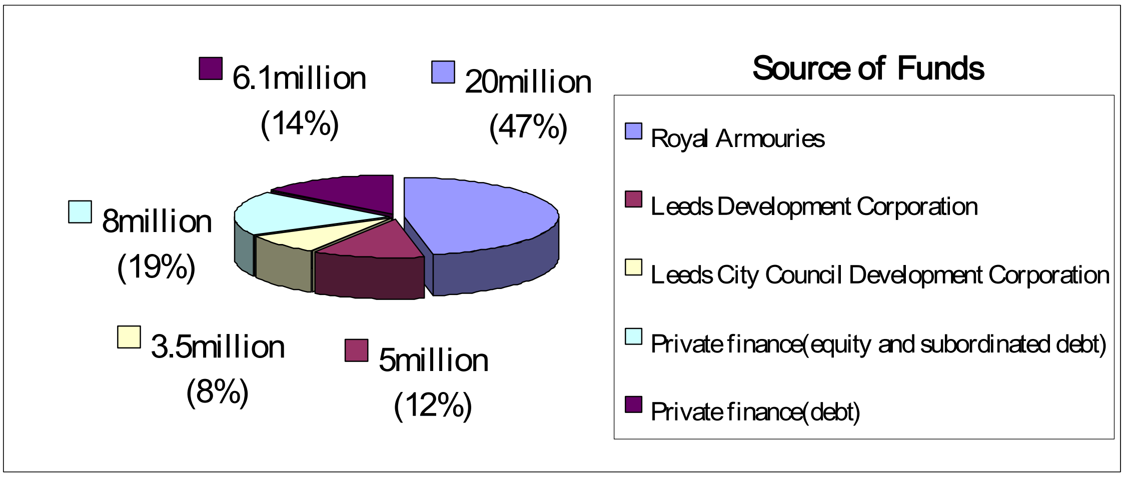

Figure 4 Source of Funds

Consequently, by early 1999 RAI's cumulative losses were estimated at £10 million, despite two refinancing by RAI. As part of the second refinancing in 1998 RAI's bankers, the Bank of Scotland, advised that it would not be able to make additional funding available to RAI after July 1999 if the financial problems persisted. Withdrawal of the Bank's support after that date would have resulted in RAI becoming insolvent. In response, therefore, in July 1999 the Royal Armouries negotiated a revised deal with RAI which ensured that the museum remained open. Under the re-negotiated deal the Royal Armouries took over responsibility for running the museum, while RAI retained responsibility for the provision of catering, car parking and corporate hospitality services at the museum (see Figure 5).

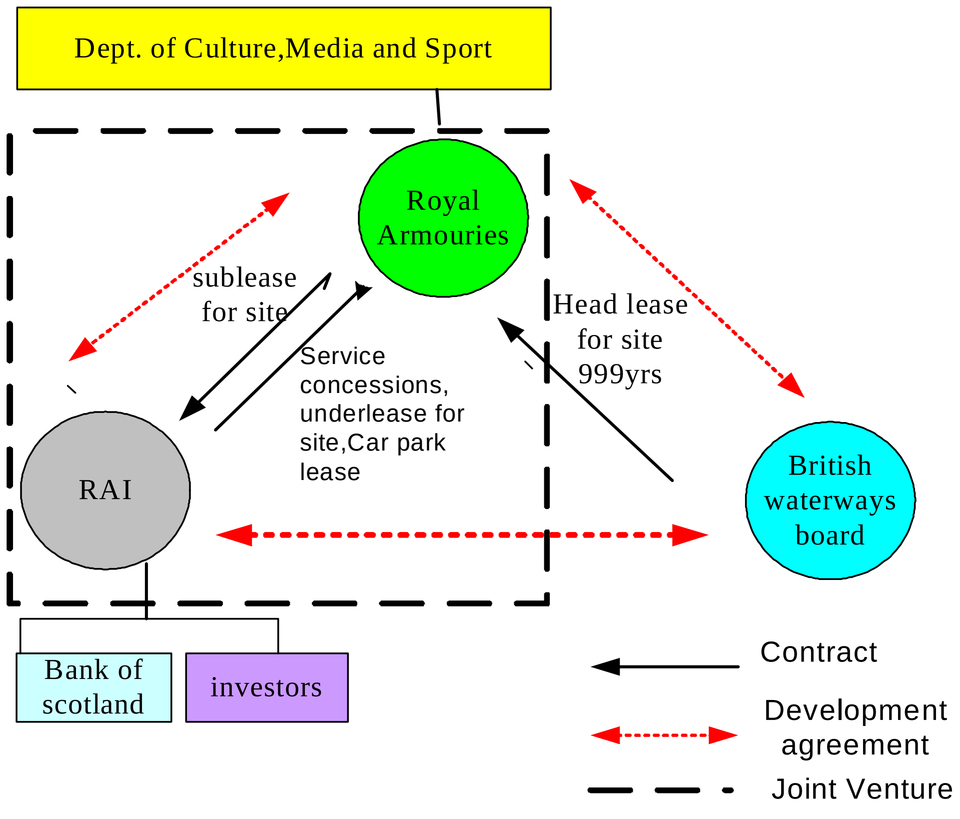

Figure 5 Renegotiation PFI relationship framework in 1999

On the basis of a report by the Comptroller and Auditor General (2000) [4], we explore the public sector's decision-making process by focusing on the forecasts for visitor numbers, the re-negotiation in 1999 and on the extent of risk remaining with the private sector under the terms of the revised deal.

3.1 The Forecasts of Visitor Numbers

The actual number of visitors to the new museum was much less than Royal Armouries and RAI had forecast. However those forecasts were based on a certain pricing assumption and the consultants warned that the actual number of visitors would vary, depending on the admission price charged. The public sector should assess the reasonableness of these projections by comparing them with the performance of comparable existing attractions. In addition, if the project involves a high degree of commercial risk, the project needs to be financed with a high level of risk capital relative to bank debt. If it is necessary to proceed with a project in the absence of adequate levels of risk capital, the government should plan for the contingency that extra funding will be required. The warnings on pricing appear to have been ignored by RAI. RAI had placed over reliance on their own consultancy advice and had charged a high entrance fee of £6.95. One of the first things that the Royal Armouries had done, on taking the museum over in 1999, was to reduce this entrance fee to £4.90.

In addition to the pricing policy, there were a number of other factors which contributed to visitor numbers being less than forecast. Such as delay in the development of the Clarence Dock area surrounding the museum.

3.2 Re-Negotiation an Existing Agreement

Whether the original strategic objectives for the museum had still been met after adopting step-in action？The National Heritage Act 1983 lays down a number of statutory duties with which the Armouries must comply, so the Armouries' objective was to avoid the museum's closure. Obviously, the Royal Armouries did not meet their strategic business objective of becoming more self-sufficient. In contrast, he has taken over the loss making aspects of the museum and will be dependent on extra funding from the government and the income from the lower-than-expected visitor numbers.

In negotiating the deal to save the museum the Royal Armouries did not seek appropriate commercial advice from an insolvency practitioner, although they were faced with a threatened insolvency. Faced with similar situations, the public sector should be clear both about their legal rights and the strength of their commercial position, and be prepared to use those rights and powers aggressively in negotiations. Under the terms of the revised deal RAI had to pay twenty per cent of their turnover to the Royal Armouries once their debt had been paid off. However, there were limits on the capacity of the museum to handle increased visitor numbers. The public sector should ensure that he has the right to share in the benefits of any future windfall gain resulting from any re-negotiated deal.

3.3 Ensuring Risk Remains with the Private Sector

Before signing the contract, the Royal Armouries had taken over comfort from assurances from their financial advisers, Schroders, that the deal was the best available from the market at the time, given the deal's parameters. In considering future deals, the public sector should get impartial advice on the merits of a proposed deal before it is signed. Under the current guidance the public sector would have had to consider at the very start of the project what would happen at the contract's end. On this deal the Royal Armouries' ability to terminate the contract and take possession of the museum due to RAI's insolvency was limited for two years. The public sector needs to consider in advance how they will eventually exit from deals.

There had been a lack of market interest in the deal when it was put out to the market and only one bid had actually been received. The operating specification which was to detail those areas where such co-operation and joint working was required was not agreed subsequently. Even the Royal Armouries were not given access to RAI's financial records and there were disagreements between the two parties over issues which were of fundamental importance to the museum's future. The public sector should be aware of such warning signs that the deal being negotiated will not eventually be sustainable.

Surprisingly the Royal Armouries had no contingency plans in place, as they considered that the risk of the project's failure lay with RAI in the private sector. However, on this deal the business risks ultimately lay with the public sector as the Royal Armouries had been unwilling to countenance the closure of the museum and had therefore stepped in to rescue the project. In considering future PFI projects, therefore, the public sector should consider where the business risks ultimately lie and draw up their own contingency plans accordingly.

4. Contract-designing and Performance Standard

The new museum involved significant commercial risk, as it was a new attraction in a redevelopment area with no proven track record of visits by the public. What gets measured is what gets done. Performance measurement can be used not only to influence behaviour in a desired direction but also to serve as a benchmark. For example, the National Museums and Galleries developed a mechanism for raising standards of efficiency and quality in the sector and to identify examples of good practice. These objectives fit with Government initiatives seeking greater accountability and proof of “Best Value” from public services [5]. Those outputs are as follows

- a Business Model which analyses the activities;
- a long-list of Performance Indicators (PI’s) for each activity;
- An agreed short-list of Performance Indicators to act as the foundation for a performance management regime.

OGC publish valuable reports, guidelines as well as PFI standard form contract [6] which reduce the transaction cost well. What the public sector measure must be meaningful and material to the fundamental mission of the organization and its operation. Strengthening economic legal infrastructure is about improving the quality and accessibility of the law and the capacity of individuals and institutions to implement, apply and enforce those laws. The benefits are:

- improve transparency, predictability and fairness in the rules and regulations and administration of the public sectors; and
- engender business and investor confidence and enhance competition; and

- lead to economic efficiencies, innovation and reduced compliance costs for business

RAI should use the agreed PI's to collect information on outputs and outcomes. Through this they can demonstrate how the museum is contributing to the achievement of government objectives; and The Royal Armouries and the lender should use the agreed PI's to assist with their evaluation of the efficiency and effectiveness of the museum. This will provide an incentive for the private sector to consider where and how to reduce unit costs.

5. Conclusions

The study makes three main types of contribution under consideration:

- introduce an example of current practice;
- consider key issues and critical factors with regard to particular types of BOT/PFI;
- discuss basic standards with which all the private sector should be expected to comply.

In conjunction with investment and facilitation initiatives, strengthening economic legal infrastructure can help deliver significant returns in the form of social outcomes and sustained economic growth. Failure to provide an appropriate standard of decision-making could prove costly as a consequence of market uncertainty and loss of investor confidence. As the issues that need addressing are complex, and in some cases entrenched in legal system, culture and judiciary, measures will need to be undertaken with a long-term perspective, giving rise to incremental but substantive improvements. It is hoped that the work of the study will be continued in the form of an ongoing issues, such as the diversity of the activities, comparability and consistency as well as balancing long and short-term objectives, within performance period by dynamic approaches.

Risk Management

CM-at-Risk Delivery System And The Miami Intermodal Center

R. Edward Minchin Jr.
University of Florida (e-mail: minch@ufl.edu)
Ralph D. Ellis Jr.
University of Florida (email: relli@ufl.edu)

Abstract

The Miami Intermodal Center (MIC) is the first "CM (construction manager)-at-risk" project ever funded by the U.S. Federal Highway Administration (FHWA). The size of the project qualifies it for "mega-project" status, but this is not the only thing that makes this an historic project.

MIC, a $2.25 billion project located just east of Miami-Dade International Airport (MIA), is envisioned as a consolidated transfer center for passengers using the airport, intercity and commuter trains, rapid transit, local and intercity buses, and cruise ships in the Port of Miami. The project is being developed by the Florida Department of Transportation (FDOT) and the Miami-Dade Aviation Department, in cooperation with the Miami-Dade Expressway Authority, Miami-Dade Transit, Amtrak, and various rental car agencies serving the airport. The MIC is actually a series of projects, including a consolidated rental car facility, a people-mover connection to the airport, and a number of road access improvements around the airport.

What really makes this project unique, however, is the delivery system chosen by the owners for the early stages of the project. All manner of fast-track construction methods have been used in building construction and industrial construction for years, but these are a relatively recent development in the area of civil, or heavy, construction. FDOT had its first design-build (DB) projects in the early 1990's, with the FHWA beginning to fund DB projects in the state later in the decade. For the MIC, however, the CM-at-risk delivery method was chosen. Very similar to the "Team Approach" taught in construction management textbooks, the CM-at-risk approach is a cost-plus-fee contract with a guaranteed maximum price (GMP). The GMP is based on the sum of the CM's fee, the CM's contingency, the money set aside for General Conditions construction, all the subcontracts, plus an estimate for unbid subcontracts. The CM agrees to pay for costs that exceed the GMP and are not a result of changes in the contract documents.

Keywords: Miami Intermodal Center, CM-at-risk, delivery system, access facility, terminal access roads, MIC/MIA, tri-rail

1. Introduction

The Miami Intermodal Center (MIC) is a world-class mega-project that has drawn intense interest and scrutiny from construction and design engineers both nationally and internationally. It combines the latest in horizontal construction, vertical construction, and project delivery methods. The project scope also includes innovations in project financing and engineering that will be noted, but not discussed at length as they are beyond the scope of this paper.

As early as 1989, the Miami International Airport Area Transportation Study recommendation for the implementation of a multi-modal transportation access facility to help mitigate the growing traffic problem in and around the airport was accepted by Miami-Dade County. However, due to lack of funding and other issues, the project was not started until 2003. MIC will be a world-class multi-modal facility that is estimated to take 15 to 20 years to construct and cost approximately \$2.25 billion.

MIC includes the first transportation project using the "CM-at-Risk" (CMAR) delivery system ever to receive federal funding. All of the work currently scheduled using the CMAR system is slated for Phase I of the project, which is now in progress and is estimated to take five years and cost \$1.35 billion. The work done using the CMAR delivery system includes the rental car facility (RCF), the MIC terminal access roads, and other items, and is estimated to cost \$230 to \$250 million and be completed in 2007.

This paper provides an overview of the project, how CMAR works, and how it is performing when compared to traditional project delivery systems.

1.1 Background

The project sponsor was FDOT, and because of its size and significance, the project was classified as a "mega-project" by the United States Department of Transportation (US DOT). FDOT would act as the "owner" of the project even though Federal Highway Administration (FHWA), Miami International Airport (MIA), Miami–Dade County, and the Federal Aviation Administration (FAA) had a vested interest in the project and could also be considered owners. Once the decision was made to build the project, a consultant, Earth Tech, was quickly added to the team by FDOT as the Program Manager.

Several decisions lay before the team. A designer had to be procured, as did construction engineering and inspection (CEI) services and construction services. A delivery system had to be chosen and numerous permits obtained. The proposed facility had to accommodate the rental car companies around the airport, the Tri-rail system (an above-ground train line that connects the three major south Florida counties—Dade, Broward, and Palm Beach—and ends at MIA), the Miami-Dade County Transit Authority (bus lines), Amtrak, cruiseline courtesy buses, hotel courtesy buses, Greyhound buses, the existing street and highway system, and numerous other transportation entities.

One of the most daunting tasks facing the team was trying to please the numerous parties of interest that ranged from the other involved agencies, such the FAA and Miami-Dade County, to private interests, such as the Tri-rail system and the car rental companies that would use the new facility. In addition, any decision regarding the delivery system had to be filtered through FDOT's long-standing policy that any prime contractor must self-perform at least 50% of the project.

2. The Project

The transportation development portion of the project was separated into two phases. Phase I will include all right-of-way acquisition, access improvements (roadways), the consolidated rental car facility (RCF), the MIA Mover (formerly referred to as the MIC / MIA Connector, this is a two-mile bridge on which either trains or trams will transport passengers between the MIC and the MIA), and the MIC Core (Phase I). Actually, only $80 million of the approximately $400 million cost of the MIA Mover will come from MIC funds, as the MIA Mover is primarily sponsored by the county and MIA. [1] Phase II, not scheduled to commence until at least 2007, will include completing the MIC Core, constructing platforms serving elevated Tri-rail, Amtrack, and Metrorail lines, and all construction of MIA landside facilities.

2.1 Phase I

While the entire program will be completed over the next 15-20 years, the first phase is scheduled to be completed over a five-year period of time at a cost of approximately $1.35 billion. This Five Year Program will consist of the activities and corresponding costs shown in Table 1.

Table 1. MIC Cost Breakdown by Activity Type

Amount	Activity
$ 615,000,000	Construction
$ 350,000,000	ROW and Environmental Remediation
$ 22,000,000	PD&E Study
$ 84,000,000	Design
$ 42,500,000	Program Management
$ 32,000,000	CE&I Costs
$ 93,000,000	Contingency
$ 65,000,000	Financing
$1,303,500,000	Total

2.1.1 Rental Car Facility

The RCF is the first major component of the MIC being constructed. It will co-locate the rental car companies currently located at the airport and many of the companies located adjacent to the airport. The financial impetus for the early commencement of the RCF was a loan from the Transportation Infrastructure Funding Innovation Finance Act (TIFIA). "The RCF is currently budgeted in the MIC work program at $218.7 million; however, a $190 million scope has been agreed to by all parties and an updated financial plan is currently being reviewed by the joint TIFIA Office. When the RCF TIFIA loan is finalized, the work program estimate will be conformed to the project budget. TIFIA loan draws are occurring more slowly than originally forecast and lower TIFIA loan balances are anticipated for eventual repayment." [2] Details of the TIFIA loan are discussed later in this paper.

The sheer size of the building (1400 feet by 1200 feet, with the top floor sixty feet off the ground) makes construction a challenge; however, the size of the building was not the main consideration. Each floor of the building will house a fuel distribution center where gasoline will be pumped into the rental cars at each level. This is the first time that any building in the United States has had elevated fuel distribution capability; special permits and numerous considerations will be required.

The RCF will include:

- Ready/return vehicle capacity of approximately 6500 vehicles
- Fleet storage capacity (vehicles not in use) of approximately 3500 vehicles
- Quick turnaround vehicle fueling and washing facilities
- Spacious customer service facilities for rental car transactions

The most interesting part of the construction of the RCF, and probably the whole project, will be the construction of the elevated fueling centers. The Senior Program Director for the project said that for the period of time that this portion of the RCF is being constructed, "the Fire Marshall will be running the project." [3] This unique construction will be a subject of widespread interest.

2.1.2 MIC Core (Phase I)

The first phase of the MIC Core will cost approximately $80 million and accommodate the bus depot, Tri-rail passenger parking, and MIA Mover Station. The MIA Mover Station will be built adjacent to the RCF. This facility will allow passengers of Tri-rail, city busses, and rental cars to board the MIA Mover, and be transported to the airport terminal. The MIA Mover will feature large cars that run on either electric rails or rubber tires and will be boarded on the top floor of the building, 60 feet off the ground. This facility is expected to be completed and operational by November, 2008.

2.2 Phase II

The transportation development portion of Phase II will consist of completing the MIC Core, constructing platforms serving elevated Tri-rail, Amtrack, and Metrorail lines, and all construction of MIA landside facilities. There is also a commercial development portion of the MIC that will be completed as part of Phase II per the Joint Development Agreement.

2.2.1 Joint Development Agreement

The Joint Development Agreement was first conceived as a revenue-producing program and comprises the commercial development portion of the MIC. An oversight committee was formed to supervise the commercial development, and they retained ERA, a D.C.-based consultant, to perform a study that found that the area in and around MIA was in need of office towers, parking, ancillary retail, and a hotel/conference center.

In early 2002, an RFP was advertised for a developer to handle the commercial development, and the apparent choice is MIC Development, LLC, a joint venture consisting of equity partners The Codina Group and Mallory & Evans, hotel developer The Continental Company, marketing giant Market Place Development, and two large AE firms. Negotiations have begun with this group, with the expected start date on commercial development set for early 2008.

The commercial part of the venture will include office towers, a world-class conference hotel, restaurants, and other businesses. The plans now call for FDOT to lease space to occupants, raising over $5 million per year to help pay the debt incurred through the loans part of the project financing. Appraisals are already being done to estimate the current market value so lease and rental terms can be developed.

A stipulation in the agreement states that if rents exceed $5million in any year, the amount of revenue over $5million will not go to pay down the debt, but must be used to pay for road and bridge construction.

3. Economic Impact

The construction of MIC will result in numerous temporary and permanent job creations within many sectors of the economy, especially construction, retail, and service. It is estimated that over the 15 to 20 years of the entire construction process, 76,000 construction and construction-related jobs will be generated, and 22,000 permanent jobs will be created to operate the facility once it is constructed. The economy and standard of living around MIA will be enhanced because the facility will encourage travelers to use the various public transportation systems integrated into the MIC. It is estimated that by 2010, 75,000 passengers will use the MIC daily. Of these, approximately 45,000 are expected to be using the MIA Mover to travel to or from the airport. [4]

4. Project Funding

Financing the MIC, with a total cost estimated at over $2.25 billion, was a challenge for the state of Florida and Miami-Dade County. Phase I is projected to cost approximately $1.35 billion over five years and has received funding from a variety of sources. While obtaining the TIFIA award brought significant funding, as well as international notoriety to the MIC project, it was certainly not the only significant source of funding. For Phase I, the MIC has received nearly $165 million in Federal Highway Administration (FHWA) grants, $386 million in state

(FDOT) funds, and a $25 million Florida State Infrastructure Bank (SIB) loan. The Miami-Dade Expressway Authority has provided $87 million in toll-backed funding, and the project has also received $18 million from Florida's SIB specifically for a portion of the project, the SR 836/SR 112 connector. The Miami-Dade Aviation Department will fund most of the $400 million cost of the MIA Mover with airport user fees.

The complete list of funding sources and their contribution can be seen in Table 2. [2]

Table 2. Funding Sources for MIC, Phase I

Source	**Contribution ($Millions)**
Prior and future Allocations of State and Federal Funds in Miami-Dade County's Transportation Improvement Plan (TIP), Long Range TIP, and Other State Funding	$249
MIA Capital Improvement Plan	$400
RCF Customer Facility Charge	$25
Miami-Dade Expressway Authority's Capital Program	$86
Miami-Dade County	$30
Ancillary Revenues for from Concessions and Joint Development	$37
FDOT State Infrastructure Bank Loan	$25
TIFIA Loan	$433
Capitalized Interest and Finance Costs	$64
Total	$1,349

Because of the close economic and geographic ties between MIC and MIA, the events of September 11, 2001 led to a reevaluation of the MIC program which focused on funding and timing. MIA has been much slower to recover from the aftershock of the September 11 disasters than most of the nation's airports due to MIA's dependency on passenger traffic from Latin America and the recent effects of low-cost air carriers operating through neighboring Ft. Lauderdale. The project elements most impacted by events since September 11, 2001 are:

- The MIA Mover
- The RCF
- Resultant program schedule adjustments for a delay of 18-30 months.

5. Delivery System

Three delivery systems were given strong consideration for each aspect of Phase I; the result was that different portions of ongoing work are being handled in different ways. Since federal funding was sought for each activity, FHWA approval was required for each delivery system decision. It was decided that portions of the work would be handled in the traditional FDOT way, which is by the linear method, or Design-Bid-Build (DBB). Other portions of the project would be handled by the Design-Build (DB) method.

FHWA had long allowed FDOT to use the DBB method for federally funded projects. FDOT has received federal funding to use the DB method for almost ten years, developing a high level of comfort within FHWA for use of that method in Florida. For the RCF and the MIA Mover

Station, however, a level of vertical construction expertise was needed that FDOT projects do not typically require.

But since the project also contains quantities of earthwork and site preparation common to FDOT projects, and roads and bridges are called for in the project, a delivery system was needed that would best meet the challenge of both linear and vertical construction.

In July, 2000, Earth Tech performed a technical evaluation of three delivery systems as a means for the design and construction of the RCF and certain other related structures. The three systems considered were DBB, DB, and Construction Manager-at-Risk, or "CM-at-Risk" (CMAR). It was decided that this portion of work, amounting to approximately $230 to $250 million, would be let under separate contract, using the CMAR delivery system. Reasons given by Earth Tech for this choice were that CMAR offered the following :

- Design process control
- Ability to meet or exceed schedule requirements
- Highly qualified contractor
- Highly qualified designer
- Budget/Cost control
- Project team formation
- Constructability input from the CM

This choice in delivery systems meant that FDOT had to waive, for this project, their long-standing rule that all prime contractors had to self-perform at least 50% of project work. In addition, in order to receive federal funding, FDOT had to make a special application to FHWA under Special Experimental Project Number 14 (SEP-14). SEP-14 is a program by which FHWA can fund a limited number of projects that don't follow existing FHWA guidelines, provided the projects include innovative construction practices or delivery systems. Until fairly recently, a DB project had to go through this process, but after several successful DB projects, the FHWA stopped requiring this special application for DB projects. The MIC is the first CMAR project ever funded under SEP-14.

5.1 CM-at-Risk

Clough and Sears state in their well-known textbook that, "An appreciable share of the private construction market is now being done using the 'team approach.' When this procedure is followed, the private owner selects the architect and building contractor as soon as the project has been conceived. The three parties now constitute a team that serves to achieve budgeting, cost control, time scheduling, and project design in a cooperative manner." [5]

Using the "team approach," the owner assembles the project's key players, such as the designer(s) and contractor(s), to study the proposed project. The team determines the project scope and budget, and the designer develops preliminary drawings from which the contractor makes conceptual cost estimates. As the process continues, the designer prepares the final drawings and specifications, and the owner makes the necessary financial arrangements. After financial commitments and required permits are obtained, actual construction begins. The designer and the contractor work closely together, modifying the design and the drawings as may be required. The process offers the owner the advantages of time savings, cost control, and improved quality. [5]

The method chosen to facilitate fast-track construction of the MIC, “CM-at-Risk,” is very similar to this textbook description of the “team approach” and can be viewed as an adaptation of this established building construction delivery system used in private industry to civil or heavy construction in a public forum. The CMAR contract is a cost-plus-a-fee contract with a guaranteed maximum price (GMP). The GMP is based on the sum of the CM’s fee, the CM’s contingency, the “general conditions construction,” all of the subcontracts, and an estimate for unbid subcontracts. The CM agrees to pay for costs exceeding the GMP that are not a result of changes in the contract documents.

CMAR theoretically reduces the amount of risk for every entity involved in the project. From the beginning, the client’s (owner’s) understanding of project requirements is combined with the wisdom, experience, and technical expertise of architect-engineer (AE) and CM firms. This team has control over every aspect of the project, and together they provide an absolute directive for design, construction, and functional requirements. One of the most important benefits is that the arrangement fosters a non-adversarial relationship that furthers collaboration in decision making. The CM can review the drawings beforehand and catch errors, reducing the owner’s risk, while the AE similarly reviews the CM’s approach to the work, providing constructive recommendations.

The CM is allowed to take bids or proposals from subcontractors after entering the contract and prior to submission of the GMP, which reasonably reduces the CM’s risk. The procedure is more methodical and more predictable than the low-bid DBB and affords the owner more control over design than the DB system. This is because the AE is under contract to the owner under CMAR instead of being part of a joint venture under contract to the owner and tied to the contractor, as is the case under DB. The lack of a tie between the designer and the contractor reduces the owner’s risk, and in reality, these factors reduce risk for all parties.

There is a contingency within the GMP to cover unexpected but justifiable costs, and a contingency above the GMP allows for owner changes. As long as the subcontracts are within the GMP, they are reimbursed to the CM, so the CM represents the owner in negotiating any changes with subcontractors.

5.2 CM-at-Risk at MIC

The MIC can be seen as a pilot project for CMAR from the FHWA standpoint because it is their first such project. It is also FDOT’s first CMAR project but is not the first for the state of Florida. The Florida Department of Management Services (DMS) has built several vertical projects using the method over the last 15 years. For this reason, DMS had personnel on the original Technical Review Committee and originally had a financial stake in the project because the CMAR contract was forged using DMS procedures. Immediately after the contracts were signed, DMS assigned all their rights to FDOT.

A negotiated fixed fee is the method of CM compensation on the MIC project. The CMs interested in this project had to submit a GMP for administering this fast-track construction project. The chosen CM is required to prequalify all subcontractors and oversee the bidding of all trades contracts. In this way, all construction work would be competitively bid. The only way that the CM could self-perform any construction would be to outbid the subcontractors on a portion of the work.

The CM is paid a management fee plus expenses for oversight and coordination of the construction process. This could include project close-out, systems start-up, as-built drawings, operations and maintenance procedures, and warranty services. The CEI consultant, Earth Tech, performs the QA verification testing, as well as the Threshold Inspection of the building (permit work). The FDOT District Materials Laboratory performs Independent Assurance and Independent Verification testing. The CM, then, is left to perform all QC and Value Engineering (VE) for the project; any savings realized by any VE change proposal is split, with 70% going to FDOT and 30% going to the CM. Earth Tech was awarded the CEI work under a separate contract from the one for their Program Manager duties.

Another contract provision allows the CM to keep 30% of the difference between the GMP and the actual cost of construction. Described by the program manager as “a double-edged sword,” this gives the CM an incentive to keep costs as low as possible, but also presents the CM with the motivation to set the GMP as high as possible. [3]

On January 29, 2001, a legal notice advertisement requesting Statements of Qualification for a CM for this project was posted. Technical Proposals were submitted by the short-listed CMs on May 1, 2001, oral presentations were heard by the Selection Committee on May 24, 2001 and Turner Construction Company was chosen as CM for the project. Delays occurred in getting the project started due to the World Trade Center and Pentagon disasters of September 11, 2001, and when the runner-up for the CM assignment protested the selection of Turner.

After the selection process, FDOT, DMS, and Turner Construction, Inc., signed a contract on March 1, 2003. The GMP No. 1 bid package was issued to Turner on April 4, 2003, and the notice to proceed came in mid-July, 2003. The Organizational Chart for the MIC project is seen in Figure 1.

Construction items were broken down into separate packages called “GMPs”, each to be negotiated separately and each with its own Letter of Authorization (LOA). At this point, the GMP packages are as follows:

GMP I – RCF foundations and underground utilities. Cost: $17.6 million.
GMP II – MIC Terminal Access Roadways (MTAR), Transit Access Roadways (TAR), tunnels, LeJuene Blvd. water main. Estimated Cost: $21.0 million.

GMP III – Tri-rail Station, MIA Mover Guideway Foundation. Estimated Cost: $22.0 million.

GMP IV – MIA Mover Station (minus 4th-floor lobby), RCF Building and bridge. Estimated Cost: $185 million.

The fourth-floor lobby is not currently planned for completion under this project. This raises the possibility of a GMP V, or that the lobby may be constructed under a separate agreement. [6]

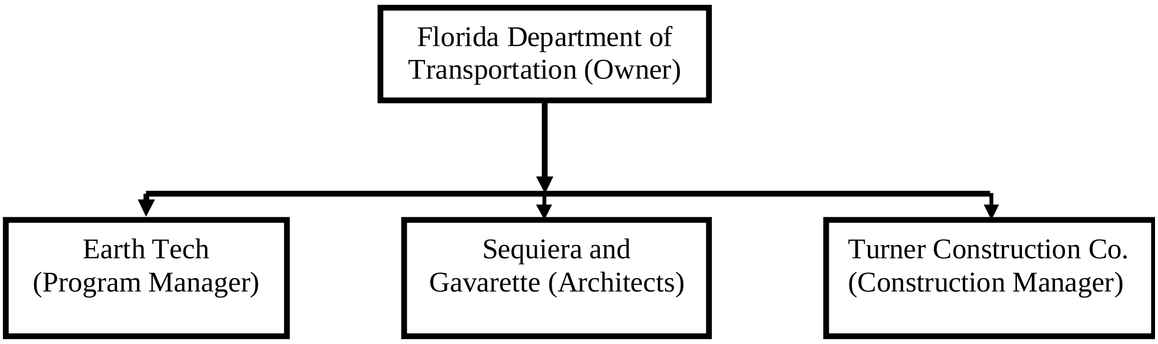

Figure 1. Organizational Chart for CMAR Portion of the Miami Intermodal Center

6. Project Progress

As of the time of this writing, GMP I was completed, GMP II was about 15% completed, Turner had been issued the LOA for GMP III, and the plans for GMP IV were at the 65% review stage. In getting to this point, the CM has overseen the driving of 2779 24-inch-by-24-inch pre-stressed portland cement concrete (PCC) piles, the construction of 672 pile caps, the placing of almost 15,000 cy of grout and approximately 11,500 cy of PCC. Also, over 120,000 cy of fill dirt has been delivered, spread, and compacted and 5000 linear feet of utility lines have been relocated.

Land acquisition and environmental remediation for Phase I and Phase II of the project have been completed. The RCF foundation has been completely constructed, and major roadway projects are under contract. MIA and Miami-Dade County are proceeding toward the procurement of an entity to perform a design-build-maintain for the MIA Mover utilizing advance funds from the county. Customer facility charges have been collected from planned users of the RCF since May, 2004.

7. System Evaluation

Theoretically, the CMAR delivery system brings a wide variety of advantages to a construction project; however, there are important elements that must be in place if CMAR is to bring all of its potential benefits to the project. Two of these essential elements are: 1) The CM must be on board no later than the 35% plans review, and 2) There must be a designer that works especially quickly and efficiently between the 65% plans review and plans completion.

If the CM is not on board by the 35% plans review, then the construction expertise that is so much a part of the CMAR design phase will be lost. In addition, if the designer does not move quickly from the 65% plans review to plans completion, the fast-track advantage will be lost because the CM cannot obtain many of the required permits without completed plans.

Unfortunately, Turner was not brought on board for GMP I until the plans were completed; therefore, there was not the level of constructability review that CMAR is known for. In addition, the project was delayed by the unexpected length of time required for TIFIA loan funds to arrive and was perilously close to being severely delayed by permit acquisition. In both cases, FDOT and the rest of the project team were fortunate. Although 50 change orders were executed in GMP I, resulting in a net cost increase of approximately $600,000, very few of them could have been avoided by a proper constructability review. As for the permits, the project team was again fortunate. The county allowed the RCF to be built under the old (2000) South Florida Building Code instead of insisting it be built under the new (2002), more demanding and time-consuming Florida Building Code, which saved time and outlay equaling at least $5 million. Project personnel estimate that had the authorities not allowed the project to be "grandfathered" into the old building code, the additional delay would have been at least a year. (MIC Personnel 2004)

Another big advantage of CMAR is that, theoretically, there should be a better relationship between the parties to the contract than under the DBB system. While all agreed that this was the case during GMP I, it is apparent that not having the CM on board until plans completion caused things to occur on the project that strained relations to some extent. For example, the CM was forced to act more like a prime contractor than a CM in some of the dealings with the subcontractors because of constructability issues and other questions that could have been solved proactively instead of reactively had the CM been on the team from the beginning. There were also issues between the program manager and the CM early in the process of GMP I that could have been avoided by having the whole team in place from the beginning.

Even with the CM coming on board late in GMP I, the evaluation of the system by the participants was positive overall. Project personnel reported a "great" relationship between the CM and their subcontractors and that there was much less of an adversarial relationship between all parties to the contract than has been experienced under the DBB system.

The difference between working on a project under the DBB system and under the CMAR system was described by one individual on the project as "two different planets. Under the DBB (low-bid) system, all of your profit is made on project changes. Contractor or CM personnel are trained to find potential changes. With CMAR, the CM is responsible for the whole job and the approach to the project is different. The CM under CMAR is much more service-oriented than a CM or prime contractor under DBB. In fact, when this company hires someone out of the DBB environment, it takes an individual about two years to convert from the adversarial attitude bred by the DBB delivery system to the more service-oriented attitude prevalent in the CMAR delivery system.” [3]

Other experiences and insights shared by those involved with the project include:

- The key element in the CMAR system on this project is the contingency fund (10% on this project). Without that, an adversarial atmosphere would appear on the project.
- Instead of the prime contractor or the CM looking for changes as on a DBB project, the subcontractors are doing so, but a strong CM insulates the owner from this problem.
- There was freedom to attract a blue chip contractor (CM), not the low bidder.
- There was much more flexibility and ability to handle the unexpected.
- There was freedom to attract a blue chip designer and pair them with the contractor.
- Much greater ability to handle things that the owner and CM are not familiar with, such as the elevated fueling facilities. [3]

For GMP II, the CM was brought in a little earlier than in GMP I; however, it was not early enough. Turner was brought in only a little before the plans for GMP II were completed but was able to influence the design via the VE process even though they were unable to help at all with the constructability review function. In short, in GMP II, Turner has been more involved in the design than in GMP I but still not fully utilized.

Turner was on board by the 35% plans review for GMPs III and IV. In fact, as of this writing, Turner had just received the 65% plans from which they will calculate and submit a GMP. The intent of CMAR as it is now being administered at MIC is for the CM to assume liability at the 65% plans review, but they have 60 days from receipt of the 65% plans to submit their guaranteed maximum price for any GMP, in this case, IV.

8. Summary and Conclusions

“MIC is a model for infrastructure development and implementation with partners including FDOT, Miami-Dade County (transit, aviation, expressway authority and seaport), US DOT (transit, highways, aviation, and Coast Guard), and various” companies from the private sector. Federal, state, county, and private funding sources are being utilized.

A TIFIA loan has played a critical role in the overall financial structure of the MIC program. It has allowed the parties to commence the project in the most efficient and timely manner and winning TIFIA loan approval won world-wide recognition for MIC.

Although the CM was not involved as early as needed in GMPs I and II, the CMAR system has still performed admirably. The adversarial relationship between owner and CM or prime contractor under the DBB system was greatly reduced even in this incomplete execution of the system. Many of the other advantages credited to the CMAR system were also apparent in the execution of GMP I and, so far, GMP II. Among these are:

- With CM-at-Risk, FDOT has complete freedom to select a design firm completely on the merits of its expertise, reputation, and concept of the project. Similarly, for the construction work, it provides an opportunity to select a contactor with the expertise needed for a particular project and an excellent track record of completing projects on time and within budget.

- Instead of the prime contractor or the CM looking for changes to increase profits, the subcontractors are doing so, but a strong CM insulates the owner from this problem.
- There is a high degree of flexibility and ability to handle the unexpected
- The owner has much more control over the design process than is possible under the DB system

For GMP II, the design was also almost at 100% when the CM was retained; thus, no constructability reviews were provided by Turner. This time, however, Turner did make some contribution to the pre-construction phase by providing VE for some portions of the work.

GMPs III and IV will be more true to the theoretical CMAR because Turner is thoroughly involved in the design and construction activities with input from the beginning through constructability reviews and VE. GMPs. III and IV will, then, provide a more complete case study of the delivery system than the first two GMPs.

Much of the credit for the flexibility and service orientation of the CM and subcontractors was directed at the contingency fund (10% on this project). Without that, it was feared that an adversarial relationship would manifest itself on the project.

FDOT is very pleased, at this point, with its decision to use the CMAR delivery system, and the research team will continue to monitor the project to learn more about the application of this method to transportation construction.

Poor Quality Costs in the Swedish Central Government Budget: the Influence on Costs For Construction Projects

Abstract

The poor-quality costs in construction projects are traditionally estimated to 1-10% of the total project cost. These estimations normally include the projects' own processes. However, in Sweden more than 50% of the costs for producing buildings are taxes. To better understand the total poor-quality costs there should also be an analysis of the processes financed by the taxes. This paper aims to map and quantify poor-quality costs hidden in the taxes, here limited to an analysis of the Swedish central government budget. All the expenditures of the budget proposal for 2005 have been classified according to their proportion of poor-quality costs. The preliminary analysis indicates that as much as 28.9% of the expenditures in the public sector are poor-quality costs. This implies that more than 15% of the production costs of an average construction project are poor-quality costs that are hidden in the taxes. A reduction of these costs would enable a tax reduction or an increase of activities to other more essential expenditures in the public sector. Consequently, it will give the customers more value for their invested money.

Keywords: Poor-quality costs, taxes, construction project, public sector

1. Introduction

There are two main reasons to quantify the poor quality costs within processes, which the governments, the county councils and the municipalities take care of.

First, firms and other organizations, which measure poor quality costs, tend to limit their measurement systems to their own processes. In a few cases they also consider their suppliers' processes. In order to be more profitable, they should however, extend the system to consider all dollars, which transfers through the organization and try to find out why the dollars leave the customers' pockets. One starting-point is here that the organization direct or indirect through their actions can influence all these dollars.

Second, in the debate about the high costs for building, the actors argue that the reason is high costs for material, low productivity etc. The Swedish Construction Federation and The Swedish Property Federation argue that the pressure of taxation is too high. They should, however, not focus on the volume of taxation, but the processes financed by the taxes. The social system takes care of many consequences from poor quality within the industry. It would be worthwhile to look closer at what processes financed by taxes could be viewed as poor quality costs and find out how much it influence the costs for a building project.

The specific aim of this paper is to quantify the poor quality costs, which are hidden behind taxes. The analysis, which is preliminary, is limited to the Swedish central government budget for 2005. An underlying practical aim is to present facts, which stimulate the debate about the costs for building and which also stimulate firms and industries improvements. An underlying theoretical aim is to broaden the views about poor quality costs by taking the customers' view, and to stimulate further research within this area.

2. Poor Quality Costs

The theoretical framework for this study is the concept of poor quality costs. For many years the concept of quality costs was used and these quality costs were divided into prevention, appraisal, internal failure and external failure costs, first described by Feigenbaum [1]. Later the term poor quality costs (PQC) was introduced to highlight that it is poor quality that causes extra costs. The focus on the quality methodologies have changed over the years from an inspection orientation, through process control, to continuous improvement, and to designing quality into the product and process [2,3].

The concept of PQC has furthermore been broadened, because the concept of quality has itself acquired a broader customer perspective [4]. The customer is according to Sörqvist [4] viewed as anyone who is affected by the products and the business, e.g. shareholder, financier, state and local government, supplier, user, buyer, company management and employee. Sörqvist [4] uses this broader perspective by dividing poor quality costs into traditional PQC, hidden PQC, lost income, customers' costs and socio-economic costs. Taguchi has also a society perspective when defining non-quality as "the losses of society caused by the product after its delivery" [5].

When the view is broadened to an industry or society perspective, the concept of PQC will include additional activities, which directly or indirectly increase the costs for the customers. The systems used in industry and society may include activities, which can be considered as not adding any value for the customer. For improving the competitiveness it is necessary to develop the concept of PQC a step further and include costs for all other non-value adding activities as well [6]. Of that reason we define PQC as all costs related to poor quality that affect the customers, short-term as well as long-term. Cost is here defined as the value of resources used.

3. Method

We started from The Swedish central government budget 2005 (see Table 1). We looked at the 485 subsidies in the 27 expenditure areas and tried to find out how much could be classified as poor quality costs. For most subsidies that we have not been able to judge how much is PQC, we have assumed that the PQC is 7.5%. This decision is based on literature studies about PQC in various businesses and experience from on-going analysis of PQC in construction-related activities. When it comes to interest on central government debt (expenditure area 26) and contribution to the European Community (expenditure area 27) we have assumed that the PQC in these areas are in the same size as the average for all other expenditure areas.

We have not considered who has caused the costs. This implies that we have seen all costs, which are related to crime and justice as PQC. It also implies that we have seen most costs related to national defence as PQC as well as most costs included in the expenditure area “immigrants and refugees” as PQC.

The analysis is preliminary. It includes a number of assumptions. However, the aim with the paper is to stimulate the debate and make industry people aware that there are major poor quality costs hidden.

4. PQC in the Swedish Central Government Budget

The Swedish central government budget for 2005 is SEK 738.0 billion [7]. Our preliminary analysis indicates that the poor quality costs within the budget is SEK 213.4 billion or 28.9% of the budget. The major costs are related to three expenditure areas: financial security for the sick and disabled, SEK 68.1 billion, defence and contingency measures, SEK 37.9 billion, and justice SEK 22,9 billion, Table 1.

Table 1: Preliminary analysis of poor quality costs in the Swedish central government budget 2005 (SEK million).

	Expenditure area	Forecast	PQC
1	Governance	7840.222	635.071
2	Economy and financial administration	11432.140	1226.938
3	Taxes, customs and enforcements	8803.944	7043.155
4	Justice	27296.871	22868.473
5	International cooperation	1239.582	277.609
6	Defence and contingency measures	44146.606	37933.585
7	International development cooperation	22417.678	4402.850
8	Immigrants and refugees	6933.423	6693.635
9	Health and medical care, social service	39817.525	8335.284
10	Financial security for the sick and disabled	129691.062	68057.398
11	Financial security for the elderly	46413.203	3799.223
12	Financial security for families and children	56356.834	4422.805
13	Labour market	69313.416	12896.106
14	Working life	1193.970	337.555
15	Financial support for students	20995.726	1574.679
16	Education and academic research	43867.639	3290.073
17	Culture, media, religious communities, leisure activities	8956.525	720.656
18	Planning, housing provision, construction	9139.412	746.336
19	Regional development	3496.768	262.258
20	General environmental protection and nature conservation	3994.805	609.406
21	Energy	1396.435	104.733
22	Transport and communications	31666.492	2461.594
23	Agriculture, forestry, fisheries etc.	14655.991	1099.199
24	Industry and trade	3891.377	374.080
25	General grants to local government	57468.750	4310.156
26	Interest on central government debt, etc.	38770.000	11175.870
27	Contribution to the European Community	26802.000	7751.138
	Total, all expenditure areas	737998.396	213409.865

5. The Effect on Construction Projects

The taxes, which the government gets from construction and other industries, puts in the same bag and then distributes to a number of subsidies. This implies, theoretically, that if for example the number of accidents in construction will be reduced there will also be a slightly less tax burden.

The Swedish Property Federation and The Swedish Construction Federation have investigated how much the tax burden is on typical housing projects. Including all taxes and government-related charges The Swedish Property Federation [8] argues that the tax burden is approximately 58.8% of the cost to produce new houses, excluding cost of land. The Swedish Construction Federation [9] takes the analysis a step further and argues that the tax burden may be even higher. The tax burden varies to some extent between different types of products. If we include the cost of land, the tax burden will vary to a greater extent, since the cost of land is significantly higher in the major cities.

Our analysis is limited to the central government's budget while the total tax burden also includes local taxes for municipalities and county councils. Let us for a while assume that the volume of PQC is approximately of the same size within municipalities' and county councils' budgets as it is in the central government's budget. If this is true, the PQC hidden in the taxes corresponds to 17.0% of the cost to produce new houses!

6. Discussion and Conclusions

This paper considers a problem within quality management practices as well as within quality management research. Quality management is built on a customer-oriented philosophy. But when it comes to investigations on quality costs and poor quality costs the customers seem to be forgotten. Instead, the companies' own processes or cash flow is in focus. By taking a customer view in this kind of investigation, a number of hidden costs for poor quality are revealed.

Our analysis indicates that the PQC hidden in the taxes corresponds to 17% of the costs to produce new houses. This is far more than what is reported in most studies of quality costs or poor quality costs within construction. The main conclusion of our analysis is that further studies are needed to better understand the total picture of PQC within construction. Then single companies and single industries better can evaluate what costs related to poor quality can be reduced or not.

Note that this analysis is preliminary and includes a number of assumptions. However, we believe that a closer examination of the central governments' budget, the municipalities' budgets and the county councils' budgets, will end up in a similar size as we have presented here. Since the main aim with this paper is to stimulate the debate about the high costs for building and make practitioners and researchers aware of these hidden costs of poor quality, we believe that this preliminary analysis is relevant and valid.

We have also made an analysis of the central governments budget for 2004 using the same assumptions. Then we found that the PQC was SEK 211.9 billion or 28.7% of the total budget. It means that the PQC within the governments' budget has increased with 0.2% in one year. The main reason is that the budget for the expenditure area "Financial security for sick and disabled" has increased.

A Risk Breakdown Structure for Public Sector Construction Projects

Marie Dalton
Centre for Research in the Management of Projects, Manchester Business School,
The University of Manchester (email: m.dalton@postgrad.manchester.ac.uk)

Abstract

This research is part of a wider project (ProRIde) focusing on the risk identification stage of the risk management process. The specific remit of the study is to analyse the text of National Audit Office (NAO) reports to identify recurring risk sources on public sector construction projects. A textual analysis software, QSR N6, is used to code the data. The risk source information in organised and presented in a Risk Breakdown Structure (RBS), a hierarchical presentation of risk sources.

The output of this study represents a contribution to knowledge in that it is empirically derived – many risk identification support tools are compiled on an ad-hoc basis through brainstorming or personal experience. This research takes advantage of a rich existing database and employs a systematic methodology to develop an RBS that is specific to the context of public sector construction projects.

Keywords: Public sector procurement, construction, risk identification, risk breakdown structures, QSR N6

1. Introduction

1.1 Overview of the ProRIde project

ProRIde (**Pro**ject **R**isk **Ide**ntification) is an EPSRC-funded project (GR/R51452) concerned specifically with the risk identification phase of the risk management process (see Figure 1). Concurrent studies within the ProRIde project examine risk identification by individual project managers [1] and work is starting on group dynamics.

Comprehensive risk identification is central to the relevance and effectiveness of the subsequent risk management process [2] - unidentified risk sources remain as unknown and unmanaged threats to the project objectives.

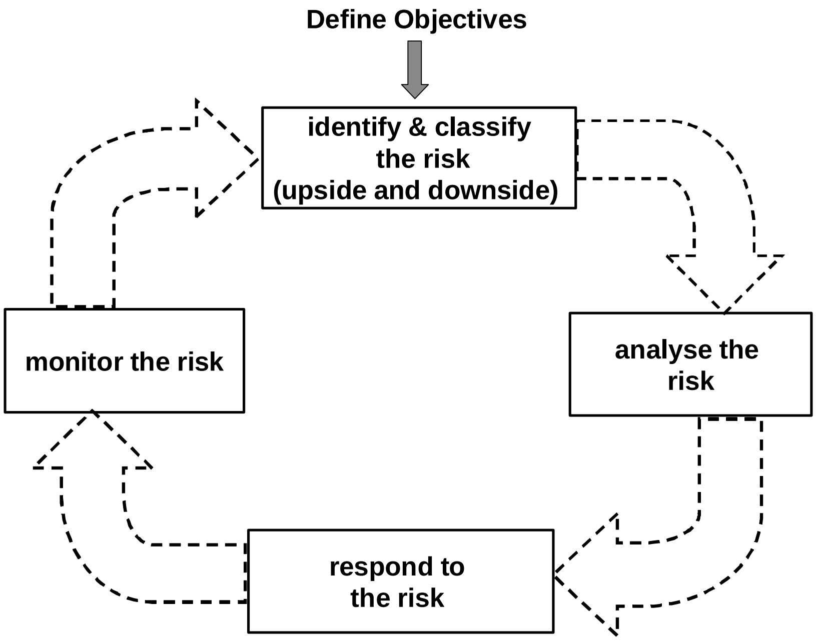

Figure 1: The ProRIde risk management process. After Winch 2002, p.322

Yet the identification stage is relatively neglected in risk management research [3]. There is much emphasis on the risk response stage of the process, with less attention paid to the initial identification and assessment sub-stages. Tah [4] observes that the risk identification stage is omitted from most risk management tools e.g. Monte Carlo simulation and sensitivity analysis, which only operationalise the assessment and analysis phases of the risk management model. Risk identification is assumed to be performed external to, and prior to, the implementation of most risk management techniques.

In the terms of the basic risk management model above, the aim of this study is to produce guidance for the identification phase based on a review of previous projects (the input arrow), leading to improved risk identification performance (the output arrow). High quality risk identification output provides a more accurate basis for subsequent stages of the risk management process.

The ProRIde scoping study [5] identified 'important common causes of concern' in the NAO reports on construction projects. The authors proposed the generation of:

'A feedback loop which offers all parties involved in the management of large, expensive, and complex projects the opportunity to improve efficiency and effectiveness'.

To create this feedback loop, this study takes the individual VFM reports to the next level of analysis. The text of the reports is combined in a knowledge base and reviewed for recurring themes. High-level lessons for risk identification specific to public sector construction projects can be drawn on the basis of multiple projects.

It is important to feed individual project learning in a wider framework so that we develop a systemic approach to risk identification. Ayas and Zenuik [6] note that despite the widespread and successful adaption of project-working, success is usually assessed in terms of a single project or organisation.

Using the past as a guide to future action has obvious limitations. No matter how many project reports are included in review, the final risk breakdown structure can never be considered comprehensive – unpredictable risks will always occur. But while we remain cognisant of this inherent uncertainty, it is important that we take advantage of the information that is available to us. This study takes a pragmatic perspective - reviews allow us to capture a certain amount of useful information and use it as a reference point to improve risk identification on future projects.

2. Risk Identification in the Public Sector

The high rate of failure on public sector projects in terms of time, cost and performance criteria suggests that a review of the Government's current risk management practice is due [7].

Risk identification for large-scale public sector projects is exceptional in terms of its scope and complexity. For example, in a multi-organisational context, as is the case for most government construction projects, it is important to identify systemic risks i.e. 'risk affecting a whole industry or service, as distinct from risks to the position of any individual organisation' [8]. The Office of Government Commerce (OGC) advise organisations to be aware of the risk management approaches adopted by their partners [9]. But NAO findings reveal that only 13% of departmental staff are aware of the risk management systems of other departments or their partner organisations in the private sector [10].

Government priorities also extend the range of risks to be identified. An obligation to secure public value and guarantee service provision means that risks posed by a wide range of external stakeholders and environmental conditions must be considered.

The potential for improving risk identification through project-based learning is limited by the movement of personnel on most public sector projects. Ideally staff would review project performance and record lessons learned centrally. But project personnel are often inaccessible after the event. Baldry [11] acknowledges that the usual method of accumulating past project experience and extrapolating to identify likely risks on future projects is not so straightforward on government projects. Concerted efforts are required to collate historical data due to 'the erosion of large directly employed, professional employee groupings within the public sector organisations' so that experience becomes 'distributed, transferred out or fragmented' (p.38).

2.1 Risk Identification Performance

A survey of risk management performance by the NAO [12] gives some indication of the Government's current proficiency in risk identification. The report highlighted the following areas of concern:

1. Responsibility for risk identification is generally allocated to board level – senior management are responsible for risk identification in three quarters of departments. Only 42% of departments report that other staff are responsible for identifying risks. A dedicated risk manager operates in only 13% of departments (p.57).

2. Departments report using a range of risk identification and risk assessment techniques, including a formal register for recording identified risks and self-assessment questionnaires for staff to record relevant risks. However, only 19% of departments are convinced of the effectiveness of these methods (p.62).

3. Fifty-six per cent of departments report that they identify the main risks relating to their key objectives. Focus group participants reported that 'objective setting and risk identification are treated as two separate processes and these are not routinely linked' (p.55). The NAO recommends that clarifying key objectives in terms of outputs and services facilitates the process of risk identification - departments can 'work back', identifying the risks that pertain to the achievement of these objectives.

4. The NAO warn against 'risk identification overload' – whereby every conceivable risk is recorded regardless of its potential probability or impact. NAO consultation with the private sector indicates that departments should focus on the top 10-15 key risks and opportunities – 'any more than this and management effort can become too diffuse across a large number of less strategically important risks' (p. 87).

5. The internal focus of most risk identification is evidenced by the three most frequently identified risks - financial risk (91%), project risk in terms of time, cost and specification (89%), and compliance risk in terms of failure to comply with regulations (85%). The NAO note the emphasis on departmental inputs and activity - there is less recognition of risk as a threat to outputs and services. The list also illustrates a relative neglect of the importance of external factors e.g. risks relating to external stakeholders.

This corresponds with the assessment of the Strategy Unit [13]. They note that the identification of financial and operational risk sources is relatively advanced on public sector projects. By comparison, the 'systematic assessment of policy risks is much less apparent' (p.46). This pattern of development is reflected in risk management generally – the area of audit / finance risk is most mature, followed by health and safety risk, operational and project risks and finally strategic risk. In relation to strategic level risk, the Strategy Unit states that 'systems still need to be developed that replicate the accountability and responsibility frameworks that exist for financial management' (p.46).

Despite the deficiencies in performance, a review of the available public sector guidance would suggest that Government is at the forefront of risk management – in theory. For example, the Strategy Unit describes the use of progressive risk identification techniques such as futures workshops and horizon scanning by government departments. Another example is the introduction of Risk Maturity Models to measure developments in risk management performance [14]. Also, considerable resources are allocated by Government to research and guidance documents for risk management. But the NAO results suggest that the practice of risk management lags behind the theory. The guidance is in place but it is not consistently implemented.

One reason for this may be a perceived gap between the available models and the conditions of the project in hand. Considerable work may be required to translate the generic guidance so that it is appropriate for individual projects. As such, an objective of this study is to produce a risk breakdown structure that is directly relevant and applicable to the circumstances and events of public sector construction projects.

3. The Current Study

3.1 Data – National Audit Office Value for Money Reports

The NAO is the external auditor for central government departments and all government agencies in the United Kingdom. The Comptroller and Auditor General has the power to report to Parliament at his / her own discretion on how government bodies have used public funds. The NAO presents approximately fifty Value For Money (VFM) reports on government procurement projects to Parliament each year.

The purpose of an NAO investigation and report is two-fold. Firstly, there is the traditional audit function - monitoring departmental spending. Secondly, the NAO has developed a more proactive function - that of adding value to government projects and thereby improving the quality of public service provision. The VFM reports combine both objectives – scrutinising performance against targets while also making recommendations for beneficial change on future projects.

The reports vary in scope, from examination of specific projects to comprehensive surveys of issues and practices across the whole of government procurement. They are primarily concerned with the performance of projects in relation to the time, cost and quality criteria. Reports generally conclude with recommendations for improved practice.

The series of VFM reports constitutes a valuable dataset that has been relatively unexploited to date. This research aims to take advantage of the detailed analysis and unique insights into the operation of complex projects that are available in the reports.

Reports that chart the entire project life cycle of a construction project are included in this study, a total of twenty-five project case histories. To assist the research effort, the NAO supplied electronic versions of all the earlier VFM reports that are not available online. A study of construction projects was perceived to be particularly worthwhile because although the NAO produce an annual report on the performance of major defence projects, there is no equivalent collation of information for construction projects. This is because no single Government department has responsibility for the construction procurement. As such there is no central structure or process for accumulating lessons learned and producing guidance for future construction projects.

Both conventionally procured projects and PFI projects have been included in the dataset. They have been treated similarly in the analysis on the basis that many of the risks to successful project management are generic, regardless of how the project is procured. However, it is anticipated that there will be some variety in the types of risk sources that pertain in each case. When the analysis is complete it will be possible to split the dataset according to procurements strategy to identify idiosyncratic risk sources.

3.2 Methodology – Textual Analysis

This is exploratory research. The aim is to produce a full account of the range and type of risk sources that occur on construction projects, rather than their frequency or impact. A qualitative research method is most appropriate to this objective.

QSR N6 is a textual analysis software, based on a code and retrieve facility. Units of text that are perceived to be connected are coded together into two different types of nodes (see the coding framework in Figure 2 below). **Free** nodes contain text units relating to independent, stand-alone issues. **Tree** nodes contain categories that are related in hierarchies. These nodes make up the coding framework for the project. The option to recode and rearrange hierarchies allows the researcher to change the coding framework as new risk sources emerge and merge. The retrieval function has several aspects. A text search retrieves text from the original document or from selected nodes based on keywords. Various 'Boolean', 'proximity' and other searches permit more complicated retrievals.

For the current research, the value of the software lies in the discipline that it affords the analytic activity of the researcher. In line with Lewins' [15] recommendation - 'it is important to know and to understand your methodological standpoint first, and then to bring a methodology to the software, rather than see the software as being the architect of your method' (p.303). In this study, the software is used as a tool to support a qualitative analysis, guided by an *a priori* organising framework – the risk breakdown structure.

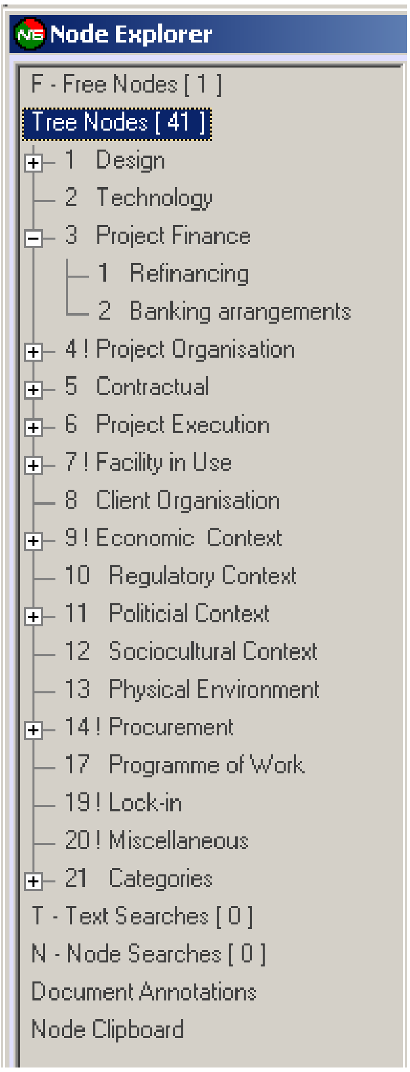

Figure 2: Coding framework in QSR N6

3.3 Organising Framework - Risk Breakdown Structures

An RBS is a framework for organising risk source data. Hillson [16] proposes the following definition:

'*A source-oriented grouping of risks that organises and defines the total risk exposure of the project or business. Each descending level represents an increasingly detailed definition of sources of risk*' (p.2).

Hillson offers a compelling account of the RBS as a means of presenting risk information to aid comprehension and guide the risk management process. It offers a more sophisticated presentation of risk information than the long lists that characterise checklists and risk registers. Checklists are one-dimensional – they do not offer insight into the structure of risk for the overall project. Neither does a list does not represent patterns of risk exposure or highlight areas that require special risk management attention.

An RBS was selected as a suitable organising framework for the current analysis. It provides a structure for the process of extracting and coding risk source information from the reports. An RBS also offers a practical solution for the management and presentation of the numerous risk source categories. An unwieldy list of risk sources can be re-organised and presented more efficiently within a hierarchical framework. There is the further advantage that the RBS and the QSR N6 coding framework share a hierarchical structure. This correspondence facilitates continuity between the data as it appears in the QSR N6 knowledge base and its summary presentation in the RBS format.

Having reviewed the literature, this researcher concluded that no existing RBS was directly relevant to the selected project reports. Therefore, it was decided to take advantage of all the risk breakdown structures generated to date by developing an synthetic RBS based on the range and frequency of existing RBS categories. The method allows the researcher to review, use and synthesise existing results in the research area. Thomas, Kalidindi et al. [17] used a similar technique, to develop an initial list of the primary risk sources on large infrastructure projects in India.

The risk source categories at the various levels of the available risk breakdown structures were collected in an Excel spreadsheet. Similar risk sources were grouped in the same column – this allocation was made when items were considered to describe similar risk areas even if they used different terminology. Some items were re-arranged and column titles were developed during a brainstorm session involving the researcher and supervisor. The resulting synthesis RBS was used as the basis of the coding framework in QSR N6.

3.4 Research Process – Iterative Cycles

A fundamental objective of this study is that the output should be empirically derived, in this case based on a rigorous analysis of the data in NAO reports. Many of the existing tools to support risk identification (checklists, registers and risk breakdown structures) do not have an empirical research basis, but tend to be the product of brainstorming or personal experience.

The research process proceeds in iterative cycles. Five reports are coded and reviewed in each cycle (see Figure 3).

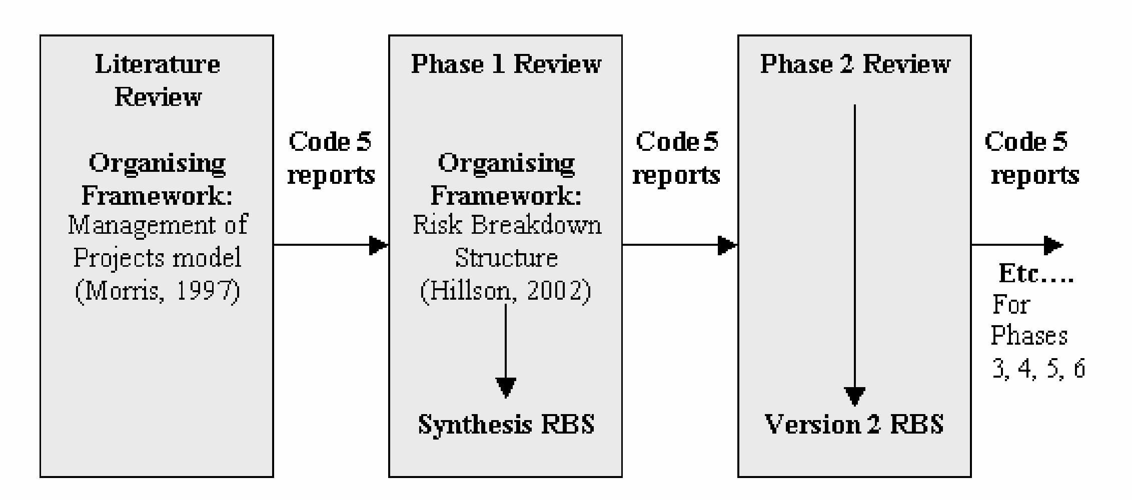

Figure 3. Model of cyclical research process

During the coding stage, the researcher goes through each report, text unit by text unit i.e. sentence by sentence. Text units that are considered to fit with existing nodes in the coding framework are coded into those nodes. Text units that do not fit into any of the existing node categories are temporarily stored in a 'miscellaneous' node.

During the review stage, emerging themes are identified, leading to either the sub-division of the existing node or the creation of new nodes. By this process the coding framework is amended and extended to accommodate those risk sources that are particular to public-sector construction projects. The developing RBS has been presented to NAO staff for feedback at regular intervals.

The cyclical review system also functions as an audit trail – developments in the risk breakdown structure and its underlying knowledge base in QSR N6 are recorded at each review stage.

The final version of the coding framework in QSR N6 equates to the output RBS.

4. Results to Date

4.1 Commentary on Version 5 RBS

To date, twenty NAO reports have been coded and reviewed. One more coding cycle (i.e. five more reports) is planned before the final version of the RBS is complete. This should be available for presentation at the conference in June. In the absence of final results, this section offers a commentary on the progress of the analysis to date.

The latest version of the RBS, Version 5, has developed significantly from the initial synthesis RBS. It contains 231 nodes compared to the fifteen nodes in the original RBS. The hierarchical structure now extends to six levels. In some cases, the nodes contain very few text units. These may be amalgamated with other nodes or removed altogether in the final analysis.

Alternatively, the new nodes may be supported by the next phase of coding, or through the further re-arrangement of text units in the final review phase.

It was anticipated at the outset that the developing RBS would become increasingly sector specific, that is, that the lower levels would refer to the construction context in detail. So far, this is not the case. In a feedback meeting [18], NAO employees agreed that the risk source categories of the Version 4 RBS were sufficiently generic to be applied to projects in most sectors. However, some of the novel risk source categories are specific to the public sector context, such as 'responsibility to the taxpayer' and 'civil estate'.

A cursory examination of the size of the hierarchies attached to the risk sources provides an early indication of risk-critical areas – the 'design', 'procurement', 'project organisation' and 'project finance' nodes are characterised by extensive hierarchies. By contrast, the 'external' risk sources are relatively clear-cut – the hierarchies for 'economic context', 'political context', 'regulatory context', 'socio-cultural context', 'physical environment' and 'programme context' do not extend beyond Level 3 of the RBS. This suggests that factors within the control of the project organisation pose the greatest risk to the completion of construction projects, although this pattern may also be a function of the focus of the NAO investigation. However, the result does correspond with research on the determinants of project success at NASA [19] in which the authors found that external factors, such as legal-political difficulties, are not necessarily 'fatal' obstacles to project success if they are mitigated through effective management of more controllable factors. But the internal factors are more significant - a poorly managed project is most unlikely to be successful. To a large extent the project's capability to deal with the external forces is determined by the quality and effectiveness of the organisational structure, the contract strategy and the financing arrangements, suggesting that it is not the external event that is decisive, but rather how it is managed.

4.2 Evaluation against Research Objectives

The research is on target to meet its objectives:

The analysis is providing a detailed breakdown of the risk sources that occur on large-scale infrastructure projects. Several of the risk sources represent a contribution to knowledge in that they are specific to a public sector context, and have not appeared in previous risk source taxonomies.

The RBS is empirically derived. A sound methodology of iterative cycles has been utilised so that coding is checked and re-checked in the light of emerging themes in the RBS. The method also creates an auditable trail of the evolving versions of the RBS.

The research has harnessed the rigour and discipline afforded by the data management functions of the textual analysis software.

The analysis is retaining the rich qualitative data. Data is stored at several levels of detail - the RBS is a summary of the text units stored in each node (the knowledge base). The original NAO data in each node is available by accessing the relevant node.

Feedback from staff at the NAO indicates that the final version RBS should have potential for further development as a practical risk identification tool. Indeed, it may be useful within the NAO as there is currently no generic risk register available to guide VFM investigations - the issues to be investigated by the NAO are chosen on a project-by-project basis. A comprehensive account of the risk sources encountered on previous projects would facilitate issue identification and provide a context for analysis.

Abstract

The construction stage is one of the major phases in the life cycle development process of a project. During this stage, it is essential for the project manager to understand and thus to determine the risk elements of the project prior to entering into a construction contract. As the determination of the contract period is crucial amongst other factors, contractors are sensitive to the time factor of a project during tendering. Time/cost trade-offs would be activated whenever the project duration is short. Unreasonably shortening of the contract period may render contractors to pass the risks back to the client through elevated tender prices or contractual claims. A fair allocation of risks can therefore balance the interests of all parties, which is essential for the successful accomplishment of a development project that helps foster a harmony relationship between the project team including the client, designers and other participants. All these ask for a good understanding by the project manager on the project nature, constraints and the complexity of a construction project.

There have been previous works studying the relationship between project durations, contract sums and floor areas, giving a generic understanding about the link between time, costs and volume of work for building projects. However, they do not address the complexity of a project in terms of site production constraints. In this study, apart from the general contract particulars, space-related factors affecting site production are also examined. This study attempts to analyse and identify the characteristics of building projects from the production perspective, aiming at enabling project managers to assess more accurately the project complexity, and thus the risk assessment and analysis for a construction contract.

Cluster analysis will be used to classify building projects into groups of various levels of complexity in a defined level of significance. The characteristics of each group will be reviewed and discussed. The interrelationship between the factors will also be examined. The findings of the study will give project managers some guidelines in assessing the risk factors of a project while the designers or the clients can appreciate the production constraints. A classification system for various levels of project complexity will be developed, with which, a better risk allocation can be made and a more realistic construction duration can be estimated

that help contractors to arrive at a reasonable tender and establish a more efficient production plan.

Keywords: Project characteristic, risk, complexity, cluster analysis

1. Introduction

The construction stage is one of the major phases in the project development process. In managing a development project, it is essential for a project manager to understand and thus to determine the risk elements of the project prior to preparation of the contract documents for a construction contract [1]. The determination of the contract period is crucial amongst other factors. Contractors are sensitive to the time factor of a project in tendering. Time/ cost trade-off would be activated whenever the project duration is shorter than the normal duration or when the project budget is exceeded [2]. Unreasonably shortening of the contract period may render contractors to pass the risks to the client through the tender sum or contractual claims. Lawyers tend to resolve the problems by revising and updating the conditions of contract [3 & 4]. A fair allocation of risks could balance the interests of the parties. This fosters a harmony relationship between the various project parties; namely, the client, designers and the construction team. This can only be achieved if the project manager has a very good understanding of the project nature and constraints.

Studies have been conducted to reveal the relationship between project duration, contract sum and construction floor areas [5]. This can give a generic understanding about building projects. However, it does not address the complexity of a project in terms of site production constraints. In this study, apart from the general contract information, factors affecting site production are included and examined. These include the design of building, forms of structure, building layout, site space and production facilities, etc. This research attempts to analyse and identify the characteristics of building projects at the production perspective. With such understanding, project managers could rate projects in terms of their complexity and are able to develop a fair risk allocation for the construction contract.

2. Appraising the Difficulties of a Project

"How difficult or complex is the project?" This could normally be the first question asked by a project manager or the senior management of a building contractor prior to the preparation of a tender or a production plan. Most construction projects have been commonly described as complex and unique that could not be defined in simplistic terms. This is certainly not a question that could be answered with just a glance at the contract documents especially during the tendering stage. In making decisions during tendering, construction planning, resource allocations and company strategies, detailed information would be prepared for scrutiny by the senior management. The critical information for a construction project will include the estimated contract sum, contract period, floor areas, building design, any special features and site conditions. However, such generic information may not be able to depict the complexity of a project and it would be worthwhile to analyse and integrate these information to develop an overall picture to reveal the project characteristics.

Facing with the time constraint in tendering and pre-contract planning, it is common for senior managers to make decisions largely based on two or three attributes of a project from a macro perspective. “Contract sum”, “construction period” and “construction floor areas” are the typical primary information to build up the decision tree. These attributes can depict the scale of a project and were thought to be good indicators for describing the complexity of the project. However, they cannot explain the difficulties or the constraints on production planning; for example, a small scale project classified in terms of the contract sum can give misleading results if the site is very confined without sufficient working space and good access. Supervisory staff at the production frontline always expresses their resentments about the oversimplification by the senior management in defining the project scope and inadequacy in resource allocation. The allegations are based on the fact that senior management may allocate the manpower and site facilities, including plant and equipment in a pro-rata scale based on the contract sum and construction floor areas.

There were some researchers studying the facility layout problems aiming at optimizing the site space at operational level [6, 7, 8 & 9]. Contrasting with them, this study aims at providing a better understanding in the classification of building projects, and thus to improve decision-making with respect to site production planning at the contract planning stage. Apart from the aforesaid attributes, seven factors will be identified, which can be extracted from the project data for analysis.

3. Factors Affecting the Complexity of Building Production

Information of 30 high-rise building projects have been collected to examine the validity and the robustness of the aforementioned three primary project attributes and another seven space-related attributes in describing the complexity of a project. These projects are widespread in size in terms of contract sum, site area and gross floor areas. Also, they consist of public housing projects, private residential projects, commercial building projects and composite developments. Table 1 shows a summary of descriptive statistics of the projects.

Table 1 Summary of Project Information

Variable	Cases	Mean	Std. Dev	Maximum	Minimum
Contract Sum	30	672.18	574.74	3000.00	41.00
Contract Period	30	26.17	4.91	37.00	18.00
Gross Floor Area	30	97106.13	73611.52	315990.63	5289.20
Site Area	30	12871.37	12523.97	67790.54	448.26
Podium area	30	5907.87	5515.91	26796.09	448.26
Tower block area	30	2794.21	2114.78	8253.34	179.29
Number of building	30	3.37	2.43	12.00	1.00
Working Space	30	6946.78	8456.72	40994.45	0.00
RWSPBA	30	2.32	1.92	8.40	0.00
RTWSPSIA	30	0.52	0.24	0.93	0.10

Where:

(i) Contract sum denotes the contract price or estimated construction budget (in millions of dollar)

(ii) Contract period denotes construction time for the construction of superstructure (in months)

(iii) Site area denotes the total site area falling within the site boundaries (in square meter).

(iv) Gross floor area denotes the total construction area (in square meter)

(v) Podium area denotes the total floor area of the podium of a building or buildings (in square meter)

(vi) Tower block area denotes the total areas occupied by the buildings above the podium floor (in square meter)

(vii) Number of building denotes the total number of buildings to be constructed

(viii) Working space denotes the site area not occupied by the permanent structures (in square meter)

(ix) RWSPBA denotes the ratio of working space to the tower block area (in square meter)

(x) RTWSPSIA denotes the ratio of working space to the site area (in square meter)

Variables in relation to site space, which are critical production constraints, are introduced in the analysis. In building production planning, the site layout plan represents the production line set-up of a factory. In formulating the site layout plan, it is necessary to balance the space requirements for different site activities. However, if space is more than adequate to meet the demand of the production process, there is no need for the trade-off exercise and it becomes largely a space allocation problem [10]. For example, if heavy building materials or components can be stored within a large storage space with good access for delivery and unloading which can be reached by a tower crane, production planning is a simple exercise to minimize the hoisting time for transferring the materials from the storage position to the work place. However, a site with irregular configuration and insufficient space, it is necessary to trade-off the storage areas for different materials or components, the schedule for the installation processes, the storage areas and the access roads. The inclusion of the space related variables gives a more accurate assessment on the complexity of projects in the context of production management.

As shown in Table 1, the seven space-related variables describe the areas to be constructed and space availability for a project. In addition to the gross construction floor area, the floor area of a tower block and the area of the podium supporting the tower blocks are included. In some extreme cases, the podium area could occupy 90% of the site area. However, the building structures sitting on top may occupy just 40% of the site area. In order to reflect the relationships between these variables, two ratios, namely the RWSPA and RTWSPSIA, are derived to assess the adequacy of site space.

4. Classification of Building Projects

It is often difficult to define the nature and complexity of a project and construction management people always use the following terms to differentiate the characteristics of a project: large, small, medium, simple, difficult, complex, complicated, highly integrated, confined, unique, etc. The use of these semantic terms can give some inference to the basic constraints of a building project; namely time, cost, quality and space, and is simple and easily understood by readers. The disadvantage is that it could be misleading to depict the complexity of a project.

In order to derive an objective classification system for projects, cluster analysis techniques, which have been widely used in areas of marketing, biology and medicine are adopted in this study [11]. To start, building projects are reviewed, classified and verified by using SPSS Hierarchical Cluster Analysis (HCA), K-Means Cluster Analysis (KCA) and Discriminant Analysis (DA). The projects are firstly classified by using the HCA and then verified by KCA and DA. The use of DA can establish classification function coefficients for classifying future projects. Further, the study attempts to compare the classification generated by using the three primary variables and subsequently by all the ten variables.

The objective is to classify the projects into groups with distinguishable characteristics. The analyses aim at dividing the project samples into five groups using the concepts of natural classification without limiting the number of group membership. This would facilitate the project mangers to describe the project definition [12].

4.1 Initial Appraisal for Building Projects

The first attempt is to compare the classification derived by using general project information, namely contract sum, contract period and gross construction floor areas. Table 2 shows the membership of the projects classified by using the general project information. Tables 3 and 4 show the characteristics of the groups in terms of minimum and maximum values of variables for the groups.

4.2 Classification by Contract Sum

In the groups classified by contract sum, the resultant groups are ranked in ascending order. Apart from Group 1, the subsequent four groups have a similar range with the group boundaries between 137 million and 183 million. Although the classification would be affected by the data in the analysis, it is reasonable to observe that the classification is similar to the conventional semantic description for a project in terms of large, medium and small.

4.3 Classification by using Three Basic Project Variables

In the classification using the three basic project variables, the groups overlap in the ranges of contract sum. It becomes inappropriate to describe the projects by using the conventional semantic terms. The characteristics of the groups are governed by the interactions between the variables which can be explained by the group characteristics and the classification function coefficients shown in Tables 4 and 5 respectively. The following characteristics are observed:

1. Groups 1 and 2 – These two groups have similar characteristics with negative coefficients for contract sum and gross floor area. It means that the contract sum is less significant to describe the project. On the other hand, the contract duration is the dominant factor and covers a broad range of 18 to 34 months. From the observations, it may reasonable to state that projects of small to medium size in terms of contract sum have significant difference in project duration, which is relatively longer than projects of other groups. It may infer that the time factor for these projects is not critical.

5	1756	1756	37	37	217,501	217,501

Table 5 Classification of projects by contract sum, construction duration and gross floor area - Classification Function Coefficients

	Group				
	1	2	3	4	5
CONTSUM	-0.0061	-0.0048	0.0098	0.0032	0.0356
CONTPERD	4.8732	6.8313	4.8786	6.7053	7.1917
GFA	-0.00000407	-0.00002373	0.00002566	0.00002750	0.00001834
(Constant)	-54.9755	-106.9848	-65.6303	-111.9356	-167.9171

2. Group 3 - The contract duration is still the dominant factor whereas the coefficient for contract sum is positive and thus has more influence on the classification. The range for project duration covers a relatively narrow range between 22 and 26 months. Further, the gross floor area has a positive influence on the classification and covers a broad range of 58,436 to 235,115 square meters. It may be reasonable to state that the projects of this group which are conventionally described as medium to large size generally having a relatively tight project duration and with a high variation in the work contents in terms of gross floor areas.

3. Group 4 - the contract duration has imposed further influence on the classification and the contract sum and gross floor area have similar influence on the classification as in Group 3. It is observed that the range of contract sum of 500 to 1179 million for this group is similar to the range of 577 to 1070 for Group 3. However, the project duration for these projects has a relatively longer duration between 30 to 36 months.

4. Group 5 - There is only one project which is the same as that in the classification by contract sum. This project is unique amongst other projects in terms of contract sum, contract duration and gross floor area. The project can be described as mega size and thus needs to be considered separately.

The project classification generated by the basic project information provides further understanding about the nature of the project and could enable project managers to identify the dominant factors of a project especially on the time factor. On the other hand the classification reveals that there may be imbalance for project duration as it appears that projects in Group 3 have a relatively tight project schedule. This would be a good reference for clients or the design teams for determining reasonable project durations.

4.4 Classification by Using Basic Project Information and Space Related Variables

With the inclusion of seven space related variables, the governing factors for the classification becomes complex and is significantly different from the previous classifications. The characteristics of the groups and the coefficients of the variables to the cluster centre are shown in Tables 6 and Table 7 respectively. The characteristics for the groups are discussed below.

1. Group 1 – Site area and the site space are the dominant variables in this group. In view of site planning, these projects have sufficient space for site layout planning as the ratio of working space to building area, between 2.21 and 5.54, is the highest among the other groups. The negative coefficient for project duration implies that time may not be critical in this group. The scale of the projects in terms of contract sum is between medium to large size. With sufficient working space and reasonable project duration, it may conclude that there will be less constraints, more flexibility on site layout planning and project scheduling.

2. Group 2 – Contract duration, gross floor area and the ratio for total working space and site area are the dominant variables in this group. The range for contract duration is between 24 and 36 months and gross floor area is between 101,838 and 146,068 square meters. Although the work contents for the project is high as reflected also in the contract sum, there are relatively less working space, between 1.76 and 3.38, in this group when compared with Group 1. The significance is shown by the high coefficient assigned to the space ratio. Projects in this group would therefore have a reasonable project schedule but with moderate difficulties in site planning.

3. Group 3 – Space related variables have large coefficients and become significant in this group whereas the contract duration has a large negative coefficient. Comparatively, both the scale and the contract duration are moderate in this group. But, the working space available is high for the projects as reflected in the ratio of working space to total floor area, from 1.68 to 5.11. With the sufficiency in working space, production planning for the projects would not be too difficult.

4. Group 4 – This group, which has the highest number of members, consists of 14 projects. Except for the contract duration, all the variables are assigned with negative coefficients. The contract duration varies between 22 and 34 months. This may be due to the broad range of contract sums, from 41 to 870 millions. The projects can be described as small to medium size. However, the total site areas for the projects in this group are small when compared with other projects and thus, the working space to

building area ratio is low. Therefore, these sites can be classified as confined site and there will have more constraints on site layout planning and production planning.

5. Group 5 – There are two members in this group. They are high-rise buildings with tower blocks sitting on a large podium area. They are large projects with high contract sum, long contract duration, and high work contents (gross floor areas). However, there is limited working space as reflected in the working space ratio (0.5 to 0.54). The sites are therefore highly confined with small working space for production planning. Project scheduling and site layout planning for these projects should be well co-ordinated so as to optimize the use of site space for supporting work schedule. Multi-stage site layout planning is expected in such site conditions.

The project classifications generated by the basic project information and space related variables provide different views on characteristics of the project and give more information about the relationship between the contract size, work contents and work space. Although the order of the grouping may not be able to determine accurately the complexity and difficulty of the projects, the classification is able to alert planners about the potential constraints on production planning in relation to project scale or project duration. The characteristics and the degree of complexity of the projects are summarised in Table 8. The indications on production complexity also enable contractors to improve risk assessment for construction projects.

5. Conclusion and Recommendations

In this study, apart from the general project information, factors affecting site production are also examined in the evaluation of project complexity and nature. This study attempts to analyse and identify the characteristics of building projects from the production perspective, aiming at enabling project managers to assess more accurately the project complexity and the project risks. With a good risk planning and risk allocation, this would mitigate contractual disputes [13].

The classifications generated in this study have successfully grouped the projects in terms of basic project information and space related variables. This study provides a new approach in analysing the interactions between the ten critical project variables. It is observed that the memberships for grouping are significantly different. The classification by using the three basic project informations reveals that there may be imbalance for project duration with respect to the contract sum. With the inclusion of the seven space related, there are significant changes in the memberships for the project groups. The resultant groups are more able to address the complexity of a project. The ranking of the project groups is able to indicate the degree of project complexity. Practitioners may apply a heuristic approach in classifying projects in similar ways. But, it may be difficult to rank the complexity accurately and consistently. This study provides a systematic approach to determine the complexity of projects with reference to the interactions between the ten project variables. The information would alert and be useful for planners to assess the risk and complexity of projects. Specific attentions would therefore be given for projects with confined site space, tight schedule and high work contents.

Apart from the variables selected, there are other project variables which could be used to assess the complexity of a project. It is suggested to explore these variables in order to build up robust models to improve the classification and to determine the risk level of a project. The findings described in this paper provide a stepping stone for future in-depth studies on project risk and contract planning.

Risk Management in Small Sized Construction Projects

Kajsa Berggren
LTU – Luleå University of Technology, Sweden (email: kajsa.berggren@ltu.se)

Abstract

Risks and other uncertainties can cause losses, which lead to increasing costs and time delays, both during the project and at the end. The need to prevent failures during the construction process and other losses related to construction has been emphasised in various reports. Example consequences are failure costs in civil works which can be close to 8% of the total budget for projects – more than 60% of these are costs due to 'self-inflicted' uncertainty. However, this paper is focused on small sized construction projects (in the range 1-15 MSEK), which are dominant in the Swedish construction sector today. They account for 83% of the total number of projects.

The aim of this paper is to describe how risks and uncertainties are managed in small sized construction projects. Some characteristics of these projects are presented, for example their organisation, financial size and type of contract undertaken. The paper identifies and describes the ways in which risk analyses are performed on a number of small projects today and where the common risks are believed to lie. The study is based on interviews with personnel selected from a number of construction companies. In order to be able to make improvements in the construction sector, a clear focus on uncertainties, which means both opportunities as well as risks, is needed. Organisations working mainly on small projects, that wish to improve their performance, need systematic methods for managing risks.

Small sized construction projects are found to be managed both intuitively, i.e. based on experience and systematically, i.e. using methodologies for risk and uncertainty management. The systems are, however, developed with the intention of fitting all sizes of projects and not specifically small sized projects. Some common risk sources in these projects are contract documentation and tight schedules, the client, individual planning and logistics, cost estimates used to compile the tender, subcontractors, technical solutions, safety of third parties and weather.

Keywords: Risk, uncertainty, risk management, uncertainty management, small projects

1. Introduction

1.1 Background

Risks and other uncertainties can cause losses, which lead to increased costs and time delays, during the currency of projects and at their end. The need to prevent failures in the construction process and other losses relating to projects has been highlighted many times over the years and figures strongly in a recent major report in Sweden [1].

The most common project size in the Swedish construction sector is less than 15 MSEK (roughly €1.65m). In the study reported in this paper, projects in the range 1-15 MSEK have been chosen, whilst those in the range of 0-1 MSEK have been excluded. According to Sveriges Byggindustrier [2], as much as 83% by number of projects are in the range of 1-15 MSEK. The reason for choosing this particular segment is that the smallest projects, the ones between 0-1 MSEK, are less interesting from a project risk management perspective. Their nature is inherently more like continuous business than project-based.

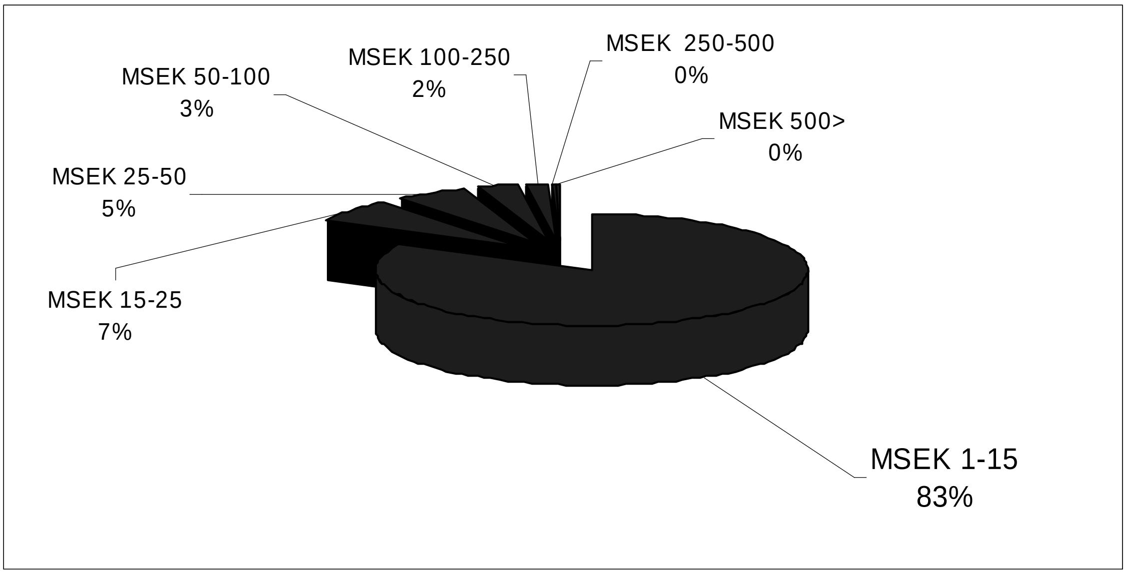

Figure 1. Number of projects divided into segments in relation to their size in the Swedish construction sector 2004.

Risk management and other types of applied management have been used routinely in construction projects, but have often been exclusive to large and exposed projects. Studies tend to cover large-scale projects, often with many different participants [3], [4] and [5]. The risks cover a spectrum of events from financial, political and legal to technical, often relating to complex construction.

In one study [6], failure costs for civil works were identified as being close to 8% of the total budget for projects and more than 60% of those costs were due to 'self-inflicted' uncertainty. The study also focused on large projects and clients' perspectives. 'Self-inflicted' uncertainty is due to ignorance of earlier experience of failures that continue to appear in similar projects in the future.

In small sized projects, the risks are more moderate and the consequences are less dramatic. These projects are more vulnerable to changes of the kind that have an impact on time since there is less chance of catching up if the schedule slips. On the other hand, the nature of the construction work and the project environments are often rather straightforward and the technical challenge is limited. This picture of the situation for small sized construction projects is based on the author's own observations and that of the study's reference group.

1.2 Aim and Objectives

The aim of this paper is to describe how risks and uncertainties are managed in small sized construction projects. Three specific objectives have been set as follows.

- Present the characteristics of small sized construction projects.
- Describe the ways in which the risk analyses are performed today.
- Define common risks that occur in small sized construction projects.

In order to reach these objectives, interviews have been conducted to collect data.

This paper presents the results of a pre-study forming a part of a research project which is investigating uncertainties in small sized construction projects. The research question to be answered in the pilot study is 'how to find out how risks and uncertainties are managed in small sized construction projects today'. Further research questions to be addressed in the research project are related to the relationship between theories, companies' policies and practical work, and also to the identification of obstacles and ambitions/incentives for uncertainty management in small sized construction projects.

1.3 Definitions

1.3.1 Small Sized Construction Projects

Searches of the literature did not provide conclusive evidence of what exactly characterises a small sized construction project, neither did discussions with different actors in the sector. The characteristics of a small sized project were subsequently discussed and agreed within the study's reference group. The result is sufficient description to distinguish these projects from very small projects, which are more in the nature of continuous business operations and, at the other end of the scale, from large projects.

The characteristics agreed upon of small sized projects for the purpose of this study are:

- contract value between 1-15 MSEK
- a site manager responsible for a maximum of two projects simultaneously
- limited construction time, maximum 12 months
- established technique, no development work
- project environment is independent
- personnel involved are more generalist than specialist

1.3.2 Risk and Uncertainty

In order to be able to discuss risks and uncertainties there needs to be some sort of definition of these concepts within the study. Uncertainty is part of everyday life, since we are not able to predict the future accurately. The amount of uncertainty and the ways in which we can handle this uncertainty could, however, be defined and structured.

According to Aven [7] uncertainty could be either aleatory or epistemic. An aleatory uncertainty is of a random nature and is hard to predict. An epistemic uncertainty is “lack of knowledge about fundamental phenomena”, which refers, for example, to the use of models and assumptions. In this study, uncertainty refers to both aleatory and epistemic uncertainty using Aven’s terminology.

Chapman and Ward [8] state that there is a need for a clearer focus on the upside effects, i.e. the opportunities. They also think that is desirable to let go of the historically close connection to events, conditions and sets of circumstances and instead shift attention to the different sources of uncertainty that could lead to threats of failure or, equally, opportunities. Their opinion is that it is vital to understand where and why uncertainty is important in a given project context and not to focus solely on threats and opportunities connected to given events, conditions or circumstances. Chapman and Ward [8] continue their line of argument with the suggestion that “uncertainty management” should replace traditional “risk management” to indicate that a wider perspective is being sought. This study starts with the aims of Chapman and Ward in order to widen the concept of risk management and use the concept of uncertainty management in its place.

The definitions of risk and uncertainty found in the literature are not consistent. There are several different definitions and approaches from different areas of research. According to the Project Management Institute [8] a definition of risk should take into account both positive and negative effects on a project objective. This is a broad view in terms of threats and opportunities and how they are connected to an event, a condition or a specific circumstance. Even if the risk according to [9] includes upside effects, the tradition is to focus on the downside, i.e. the negative effects. Project risk is defined as the “combination of the probability of an event and its consequences for project objectives” [10]. This definition is well known in the construction sector and elsewhere and is, by tradition, closely associated with a threat. Conversely, opportunity is neglected despite the enlightened definition found in [9].

It is necessary that each study defines its own approach and view of risk and uncertainty. In this study, the term uncertainty is used to point out the possibilities for both types: “risks”, with the negative effects; and “opportunities”, with positive effects. The definition of risk used here focuses on the negative outcome of an uncertainty and is seen as more dramatic than uncertainty.

Uncertainties are handled everyday on a construction project, but not all are of the type that needs special attention. In this study, uncertainty is defined as something that occurs and which was neither foreseen in the project description nor in the contract, being often caused by lack of knowledge on the part of one or more of the parties. The uncertainty could be an event that occurs during the project. It could also be something that is known from the beginning that makes the project unique, i.e., that makes it different from the standard procedure. Those uncertainties could lead either to risks or opportunities and need to be taken into account.

1.4 Research Limitations

Risks appear at different levels and likewise have different consequences for their surroundings. Depending on the approach taken, different risks will be found. In this study, risks in construction projects are examined, from the contractor’s perspective. Risks that appear at other levels are not considered, although they could affect the project’s objectives (figure 2).

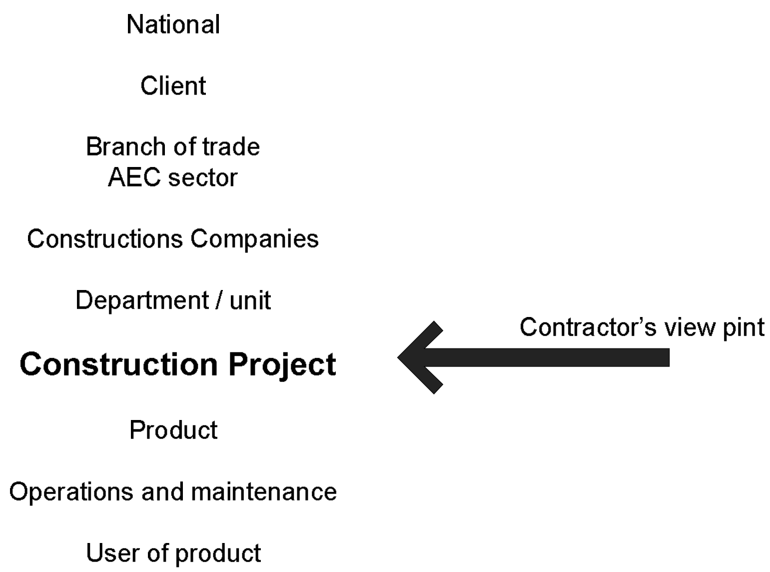

Figure 2. Selected approach for this project.

In the context of a construction project some further limitations regarding uncertainties and risks are considered in the study. Risk sources which are outside the framework of the study are, for example, political decisions, the financial situation of the client as well as the contractor, changes in organisation and illness among personnel involved in the project. These risks could have both positive as well as negative effects on the project's objectives, but are often out of the control of the site manager. For that reason, they will be left outside this study. Risk sources that are to be considered in this study are the project's economic boundaries, relationships with the client, technical solutions, aspects of production and weather. These risks are either within the control of the site manager or affect the project directly without interference from other levels of the company's organisation, for example, weather. Between these defined areas, risk sources from geotechnical engineering and the work environment will be found. These two areas represent many of the risks in the construction sector and have been studied separately earlier in other studies [3]. For this reason, they will not receive any special attention in this study.

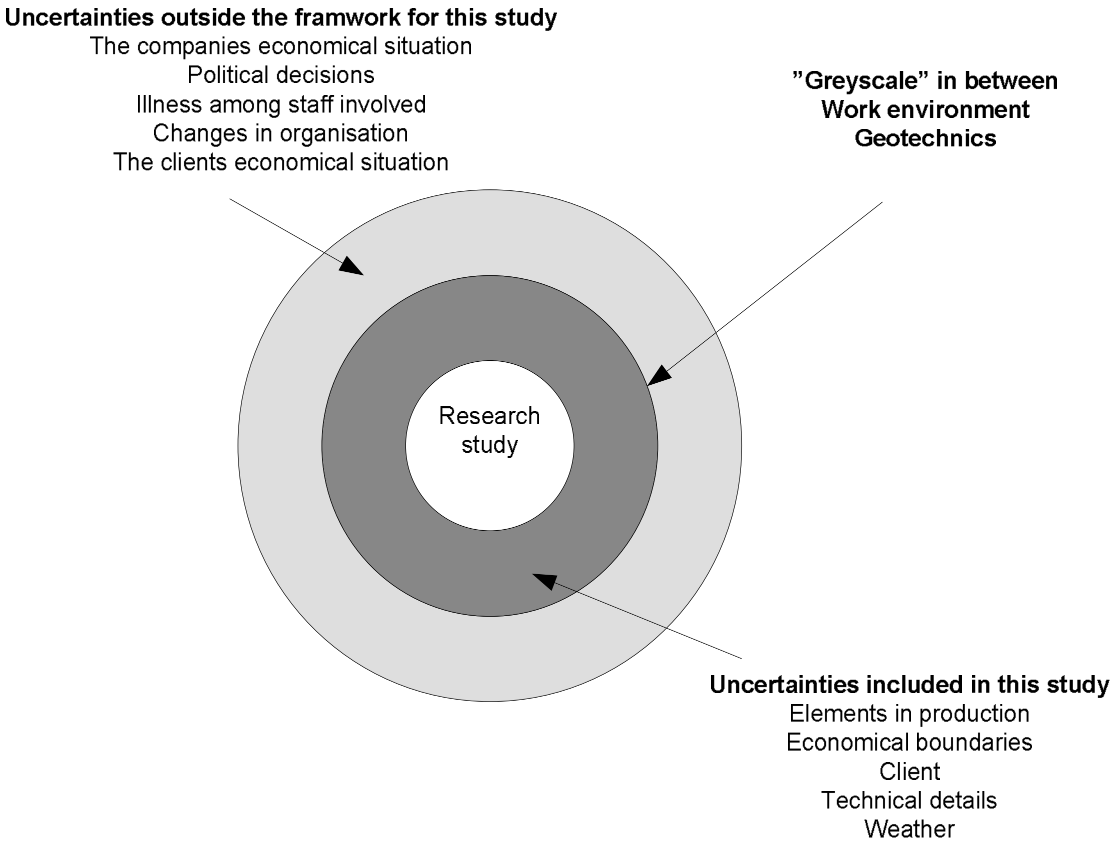

Figure 3. Risks and uncertainties in relation to the project.

2. Risk Management Today

2.1 Collection of Data

2.1.1 Method for Data Collection

The principal method used to collect data is interviews with managers of different projects from different companies. The strategy used for selecting projects is that the project must be either in a state of production or “fresh in memory”. Projects that have just started have not been selected because of the risk of the researcher affecting how risks are managed if the project is in the planning phase. There could be, as well, uncertainties in the answers if the projects were finished and the site manager had moved on to another project. Projects should also be selected according to criteria in the definition of small sized projects, not by who happens to be the site manager. Interviews with managers of projects from different construction companies have been adopted to provide a flavour of the wider construction sector.

In order to be able to see patterns in data from the interviews, the information has been sorted into different categories. Projects have been sorted by type: buildings, new production and renovation, and ground works. There is also some categorisation relating to the geographical situation, i.e. a medium sized community such as Luleå and a large city such as Stockholm, and the age of the site managers.

2.1.2 Interviews

Ten interviews have been undertaken with personnel from five different construction companies in Luleå and Stockholm, Sweden. The interviews were conducted in a semi-structured manner with a number of questions prepared in advance. The interviewees were free to speak about risks and opportunities in their projects and the researcher asked questions and gave some guidance to ensure that the prepared questions were covered. The interviews were conducted in a positive atmosphere and the interviewees have expressed an interest in seeing the final results of the study.

2.2 Findings

The findings from the interviews give a picture of what site managers in a few small sized construction projects think about risk management. They have shared both how they work with uncertainties, risks and opportunities and also indicated what they regard as the most common risks from their perspective. They have also given their view on what is defined as risk and uncertainty.

2.2.1 Perspectives on Risk Management

According to the site managers, risk is something that can have negative consequences for the project and is more dramatic than uncertainty. Conversely, uncertainty is regarded as something that can have positive as well as negative effects.

According to the site managers of the projects investigated, there exists a systematic framework for how risks and uncertainties are managed. There are manuals, routines and patterns to be used, not specifically for small sized construction projects, but specific to the actual type of project. For example, there are manuals for risk identification in ground works, general construction and buildings.

Managers of these small sized projects use the manuals and patterns to a certain extent, with some differences in application amongst them. They apply what they think is useful and leave the rest of the documentation alone. It is notable that there is a difference between the interviewees with respect to their age and experience. The older and more experienced managers tend to document less than others. This means that there are some who actually follow a systematic approach and others who work on intuition based on experience. Common for several of the managers is that they think continuous planning is the best way to manage uncertainties. "Risk analysis is quite good, but it is good planning and logistics that offer the best possibility for minimising uncertainties" (Andreas Rydberg, site manager NCC). In terms of planning, they are able to identify new uncertainties and to take precautions with respect to risks identified in the risk analysis. Risk analysis is performed for the tender and is part of the information the site manager gets before he takes on the project. The site managers refer to this risk analysis as a "living document" that should follow the project throughout the construction process. However, there are differences in how this is actually performed.

Risk analysis and "risk thinking" is not dependent on project size according the site managers interviewed. The approach to risk thinking is more dependent on the type of project than on the contract size of the project. It is the consequences of the risk that decides if the risk is qualified in the risk analysis and, in the first instance, the consequences for health and safety (Patrik Lamberg, Skanska). There are neither differences in available documentation nor in the extent of information in the documentation between large and small sized projects. This means that in very small projects the managers think that more time would be consumed to do documentation for the sake of the system than is actually required for production. The consequence of this is that the managers skip part of the documentation, if not most of it. There is also a time related aspect of these small sized projects expressed by this site manager: "In small projects it is vital that the personnel involved start off immediately since the time available is limited" (Leif Eklund, NCC). There are more possibilities to save a large project if a risk should appear, but the consequences of that risk if not saved might be large. The consequences of that same risk in the small project would be less, but might not be as easy to save due to tight schedule.

2.2.2 Identified Risks

In the small sized projects there are some risks that are more common than others. The relation to the client is one; lack of information in documents provided by the client is another. Yet another risk or actual uncertainty is the tender that establishes the boundary of the project. It is not possible to receive more money than the tender (i.e. contract) sum. The interviewees also think that there is a considerable difference in approach to risks and opportunities depending on what kind of contract is used. General contracts are considered safer in all respects. All aspects should be included and if something is missing it is the client's responsibility to solve the problem, not the contractor's responsibility.

For ground works projects the managers feel that there are a few risks. Small projects are rather straightforward, with known technology and known conditions in the project environment. The risks that appear are the same ones from time-to-time and there is limited uncertainty that crops up along the way.

In renovation projects, more uncertainties appear during production. The activities and technical solutions often need to be adjusted at the site level due to lack of information in the tender about the existing building. There are seldom standard solutions and whether something is a risk or an opportunity is much dependent upon the attitude of the client. Since there is a lot of uncertainty when doing renovation work it is hard to achieve a complete and reliable cost estimate for the tender. The tender (and, hence, the contract sum) does, however, define the financial boundaries for reaching the objectives of the project. This is also to be considered as an uncertainty.

One considerable uncertainty in new building projects is a tight schedule. Physical factors such as drying time for concrete are sometimes neglected, with the consequence that projects can end up with damp concrete. The risk of built-in faults could cause higher costs for both the contractor and client if not handled properly. Building projects also often include subcontractors and this involves uncertainties in relationships as well as in their attitudes to risk and uncertainty management.

Common risks for the small sized projects in this study are, without any ranking:

- contract documentation and tight schedules
- the client
- individual planning and logistics
- cost estimates in the tender
- subcontractors
- technical solutions
- safety for third parties
- weather

3. Conclusions and Further Research

The definition and characteristics for small sized projects are:

- contract value between 1-15 MSEK
- a site manager responsible for a maximum two projects simultaneously
- limited construction time, maximum 12 months
- established technique, no development work
- project environment is independent
- personnel involved are more generalist than specialist

Results from interviews show that there are common factors for small sized projects. These projects are managed both on intuition based on experience and systems for risk and uncertainty management. The systems are, however, developed with the intention of fitting all sizes of projects and are not specific to small sized projects. This leads to differences in the ways of applying risk management and is much dependent upon who is doing the risk analysis more than what the management system might advise. Site managers are also dependent on their own planning rather than having support from other personnel in the organisation.

Results from this pre-study have helped to sharpen the questions to be addressed in the next stage. The aim is also to give a picture of where risk management in small sized construction projects stands today. Knowledge about this situation makes it possible to continue with the remaining research questions:

- What are the differences between theories, companies guiding principles and the practical work in order to conduct uncertainty analyses?

- Why does uncertainty management work satisfactorily in some projects and not in others? What are the obstacles and ambitions of uncertainty management?

The plan for future work is to perform case studies during late 2005. In those case studies, further empirical results will be collected in order to arrive at an understanding for the performance of uncertainty management in small sized construction projects. The result of this future work will be a licentiate thesis to be finished by late 2006.

Acknowledgements

The author would like to thank the people involved in the research project's reference group for inputs and discussions in the research area. They have been of great help in the task of finding definitions and defining research boundaries. The reference group consists of people from different companies representing clients, contractors and consultants with practical as well as research experience. They have all reached advanced positions in their field and it is a major benefit for this study to have access to their experience and knowledge.

Thanks are also due to Valter Hultén of Sveriges Byggindustrier for his help with statistics on number of projects.

Using a Construction Process for the Risk Identification

Anita Ceric
University of Zagreb, Croatia (email: anita@grad.hr)
Peter Brandon
University of Salford, UK (email: P.S.Brandon@salford.ac.uk)

Abstract

Every construction project can be divided into discrete phases each of which has its purpose, duration and scope of work. Risk management is a continuous process and should span to all phases through the project. A realisation of construction project is a process. A process is a group of activities undertaken with the goal of successful project realisation, and these activities are potential risk sources that may lead to an unsuccessful project. Risk management should be subordinated to the construction process.

This paper shows a new approach to risk identification in construction projects: process - driven risk identification. The Process Protocol developed at Salford University was chosen to show how construction process can be used for the identification of key risks. The Process Protocol is a plan of works and divides the construction process in ten phases from the Demonstrating the Need to Operation and Maintenance.

Keywords: Construction process, risk management, risk identification, Process Protocol

1. Introduction

Every construction project passes through phases, each of which has a purpose, duration and scope of work. Breaking the project down into phases is an important part of every construction process. The project must start from some kind of definition of need, after which follow design, contracting, construction and project completion [1]. Risk and uncertainty are inherent in all the phases through which the construction project passes, from Demonstrating the Need do Operation and Maintenance. Risks do not appear only in major projects. Although size may be a cause of risk, complexity, construction speed, site and many other factors that affect time, cost and quality to a greater or lesser degree cannot be overlooked. All the participants in the deciding process should observe risks and their effects on all key points of decision-making before and during project realisation.

Process in construction needs important changes and should be continuously improved. The process itself, and the changes and improvements made to it, are accompanied by risks whose adverse effects may increase planned costs and the time necessary for project completion, and decrease execution quality. Efficient and quality management of risks should make these changes in the construction industry possible and enhance quality and efficiency. Changes may be brought to the construction industry through improved risk management. One possibility is to study the causes of risks. In this case it is possible to muster the help of experts in that field, to identify the risks in all the phases of the project life cycle in great detail, to use a large database compiled from prior experiences on similar facilities, and to propose the most adequate risk response. This approach to improved risk management is partial solution with limited applicability.

A new aproach described in this paper starts from the fact that executing a construction project is a process and risk management should be adapted to this process. Risk management is a continuous process needing an integral risk management system in all the phases that the construction project passes through. It is necessary to identify the key risks that appear in all the phases through which the construction project passes, regardless of the type and size of the facility [2].

Risk management always starts with risk identification, which may be considered the most important phase of the risk management process [3]. Its purpose is to compile a list of risks important for a particular project. To form this list, it is first necessary to research the potential sources of risk, adverse events that include risk, and the unfavourable effects of an undesirable scenario. Risk identification greatly depends on the manager’s experience. If his/her experience with particular methods and techniques of risk identification is good he/she will continue to use them, whereas bad experience leads to avoiding approaches prepared earlier.

2. Process in Construction

A process is a series of activities (tasks, steps, events, operations) that takes an input, adds value to it, and produces an output (product, service, or information) for a customer. Customers are all those who receive that process output [4]. Construction developed as an industry when the approach to it changed and the process was introduced in building. In comparison with other industries, many special features burden process in construction and this makes changes leading to process improvement difficult. Structures are often very large and complex and it is necessary to organise construction processes on the building site according to space and time, while making optimum use of existing capacities. A production process of this kind is almost impossible to simply transfer among structures of different sizes and complexities. Production processes in construction last for a very long time, which increases the probability of detrimental events and the risk of running behind schedule. In its level of mechanisation construction still lags significantly behind other industries, and although machinery is increasingly replacing human work this is taking place much more slowly than elsewhere. Unlike industries predominated by production for an unknown client, structures are almost as a rule commissioned by a client or investor who stipulates the location, size, quality and purpose of the future product. Thus the investor should take part in the production process. Investors are usually inexperienced in this, which makes process development in construction additionally difficult.

According to Hughes [5] every project goes through similar phases in its evolution. The phases may vary in size and intensity, depending on the project. Hughes compared 7 plans of work published to date and concluded that many of them are more than a check list. Activities in construction projects to make up plans of work should be described in as much detail and in such a way that different projects may be compared. It is much more useful to concentrate on common aspects among projects than to begin analysis by describing the unique points of each project. He stated that the uniqueness is at a greater level of detail than the commonality, and therefore it should be modelled as such.

The division of the project into phases resulted from the desire to find a set of activities that should be carried out in the realisation of every construction project. This is the first step in establishing the construction process. Flanagan and Norman [6] divided the construction process in 4 phases. The RIBA Plan of Work [7] proposes 11 phases. The BPF Manual [8] proposes 5 phases. The Construction Industry Board [9] also divides the process in construction in 5 phases.

The Generic Design and Construction Process Protocol was developed as the result of a research project at the University of Salford by Professor R.Cooper and her team, in cooperation with several companies that were in various ways connected with the construction industry. The EPSRC (Engineering and Physical Sciences Research Council) under the IMI (Innovative Manufacturing Initiative) financed the project.

The Process Protocol [10] divides the construction process in 10 phases:

1. Demonstrating the Need
2. Conception of Need
3. Outline Feasibility
4. Substantive Feasibility Study & Outline Financial Authority
5. Outline Conceptual Design
6. Full Conceptual Design
7. Coordinated Design, Procurement & Full Financial Authority
8. Production Management
9. Construction
10. Operation and Maintenance

Lee, Cooper and Aouad [11] gave some advantages of the Process Protocol as an industry standard. It is these advantages that form the basis for an efficient framework for managing risk in construction projects:

1. *It takes a whole project view*. Process Protocol manages the project from recognition of the need for a building to its operation and maintenance and it is basically a generic process. Risk must also be managed through all the project phases independently of project type and size. Risk management must be placed in the function of the generic process, which means it is necessary to develop process-driven risk management.
2. *It recognises the interdependency of activities throughout the duration of projects*. Every activity that takes place within a project includes potentially risky events. Identification, analysis and response to these risks are the basis of every risk management framework. However, some activities are interdependent, overlapping or stretch through one or several phases of the project. This interdependence carries new risks which the framework must manage.
3. *It focuses on the front-end activities, paying attention to the identification, definition and evaluation of client requirements*. This makes it possible, at the end of each phase, to implement a new identification, analysis and find an appropriate response to the risks of the following phase.
4. *It provides the potential to establish consistency to reduce ambiguity, and it provides the adoption of a standard approach to performance measurement, evaluation and control to facilitate continuous improvement in construction*. Consistency, performance measurement and continuous improvement in construction are the foundation on which every risk management framework must develop.
5. *The stage-gate/phase-review process approach used facilitates concurrency and progressive fixity and/or approval of information throughout the process*. It illustrates the need for completing all necessary phase activities before proceeding to the next phase (hard gates) or allows concurrency (soft gates) without jeopardising the overall project success. Some types and/or sources of risk stretch through several project phases. Gates are the checkpoints where prior activities are reviewed and the decision made to start the next phase. The hard gate/soft gate philosophy may be directly applied to the risk acceptancy philosophy. Thus in risk terminology hard gate means that the risk is unacceptable and must be eliminated or transferred, and soft gate means that the risk is acceptable provided it is managed.
6. *It enables co-ordination of the participants and activities in construction projects and identifies the responsible parties*. Process Protocol groups project participants in Activity Zones according to their responsibilities. In Process Protocol risk is managed by introducing a new Activity Zone: risk management.
7. *It encourages the establishment of multi-functional teams including stakeholders. This fosters a team environment and encourages appropriate and timely communication and decision making*. One of the greatest risks in the early phases of the project is misunderstanding the client’s real demands. As an answer to this risk, Process Protocol anticipates the client’s active participation in all the project phases.
8. *It facilitates a legacy archive whereby all project information is collectively stored and can be used as a future learning vehicle*. The legacy archive is a very good place for

accommodating the Risk Register and database that may serve to identify, or analyse risk.

3. Identifying Risk in Construction Projects

As it unfolds the construction projects passes through several phases and in each of them it is possible to identify a large number of potential risks, i.e. events whose unfavourable outcome may be adverse for project success. Something could go wrong during practically any activity in project realisation. It would be very difficult to make a general list of all the risks for construction projects of any size or type, which would cover all the specific features of a particular project. A list of this kind would contain a certain number of high-exposure risks, but also a great number of risks whose exposure is such that they could practically be neglected. There would never be enough data for a quantitative analysis of a large number of risks, whereas a qualitative analysis of a large number of risks would be a time-consuming process subject to inconsistent assessments because of the great number of decisions that the risk manager would have to make to obtain their exposure and determine risk acceptability.

Reference sources provide a large number of attempts to compile a specific risk list in construction projects (Table 1). Most of these lists group risks in categories thus forming a hierarchical risk structure. The risk manager may analyse and compare the risk exposures of entire risk categories, he may select one or more key risks from a category and disregard all the others, or he may analyse risk acceptability for all the identified risks in a particular category.

Table 1 shows risk categories in construction projects according to several authors [12,13,14,15,16]. The risk categories in other industries are similar. These risks may appear and be analysed in all construction projects regardless of size or type. Although similar risks often appear under different names, the table shows the great diversity in identifying risk categories among different authors. The five risk lists in the table contain as many as 31 risk categories.

Risk identification with the help of previously existing risk lists is completely adapted to risk-driven project management and does not take into account that executing a construction project is a process and that risk management must be subordinated to that process.

Table 1: Risk lists

	RISK	CARTER at al. (1994)	GODFREY (1996)	SMITH (1999)	DEY (2001)	RAMP (2002)

4. Risk Identification Based on Process Protocol

The risk management process, and thus also risk identification, which is part of it, have to be subordinated to the construction process. A process is a group of activities undertaken with the goal of successful project realisation, and these activities are potential risk sources that may lead to an unsuccessful project. The construction process consists of phases through which the project passes. Regardless of the project characteristics, the key risks of the construction project are the risks that may prevent the goals of a particular phase in the process from being achieved.

The goals of each phase depend on several activities or processes that affect phase realisation in various ways. Not achieving the goals of one or more of these processes may lead to non-achievement of the goals of the phase they belong to. Depending on their complexity, some processes contain sub-processes that may be broken down even further.

Independently of level, the processes in a particular phase that have the greatest probability and the greatest impact on the time, cost and quality, and thus also the greatest bearing on successfully achieving the goals of that phase, are the optimum choice as sources of key risks that are not project related. This means that the key risks on which the success of the process depends can be reached by analysing the construction process. In this way risk management is placed in the service of the construction process, and leads to process improvement.

Process Protocol II, developed by R.Cooper at Salford University in cooperation with Loughborough University, resulted in breaking down high level processes (Level I) into sub-processes (Level II and Level III) in each phase through which, according to Process Protocol, the construction project passes from Demonstrating the Need to Operation and Maintenance [17]. Process maps were made for each level. These process maps show the advantage of Process Protocol over other plans of work because they provide better insight into the elements of the process and thus also into risk identification. Figure 1 shows an example of dividing a process into sub-processes according to Process Protocol II. For Phase Zero, *Demonstrating the Need*, it shows the division of the high-level process *Establish the Need for a Project* (Level I) into sub-processes (Level II and Level III).

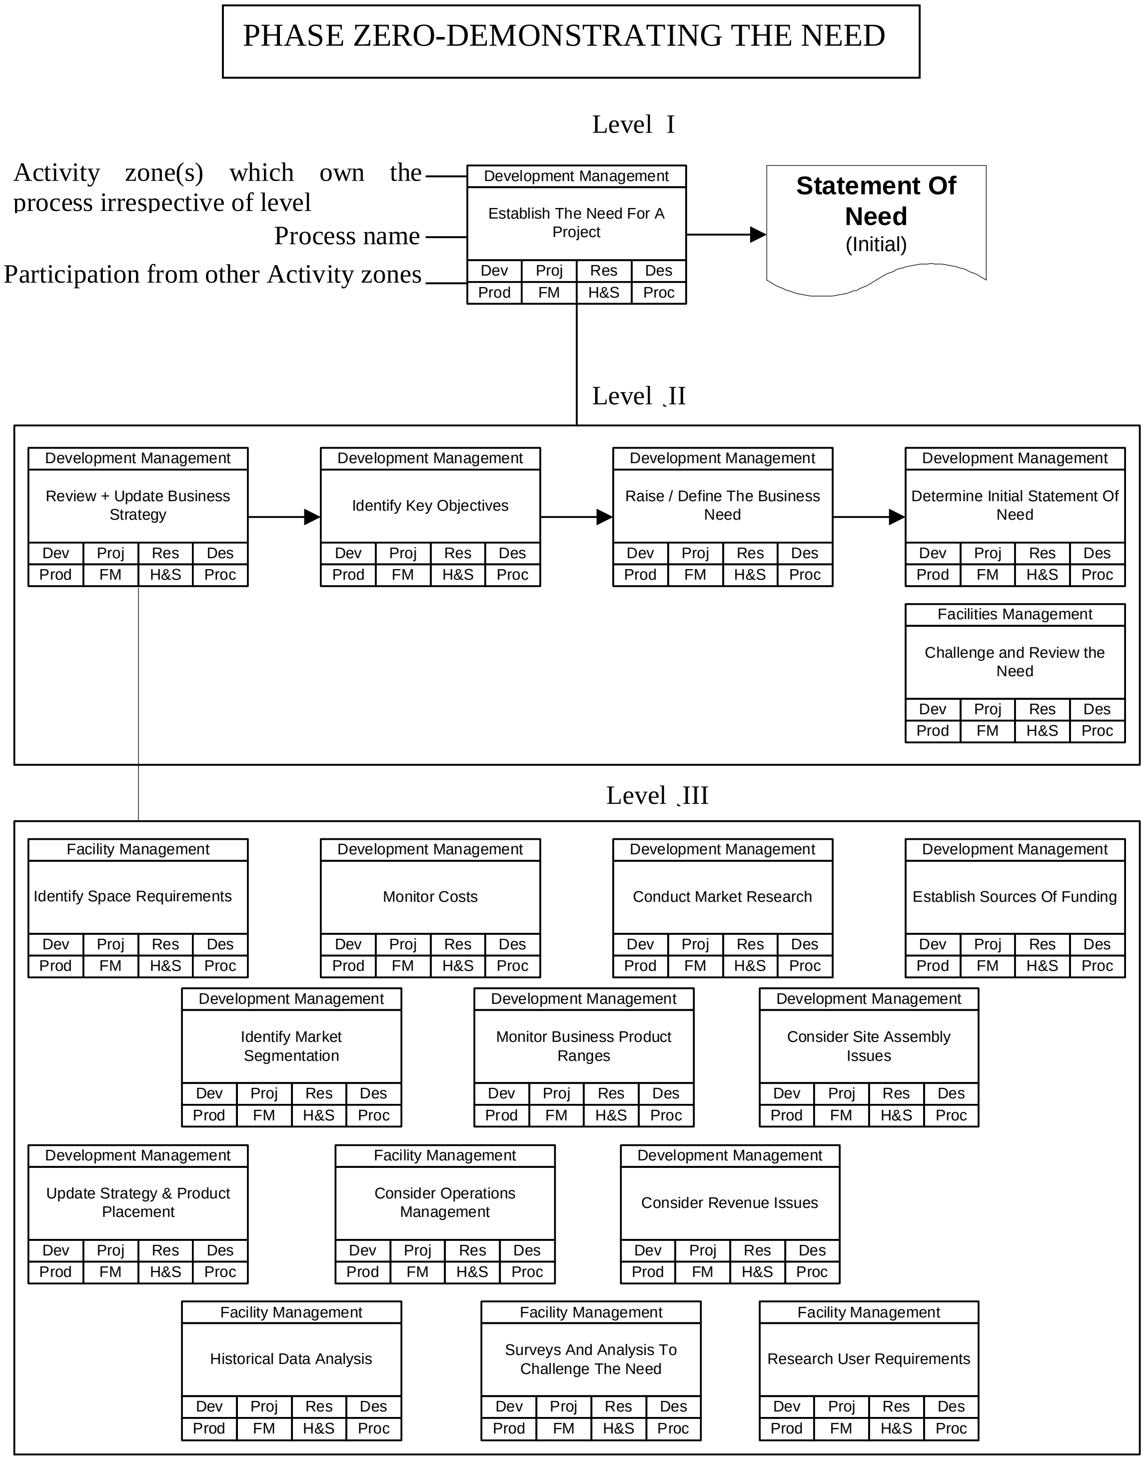

Figure 1: Development of sub-processes

Abbreviations: Dev - Development Management, Proj - Project Management, Res - Resource Management, Des - Design Management, Prod - Production Management, FM - Facility Management, H&S - Health and Safety Management, Proc - Process Management

The author of this paper compiles the proposed list of key risks for Phase Zero, *Demonstrating the Need* to show how construction process and sub-processes can be used for risk identification:

Risk 0-1: Unsatisfactory Market Research

In this earliest project phase it is necessary to research the market of existing structures which may help the client express his requirements or demands as clearly as possible. This is especially important as some of the stakeholders will be participating in the realisation of such a project for the first and only time. When they see what they could obtain, clients will be able to express what they really want much more clearly. Without market research and the presentation of the research results to clients there is a significant risk that the goals of phase zero will not be fulfilled.

Risk 0-2: Ill-defined Initial Statement of Need

All the client's needs, goals and demands should be described in as much detail as possible in a document according to Process Protocol called Statement of Need. In this early project phase it is very difficult to define all the demands and needs. In further project phases the elaboration and evaluation of potential solutions will lead to their reduction or may even extend the demands of the client, i.e. the stakeholder.

Risk 0-3: Incomplete Stakeholder List

Each stakeholder has his needs and demands, depending on his investment in the project. An incomplete stakeholder list makes it impossible to form all sources of funding and means that demands differing from earlier ones may appear. An incomplete stakeholder list is a risk for the entire phase zero not fulfilling its basic goals.

Risk 0-4: No Historical Data Analysis

In the earliest project phase, after the client's needs, goals and demands have been defined, it is necessary to analyse available data about all risk sources on similar projects that have already been executed. There is also a risk of leaving out of the risk list a risk that in the past showed significant risk exposure in a project phase. Analysing available data considerably contributes to a better understanding of the problem.

Risk 0-5: Poor Communication

In the earliest project phase it is necessary to establish a communication strategy within the management team participating in the project phase (development, resources, facilities, project and process management) and between the management team and the client and stakeholders. Success in realising the goals of phase zero greatly depends on this communication.

5. Conclusions

Risk management is by nature a cyclical process. Risks must be identified before the beginning of project realisation or the realisation of any phase through which the project passes. The environment in which the project is realised produces new risks during project realisation. The new risks must be analysed together with those identified and analysed earlier, in a continuous attempt to assess the probability and adverse effect of new risks in relation to existing ones. This creates the need for continuous risk management in all phases of project realisation.

The execution of a construction project is a process. The process in construction contains many special features in comparison with the process of other industries, which are an impediment for changes leading to process improvement. The risk that the project might be unsuccessful is in fact the risk that particular elements in the construction process might be unsuccessful. Risk management should be subordinated to the construction process. Improving certain elements of risk management lead to better understanding and to changes, in other words, to improvement of the construction process, which is one of the main goals of the construction industry.

The Construction Process Protocol is by nature a generic process and is thus suitable for the construction process within which risk management will be situated. As a plan of work, Process Protocol enables managing the project from Demonstrating the Need to Operation and Maintenance regardless of the type, size and purpose of the project that is being realised. According to Process Protocol, every project can be executed through the successful execution of 10 phases. Every phase contains so-called high-level processes as a group of activities that must be realised for the successful conclusion of that phase. High-level processes are broken down into sub-processes in as many levels as the Protocol user deems necessary for the project. The break down of the process in sub-processes provides a good foundation for identifying key risks that are independent of the project being realised. Sub-processes are potential risk sources so risk management in fact means ensuring the success of each sub-process within the entire construction process. Ensuring the successful execution of the construction process leads to process improvement, which gives additional weight to Process Protocol.

Breakeven Analysis for Selecting Construction Methods: Precast vs. Cast in Place Concrete

Ibrahim Al-Hammad
Faculty of Civil Engineering, King Saud University (email: alhammad@ksu.edu.sa)

Abstract

In Saudi Arabia, it is common practice that most of the structures of individual housing and small building is erected by Cast in Place (CIP) concrete while most of the structures of mass houses and large building and malls are one of Precast concrete (PC). The reason for the previous characterization is dictated by the economics, shortening of construction period, knowledge of the contractor, and aesthetics. Gradually but slowly, PC is taking more territory for the traditional CIP. The aim of this paper is to devise criteria for selecting either of the above methods from an economic perspective. The criteria will help the owner/contractor/designer to decide the favor ability of either construction method based on the size of the project.

Keywords: Precast Concrete, cast in place concrete, and construction method, Saudi Arabia

1. Background

Many structural systems have been used in the housing and building industry of Saudi Arabia which is predominated by the two systems, Cast-in-Place concrete structures, short named CIP; and that is of Precast concrete structure, short named PC. This practice has been dictated by cost competitiveness, contractors experience, aesthetics, flexibility and lower cost of change orders and other factors. It is common to have individual family detached dwellings of two stories built with CIP concrete because it is more economical and flexible whereas mass housing and large commercial and office buildings are built with PC concrete for their modular design, repetition of standard structural members, and economics of scale.

The choice between the two structural systems by owners/designers/contractors, based on their areas or space volumes and thus costs, are comparable in some cases of construction projects.

2. Problem Formulation

Designers and Engineers are frequently requested by the owners to advise them more accurately on the most economical structural system when their estimates are based on previous projects, quotations and rules of thumb. Hence, in the case of evaluating a CIP concrete structure versus PC concrete structure for a given project, a quantitative method of comparing the two alternatives in terms of their construction costs, is desirable in the early stages of architectural and structural design. The total costs for the contractor in a construction projects equal to the total direct costs and total indirect costs. For simplicity, this relation can be expressed as cost function as follows [1]:

$$\sum RC\_Cost = \sum DC \times Qi + \sum IC \times Ti \qquad \textbf{Eq.1}$$

Whereas the following symbols represent the stated variables:

RC_Cost (in SR):	Total concrete cost in Saudi Riyals for either CIP or PC.
DC (in SR/Cu Meter):	Direct costs of proportional erected concrete (i.e. dependant on the quantity of erected CIP or PC concrete).
***Qi (in Cu Meter)*:**	Quantity of concrete in cubic meter for either CIP or PC.
IC (in SR/day):	Indirect costs for concrete works that is proportional to the duration of concrete erection.
Ti (in Days):	Duration of Concrete Erection (including Manufacturing for PC Concrete)

The relationship between the cumulative cost of concrete works (including pouring/erection) and quantity of concrete measured in cubic meters can be simply expressed by the following equations.

3. Example Project Real Data

To examine the formula for selecting either of the two structural systems of CIP or PC, relevant input data is drawn from two compatible projects utilizing both structures. Table 1. presents unit prices and quantities of concrete for major structural members for CIP and PC systems, which are drawn from two colleges building projects in King Saud University located at Riyadh, Saudi Arabia [2], [3]. The two projects have similar project definitions and are presumably equivalent in price, size and quality. The CIP concrete activity duration, per schedule of the contractor when reviewed by the author, is 320 days while the PC concrete activity duration (design and manufacturing and erection) is 240 days.

Table 1: Quantities of Concrete Works by Structural Members [2], [3]

	College of Architecture and Planning Project			College of Computer Science Project		
Type of Structure	**Cast-In-Place Concrete**			**Precast Concrete**		
Structural Member	**Quantity of Concrete (In Cu Meter)**	**Unit Cost (In SR/Cu Meter)**	**Total Cost for Individual Structural Element (In SR)***	**Quantity of Concrete (In Cu Meter)**	**Unit Cost (In SR/Cu Meter)**	**Total Cost for Individual Structural Element (In SR)**
Foundations	2675	700	1872500	2174**	650	1413100
Columns	772	800	617600	564	1520	857280
Beams	4702	800	3761600	4100	1700	6970000
Slabs	6295	800	5036000	2678***	700	2574600
Stairs	161	900	144900	161	2800	450800
	Cumulative Costs		11432600	Cumulative Costs		9691180

* SR, Saudi Riyal, is Saudi Arabia currency which is equivalent to US $ 0.27
*CIP Concrete is used for foundations and slab on earth for PC structure
** Volume of the PC slab is much smaller than the CIP slab since it is a hollow slab with 0.3 meter of thickness

4. Formula Derivation

4.1 Cast-in-Place Concrete (CIP) Structure Costs

From Table 1., total Quantity of CIP concrete is 11,769 cubic meter is to be erected in 320 days (from project schedule) at average price of 800 SR/M³ for all structural members excluding foundation and stairs (which are common for both alternatives); therefore

Total cost = 11769 * 800 = 9,415,200 SR.
Assuming an inverse linear relationship between concrete cost and duration of its erection and that all concrete works fall on the critical path, then

Cost of 1000 m³ CIP concrete = 8,000,000 SR Eq 2.
And if the Time for erecting 11769 m³ of concrete is 320 days; then
Time to finish 10,000 m³ of concrete is 272 days.

Assuming indirect cost & profit margin is 25% (of 8 millions) of total costs which is 2,000,000 SR; and then
The indirect cost & profit margin / day = 2,000,000 /272 = 7353 SR /Day Eq. 3
Thus, the direct cost for 10,000 M3 of CIP concrete is 6,000,000 SR, i.e.
Direct Cost = 600 SR/ m³ Eq. 4

For simplification, the findings of equations 2-4 are represented by the following variables:

DC1: Direct cost = 600 SR/m³
T1: Time for finish 10,000 m³ = 272 days
IC1: Indirect cost & profit margin = 7353 SR

Substituting the above variables in Eq.1, then it can be written as follows:
Total Costs (in SR) of CIP concrete = DC1*Qi + IC1*Ti
= 600 * Qi + 7353*272
= 2000016 + 600 * Qi Eq. 5

4.2 Precast concrete (PC) Structure Costs

From Table 1., total Quantity of PC concrete is 12699 cubic meter is to be erected in 240 days (from project schedule) at average price of 1060 SR/M³ for all structural members excluding the foundations and stairs; therefore,
Total cost of PC concrete = 12699 * 1060 = 13,460,940 SR.
And by extrapolation between concrete cost and duration of its erection given all concrete works fall on the critical path, then

Cost of 10,000 m³ PC concrete = 10,600,000 SR Eq 21.
And if the Time for erecting 12699 m³ of concrete is 240 days; then
Time to finish 10,000 m³ of concrete is 189 days.

For the sake of simplicity, assume that the indirect cost & profit margin for the PC contractor is similar to contractor of the CIP, then
IC2 = IC1 = 7353 SR/Day Eq. 31
Total Indirect Cost for PC concrete = 7353 SR/Day * 189 Days
= 1,398,717 SR

Thus, the direct cost for 10000 M^3 of PC concrete = 10,600,000 SR – 1,389,717 SR
= 9,210,283 SR, or
= 921 SR/ M^3 Eq. 41

For simplification, the findings of equations 21,31 and 41are represented by the following variables:

DC2: Direct cost = 921 SR/m³
T2: Time for erecting 10,000 m³ of PC concrete = 272 days
IC2: indirect cost & profit margin = 7353 SR

Substituting the above variables in Eq.1, then it can be written as follows:
Total Costs (in SR) of CIP concrete = DC2*Qi + IC2*Ti
= 921 * Qi + 7353*189

$$= 1389717 + 921 * Qi \qquad \text{Eq. 51}$$

4.3 Finding the Breakeven Point

Having developed Eq. 5 and Eq.51 for the relationship between both CIP and PC quantity of concrete versus total costs of erection, then a breakeven point whereby both linear equations are equal in total costs and equal in quantity of concrete can be found by equating Eq. 5 and Eq.51 as follows:

TC1 = TC2, i.e., 2000016 + 600 * Qi = 1389717 + 921 * Qi, and thus

Qi = (2000016 - 1389717) / (921 – 600) = 1901.24 Cubic Meter of concrete.

Table 2. Presents the values of CIP concrete and PC concrete costs in SR/Cu Meter for ascending quantities of concrete in Cu Meter. When the two previous variables plotted in X-Y plane as in figure 1, which it shows the breakeven occurs at Qi = 1901.24 Cubic Meter at a total cost of 3,200,016 SR. From the figure, we can see if the total quantity of the used concrete is less than 1901 cubic meter then it is cheaper and favorable to use the PC concrete while if the required quantity of concrete is more than 1901 cubic meter, then it is cheaper and favorable to use CIP concrete for the structure of the building.

Table 2 : Data of the Concrete Quantities vs. CIP/PC Costs

Data No.	Quantity of Concrete (Cu Meter)	Cost of CIP Concrete (SR/Cu Meter)	Cost of PC Concrete (SR/Cu Meter)
1	500	2300016	1850217
2	1000	2600016	2310717
3	1500	2900016	2771217
4	2000	3200016	3231717
5	2500	3500016	3692217
6	3000	3800016	4152717
7	3500	4100016	4613217
8	4000	4400016	5073717

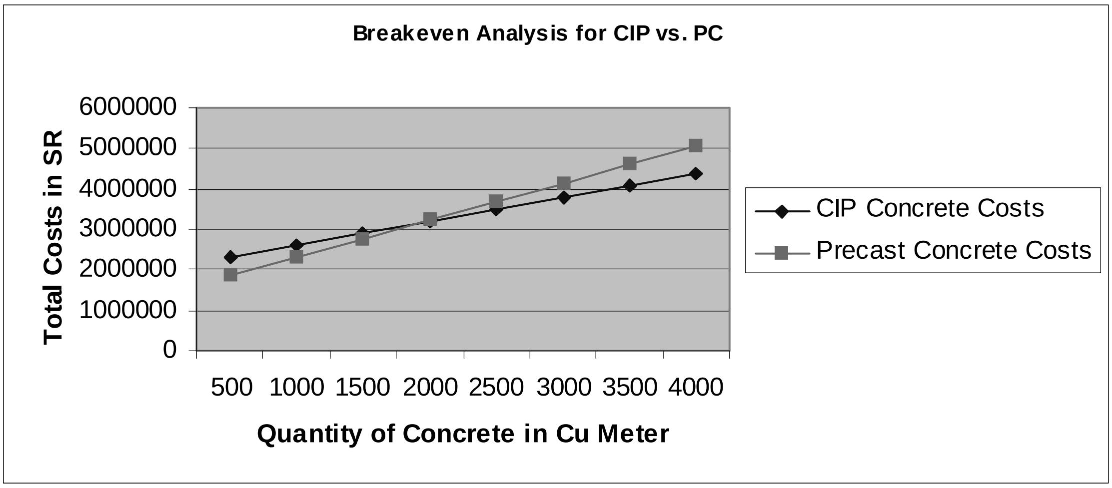

Figure 1: Plot of Concrete Quantities vs. CIP/PC Costs

5. Conclusions

Breakeven formula is derived to preliminarily evaluating and selecting best alternative between two competing construction methods offered by two different contractors for the structural members, those of Cast-in-Place concrete vis-à-vis Precast concrete. The criterion for selection is based on the most economic solution. The quantities of works, i.e., concrete, are treated as independent variable while the component of contractor overhead is held constant and equal for both contractors. The outcome of this research assist decision makers and engineers to compare both concrete construction methods early in the construction planning phase of a project. The approach developed herein can be also applied for similar construction methods for other project activities.

The author intends to further treat the validations of the findings in upcoming paper.

Systemic Innovation in the Management of Construction Projects and Processes

In an industry that is dominated by one-of-a-kind projects, and a thin profit margin, a key challenge in the new global economy is to ensure delivery of projects that are on time, within the cost limits, of high levels of quality, sustainable, and provide value to the customer. All this, while ensuring that contractors remain profitable without raising project costs. This calls for systemic innovation in the management of construction projects and processes that takes into consideration all relevant aspects and stakeholders of the complete building lifecycle.

The challenge of systemic innovation in the management of construction projects and processes has been taken up in this book. Contributions and experiences from Australia, Brazil, China, Croatia, Finland, Norway, Saudi Arabia, Sweden, Taiwan, The Netherlands, United Kingdom, and USA unveil how systemic innovation is being used to manage projects, product processes and control, productivity and performance improvement, product delivery systems and contractual practices, and risk management.

This book is part of a series of scholarly books on *Combining Forces – Advancing Facilities Management & Construction through Innovation*.

Preface

This book highlights facilities management and its business experiences from four continents as they were presented in an international CIB 2005 Helsinki Symposium. The book containing 57 papers is divided in six chapters each describing highly interesting topics of built facilities and their management.

The changes and recent developments in facility management industry have been very efficient: new knowledge and solutions are widely used and business is coming more and more globalise. Those who can successfully interpret changes happening in the construction and facilities businesses can achieve significant gains. Business environments are constantly changing thereby providing new opportunities for innovative firms.

Emerging solutions for defining end products, relying heavily on the preferences of users to guide all services are clearly providing a mind shift from supply-driven to end-user-driven attitude. The needs and expectations of customers and end users are highly ranged.

Today's businesses and working life demand highly usable workspaces and flexible spaces and buildings and also versatile new facility management services. Present needs cannot be extrapolated over decades. Active, innovative research and development work is needed all the time.

Also facility management needs sustainability. Sustainable concepts, sustainable buildings and infrastructure are affecting facility industry and business, its management and the underlying knowledge, methods and solutions.

Also new concepts, methods and solutions for explaining built environment quality, safety and functionality are covered by this book.

We hope this book finds interest among practitioners and researchers willing to implement and develop further the facility management as an independent service industry and business area.

Abstract

In Japan, long use of social capital stock is now our crucial task in terms of both fiscal issues and global environmental problems. "Strategic Stock Management Method" that we developed is a group management method of social capital stock, and in the sphere of building, it consists of, a) simplified evaluation method, b) combination of various types of building life prolongation technologies, and c) impact analysis of management schemes to various social and environmental aspects. This paper examines the problems for stock management that confront us and presents our concept of "Strategic Stock Management", and taking public buildings of a city as objects of case study, show its effectiveness to our problems.

Keywords: Public Building Facilities, Group Management of Facilities, Stock Management, Asset Management, Simplified Evaluation Method

1. Building and Infrastructure Stock Management in Japan

In spite of scrapping and building of massive buildings and infrastructures Japan has undergone during the rapid economic growth and social transitions, long use of housings and social capitals are now our crucial task in terms of both fiscal issues and global environmental problems (Figure 2 - 5).

Owing to the rapid development of Japanese economy and accumulation of construction activities, massive stock of buildings and infrastructures has been formed, but the progress of time and the development of living environment have invited the rapid obsolescence of its function in the both terms of soft and hard. As for publicly managed housing and social capital under the present severe financial conditions of public investment reductions, the maintenance and the replacement cost for the voluminous stock is estimated to leap in the near future, and new building and construction investments will be even harder.

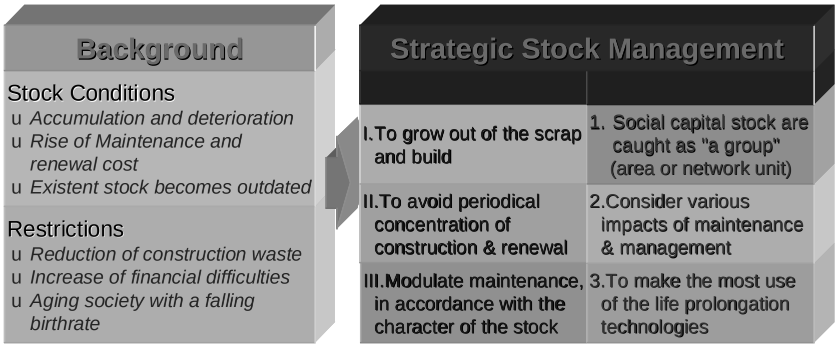

Figure 0: Backgrounds and Conditions of Strategic Stock Management

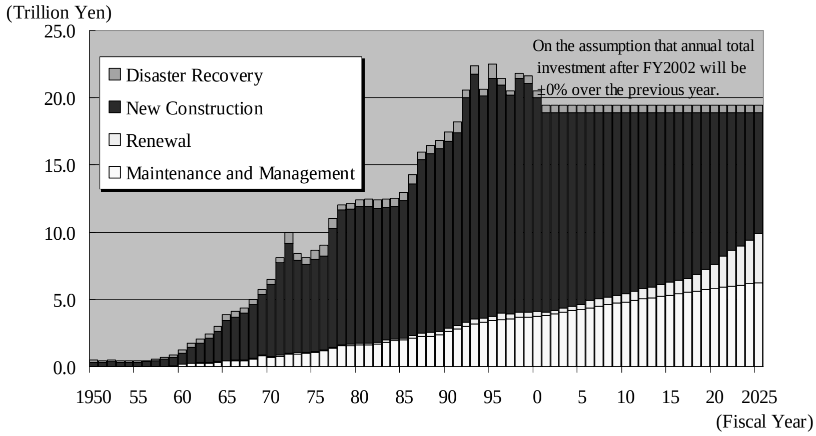

Figure 0: Estimates for Investment of Social Capital Stock in Japan (by MLIT 2002)

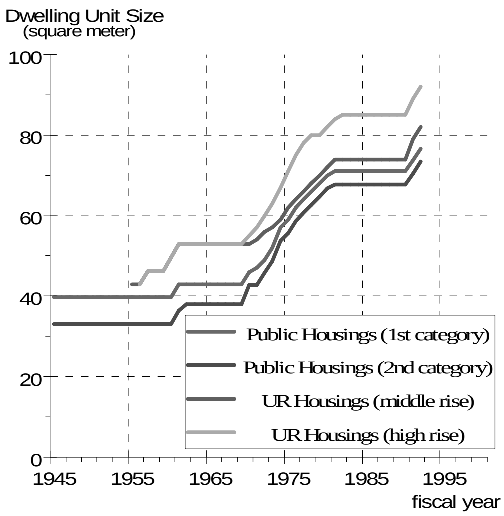

Figure 3: Outdating of Existing Stocks

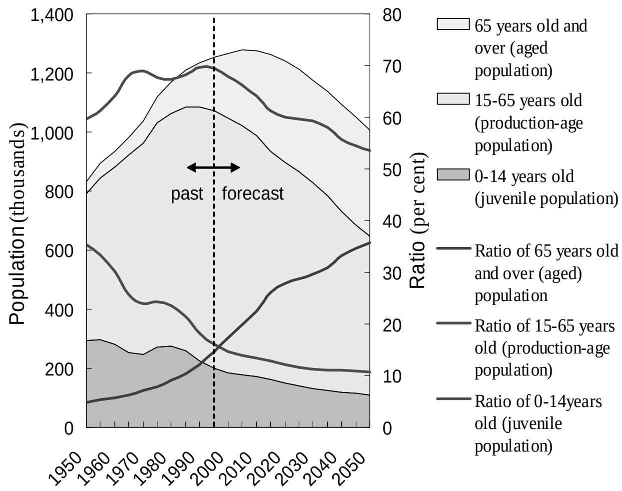

Figure 4: Change of Social Conditions (Population)

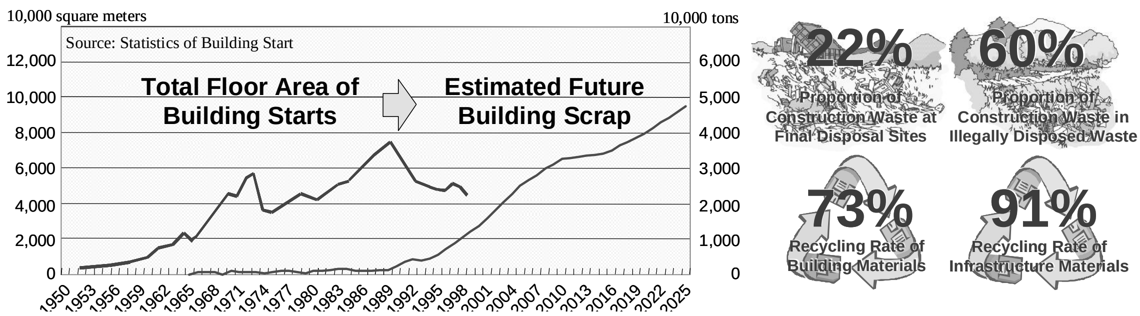

Figure 5: Necessity to Control Production of Building Waste

On the other hand, with the issue of global warming focused on, the decrease of waste and global warming gasses from building and construction activities is demanded.

What we must do, along with developing and making use of technologies to extend the service life of individual buildings and infrastructures is to develop technologies to control the life span of all social capital to adjust the peak demand for renewal. It is for this context that our institute is conducting studies into the 'Development of Asset Management Technology for Housing and Social Capital' (2001-2004), with the objective of developing a "Strategic Stock Management" method that will enable us to maintain, manage, operate and renew multiple facets of our social capital in a planned, strategic manner (Figure 1).

2. The Concept of Strategic Stock Management

The concept of "Strategic Stock Management" at our start point can be described as following.

If we are to make more effective use of housing and social capital, it is vital to have a grasp of the conditions of each facility and manage each appropriately. To allow selection of the most appropriate for maintenance and management depending on facility conditions and functions, evaluation of the characteristics and effectiveness of separate technologies are required. According to the diagnosis of the degree of facility deterioration, we can extend facility service life that will ensure the required functions for the necessary periods through repair and reinforcement, or extend service life by converting use of the facility.

As we evaluate the effects of these technologies, it will make possible to formulate and evaluate maintenance and management plans for each separate facility -- plans with comprehensive perspectives including environmental impact, costs, and user convenience. Specifically, we compare the different plans in comprehensive ratings that consider cost and environmental impacts in order to choose the best plan. Here is an example of how selection would be made from among plans A, B, C, and D (Figure 6). Plan A calls for maintenance of the facility in a way that makes it possible to maintain its performance consistent with its original purposes until it reaches the end of its life span. Plan B call for maintenance to be carried out at lower levels than are required by Plan A, but schedules major scale repair work at some future point. Plan C would convert use of the facility before the end of its designed life span and would maintain the facility in a way to support its expected performance until the target date. Plan D would retain the facility even after the end of its designed life span by converting facility use in a manner different from Plan C.

However, formulating the best maintenance and management options for individual facilities is not sufficient to formulate appropriate plans for maintenance, management, and renewal that cover the overall inventory of the stock. To that end, we have to, in a certain management unit, overlook the whole facilities, estimate the change of necessity and coordinate maintenance and management plans of each facilities so as to maximize the function, minimize the environmental load, average financial expenditure of the facility as a group (Figure 7).

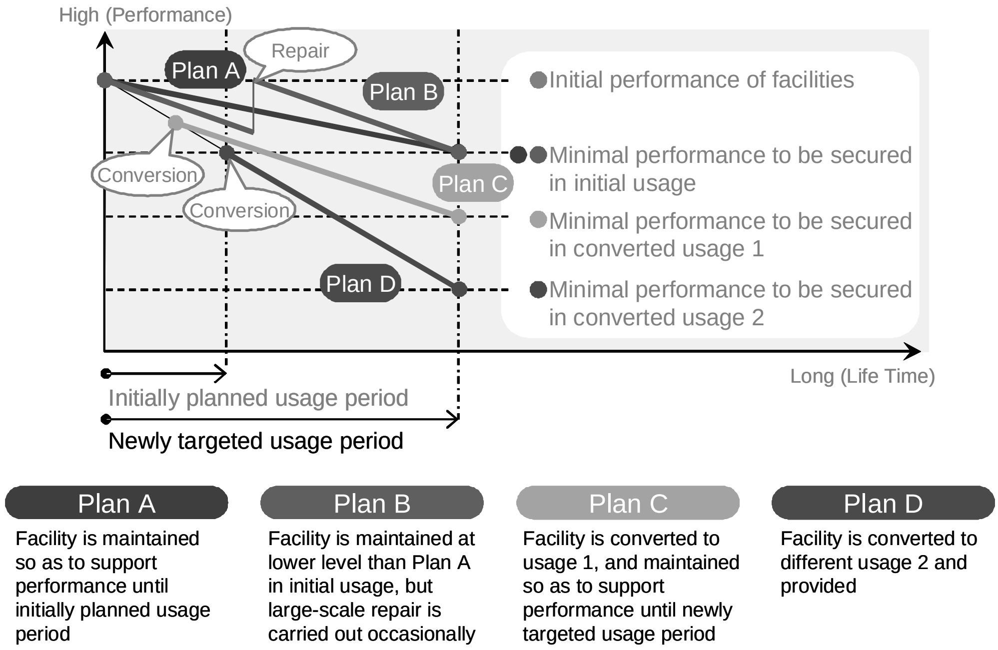

Figure 6: Planning of an Optimum Management Plan during the Usage Period

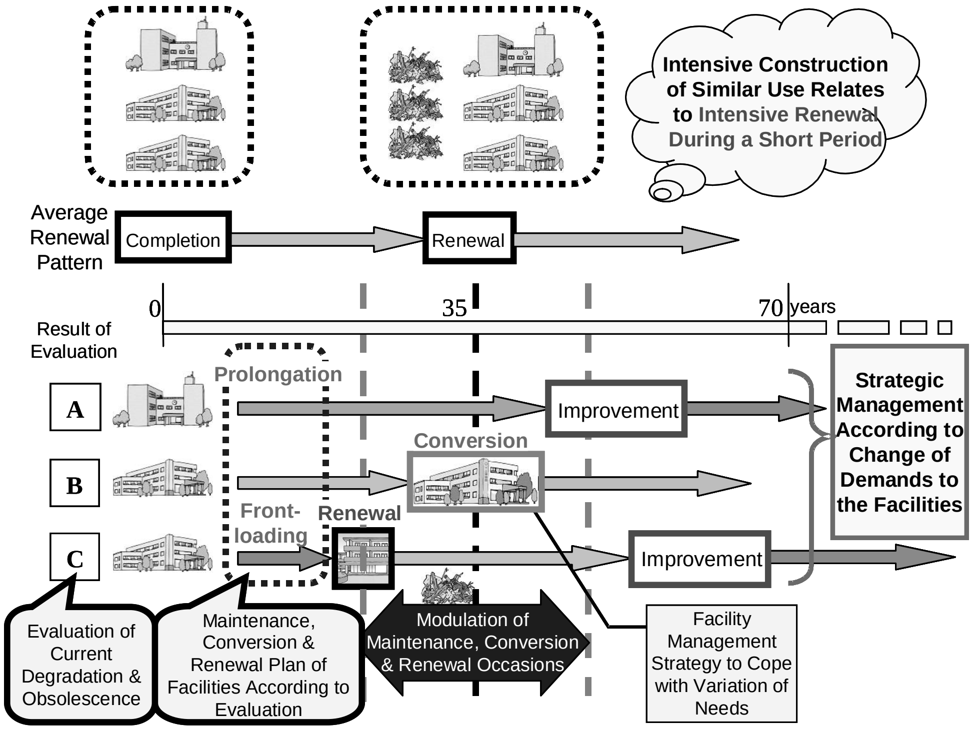

Figure 7: Approach to Group Management of Facilities in Strategic Stock Management

In brief, what we tried to achieve through the development of an overall strategic stock management system is to establish the comprehensive technology to manage and operate more than one facet of housing and social capital, i.e., ‘stock’, in a certain area by making the best use of technologies to extend life spans, repair, enhance functions or convert facility use with consideration for social aspects such as financial conditions, asset value, the impacts on global environment, effects on communities, historical value, and perhaps, preservation of scenic beauty.

3. Developing Evaluation Methods of a Building

The actual research and technology development were executed targeting public buildings of small and medium size local governments (municipalities). Through questionnaires the characteristics of building stocks and their management in these bodies has been identified as the followings.

- They have many building stocks, which are comparatively old, and of various use. The local government owns 780 thousand buildings and 500 buildings in average, while the national government owns 150 thousand buildings. Schools and public housings account for 2/3 of the buildings, and in total, their variety of use is 28 categories. Approximately 60% of the buildings are more than 20years old, and 55% are built before the new earthquake-resistant design method came in to effect (1981).
- The facilities are managed by each department in charge, and not by a single facility managing department who manage the whole stock. Building engineers occupies only 1.5% of the whole employee, and engineers play only a small part in facility management. Data accumulation for management is insufficient and there isn't a common form of facilities register in most municipalities let alone taking of maintenance and repair record.
- Despite inspections of building elements and equipments take place, diagnosis and examination of a whole building is rare. Only corrective maintenance is done only coping to troubles after they become obvious and preventive maintenance or long-term repair program rarely takes place. Because of financial difficulty, seismic rehabilitation remains undone.

Thus the situation in these municipalities are that, despite the amount, variety, deterioration and outdating of their building stocks, they do not have a comprehensive plan to cope with, lack accumulation of inspection data to support the necessary decisions, and are short of persons of talent who make the steps forward.

To solve these problems, we have developed an evaluation system of the buildings that are simple; not time and money consumptive, understandable, and can be carried out by in-house non-expert. To do this we have prepared filling sheets, by checking the items of which, a rough evaluation is executed. There are three types of evaluation and there are filling sheets for each type.

The first is for understanding and evaluating the present condition and function of the building. By checking the 32 sub-items they will be summarized to 15 main items or 5 categories of performance level as of Table 1, and the elements and the details which need repair and improvement is clarified.

Table 1: Performance Evaluation Categories and Items of Existing Buildings

Category	Main Item	Subitem (Performance or Alternative Characteristics)
I. Safety	1. Safety of Building Frame	1-1. Completion year of the building
		1-2. Execution of seismic strengthening and structural resistance
		1-3. Deterioration of the building frame
	2. Safety of External Facing	2-1. Waterproofing of the roof
		2-2. Leak from the external facing
		2-3. Deterioration of exterior materials
	3. Disaster Prevention Safety	3-1. Indication items by fire inspection
		3-2. Evacuation safety
		3-3. Problems of fire protection and crime prevention equipments
II. Function	4. Spatial Extent	4-1. Story and ceiling height
		4-2. Size of the rooms and convenience
		4-3. Deterioration of interior materials
	5. Indoor Environment and Faciity Functio	5-1. Performance of air conditioning, sanitation, sound, and light
		5-2. Performance of equipment machines and convenience
		5-3. Equipment capacity and crime prevention performance
	6. Barrier Free	6-1. Response of the building
		6-2. Response of the equipment
	7. Information Capability	7-1. Wiring space (OA floors)
		7-2. Reliance of information equipments against disasters and crime
III. Environmen	8. Decrease of Environmental Load	8-1. Energy and resource conservation response
		8-2. Longevity response
	9. Environmental Conservation	9-1. Consideration for the surrounding
		9-2. Ecomaterial, waste removal
IV. Sociality	10. Landscape	10-1. Contribution to landscape
	11. Locality	11-1. Consideration for local history, culture and climate
	12. Capacity	12-1. Floor area per user
	13. Utility	13-1. Utilization factor
		13-2. User satisfaction level
V. Economy	14. Maintenance Costs	14-1. Annual cost (electricity, gas and water supply)
		14-2. Operational cost prospect (per life-cycle)
	15. Asset Value	15-1. Residue value
		15-2. Service level of the facility

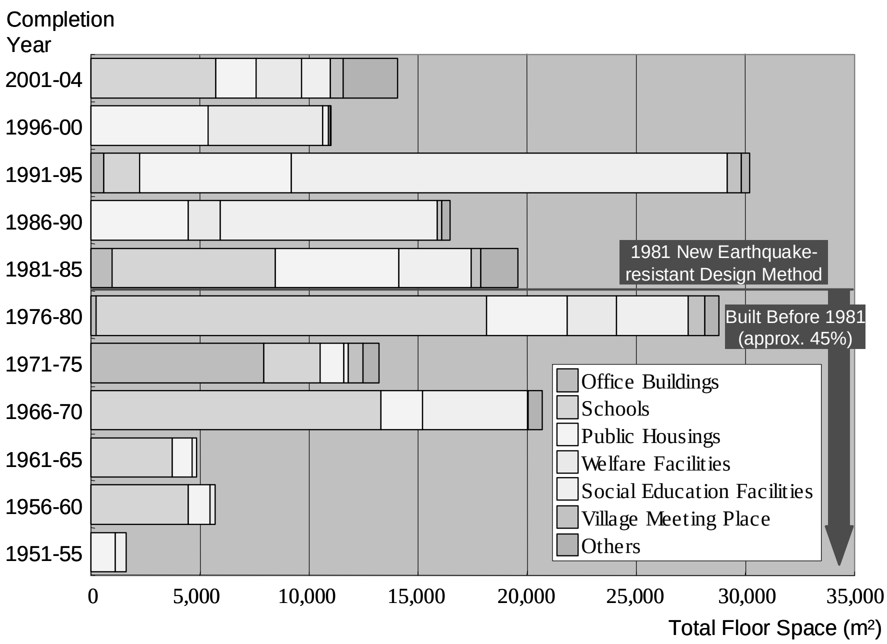

Figure 8: Building Stock of I-City by Completion Period

The second is improvement evaluation, and by filling in the sheets using cost sheets, you can estimate in rough the cost to raise the performance that is evaluated as inferior by the present condition evaluation.

The third is use conversion evaluation, which will be carried out for buildings that were considered low performance under the current use. Probability of converting to another use will be evaluated by checking the filling sheets.

4. Case Study of Evaluation in I-city

I-city was chosen as a case study of Strategic Stock Management. I-city is situated 70km from megalopolis and has a population of approximately 50,000, which recently is slightly decreasing. Revitalization of the city center, and coping with the aging population combined with the diminishing number of children, like in most of the local cities are of the main issues of local government policy that relates to facility management.

Figure 8 shows the building stock owned by the city, by use and completion period. The total floor area sums up to 167 thousand sq meters, of which 57 thousand sq. meters (34%) are schools, 44 thousand sq. meters (26%) social education facilities and 34 thousand sq. meters (20%) public housing. There are few old public buildings over 50 years of age; mostly wooden public housings that sums up to 1600 sq. meters (1%). However, nearly half (45%, 75 thousand sq. meters) are built before the new earthquake-resistant design method came in to effect (1981) and their earthquake resistance are doubtful. The description of chapter 3 applies to the situation of stock management of the city.

Figure 9 shows in radar chart the result of performance evaluation trial for 6 facilities that are taken up for group management in chapter 5, out of 13 facilities where evaluation is carried out. Through the evaluation trial, evaluation by the filling sheets has shown effect in the following points and proved to be practical.

- The whole public building stock of the municipality can be evaluated. By evaluation of administrative staff member team themselves, grasping and solving of the problem of the whole concerned with the facilities becomes possible.
- A specialist was asked separately spending time and expenses so far, but as for this method, where a specialist are found to be necessary, they can be asked and examined afterwards.
- Evaluation of whole of the facilities which was difficult so far can be carried out in comparatively short time and quantitative data accumulation, building index preparation and similar example comparison become possible by carrying it out once every five years, and they can be set up as a bench mark.
- Efforts to renovation and conversion will become easy.

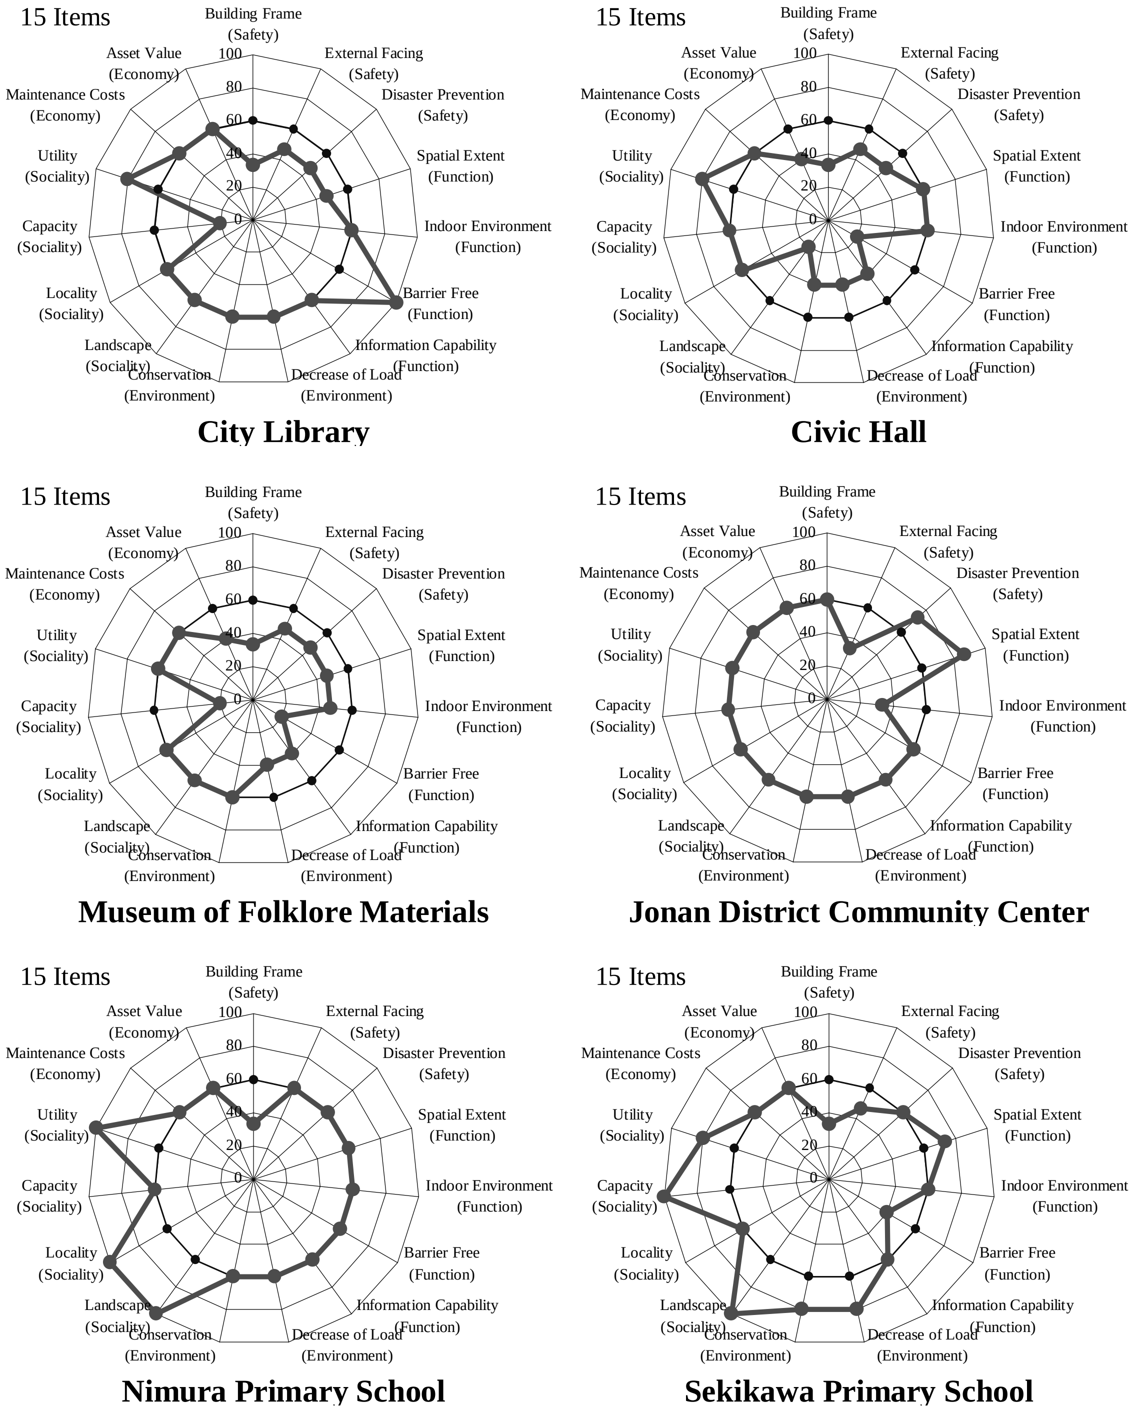

Figure 9: Performance Evaluation of I-City Public Buildings

5. Case Study of Group Management in I-city

After each public building has been evaluated, group management of the facilities will take part. The objective of group management is to examine and compare the change of function level and the social impacts of a set of management plans; maintenance, repair, conversion, rebuilding and new construction; of facilities in the management unit, and to choose the best according to higher policy. Generally, consideration of group management will take the following steps.

A. Preparation
- (i) Sort out of the present condition of the facilities
- (ii) Sort out of the presuppositions and scenarios of the group management
- (iii) Evaluation of the buildings that are considered in the scenarios
- (iv) Population forecasting

B. Examination of each scenario
- (i) Arrangement of public facilities improvement plan of the area
  - a) Review of public facilities improvement plan
  - b) Consideration of future maintenance and renewal of facilities
- (ii) Estimation and levelling of future financial burden for maintenance and renewal
  - a) Estimation of future financial burden
  - b) Levelling of future financial burden
- (iii) Cost benefit measurement and impact analysis of the scenario
  - a) Economic ripple effect measurement
  - b) User benefit (level of service) measurement
  - c) Environment load measurement
  - d) History and culture consideration

C. Comparison of scenarios

In the case study of I-city we have examined 3 cases of group management, but hereafter, the first and second will be referred to.

The first case is rearrangement of facilities triggered by a large scale cultural facility. The existing city library of I-city was built in 1980. Despite the floor area of 1,521 sq. meters, it was originally planned to shelve 500 thousand books, whereas at present the collection is 1,500 thousand. The City's original plan to cope with was to build a new cultural complex with a new library which can shelve 3,000 thousand books, under the circumstances then that the City will amalgamated with other 3 adjacent municipalities. The reality now is that the amalgamation is with only another, and there is need to consider optional plans.

Under the circumstances, we have set up 3 scenarios (Figure 10): 1. Repair and prolongation of the present library. 2. Enforcement of the complex cultural facility plan and use conversion of buildings after removal. 3. Control and distribution of demand level to the present facilities (only the southern part of the city is studied).

Figure 11 and 12 shows the occasion, details, and expenditure (excluding subsidies for new facility) of maintenance and management for relational facilities of each scenario after the levelling process. Including the results of social impact evaluations, the conclusion was that by utilizing present facilities, with as much cost as for improvement of present library, and far less than for a new one, improvement of user benefit, high level of local economic ripple effect measurement and decrease of environmental load will be possible.

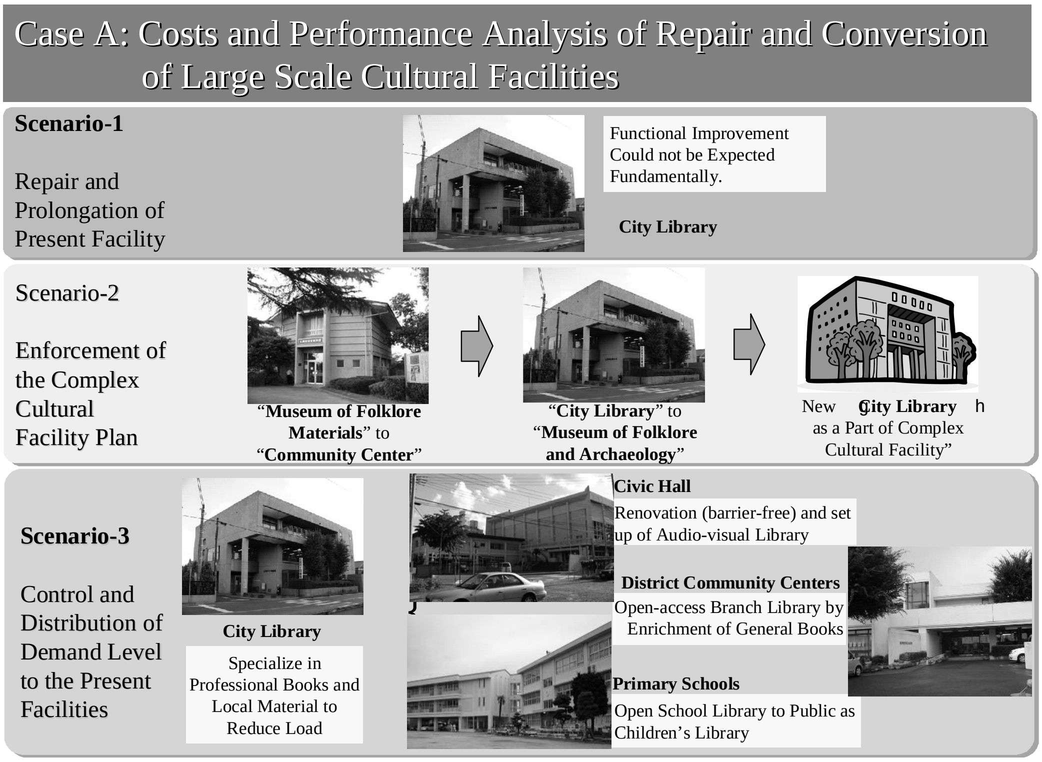

Figure 10: Group Management Scenarios of Case A

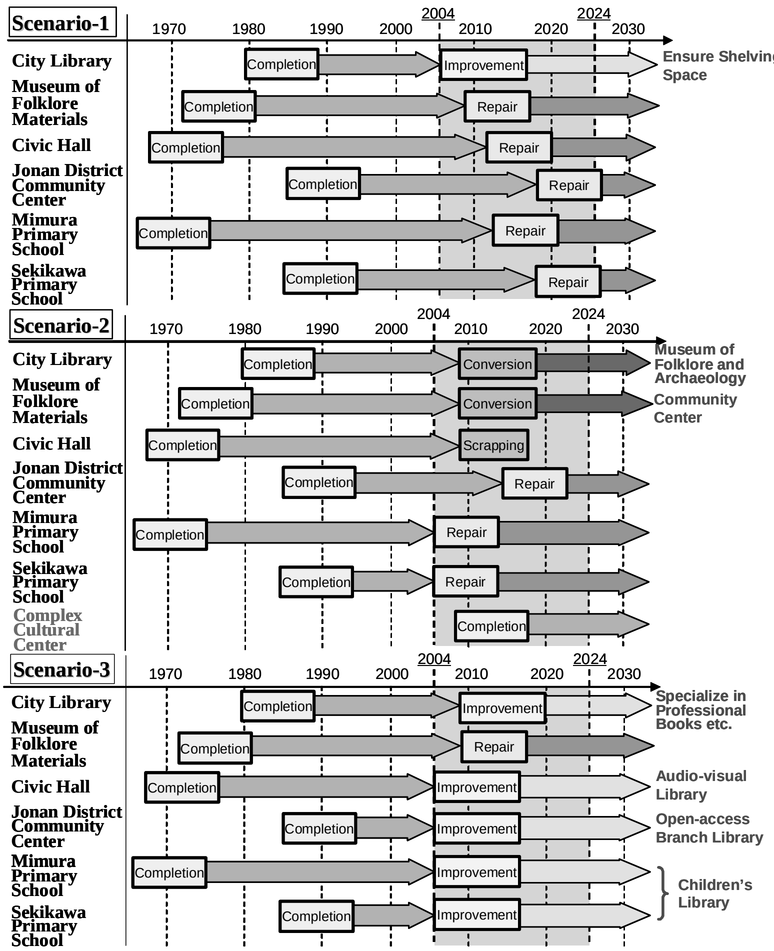

Figure 11: Maintenance & Management in Case A

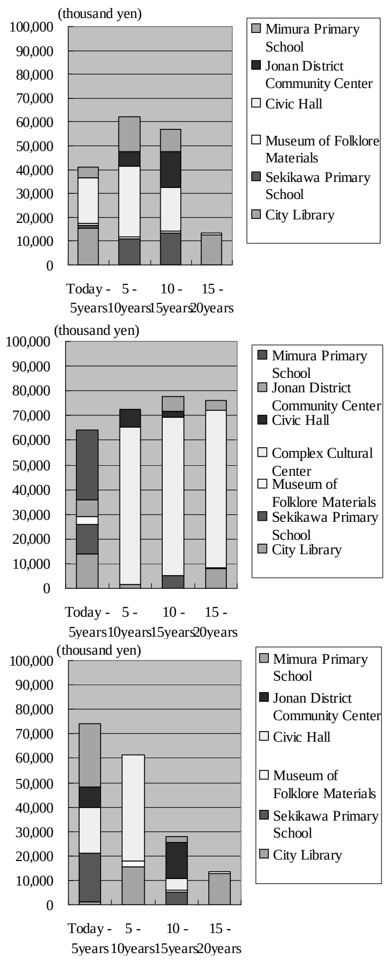

Figure 12: Expenditure of Case A

The second case is preparation of small-size close-to-life day-care welfare facilities. Under the progress of nationwide aging society and increase of nuclear families, the need for elder care facility is growing. The traditional provision of the facilities were, construction of a large scale multifunctional welfare center, whereas need for small-size close-to-life welfare facilities to support home nursing care is increasing. In I-city too, a large scale facility has been built in a northern rural part of the City, and there is growing need for smaller ones.

For this case, we decided to study about the southern part of the City and we have again set up 3 scenarios (Figure 13), including the traditional style: 1. Construction of large scale multifunctional welfare center. 2. Construction of (two) new regional welfare facilities. 3. Distributed welfare service by utilizing present community centers.

Figure 14 and 15 shows the occasion, details, and expenditure of maintenance and management for relational facilities of each scenario after the levelling process. Including the results of social impact evaluations, the conclusion was that utilizing present facilities (scenario 3), was a little costless than the others, the local economic ripple effect measurement was higher, and decrease of environmental load was greater, and by utilization, improvement and repair of village community centers will be possible as a public project (else left to the community).

6. Conclusion

Targeting small and medium size local governments whose building stocks, under the financial and manpower problems, are not well utilized effectively, we have developed a method to evaluate present performance level, upgrading of performance by improvement and its cost, and possibility to convert to use of more demand, of the buildings by in-house staff members simply. Another development is, using the result of the evaluation, and a group of facilities in the area as an object, methods to design a number of optional maintenance and management plans, guided by higher plan and change of socio-economic conditions, and evaluate and compare the upgrading of facility's performance by improvement, cost and spending and social impacts under the plans, and to choose the adequate one, which in total will facilitate optimization of total cost, environmental load, and service level. The case studies in I-city has given its concrete example, and proved to be effective.

The FM Industry and Adding Value for Clients

Gerard de Valence
School of Construction, Property and Project Management
University of Technology Sydney (email: g.devalence@uts.edu.au)

Abstract

Many writers on FM stress the importance of the role FM should take in enhancing business performance. So far, the idea that FM itself is essentially strategic in nature, rather than operational, has not been widely accepted by senior management. Different writers take different approaches to this and there is no lack of ideas on how FM can be linked to business performance. This paper argues that the key issue is to help organizations increase the value gained from their use of the space that facilities provide. For the FM industry to significantly change the role it performs for clients and become a strategic rather than operational function will require a long-term approach using four approaches to value-adding for clients. This would be a major change in direction, both for the industry and the perception of FM by clients.

Keywords: Facility management, industry growth, value-add, strategic function

1. Introduction

The task of delivering 'value for money' is an important part of facility management (FM), but it is often not clear what 'value' is in the context of FM. Many writers on FM stress the importance of the business environment and suggest that there is a strategic role for FM in enhancing business performance. This would certainly add value. However, despite the importance of the workplace as a strategic management tool Price (2001) argues those involved in property and facilities, whether in research or professions, do not know how to describe themselves in terms of strategic value added. In his view "buildings operations and maintenance contracts dominate the FM market place. FM practitioners tend to focus on managing costs rather than thinking in terms of adding value" (Price 2001: 1).

While the idea that businesses use their facilities as a strategic resource is not controversial, the claim that FM itself is essentially strategic in nature, rather than operational, has not been widely accepted by senior management. FM is frequently referred to in the context of providing support to business. This divergence of views has encouraged a debate over the future development of the FM industry.

This paper first looks at the debate over the future of FM. In this debate the different directions the industry could, or should, take in its development have been identified, often reflecting different ideas held by these researchers on what FM actually is, or should be. Secondly, the paper considers the relationship between the growth of FM as an industry and the role that the increased use of outsourcing has played in that growth. There is a brief discussion on the nature of value to clients and building owners. This leads to the main contribution of the paper, identification of the four approaches available to the FM industry that can improve its ability to add value for clients. The conclusion sums up these points.

2. The Debate over Future Directions

There has been an ongoing discussion about the future development of FM and the role FM should take in enhancing business performance. While the idea that businesses use their facilities as a strategic resource is not controversial, FM is often seen in the context of providing operational support and the claim that FM itself is essentially strategic in nature has not been widely accepted by senior management.

Different writers have taken different approaches to this. Duffy and Tannis (1993) emphasise the role of workplace design and productivity. O'Mara (1998) is concerned with the drivers of corporate change and development. Alexander (1996) sees FM as enabling organisational effectiveness, and argues for FM to be 'an enabling mechanism which responds to the evolving needs of business' His belief is that the discipline should not be mistaken for a support function. Becker and Steele (1995) carry the workplace ecology argument through to its logical conclusion. Finally, McGregor and Then (1999) make the case that FM is the 'business of space' and Tay and Ooi (2001: 360) claim that "the core competence of a facilities manager is strategic level FM matters while overseeing operational matters … FM must play a bigger part in overall business development, becoming a strategic rather than operational issue".

This range of ideas is matched by the diversity of opinion on what FM is. Tay and Ooi (Table 1 below) reproduce eight definitions that vary from the comprehensive approach of Alexander (1999) or Nutt (2000) to the workplace and business focus of Becker (1990), Then (1999) and Varcoe (2000). Out of these ideas a debate about where FM is going, or should be going, has developed.

Nutt (2000) starts with the statement "the strategic objective of facility management is to provide better infrastructure and logistic support to business and public endeavours of all kinds across all sectors". Again, here is the emphasis on strategic aspects of FM that is not found in practice. Nutt identifies and discusses four basic trails or pathways to the future which are explored. These correspond to the generic types of resource that are central to the FM function: the management of financial resources, human resources, physical resources, and the management of the resources of information and knowledge.

The ideas and analysis that underpin the four trails are important and interesting. It is not clear, however, that they establish a genuinely strategic role for FM, rather than a complex operational role with some longer-term aspects. What the trails identify is the range of core areas for FM, and how developments in technology, work patterns and so on will challenge the industry to develop these core areas over the next couple of decades. In themselves, the trails will not provide the basis for a strategic role for FM, although the opportunities for making powerful contributions based on one or more of the trails are there for taking. Also, the four resource trails seem likely to be subject to radical change towards 2020, with a wide range of possible futures. While the trails share a common objective - to provide strategic and operational support to all of our endeavours - they work to different agendas, serve different interest groups, with conflicting priorities and ambitions.

Table 1. Sample of FM Definitions

Author	Definition of FM
Becker (1990)	FM is responsible for coordinating all efforts related to planning, designing and managing buildings and their systems, equipment and furniture to enhance the organisation's ability to compete successfully in a rapidly changing world
Nourse (1990)	FM unit is seldom aware of the overall corporate strategic planning, and does not have a bottom line emphasis
NHS Estates (1996)	The practice of coordinating the physical workplace with the people and work of an organization; integrates the principles of business administration, architecture, and the behavioural and engineering science
Alexander (1999)	The scope of the discipline covers all aspects of property, space, environmental control, health and safety, and support services
Then (1999)	The practice of FM is concerned with the delivery of enabling workplace environment – the optimum functional space that supports the business processes and human resources
Hinks and McNay (1999)	… common interpretations of the FM remit; maintenance management; space management and accommodation standards; project management for new-build and alterations; the general premises management of the building stock; and the administration of support services
Varcoe (2000)	… a focus on the management and delivery of the business 'outputs' of both these entities [the real estate and construction industry]; namely the productive use of building assets as workplaces
Nutt (2000)	The primary function of FM is resource management, at strategic and operational levels of support. Generic types of resource management central to the FM function are the management of financial resources, physical resources, human resources, and the management of resources of information and knowledge

Source: Tay and Ooi (2001: 358)

For Duffy the history of facilities management has been one of rationalisation. As the discipline developed cost cutting became the predominant objective and the chief distinguishing feature of facilities management in practice. What could have happened was the linking of design and FM, but after twenty years this link has not been established. "What has happened has been very different from what we expected. The skill of managing office space may have developed but the office environment itself remains very much as it was." (Duffy 2000: 372). He sees the challenge as being using design to achieve business goals, and this will require the reinvention and the reintegration of the entire business of design, construction and space management.

Duffy has highlighted the dilemma under discussion. A greater link with design and development of workspace would give FM the strategic role that is being sought. Design is early stage, planning intensive work and involvement here by FM practitioners would deliver strategic significance. However, once again the fact that this is not the case illustrates how difficult it will be for to achieve place in these strategically important stages.

Bon et al (1998) argue that corporate real estate management (CREM) requires an organisational structure that stimulates interaction between researchers and practitioners of CREM. They conclude that the development of management tools for CREM will require close collaboration between researchers and practitioners, with much of the research being conducted by CREM practitioners themselves. Performance measurement is one of the first steps in this direction. Therefore, the most important task is the development of management tools that can help close the feedback loop between managerial action and property performance.

A research intensive approach has much to recommend it, particularly in regard to medium-term improvement in the industry's performance. Will this also deliver strategic relevance? That probably depends on the scope, scale and focus of the research. However, practitioner led research is likely to go down the operational path the industry is already following, if for no other reason than that would be what appeals to the industry's clients.

Price (2002) argues for FM to be more focused on business language and a move from performance measured in terms of outcomes to performance considered in terms of outputs. His evolutionary perspective, also found in Price (2003), suggests that FM has yet to find its place in the marketplace for both ideas and business services. In many ways this sums up the key elements of the debate over the future development of FM rather well, given that FM is typically an outsourced function. In fact, the success of FM as an industry has been closely tied to the growth of outsourcing.

3. Outsourcing and the FM Industry

The response of many large organisations to the increase in demands for better performance, global competition or pressure on their balance sheets was to identify core activities and outsource as much of the rest as possible (Incognito 2002). Indeed, the growth of FM as an industry has been underwritten by the increasing use of outsourcing for non-core functions as business put the ideas of Hamel and Prahalad (1994) into practice. This has been crucial in establishing FM as an industry sector in its own right as organisations moved responsibility for asset management to specialists (Katsanis 2003).

However, if FM is largely responsible for managing an outsourced part of business operations (the use of physical space), how can it be included in the management tasks given to the senior executives responsible for strategic planning for these businesses? In this case, the success of FM will deny it the chance to become the strategic contributor to business performance that so many have claimed for it. Indeed, the more successful FM becomes at taking on and managing an outsourced function, the less likely it becomes that it will be included in the higher councils of management decision-making and strategy. Further, if FM is not included at this level of decision making, how will it be able to increase the value it adds for clients?

The argument for outsourcing is typically based on the perception of cost savings and improved quality. This comes through reduced capital outlay on facilities, manpower and equipment for the client while the provider is responsible for updating and maintaining equipment and technology. Other commonly recognised advantages of outsourcing include freeing up of resources, variable capacity, knowledge transfer from outside specialists, economies of scale by vendors, and it is particularly suited for specialised or risky operations (Embleton and Wright 1998). Outsourcing is seen as a means of concentrating an organisation's resources in its core competencies (Campbell

1995). May (1998) argued that many organisations spend a disproportionate amount of management time managing non-core activities and that outsourcing can increase competitive advantage.

The growth of FM as an industry has been driven by outsourcing, and the future growth of FM will also be driven by outsourcing. There are still large industry sectors where FM is done in-house, higher education is a good example. As clients become more comfortable with using contractors to supply specialist services and the FM in industry becomes more sophisticated in its marketing, customer relations and performance measurement, the potential for continued growth is clear. There is of course a countervailing tendency of clients to take some functions back in-house due to reassessment of importance of technical requirements (Luciani 2005), but the overall trend should be toward more use of outsourcing in certain client industries.

While the figures for outsourcing and views on these advantages and disadvantages would vary across countries and industries, they reinforce the argument that the scope for growth of the FM industry through outsourcing is enormous. However, the problem of strategic relevance found in the current situation thus appears in the future for FM, with the same fundamental cause: managing an outsourced function may be important, but it is not strategic. If the future growth of FM is tied to the increased use of outsourcing, as growth in the past has been, the challenge for FM to become a key part of an organisation's strategic planning will become greater. Growth in the size or the turnover of the industry will not, in itself, solve the problem.

The opportunities that design integration, workspace management, research focus or the four 'trails' identify are more like extensions to the outsourcing based growth path rather than full alternatives. Extensions because they add depth to the outsourcing based model, but do not add breadth or offer a substantially different growth path. How to deliver different forms of 'extended outsourcing', where there are more of the higher value-added services present in the outsourced package, may be the key challenge in the future of FM. But what is value in the context of buildings and structures?

4. Value to Clients and Owners

How do buildings create value for construction industry clients and building owners, and what is the role of the FM industry in maintaining or adding value to clients and owners? That clearly depends on what particular concept of value is to be applied, out of the range that are possible.

Best and de Valence (1999) suggested that, for buildings, the forms of value include: utility; use as accommodation or for income; exchange or sale value; esteem, prestige or iconic value; and a quality-cost-functionality relationship (pp. 14-17). Similarly, Spencer and Winch (2002) cover three broad sources of value: financial value, based on capital and operating costs and investment value: business processes and the people, space and productivity matrix; and the symbolic and aesthetic value of buildings. There are many other variations on these ideas (see for example Kelly, Morledge and Wilkinson 2002).

For the FM industry, the idea of value has to be strongly related to the performance of the space occupied by the client, in the client’s terms. This makes a ‘one size fits all’ definition of value difficult to find, because clients come in many shapes and sizes, with a wide range of requirements and levels of service demanded.

5. Adding Value

How can the FM industry improve its ability to add value to the way businesses approach the role, function and use of physical space? One way of responding to this challenge is to break the answer down into several parts, like a puzzle the industry has to solve. Four distinct but interrelated approaches to adding value for FM clients are identified and discussed below.

The first approach is based on the idea of business performance itself. Despite the emphasis placed on this, it is neither obvious nor constant. Both how performance is measured and how it is rated change over time. For example, the impact of Kaplan and Norton's (1996) idea of the 'balanced scoreboard' has been significant. Likewise, the growth of 'triple bottom line' reporting (financial + social + environmental results). Other measures that are widely but not universally used include R&D, innovation or revenue from new products, market share and financial ratios such as return on equity, revenue and profit growth. The implication here is that the specific indicators a FM client uses to measure performance need to be understood and targeted by the FM provider. Further, the particular measures applied to facility use and performance need to be developed for each client and made relevant to the client's business practices and objectives.

A second approach to the problem is the changing nature of strategic planning. The detailed, prescriptive form of business planning is no longer popular, and what is considered strategic in business also changes over time. When Jack Welch became CEO at GE in 1983 one of his first actions was to close down the strategic planning department (with 200 people), and start the annual seminar series at Crotonville that became the foundation of GE's success (Welch 2001). Mintzberg (1994) discusses the history of strategic planning in business, and argues that neither business planning nor strategic analysis are any less important now than in the past. It is how these are done that creates their relevance or lack of it. The opportunity here is for the FM provider to apply the specialist expertise and experience gained from improving facility performance and to identify how value can be added for clients in the long term, through more innovative design, use and management of facilities.

A third approach to meeting the challenge concerns the development of the industry. Tay and Ooi (2001) suggest a number of areas for theoretical development in FM (see Table 2 below) and three main building blocks of FM professionalism. First, FM as a discipline must be clear on its roles in industry and in organizations. Second, for FM to be taken seriously by management it has be a contributor to profits and manage facilities to enhance performance of the firm. Thirdly, FM must develop its own specialist knowledge and toolbox in managing the workplace across six areas, with an emphasis on workplace performance and performance measurement. They conclude that FM remains reliant on management and technical knowledge from other fields. The FM industry needs to establish a core knowledge base and the techniques available for its application.

Reliance on management and technical knowledge from outside FM is not in itself a problem, especially in a time of positive externalities from knowledge, an emphasis on training and human capital, and increasing returns from the effects of network economics on industry. Perhaps the challenge has more to do with sorting the wheat from the chaff in management ideas, not getting distracted by management fads and buzzwords, and coping with information overload with so many business management books being published.

Table 2. Suggested Theoretical Developments in FM

Scope of FM	**Suggested areas for theoretical developments**
Location	Developing a model for locational decisions Studies on the relationships between locational choice and business performance
Type	Understanding workplace requirements for various facility users, e.g. schools, hospitals, factories, etc.
Quantity	Developing a model to forecast space requirements
Quality	Performance measures to assess the quality of workspace Developing performance standards
Allocation	Studies on emerging work patterns and their impact on space allocation
Content	Studies on the relationship between content layout and work performance

Source: Tay and Ooi (2001: 362)

Finally, the fourth approach is the type of contribution FM makes to its clients. Profit margins can be increased by either driving down the cost of products and services, or by pushing up their value and increasing the price customers' will pay. The strategic objective is to maximise the difference between value and cost, and to build value which customers perceive to be better than that offered by competitors. For most businesses changes in revenue presents both the greatest opportunity and the greatest threat, and is more significant than major costs such as staff, technology and equipment and occupancy costs. Therefore there are greater opportunities to improve organisational performance through revenue and productivity improvement rather than through cost reduction and the risk to revenue and productivity due to poor facility design and management is far greater than the expense of building or occupying space.

Lower facility costs lead to lower production costs, and to reduce occupancy costs organizations can take a range of measures, such as re-negotiating leases, teleworking and hotelling and lowering the workspace ratio (Turner and Myerson 1998). The workspace ratio varies between industries, for example the Property Council of Australia found the financial services sector averages about 15 square metres per employee and the legal sector averages 20 square metres per employee. For any organization there is some level of optimal space efficiency (Smith 1999). Another factor that is important in industries undergoing restructuring and 'creative destruction' is reducing the cost of churn (relocating employees). For firms in these industries the cost of churn can be as high as rent. Space can contribute to strategic change through aligning facilities with organisational objectives, structure, cultural values and workstyles. Finally, organizations continually seek ways to reduce capital costs of buildings, but capital expenditure is minor when compared to costs over the life of the fitout and services. The issue here is maximising the benefits of capital spent to get the best return possible.

On the value side, strategic decisions on property location, space forecasting and usage are important. However, what is crucial is how FM can contribute to developing the competitive advantage of the firm, particularly for firms or organisations attempting to enter new markets or confront global competitors. These firms are typically increasing their efforts to innovate and to develop new products or services. Also, facilities can be a source of competitive advantage if location or amenity is a barrier to entry for potential competitors

Organisations are also looking for work environments which improve productivity and efficiency, support innovation and learning, allow introduction new ways of working, increase information exchange and accommodate a diversity of management and work styles (Zelinsky 1998). The pressure to achieve higher productivity through use of teams with more effective means of communication, both electronically (through bringing different departments together) and spatially through workplaces designed to encourage increased group and shared working patterns, is one of the great opportunities for FM to add vale to clients.

6. Conclusion

Organisations spending money on the renovation or maintenance and use of a building try to get value for money, usually within a fairly clear budgetary framework. Those who authorise the expenditure will be looking at how much is spent, what return can be expected and how satisfied they will be by the outcome. The task of FM is to help users get the most benefits from their properties and facilities.

There has been an active debate over the future direction and development of the FM industry. This debate has highlighted a number of key issues for the industry, but also bought out the wide range of approaches taken by participants to both these issues and the appropriate role of FM.

This paper has argued that, if the FM industry is to significantly change the role it performs for clients and become a strategic rather than operational function, it will require a long-term approach focused on value-adding rater than cost saving. This is a major challenge, both for the industry and its clients. This paper then identified four distinct but interrelated approaches to adding value for FM clients.

The first approach involves performance measurement. By developing specific measures of performance to apply to facilities, to be targeted by the FM provider the industry can help organizations meet a range of performance criteria. These will vary between organizations and will typically be customized to take into account the location, purpose and strategic significance of the facility. Establishing for each facility this strategic significance could be the means to become relevant to and provide input to organizations' strategic planning.

The second approach is to increase this strategic relevance of the FM provider’s contribution to the client’s business practices and objectives. The opportunity here is to identify how value can be added for clients in the long term, through more innovative design, use and management of facilities.

The third part is developing FM professionalism. This involves the use of analytical tools for locational decisions, space use, work patterns and other characteristics of the modern work place. The objectives of this analytical approach are to help organizations lower occupancy costs and increase the value gained from their use of the space their facilities provides. This is the fourth and most important part of the answer. In a world of ever-increasing competitive pressure and shorter product cycles, value creation is the key to survival for many organizations. By making itself an integral part of the value creation process, FM will become a strategic function.

Until recently few organizations paid much attention to how the planning, design, and management of their buildings and associated systems, equipment and furniture affected the organization's ability to meet its business objectives. Information technology and competition, which have driven organisational changes, have placed new demands on organizations' physical resources, increasing awareness of the importance of FM. As this has happened, the role of the facility manager has grown to include more than the maintenance of the physical structure of the workspace. There is an opportunity to shift the emphasis from controlling the cost of occupying and using facilities to the contribution of the workspace and its infrastructure to the productivity of the organisation and the efficiency with which it uses its resources. This fourth approach would allow the FM industry to add significant strategic value to the operations of clients.

Therefore, the opportunity exists for the FM industry to increase its strategic relevance to clients. The idea that businesses use their facilities as a strategic resource is not controversial, but because FM is typically an outsourced function the idea of FM as strategic, rather than operational, has not been widely accepted by clients. Different writers have taken different approaches to this and there is no lack of ideas on how FM can be linked to business performance. This paper has argued that the key issue is to help organizations increase the value gained from their use of the space that facilities provide. For the FM industry to significantly change the role it performs for clients and become seen as a strategic partner, rather than as an outsourced operational function, will require a long-term approach focused on value-adding rather than cost saving.

Change Management within FM

Alexander Redlein
IFM/TU Vienna, Austria (email: redlein@tuwien.ac.at)

Abstract

FM is always related to changes: Changes within the core processes having impact on the requirements for facilities, changes in technology and processes demand higher productivity and effectiveness. However, in contrast to the core business, methods of classical change management and process re-engineering are not yet applied in Facility Management.

This paper shows how classic methods of change management, process modelling and re-engineering can be used in the field of Facility Management. It presents a theoretical overview about the current methods and describes their advantages and disadvantages.

In the second part, the usability of these methods within FM is analysed. In about 20 case studies with companies the methods for process modelling and re-engineering were tested in practice. The results of the case studies are presented. Based on the results, adaptations and further developments of the current concepts to improve their usability within FM are pointed out and a new methodology based on classical process modelling and re-engineering methodologies is presented.

The new methodology ensures that the strategy of the company as a whole and the strategy in respect to facilities are taken into account. It also ensures, that all relevant processes are defined and the necessary changes in organisation and ICT are identified and implemented in a proper way.

This methodology has already been used in case studies and proofed its usability.

Keywords: process optimisation, process re-engineering, IT and organisation

1. Introduction

Within all industries modern companies have to change to survive in a rapidly changing world. Whereas 30 years ago an employee did the same job for his whole work-live, today’s employees have to adapt to new situations and tasks quite often. Project orientation and new forms of collaboration led to more flexible forms of organisations. Today it is common to change the team and the workplace at least once a year. In some industries like telecommunication changes happen even more often. These changes also have impact on the core FM processes.

In most cases changes and optimizations within the core processes are carried out by using the methodology of business process reengineering. Business process reengineering can trigger the necessity of structural measures in order to provide the required infrastructure, can lead to changes in technology and trigger processes within FM. Therefore, process optimisation projects contain, apart from the usual activities of process optimisation, also the matching with the infrastructure. This is an iterative process, changes in the core processes lead to changed requirements for infrastructure, which offer altered framework conditions for the core processes. This can lead to changes and opportunities within the core processes. An optimum organisation for these highly dynamic and complex planning projects consists of the following teams (extended project team; see [1], p. 145):

- the team for an optimisation of the core processes, mostly lead by the organisation development;
- the team for the planning of the infrastructure (building, systems, etc.), lead by the process controller of the planning process;
- the controlling team with the task to safeguard the co-ordination of both teams.

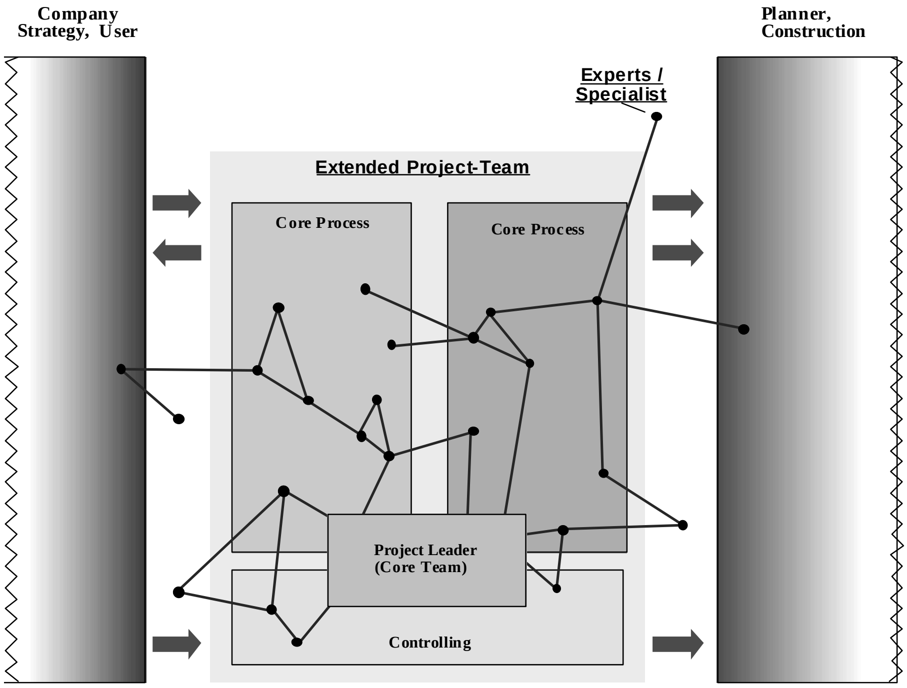

Figure 1: Organisation of highly dynamic and complex planning projects [1], p. 145

These teams are subordinated to an overall project leader, the overall process controller. He has to safeguard the comprehensive cost-benefit optimisation of the project. Today traditional planners cannot perform these tasks and are often not accepted in this role by the owners of the building, because they lack the knowledge of process optimisation. However, there is already an approach of planners towards this role. Some companies, such as Bene Consulting or DOMUS FM, already perform process analyses in order to merge the results into programming. But these planners do not perform an optimisation of the core processes or do not even trigger optimisation. Therefore, their approach lacks optimisation of core processes, but they cover the remaining activities of the process controller.

Traditional organisational consultants also cannot fulfil the tasks of a process controller in a comprehensive manner, because they lack experience of the planning of the infrastructure. A further potential process controller is the facility manager. He frequently assumes the role of the process controller for the planning of the infrastructure in case of utilisation by the proprietor. He is seldom given the task of optimisation of the core processes, although in some FM definitions also the tasks of personnel development are allocated to the facility manager. The future will show who is able to assume the comprehensive role.

Besides this question, who should carry out the tasks, there is another question, an even more interesting. It is about the methodology to be used for the optimization of the FM processes. In literature there are no guidelines. Therefore a team of researchers from the Viennese Technical University searched for methodologies employed in the core processes. The most widely spread and accepted one is business process reengineering. Therefore this methodology is analysed in detail within the next section.

2. Business process reengineering

A few years ago, most companies were organised according to Taylor. Work was splitted up in small tasks, being carried out by specialists. Between this specialists there was a lack of communication. There were even communication barriers. It was almost impossible to reach goals of time-, cost-quality and innovation leadership. Therefore, a change took place within most of the organisation.

The companies began to define their core competences. The core competences of a company are the specific abilities, which differentiate a company from others. Thus, as a basic data source to determine their core competence, they used the analysis of the needs of the customer, market analyses, analysis of the own potentials and benchmarking with the competitors in the industry.

Based on this, business process reengineering was used to “optimise” the core processes. Business process reengineering leads to a fundamental rethinking of the processes within a company. The goal of this rethinking is to gain time and cost reduction. This leads to a new conception of the work/tasks which have to be done.

Instead of Taylorism, which is characterized by the division of the work into small tasks carried out by different specialists, business process reengineering combines tasks, that belong together, to larger process steps. These lager steps have to be carried out by one person instead of many (comp. [2]). The main goal of business process reengineering is to define simple processes with few interfaces by creative reintegration and redesign of the core processes (comp. [3], p.5 and p. 49]). This also means a change of the organisation. The current horizontal organisation is changed into a vertical organisation characterized by team work.

The base line for all these changes are the needs and expectations of the customers. By changing the organisation (processes and company organisation structure) the company should be enabled to provide a better service to the customer according to his needs, and should be easily capable of adapting to changes in the customer’s requirements. In order to be able to carry out these changes the general management has to support these activities.

According to business process reengineering, the change process consists of the following parts ([3] p.42):

Renewing: In this step the needs of the customers are analysed and new business areas are defined (comp. [4], [5] p. 34ff, [6])

Relocating: In the next step changes of the location and production methodology are to be defined (comp.[7] p. 286ff, [8])

Reengineering: The next step represents the core business process reengineering, which includes the redesign of the core processes and the change of the company organisation structure (comp. [9], [10], [11])

Revitalizing: The next step is to develop the knowledge of the employees (comp. [12], [5] p. 251ff, [13], [14])

Reframing: The last step is to realize the mental change by changing the subjective behaviour (comp. [15], [16] p.116 ff)

Business process reengineering itself consists of the following steps (comp. [3] p. 50):

Communication of the necessary changes: The communication of the goals and areas of changes has to be done by the board of directors. In this step the teams and the process owners have to be defined for each process. This step should give confidence to the middle management, trade union and the employees. Change can often lead to fears about employment which leads to opposition to change.

Identification of the core processes: The core processes which are important for the success of the company have to be defined. Basis for the estimation of the importance are descriptions of the processes at a high abstraction level.

Selection of the core processes that have the highest need for change (not working properly, causing problems, not fulfilling customer needs, possibility to change processes): This step also includes the definition of more detailed goals for the selected processes regarding time, cost and quality.

Analysis to understand processes: This step is based on workshops, interviews and observations. It is quite often supported by external consultants as they might bring in new ideas.

Collect ideas for redesign and optimization: This step is carried out together with the process team and internal/external process specialists to find new ways of carrying out processes.

Development of concept: Based on the gathered knowledge and ideas a concept for the optimization of the core processes is defined. This concept includes the process steps, the organisation and the ICT support. In this step the following principles have to be taken into account:

- Relocation of decisions to working level
- Definition of tasks per organisational unit in a way to reduce interfaces
- Reduction of controls
- Combination of organisational units

Coaching of process owner: The last step is the coaching and training of the process owner and his team, so that they are capable of taking over the new tasks and responsibilities.

All these steps should follow the core principles [9]:

- Follow the natural sequence of process steps
- Definition of process variants (e.g. simple/difficult task)
- Redesign of customer contacts
- Introduction of a responsible person for all customer contacts to co-ordinate all tasks carried out for each customer
- ICT to enable new solutions

The change process based on the results of the business process reengineering can be carried out in two different ways:

Firstly by a radical change of a few core processes (American attempt comp. [9], [17], [18]) or secondly by a continuous improvement within the current structures according to Kaizen and [19] (Japanese attempt).

The American attempt leads to a lot of problems with the employees who often oppose to the changes. It also causes problems with the trade unions as they fear that the changes cause the loss of jobs. The Japanese way often cannot reach the goals as changes happen very slowly and the final target can only be reached after a long period of time.

Combining these two extremes leads to the European way of change management by business process reengineering. The European way makes changes step by step and in this way the whole company is changed and not only a few core processes. It also includes tasks to change the habits and the qualification of the employees (comp. [20]). This European way of change management is also called evolutionary change management.

3. Advantages and disadvantages of business process reengineering within FM

For process optimisation and change management in the area of core business the methodology of business process reengineering is known and accepted. Business process reengineering provides a methodology for managing the change process. It can be used for every project within every industry reaching from production processes to office automation.

Consultants and managers are well trained in this methodology. Therefore internal or external support can be found easily. In literature best practise examples can be found for several processes within different industries.

Based on this knowlegde a research group of the Viennese Technical University applied the methodology of business process reengineering within 20 case studies. The case studies were mainly carried out in companies running office buildings. The sample consisted of different industries reaching from production industry (e.g. Beiersdorf AG), banks and insurances (e.g. Dresdner Bank, Bank Austria), energy providers, public bodies (Ministry of Finance) and hospitals to outsourced facility management companies and real estate managers (e.g. LGM, SGM, ATIS international). Their FM departments wanted to improve their efficiency and effectiveness. The goal of the research projects was to optimize their processes, organisation and ICT support. One main goal was to improve the customer orientation and in this way the customer satisfaction. The second important goal was to reduce costs.

After the first case studies the following weaknesses of the methodology within FM were recognized:

1. Business process reengineering has *not been applied to FM processes* by now. Consultants and organisation managers know the methodology but not FM. They also do not know the specific problems and drawbacks in the area of FM. In literature no FM relevant best practise can be found and there are no specific guidelines.
2. Within business process reengineering normally only external customers are taken into consideration. FM also has to take care of *internal customers* as each employee of the company is a customer of the FM department.
3. A *detailed structure or guideline* how to apply the methodology within each step *is missing*. The methodology provides an overview guideline on what steps have to be carried out, but gives no advice how the steps can or should be carried out in detail. This internal guideline is especially missing within the first step "**Communication**" and the step "**Analysis to understand processes".**
4. The *start of the business process reengineering projects was difficult*. The strategy of FM and the goals of the process optimization project the strategy have to be defined before the board can communicate them. This task has to be carried out on a team basis - consisting of the facility manager and the board. A definition of the FM strategy without detailed knowledge of the companies strategy and the board will often lead to wrong decisions as company goals and strategy have a strong influence on FM. For example when the company grows or reduces FM has to include this change in its strategy.
5. The step "**Analysis to understand processes"** mainly consists of workshops and interrogation of the employees on how they currently do their work in order to define the current processes. Therefore process modelling methodologies are used. But the business process reengineering methodology gives no advices on which methodologies fit best. A second problem is that this step takes very long and team members are often not willing to carry out the next two steps "**Collect ideas for redesign and optimization"** and **"Development of concept".** Therefore in many cases the only optimization reached within a business process reengineering project is that the actual process is supported by ICT. But this cannot leverage the whole potential of optimization.

In order to overcome these disadvantages, the classical business process reengineering methodology was enlarged in two areas.

The *value analysis* was used to provide a better general structure and guideline to the projects. The value analysis has the advantage that it can be used for any project type. It provides a clear and structured guideline how to carry out projects. By adding the parts of the value analysis to the classical business process reengineering methodology the disadvantages 3 and 4 could be solved.

To overcome problem 5 the *Scheer Architecture for Information Systems (ARIS) methodology* was applied for the steps "**Analysis to understand processes",** "**Collect ideas for redesign and optimization"** and **"Development of concept"**. This methodology is used frequently for process modelling. It supports not only modelling the processes and its steps but also includes the organisations carrying out the steps and the ICT tools supporting the steps. The use of the ARIS model without applying the business process reengineering methodology would not provide the required results as the ARIS methodology is rather restricted to modelling processes and does not include areas like strategy analysis and change management.

4. Value Analysis

The value analysis is an efficient way to optimise products and immaterial objects like processes and concepts. It was developed by General Electric at the end of the 40s as a tool for cost reduction. Since 1962 it is also used in Europe, with the goal to analyse and optimise structures of functions under the aspect of value increase. Based on this idea it soon developed to a more powerful tool than a simple method for cost reduction. In this new form it could be applied for the quick and effective generation of new concepts, but also for the improvement of existing ones. (see [21] p. 371 and especially [22] 479 f.)

According to DIN 69910 and ÖNORM A 6750-6757 the value analysis consists of the following steps:

Table 1: Steps of the value analysis

Basic Steps	Intermediate Steps	Goals
Step 1 Prepare for Value Analysis	Intermediate step 1 set up goals in rough outlines	The first step is a definition of the goals. This makes it possible to check the result of the project later. The details can be added later in the project. In the case of the FM projects this step has to be carried out together with the facility manager and the board of directors.
	Intermediate step 2 plan value analysis work	The next step is the creation of a project schedule (people, tasks, time, ..). The required persons must be selected and teams must be formed. They must be informed about the personnel resources they have to spend and the work they have to deliver for the project. This step is headed by the facility manager.
Step 2 Define Situation	Intermediate step 1 gather information	As to provide a profound basis for the subsequent work, available information must be gathered and sorted out.
	Intermediate step 2 define functions	The functions are identified and specified. The level of detail depends on the goal of the analysis.
	intermediate step 3 estimate tendencies	The market tendencies have to be estimated. This makes it possible to evaluate the probability of changes.
	Intermediate step 4 identify costs	The costs of each function defined above must be calculated.
	Intermediate step 5 define situation	The definition of the whole situation can be derived from the information above. The knowledge about functions, costs and the estimation of tendencies make it possible to describe the situation in detail.

As can be seen easily, step 2 corresponds with the steps of the business process reengineering methodology. The research team decided to integrate only the first step of the value analysis into the business process reengineering methodology but to keep the steps of the value analysis in mind as a more detailed description or guideline for the steps of the business process reengineering methodology.

5. ARIS Model by Scheer

The ARIS model is a well known modelling methodology within ICT. It consist of 4 “views” which describe the following elements (comp. [23]):

Process View: This part of the model supports the description of processes. The description can be on a very abstract level using flow charts or on a very detailed level using EPK (Ereignisgesteuerte Prozess-Ketten).

Data View: This part supports the description of the required data structure. The description is mainly done by Entity Relationship Diagrams (ER-Diagrams) showing the required entities like building, floor and room and the relations between them.

Organisation View: This part describes the organisation structure. Beside the organisational units and their structure roles are defined. A role represents employees carrying out similar tasks.

Control View: This view brings together the elements of the views described above. It shows the relations between them. That means it describes the flow of process steps, describes which process step is carried out by which organisational unit (role) and defines which step is supported by which ICT tool.

The methodology can be used to model the As-Is status of the processes and the Should-Be status.

6. New methodology

In the course of the case studies it was found out that there is the danger to model the As-Is status in strong detail. This procedure takes a long time. As the team members have to carry out their “normal work” beside the project they become tired. As a result, when the As-Is analysis is finished, they are not willing to support the next steps. As a solution for this problem the research team combined the steps “**Analysis to understand processes”** and “**Collect ideas for redesign and optimization”**. This was done in an easy way. The process steps not being carried out properly or being missing at all were included in the As-Is analysis, but they were marked with a red colour. This means that the starting points for improvement were already included in the As-Is analysis. This change in methodology led to more encouragement of the team members as they could already see in the As-Is analysis were changes and optimization should take place. In some cases the Should –Be structure was already developed.

This change in methodology made it easier to carry out the next step **“Development of concept”.** In this step the Should-Be situation has to be defined. As the process steps that were missing or not properly carried out are already included and marked “red” within the process charts, the staring point for the optimization is already defined. So the time and effort to define the Should-Be situation was reduced dramatically.

The experience of the case studies regarding the disadvantages of the classical business process reengineering methodology and the enlargement of the classical methodology by the value analysis and the ARIS methodology to overcome this shortcomings, led to a new methodology consisting of the following steps:

Prepare business process reengineering project: The first step is a definition of the strategy of FM and the goals of the project based on the general strategy of the company. This makes it possible to check the result of the project at the project end. This step has to be carried out together with the facility manager and the board of directors. In this step the teams and the process owners also have to be defined.

Communication of the necessary changes: The communication of the goals and area of changes has to be done by the board of directors. This step should give confidence to the middle management, trade union and the employees. As often change leads to fears about employment which leads to opposition to change.

Identification of the core process landscape[1]: The core FM processes have to be defined. Basis for the estimation are descriptions of the processes at a high level of abstraction. This step also includes the definition of more detailed goals for each process regarding time, cost and quality.

Analysis to understand processes and collect ideas for redesign and optimization: This steps uses workshops, interviews and observations. The internal team is quite often supported by external consultants, as they can bring in new ideas.

Development of concept: Based on the gathered knowledge and ideas a concept for the optimization of the FM processes is defined. This concept includes the process steps, the organisation and the ICT support. Outcome of this concept are the required changes in organisation (new organisation structure) and ICT (e.g. tools, ICT landscape, integration of tools).

Change management for organisation: According to the requirements of the concept the organisation has to be changed.

ICT implementation: According to the requirements of the concept the new ICT landscape must be implemented and integrated.

Coaching of process owner: The last step is the coaching and training of the process owner and his team, so that they are capable of taking over the new tasks and responsibilities.

The new step “**Prepare business process reengineering project”** makes sure that the strategy of the company as a whole and the strategy in respect of facilities is taken into account. The step

[1] Selection of the core processes was skipped, as it was found out that FM process landscape consists only of seven to ten processes and all of them were important for the success of FM. So all of them had to be taken into consideration.

“**Identification of the core process landscape”** assures that all relevant processes are defined. The step “**Development of concept”** identifies the necessary changes in organisation and ICT. Together with the steps “**Change management within organisation”** and “**ICT implementation**” a proper change management and implementation is granted.

7. Conclusions

This new methodology was already used in several case studies. It could be proofed, that by enlarging the classical business process reengineering methodology by the value analysis and the ARIS methodology, the disadvantages could be overcome. The new methodology proofed its usability and efficiency in the case studies carried out.

Nevertheless, the appliance is still very time consuming. Therefore, in the next step the research team wants to define reference process models for most of the “core” FM processes. These process models can be used as reference for the modelling of the processes within the companies, which will reduce the efforts in time and cost.

Quality Assurance in the Facility Management for Public Real Estate

Maria Rita Pinto*
DICATA, University of Naples "Federico II", Italy (pinto@unina.it)
Stefania De Medici**
ARP - Syracuse, University of Catania, Italy (s.demedici@unict.it)

Abstract

In order to reduce the burden of an efficient and effective direct management of the real estate, Public Organizations often delegate the management of their heritage to Private Organizations. A whole control of management activities and the assessment of quality represent the first request expressed by the Public purchaser.

The present paper points out methods and tools to control the management procedures of the public building heritage entrusted to Private Organizations. The work establishes parameters that affect the building's quality and the conditions in which the information examination and exchange among operators is to be carried out.

The control activity requires a continuous monitoring of management procedures, that can be performed only by an adequate informative system focused on the basis of the specific characteristics of the real estate and of the contractual agreements. The system should guarantee a continuous exchange of information between the owner and the Management Organization, in order to reach the quality control of the facilities management, and to convey the needs of the purchaser, determined by its political, social and economic strategies. Moreover, in each step of the management process, the Public Organization should have the access to specific information, as the following:

- building and plant data;
- maintenance plan and procedures of intervention;
- working progress and shifting by timing plan;
- resources in relation with the available budget.

These data should be periodically controlled by the purchaser in order to verify the quality of the management activity and give the Management Organization corrections to optimize the facility management. The continuous update and aggregation of information through the informative system and the control of each step and procedure done by the Public Organization, allow a timely action in case of disorders and not-performance of the contract.

The research purpose is to create a methodology for quality management to reduce the risk of mistakes in the steps of analysis, inspection and intervention, singling out the responsibilities of the maintenance managers and verifying the respect of procedures and activities included in the contract. The plan is focused on meaningful parameters to control the performance levels that should be guaranteed by the Management Organization, in terms of:

- reliability of the buildings' information;
- effectiveness of the diagnosis;
- ability to forecast;
- timeliness of intervention;
- optimization of the cost;
- satisfaction of the users.

Keywords: quality, facility management, public real estate, informative system, control.

1. Introduction

The singling out of strategies and procedures aimed to recover, maintain and exploit the public heritage is one of the main objectives in order to optimize the built resources. The Public Administration development policies should direct the planning of maintenance for the public real estate. The knowledge of these policies allows the optimization of investments in relation with the performance levels required. In fact, the result of an effective and efficient management of the public real estate enhances the whole area, having positive repercussion on the private heritage too [3].

Nevertheless the Public Organizations owner of big real estates often entrust private companies to manage their property. This choice is due to shortage of their staff and liquid assets, lack of competence in building maintenance, complexity of the management procedures of contracts and financing [1]. In fact, in order to optimize the public resources, today the Public Administrations rely on themselves only for their core business, such as the activities that have to satisfy the needs of citizens. Therefore, for the technical services, as for the larger part of their accessory activities, they usually entrust private companies. Nevertheless, the Public Organization should continue to control the activities performed by the Manager Organization, verifying the information reliability, their updating, the correct use of the collected data in inspections, diagnosis and intervention steps. This information allows the purchaser to control the conservation condition of its real estate and its value in time, in order to single out and assign the maintenance financial resources.

The present study's aim is to supply the Public Organizations owners of building heritage with a methodology and tools to control the management of their real estate. Today, the Public Organizations need effective tools to control the quality of the facility management, in order to verify the respect of contractual agreements, the coherence with the strategic policies planned by the purchaser, the conservation and exploitation level of the real estate.

The facility management is characterized by different activities and services, constantly performed in time, that require a managerial approach, involving different competencies. The Manager Companies should be flexible and dynamic, adjusting their organization to the specific need at the specific time.

In Italy, in the last ten years many companies involved in management of big real estates have been formed [8]. They can provide technical, legal and administrative services. Nevertheless the Public and Private Organizations that have entrusted their real estates to Private Manager Companies did not concretely benefit of their action, neither in maintenance nor in exploitation of the heritage, or in optimization of the financial resources available.

The ineffectiveness and the inefficiency of the management activities, in the case of facility management contracts, depend on many factors, mainly in building maintenance. In fact, the quality of the results is related to variables that can be found in each step of the management process, starting from the interventions programming to its carrying out.

In order to increase the management quality, the purchaser organization should perform control activities along the whole process, requiring corrective measures timely. But the Public Administrations are not ready to carry on this role yet; in fact, in the facility management contracts, they delegate not only the maintenance intervention, but the whole management activities, including the survey of the technological efficiency of the buildings, their maintenance need and planning of management actions. Meanwhile, the purchasers are not able to control the management results, both in terms of comparison of costs and benefits, and in terms of quality of granted services. The Public Organizations sometimes evaluate the tenders made for the contracts, taking into account the proposed methods and tools to control the services quality: this means that the Private Organization suggests itself how to control its own job! In other circumstances, the control consists in formal checks: delivery reports on fixed days, completeness of reports on the activities advancement, delivery of cost control reports and certificates.

The complexity of managing a big real estate is mainly due to its heterogeneity: public heritage usually includes buildings of different ages and with various uses. The age is strictly related to the buildings' features (typology, materials, construction techniques, finishing, etc.), that affect the choices of maintenance intervention. The use determines requirements that should be satisfied by the building: the minimum performance levels that must be guaranteed change in relation with the users' needs. Durability of technical elements is affected at the same time, by materials, construction techniques and use. Therefore, the frequency of check, inspections and maintenance interventions are related with buildings' features and use.

Durability is also due to the materials and intervention techniques employed in building construction and maintenance. Public real estates usually include stone or brick-wall, reinforced concrete, steel, mixed structure, etc., with different types of technical elements and plants. This variety in building typologies, requires a careful control on the analysis methods, the frequency of inspections, the choice of intervention performed by the Manager Organization, that should be adequate to each case [7].

2. The Control Activity in the Steps of Maintenance Management*

The management of public buildings requires a thoroughly organized census and analysis. The absence of these has often conduced to an insufficient knowledge of the building, to the use of ineffectual technical and financial policies.

The process of census starts with the individuation of the building. The following steps are the knowledge of building, its coding and classification, and the evaluation of the building. The lack of knowledge of the real value of public properties and their temporal deterioration does not permit the setting up of a good maintenance policy, and does not allow adequate financing of extra-maintenance and investing.

In fact, the maintenance policies are often founded on urgency, based on rapid evaluations and lack of objectiveness. The maintenance management of public buildings is often founded on innovative ways, like Global Service. Unfortunately, in Italy the step of census is frequently skipped or it depends on the Global Services' bidder [4].

The Global Service contracts usually settles that the quality of the management activities have to be controlled on the basis of minimum performance levels, that should be previously fixed. These levels should be established not only on the basis of the buildings use, the laws and the technical standards, but also on the ground of economic parameters, defined according with the purchaser's strategies and the users' needs. In fact, the programming of maintenance should be founded on a clear expression of the purchaser's aims: the lack of a briefing activity affects the effectiveness and the efficiency of maintenance.

Often the Public Organizations decide the priority of intervention on the basis of political strategies, not considering available funds and effective needs. They are unable to establish building policies compatible to all. This because there is no definition of roles among political and administrative bodies, and most political bodies do not program further ahead than their predicted term.

Another problem is the internal conflict within the Public Organization itself. There is a lack of connection among different sectors, such as management, financial services, technical services, acquisition or sale of buildings, and urban planning. This is due to a lack of skills in the management of buildings, which can be explained through the following considerations: the introduction of managerial logic requires gradual innovation and skills diffusion; the management policy is static; the management policy is often considered an exclusively political issue, that does not require a technical support; the organization does not allow relationships among its internal units.

Some Public Organizations tried to solve the problem of lack of knowledge of their buildings through an initial step of census (individuation of the building; knowledge of building; coding and classification of the building; evaluation of building). Nevertheless, many Public Organizations that undertake the Global Service, have a lack of adequate legal, administrative, physical and functional knowledge of the buildings, so that the object of the contract and the costs are often not well established. In the end, the control of the quality assurance and of the offered services is difficult for the Public Organization for this lack of knowledge.

The control activities that the purchaser should perform in maintenance management can be summarized as follows:

STEP 1 - Building knowledge

In this step the quality control should be focused on the following parameters:

- completeness of information on the building's technical elements;
- adequacy of survey methods, evaluated on the basis of the needed detail degree, of the available financial resources, on the skill of the operators involved in the survey, on the available equipment, on the accessibility condition of the building and its parts.

The building information should be surveyed using check-lists, in order to guarantee the comparability of data and to easy up and quicken the operators' activity.

STEP 2 - Planning of inspections

The inspection methods and frequency should be adequate to the building's construction features. For big and heterogeneous real estates, it is necessary to plan inspections on the basis of the information surveyed in each building. Durability of the materials and technical elements, building localization and use are the parameters that should be controlled to program the inspections.

In order to guarantee the quality in inspections we should control the following parameters:

- required operators' skills in inspection activities and necessary equipment;
- environmental conditions of each building (air pollution, traffic, acid rains, etc.) that influence the scheduling of inspections;
- accidental factors, that can speed up the degradation process or produce damages, requiring unforeseen inspections or interventions;
- accessibility condition of the building and its parts, that affect the completeness of information.

The prevision capability is founded on an effective and efficient inspection plan and on reliable diagnoses. The quality control in inspection activities allows the Manager Organization to optimize maintenance, reducing, in time, the controls frequency and the interventions extent.

STEP 3 - Diagnosis

The results of the diagnostic activities depend both on the accuracy and completeness of the surveyed data, and on the professional skills of the operators involved in data management. A correct diagnosis can ameliorate the maintenance, guaranteeing timely interventions and increasing building's life cycle. Often the relationships between degradation causes and degradation phenomena is not easily comprehensible. This because many causes can be related to a single degradation/damage phenomenon or the decay can be the result of a chain process.

In the diagnostic step, the quality control should be focused on the following parameters:

- reliability of the relationships between causes and degradation phenomena;
- accuracy of the analysis of degradation evolution;
- survey of the effects of damages and decay of each technical element on the whole building system.

STEP 4 - Intervention

The information system for maintenance management should describe the interventions needed to improve the technical elements' performances, showing the intervention's frequency and length, the operators, the equipment and the required materials. The information system should also show risks or troubles for the users involved in the maintenance intervention.

The quality control should be performed on the following parameters:

- congruency between the frequency of intervention and the information on materials and technical elements' durability;
- timeliness in the diffusion of diagnostic information, in order to quickly activate the intervention;
- adequacy of intervention techniques, in connection with the materials and the construction techniques of each element, and with the building restraints and available resources;
- effectiveness and efficacy of the available equipment and their compatibility with the type of intervention to be performed.

It is also necessary to control the intervention results:

- efficacy of the intervention, on the basis of the achievement of performances required;
- skills of the operators involved in maintenance interventions;
- intervention timeliness and length;
- costs, due to materials, components, manpower employed and length of intervention.

The information surveyed for maintenance management is usually recorded in electronic databases provided with a data processing system, that uses periodically updated databases [2]. The information is collected at the beginning of the contract and by periodical inspections, and all the interventions are recorded. The computerized management allows the continuous control of the activities performed by the Manager Organization, if the purchaser can access to the informative system [5-6]. Therefore, the Public Organization should include in the contract the bond for the contractor to guarantee the access to its database within the time prescribed by the quality control prescriptions.

Many Public Organizations have increased the number of services included in the contract. In the Global Services are often included the program and the carrying out of ordinary and extraordinary maintenance interventions, the management of buildings knowledge, of rents, defaults, and evictions, doorman services, cleaning service, and electricity supplying. Therefore, a quality management is necessary to control the offered services. In planning the quality, the Public Organizations can analyze and establish the way for the execution of the contract.

The application of a Quality Plan to the Global Service contract allows to avoid the selection of not qualified companies, to guarantee adequate logistics, to clarify the management method proposed by the contractor, to establish sub-contracts, to evaluate professional skills and qualification of the contractor, to understand the work methods proposed by the contractor, to review the services plan, and to analyze the quality control plan of the Manager Organization.

It is necessary to introduce in the Italian Public Organization a new professional skill, the Process Manager, in order to manage and control the whole process, and to guarantee the respect of the contract.

A high ability in planning and control of the maintenance is required to the Public Organizations. In fact, this task can not be completely delegated to the contractors, because they can not manage the social policy, the financial strategy and the budget for investments in the public estate. This estate is unsteady, because it is conditioned by obsolescence, need of maintenance interventions, requiring continuous management and control of the choices.

3. Study - Case: the School Buildings' Management in the Province of Naples**

The Province of Naples, an Italian local Public Organization, manages about 300 school buildings. With an agreement signed in 2000, the Province entrusted the ASUB company for the management of the school buildings, in order to maintain the efficiency of its property. ASUB is a limited company in which the local public authority holds the majority of share and it performs preventive and damage ordinary maintenance. The extra-ordinary interventions are usually directed by the Province's Maintenance Office.

Today the Province has an office directly involved in maintenance of school buildings, organized in four units, each one responsible of about 75 schools, and an office that manages the relationships with the ASUB (Activities Direction Office for ASUB). This because the ASUB required a single referent in the Public Organization.

The contract with ASUB included the census of the real estate, the surveying of the maintenance status and the management of maintenance interventions. The surveying was created to allow an electronic management of information, starting from a detailed knowledge of the buildings.

The census card includes information about the building, assigning it an identification code. The date of drawing up as a time reference, and the name of the surveyor are also reported. In the first section of the census card is given general information about the building:

- localization (main entrance, secondary entrance, name of the school, Council, District);
- owner data (name, address, city, telephone number, type of building: the whole building, blocks of buildings, part of a building);
- land-registry data;

- quantitative data (building area, green area, waterproof area, maximum height, number of floors, number of underground floors, number of staircases, building volume, underground volume);
- presence of cavity under the building;
- accessibility (vehicular and pedestrian accessibility, street and pedestrian access width, traffic, near by adjacent buildings).

The second section of the card reports structural information, as follows:

- vertical structures (stone or brick-wall, reinforced concrete, steel, mixed structure, etc.);
- horizontal structures (vaults, mixed floors in reinforced concrete or steel and bricks, etc.);
- roofs (sloping roof, vault roof, flat roof, etc.);
- internal staircases (reinforced concrete, steel, brick-wall, etc.);
- emergency outdoor staircases (number, structure features).

In the third section of the census card the following information about the other elements of the building is reported:

- wall panes (tufa-wall, brick-wall, cavity brick wall, prefabricated panes, etc.);
- external wall-finishing (plaster and paint, ceramic tiles, glass-sheet façade, marble or stone plates, etc.).

Plants are described in the fourth part of the card, as follows:

- lighting (presence of lighting in common areas, automatic gates, electric plant of the doorman's lodge, earth plant, lightning-conductor plant, etc.);
- water plant (connection with the public sewage system, presence of pumping system, etc.);
- fire water plant (connection with the public system, autonomous water reservoir with motor-pump, portable fire-extinguishers, etc.);
- heating system (centralized system, type of fuel, presence of chimneys, etc.);
- other kind of plants (gas, air conditioning, intercom, video-intercom, elevators, lifts, etc.).

The card also reports all the plants certifications and the general conservation conditions of the building, with the judgement of the surveyor, on the basis of parameters described in the contract (very good, good, mediocre, poor, unusable).

The building information comes with drawings in vectorial format: plans, front views and sections fitted out with the use of each room, symbols and codes of the most part of the technical elements and the plant. These codes are reported in tables containing data on the location of each technical element (floor number and room), class of elements (floors, coatings, windows, electric plant, heating system, etc.), description of the element (ceramic tiles, washable paint, casement window in aluminum, plug, fan-coil, etc.), quantity or dimension (number, square meters, etc.) and judgement about conservation conditions or effectiveness.

The contract includes some programmed intervention, scheduled on the basis of buildings' materials and construction techniques or for the plants' features. The contract also establishes periodic inspections in the buildings in order to control the maintenance status (Figure 1).

Even if the buildings' information surveyed seems to be exhaustive, the purchaser does not control the updating. In fact, after the sample check performed by the Maintenance Office operators at the end of the census step, the systematical control on the information reliability is not performed. In fact, the information is not recorded in an informative system directly accessible both by the purchaser and the Manager Organization. Therefore, the Province can't control if the ASUB periodically updates the information.

The management contract includes an annual cost per square meter for ordinary maintenance, defined by the analysis of historical information and data by literature on maintenance costs. The total cost for each school is calculated adding 10% of the external areas to the internal surface of the building. The contract establishes that 70% of the interventions performed by ASUB are included in a fixed amount agreement and 30% are calculated on a measurement and payment base. The fixed amount is annually granted, and includes boundary and optional interventions.

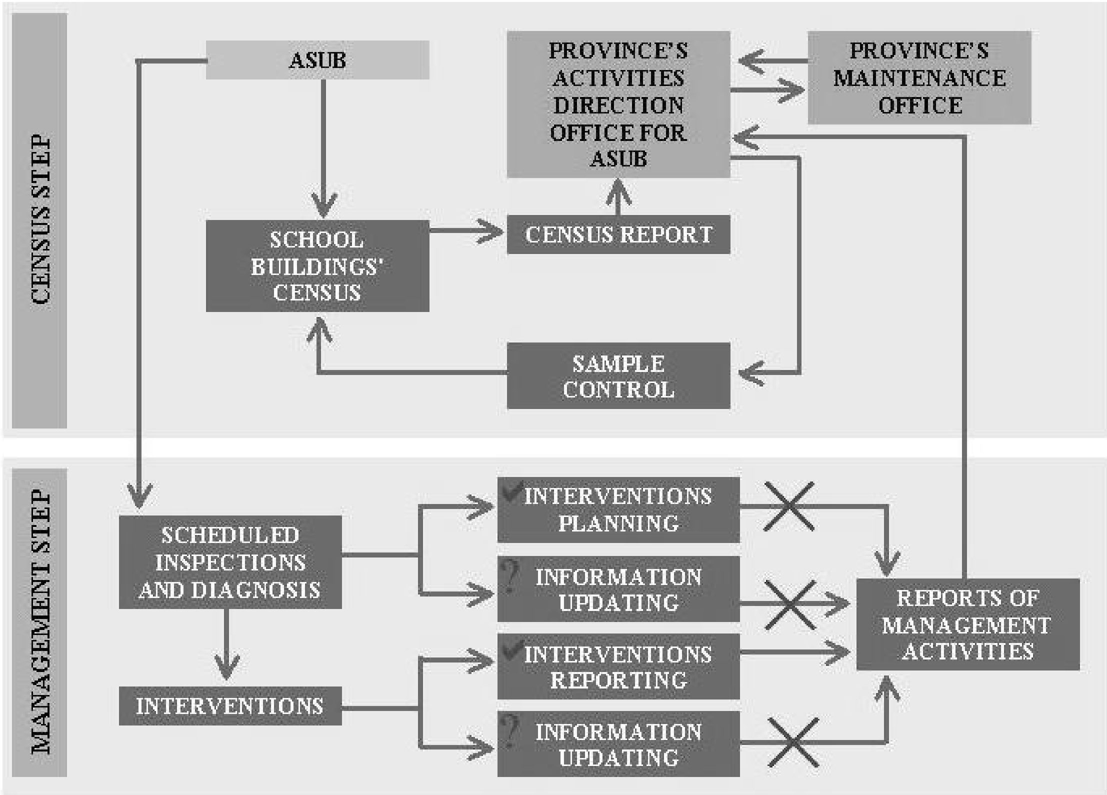

Figure 1: Information flow for the school building's knowledge in the Province of Naples

The ASUB sends to the Activities Direction Office for ASUB the reports of the intervention performed included in the fixed amount payment (Figure 2). In spite of the fact that financial penalties are established if the Manager Organization does not perform the interventions required, the control of the optional interventions is not systematically performed. The extra-ordinary maintenance and the ordinary intervention not reported in the contract are computed by measure. The accountancy reports and the intervention performed by ASUB are controlled by the Activities Direction Office for ASUB. This office can't control in situ each ordinary intervention performed. The Province's Maintenance Office also does sample controls.

The main problem of this management system is the control on the information flow: the need of intervention can be foreseen, can be surveyed in the inspection activities or can be required by the users if a damage occurs.

The users' request of intervention can be addressed both to the ASUB or to the Province's Maintenance Office. This office asks the Activities Direction Office for ASUB to report the request to ASUB, but it does not receive the information about the results of inspection or intervention.

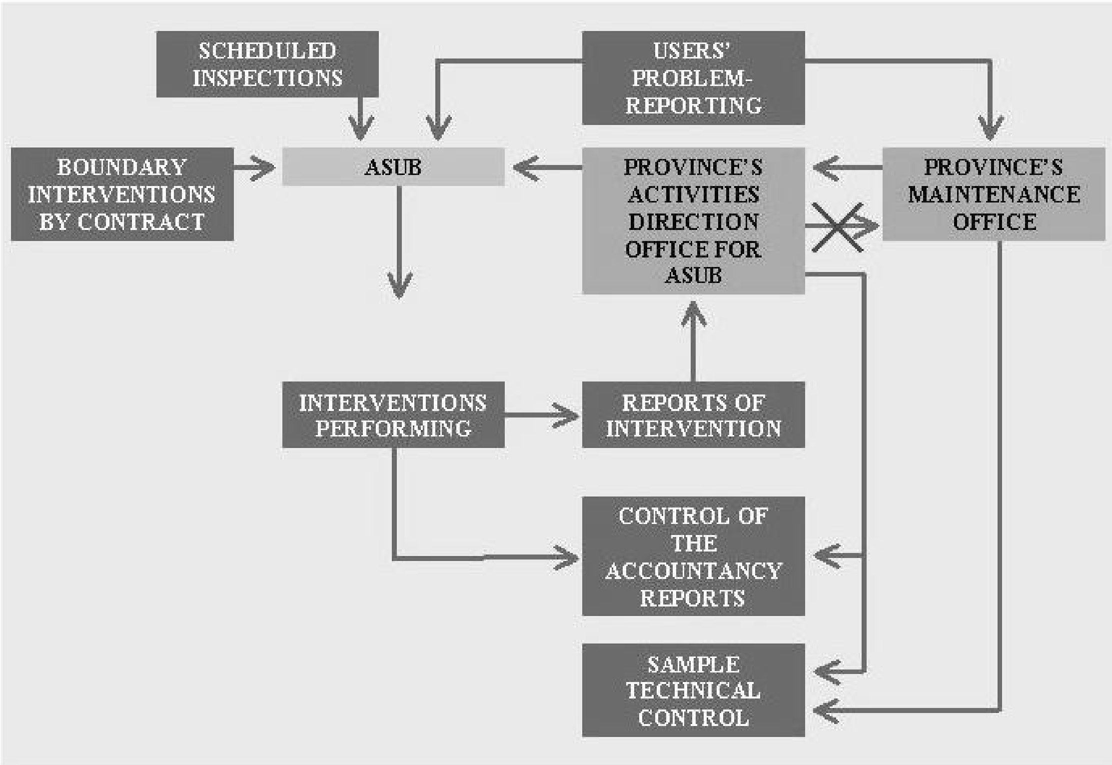

Figure 2: Information flow for the school building's ordinary maintenance in the Province of Naples: the Province's organization produces confusion in duty.

4. Conclusions

The quality control in management of real estates is a strategic activity that can guarantee the economical value conservation and the enhancement of the public building heritage. The purchaser, entrusting Private Organizations management activities, should maintain a strategic role in planning and control. It should define the maintenance policy on the basis of both the surveying of users' needs, and the available funds.

The control should be performed on specific indicators:

1. Building analysis and diagnosis:
- Buildings knowledge: adequate information about materials and construction techniques (STEP 1).
- Functionality definition of the technical element: definition of the function that each element should perform (STEP 1).

- Conservation condition evaluated on the basis of effective degradation and damages: type and intensity of the surveyed phenomena in order to guarantee a reliable control and to increase the quality of information for the maintainers (STEP 2 – 3).

2. Forecast capability:
   The systematization of the information surveyed in the periodic inspections allows the optimization of the available resources, reducing, in time, the number of inspections and the extent (and the cost) of the interventions. The forecast capability is related to an effective inspection plan and to correct diagnoses of building degradation and damages (STEP 2 – 3 – 4).

3. Timeliness in intervention:
   The definition of intervention priorities should be founded on different criteria, on the basis of the maintenance strategy adopted. In damages maintenance the purchaser should evaluate the time past between the knowledge of the damage and the execution of the intervention. In planned maintenance the respect of scheduled activities and the forecast capability (STEP 4).

4. Intervention costs:
   The purchaser can previously establish costs on the basis of the kind of interventions, to fasten the accountancy reports and to foresee the total amount. But these fixed costs should be based on materials, construction characteristics, degradation and damages surveyed, and use of the buildings (STEP 4).

5. Users' satisfaction:
   This indicator can be evaluated on the basis of the timeliness in interventions and of their effectiveness. In the Global Service contracts, the Manager Organization usually receive the users' requests of intervention.

Starting from the aforementioned indicators, the Public Organizations can directly control the information of the activities performed by the Private Organizations entrusted in building management. These should report to the purchaser clear, complete and measurable information. The information should be compared with the results of the controls performed in situ, in order to verify its reliability.

Performance Measurement Applications in Facilities Management: An Investigation into the Future Directions

Dilanthi Amaratunga, Udayangani Kulatunga & David Baldry
Research Institute for the Built and Human Environment, The University of Salford, UK

Abstract

Facilities Management (FM) is very frequently described as, "an integrated approach to operating, maintaining, improving and adapting the buildings and infrastructure of an organisation in order to create an environment that strongly supports the primary objectives of that organisation". The practical and strategic relevance of FM to organisations in all sectors of the economy is now increasingly recognised. Accordingly, organisations seek to improve their competitiveness by introducing a core business philosophy and restructuring to release senior management time and improve effectiveness. Managements have begun to realise that for organisations to benefit from their enormous investment in facilities, they have to begin managing them actively and creatively with commitment and a broader vision. Formulation of techniques that are capable of assessing "facilities performance" in terms of quality, cost and effectiveness, is therefore critical for "Organisational" and "FM" advancements. Research has emphasised that there is a clear need to measure FM performance which would integrate both the business and facilities domains. Accordingly, this paper summarises a literature review of current leading-edge performance measurement and management practices within facilities management organisations and conceptual models of performance measurement and management from other industries. Accordingly, the paper identifies the directions to develop performance measurement systems in FM with specific links to measure facilities relationships with those of the core business.

Keywords: Facilities management, performance measurement, core business

1. FM and its importance in todays' business environments

Facilities management (FM) has traditionally been seen as simply the management of buildings and building services. FM is a key managerial discipline and large corporations are increasingly recognising its importance in respect of achieving organisational goals and objectives.

A variety of definitions of facilities management have arisen:

- “An intergraded approach to maintaining, improving and adapting the buildings of an organisation in order to create an environment that strongly supports the primary objectives of that organisaiton” [1];
- “The process by which an organisaiton ensures that its buildings, systems and service support core operations and processes as well as contribute to achieving its strategic objectives in changing conditions” [2];
- “The integration of multi-disciplinary activities within the built environment and the management of their impact upon people and the workplace” [3];
- “A process by which an organisaiton plans, delivers and sustains excellent support services in a quality environment to meet caning strategic business objectives at best cost” [4]

A number of basic issues may be derived from these definitions:

- FM is a function containing a series of linked activities demanding a requirement to co-ordinate all activities pertaining to the planning, design, and management of an organisation’s physical resources;
- FM is responsible for co-ordinating planning processes and managing a building’s continuing development and changing use patterns, as well as for maintaining the building
- The goal of FM is to contribute to organisation effectiveness by helping the organisation to allocate its physical resources in a way that allows it to flourish in competitive and dynamic markets.

<u>but</u> as shall be seen in due course:

- FM is not just about the maintenance and operation of buildings although so much of its activities are building-related. More accurately it is about the management of a range of services, of a variety of forms, which are necessary to support the primary activities of an organisation;
- These services are invariably people intensive which means that human resource management issues and the so-called “soft” issues are highly significant; and
- FM has no raison-d’etre or justification of its own - it only exists as a means to support the primary, goal-seeking, activities of the organisation. Nevertheless the potential impact of the efficacy of FM upon organisational success may be highly significant.

FM is intrinsically bound up with creating the conditions in which business effectiveness may be achieved. All decisions taken about FM are business decisions albeit subject to technical or organisational criteria. The business case for developing and applying the discipline of FM depends upon an understanding of the potential the approach holds for creating quality working environments to support key corporate activities. Effectively planned facilities and quality support services can generate significant business or organisational returns.

The conditions within which facilities are operated and developed, and therefore the contribution they can make to the organisation, need to be set at the most senior level in an organisation. Strategic business decisions about responses to market conditions, competitive pressures, statutory obligations, and organisational restructuring are all business decisions which will have direct facilities implications. Company policies for production, marketing, human resource management, and finance each have profound significance for the manner in which facilities management services will be required to be delivered. In this context, following section highlights strategic role of FM.

2. Strategic Role of Facilities Management

FM has three facets in organisations: sponsorship, intelligence, and service management, according to Williams and Roberts (2000) [5]. CFM (2002) [4] identifies sponsorship FM role as the “translation” role with a strategic focus:

- Get the chief executive officer and senior management involved in the process and make them are of the possible outcomes;
- Strategy involves a change management process, which will have an impact on the built environment and the human resources;
- The focus of the strategy is the community, not the building or property, or a project;
- Every individual in the company (from top management to staff) see the project as a business project, which has an impact on the business objectives

Nevertheless it is true that many organisations remain blind or indifferent to the strategic potential of FM to stimulate strategic change or competitive advantage. Instead of being seen as a strategic tool the built assets and human resources and systems remain defined as an obligation or liability, that is as unavoidable costs and charges, cost centres rather than profit centres.

FM and the business or organisational sector may be able to reach a better understanding of each others needs and potential by the co-ordination of decision-making which demands a facilities input, and which would help to bridge the gap between primary business and support activities, i.e. core and non-core. There is a powerful need for a generalised set of principles for the contribution of FM to the defining of business problems, the analysis of options, and the strategic choice of solutions. The discipline itself needs to adopt a more strategic posture about its future path, by protecting and developing the distinctiveness of its range of management activities and mix of managerial and technical skills, thereby confirming its relevance to the whole business process.

This leads to another role, which FM is playing increasingly in performance measurement (PM). The need to monitor, assess and measure FM performance to enhance workplace productivity has become critical, particularly from the strategic point of view of FM.

3. Role of performance measurement within business environments

PM is mostly identified as a system which enhances individual performance to support or achieve the organisational goals [6]. As continuous improvement in a business cannot be gained without measurement of its performance [7], measurement of performance has been given a prominent place in any organization. Kagioglou *et al.,* (2001) [8] defines, the PM as “the process of determining how successful organization or individuals have been in attaining their objectives and strategies”. Since PM systems encompasses supporting infrastructure a more wider definition has been given by Nelly (1998) [9] as the quantification of efficiency and effectiveness of past actions by means of data acquiring, collection, sorting, analysing, interpreting and disseminating. Cain (2004) [10] identifies PM as the first stage to any improvement process that benefits the end users with lower prices, and the organizations with higher profit margins whilst enhancing the quality of the product. Thus, it can be said that PM is an important aspect for any organization to evaluate its actual objectives against the predefined goals and to make sure that the organization is doing well in the competitive environment. Love and Holt (2000) [11] summarise the importance of PM as it: Ensure that customer requirements have been met (and if not, why); Enable establishment of achievable business objectives and monitors compliance thereto; Provide standards for business comparisons; Provide transparency and scoreboard for individuals to monitor their own performance; Identify quality problems and those requiring priority attention; Give and indication of the costs of poor quality; Justify the use resources; and Provide feedback for driving the improvement effort.

This section has highlighted the importance of PM in business environments. In this context, the following section identifies its role within Facilities environments.

4. Critical role of performance measurement systems within facilities environments

The importance of PM in FM organisations are been well documented in the literature. Alexander (1996) [12] identifies measurement of performance as one of “three essential issues for the effective implementation of a facilities strategy”. Due to the increased complexity of FM organisations facilities managers are accountable for the senior management regarding the FM contribution to business results and for the economic health of the organisation, the senior management at the core of the business will want to know the performance of facilities. In addition, the contributions made by the FM organisation would be assessed by the stakeholders of the organisation. Thus, facilities managers are under pressure to improve the performance in FM organisations to justify their success to the management as well as to the stakeholders. In this regard PM can play a major role in FM organisations by providing periodic information about the attainment of goals and objectives in the organisation and can guide the management towards new directions to enhance the facilities within the organisation.

Amaratunga and Baldry (2002) [13] identify the ways in which FM could contribute to the performance of an organisation such as strategy, culture, control of resources, service delivery, supply chain management and, management of change. Spedding and Holmes (1994) [14] state that FM should not only focus on reducing the running cost of the building, but also should consider the effective and cost efficient ways of space management and achievement of organisational goals. Therefore, to identify the effectiveness of the contributions of FM functions, performance has to be measured. Thus, PM systems play a critical role in this aspect.

Facilities managers are increasingly valued for their entrepreneurial skills and knowledge of the core organisation, with the ability to pre-empt and translate the organisation's need for change into facilities strategies which underpin operational objectives to yield competitive advantage. Further more, strategic appreciation and development has been viewed as the corner stones of any facility management strategy. Thus, it can be argued that PM applications within FM organisations can assist the facilities managers toward achieving the strategies in the changing business environment.

The concept of providing one working space for all the employee activities of the organisation has been changed and the concept of "activity settings" which looks at different work settings ranging from open plan, meeting spaces, quiet concentration areas, conference rooms etc. has been emerged. Thus, corporate office space planning has become an important characteristic of FM organisations and the efficient and effective management of office environment has challenged facilities managers [15]. He argues that the old adage "you can't manage what you can't measure" fit the corporate infrastructure well. Thus, PM can play an important role in FM organisations by providing quantitative and qualitative data in terms of the effective use of the building space.

The above context shows the important role played by PM in FM organisations in way of providing valuable information regarding the attainment of aims and objectives of FM organisations. In this context, following section identifies current, leading edge, PM practises within FM organisations.

5. Current performance measurement and management practices within facilities management organisations

The importance of assessing performance in FM and a general need for the assessment of FM were discussed in the above section. In recent years, a number of management tools have been found to be particularly useful in the area of FM evaluations. The provision of information decision-making is a key component of a facilities strategy, in particular literature emphasises the usefulness of facilities performance measurement techniques.

The tendency of using the PM frameworks instead of the traditional measures can be identified in the PM applications in FM. For instance, the application of Balance Scorecard [16]. Further, the development of frameworks (Service Balanced Scorecard) based on the fundamental principles of Kaplan and Norton's Balanced Scorecard can be found which appraises the performance of property organisation's against their the strategic aims [17].

Process based approach to evaluate the performance in FM organisations can be found in the current FM literature [18]. This identifies the importance of process thinking in FM organisations as it would help to align the activities of the team members towards a common goal. They argue that even though the FM has been defined in many ways, most of these definitions identify the core competencies of FM as understanding business organisation, managing people, managing premises, managing services, managing the working environment and managing resources and recognise FM as a business process. One of such approaches is the application of the SPICE (Structured process improvement for construction environments) model.

Further, a survey as reported in Amaratunga & Baldry (2002) [19] as presented in

Table *1* presents a picture of PM practices within FM organisations. This random sample may have produced a lower proportion of respondent employing the measurement techniques.

Table 1: Use of approaches/techniques for the measurement of FM performance

Approach for the measurement of FM performance	***Number using the approach***	***Proportion against the total sample***
- Business excellence model (EFQM)	3	20.00%
- Best practice Benchmarking	5	33.30%
- Total quality management	1	6.67%
- Customer satisfaction surveys	10	66.67%
- Post-occupancy evaluation	6	40.00%
- Evaluate return on funds employed	-	-
- Through observe of complains	7	46.67%
- Employee indexes	-	-
- Measurement against service level agreement	1	6.67%
- No method used	1	6.67%
- Any other method	-	-

The use of a broad range of approaches to the measurement of performance in FM was confirmed by the survey and the interviews carried out. It was further confirmed that appraisal techniques for assessing performance should become an essential part of the FM process, particularly those that provide information that can be arrayed so as to ensure management can learn about the consequences of their actions.

There is frequent comment that there are too many performance indices (especially in terms of cost) in the FM market. Therefore, a more positive and preferable stance in respect of performance measurement in FM is needed and the evaluation process should stand up to scrutiny and allow the measurement of FM performance of individual services as well as aggregating this information into indices and integrated performance measurement “universes”. This should allow assessment of FM performance covering various perspectives of FM together with FM’s relationship to the core organisation, although to date the key problems have been those of performance measurement techniques’ availability. This leads to the exploration of similar applications within other industries from whom, FM can learn lessons forms. In this context, the following section highlights some of the most common PM approaches available within other industries.

6. A literature review of conceptual models of performance measurement and management from other industries

In order to overcome the problems associated with the traditional measures such as encouraging short-termism [20], [21]; inability to provide stakeholder perspective [22], [23]; lack of focus on the strategy [21] etc., and to facilitate the effective and efficient PM in the current business environment, various integrated and multi-dimensional PM systems have been developed.

The newly developed integrated performance frameworks have attempted to tie the performance metrics more closely with the firm’s strategy and the long term vision [23]. This is due to the recognition of the importance of deriving the performance measures from organisation’s strategy [24], [25], [26]. Further, it was argued that there is a need to align the financial and non- financial measures that fit within a strategic framework [27] and [28] where the non-financial measures reflect the organisational objectives while the financial measures indicate the bottom line results [29]. In addition the need of PM systems to provide a balanced overview was highlighted by many authors [30] and [31]. Accordingly, the following section discusses the common PM frameworks used in other industries.

The importance of deriving the performance measures from the strategy of the organisation has been recognised widely [24], [25], & [26] thus the newly developed integrated performance frameworks have attempted to tie the performance metrics more closely with the firm’s strategy and long term vision [23].

7. Supply chain performance

Over the past two decades, manufacturing industry has changed in to a highly competitive field due to the emerge of foreign and local competitors. Due to this competitiveness many firms are adopting different strategies to secure their market share. One of such is merging with suppliers by forming long term strategic partnerships which is known as supply chain. Supply chain has been defined as ‘a system whose constituent parts include material suppliers, production facilities, distribution services, and customers linked together via the feed forward flow of materials and the feedback flow of information’ [32]. Several models have been developed [33] & [34] to measure the performance in manufacturing supply chain.

7.1 Evaluating managers’ performance

Another strategy developed in the manufacturing industry is to build up the flexibility of the firms [35] to meet the goals of the organisation in a more dynamic manner. A study has been done in this area [36] by evaluating managers’ performance through manufacturing flexibility measures.

7.2 Measuring the long term performance

Measuring the long term performance in manufacturing industry is another approach used [37]. Performance metrics such as advanced manufacturing technology usage, advanced management practices usage, globalization and cooperation capacity and the match between manufacturing capabilities and market requirements are considered to ascertain the long term performance.

7.3 Service Balance Scorecard

Traditionally the performance in Local Government Authority’s are measured using financial measures such as occupancy cost to m2, full-time employees, lease cost, lease income, capital expenditure, total revenue etc. Service Balance Scorecard (SBS) has been developed to eliminate the problems associate with the aforementioned traditional measures and a study has been done in this area [17]. The SBS provides a new method to evaluate facilities linked to a Local Government Authority’s by measuring the performance in terms of Financial perspective, Building perspective (how well the facility is used in terms of time), Services perspective (how well the facility delivers, services to the community in line with the Local Government Authority’s objectives) and Community/customer perspective.

7.4 Satisfying the customer expectations

Even though the supply chain performances are traditionally focused on operational logistic activities, the trend has moved towards satisfying the customer expectations [38]. This has driven the performance measurement towards strategic measures [39]. Research has been carried out to evaluate the supply chain performance using process capabilities, technology capabilities and organisation capabilities from operational and strategic point of view [38].

7.5 EFQM model

EFQM model is developed on the principle that “Excellent results with respect to Performance, Customers, People and Society are achieved through Leadership driving Policy and Strategy, that is delivered through People, Partnerships and Resources and Processes” [40]. The model consists of five “Enablers” namely leadership, people management, policy and strategy, resources, processes, and four “Results” called people satisfaction, customer satisfaction, impact on society and business results. The enabler criteria concerned with how the organisation undertakes key activities while the results criteria are concerned with what results are being achieved. A logic called RADAR lies at the heart of the EFQM model consists of Results, Approach, Deployment, Assessment and Review. Thus, when using the model with an organisation, the Approach, Deployment, Assessment, and Review elements of the RADAR logic should be addressed for each Enabler sub-criterion and the Results element should be addressed for each Results sub-criterion.

The model has a non-prescriptive approach and can be used to carry out excellent quality management and self-assessment of the organisation. The organisation can use the model to develop their vision and goals for the future in a tangible and measurable way, help to identify and understand the nature of the business, identify the cause and effect relationships, use as a diagnosis tool for assessing the current status of the organisation [40].

7.6 Performance Prism

Performance prism consists of five interrelated aspects: Stakeholder satisfaction; Strategy; Processes; Capabilities; and Stakeholder contribution. Similarly to the BSC, the performance prism looks at the needs of stakeholders, but in a broader way. Further, performance prism does not limit by addressing the needs of shareholders and customers as in the case of BSC, but goes beyond that and addresses the needs of employees, suppliers, intermediaries, regulators, community as they too have a substantial impact on the project performance [41].

In most of the PM frameworks, the measures are derived from the strategy, but in the performance prism it is the other way around. The strategic, process and capability aspects of the performance prism have been derived by considering the requirements that is needed for the stakeholder satisfaction which is different from the general approaches of the PM frame works. Furthermore, performance prism identifies the reciprocal relationship between the stakeholders and the organisation. Therefore, focusing on the stakeholder contribution can be identified as a unique feature of the performance prism [42].

7.6 Other mostly cited models

In addition to the above PM frameworks, SMART (Strategic Measurement and Reporting Technique) developed by Wang Laboratories [43] which includes the internal and external performance measures, Keegan et al's (1989) [44] performance metrics based on the combination of cost and non cost measures can be identified. The Macro Process Model, developed by Brown (1996) [45] is based on the concept of cause and effect relationship of the organisation which shows the links between five stages of a business process (inputs, processing systems, outputs, outcomes and goals), and the performance measures.

The PM models used by other industries were reviewed in the above section. It can be identified that every model has its own set of advantages and disadvantages and the suitability of a model to a particular scenario is governed by these advantages and disadvantages.

8. Directions to develop performance measurement systems with specific links to measure facilities relationships with those of the core business

As discussed in section 4, PM plays a critical role by providing concrete evidence about the successful attainment of organisational goals and objectives in FM organisations. A criticism levelled at FM researchers is that they do not use the concepts of PM in as rigorous a manner as, for example, business performance theorists. Furthermore, they make no use of more general discussions of performance measures, e.g. the usefulness of constructing a PM framework for FM, and add PM into models of FM processes in the same way that they add project management techniques. The study of PM in a FM setting has therefore been somewhat superficial. However, it was identified in from the section 5 the positive motive of PM applications in the FM organisations.

The commitment from the people factor involved in FM organisations has a major role to play. For instance, evaluation of the efficiency and effectiveness of the existing building in terms of user satisfaction, identifying new improvements to buildings etc. are major roles of facilities managers. Therefore, similar to industries like construction, "people factor" can be considered as one of the important assets of FM organisations as improvements and challenges in the FM organisations can be met through the work force. The importance of human resource performance evaluation systems to organisations in general [46] & [47] has been highlighted by many human resource researchers. Further the need of aligning the human resource management applications of the firm with other management activities, creating a positive relationship between the organisational performance and the human resource practices focused on employee commitment are being well accepted in the studies done in other disciplines [48]. Therefore, such directions can be taken by FM organisations by measuring the performance of its workforce.

Quality of designs has been identified as an important dimension of buildings [25], [49], & [50]. However, due to the emphasis made by various authors [51[& [52], a new culture has been embarked in the UK construction industry towards measuring the performance [53] and more emphasis has been focused on the performance of the physical process [54] neglecting PM during the design stage. Lack of attention towards the PM during the design stage of buildings may forego the efficient and effective use of space within the building. Thus, measuring the performance during the design stage of FM organisations can be taken as a new direction.

The industries like manufacturing has identified the importance of creating long term strategic partnerships with both upstream and down stream partners such as suppliers, customers, and logistics service providers and the need of integrating and managing the multiple processes within and beyond the boundaries of individual organisations in the supply chain [55]. The research done in other industries revealed that the PM in supply chain facilitates the inter-understanding and integration between the supply chain members and the results indicates the effects of strategies and potential opportunities [56]. Furthermore, aligning the performance measures with the corporate strategy of the organisation have been well experienced by the PM studies in supply chain management in other disciplines as it would make sure that the supply chain processes are delivering the value to the customers and acting as a core competency of the organisation [39]. Further, PM of the whole supply chain and all of its entities has been identified as a strategic issue by many industries [57].

9. Conclusions

Appropriate measurement procedures can provide major benefits. When applying current measurement principles applicable to FM environments, several problems have to be faced: it is difficult to isolate FM's contribution to organisational performance from the other business activities because it is always the intertwined efforts that eventually result in outcomes in the market place; the problem of matching specific FM inputs and intermediate outputs with final outputs; a third major measurement problem is the time lag between FM efforts and their payoffs within an organisational setting; besides problems with the selection of performance metrics, there is also the problem of determining the right norms to compare with; and another issue, which is already mentioned in the previous section, is the acceptance of performance measurement in FM.

Therefore, it is argued in this research paper that performance measurement techniques available in general management literature haven't been fully transformed into FM literature, emphasising the research need in performance measurement in FM. The process should include links to the core business at a corporate level.

Abstract

Facilities management is a key managerial discipline and large corporations are increasingly recognising its importance in respect of achieving organisational goals and objectives. Enterprises are able to improve their performance by the more effective use of resources, the matching of appropriate support systems to business activities, and the application of assertive management by those best qualified and equipped to carry it out. However, FM organisations lack clear guidelines to direct their improvement efforts and to benchmark their performance against other organisations. The SPICE FM (Structured Process improvement in construction environments – facilities management) maturity framework was developed as a response to this requirement. SPICE FM draws a distinction between FM organisations that have 'mature' or well-established processes, and those where the processes are 'immature'. This paper briefly describes the characteristics of the SPICE FM Framework, followed by a review of the key findings from the case study undertaken.

Keywords: facilities management, SPICE, process capability assessment, performance

1. Process Thinking in FM

A process has several essential features, which Ould (1995) [1] lists as follows:

- A process involves activity. People or equipment do things.
- A process also generally involves more than one person or piece of equipment. A process is therefore about groups, and concerns collaborative activity.
- A process has a goal. It is intended to achieve something and to produce results.

A process determines the way we act and react. The activities and tasks we perform to achieve a certain goals form the "process" for achieving that goal. A disciplined process will result in ordered and consistent patterns of behaviour, whether by individuals or by groups of people. The process defines how we act or react, or it defines the activities needed to fulfil a certain task. We have a process for 'going to work', a process for 'defining service standards', and so on.

In this context, most FM organisations focus on the services they provide. In such a business culture, people are naturally inclined to emphasise issues that are tangible, visible or measurable. Many organisations are likely to resist process improvement activities that do not contribute to short-term tangible results. Consequently, FM managers often view process related work as low priority. In contrast, process-focused organisations consider tangible results in service delivery to be just one aspect of the business picture. For such organisations, how the service is delivered is equally important. The objective is that process thinking should be accepted and used consistently. The process is seen as a disciplined way of conducting business. In contrast to functional definitions, a process perspective in FM focuses on the tasks and activities that take place internally in the FM organisation. The emphasis is on how the work is done, rather than the functional responsibilities.

In this context, SPICE FM is primarily concerned with management FM processes. The underlying philosophy is that if management processes are well performed, they will have an impact on the performance of core processes. SPICE FM does not prescribe how organisations should perform core processes. Instead, it focuses on creating a management infrastructure that allows members of staff to perform core processes successfully.

2. SPICE frame work

The SPICE FM process maturity model promotes continuous process improvement based on many small, evolutionary steps. It provides a system for initiating and implementing continuous improvement. The model divides these evolutionary steps into five maturity levels, which lay the foundations for continuous process improvement. The maturity levels form a scale for measuring the capability of an FM provider's management processes. Each level of maturity is defined by a set of key processes. When an organisation is successfully applying each key process, it can stabilise an important part of the service delivery process and achieve the next level of maturity. The five levels also provide guidelines on how to prioritise efforts at process improvement. Figure 1 illustrates the five stages of the SPICE FM framework. For each level, the model specifies a number of ‘key processes’. By following the steps in the model, an organisation can achieve effective and continuous improvement based on evolutionary steps. An organisation can only be at one level of the model at any one time. If an organisation is at level 1, but implements some of the key processes of level 3 or 4, it is still considered a level 1 organisation. This is because each level lays successive foundations for the next. An organisation has little to gain by addressing issues at a higher level if all the key processes at the current level have not been implemented. To date, the research has focused on defining the characteristics of Levels 1 and 2 of the model.

2.1 Stepwise improvements in organisational maturity

The process maturity model lays foundations for continuous process improvement, by establishing controls on service delivery *management processes* before focusing on technical issues. Starting with ad-hoc processes, the evolutionary 5-stage model guides FM organisations towards developing their process capability. In the SPICE FM framework, organisations at level 1 have little process focus. Organisations at level 2 have achieved high capability in managing service delivery. Level 3 focuses on knowledge management and sharing best practice across the organisation. In levels 4 and 5, the model introduces statistical controls and measurement. Level 1 of SPICE FM is the entry to the framework and has no key processes. Organisations at level 1 focus on achieving the seven key processes at level 2. This lays the foundation for the key processes at the next level. Each key process is defined by a set of critical practices that indicate if the process has been implemented in a way that is effective, repeatable and lasting.

Table 1 lists the key processes at level 2 and their "enablers". The SPICE FM approach is not prescriptive in terms of how activities are performed. Instead, the model focuses on the broader issue of process management. Effective process management encourages and supports innovative approaches to solving day-to-day business problems, rather than constraining organisations to a particular way of working.

Figure 1: The SPICE FM process maturity model

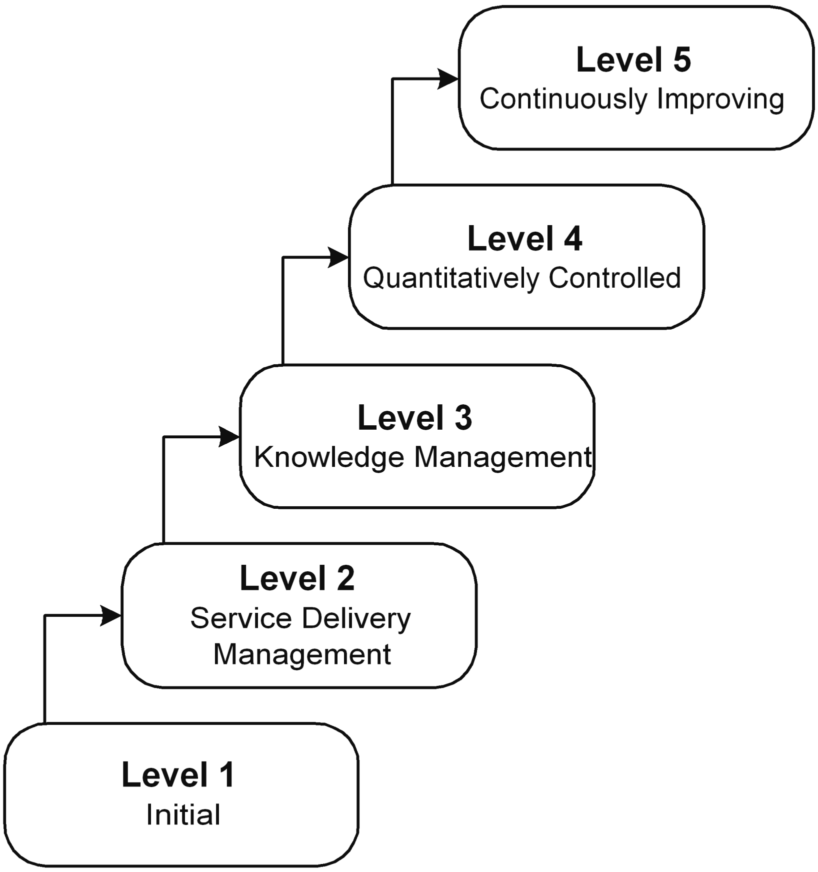

Table 1: Level 2 key processes and their enablers

Level	Key Process Areas	Generic Process Enablers
2 - Service Delivery Management	Service Requirement Mgt. Service Planning Service Performance Monitoring Supplier and Contractor Mgt. Health and Safety Management Risk Management Service Co-ordination	Commitment Ability Activities Evaluation Verification

2.2 Level 1 – Initial

Level 1 is the basic entry level to the model, and has no key processes. An FM provider at this level has little focus on process, and service performance is poor. Good practices are local, and are not repeated or 'institutionalised' across the organisation. The ineffective capture and co-ordination of service requirements tends to undermine good practices. Organisations make commitments that staff or the supply chain cannot meet, which results in crises. During a crisis, facilities managers typically abandon planned procedures; instead, individuals do whatever activities it takes to get the job done, with little regard for the effects on other people. Time, cost, quality and customer satisfaction may all suffer. Level 1 organisations must implement all of the level 2 key processes in order to progress, or 'mature', to the second level of the model.

2.3 Level 2 – Service Delivery Management

At this level, service performance can be predicted to a certain degree. A level 2 organisation has established policies and procedures for managing and delivering customer requirements. Service performance standards are established, and service delivery is co-ordinated to minimise disruption to the core business. As the service is being delivered, continuous monitoring ensures that performance standards are met. At level 2, FM providers have effective processes to directly meet the requirements of the core business. An effective process is one that is practised, enforced, trained, documented, evaluated and able to improve. To date, most of the efforts of the SPICE FM project have concentrated on defining and raising confidence at level 2 of the model. The research has identified seven key processes at level 2 which are described below.

- **Service requirement management** - Effective management of customer requirements identifies the needs of the organisation and its users. The service delivery team identifies how many tiers of customers it has and how their requirements differ. The team has a clear sense of priority in term of its customers and the service mixes it offers. Service level agreements and performance standards are developed and continuously reviewed to remain consistent with customer requirements. They are also communicated to all staff involved in service delivery.

- **Service planning -** Service planning establishes realistic schedules of work based on customer requirements. Estimates (e.g., resources, maintenance schedules, budgets, purchasing) are prepared for all work to be performed (e.g., scheduled and reactive maintenance).
- **Service performance monitoring -** Service performance monitoring ensures that services are delivered in a manner that is consistent with the service level agreements and performance standards established with the customer. Feedback is gathered (e.g., from customers and staff) to monitor customer satisfaction levels. Performance measures (e.g., waiting times, error rates, processing times) are reviewed on a regular basis, with the involvement of staff, and corrective action is taken when service delivery deviates significantly from service plans.
- **Supplier and contractor management -** This key process starts with the selection of suitable suppliers and contractors. Service level agreements and performance standards are established and their performance is continuously reviewed.
- **Health and safety management -** Health and Safety Management ensures that services are delivered in compliance with, or exceed, all mandatory health and safety legislation. Health and safety risks are identified, assessed, and action taken to eliminate or minimise the likelihood of any incidents.
- **Risk management -** Risk management involves identifying and evaluating risks so that action can be taken, either to reduce the likelihood of an event occurring or to limit the consequences should that event occur. Risks are identified in all areas of the business (e.g., to the environment, supply breakdown, property, financial performance). Employees are actively involved in identifying risks and taking steps to prevent risks becoming a reality.
- **Service co-ordination -** Service co-ordination draws on the experience of other service teams, suppliers and customers to meet customer requirements effectively. Co-ordination between these three groups ensures that disruption to the core business is minimised. Representatives with responsibility for co-ordination are appointed, and co-ordination methods are agreed.

2.4 Level 3 – Knowledge Management

A level 3 organisation builds on the achievements of level 2. At this level, the organisation has the capability to capture and share knowledge across the organisation. So far, the SPICE FM research has had less focus on level 3, which is anticipated to be the subject of future research.

2.5 Level 4 – Quantitatively improved & Level 5 - Continuously improving

So far, the SPICE FM research has had little focus on level 4 and 5. At Level 4, the organisation will have a programme that measures productivity and quality for important process activities related to service delivery. This programme forms an objective basis for measuring the process, customer satisfaction, and harmony across the supply chain. Organisations gain control of service delivery by narrowing variations in process performance, so that they fall within acceptable boundaries. Meaningful variations can be distinguished from random variations. The expectation at level 5 is that the entire supply chain is focused on continuous process improvement. Level 5 organisations can identify weaknesses and strengthen processes before any problems emerge, and can do so in a collaborative manner. Data on the effectiveness of the process is used to perform cost benefit analysis on any new technologies and on proposed changes to processes. This increased level of understanding allows organisations to consider large-scale changes to their processes. Innovations that exploit best practice are identified and adopted throughout the organisation.

3. Process Enablers

Anecdotal evidence from the research suggests that if managers are asked: "Do you implement level 2 key processes?" they are likely to respond "yes". On the other hand, current studies indicate otherwise. So how can managers ensure that they are performing the key processes adequately? The SPICE FM research has identified five process enablers, which are either activities or modes of thinking. These enablers are pre-conditions for implementing the process. They are based on principles established in CMM® [2] and SPICE [3] that were developed for the software engineering and construction sectors respectively. Process enablers focus on the results that *can be expected* from a key process. This is a forward-looking approach, which indicates an organisation has process capability *before* a process takes place. Process enablers detail the features a key process must have before it can yield successful results. Ensuring that all the process enablers are in place improves the performance and predictability of key processes. Process enablers apply across all the key processes.

- **Commitment -** This involves an organisation taking action to ensure that the process is established and is lasting. Typically, this means establishing policies that are shared by the whole organisation. Some processes need sponsors or leaders in the organisation. Commitment ensures that leadership positions are created and filled, and that the relevant organisational policy statements exist.
- **Ability -** This describes the conditions that must exist before a process can be implemented competently. It normally means having adequate resources, an appropriate organisational structure, and training in place.
- **Verification -** A verification procedure checks that activities are performed in compliance with the agreed process. Adopting such verification checks as a process enabler emphasises the need for independent quality assurance. The focus is on *external* verification of processes.
- **Evaluation -** This involves internal process evaluation and reviews to help control and improve processes. During the early stages of maturity, this will mean efforts by the team to improve existing processes. The focus here is on the project team's *internal* improvements.
- **Activities -** This describes the activities, roles and procedures necessary to implement processes. They typically involve establishing plans and procedures, performing the work, tracking it, and taking corrective

4. Core, support and management processes

Business processes can be divided into three broad types: (i) core processes; (ii) support processes; (iii) management processes. Core processes concentrate on satisfying customers. They directly add value to the product in a way that clients understand. These processes respond to the needs of customers and generate customer satisfaction. Support processes concentrate on satisfying 'customers' within the organisation. They might add value to the business indirectly, by supporting a core business process, or directly, by providing a suitable environment. Management processes are concerned with managing the core and support processes. SPICE FM is primarily concerned with management processes. The underlying philosophy is that if management processes are well performed, they will have an impact on the performance of core processes. SPICE FM does not prescribe how organisations should perform core processes. Instead, it focuses on creating a management infrastructure that allows members of staff to perform core processes successfully.

5. SPICE Applications in the Retail Sector

The SPICE FM framework described above was tested in a series of case studies with FM providers to ensure that its outputs are appropriate to the FM sector and of value in the real world. Members of the research team worked closely with FM providers and clients to test the SPICE FM framework in a variety of real-world scenarios. In this context, this section of the paper documents the findings of one such study, undertaken at the Property Services Department within a leading retail group in the UK.

The primary objective of the case study was to establish whether the concepts behind the SPICE FM framework are applicable and relevant to a FM provider in the private sector.

5.1 Study methodology

A series of meetings with the management team at the Property Services department gained the necessary commitment to proceed with the study. This paper does not disclose the precise source of process capability findings. This ensures that members of staff can speak openly about their perceptions of the organisation. The confidentiality of assessment data was made clear to all members of staff that participated in the study.

As already mentioned, this study aimed to assess the capability of the management processes that support the implementation of the Department's business strategy. Below is a list of the key assessment activities undertaken:

- **Departmental management interviews** - The objective of the interviews was to understand: What management views as the critical issues facing the department; What process capability management believes the department has; How policies and procedures are defined; How communication flows through the organisation; and How process improvement fits into the department's vision.

- **Employee interviews** - A representative cross-section of employees were chosen to participate in semi-structured interviews, ensuring an unbiased view of the organisation.
- **Document review -** The research team reviewed items of documentation that employees referred to in interviews. This was to establish whether such documents actually exist, what form they take and their availability to staff.

A detailed description of the SPICE FM process maturity model is already given. The key processes considered within this study were the SPICE FM Level 2 key processes: - Service requirement management; Service planning; Service performance monitoring; Supplier and contractor management; Risk management (including health and safety); and Service co-ordination. These key processes were assessed against the process enablers, as already described in section 3 above. SPICE FM process maturity model identifies five process enablers, which are types of thinking or activities that are pre-conditions for implementing the process. Process enablers focus on the results that can be expected from a key process. This is a forward-looking approach, which indicates an organisation has process capability before a process takes place.

6. Case Study findings

This section refers specifically to the results and outcomes from using the SPICE FM model within the Property Service department. An important objective of the case study has been to understand how the criteria identified in the SPICE FM process model relate to the department. Using the results of the assessment undertaken during the study, this section highlights some of the areas in which the department satisfies or fails to satisfy the key criteria of the key processes and their enablers.

6.1 Service requirement management

Effective management of service requirements identifies the needs of the organisation and its users. The service delivery team identifies how many tiers of customers it has and how their requirements differ. The team has a clear sense of priority in term of its customers and the service mixes it offers. Service level agreements and performance standards are developed and continuously reviewed to remain consistent with customer requirements. They are also communicated to all staff involved in service delivery. The process meets the needs of both responsive and preventative maintenance requirements

The integrated helpdesk is used by the department to record requests from individual stores. Specialist support is available to the operators to respond to more complex queries. The Property Management System establishes schedule of compliance (asset registers, PPM plans and performance criteria). The asset register names appropriate specialist contractors – including primary and secondary options where appropriate. A combination of on-the-job training and procedures are used to train operators. The supervisor is in the process of expanding this into a more comprehensive training schedule. The move towards an integrated helpdesk has improved resource efficiency and ensures effective backup is in place for busy periods. Out of hours provision has also been addressed.

6.2 Service planning

Service planning establishes realistic schedules of work based on customer requirements. Estimates (e.g., resources, maintenance schedules, budgets, purchasing) are prepared for all work to be performed (e.g., scheduled and reactive maintenance). The department has well established systems in place to plan service provision in line with service level agreements. Service level agreements establish clear expenditure guidelines and budgets for individual chains and allow the department to service chains in line with their specific requirements (e.g., the balance between proactive and reactive maintenance). The department has distinct prioritisation levels for jobs that form the basis for establishing target times. The escalation procedure for prioritisation appears well established and understood by staff. tment has distinct prioritisation levels for jobs that form the basis for establishing target times. Costs for maintenance activities are clearly defined based on a schedule of rates for each contractor (including call out rate / hourly rate). Clear guidelines for approval to proceed are in place based on automatic approval mechanisms. Managers have recognised that efficiency savings can be made through a more intensive planning process. This indicates evaluation of the process is taking place.

6.3 Service performance monitoring

Service performance monitoring ensures that services are delivered in a manner that is consistent with the service level agreements and performance standards established with the customer. Feedback is gathered (e.g., from customers and staff) to monitor customer satisfaction levels. Performance measures (e.g., waiting times, error rates, processing times) are reviewed on a regular basis, with the involvement of staff, and corrective action is taken when service delivery deviates significantly from service plans.

Significant efforts have been made to introduce key performance indicators. The department has a wide range of systems in place by which to monitor its performance. Examples include: Financial reports; Weekly reports; Call statistics; Complaints / complements log; Job Checking report; Quality audits; Work record sheet auditing; Invoice auditing; and Year on year profiles. However, there is little evidence that the new reports and key performance indicators are being linked to the needs of the core business. For example, the department appears keen to demonstrate the importance of the FM function to the core business, emphasising the cost of maintenance and the need for proactive maintenance. However indicators are not being developed to address these issues. Although some feedback is gathered at a branch level, it is sporadic and probably inadequate to provide an accurate reflection of customer satisfaction. Tools such as post project reviews and more comprehensive questionnaires were suggested by staff to address this. Despite the similarity between the chains served by the department there appears to be little or no internal benchmarking. Such systems could be used to demonstrate the effectiveness of a chain's property management strategy relative to others in the group.

It is clear that the department has spent significant resources identifying and implementing improvements to its monitoring and reporting structure and these appear to be largely successful. However two areas were identified by this assessment for improvement: more extensive monitoring of individual maintenance tasks (at a branch level) is required to ensure quality standards are being met. Additional resources may be required to address this issue satisfactorily; and although key performance indicators have been fundamental to the changes in reporting, their relationship to the core business appear unclear.

6.4 Supplier management

This key process involves the selection of suitable suppliers and contractors. Service level agreements and performance standards are established and their performance is continuously reviewed.

Due to the nature of the departments operations (i.e., subcontracting of work to external supplies), there are significant overlaps with comments in other key processes. The retail group operates a strict buying policy that is well communicated and understood by staff. The department has a clear objective to streamline the current supplier base in an attempt to improve services and gain ownership. Related to this is also a desire to move towards total FM - supply, install and maintain. This objective is understood by staff within the department. Service level agreements are in place with the supplier base creating performance standards and establishing levels of cover within different contracts. However monitoring of suppliers is simplistic (e.g., random checks, clerk of works, named and shamed, periodic review meetings) and is felt by staff to be ineffective. There is little data available to establish whether performance standards are being achieved. The department has expressed a desire to introduce more objective incentive targets in the future that will make the service level agreements more comprehensive. The department has recognised that the performance of suppliers reflects on its own image within the Group and is taking steps to address these weaknesses. At the time of assessment, there was evidence of significant shortcomings in the systems for selecting and monitoring the department's supplier base. However it is clear that the department has recognised these problems and is in the process of identifying and implementing steps to resolve them

6.5 Risk Management

Risk management involves identifying and evaluating risks so that action can be taken, either to reduce the likelihood of an event occurring or to limit the consequences should that event occur. Risks are identified in all areas of the business (e.g., health and safety, environmental, supply breakdown, property, financial performance). Members of staff are actively involved in identifying risks and taking steps to prevent risks becoming a reality.

At the retail department, formal risk management is limited to health and safety issues. An external consultant is responsible for the majority of health and safety issues. Consequently it was not feasible to examine the process in detail during the case study. However, the department has a clear reporting structure and systems in place for recording and monitoring health and safety issues. The procedures developed to manage unplanned events suggest some awareness of broader risk management issues within the department.

It lacks a clear directive from senior management to manage broader risk issues. The majority of staff are unfamiliar with the concept of risk management and are therefore not in a position to play an active role in the management of the Group's risk – in particular, an awareness of how their job might impact the core business. Consequently the department's employees are unaware of risk management and have received no specific training. Some escalation procedures are in place to manage the unplanned event. Employees feel that the Group is committed to managing health and safety and in particular, recognise its importance to the core business. The department employs an external health and safety consultant "Safety Works" to investigate health and safety problems. The consultant issues questionnaires and carries out audits to ensure method statements, risk assessments, policies and training are in place. There is a well defined accident reporting structure in place. However the role of the health and safety manager within the department is poorly defined, lacking clear scope and objectives. The significance of the department's operations to the core business suggests that this is an important issue to address in the future.

6.6 Service co-ordination

Service co-ordination draws on the experience of other service teams, suppliers and customers to meet customer requirements effectively. Co-ordination between these three groups ensures that disruption to the core business is minimised. Representatives with responsibility for co-ordination are appointed, and co-ordination methods are agreed.

The restructuring of the department to offer a cross chain service has improved integration and communication internally. The relationship between the department and individual stores is remote due to the work being performed by external suppliers. The department has little insight into the effectiveness of the suppliers' co-ordination with individual stores due to the poor monitoring of individual jobs. The 'Vision' process is actively bringing together different sections of the department to improve service delivery. By addressing operational management and reporting issues collectively, this should aid process integration. However, the membership of the Vision group remains small. Some of the department's systems have not been effectively integrated to reduce duplication.

It is clear that integration and co-ordination have improved in recent months as a result of the significant changes taking place within the department. The main weakness concerns the relationship between the department and the customer, due to the poor supplier monitoring and communications currently being utilised. This issue should at least in part be addressed by changes to supplier management monitoring process.

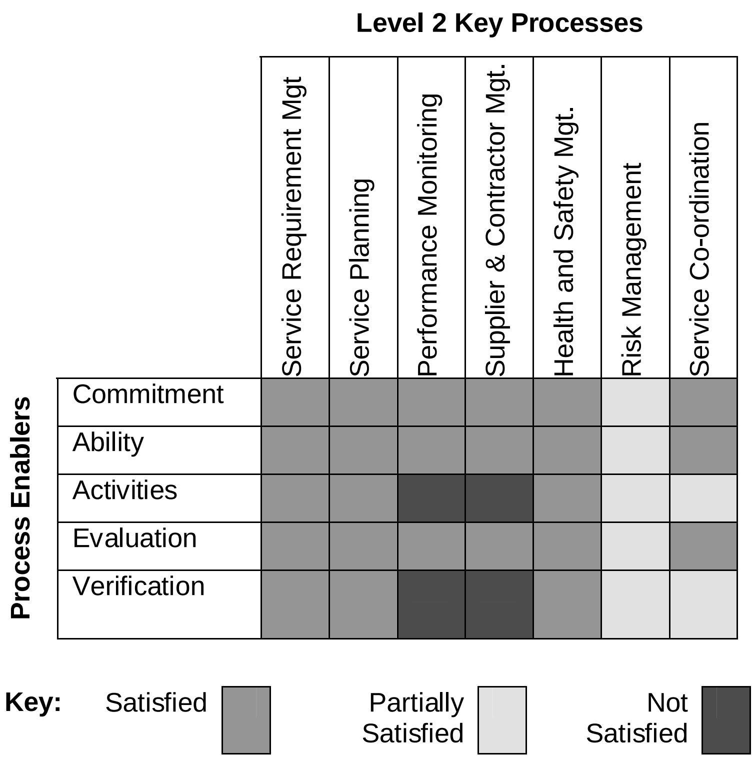
6.7 Process Evaluation and Verification

Evaluation involves basic internal process evaluation and reviews. These internal evaluations are used to help control and improve processes. During the early stages of maturity, this translates into efforts by the team to improve existing processes. The focus here is on the project team's internal improvement efforts. A verification procedure checks that activities are performed in compliance with the agreed process. Adopting verification as a process enabler in turn emphasises the need for independent verification by management and quality assurance. The focus is on external verification of processes.

The department is progressing with a significant change programme, supported by a dedicated resource to identify and drive improvements. A comprehensive "joint action plan" is in place to continually evaluate its operations, identify improvement areas and establish actions based on those requirements. Each action is assigned to specific staff and has clear target implementation dates. The "joint action plan" has a relatively small membership base, making it difficult for some employees to have an input into the process. The quality of communication to those employees has been variable. Consequently, everyone is aware that changes are taking place but the effect of those changes is sometimes not apparent. The value added to the core business through the change programme is not clear. The reporting systems being established within the department provide a checkpoint to ensure that the correct process is being followed. Some formal auditing of suppliers takes place, particularly in relation to health and safety issues. Procedures within the department tend to be informal rather than documented. To ensure that new reporting systems and processes are understood and adopted by staff, it may be necessary to formalise them, including the identification of clear responsibilities and duties. It is clear from the assessment that the department has established a suitable infrastructure to continuously review and improve its key management processes. Verification is also being addressed by this action, through the introduction of a new reporting structure.

7. Summary of process capability assessment

Figure 2: The department's process capability matrix



During the period of the SPICE FM study, the department was part way through a significant change programme aimed at improving the department's processes and reporting systems.

The change programme complicates the findings due to the inevitable collection of contradictory evidence – a before and after scenario. The SPICE FM assessment emphasises the importance of establishing the necessary infrastructure to support and improve processes over time and it is clear from the assessment that the department has allocated significant resources and introduced new systems that address this issue directly. Although the department still has some weaknesses to address, the necessary infrastructure is being put in place to identify and correct these issues in the future. Indeed, because of this infrastructure, many of the weaknesses raised in this report may already have been identified by senior management. Figure 2 is an attempt to summarise the department's process capability against the SPICE FM model. The matrix highlights the mature nature of its processes following the change programme. The main concern surrounding the change programme is the lack of clear strategic direction. Consequently, despite the efforts and likely performance gains the benefits to the core business are likely to remain unclear.

Encouraging Facilities Managers to Conduct Post Occupancy Evaluations

Nina Ryd,
Facilities Management Consultants Inc., Sweden (email:nina.ryd@fmkonsulterna.com)

Abstract

A range of methods for building evaluation exist. In post occupancy evaluation (POE) methods the focus is on user satisfaction. It is a formal evaluation of buildings made by its occupants after it has been completed, to identify areas that do not meet users' requirements. However these kinds of evaluations are seldom done in Sweden. This paper reports preliminary findings from an ongoing research and development project intended to implement the latest thinking and experience on POE into facilities management practice. The overall aim is to provide the Swedish market knowledge of how to make POE better, faster, cheaper and implemented in practice. Barriers to POEs are scrutinized, as well as suggestions of how these barriers might be overcome. An interview and questionnaire based method is applied. One basic assumption is that results from POEs is essential as input in the construction briefing process, as feedback for productive feed forward. Data generated during an evaluation is suggested to be used in the briefing process for a new building. The results provide insight contributing to the facilities manager's understanding of the potential benefits that an organisation can gain through the use of building evaluations.

Keywords: evaluation, tools, facilities management, briefing/programming*, corporate real estate, end users.

**The British concept construction and design briefing is used as a synonym to the American concept architectural programming throughout this paper.*

1. The Encouraging POE Project

1.1 Overview

This paper report preliminary findings of an ongoing research and development (R&D) project that aims to put into practice the latest thinking and experiences on Post Occupancy Evaluation (POE) and Building Performance Evaluation (BPE) at the strategic and operational levels for, facilities manager, clients, and building occupants. The project is founded by FORMAS, the

Swedish Research Council for Environment, Agricultural Sciences and Spatial Planning, during the period of October 2004 until June 2006.

The overall aim is to bring together knowledge and experience from practice and research, to provide knowledge of how to improve Swedish POE, make them quicker, and cheaper, and to develop compatible, robust methodologies for use throughout the life cycle of buildings, usable for facilities manager among others.

1.2 Industrial Relevance

This R&D project bring together contributors from the industry, real-estate companies, and the real estate division of one county council, one municipality as well as from universities [1], where new ideas about building evaluation can more easily be developed, reach industry's expectations and, methodically discussed.

The practical value of the project is expected as following:

- to consider barriers to post occupancy evaluation across a range of industry representatives
- put forward suggestions as to how these barriers might be overcome
- use the results from a POE as input in the construction briefing process
- In doing so it:
- encouraging the facilities managers improved use of feedback
- presents a way of measure building performance goals adjusted to a Swedish context
- presents barriers to POE as perceived by clients, facilities manager, designers, contractual bodies and POE activists and describes the perceived benefits of POE
- makes suggestion as to a way forward that might overcome the perceived barriers, including alternative means of dispute resolution - encouraging post occupancy evaluation
- outlines POE services offered for facilities manager as an aid for them to identify the purpose of an evaluation before selecting a suitable method.

In terms of the interaction between clients and users it is often suggested that the greatest improvement would come through the provision of systemised feedback and in instituting post-occupancy evaluation. It is unrealistic to expect buildings to operate perfectly at handover, some degree of post handover tuning are essential. In response to Rethinking Construction [2], The British RIBA Practice Services proposed a move towards making POE a standard service. This project will survey the Swedish conditions for such an approach and the conditions for the facilities managers taking a more offensive part in the evaluations process.

2. Post- Occupancy Evaluation and Value Management

Post-occupancy evaluation (POE) is the process of evaluating buildings in a systematic and rigorous manner after they have been built and occupied for some time - a definition of post-occupancy evaluation offered by Preiser et al. [3]; [4]. The evolution of POE begins with unique case studies in the late 1960s and continues to system wide and cross-sectional evaluations in the 1970s and 1980s. These assessments focused mainly on the performance of buildings. Now days' building performance evaluation (BPE) and universal design evaluation (UDE) stress a more holistic, process-oriented approach to evaluation. Prieser [4] emphasize that this will lead to that not only facilities, but also the forces that shape them (political, economic, social, etc.), are taken into account.

In the future, Prieser [4] expect more process-oriented evaluations to occur, especially in large government and private sector organizations. Ideally, the information gained through POEs is captured in lessons-learned programs and used in the briefing, planning, and design processes for new facilities to build on successes and avoid repeating mistakes. Consequently, POE is not the end phase of a building project; rather, it is an integral part of the entire building delivery process. It is also part of a process in which a POE expert draws on available knowledge, techniques, and instruments in order to predict a building's likely performance over a period of time. In this sense, a process is understood as a bounded group of interrelated work activities providing output of a greater value than the inputs by means of one or more evaluations.

The concept evaluation include value, thus, occupant evaluations must state explicitly whose values are referred to in a given case. An evaluation must also state whose values are used as the context within which performance will be tested. This research and development project focuses on the values behind the goals and objectives of those who wish their buildings to be evaluated, in addition to those who carry out the evaluation. Value, in its relevant sense, describes benefits to the client and can be quantified in business terms; for example, value describes the improvements patients experience during treatment, or the value an employer or an employee receives from creating a better working environment. Kelly et al. [5] define value from the client's point of view as a relationship between cost, time, and quality where quality includes esteem, exchange, and use. Furthermore, Kelly et al. [5] defines a value system as the representation, at a fixed point in time, of a discrete range of variables against which all decisions affecting the core business or a project can be audited. The variables are determined by time, cost, and quality. Value Management (VM) is a planned, multidisciplinary group decision-making process that supports the improvement of the value of a project, process, or product in a manner consistent with the business goals of the stakeholders and customers [6]. While this often leads to cost savings, more importantly it provides the best outcome for a project by considering a variety of evaluation criteria. These assessment criteria are most useful in POE:s and help clients, facilities managers and other stakeholders identify a desirable building project

The understanding and fulfilment of requirements is also closely related to the concept of quality, which is a measure of the extent to which requirements and expectations are satisfied in relation to their own set of values [7].However, this research project focus on the construction client as one major stakeholder for such an evaluation and the Facility Manager as the adviser in quality evaluation matters.

2.1 Experience from Existing POE Methods

From current research and practice [4]; [5] certain types, or levels of effort of POEs can be identified. For example: -indicative, investigative, and diagnostic as well as its different phases – planning, conducting, and applying. These can also be divided in two main categories – user based evaluations or expert based evaluations. The facilities manager role is to be familiar with the different types of POE:s and recommend whether more or less expert-oriented methods is needed. Hence, qualified evaluators usually carry out the process and users contribute at the request of the evaluators. The facilities manager is thus assumed take responsibility of the planning, preparation, selection of interests groups, as well as review of the evaluation.

Within the limitations of this paper, it is not possible to completely describe the different POE types. However, this paper would not be comprehensive without concise accounts of these types.

Indicative POEs give a hint of the most important strength or success as well as weaknesses or failures of a building overall performance. Data collection is made fast and easily available. Indicative POE:s usually consist of selected interviews with well-informed staff members, as well as a subsequent walk-through evaluation of the facility. The typical outcome is understanding of issues in building performance and recommendations presented in a short report.

Investigative POEs go into more depth, often as a second stage after that a problem has been identified during an indicative POE. This level of evaluation relays of a more sophisticated data collection such as for example comparison with reference buildings as one way to identify the reason to problems. Evaluation criteria can also be found in the functional briefs, or have to be assembled from guidelines, performance standards, or available literature on the specific building type. The result from an investigative POE is presented in a report and gives a more thorough understanding of the foundation and matters in building performance together with plans for action.

Diagnostic POEs contains of a multi–method strategy, counting questionnaires, surveys, observations and physical measurements by the intention to compare physical environmental measures with subjective occupant measures. The outcome is usually long-term oriented as the results after several months of assessment generate new knowledge about the performance of the specific building as more general aspects of the whole category of that particular building type.

For each level of POE there are tree phases - planning, conducting, and report of findings. In this R & D project the facilities manager is suggested to take the responsibility for the planning phase and preparations of the POE project. One assumption is that the facilities manager should be able to identify the purpose of the evaluation and after that select an appropriate level of conducting the POE. This assignment includes investigation and feasibility, resource planning, and in case of need even research planning together with qualified evaluators. The facilities manager is thereby responsible for that the constraints for the POE project are well-known by the participants. The facilities manager is also responsible for the schedule, costs, and skills needed. When the evaluation is completed the facilities manager should report the findings in a proper way to staff members as well as to the facilities department as an outlook for future action.

3. POE for Construction Clients and Facilities Manager

In much of the recent debate on the construction industry, construction clients are pointed to as the major steering force for directing the construction processes and results [8];[9]; [10]; [11]. The construction client is also responsible for ensuring that wishes and preferences of the end user are met and that all laws and regulations are complied with. A construction client is a person or organisation that contracts the construction of an object (a building, road, bridge, facility) [12] either for their own use or someone else’s. The construction client may be the real estate owner or the one who orders the proposed construction. Sometimes, but not always, the client is also the user of the building. Regardless, the construction client often represents many different interests in terms of required services, functions, designs and interpretation aspects. This is a function that represents the owner’s interests, perhaps even representatives of the client, the end-user, the operations that will use the facilities and different groups and organisations that in one way or another are influenced by the proposed planning, production, operation, and/or demolition process.

The basis for being able to satisfy the needs of the client, however, is a good understanding of the client’s situation, which demands effective means of working within the construction and management processes [13]. Large client organisations who procure new buildings on a regular basis, the maximum value only can be achieved if it is used in conjunction with an ongoing commitment to post-occupancy evaluation. Construction briefing and POE:s is seen to provide the means of ensuring that an individual building design satisfies an organisation's strategic property needs. However, it is also necessary to recognise that an organisation's strategic property needs will continually be in a state of change. As the Facility Manager have the responsibility to strategic planning, aligned to business needs and demonstrating contribution to archiving explicit business needs this acquire effective change management in combinations with evaluations skills. Consequently, economic and functional under-performance can only be avoided by regular performance evaluations of existing facilities in accordance with changing requirements [14].

4. Systematic Feedback to Improve the Briefing Process

The less well exploited opportunities for improving performance, reducing costs and abortive design time lie in the rationalisation of the client's briefing and evaluation process. The major focus has been on improving the construction design and delivery with much less concern for achieving gains by rationalising the client briefing and evaluation. The improvement of the client briefing and evaluation process by systematising the gathering and application of feedback from completed projects to improve the construction industry productivity, building performance and user satisfaction.

This R & D project will encouraging the improved use of feedback particularly for clients with continuous building programmes that will facilitate the prescription of tried and tested solutions yet allow and encourage value-adding innovation in a controlled manner.

5. Preliminary Findings – Feasibility Study

In order to understand the problems and barriers to POE:s one initial feasibility study were carried out. This investigation includes literature studies and a workshop with the industrial partners. The findings from literature studies regarding the use of post occupancy evaluations and the tools utilise will be combined in order to provide a deeper understanding of the mechanisms that are fundamental for minimising the barriers of innovative post occupancy evaluations. The workshop provided some preliminary findings that are to be compared with the outcome from future following interviews, a comprehensive questionnaire and deeper analysis of the literature study.

Preliminary results indicate that:

- There is a call for for checking that the desired objectives are met. The industrial partners' claims that thorough requirements are not met in the final product too often. However, the partners neither conduct nor have appropriate verification methods for assessing the desired performance of given building properties.
- The partners wish to ensure that the desired performance targets will be fulfilled. And if this is not possible, they want to know this beforehand. There is a call for early and continuous verification to take place in the design process and not only as a post occupancy evaluation.
- Expectations, goals, and objectives for the evaluation program are to be stressed. The focus of the evaluation /POE information-gathering process has to be more expressed towards respondents.
- There is a wish for feeding back the results of a POE to building practice, enable or constraining the performance approach and its benefits. Information gathered through evaluations/POEs should be tied into feedback loops for planning, briefing, and capital asset management.

- The partners seek for arguments, criteria and driving factors for establishing whether an evaluation should be conducted or not - with the intentions to empower the facilities manager.
- The facilities manager has an important role in being familiar with different types of POE:s and recommend whether more or less expert-oriented methods is needed. The facilities manager is also assumed to take control of the planning, preparation, selection of interests groups, as well as review of the evaluation.

The next steps in the process are as follows:

1. Start-up (October 2004 – mars 2005): A feasibility study in the form of studying the participating partners POE tools, perspective and other background material. Planning of the following empirical study, and the formulation of questions for the interviews and questionnaires. Contact with key persons within selected construction client organisations.

2. Data collection and theoretical analysis: Data collection, retrospectively by a detailed evaluation of a selection of the industrial partners recently completed new- build and refurbishment projects. The carrying out of the first series of interviews based on the selection strategy from the feasibility study. Preliminary analysis. Interim presentation in the form of POE-seminars. The formulation of questions for follow-up questionnaires.

3. Continued data collection and theoretical analysis: Follow-up interviews and implementation of questionnaire study. Continued processing and analysis of the case-study data gathered in. Workshop techniques with the industrial partners and members of specialist occupier-focused organisations with various backgrounds such as health, education, academic institutions, housing, and others.

4. Analysis of data and final report (June 2006): The final report, a national implemental POE tool and efforts to spread the findings of the project. Opportunities for improvement developed through workshops into a generic briefing and evaluation framework appropriate for organisations with continuous building programmes.

6. Conclusions

In the framework of this R&D project the participants have stated that the assignment for the future work is to:

- focus on tools and techniques for management of requirements throughout the entire construction and design development process by making available internationally based briefing and evaluation support methodologies, tools and concepts through research, management, execution and dissemination.

That is the goal we are pursuing for and it goes beyond merely establishing a set of evaluations tools. As presented earlier in this paper there are already progresses in parts of the briefing process but big gaps still exist in the evaluation process to really enable the mission statement to be realised.

A Simple Reliability Analysis of Essential Services in a Building

Timothy Michael Lewis
Department of Civil and Environmental Engineering, The University of the West Indies,
St Augustine, Trinidad & Tobago, W.I. (Email: tmlewis@eng.uwi.tt)

Abstract

In a hot tropical climate it is important to have building services functioning in such a way as to provide a suitable level of functionality and comfort for the normal use of that structure. A fairly modern university building in which high levels of sustained concentration are expected to be maintained needs certain basic standards of service, such as those of lighting, ambient temperature and availability of water for drinking, washing and waste disposal. A study was undertaken of a particular building of this description that has suffered from fairly regular interruptions in service ever since it was completed. A study was undertaken to record the interruptions to services to the building during the year 1999, and a simple reliability analysis suggests that the level of service was below what should be considered acceptable.

Keywords: essential services, electricity, air-conditioning, water, probability.

1. Introduction

When a building is being designed and constructed one of the key parameters that must be taken into account is the functionality and comfort for the normal use of that structure. The building's performance when in use can be affected by its design, its construction, its maintenance and by factors that are external to the building. The ideal is to provide a building that is comfortable, efficient, safe, healthy and durable. The recent focus on 'sick buildings' in various parts of the world has also brought home the economic impact of malfunctioning building systems in terms of the human costs incurred. The huge increases in energy costs have also alerted building designers and users to the importance of energy in the life-cycle costs of buildings, and increasing general awareness of the issues related to global warming and sustainability have also served to change the focus of building system design.

In a tropical climate, as exists in Trinidad & Tobago, design practices nowadays take into account most of these factors, however, the University of the West Indies has a significant legacy of buildings completed more than a decade ago in which the design parameters were less far sighted. There are also differences between building designed and constructed in the optimism of boom periods, and those constructed during the pessimism of a slump. In the former case, for example, less attention was paid to sustainability and life cycle cost issues than in the latter. This has had far reaching implications for the long-term facility management of these buildings.

Little systematic research has been done into the performance of the buildings within the University Campus so a start has been made into the recording of the breakdown of the systems in place in order to establish the sacle of the problem, and then to diagnose, explain and attemp to provide solvutions to the failings identified.

2. The Building Systems

In a tropical climate the design of buildings for comfort must address, particularly, the flow of heat from outside, as well as disposal of the heat build up from occupants and appliances inside the building. In old-fashioned structures the design encouraged cross ventilation using the tendency for heat to rise as well as the natural wind patterns to keep the internal spaces cool. Very modern buildings use photo-voltaics and solar energy and limited air conditioning to assist nature. However, buildings designed and constructed during the boom years of the late 1970s and early 1980s in Trinidad & Tobago, made no such concessions. Although the standards and regulations regarding what are considered essential building services have not changed significantly, the approach adopted by most architects has. The result has been that a number of the buildings of that period have proved to be problematic in operation, and have had to be retrofitted with systems designed to improve their performance. This is not to say that the buildings were badly designed for the time when they were designed. They were well designed given the knowledge and objectives of the period, however, things have changed since the building was completed. [1]

As an example, the building in question was designed as a solid, box-shaped, mass-concrete structure, in which the separate rooms and offices needed to be air-conditioned. The system chosen was a water-cooled system, with fan-based blowers in each room. It was also designed on the premise that it was cheaper to leave the lights on inside the building permanently than to install switches and allow occupants to turn lights on and off. The reduced wear and tear on bulbs and the saved expense of installing wiring and switches was felt to more than offset the cost of electricity being wasted in empty rooms. In addition there was the benefit of the aesthetic cleanliness of walls without wires and switches. As time has passed, the logic behind these choices has become suspect.

The key services to this structure are those that make it usable in the most basic sense. Because of the building’s configuration and structure, it experiences significant heat gain during the day and because the building is designed to be closed up (i.e. the doors have return springs to close a door after it has been opened) it has very little natural ventilation. As a result air conditioning is essential – all the more so in rooms like lecture theatres where relatively large numbers of people gather for extended period, and computer laboratories where the equipment generates significant heat. Because the air conditioning is water based, it is necessary to have water to feed the system, and electricity to activate the blowers. In a building in which staff and students need to be able to read and write documents of various kinds it is obviously necessary to have adequate lighting, which again requires electricity. Similarly in a large public building where people will be spending a major part of the day it is necessary to have water available for drinking, washing and the flushing of toilets. The lack of water for air conditioning also signals a lack of water for fire fighting, and this threatens security as well as comfort levels. Thus, if any one of these three services (air conditioning, electricity and water supply) is unavailable the building becomes very un-user-friendly.

3. System Reliability

Reliability is a broad term that focuses on the ability of a product to perform its intended function. Mathematically speaking, assuming that an item is performing its intended function at time equals zero, reliability can be defined as the probability that an item will continue to perform its intended function without failure for a specified period of time under stated conditions. [2]

Engineers undertake reliability analysis in order to measure and predict the reliability of mechanical or electrical components and systems. Measurement is based around the occurrence of failures, and analysis depends largely on statistical probabilities. The probability of the survival times for components and systems can be used to help predict their life expectancies. The more complex the set of components and their interdependencies that maintain a system in effective operation, the less reliable that system becomes. When that system is one on which our comfort and convenience depend then it is unfortunate when it breaks down; when it is one in which failure can be life-threatening then it is critical.

A simple measure of reliability can be obtained in terms of the proportion of the actual recorded observations relative to the total instances on which an observation could be made. This can be represented in one of two ways, as shown in equations (1) and (2):

$$\text{Reliability} = \sigma_{(\text{actual measure})}/\sigma_{(\text{total possible observations}} \qquad (1)$$

$$\text{Reliability} = \sigma^2_{(\text{actual measure})} / \sigma^2_{(\text{total possible observations})} \qquad (2)$$

In the case of equation (1) the reliability is measured as a simple ratio of the number of occasions when a service is not available to the total number of occasions when it could be available[1], and

[1] What we are doing here is to use a raw count of occasions when a service has been unavailable in order to determine its frequency – and hence the relaibility of the system. In the example of the air conditioning there were 105 days on which the service was out of action out of a total of 250 possible days, so the

where a system involves a number of independent processes working together, identified as $\sigma_1, \sigma_2, \sigma_3$ for example, the value of the reliability index is derived as the multiple of the separate ratios, hence:

$$\text{Reliability} = (\sigma_1/\sigma)(\sigma_2/\sigma)(\sigma_3/\sigma) \qquad (3)$$

In the case of equation (2) the total system reliability is given by the sum of the individual measures, and because we are not dealing with variances here, the use of standard deviations is not really appropriate. However, the strength of the relationship between two states is sometimes expressed by squaring a measure of their interaction (the correlation coefficient) and multiplying by 100[2], it may be acceptable to measure the overall reliability of a system by squaring the reliability index for each parameter affecting the system and adding these values. The reason why squaring the index may be appropriate is a result of the way in which correlation is defined, hence

$$\text{Reliability} = (\sigma_1/\sigma)^2 + (\sigma_2/\sigma)^2 + (\sigma_3/\sigma)^2 \qquad (4)$$

There are much more complex models of reliability available based on such measures as the mean time between failures (MTBF) for example, however, given the coarseness of the data acquired for this study, the equations here are more than adequate. The reliability values obtained from these two simple models are compared to see what difference in reliability is indicated.

4. The study

The building used in this brief study was the civil engineering building, known as Block 2 at The University of the West Indies, St. Augustine, Trinidad & Tobago for the year 1999. The basic methodology was to keep a daily record in a desk diary of the occasions on which any or all of the specified services were non-functional. Because of the coarseness of the raw data, the lack of explanation for the events causing loss of service and the preliminary nature of the study, no detailed statistical analysis has been undertaken. All that has been done is to calculate the values of two alternative ‘reliability indices’ that can indicate the overall system reliability - where:

P(x) = Probability of an event x

---

measure of reliability is that on 42% of working days, there was no a/c. This approach is used because of the familiarity of the concept of a percent frequency.

[2] The resulting statistic is known as variance explained (or R^2)

A = Air-conditioning malfunction

E = Electricity outage[3]

W = Disruption in water supply

$P(x) \approx$ [(Number of days failure occurred)/(Total number of working days 250)]

$P(A) = 0.42$

$P(E) = 0.04$

$P(W) = 0.27$

Assuming that P(A), P(E) and P(W) are independent processes, the probability that on any given day the three essential services are concurrently **working** is – using equation (3):

$= (1 - 0.42)(1 - 0.04)(1 - 0.27) = 0.58 \times 0.96 \times 0.73 \approx 0.40$

and the probability that on any given day the three essential services are not concurrently working is – using equation (4):

$= (0.42)^2 + (0.04)^2 + (0.27)^2 = .176 + .0016 + .073 \approx 0.25$

Giving a probability that the three essential services are concurrently working on any particular day as around 75%. Instinctively this 'feels' like a more reliable value for the probability of the all the systems working, given the practical experience of the day-to-day serviceability of the building. The value of 40% for the building availability is very low, and although it was a particularly bad year, it seems unlikely in retrospect that it was so bad. It must also be noted that there were breakdowns of various systems that lasted for extended periods, such as several weeks without air conditioning. So the values do not represent discrete occurrences of breakdowns of particular days, but rather an overview of the effect of breakdowns on the system.

It must be said that the 'better' value for the probability of all systems working, of 75%, is not very good, as the failure of any one of these systems is sufficient by itself to make the building virtually uninhabitable. The problems that are responsible for this poor level of reliability are almost entirely extrinsic. The supplies of water and electricity which govern the functioning of the building support systems are public utilities outside the building and the campus, over which nobody within the University has control. However, the choice of a water cooled air conditioning

[3] This does not include voltage surges or short term, transient outages.

system built in an extra mode of failure for this critical system – it fails when there is no current and it fails when there is no water. In addition the choice of a central air conditioning system means that when it is down, none of the building is properly usable. The central system is also running all the time, cooling the building even when it is empty. Although it would have been a larger capital expenditure at the outset, much more flexibility and economy in operation would have been achieved by designing individually controlled air conditioning systems with thermostatic controls that automatically cut off when the temperature reaches its design level.

5. Conclusions

Obviously it is desirable to have a building that is used for University staff and lectures available almost 100% of the time. Thus it is necessary to improve the reliability index of the building's availability from its current value of around 75% up to around 100% by improving the systems that cause it to be unavailable. There are various techniques available to help identify problems and solutions including Fault Tree analysis and Failure Mode and Effects Analysis. These techniques can highlight the effects of failures in elements of the design in order to help find ways to reduce the probability of a loss of service occurring.

An economic cost-benefit analysis can help to identify which amongst the technically feasible solutions are economically feasible as well. Given the change in the economic parameters that exist nowadays compared with those that existed when the building was designed and constructed, it is almost certain that the support systems are not optimized for today's market. Given also the failure of those systems to provide a sufficiently reliable building in terms of its availability, then there is a clear need for a review of its critical design characteristics. The two key elements are electricity and water, and if the supply provided by the public utilities is inadequate, then the building systems need to be designed to take this into account. Depending on the cost functions, this may mean either building storage for sufficient water and installing stand by generating capabilities or redesigning the systems to operate differently.

It also seems likely that the economic efficiency of the system is now poor given that there is a lot of waste of energy through air conditioning and lighting that is not turned off when rooms are not occupied. Although this does not show up in the analysis carried out for this study, it is an observation that is hard to avoid.

6. Acknowledgement

I should like to express my gratitude to my colleague Dr Gyan Shrivastava[4] who kept the detailed records of the availability of services in this building, on which this commentary was based

Demonstrating the Added Business Value - Appraisal of Tools and Methods

Riikka Huovala
DEGW. Workplace strategies (rhuovala@dewg.com)
Keith Alexander
University of Salford. Department of Construction and Property Management
(K.Alexander@salford.ac.uk)

*This paper reports findings from Masters of Philosophy thesis completed whilst working in Centre for Facilities Management, School of Construction and Property Management, Salford University. Subsequent to this work, the author is currently working in DEGW, London.

Abstract

This paper is concerned with the appraisal of current workplace performance measurement tools and methods, and identifying flawed understanding within them to distinguish how they could be further developed to enable better demonstration of added business value through workplaces. Thus this paper presents an exploratory framework (rather than a review of previous work) for those facilities/workplace managers as well as academics and consultants who are keen to develop business oriented workplace performance measurement tools.

Practice-initiated problems have been used as a basis for this research, representing a timely, real world, enquiry. The aim of the research was to reflect on and critically appraise the current tools and methods documented in literature and used in practice - 14 varying tools were identified and examined. The setting of logical and comprehensive criteria for the critical appraisal became a fundamental challenge -better understanding of different approaches to workplace performance measurement was needed. This was achieved through a parallel review of the Centre for Facilities Management's case study database and through a literature review. Further interviews were also carried out with the FM practitioners to confirm the findings and to better understand their practice of workplace performance measurement.

Gap analysis of the identified methods and tools, and the proposed criteria was undertaken. It was recognised that these tools and methods place little emphasis on supporting the continuous change within organisations and that an understanding of people activities, such as communication and team interaction, was under developed. Paper concludes with recommendations for further development for workplace performance measurement tools and methods.

Keywords: workplace performance, tools/methods, Facilities Management, usability

1. INTRODUCTION

The competitive market has pressured companies to produce more, to a better quality, in less time with fewer resources, hence the drive to increase business productivity and cut costs. At the same time the nature of work is becoming less tangible and the employees are increasingly considered as the most valuable resource of an organisation. One consequence of this is that the relationship between an organisation's measured resources and its market success has become tenuous[1]. This leaves organisations in a situation where core competencies, such as the ability of employees and teams cannot be tangibly measured and listed on balance sheets. Nevertheless, the traditional approach to increase productivity has been to reduce costs and especially costs not directly involved in creating tangible value are usually the first ones to be scrutinized [2]. In the field of facilities management this has meant that the need to demonstrate the contribution made to improve productivity has intensified. Nutt et al.[3], for example, suggests that two of the key questions for the future of FM includes how to create, quantify and demonstrate linkages between FM and business, and how to assess and measure the contribution of FM to improving business productivity. One fundamental attempt to illustrate this contribution has been directed toward high performance workplaces – and the demonstration of the business value through workplaces. This has meant that facilities managers and other related disciplines have to go beyond the traditional methods of controlling costs and maximising the value of the built assets by utilising space, by placing more emphasis on the impact workplaces can have on the performance of the people.

Similarly, in addition to the general discussion in the field, the practitioner-led Facilities Management Forum (facilitated by Centre for Facilities Management and led-by senior managers of large UK/global organisations[i]) initiated, in 2002, a research enquiry to gain more knowledge about workplace performance measurement and associated tools to provide a framework for the demonstration of the business value. The Forum group agreed that [4]:

1. *The FM practice suffers from an over-emphasis on cost reduction, which limits the ability to demonstrate potential workplace improvements due to the insufficient evidence of the value these would add to the business.*
2. *They also suggested that 'one reason for this is a lack of workplace performance measurement knowledge' as the measurement of workplace outputs has until recently been largely non-existent*
3. *Those measurements being developed focus on the efficiency in Facilities Management processes (such as cost against cleaning process), rather than the development of effectiveness measures (such as contribution of clean buildings to the reduction of sickness and absenteeism), which would create a link between Facilities Management input and output and would be seen as a contribution of FM to the core business.*

[i] The CFM forums facilitate the open exchange of facilities management best practice and provide structures for a non-competitive environment to debate common issues, concerns and market trends. The CFM forums work on an action research basis (as defined in Alexander *et al* 2003) and therefore the main principle in the collaboration is to narrow down the research interests through the activities and interests of the participating organisations. Forums operate in two ways. In the first instance, there are workshops, which encompass discussion and debate about topical FM issues, with guest speakers from within and outside the industry driving forward the discussion themes in a bid for breakthrough solutions. In the second instance, forums generate long-term research projects.

4. *Further it was identified that there is a lack of qualitative measures. It was suggested that metrics that fail to measure quantitative and qualitative performance outcomes may depict an inaccurate picture of what really happens in the organisation.*

From these issues the practical enquiry (as used in the forum) was formed: ***How to demonstrate the business value of improved workplace performance?*** This enquiry motivated the authors to carry out further investigation, with more theoretical rigour, to run parallel and subsequently to the implementation of a workplace performance framework developed for this forum activity. It was believed that a more thorough understanding than was possible to be gained within the business timescales was needed and therefore the practical enquiry was lifted from the forum for the purposes of theoretical reflection.

Subsequent interviews with the practitioners within the six case study organisations further validated the forum enquiry. The following statements were recorded when senior managers were asked about their concerns associated with workplace performance measurement :

- *'The facilities management calls for a means of collecting 'soft' data to support better management decisions.'What should Central Services do in order to reflect the corporate value in physical workplaces?*
- *'What would the appropriate tools for measuring the performance of FM be that go beyond the focus on 'cost per' and are valued by the business?'*
- *'How can we implement flexible workplace concepts to meet business needs in terms of trust (related to staff absence), communication between managers and employees and team working to support off-site working?'*
- *'How to improve the employee's working environment to enhance performance?'*
- *'How to measure office effectiveness and to demonstrate that certain layouts have increased input?'*
- *'How frequently workplace performance should be measured?'*

In this context, these practical enquiries were expanded upon to define research questions and the scope. The following questions were created:

1. *What requirements can be identified in literature and in practice for the measurement of workplace performance to enable the demonstration of the value of the workplace to business?*
2. *What tools and methods that aim to demonstrate value are currently documented in literature and used in practice and what do they actually measure?*
3. *How do these tools meet the set theoretical and practical requirements identified?*

The paper first describes a research process, emphasising a practice-led research approach. In turn, this is followed by three sections, each providing identified answers to the three research questions presented above.

2. RESEARCH PROCESS / METHODOLOGY

2.1 Practice-led research

Instead of following the conventional approach of identifying research problems through an extensive literature review and aiming to find answers to these (theoretical) problems through investigations within practice, this research emphasises the importance of defining the research topics through understanding the practical enquiries in the field (of FM). Thus, the participation of practitioners is fundamental to the usefulness of the research undertaken, as they contribute to the research process and the monitoring of the relevancy of research to practice. The importance of involving practitioners in the defining of a problem has been emphasised [5,6,7,8]. Lawler [5] states that: '*clearly the researcher ought to offer expertise about theory, past research, and methodology, but needs to rely on the members of the organisation to provide expertise about the practise. For this to happen, the practitioner has to be involved in the study at a more than superficial level and, indeed, has to influence both the kind of topic studied and methods used*. It has also been recognised that the thorough knowledge of prior research is very important, it is very rare for good research ideas to be derived directly from literature [6].

2.2 Research process

The practice-led research process and methods used are presented in the Figure 1. The research questions (as presented above) were narrowed down through a content analysis of the problem defining process of a FM practitioner-led research forum and through an initial literature review. As the setting of logical and comprehensive criteria for the critical appraisal became a fundamental challenge - a better understanding of different approaches to workplace performance measurement was needed. This was achieved through a parallel review of the Centre for Facilities Management's case study database and through a literature review. Further interviews were also carried out with the FM practitioners of the research forum, but also with other case study organisations (to gain a broader view) to confirm the findings and to better understand their practice of workplace performance measurement (six case studies).

As a result, exploratory criteria were developed and further examined. Parallel to the case study investigations, eight workplace performance measurement tools/methods were identified within literature. A gap analysis was carried out to define how the tools used in practice and identified in literature met the created criteria for workplace performance evaluation, providing suggestions for the further development of measurement tools.

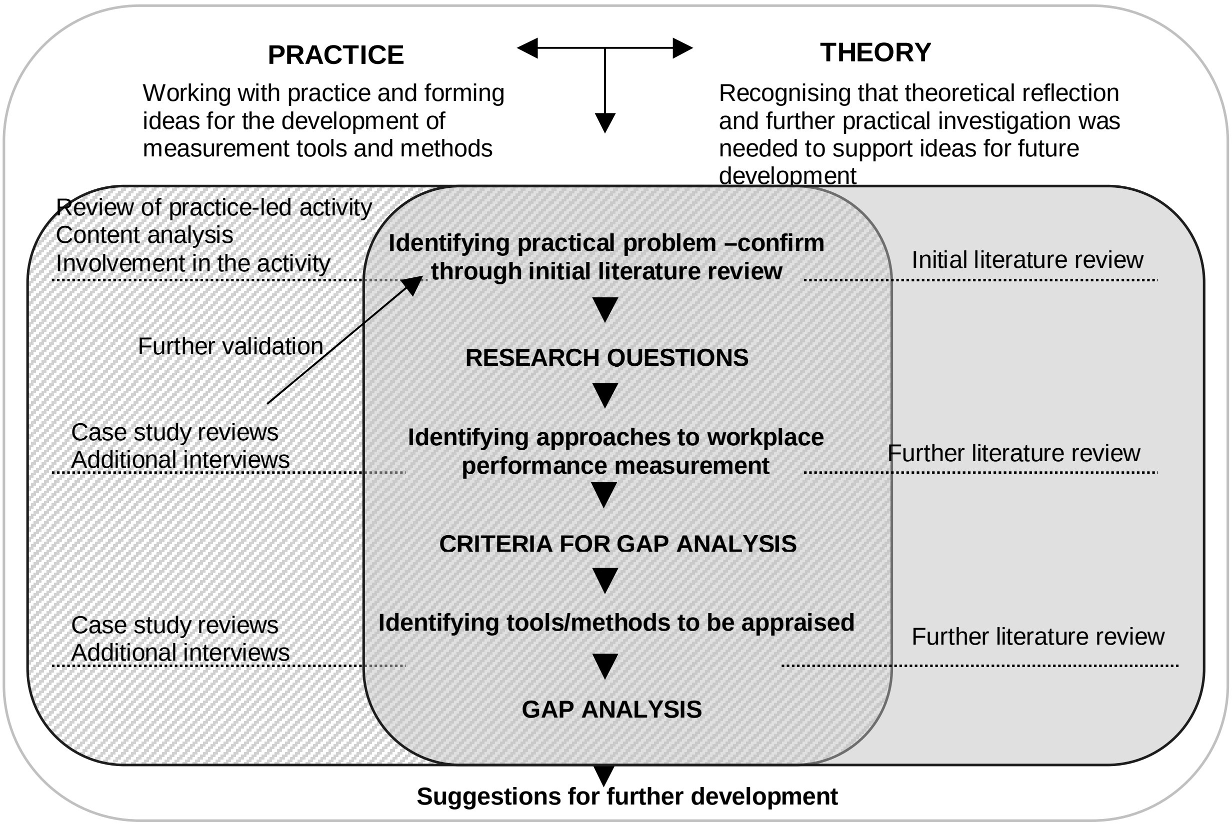

Figure 1: Parallel research process of practical and theoretical reflections

3. WORKPLACE PERFORMANCE MEASUREMENT

Research Question 1: *What approaches/ requirements can be identified in literature and in practice for the measurement of workplace performance to enable the demonstration of the value of the workplace to business?*

As the authors' aim was to define what is meant by workplace performance and what elements it consists of (to better understand what should be measured) different definitions, and practical examples were initially examined. It was recognized, as the nature of practical enquiry demonstrated, that amongst practitioners there was a clear lack of definitions for workplace performance. Instead, it became more relevant to understand what was driving measurement in the case study organisations. The following drivers for practice approaches were provided:

- Need to develop other means of collecting 'soft' data to **support better management decisions**.
- The results need to be transferable into reasonable indicators to **feedforward** to probability cash flow

- **Identifying spatial needs -** focus on collecting information concerning work functions- what facilities are used and when.
- Collecting information on the **current situation -** to understand where the company is now and **what should be improved**
- Providing a further benefit of data collection as to **illustrate change** (improvements) over time.
- **Identifying the major issues** relating to the ways of working
- External benchmarking comparisons are seen as a useful **reassurance** that the service is competitive/effective compared with other market benchmarks.

These identified, practical, purposes for measurement reflect on literature. Nani et al [9] see performance measurement as a means of monitoring and maintaining organisational control to ensure that strategies that lead to the achievement of overall goals and objectives are pursued. The purpose of performance measurement is also to clarify *organisational success* and to *inform and guide change* (continuous, improvemental and emergent change and discontinuous change) [10]. It is also proposed that applying disciplines of performance measurement helps to *determine the crucial success factors* for the overall organisation as well as for the delivery of the specific function or operation concerned [11]. Performance measurement is used for purposes of *problem finding and solving*, and it therefore supports efficient decision-making. It also helps to *identify the success of improvements*, determine whether the *customers' requirements are met* and where *improvements* are needed. Further, measurement helps in the understanding of *processes* (in terms of confirming what is known or revealing new) and to *ensure decisions are based on fact* [12,13].

However, even though the drivers were clear, it was recognized that in literature there are numerous different approaches to defining workplace performance, also the terminology was perceived to be inconsistent. Examples of the used terms are: building performance, office productivity, workplace functionality, office environment and facility performance. Therefore, an initial attempt to define the criteria for the evaluation transpired to be complex, and instead, the overall understanding of the approaches was to be achieved through experimenting, at a more general level, different dimensions of measurement. As a result, four different approaches were identified. The distinct division between these approaches was the point of focus on either improving a product or a process. Similarly it was recognised that there was a division between measuring to gain benefit for construction industry and measuring to gain benefit for business itself. These approaches are demonstrated in Figure 2.

Approach 1: Construction Product

It was identified that one approach to workplace evaluation was to evaluate a building. In these cases literature often refers to a building's capability to meet the mandates and health and safety regulations. An approach of this kind is perceived to focus on the physical (tangible) elements that are valued from a quantitative perspective rather than a qualitative one. Also, the efficiency of different elements of the building (products) is assessed rather than the effects of them (on business process). Findings from these kind of approaches are often fed back to the construction industry to reflect on the failures within the building [14].

Approach 2: Construction process

Similarly, the construction industry benefits from evaluating the physical product, and failures within, by reflecting the results on the construction process and how the briefing or management of the process, for example, could be improved.

Approach 3: Product for Business

The focus in this approach is perceived to be on the workplace environment and people (occupiers') perceptions are considered as an integral part of the evaluation. However, people are only considered from a physical well-being point of view and better performance is to be achieved through a well functioning building (air-condition, ventilation, operable windows etc.). Similarly, a well-functioning building is a target when evaluating functionality. Nevertheless, not only the relationship between the physical environment and the individual is considered, but also the fitness (of workplace) for purpose from an organisational point of view is reflected on. Functionality is achieved if the original brief has been met or the objectives of the accommodation plan have been attained [15]. In this instance, also qualitative (subjective) issues are considered (fit for purpose, flexibility etc.).

Approach 4: Business Process

Originating from the product design/software industry, it is proposed that more focus should be placed on people activity. Furthermore, emphasis should also be placed on social and cognitive aspects rather than considering people only from a physical/ mechanical point of view - 'repertoire of action and potential to break down' [16]. Characters of measurement associated with this approach should focus on the users: ease of use, usefulness, user-friendly etc. Usability in the product and software industries is widely accepted as a critical element for a product to be successful.

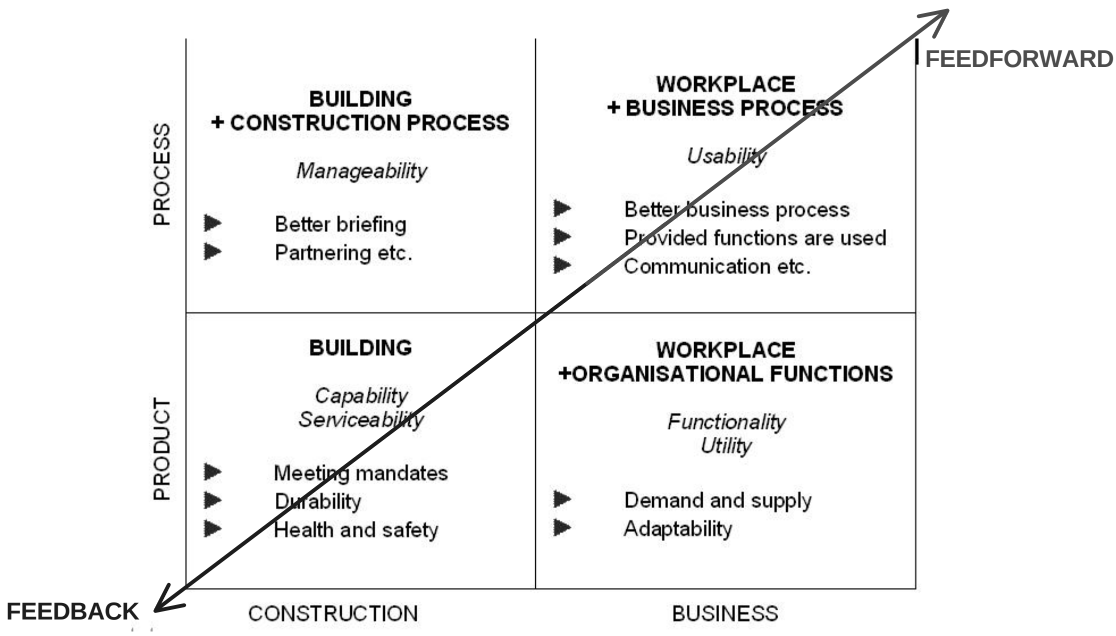

Figure 2: Approaches to workplace performance measurement

Feedback- Feedforward

It is also proposed that there is a fifth dimension to the approaches presented above: By evaluating the usefulness (of provided functionality) as in the approach 4, the knowledge gained is specific to that organisation and thus the nature of the feedback is to feed it forward to the development of processes and strategies within that organisation. Conversely, the assessment of the building from the physical point of view (approach 1) tends to provide feedback that is most useful for the construction industry. Thus, more focus should be placed on identifying how the business could benefit from evaluating the different elements of a workplace. Whereas assessing functionality aims at improving the physical product (workplace), usability aims at improving the business processes through better understanding them and through evaluating how the provided functions are actually used. It is proposed that the latter approach (Business process / usability) is seen to benefit the organisation the most as the results of workplace performance measurement can be fed forward to the future management of the workplace.

4. WORKPLACE PERFORMANCE MEASUREMENT TOOLS

> **Research Question 2***: What tools and methods that aim to demonstrate value are currently documented in literature and used in practice and what do they actually measure?*

To provide a context to the gap analysis, an overview of different approaches to workplace performance measurement within the six case study organisations and eight identified measurement tools/methods[ii] documented in literature is to be provided. The tools and methods used in the case study companies are first discussed. An overall comparison of the identified approaches is discussed in the next section.

4.1 Tools/methods in practice

All of the case study organisations had some means of monitoring workplace performance - most commonly: meetings with business units, monitoring of occupancy costs and utilisation of space studies. Occupant surveys and similarly Post Occupancy Evaluations (POE) type of surveys had usually been undertaken only once. Table 1 summarises six approaches that were considered as tools/methods.

[ii] The term ‘tool’ in this study is referred as to a research/data collection tool/method rather than, what could be perceived as, a verified measurement tool. The selected *tools* for the appraisal include various research tools/methods under development, but also more verified tools (mainly used in consultancy) are taken under examination. Common to these is a questionnaire-based approach to evaluation.

Table 1: Summary of the approaches to measurement in practice (case studies)

Method/tools	**Approach**
Time utilisation studies	Focus is on meeting the business needs to reduce costs (A, E, F).
Satisfaction survey	Focus on getting feedback on physical elements of the building and the service delivery (F)
Workplace performance survey	Focus on defining what aspects within the (physical) workplace and support services hinder task completion. (A,B,C)
POE	Focus on reviewing whether mechanical systems work in the new building. (A)
	Aim to identify satisfaction with environmental conditions and physical elements of space – whether workplace meets the expectations. (B,C)
	Aiming to understand how the space support business aims and objectives and functional requirements (F)
Communication network analysis	Focus on identifying who communicates with who – how is knowledge distributed and what impact space layouts and workplace improvements have had on communication (F)
Walk-through	Aim to identify what improvements in the management of workplace could be made and if physical changes needed. (D)
	Checking the quality of service delivery. (E, C)

4.2 Tools/methods documented in literature

Eight tools and methods were identified from literature (Table 2). A characteristic common to all of these was the development of performance of workplaces. All of these tools and methods include an occupant questionnaire (mainly targeted at staff, but in some cases at senior management only) and some of them also include specialist observations and measurements of the building and the environmental conditions within. However, the focus is not specifically on a process or method of data collection used, nor placed on the specific questions asked, but in the basic principles of the surveys. This is to better understand what these tools are aiming to measure and whether they meet the criteria identified in literature and in practice (which they were not necessarily developed to meet), and to identify what has already been done and tested and what areas need to be concentrated on in the future development of measurement tools and processes.

Table 2 – Tools under investigation

Tool	Approach
1. Workplace utility survey [17]	To assess usefulness, through defining the difference between the expectations and perceptions of the building's users.
2. User based building performance appraisal survey [13]	Provision of office accommodation design/ quality characteristics (supply) measured against specific property requirements (demand)
3. Hierarchical analysis model (HAM) [18]	To recognize the confrontation between the supply and demand of a set of building attributes, by identifying what kind of activity or organization does the building intend to suit (supply), and what kind of resources, installation or localization must be considered to suit a certain activity or organization (demand).
4. Office Environment Survey – Building Use Studies [19]	To identify positive and negative relationships between indoor environmental factors and human productivity.
5. Building-in-Use Assessment [20]	To determine patterns on comfort and discomfort throughout the building based on users' experiences and perceptions (functional comfort) and to relate this to physical environmental elements (such as floor layout differences, type of workstations etc)
6. Office productivity survey [21]	Matching facilities and building services to the specific business needs of the different departments within the building, through defining downtime factors, satisfaction and self-assessment of productivity. Defining the elements of the physical environment and how they can enhance or hinder performance.
7. The Serviceability Tools & Methods (ST&M)[22]	To specify the performance requirements for facilities, and to measure how well a design proposal, or an existing facility meets those requirements.
8. Workplace innovation Survey [23]	To enable analysis of the impact new workplace environments have on the performance (productivity, quality, flexibility and innovation) of organisations accommodated in these concepts, and to gain insight in the effects of technical, economical, social and organisational developments on the workplace.

5. GAP ANALYSIS

Research question 3*: How do these tools meet the set theoretical and practical requirements identified?*

The gap analysis is formed by evaluating the introduced tools (used in practice and documented in literature) against the proposed criteria (Figure 2). Thus, the provided matrix is updated to illustrate the current and proposed approach to workplace performance measurement through placing the introduced approaches onto this matrix according to the following aspects:

- To what extent have the organisational requirements been considered? Have they been considered from the point of view of space provision (functionality) or from the point of view of the actual support the space provides for business processes (usability)?

- Is the focus on improving the physical elements of the building (capability and functionality), on the process of constructing/ managing the building (manageability), or on improving the business processes (usability)?
- Is the main aim to collect information to feed back to the construction industry on their processes or products, or to feed forward to the business to enable the development of processes and strategies within their workplace provision?

As a result of this exercise, the demonstration of the gap between the current approaches and the proposed approach was enabled, as illustrated in figure 3 (blue circles illustrate the studied approaches and red the proposed target).

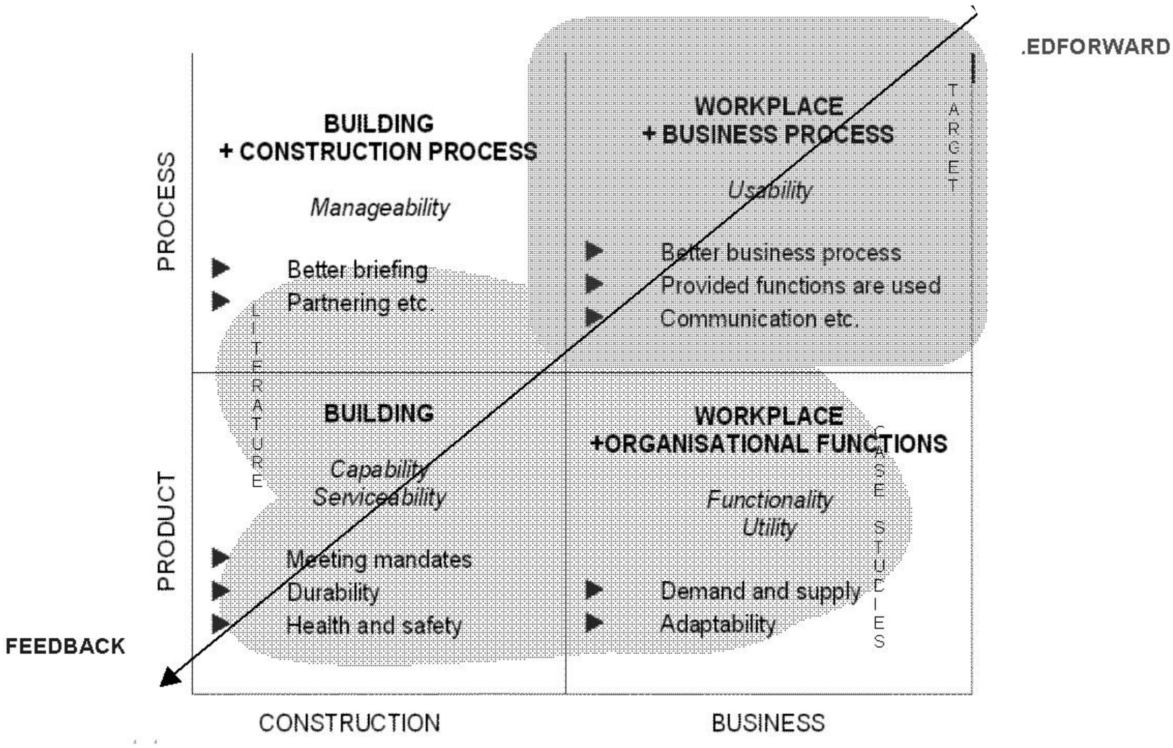

Figure 3: Gap between proposed and identified approaches

Thus it is proposed that there are no appropriate tools and methods identified for demonstrating the business value through workplaces. The following key reasons to justify this emerged:

1) Approaches focus mainly on providing feedback on the qualities of the workplace ‘product’ for the construction industry, thus little emphasis is placed on collecting information to support the continuous change within organisations (feedforward).
2) Focus is mainly on improving the physical workplace rather than the efficiency of the business processes – measuring the product rather than measuring the *effects* of the product.
3) An understanding of people activities, such as communication and team interaction that support business processes was underdeveloped.
4) The focus was mainly on defining the performance of a physical workplace, rather than the effects this has on the people activities.

6. Conclusions

As it has been emphasised, the workplace performance measurement should, instead of viewing workplaces purely from a functionality point of view (assuming that if the space supports the business functions it is useful), the usefulness of the workplace in use, during the activities, should be evaluated. Usefulness, learnability and ease of use were some of the qualities to be promoted. The aim should be to evaluate the effect of the workplace on the activities. By evaluating the usefulness of functionality, the knowledge gained is specific to that organisation and thus the nature of the feedback is to feed it forward to the development of processes and strategies within that organisation.

It is believed that the selection of tools that were documented in literature is fairly representative within the different UK approaches, but further investigation (prior to this thesis) is needed to confirm this i.e. an up-to-the-minute review of literature and other available material needs to be carried out. The scope could also be extended to an international level to identify whether different approaches have been taken elsewhere, for example, during the course of the study the authors have become aware of US based research that has established links between workplace design and job performance, job satisfaction and communication [24].

Less focus was placed on defining the processes of measurement as to who participates, when they are undertaken, how exactly they are carried out (reliability and thoroughness) and also 'by whom' and 'for whom' they are carried out. The impact of these elements needs to be further investigated.

The timing of the assessments and the replication of these, for example, are important areas of investigation, this, in turn, places importance on both the planning and design processes and on the on-going management processes. This enables the aims businesses set for new workplace settings to be reviewed and whether they have assessed the success of the outcome; but also whether there are/have been assessments of on-going (changing) business aims and any integration of these into the workplace settings.

(e-mail: smithjj@unimelb.edu.au)

Abstract

In this Melbourne local government area the proposed library-community centre was the largest construction project ever attempted by the Council (A$8 million). This project incorporated innovative briefing methods through the use of a performance brief, which was developed and agreed with a range of stakeholders. This work focuses on the interactions, activities and processes following the initial development of the performance brief.

The study examines the processes used by the Council managers as a provider and developer (client) of the facility on behalf of its rate paying public. Recording and analysis of the processes captured the organisational learning that occurred during delivery of the project. The learning outcome is a model for future practice to guide this Council and other similar community based projects.

Research data gathering has included review workshops, interviews with project team members, attendance at consultations with community facility user groups, analysis of Council project documents and other Council documents. Analysis has been by means of a qualitative methodology analysing the textual materials with coding and time-event mapping techniques to identify key events and themes.

The project has provided sound lessons in strategic connectivity with organisational and Council strategies, the inclusion of a range of stakeholder interactions and consultations of real benefit to the value of the project, the use of innovative performance briefing methods and identifying the characteristics of an informed and engaged client. The study synthesises the key aspects of the project into a normative community based project model that represents the lessons learnt in the delivery of this library- community centre.

Keywords: design management, community interaction, project processes.

1. Introduction

The importance of including stakeholders in project processes is being increasingly recognized as important in delivering satisfactory project outcomes (Gray, et al, 1994; Kamara and Anumba, 2001). This is despite Walker's (2002) observation about 'unreliability' in stakeholder assessments across project lives. It is possible that part of this unreliability arises from not adequately engaging with and binding stakeholders into project processes from early stages.

This paper builds on earlier work by one of the authors into processes at project inception (Smith 2002) by examining the implementation of a stakeholder approach throughout pre-construction processes. The project examined is an *Urban Village* Library-Community Centre and originated from an external review by one of the authors of the processes designed and implemented by Council in delivering this important project. The Library-Community Centre is the largest construction project undertaken by this municipality (a middle suburban local government in Melbourne) with construction expected to be completed in mid-2005.

This paper is divided into three major parts as follows:

1. an identification of the most significant processes used in delivering the project including strategic connectivity;
2. an examination of the role of clients in construction projects and how the municipality has acted as a client in this project. This includes consideration of the interactions (including, but not exclusively, consultation) involved in delivery of the project; and
3. the 'Glen Eira Model' of project delivery processes is presented as a model process consolidating the lessons from this project as a guide for future local government facility projects.

2. Data collection and analysis

A variety of data collection methods have been used in the course of these reviews. These include:

- Review Workshop with Council stakeholders in March 2004;
- Interviews with project team members;
- Attendance at consultations with community facility user groups;
- Analysis of Council's project documents;
- Analysis of other Council documents such as Council meeting minutes, and municipal newsletters; and
- Analysis of local newspaper articles.

These data collection methods are in addition to those used by project team members during the project. Analysis has been by means of a qualitative methodology analysing the textual materials using coding techniques to identify key events and themes. Green (1996) describes this methodology as a Naturalistic Enquiry and notes it is overlooked in, yet is of importance to, research in the management of the built environment (in Green's case – construction management, but equally applicable here).

3. Processes to date

The four key processes identified in this review are:

1. **Strategic development** consisting of five strategies – two organisational and three municipal[1].
    a. Organisational – Service delivery (primarily Library, elderly citizens, and child care) and a Corporate Real Estate (CRE) strategy that matches the property portfolio better with organisational strategic aims; and
    b. Municipal:
        i. Local business development through support of threatened sub-regional strip shopping centres (Urban Villages strategy); and
        ii. Strategic Land-use planning (Urban Villages Strategy).
        iii. Community development through renewal of several community support assets.

    The development of the Council's Urban Villages Strategy was conducted in parallel to the development of its Library Strategy.

2. Council stakeholder **Strategic Needs Analysis Workshops** (Smith and Jackson 2000, Smith et al. 2004) in May and August 2000 has had several consequences:
    a. Strategic alignment between facility objectives and Council strategy;
    b. Council stakeholder 'buy-in'; and
    c. The generation of a *Performance Brief* used, in conjunction with an *Indicative Functional Brief*[2] to guide the project and in selection of the project consultant team.

---

[1] Municipality is taken as the administrative area and its population, whereas the Organisation is the Council with its governing, administrative, managerial and service delivery functions.

[2] Performance-based briefs are thought to encourage innovative solutions to meet client needs and objectives and are framed as statements of required performance against project outcomes. Performance-based briefs may not contain, for building projects, definitive statements of functions and their requisite areas that are to be included in the building. Such definitiveness is more the domain of Functional Briefs. The use of an indicative functional brief established latitude that required negotiation within the stipulated performance parameters.

The client representatives commend the approach for its ability to negotiate the removal of sectional and political interests and any preoccupation with project minutiae by concentrating on the big 'picture

3. **Project's consultant team selection and appointment** consisting of consultant team Registration of Interest (ROI), short-listing and interview, and inspection of nominated architectural projects prior to final selection. The capacity to conduct community consultations was a key selection criterion.
4. **Consultation** has been a feature of this Library-Community Centre project with several consultative processes, both in the project itself and in the preceding Urban Villages Strategy which provided the siting rationale. Consultation is discussed further, below, in Interaction Processes.

4. Linking to strategy & strategic outcomes

Strategic planning and connection to organisational and municipal strategies are important features of this process. Of particular relevance are the Urban Village strategy and the planning amendments that followed these early stage developments. Community Consultative Committees for each of the Urban Villages made up of Councillors and community representatives were used during preparation of the Urban Villages strategy, commencing in 1997 (City of Glen Eira 1999) up until the adoption of the Urban Village Structure Plan in July 1999. Subsequently, amendments were made to the municipal Planning Scheme to incorporate the Urban Villages concept into the Planning Scheme requiring further consultation required by State Government legislation. The Library-Community Centre project specific consultations starting in late 2001 benefited from the previous consultation processes as they followed soon after these Planning activities in a roughly contiguous process spanning 4 to 5 years.

Assessments to date show that the proposed Library-Community Centre plan meets the five Council strategies identified earlier. It is both a supporter of community support policy (*a heart of the village*) and as a driver of change (catalysing behaviour change) and land use commensurate with the Urban Village concept. There are indications of anticipated positive behaviour change by municipal residents that is expected from and intended to be gained from the project.

5. Role of Council as a client

It is not unusual for construction projects to have several sub-clients each with an interest in the project outcomes (Walker 2002, p87-89). These sub-clients may, variously, have formal decision-making and governance roles, or roles as nominated client project representative, or champion, or as users. In this project, as for all local government projects, there are five sub-client groups, or clusters of groups (also called stakeholders). However, it should be noted that where an external funding authority exists, such as state or federal (central) governments, a sixth group would be added to the list.

1. Council (as Councillors). The group with formal legislative authority as decision-makers and holders of governance responsibility.

2. Council (as Council officers). The cluster of groups with a role as client representatives responsible for the project's day-to-day management and administration. This cluster includes a nominated project representative (Manager Corporate Assets in this project) as well as Council officers from stakeholder groups within Council. Such groups with a service delivery interest in the completed facility are the recipients of 'Internality effects' from the facility, being the effect the facility has on their operations[3].
3. Facility users from the community (as part of the municipality). Members of this cluster are also recipients of 'Internality effects' from the facility as a direct consequence of their use of the facility.
4. Neighbours (as part of the municipality). This group are the recipients of 'Externality effects' that are the impacts that flow outwards from a facility as a consequence of siting in a particular location.
5. Municipality (as a whole). Frequently styled as 'community', municipality is the preferred terminology as community is a contended term (Gibson and Cameron 2001)[4]. Also the recipient of 'Externality effects,' which are more diffuse in impact when considered at this level of generality.

The project's Council officer managers have been aware of these client groups and have incorporated interactions with them in the course of the project, particularly levels 2, 3 and 4 above.

6. An informed client

One of the key features of this project's delivery is how the Council has acted as an *informed* client in the project delivery process. In this project, Council, as client, has been highly motivated through awareness of the project's importance to Council and the municipality[5]. In addition to being informed about Council's client role, discussed above, the Council officers demonstrated informedness about:

- Their individual service;
- The combined overall Library-Community Centre facility;
- The synergies derived from the combination of services onto a single site;
- The Urban Design and Urban Planning context; and
- Site constraints and opportunities.

[3] Facilities, for the purpose of this discussion, are a conflation of the physical entity (building) and service delivery from that physical entity (Building + service) as defined by Brackertz & Pontikis (2000) + site + context, be that physical context (neighbourhood), and political, social and psychological contexts.

[4] There are two main categories of community. Firstly, there is a 'community of place' that assumes a consensual harmonious view where differences are ignored through an emphasis on common territorial or spatial interests (Saunders (1979); Martin (1998); and Lowndes et al. (2001)). The second is a 'community of interest' where a common stake creates a specific grouping (Martin (1998); Lowndes, et al. (2001)) .

[5] The metaphor 'Jewel in the Crown' was invoked more than once.

Being informed may derive from being an *experienced constructor* ((Walker 2002) citing (Masterman and Gameson 1994)). Local government, while experienced in construction, builds each type of facility infrequently which erodes assumed experience levels. To increase that experience level requires research and other informing processes during the project processes.

Research and informing is infrequently or poorly done by clients, drawing instead on their stock of 'lived' experience of the built environment (and in particular – facilities in this instance). This is risky as that the experience may be flawed being based on exposure to poor facilities (which may be the reason for them being replaced), or on facility and building types unlike those that constitute the project. In this project research at service delivery level occurred through review of work practices, consultant advisors on occupational health and safety, and inspection of exemplars.

The exposure key client groups – Council officers and Councillors – to exemplar projects, both positive and negative has had important consequences in attaining levels of informedness. The exemplars have been at the levels of the constituent facilities, such as Library, Child care, Community centre, and urban development projects where Council properties were key constituents in contributing to and leveraging urban development projects providing Council's desired outcomes. The latter investigations occurred at an early stage with Councillors and Council executives (decision-makers and influencers of decisions) participating. Exemplars were also used in interactions with facility users as part of an educative, expectation adjusting process.

A subtle, but important, part of this examination of exemplars is not using them as a model that may be copied directly to the project, but through suggestions that the new Library-Community Centre 'May be like this,' or 'This is similar to an outcome that this project may produce,' or enquiring 'How does this work?' The exemplars acted an 'inspiration' – in a mind opening sense, as there were positive and negative ones.

The use of exemplars in this way has, at least, two effects. Firstly, it focuses on outcomes from facility delivery processes rather than purely the physical product or environment. Outcomes may be service delivery, social, community support and development, urban development or similar. Secondly, it evokes affective type evaluations[6] which at the most global level are of the form 'We/I like/do not like ….' Or, 'We wouldn't want that.' Comments of this ilk certainly emerged from the data relating to exemplars.

Overall, this 'informedness' has contributed to an exemplary process that may act as a model for future project processes. This process is summarized later in the paper.

[6] Affect is a general class of psychological processes (Affect, Cognition and Behaviour) that include feelings, emotions, moods and similar aspect of beliefs, values and attitudes (Amedeo, D. (1993)).

7. Interaction processes

The Urban Village Library-Community Centre project can be characterised by the high level of consultation that has occurred in the project's Planning and Design phases. Review of the literature during the course of this research revealed a range of possible ways of engaging with project stakeholder and community groups.

The term 'Interactions' was preferred to 'Consultations' as the authors consider interactions in management consist of more than consultation, including a range of possible management activities used in achieving project ends which may include meetings, data gathering and decision-making interactions. Unfortunately, limitations of space prevent a detailed discussion of the types of interactions, but (Heywood et al. 2002) propose a typology of interaction practices in a local government context.

The municipality's CEO noted at a Community Forum in May 2001 that this Council used at least 15 consultation (interactions) methods in its activities. Some of these are legislated in Planning or Best Value requirements, and some are not applicable to project delivery. For example, elections, and the focus groups and telephone survey interviews operate only in a more general sense as part of setting and confirming organisational priorities and agendas through research.

8. Types of interactions

It was important to have appropriate interactions occurring at times of maximum advantage to the project's delivery. The project benefited from its links with the Urban Villages strategy and their Urban Planning interactions. Within the project there have been several timely types of interactions, including:

- The use of Strategic Needs Analysis Workshop leading to the preparation and agreement of the content of a *Performance Brief*;
- Research by Council officers into the constituent facilities (use of exemplars), and review of current work practices, and the like (as noted above).
- Data gathering and brief building interviews (individual and group) by the project consultant team at the commencement of the Design phase. This provided necessary, specific information from the project's sub-client groups;
- Project Control Group meetings continuously (approximately fortnightly) throughout the Design phase made up of design team members and Council stakeholders;
- First Community Review and Input Consultation with responses from the round of interviews evident;
- Subsequent rounds of Community Review and Input Consultation at the end of stages and precluding subsequent stages;

- Linking with Public Relations releases by Council at the commencement of project stages;
- Important, in terms of project governance, are approval interactions at stage ends both with Councillors and PCG; and
- While it is still to occur, a review approximately 6 months following occupation would be another possible interaction.

The content of consultations was important. Initially the design team relied on 'Asking' and 'Listening' type interactions in the data gathering and brief building; that is listening without having explicit, concrete requirements already set[7]. Consultations of this form were a requirement of the project's performance briefing approach as definitive functional statements were not provided initially but which required negotiation achieved in this project through:

- The early use of design drawings to respond to the briefing information provided; and
- The Project Control Group (PCG) meetings noted above.

In this process data gathering was not on the basis of 'Tell us how much space you need,'[8] but rather on the basis of, 'Tell us what you do in your spaces.' The dimensions of existing spaces were ascertained from facilities' existing conditions drawings. This approach had several benefits for the project as it utilised:

- The workplace activity and service delivery knowledge from Council officers;
- The activity basis knowledge of users; and
- Architect's integrative capacity and expertise in spatial matters in 'design'.

Several benefits flowed from this approach. Firstly, it avoided the premature fixing of space demands acting as a 'circuit-breaker' between existing space occupied and that to be provided in the new facility. Secondly, in capturing the activity knowledge of facility users and service providers the spatial consequences of those could be ascertained by experts in building spatial matters (architects and the like). And, thirdly, this listening data gathering process utilised the integrative capacity of architects in 'design' to translate the received information into design solutions that responded to the *Performance Brief*, information received in consultation[9].

Evidence of this 'listening' approach was apparent in the presentations by the design team to the Community Review and Input Consultations. It was noted that they always referred to the points that the particular group had mentioned as important to them in previous interactions. Major benefits of this approach have been stakeholder buy-in (a psychological commitment and ownership of the project) from the earliest phases of the project and the achievement of high

[7] It should be noted that Council officers had conceptualised where the project might go as a result of the Strategic Needs Analysis and performance briefing, without necessarily pre-empting input from consultees and project consultants.

[8] This approach is often used to construct functional briefs.

[9] Which were considerable, being an elongated rectangular site located between and interfacing with both a residential area and a sub-regional strip shopping centre.

satisfaction levels now noted as being expressed by community groups and have been so from the earliest parts of the Design phase.

9. Project reviews

Project reviews have consisted of Schematic and Design Development reports from the design team for sign-off by the Council before proceeding to further project stages. Formal review meetings were not conducted to assess achievement of the Briefs (Performance and Indicative Functional)[10]. Rather, continuous review through the Project Control Group meetings and the Schematic and Design Development reports sign-off achieved much the same effect.

At the completion of Schematics Stage and before Design Development commenced a series of one-on-one internal review meetings between the Manager Corporate Assets and Council client groups assessed design and brief status.

Finally, the Review Workshop that examined processes used in delivery of the project to encapsulated the organisational learning to date and acted as a transmission of project history and learning following staff turnover during the project.

10. Project overview

10.1 Satisfaction with project processes

A high degree of satisfaction has been expressed with the project and project delivery processes to date. ‘Happiness’ and ‘pleased’ are frequently reported responses from individuals and groups participating in project interactions.

The satisfaction of project participants is based more on the fact that they were consulted, rather than what they saw as important was being included in the project; and seen as important by the project team; certainly in the emphasis given to these important items in reporting back to project participants.

10.2 Criticisms with the project processes

Given the satisfactions noted above and the positive reporting of project processes in this paper, it would be anticipated that there were few criticisms to date. This is the case. Criticisms coalesce around two points. The most minor of these is some of the arrangements for

[10] Note that the term, *achievement* is preferable to *compliance*, which does not fit the concepts of performance in the performance briefing approach used in this project.

consultations could have been better. The more important point that received more criticism was related to project delays.

From the elderly citizens came a telling and poignant critique of the project delays. Having contributed to making the project processes successful, thus far, there were speculations whether they would live long enough to have their efforts rewarded in seeing the new Library-Community Centre open.

Project delays could be attributed to three causes. Firstly, ‘political’ reasons which would be linked, in the main, to matching organisational funding requirements. Secondly, the compulsory acquisition of adjoining properties, which took time to resolve. Thirdly, that all of the project’s Urban Planning requirements were not made clear enough early in the project enabling all the project requirements to be dealt with in a single planning application process. It should be noted that this criticism is one that is frequently made by many sponsors of development projects in both private and public sectors.

11. The ‘Glen Eira Model’

To date, the project delivery process for the Urban Village Library-Community Centre has been exemplary through the strategic connectivity achieved, the inclusion of a range of interactions of real benefit to the project, the use of innovative performance briefing methods, and an informed, engaged client across the levels of sub-client. These characteristics have all contributed to the derivation of positive project outcomes.

Given the success thus far, it is possible to condense out key aspects of the project delivery into a normative community based model – ‘The Glen Eira Model.’ The Model is a representation of the lessons learnt in the delivery of this Library-Community Centre, and as a model process may be used to guide other local government facility projects. The important first part of the process the strategic management component of the model is summarised in Figure 1, below. However, in its entirety the model and process contains three connected streams as follows with the significant features noted:

Stream 1 – Strategic

- Strategic connectivity;
- Service delivery strategies with requirements for a built environment;
- *Strategic Needs Analysis* Workshop and creation of a *Performance Brief;*
- All possible Council stakeholders invited and present, and
- Output – Performance brief and indicative functional brief.

Stream 2 – Informing

- Informing via exemplars;

- Types of questions asked of exemplars, and
- Building knowledge as a basis for detailed briefing.

Stream 3 – Design management

- Use of performance brief;
- Consultant selection that was responsive and with a consultative track-record;
- Project Control Group with all possible Council stakeholders participating;
- Brief building through:
    - interviews with all possible stakeholders, and
    - Community groups' interviews
- Consideration and inclusion of recipients of 'Externality' and 'Internality' effects from the new facility in project processes;
- Early use of drawings, particularly 3-dimensional ones in consultation;
- Use of tactical Public Relations;
- Iterative/feedback reviews/consultations with stakeholder Community groups, and
- Review to confirm achievement of Performance Brief objectives.

12. Conclusion

The project delivery processes for this Urban Village Library-Community Centre has been an exemplary implementation of a stakeholder approach to project delivery. Lessons that may be taken from this study include:

- High levels of strategic connectivity showing relevance to and of Council stakeholder strategies;
- Client (as project delivery manager) awareness and engagement with client sub-groups identified (stakeholders);
- Development of client informedness through research and access to exemplars by client sub-groups;
- Deep and contiguous[11] interactions with stakeholders throughout project processes;
- Content of interactions is important, particularly the form of questions asked; and
- Development of a normative model encapsulating organizational learning from this project.

[11] Contiguity is suggested as a form of connecting content from one interaction to the next.

13. Acknowledgements

The authors wish to acknowledge the Australian Research Council, and the City of Glen Eira for their financial and strategic support for this project.

Emerging new FM aspects

The strategic impact of managing risk with high performance, high cost shopping centres

Prof. John D. Gilleard
The Hong Kong Polytechnic University (email: John.Gilleard@polyu.edu.hk)

Abstract

This research paper compares and contrasts the risk management approach adopted by a major public sector operator of shopping centres in Hong Kong with those managed by the private sector. By adopting a structured survey, the paper establishes 'risk items' identified by the public sector organization; the response by the organization to these risk items; and a comparison with their response to that of the private sector. Survey results indicate that managing risk in shopping centres is complex, where relatively small disorders can create a significant impact on a centres' successful operation. The survey also revealed that the public sector operator's risk assessment awareness was weak, generally focusing on emergency guidelines for previously known, identified risk items. In addition, public sector response to risk was determined to be overly bureaucratic, with a potential for crises to degenerate to a disaster. This may be contrasted with the private sectors whereby risk is, by and large, proactively managed through active avoidance measures, risk reduction and risk transfer. The paper concludes by recommending a facility management response to managing risk for public sector shopping centres.

Keywords: Risk management, shopping centres, comparative survey, public / private sector

1. Introduction

"*When the going gets tough, the tough go shopping*", Anon.

Hong Kong is home to seven million inhabitants, and the city's tourism board expects the tally for tourist arrivals in 2004 to exceed 21.4 million, a record for Hong Kong. The city prides itself as a "*shopper's paradise*", a theme trumpeted loudly by the Hong Kong Tourist Authority. Sceptics may wonder at the veracity of this notion, yet few would deny that shopping in Hong Kong is a serious business. Locals and visitors alike have a wide choice of shopping venues, from the hustle and bustle of Causeway Bay on Hong Kong Island, with its cluster of Japanese department stores, dense street side markets stalls and more recent up market exclusive designer label shopping emporiums. Kowloon-side also offers a similar range of traditional shopping experiences among the environs of Nathan Road, Temple Street and Canton Road. During the last twenty years Hong Kong has also added the ubiquitous shopping centre, from the prosaic out of town "*local*" shopping arcade with its Chinese wet market, government offices and retail outlets to amazingly glitzy malls that provide both entertainment thrills as well as retail therapy. On Sundays and festive holidays these venues often arrange promotional activities to attract visitors, and it is not uncommon for the serious shopper to have to weave around these watching crowds in order to continue their hunt for bargains, exclusivity or the merely fashionable. Under these circumstances, shoppers are probably more mindful of the risk to their wallet than their physical security, assuming that risk, in whatever form, is being managed "*behind the scene*" by trained property managers whose skills and knowledge are sufficient to deal with all eventualities. This naïve assumption is perhaps understandable, for few untoward occurrences have (publicly at least) taken place among Hong Kong's shopping centres during the last few years. Nevertheless, the public has a right to demand at the very least that those who manage facilities are aware of potential risks, and have contingency plans to ameliorate crisis or disasters from occurring.

1.1 Risk Management

Risk management is the process of measuring, or assessing risk and then developing strategies to manage the risk. Ideally, risks with the greatest loss and the greatest probability of a risk occurring are dealt with first, and risks with a lower probability of occurrence and potential lower loss are dealt with later. Unfortunately balancing the likelihood of an event occurring against its potential loss is extremely difficult, and property managers charged with maintaining shopping centres frequently face difficulties that extend beyond their built fabric. For example, shopping centres, similar to other buildings that accommodate public space, typically bring together relatively large numbers of people (shoppers) whose knowledge of the facilities is low. These shoppers may be first time, or infrequent visitors whose general awareness of the centre construction, layout, safety features or safety personnel is generally weak. Shopping centre design attempts to mitigate potential hazards by imposing restrictive building codes and regulations, particularly those related to fire safety. Even so, without effective property management, architectural good practice can be frustrated by uncaring or ignorant behaviour, [1].

The UK's MI5 Security Services [2] has recently published a guide for protecting assets. Although focused on terrorism, the guide offers a general review of managing risk. The guide adopts an integrative approach, highlighting four main issues, i.e. 1) identify the threats; 2) establish what you want to protect and your vulnerabilities; 3) identify measures to reduce risk (security improvements / plans; and 4) review security measures and rehearse / review security plans. The singularity of the guide highlights the times that we live in, albeit to date the threat is more in the imagination than the execution. However, being prepared for eventualities is the hallmark of good risk management and the guide offers excellent advice. For example, is there anything about a shopping centre, staff or its activities that would attract (in this case) terrorist attack? It also questions whether the centre's location would mean that it may suffer collateral damage from an attack on a high risk neighbour. (Given Hong Kong's proclivity for mixed use commercial development, blending shopping malls and high rise office space with hotel and serviced apartment accommodation, this latter scenario is more likely.) The guide's advice on what to protect is instructive with its focus on people (staff, customers, visitors and contractors);

physical assets (building fabric and contents); information (electronic and non-electronic data); and processes (supply chains and critical procedures). People take top priority when assessing the consequence of risk, with other assets depending on the nature of the business. In the current context, shopping centre managers normally have well rehearsed contingency plans in case of fire and crime. In addition, the guide reminds shopping centre HAs that they should also have procedures for assessing the reliability and integrity of those they employ. This is an increasingly difficult and controversial issue, particularly in Hong Kong where contracting out of safety and security personnel is common. The MI5 Security Advice also highlights this point "*There is little point in investing in costly security measures if they can be easily undermined by a disaffected inside, or by a recruitment process that permits people wanting to cause harm to infiltrate the organization.*" Continuing, the guide continues by emphasizing the need to conduct regular reviews and rehearsals to ensure that security and safety plans remain accurate and workable, and take into account any temporary or permanent changes to both the physical assets (the shopping centre) of procedures (information and communication system, health and safety issues). The guide also emphasizes the role of vigilance among shop tenants, shoppers, visitors and contractors when confronting untoward events.

1.2 Risk preparedness

The Genesis for the study was a freak accident that occurred at one of Hong Kong's suburban shopping centres. A nine year boy fell through an unsecured glass balustrade resulting in serious head injuries. Fortunately he made a full recovery. An investigation instigated by the centre HA concluded that the original building contractor was liable for the accident. (The shopping centre was relatively new.) As a result the HA suspended the contractor's new project tendering rights for a period of six month. The decision initially closed the case. However, public misgivings lingered over the accident. For example, public opinion questioned why the HA had not monitored the construction work more diligently, or why at handover a thorough check of the centre had not found the problem. Knowing that the centre's day-to-day property management had been contracted out, they also questioned why this company had failed to undertake periodic inspections of the balustrade? These questions go well beyond simply knowing the technical cause for failure: they fundamentally question the existing design – construct – commission – operate paradigm. Knowing that each phase of the project is directed by competent professionals, the public's misgivings are understandable. Simply put "*who is responsible for checking as built systems and determining risk?*" "*Is risk awareness in shopping centres inadequate?*" "*Are current property management systems sufficiently flexible to deal with risk?*"

To answer these questions, a small scale research study was undertaken, [3]. The study adopted a three pronged approach. First, a literature review was undertaken. Second, a series of semi-structured interviews were conducted with shopping centre HA representatives and personnel. Interviewees represented both the public and private sector, including in-house and contracted out personnel. Interviewees represented mid-level managerial grades tasked with either overseeing property management contracts, or with direct day-to-day management issues. All shopping centres formed a part of Hong Kong's largest public sector housing authority's portfolio. Interviews were divided into two parts. The first part requested information pertaining to the interviewee’s organizational, management structure and their general awareness of risk within shopping centres. The second part reviewed their knowledge of the organization’s business continuity planning and management. During each interview supplementary questions explored the existing procurement, operation and maintenance systems, and inquired of the difficulties (if any) of implementing these systems. Thirdly, an observational record was conducted over a one year period. The last provided sufficient insight to verify that risk “*hazard, chance of bad consequences, loss etc, or exposure to mischance”*, OED, rarely occurred without some foreknowledge. Unfortunately the observational evidence indicated that these warnings were frequently overlooked or went unnoticed due to ignorance, negligence or sloth. The study also indicated that preparedness for risk appeared to be variable, with some centre managers uncertain whether problems had been caused by natural force, human error, deliberate damage or progressive deterioration.

1.4 Interactive complexity and tight coupling

Two identified factors or properties determine whether a potential danger is more “risky”, i.e. ‘interactive complexity’ or ‘tight coupling’ [4]. Interactive complexity describes the potential for unforeseen interactions to occur where complexities and interdependence of relevant factors are unpredictable. For example, the failure of a computerized building services system that causes the breakdown of other systems may eventually paralyze most other systems. Tight coupling describes rapid and uncontrolled propagation of undesired events due to failure. The process happens very fast and cannot be turned off until the failed parts are isolated. Complexity and coupling may also be interrelated. For example, locating building systems in too small a space with complicated access may lead to missed routine maintenance. In consequence, this may lead to possible difficulties in isolating failed components thus resulting in a potentially more widespread catastrophe. High system complexity also demands greater technical awareness among operation, maintenance and management personnel. Where these conditions apply, system buffers and redundancies, deliberately designed into the system, act as a safety feature. However, without an intrinsic understanding of system safety and reliability issues, catastrophic failure can easily occur.

2. Risk and diversity in shopping centre design

The Hong Kong Housing Authority (HA) owns 650,000 public rental flats, housing approximately two million people (about one-third of Hong Kong's population). To bring convenience to and cater for the daily needs of public housing tenants, the HA also builds shopping facilities in the vicinity of our estates.These centres provide retail, recreation and leisure, health and social functions, etc. The HA categorizes shopping centres into four distinct groups, i.e. District Centres, Greenfield Centres, Large Neighbourhood Centres and Small Neighbourhood Centres.

District Centres are characterized by their strategic location, typically adjacent to mass transport railway stations serving a comparatively large catchment's area. The level of retail provision is usually high, catering for both local and outsiders. District Centres typically support a population of 150,000. Major tenants include department stores, supermarkets, Chinese and western restaurants as well cinemas. Building service provision is high, with full HVAC, escalators and lifts. Greenfield Centres are 'first generation' shopping centres located in New Towns. These centres typically enjoy good business during the early years due to the absence of competition. However, as the New Town matures, the population increases and private sector development is encouraged Greenfield Centres face increasing competition. Consequently these centres are normally upgraded to a level similar to District Centres. Large Neighbourhood Centres are typically located within public housing complexes away from private sector housing. Typically, they serve a community of 25,000 to 50,000. Their primary market is nearby public housing tenants, although well managed centres have the potential to attract outside customers. Major tenants are usually at least one Chinese restaurant, supermarket, and fast food café. Neighbourhood Centres are limited to no more than three floors, with escalators providing vertical movement between floors. Usually these centres are located close to main roads and bus terminals. Small Neighbourhood Centres are small commercial centres serving communities with a population of 25,000 or less. Typically, these centres are single storey located on the ground floor of a multi-storey housing complex. Retail provision is limited to a supermarket, small wet market and a convenience store. Usage level is normally low due to keen competition in the vicinity and because there is little prospect of attracting outside patronage.

During the 1990s the management of these shopping centres changed from in-house to one where the majority were outsourced, or contracted out. Two separate schemes were adopted, i.e. Single Operator (SO) and Private Management Agents (PMA). The SO scheme aims to enhance shopping centre management standards by developing a close partnership with the HA and the SO. Under negotiated lease terms the SO operates, manages and maintains the whole centre for periods of six to nine years. The SO is allowed to sub-lease separate units in the centre to third parties, or licensees. In agreement with the HA, the SO is also permitted to make minor alterations and decorate the centre. The primary aim of the SO scheme was to harness private sector expertise in the management of the shopping centres, e.g. shop layout, trade mix and promotional activities, etc. At a secondary level, the scheme also had the advantage of redeploying shopping centre estate staff. Disengagement by the HA from day-to-day management also provided an opportunity for top management to deal with strategic issues, whilst withdrawing from tactical, day-to-day concerns. Under the SO scheme the HA performs the role of intelligent-client, concerned with establishing, reviewing and monitoring the SO contractor's performance and securing compliance of the contracts terms and agreements. However, once the SO scheme had been operating for a number of years a number of weaknesses appeared. For example, in some instances, the HA was unable to ensure that the SO delivered the best quality of services to the public. By forfeiting the right to select sub-leasers, the HA was also unable to influence or protect essential yet low margin retail outlets or public service facilities. Experience also indicated that at the conclusion of the lease major renovations to the shopping centre were unavoidable.

The Private Management Agent (PMA) scheme introduced in the late 1990s attempted to address some of the problems of the SO, particularly those concerning tenant mix. PMA contracts are normally for a two year period, with the right for an additional two year renewal. The PMA contractor is paid a fixed fee for services provided, and reimbursed for all costs incurred in connection with the operation and management of the centre, e.g. electricity, water, consumables. The duties of the PMA contractor are defined as: to collect revenue and other payments to the HA; to follow up delinquent payments; to enforce tenants' contractual obligations; to be responsible for all minor repair and maintenance of the building fabric and building services systems; to provide daily cleaning and security; to prevent illegal hawking; and lastly to plan, organize and coordinate promotional activities. On the other hand, the HA retained the right to handle all leasing matters and tenant selection; set rent levels and tenancy agreements; deal with tenancy renewals; act as final arbitrator between the PMA contractor and tenants; and monitor and assess PMA contractor performance.

The PMA scheme has been judged to be a success, with the majority of the HA's shopping centres now managed in this way. Nevertheless, during the research a number of HA representatives expressed concern at the relatively high turnover rate of PMA staff, with its attendant need to train and offer guidance to new PMA employees. They were also voiced disquiet about the unwillingness of some PMA contractors to deal with the public. For example, one representative stated that some PMA contractors were slow to respond to requests for repairs and maintenance, and that they lacked initiative with respect to environmental issues. He considered that, in this case, the PMA contractor lacked experience in handling the agent / tenant / customer interface. This is perhaps not unsurprising since pre-registration criteria for potential PMA contractors tends to emphasize property management skills, financial integrity and legal knowledge rather than customer services' skills. Further, observations indicated that PMA staff tended to rely heavily on the HA representative to handle sensitive public relations issues. Concern was also expressed that the PMA scheme created problems in communication and coordination between the HA representative and PMA staff. This may be a reflection of the potentially adversarial relationship between the HA representative and PMA contractor whereby performance standards are strictly enforced through legal interpretation of the contract specifications. This was also true for SO contracts, although one interviewee stated that poor performance of a PMA contractor might result in a warning letter; whereas a SO contractor may incur a financial penalty or possibly termination of contract.

Interviewees were also asked to identify risk elements related to their potential threat, expressed in terms of emergency, interruption, severity and frequency, tables 1 and 2.

Table 1: The relationship between emergency and interruption related to shopping centre risk, or threats.

Threats	Emergency			Interruption		
	Low	Medium	High	Low	Medium	High
Natural hazards		X			X	
Man-made errors		X		X		
Progress deterioration	X			X		
Deliberate damage	X				X	
BS system breakdown		X				X
Fire			X			X
Personal injury			X		X	
Renovation / improvement	X					X
Criminal activities			X		X	
Uncommon disaster			X			X

Table 2: The relationship between severity and frequency related to shopping centre risk, or threats.

Threats	Severity			Frequency		
	Low	Medium	High	Rare	Seldom	Often
Natural hazards		X			X	
Man-made errors	X					X
Progress deterioration		X				X
Deliberate damage		X			X	
BS system breakdown		X				X
Fire			X	X		
Personal injury		X				X
Renovation / improvement	X			X		
Criminal activities		X			X	
Uncommon disaster			X	X		

As the tables illustrate some risks are deemed to be more important than others, either due to their propensity to occur or severity of problems manifest from occurring. Interrelated but not assessed is the impact on business continuity in the event of a serious breakdown. Nevertheless, the two tables help to prioritize commitment and remind the centre managers of the most critical and important issues in operating the shopping centre, i.e. health & safety of the public, tenants and staff; maintenance of building services systems; and maintainability of business.

When asked to reflect on the most common emergency to occur within the shopping centres, the interviewees identified three issues, i.e. personal injury - slipping or falling; power outage; and flooding. Response to an emergency usually related to the availability of on-site resources, the experience of front line staff and written guidelines. However, SO / PMA staff criticized these guidelines, identifying a general lack of experience from those charged with drafting them. They also commented that these guidelines did not always clearly identify responsibilities. The respondents were asked to comment on their knowledge of risk planning. Most knew that emergency and safety plans existed but few could identify who within the organization constituted the emergency team or what backup or recovery systems existed. They were also unaware if a public relations strategy formed a part of emergency planning.

3. Conclusions

The study indicated that risk awareness was not linked to the management structure of the shopping centre, nor was it substantially impacted by whether the centre's management was in-house or contracted out. Nevertheless, a lack of contractual clarity in defining risk responsibility does seem to have had an impact. Additionally, because of the HA reliance on contracting out, with its attendant loss of control of on-site staffing, training, and quality control, securing the right contracting-out partner was considered to be essential. Unfortunately, guidance on the selection of SO or PMA organizations tended to emphasize cost targets, not quality, timeliness and good practice. Ultimately this approach may be said to be counter productive. Poorly trained, low waged and unmotivated personnel have limited capabilities for dealing with a crisis. What is needed are staff who can recognize an unfolding situation, instinctively knows how to react and well able to communicate the threat or risk to authority. If a security guard has to evacuate a shopping centre they need to have an understanding of how to do it, or at the very least they have the initiative / authority to make it happen.

The study also indicated that although senior management were cognizant of documented risk exposure, they were less certain on how to deal with unconventional problems. For example, during the interviews good practice relating to shoplifting and vandalism was discussed. However, no mention of the possibility for acts of terrorism was raised. In the context of Hong Kong this may be understandable since outside terrorist threats would appear to be minimal. However, shopping malls are increasingly raised as possible targets in both the US and Europe, [5]. Recent troubles in the Philippines, Indonesia and Thailand belittle Hong Kong's absence of concern. If such sentiments seem too alarmist it is only necessary to go back to Hong Kong circa 2003 to find evidence where, initially at least, risk preparedness was woefully lacking. From March to August 2003 Hong Kong was on high alert for the SARS virus, a virus that eventually killed 299 and infected almost 1800. The virus also had a severe impact on Hong Kong's economy. However, in the early days little was understood about the virus in terms of transmission. Consequently, shopping centres, intended to be friendly locations, were treated by customers as potential hazards. Restaurants, cinemas and many public venues were deserted and universities and schools closed. Shopping centre owners were alarmed at the prospect that their property would be associated with the SARS virus. Eventually, they went to enormous lengths to ensure that the risk of infection and contagion was minimized. However, in the beginning few had contingency plans to deal with the SARS crisis at the beginning. Gradually, operators introduced extensive SARS preventative measure, e.g. disinfecting common areas, lifts and entrances on an hourly basis; air-conditioning filter replacement rates increased; outdoor air intake increased as well when feasible natural ventilation was adopted. In an attempt to gain the approval of their tenants and their tenant's customers one Hong Kong private developer acted very quickly by issuing instructions to their centre management staff and security guards "*to be* *extra vigilant and actively monitor tenant activities….report any unusual occurrences to the Property Manager for them to confirm a potential change in the level of risk…..vacation of premises, changes to cleaning schedule of premises, request for additional ventilation or air filter cleaning, extensive wearing of face masks, and attendance of medical/ambulance personnel to the premises or rumours of an incidence of infection*.” By raising the company’s level of risk awareness the firm was assuring both employees and tenants that ‘*expecting the unexpected*’ was good risk management. They recognized that they needed to “*identify potential impacts that threaten an organization and provides a framework for building resilience with the capability of an effective response that safeguards the interest of its key stakeholders, reputation, and brand and value creating activities,* [6]. Under these circumstances effective public relations was seen to be as important as technical know how. The obvious lessons to be learnt from SARS is “expect the unexpected” and develop a comprehensive business continuity plan sufficient to include an effective emergency response, a workable contingency arrangement and a feasible recovery plan.

Postscript: Since the study was completed the HA has initiated a major scheme to bundle all shopping centres and car parks in a Real Estate Investment Trust, or REIT. The Link REIT is composed of the HA portfolio of 2.85 million sq. ft. of retail space and 59,000 commercial parking spots. The initial public offering is valued at almost US$2.7 billion, making it the largest REIT offering in history. It was expected to debut on Hong Kong's Hang Seng exchange December 2004 but due to legal issues the launch has now been delayed. However, the Hong Kong Government is confident that the Link REIT will eventually go ahead.

Parking Storage Planning and Facility Installation in Buildings

Jin-Fang Shr
Associate Professor – Department of Construction Engineering, Chung Hua University, Taiwan
(shrj@chu.edu.tw)

Abstract

Increasing the prosperous economy and national income, a convenient lifestyle needs more automobiles. According to the Government of Taipei statistics, the metropolis owns 62,536 chargeable parking spaces and 670,999 vehicles registered in Taipei, indicating that approximately 11 cars share a single parking space. This fact means that existing parking spaces are not enough to accommodate the number of automobiles. Upon integration into the international free economy and entry into the WTO, a suggestion is to reduce import duty on automobiles. This way leads to a rapid surge in the purchasing of automobiles and an increase in parking space demands. Meanwhile, in Taiwan's previous development plans, no parking spaces were set-aside in the downtown area of Taipei. The ideal areas in downtown feature high costs, are difficult to acquire and the amount of traditional ramp or flat parking spaces are not effectively adequate. In view of that, large-scale construction corporations have cooperated with Japanese experienced parking facility manufacturers to solve the problem and create new business opportunities. The latest automatic mechanical parking storage facilities provide much needed parking space and make the multi-sectional parking facility attached to main buildings a standard. This results in new opportunities for the construction industry.

Keywords: Parking storage, park, facility, car

1. Introduction

Current macroeconomic distress has resulted in a downturn for the entire building industry and the price of real estate also dropped significantly. Therefore, hard-won parking spaces are more popular and prominent. The series of products launched by construction corporations, combined with parking space storage, provide households who originally possessed cars with parking spaces, as well as additional income for office buildings. This fact obviously proves that there would be more common scenario in the future real estate market. Nevertheless, this breakthrough would bring about quite different and new circumstances to the space of the architecture itself, and also construction cost and environment. This study intends to provide useful information, for attracting potential purchasers and new ideas will be presented for investors.

2. Literature Review of Parking Storage Facility

The "Advanced Storage" fully automatic parking system, also called the "Large-Scale Plane Reciprocating System" in the Norm of Type Determination by Japan's Ministry of the Economy, mainly consists of tower and underground storage systems in Taiwan. The basic movements are as Figure 1.

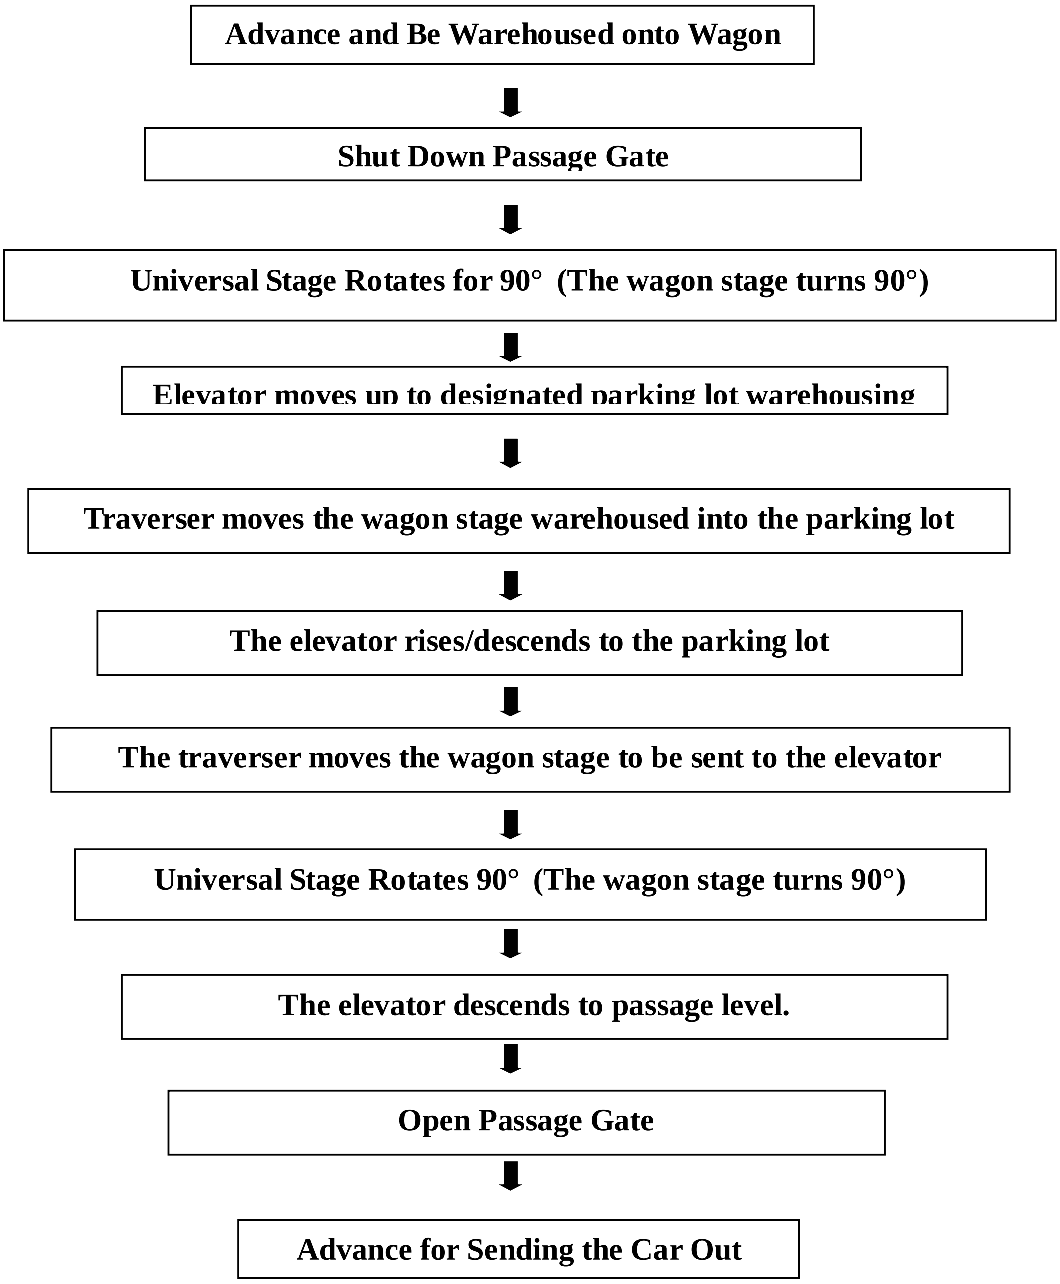

Figure 1: *Basic Movements of the Parking Process*

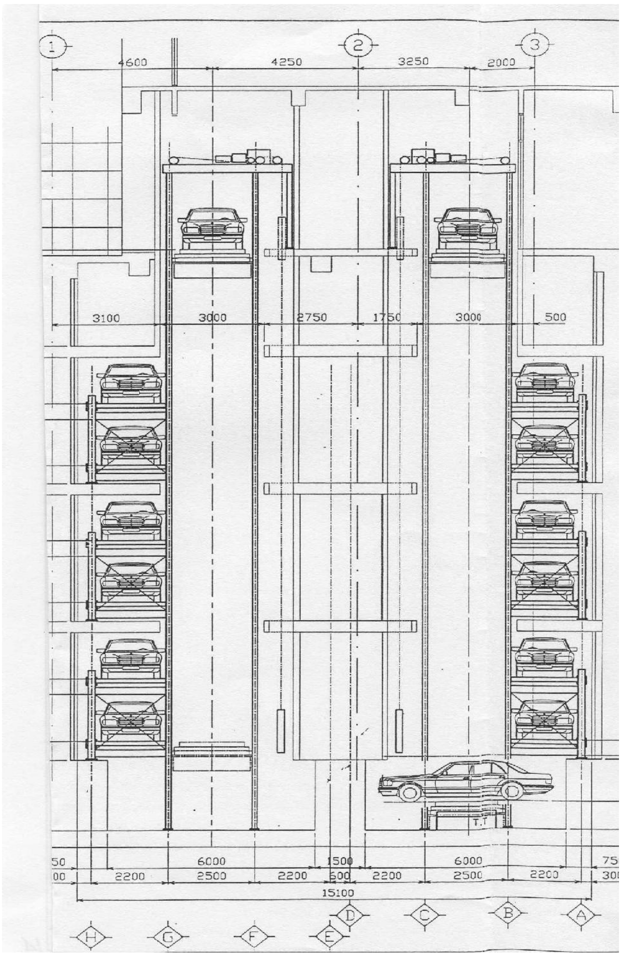
The components of fully-automatic parking storage system are mainly introduced as follows:

- Parking Area for Garage Entry/Exit (Figure 2)
- High-Speed Elevator (Figure 3)
- Multi-Layer, Synchronized-Operation, High-Speed Jack Plane
- Multi-Layer, Multi-Row, Parking Lot (Figure 4)
- Active Automobile-Safety Monitoring Network
- Operating Control Information Transmission Network
- Electronic Vehicle Passage Management & Subscription (Figure 5)

Wen-Ting, Liao, 2000 Jan.



Block Diagram of the Parking Storage System Structure

Figure 2 : Parking Area for Into/Out of Garage

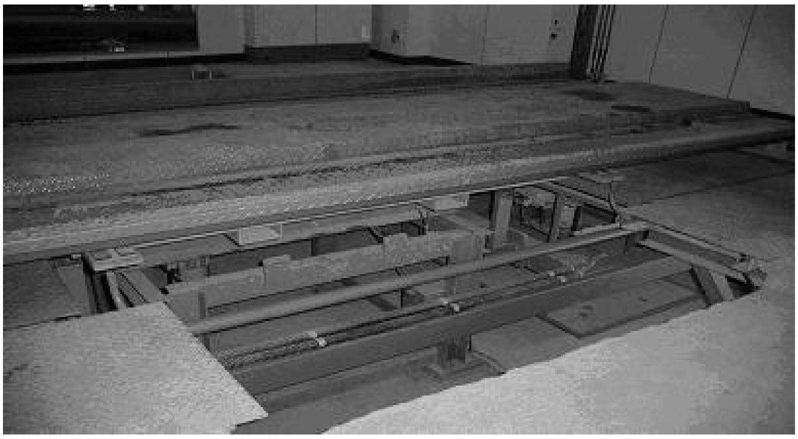


Figure 3: High-Speed Elevator

Figure 4: Multilayer Multi-Row Parking Lot

Figure 5: Electronic Vehicle Passage Control

Due to different design organizations providing a variety of design philosophies, market partitioning and technological integration methods, this study organizes those fairly common and relatively competitive parking storage systems in the market, generally introduced here:

1). Crawler-Type System: Vertically elevated, multiple groups of crawlers or universal rollers, traverse traveling driven by motor in order to conduct transport.

2). Wagon Stage Plate-Type System a): Vertically elevated, traverse steel tracks, wheeled secondary frame, operated by mainframe power (see Figure 6).

Wagon Stage Plate-Type System b): Vertically elevated, the traverse motion is initiated by the traverse's radial arm, which clamps to the groove attached under the wagon stage plate, leading it to laterally move the secondary frame (see Figure 7).

3). Comb-Type Frame System: Both vertically and laterally moved by the mainframe, the comb-type wagon stage plate makes the need for exchanging secondary frames unnecessary. Its design principle indicates that while the automobile is accessed, no empty sweep template should be reset, concerning the operation between every parking lot and a jackplane lot, whose process reduces a car's passing time (see Figure 8).

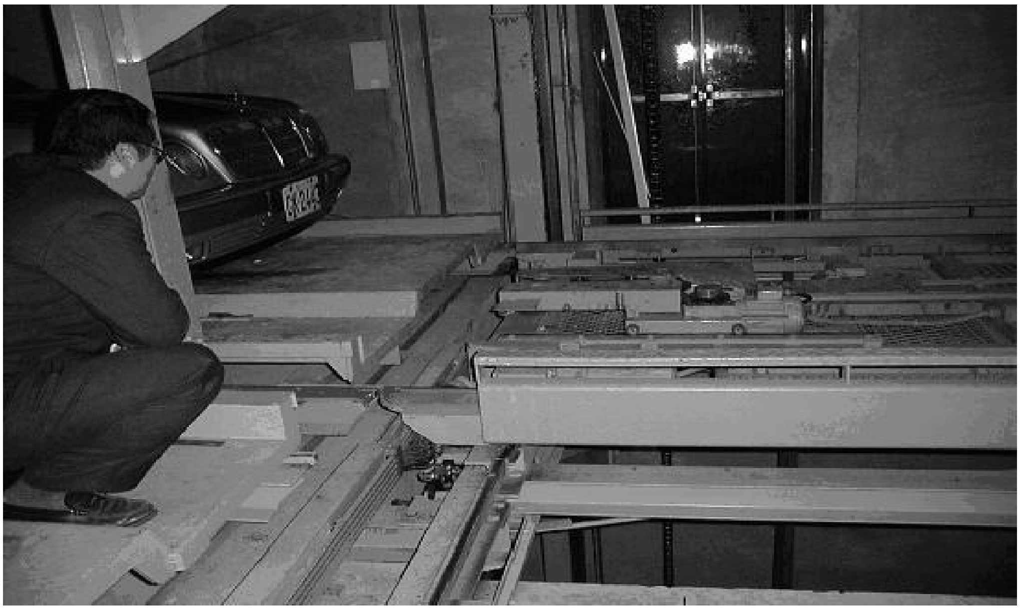

Figure 6: Wagon Stage Plate System 1

Figure 7: Wagon Stage Plate System 2

Figure 8:. Comb-Type Frame System 3

3. Analysis of Investment Appraisal

3.1 Background

In view of the increasingly deteriorating issue of car parking, accompanied with the traffic turbulence caused by illegal curb parking and the high cost of traffic jams, the government faces the situation that if those problems are not properly resolved, economic development will certainly be retarded. Besides passively restraining the decrease in the amount of cars, the policies of great importance adopted by the government are to proactively compile the budget according to the "Program of Ameliorating Parking Issues" and further accelerate the amendment and implementation of laws and regulations concerned. For example, regarding the parking storage affiliated inside architectures, available laws or regulations in Taipei cover the Essential Encouraged Aspects on Public Parking Spaces Extended Inside Architectures, which stipulates that the structures allow additional established parking spaces that should be incorporated into the floor area as calculated in the floor area ratio. The calculating process should be conducted according to the formula shown as follows (the added parking spaces do not need to be taken into consideration during the calculation process; however, the uncalculated area per building should not exceed 40 square meters.).

FA **FA** **FA**

FA Total floor area concerning the allowed essential floor area ratio as calculated.

FA Referred floor area calculated on the basis of the designated floor area ratio in the Urban

Planning Law and related laws and regulations.

FA Floor area calculated by the floor area ratio of the allowed additional established parking space, which should be less than 1/5 of the reference floor area and be incorporated into legal parking spaces as calculated.

3.2 Location Factors

The location factors that should first be taken into consideration in investing in parking areas are, including land application, compilation of city planning, average automobile occupancy ratio as concerned, existing regional number of parking spaces, time spent searching for a parking space, and the punishment possibility of broken-through parking, etc. For land that cannot be customized, the selection of investment bidding is fairly difficult to control. Thus, case analysis is demanded to be conducted for each bidding process. The average "parking supply and demand statistics" sufficiently known are used to determine the market value of the region concerned for investment.

3.3 Relation between Cost & Price

Cost factor analysis mainly includes land price, construction cost, operation cost, and maintenance cost, etc. The case of an office building in Hangchounan Road, which was launched by Fubon Land Development in the 1990s, is an example described below:

The base's total area accounts for approximately 148 plateaus, with the cost at approximately 1,500,000 Taiwan Dollars (TD). According to the planning design, the structure has been equipped with 54 parking spaces in its internal parking storage, with an individual cost of approximately 250,000 TD The case has installed 54 parking spaces on 20 plateaus. The relation between price and land cost is shown in Table 1 as follows:

It is assumed that the parking space's market quotation is acceptable for consumers, and higher than the pre-set rate of return. Therefore, the case is very profitable if the land cost is determined to be 1,500,000 Taiwan Dollars per plateau.

Table 1 :. Relation between the Cost & the Land Cost of Parking Storage Unit: 10,000 Taiwan Dollars

Program No.	Land Cost (TW)	Total Parking Space Cost (TW)	Individual Parking Space Cost (TW)	Estimated Rate of Return (%)	Price (TW)
1	3,000	1,350	80.5	25%	100.6
2	3,000	1,350	80.5	30%	104.6
3	3,000	1,350	80.5	40%	112.7

According to the case, it is obvious that the final price of the parking space depends on land cost. In other words, if the land cost is fairly high, the price of the parking space will not be correspondingly increased due to a restrained market quotation, cause of limited construction cost adjustment. Therefore, the tender investment would probably fail and eventually be terminated.

4. Condition Analysis of Architectures

4.1 Foundation Conditions

The foundation's ground shape and area are main factors in determining the appropriate type of off-road parking area. According to the Parking Area Layout Manual, it stipulates that mechanical parking lots may be installed if the foundation's width is less than 35m or the area does not exceed 1,500 square meters; cause by the limitation of the restrain of landform that self-automatic parking lots could not be established . Therefore, the optimum parking area can eventually be determined when the foundation area is between 1,500 and 4,000 square meters, by measurement accounting to adopted local conditions, evaluations, and comparisons of various parties (Ta-Yu, Lin, the Institute of Traffic and Transportation). Current data according to partitioning and estimated designs are provided at the website on capacity calculation of architectural design (www.iarchi.net), various references could then be further calculated as required by the designing process.

4.2 Roadside Traffic Factors

Under the volume specifications on architectural design and construction of the Building Technology Instructions, the automobile entranceways of such structures should not be placed on roads or locations as follows:

1) Road junctions, chamfering lines, initial points of a corner, zebra crossings, traversing of a bridge, and 5 meters within a subway entrance.

2) Roadway with a slope greater than 8:1.

3) Less than ten meters away from a bus station or railway level crossing.

4) Twenty meters within the passage ways of kindergartens, public schools, schools for the deaf, mute and/or blind, reform schools for the disabled, parks, etc.

5) Other roads or localities deemed as harmful for public transportation as determined by competent departments in the construction industry or transportation.

Open space should also be additionally prepared for an automobile's passage on the basis of calculation from one point of the automobile's passage center line, 2 meters behind a building line to the area over 60 degrees left and right of the vertical lines of the center line. The land covered should be regarded as an open space without holding the line of sight. A waiting area with a width and depth both over 6m should also be prepared due to the construction of parking areas. Otherwise, flow rate for this area's road system will fluctuate. Analysis for primary roads, secondary roads and regional roads (laneways) in the concerned area must be carried out, regarding issues such as road width, number of lanes, partitioning type, one-way or two-way lane, roadside parking control, vehicle flow rate statistics on intersection peak hours both in the morning and evening, and mean vehicle delay time, etc

4.3 Matching Requirements of Structure

1) Structural Section –The most suitable beam column construction must be calculated to match the entire system during establishment of the parking storage facility, which has a much higher requirement on the arrangement of parking lots and parking areas, the spacing layout and column positioning, the opening position of floor slabs with reinforcement, as well as the static loading on floor construction. The structural drawings should be reviewed in advance to avoid after-the-fact revision that may pose a danger to the construction's structural strength.

2) Electric & Fire Control Sections – Generator capacity, short-circuit tripping design and installation of maintenance lighting should all be taken into account, and the fire control section equipped with double-purpose equipment. This equipment should be both fully-automatic and manual, and meet the concerned fire code specifications. High-end industrial computers serve as a control center for smooth, rapid and secure operation of the parking facility under whatever operating mode, fully-automatic, semi-automatic or manual.

3) Management System –Improper operation should be prevented from occurring which could cause malfunctioning when the parking facility is in operation, and periodical maintenance is also of great importance. It is absolutely forbidden to have the equipment repaired by non-professional manufacturers. In addition, pre-service training should also be provided for operators concerning non-sophisticated trouble-shooting and emergency response. The service life of parking facilities can be prolonged while the safety of the entire structure is fully guaranteed.

4.4 Evaluation of Environmental Issues

Multipurpose projects should be advanced according to the concerned area's development. Such issues are required to be taken into consideration in combining parking storage together with buildings including: feasibility, the compatibility with it's surrounding environment, the impact on nearby traffic flow and the safety of residents in the region, the prevention of noise and air pollution, etc, should be included in the evaluation of the environmental impact for discussions in an item by item manner.

Regarding air pollution, outdoor air pollution control measures should be prepared well according to specifications in the "Air Quality Standard of Taiwan" (as shown in Table 2). Meanwhile, ventilation systems should also be mounted to ensure air quality according to the "Volume of Equipment of the Building Technical Instructions", stipulating that "In the parking area with a floor area over 500 square meters, mechanical ventilation should be provided for with the ventilation volume of over 35m3/hr per square meter for each floor."

Table 2: Air Quality Standard & Pollution Control Countermeasures in Taiwan

Standard	Aerosol Particle (um/n m)		Sulfur Oxides (ppm)	Nitrogen Oxides (ppm)	CO (ppm)
Air Quality	Limited value excluding the particle with a diameter over 10um Monthly average: 210 Yearly average: 160	Limited value including the particle with a diameter over 10um Monthly average: 260 Yearly average: 170	Hour value=0.3 Daily mean of hour values=0.1 Yearly mean of hourly values=0.05	Daily mean of hourly values=0.05 The number of days exceeding the limited value in a whole year should account for no more than 10% of the total.	Mean of 8 hours of hourly values=20ppm Daily mean of hourly values=10ppm Hourly value at whatever location/time= 40ppm
	The monthly average value should exceed the limited value for at most twice in a whole year.				
Countermeasures	To match traffic impact evaluation results, the parking area's passageway should be arranged on the road section with comparatively high traffic service quality. This is in order to avoid a high-volume discharge of pollution, which is generated by low-speed operation or traffic jams.				

Controlling the situation of countermeasures on noises vary with different noise sources Due to the semi-enclosed space of indoor parking lots, and regarding the propagation of sound, the sound wave travels parallel to the work direction of vehicles spreading outdoors, while other sounds are also reflected and transmitted between the indoor walls. The types and countermeasures of noise sources are shown in Table 3.

5. Conclusion & Prospect

Parking storage facilities are an ideal instrument in the solution to a metropolis' severely insufficient parking spaces. However, a wide range of aspects should be taken into consideration when determining the establishment of parking storage in buildings. These include: processes related to such fields as government laws, regulations and policies, the mentality and financial operation of owners, architects' planning and design and the strength calculation of structural engineers, the construction accuracy of related manufacturers and their technical exchanges with overseas counterparts, agent companies' marketing philosophy, customers' acceptance, and the response of neighboring residents, etc. After all those aspects are well arranged and integrated, the feasibility study can be finally determined in establishing parking storage and successfully combining the structure within the parking facility. Therefore, an old adage states that "good creation yet unfeasible" can be avoided.

Table 3: Noise Sources & Corresponding Preventions

Noise Sources	Causes	Methods
Vehicle Noise	**Power system and running noise generated by the friction or vibration during contact with external surroundings.**	**Vehicle noise is not completely generated by the establishment of parking space, and laws and regulations concerned stipulate that the automobile speed in lanes around the parking space should be kept under 15km/hr. Furthermore, it has also been determined that the speed of entering the parking space should be no more than 10km/h which would yield no noise level disturbance to surrounding residents. With regard to ramps, floorboards and sidewalls made of special materials should be implemented to absorb the noise generated by accelerating or decelerating vehicles.**
Mechanical Noise	**Operation of mechanical component parts.**	**Washers should be installed on the interfaces between the mechanical equipment and major structures. This process is required to conform to the "Maximum Limited Noise Level of Noise Control Standard".**
Ventilation Noise	**Start-up or operation.**	**Acoustic treatment could be utilized concerning the ventilation noise, such as a single wall, jacketed wall, sandwich wall, damping materials, etc.**

(Chen Yung-Yu, 2000 / 01)

Once the vehicles on the road have been halved, roadsides are not crowded with automobiles and all issues concerning car parking in a city are completely resolved. The road is actually the most original and creative artist in metropolitan life (Hsiehku International, webpage from www.dodohome.com.tw). The smooth, rapid, secure, timesaving and convenient parking lot is now coming into being!

Maintenance of university premises - principles, tools and experiences in practice

Martti Hekkanen
VTT – Technical Research Centre of Finland (email: martti.hekkanen@vtt.fi)

Abstract

The importance of renewal and repair older ecucational buildings is rapidly growing. Changes in use and at same the time the aging of HVAC-systems and building stocks causes need to plans repairs beforehand. The fair divide of costs is more and more important because of lack of funds. The positive side of lack of resources is that to day both the owner and the user have to think very carefully which rooms are really important. In the paper two simple pc-tools are presented. Both can be used when making long time maintenance plans and diving the costs of renovation by transparent and fair way.

Keywords: maintenance, maintenance costs, university premises, quality

1. Background and purpose of the lecture

In the real estate business the owner manages and maintains facilities for which the user, in the role of the client, defines functionality goals. In many cases the requirements set for facilities during the construction phase change. Alongside a long-term technical maintenance and repair plan, it is necessary to compile a facility development program based on the needs of the client, in other words, a functional maintenance and repair plan.

Program integration is a technically and administratively demanding process that requires customer service management, integration of a technical repair plan, efficient quality assurance during the repair process and careful documentation after implementation. To deal costs by transparent and right way betveen the owner and the user - that is in many cases the most hardest phase.

The currentness of the problem is rapidly growing. Educational, office and commercial buildings in Finland will enter their technical renovation phase in 2010 - 2020. The need to make functional changes grows as clients use facilities more efficiently. So far, no rules of the game or theories for implementing the process have been compiled.

In this presentation I'll show you some examples of simple pc-tools by which we can use to shed light on problems that arise when integrating technical and functional maintenance programs.

2. Planning of renovation

2.1 The Basis

Maintenance keeps the technical properties of a building in operating condition that corresponds to the original level. Programming of maintenance refers to a process in either the construction phase or the maintenance phase whose goal is to implement maintenance on the basis of a real estate strategy approved by both the owner and the client. A real estate strategy describes the goals which the owner and user set for the functional use of a facility. If the owner and user do not have a common real estate strategy, it is necessary when programming repairs to simultaneously examine a technical maintenance plan compiled by the owner and a functional maintenance plan compiled by the user. In such a case the plans are integrated by either speeding up or delaying technical maintenance according to the dictates of functional changes. Figure 1 presents common goals for which a real estate strategy is compiled. The importance of the goals varies, depending on the functional use of the building.

Safety in use
No disturbances in use
Support to the customer's business idea
Possibility to focus earmarked funds for planned renovation works
Possibility to measure services right and by that way find smooth stress of resources
Possibility to combine owner's and use's maintenance processes

Figure 1:. General goals for optimized maintenance and repair

The programming process consists of four phases. It includes parallel development tasks. The programming process is presented in figure 2. In phase 1 the process is assigned objectives based on the real estate strategy, and tools for cooperating are created for the owner's and user's organizations responsible for maintenance process. Repair and renewal plans are compiled in phases 2 and 3. The owner's repair plan is technical and focuses on maintenance of external structures and the building's basic technical systems. The user's renewal plan includes improvements caused by functional changes to the facility and repairs to the distribution systems of the building's technology. The limits of responsibility for maintenance are agreed on in phase 1. Phase 4 is critical from the standpoint of the success of the process. The user's customers are informed of the progress of the repairs and, for example, achievement of the goals set for the indoor climate. The measures are documented on the basis of rules of the game agreed on in phase 1.

Quality assurance covers both the technical quality of the measures and the functional quality of the process. Necessary development measures are implemented and the process is made into a routine.

In phase 4 repair costs have to be dealed between the owner and the user. Usually the owner is responsible all the planned repair costs. The functional aging cause needs for new rooms and better technical systems.

Part of these costs belongs to the user. The common way is that the the owner pays the renovation and the costs are to be included to the rent.

Co- operation process of renewal and repair work between the owner and the user (the client)
Repair and renewal plan for technical aging made by the owner
Repair and renewal plan for functional needs made by the user
Combinition of technical and functional repair and renewal plan

Figure 2. Phases of the maintenances process between the owner and the user

2.2 Implement the co-operation between user's and owner's maintenance organizations

In the 1st phase of the process the user's and owner's representatives agree on the principles to be applied in making more efficient use of the facility. These principles are:

- distribution of responsibility for maintenance between the owner and the user
- principles to be followed during implementation of repairs
- entry of changes made during repairs into the real estate information system and documentation of repairs
- planning meeting agendas and schedules

Development of cooperation is the key question of the process. The significance of this activity increases as buildings age and the need for repairs become concrete. Development of co-operation in new buildings can take place more freely.

2.3 Compiling a technical repair plan

A preliminary repair plan should be made already when the building is taken into use. The objective of a theoretical repair plan is to assess the proper level of costs during the life cycle. The assessment is based on suggested repair and renewal phases and investment costs. The assessment makes it possible to calculate a reservation for maintenance, which indicates what portion of the rent income from the facility needs to be set aside for future maintenance. Because tax legislation does not allow advance transfer of reserves for maintenance, the significance of the calculated reservation for maintenance is to indicate to the owner and user the magnitude of the costs. The theoretical assessment does not need to be very detailed, it is only used to determine the target level.

A repair plan that covers the entire life cycle or a life phase includes an estimate of costs and the timing of measures that will be implemented. The need for repair is grouped as follows:

The renovation phases can be selected in 5-year periods, for example. The economic life is usually considered to be 25 - 100 years. It is recommended to make the plan for 50 years The calculated interest rate can be freely selected (see figure 3). In planning life cycle-long maintenance, assessment of alternatives should take into consideration both the costs of the investment phase and future energy and maintenance costs.

The estimation is made by LCC. It gives us oppurtunity to see, what is the relation between investment costs and repair and renewal costs. This method is very usable in new constrcution models (so called Life Cycle Models). Anyway it must be remembered that the plan consists only repairs and renewal based on technical aging. Most cases changes in rooms are much bigger need for renovation in real life.

Figure 3: The magnitude of repair costs is determined with the help of a maintenance plan compiled in the investment phase. It is recommended that the repair plan is based on life cycle costs, not only investment costs.

The accumulation of repair costs during use is usually not linear. The need for maintenance in the initial phase is minor and the need increases as the building ages. Nevertheless, in order to plan maintenance, an estimate of maintenance costs is needed. An educational building is used as an example, where the economic life is considered to be 50 years and the calculated interest rate is 3 %. Figure 4 present accumulated maintenance costs during the life cycle.

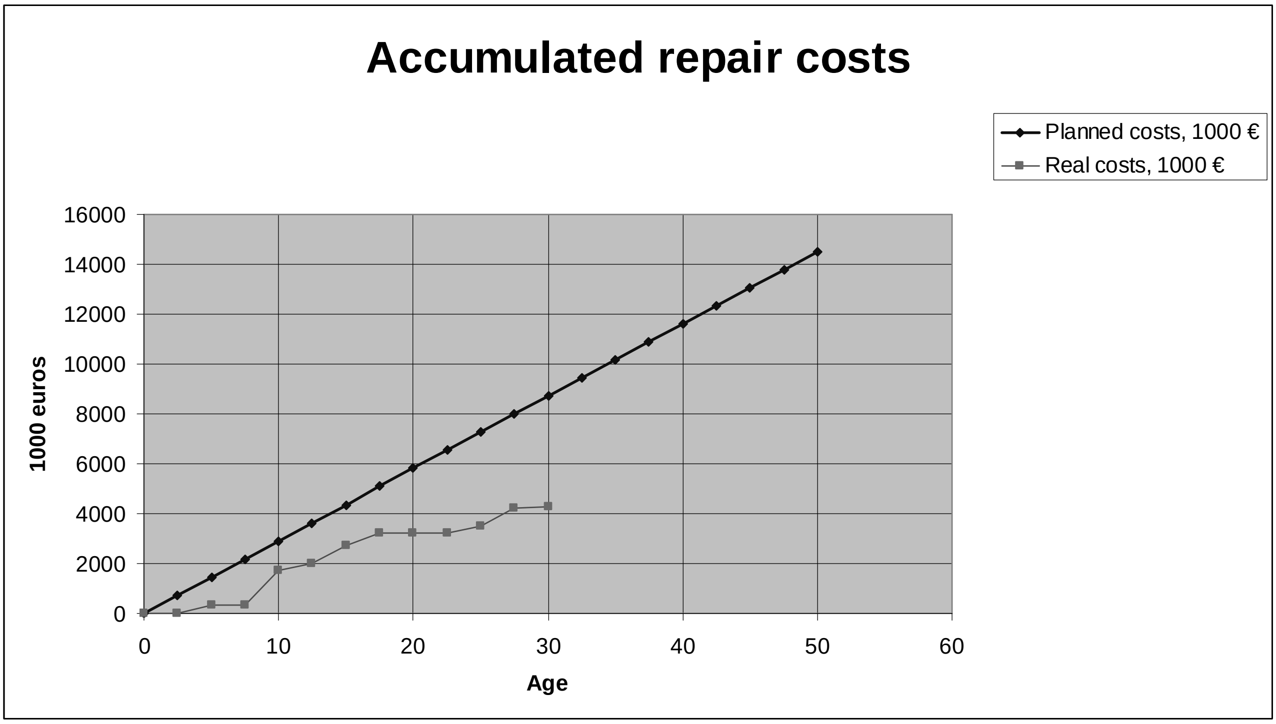

Figure 4: Timing of maintenance costs during the life cycle when accumulated maintenance costs are assumed to be linear. The white arrow indicates the difference between actual and theoretical repair costs during the life cycle.

In practice, it is not possible or even expedient to adhere completely to the theoretical repair model. There is considerable variation between the maintenance phases of different buildings, and other repairs resulting from changing needs in functionality are also always done in conjunction with maintenance.

In actuality, the need for repairs is based on periodic condition assessments and supplementary condition studies. A general operating model for condition assessments has been developed in Finland for both residential buildings and commercial and service buildings. Guidelines also exist for the most important condition studies.

A repair plan is always separately compiled for building components for which the owner is responsible (structures, building's technical systems) and for facilities where responsibility for maintenance can be divided between the owner and the user.

2.4 Compiling a functional repair plan

The owner's task in the maintenance process is to maintain such features of the building which ensure that the user's activities are safe, healthy and as profitable as possible. The user's needs change over time. Changes in functions may require

- new construction to provide additional facilities
- changing the facilities to better serve activities (dividing or combining rooms)
- improving the properties of facilities by technical means (structural improvements or technical improvements)

Figure 5: The user compiles a general schedule for functional improvement projects, which is integrated with the owner's technical maintenance plan.

Small user organizations usually do not have resources for programming functional changes. The problem with large users is the considerable number of customers, in which case programming needs to combine many different wishes.

Figure 5 presents a good example of a maintenance plan compiled by a user, where projects are timed over the planned period. The length of the planned period is usually 5 years.

2.5 Integration of the technical and functional plans

In order to be able to integrate technical maintenance, which is the responsibility of the owner, and functional improvements, which are the responsibility of the user, the user's maintenance plan needs to be joined to the technical maintenance plan. Part of the cost effects belong to the maintenance responsibility of the owner, and part are the responsibility of the user. In practice, the owner usually has the repairs done, and changes which are clearly caused by functional needs have an effect on the rent of the facility.

In integrating it is important to determine how the responsibility for repairs is to be divided between the user and the owner. The distribution can rarely be made only on the basis of the technical age of the building components, since it is possible that varied amounts of repairs have been made to the building components during their usable life. Furthermore, functional changes are made in the facility which result in changes to its properties. Figure 6 presents a model for dividing costs.

3. Conclusions

Organizations that are responsible for users' and owners' real estate management in Finland are generally professionally very competent. There is an abundance of technical tools for facility management. It has usually been possible to agree on the main principles used to reflect the costs of maintenance and modifications in facility rent.

The need for functional development of facilities in university buildings, in particular, will be very significant in Finland in the near future. Universities in Finland mostly operate in facilities owned by Senaatti-kiinteistöt. Senaatti-kiinteistöt is a professional real estate owner whose main objective is to function as a service organization and as far as universities are concerned, to be a responsible partner that develops its facilities. The development of the products presented in this presentation has been commissioned by Senaatti-kiinteistöt.

Enhancing partnership is a continuous process. At the strategic level, partnership can be developed, for example, as follows:

1. Compile a vision of operation in 2015, for example, together with the user

2. Compile an estimate of the facilities needed to implement the vision

3. Compile economic planning calculations of the effects of the costs of the target state on the user's operating costs and prioritize the vision's focal areas of development

4 Compile a plan of how technical repairs can be made to support implementation of the vision in the best way possible

5. Develop the owner's customer relations management, create real benefits based on a regular customer relationship.

At last - buildings are only resources. The money we need for maintenance and operations is also a resource. We have to remind that universities are places where the seeds of better global future are seeded. That is why it is highly recommended that co-operation process between owner and client consists of any high barriers. My own experiences after having involved as a small part of the process tor three years are, that people in both sides are so educated that provisions for managed co-operarion really exist.

Relating Housing Maintenance and Professionalism of Owners

Roode Liias,
TUT – Tallinn University of Technology (email: r.liias@anet.ee)

Abstract

Reports about poor condition of dwelling stock discuss about lack of proper maintenance and about poor repair of the dwellings in shared ownership. These reports do not always touch the role of the (co-)owners in the whole process, rather the papers are concentrating on the affordability issues – the vast majority of the households still cannot meet their housing costs.

Current paper is based on the results of research done for the Nordic Council of Ministers funded project 'Developing professionalism for housing maintenance management in the Baltic States'. Housing maintenance related professional associations of the three Baltic States have been the major partners to this project.

The following issues are to be discussed in the paper:

- role of condominiums (home-owners associations) and the relevant non-governmental institutions when improving the housing environment
- professional services and raising public awareness about housing maintenance
- lack of reliable data about housing conditions

Contemporary facilities management (incl. housing management and maintenance) requires wider introducing of the principles of informed owner in the property market, requiring significant degree of operational knowledge and experience. Housing maintenance has become a customer-oriented service industry where the service providers are organised and running their schemes for professional certification. Especially in the transition economies the key-counterparts – the owners of the dwelling units – are often lacking any informational support and possibilities to co-ordinate their activities.

Keywords: facilities management, maintenance; housing stock; owner-occupation; intelligent owner

1. Role of maintenance when preserving property

Until very recently, designers of buildings and advisors for the property owners have focused their main attention on capital costs, paying little heed to the interest to forecast maintenance and other running costs. Yet over the life span of a building, expenditures for maintenance and proper repair may be at least 2 or more times of the initial costs. [1] Moreover, though manufacturers advertise about availability of maintenance-free materials, the costs for maintenance are growing on most of the buildings.

'Maintenance' as term has been missing from the professional terminology not only in the East and Central European (ECE) countries, but this term has not always been very clearly defined in the western countries. [2] Rather often maintenance is used in direct connection with repair and refurbishment activities; accordingly these activities and the related to these costs are sometimes handled as one causing major confusion in the field. [3]

Any structural part of a building or a utility-system requires relevant maintenance to be planned and carried out there to assure they provide the necessary service for the users and the environment remains safe and sound. Correspondingly, not only the originally installed and currently ageing structures of buildings (built either during the soviet period or even much earlier), but even the newly built, or refurbished, or restructured, or reinstalled finishing and structures, though especially the engineering service systems would require planned care taking. Even the very different construction projects developed today rather often do not foresee any activities for regular maintenance during the period of use.

Buildings – their structures and the engineering services – that are not maintained as required will cease to fulfil their intended functions. Regular maintenance that has been carried out just-in-time for preventing and doing away with the defects while they are still minor is generally considered as the most cost-effective strategy for providing well functioning buildings. Planned maintenance can normally prolong the useful life-time of the structures and systems almost indefinitely as replacement will be required less often; accordingly operating costs will be reduced for the owners and users, but also less resources will be used and wasted for the society in general. Moderate financial inputs into maintenance enable operators to extend the life-span of an existing building until a replacement will be required.

Buildings are developed to satisfy different human needs – we may talk about buildings that are developed for different business but also living purposes. 'Facilities management is the provision of the physical infrastructure necessary to best support the achievement of an organisation's primary objectives. It is a managerial service related to the continuous provision of space for working and living.' [4] This is one of the oldest and the most traditional definition for facilities management (FM) provided in academic literature. Thus, all the activities related to servicing the buildings and the users located there may be covered by the umbrella term FM. And it is of major importance to understand that these are not only the walls and structures (created by the construction professionals) that are required by the different users of the buildings – the users require quality-services to be provided during the period of use.

In fact, any company, and a public office, and a household are organisations requiring adequate space for their major activities – either for business, or for public administration, or for living. This-why for a FM professional there should be no major difference what is the purpose of the organisation he is servicing – facilities manager has to understand the specific interest of the end-user-organisation and based on this information as input to build up a network of in-home or outsourced service-contracts from different most adequate providers. Maintenance services are amongst these services that are to be provided for the buildings anyhow to satisfy the requirements of the users.

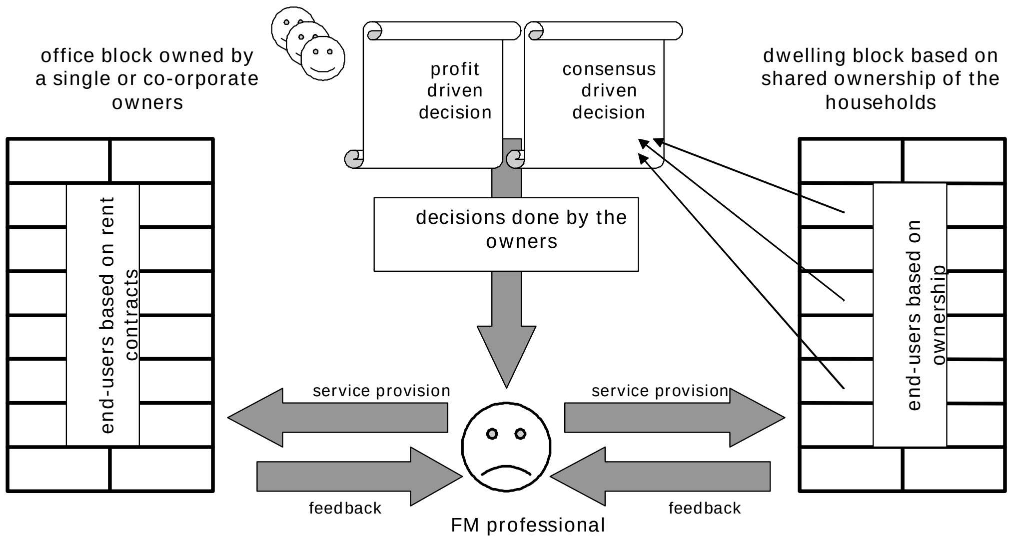
Maintenance services provided by a relevant contractor do not automatically create a good environment for the users – maintenance helps only to develop required conditions for suitable and adequate using of the premises. Though, poorly provided maintenance always leads the users of the premises to question the facilities manager about the reasons for not adequate quality of services delivered for them. Poor quality of maintenance is usually a result of lack of consciousness and knowledge among one or more of the parties acting in the FM market.

2. Relating housing sector and facilities management

Dwellings are valuable assets which are normally built up using substantial investments over a long period of time, but these assets are not always managed and maintained with the care that they actually deserve. The experience of the author of the paper gives the evidence that in many countries in East Europe building maintenance is insufficient or in fact non-existent. [5,6] The resulting deterioration reduces the ability of dwellings to perform the intended functions designed for these buildings. For example, a heating system requires similar maintenance technology to be implemented either in a block of offices or in a block of flats – only the output performance level may differ as to timing of the inside temperature requirements may differ.

Though for the maintenance service providers there is no technological difference when arranging and providing services for the user organisations in different buildings, there is still considerable difference for the facilities manager especially when business and housing premises are concerned. (Figure)

A block of offices is owned either by a single owner or by a corporate owner; most of the small business organisations are relatively short-term tenants in these office-blocks using one or a couple of office units there. The owners of these blocks are interested in having tenants using the premises and facilities. Tailored for the user's needs and in adequate repair premises are prepared for them; afterwards regular and reliable cleaning service – but not only – plays an important role to assure satisfaction of the tenants as the clients. Quite often in 2-3 years most of the user-organisations restructure their company-structure, sometimes this restructuring may be rather considerable. The facilities manager has to refurbish and rebuild the premises, though technically these premises may be excellent and they may still meet the common aesthetic requirements. The user organisation may even move out of these excellently maintained premises in any moment not dependant on the quality of services provided for him; removing elsewhere may be related to better functionality or better location of the new premises that will fully meet the current needs of the organisation. In any case the facilities manager in charge for the premises has to start looking for the next tenant organising total refurbishing even if there have been no any crucial damages



caused to the vacant premises.

Figure: Role of FM professional when managing different properties

In a block of flats in the case of condominium type shared ownership organisational behaviour is different. Considering the experience of the Baltic countries due to massive privatisation of flats in large-scale housing in average there are about 50 up to 100 co-owners in a block there. In this case though the ownership-rights for the block are shared, each household has still the right to say a word and participate in deciding about the repair-level of the block. In the case where the owner-occupation ratio absolutely prevails – in Estonia and Lithuania the total ratios of owner-occupation is more than 95 per cents – getting consensus is extremely difficult; when making decisions each household will rank their household-interests as the priority ones. As currently there is still not much variety and possibilities for the households to move into different blocks being more adequate and affordable for them, accordingly the structure of the residents in the blocks remains stable and each of these co-owners will give the highest priority to private and household's interests.

The major difference when maintaining these two blocks is based on the motivation of the decision-makers. In the office-block the owners are profit-led when making decisions and quite often they use the facilities manager as the adviser to get financially the most feasible solution. On the contrary, most of the flat-owners have limited budgets for their households though they are also looking for ‘best value for money’ they are aiming to the same target through cost-reduction. On the general meetings of the owners rather often there appears the clear conflict in the interests of the owners and the facilities manager – the latter is obliged to carry out professional service which is inevitable related to certain costs, on the other side his activity is limited with costs which rather often are not adequate for the target.

Facilities manager is the mediator, not the decision maker, who has to turn the owners’ decisions into practice through providing relevant maintenance services. In different blocks decisions may be differently targeted, though the technical specification of the service is quite the same; in any case the facilities manager cannot initiate providing any services that are against the will of the owners.

Rather often it is stated in the papers and reports that massive home-ownership in large-scale housing stock is not affordable! [7] As the quality of these blocks from 60es – 80es is poor and no refurbishing has been done there for about two generations, correspondingly to make these blocks habitable to meet the current technical requirements will require too much sources by the households to be invested. Though most of this housing stock in the ECE countries is currently privately owned and the flat owners (or homeowners) are responsible for all the costs related to these blocks, still there remains rather heavy burden on the society as well. Too many of these households – though being the owners of the properties – still require different housing allowances and the neighbourhood renewal projects require also considerable investments to be done by the authorities.

The numerous surveys give clear evidence that the households and the homeowners’ associations (HOA) quite often reduce their housing costs through avoiding preventive maintenance. Only emergency maintenance is considered to be inevitable, but in long-run this is always relatively more expensive as ordering the works for preventive and routine maintenance.

The attitude to solve the affordability related problems through avoiding maintenance gives only short-term ‘profit’ or ‘benefit’ for the home-owners – affordability level of the sitting households is improving, the next generation has to pay the ‘not-paid’ bills. Doing away with regular maintenance reduces the level of sustainable living-conditions both for the households located in the block, but also for the society in general. Dwellings that lack normal maintenance will burden the next generations with much higher costs related to housing stock; if by this time it will be still feasible to make any investments to improve these facilities. In any case the initial target to create the housing stock of adequate quality will remain unreachable; avoiding maintenance will reduce the general level of sustainability in the society and in housing sector. This is the decision-maker’s ‘trap’ in there.

Decision makers in housing often do not pay much attention to management aspects of the building. This may be because they are not fully aware of the financial implications caused by poor care to the buildings they have been appointed to manage. This is still a rather typical approach to the problems in the housing sector – there is an institutional ‘somebody’ who is the decision-maker and everything depends on his awareness and competence. Poor maintenance usually results from lack of awareness amongst these decision makers and the residents of the buildings; therefore the buildings are not managed professionally and maintenance in particular is not given high enough priority – resulting in unnecessarily high operating costs and low building standards. Improvements in the management of such large building stocks can save reasonable amounts of money.

High prices for houses and fees for housing services, also for maintenance works, are much discussed in media; also the problem of continuous disrepair is understood by most of the households. As the property owners they are legally responsible for funding all the works to keep up their properties meeting certain standards; but money required for maintenance works comes directly from the budget of the households accommodated in the block, households are interested in influencing the decisions done in the way that the expenditures from the budget of their household would be minimal – low costs are ultimate priority! In fact, this is fully clear and understandable from the human point of view. This why, all the scheduled activities of preventive nature – if not inevitably required when the decision has to be done – are post pond. Shortage of funds by the owner-occupier households is the reason for poor maintenance, but also lack of awareness about the consequences when scheduled preventive works are not executed.

The basic human need for shelter is defined as the housing problem in terms of quantity and quality: is there enough housing to go round, and is it of satisfactory standard? But often the physically decent or even excellent standard cannot guarantee satisfaction for the tenants when the facilities in question are poorly managed, or the expenditures for keeping these up are not affordable for the person responsible for cost-covering.

Successful management of dwellings is almost completely based on skills and efficiency of facilities management services provided, therefore requiring skills and knowledge not only about the financial and technical-engineering aspects, but also social-managerial aspects are of crucial importance.

3. Intelligent owner – key-actor in the market

Professional and quality FM services are always connected with relevant expenditures; any property owner will require these services to be provided. Therefore, based on the basic principles of FM [8] only the largest property-owning organisations can benefit from the strategic approach to FM. The whole housing sector – though it consists of a large number of estates of reasonable size – during the privatisation has been split into rather small and independent management units (home-owners' associations – HOA-s). Professionally reasonable FM advice can be provided for the whole estate, but these recommendations may be of no great value for particular block and for a HOA as they may be in lack of relevant finance; but even if the money would be there, not always there is common understanding in this block about using these sums.

During transitional changes the general trend in the housing sector has been from a parochial and highly regulated and centrally managed market to one, which is increasingly deregulated and split into small and rather unprofessional units where conflicts and different viewpoints and interests govern. Even if professional FM-consultancy is provided for the HOA to improve the current condition in the blocks, the final decision lays anyhow after the owners who will vote democratically keeping in mind private priorities. The majority of owners are not professionally skilled as for construction, maintenance and facilities management services.

The role of an informed owner in the property [9] but also in the housing market requires a significant degree of operational knowledge and experience to:

- understand and clearly specify the service requirements and targets that are most suitable for the property they own;
- arrange the relations amongst the co-owners when managing property;
- understand and develop service delivery strategies and to manage the implementation of outsourcing strategically most important services;
- agree when monitoring the standards used when describing quality levels of services and benchmarking performance;
- manage different contractors for cleaning, maintenance and repair works and monitor their performance level;
- understand relevant financial, technical and managerial reports provided for them;
- be ready for negotiations with contractors or users of the spaces and for decision-making agreeing changes to service requirements;
- develop his/her own owner's skills through awareness raising, but especially through regular training.

Based on the criteria listed above, educating the property owners (especially owners in the housing sector), it is vital for managers and operators to enable them to fulfil their roles and perform their full professional potential in the market.

Administering of owners obligations may be viewed as a three-fold list of activities to be covered. An owner has to consider any activity listed how it can be carried out in practice to meet his or her interests in the best possible way:

long-term decisions

- introducing a maintenance manual for the property – the building and its structures – and assuring reasonable performance of it
- compiling a relevant economic plan (business-plan) to run the property following the requirements described in the manual
- planning schedules for maintenance works for the forthcoming years

- preparing and signing long-term contracts for preserving the property and getting necessary utilities services
- assuring the availability of professional supervision to guarantee that all owners interests are reasonably followed
- deciding about developing different projects to refurbish and renovate the building to improve its quality and meet the changing needs of households

operative decisions to

- assure that routine and regular monitoring of the situation and condition-assessment is be carried out on the property
- supervise over different contractors/workers performing scheduled maintenance works
- plan and order all necessary security measures, incl. negotiating reasonable insurance
- assure that professional teams are available to treat emergency situations
- take decisions about organising tenders; incl. setting up a list of criteria for selecting the best bid
- prepare and sign contracts for maintenance with suitable contractors

administrative decisions

- taking reasonable decisions about employing staff and assuring that the owner can properly fulfil an employer's role
- forwarding relevant authority to any person who can represent owners in negotiations or dispute settlements
- related to administering financial and technical documentation about the property
- assuring the availability of all necessary reports and taking decisions based on analytical data about the results of maintenance

4. Some conclusions and findings

Contemporary property management (incl. housing management and maintenance) requires introducing the principles of the informed owner in the property market, requiring significant degree of operational knowledge and experience. Housing maintenance is a customer-oriented service industry. The service providers are organised to professional associations and running their professional competence and certification schemes. The key-counterparts – the owners – are quite often lacking any informational support and co-ordination in their activities.

The following questions are still to be highlighted for further studies and debates:

- who should have the major incentives in the society and/or in the business sector for organising and training the residential property-owners in the society?
- what is the role of the state and/or the municipalities when organising these awareness raising schemes who have been the institutions standing behind the massive privatisation?
- what is the public attitude and the general understanding of ethical behaviour in the market – is it considered fair behaviour when the service providers themselves start training the owners as their potential clients?

The result of the study done within the project however has been targeted is to rise as many questions as possible, though currently it was even impossible to supply the data that was requested. One finding that came through very strongly is that many individuals and institutions involved in the study have not robust performance about management and maintenance systems in place.

Difficulties have been experienced concerning the use and meaning of terminology. It cannot be the aim to come up quickly with fully harmonised maintenance related terminology. Currently maintenance is rather widely used not only by the professionals, but mostly by the politicians and in the legislative documents as an umbrella-term and though several publications and presentations done during the last couple of years it will require much time to become accepted in the society.

Most of the estates visited during the project are in poor physical state due to the neglect of essential repairs and maintenance for many years. In many large-scale housing estates especially the residents have become dissatisfied with the management of their estates; the residents – mainly the owner-occupiers of the privatised flats on these estates – complain of lack of commitment by the authority staff which is said to result in repairs and cleaning not being performed and in general neglect of the estate and its surroundings. Thus, the authorities have treated the privatised housing as property owned by them – the actual owners are fully distanced from the possibility to make decisions.

Collaborative activities are needed amongst leading practitioners, education and research sectors to ensure that the processes in housing maintenance are fully understood by the decision-makers, knowledge and experience are shared by the counterparts and that professional and ethical standards are established to provide the benchmarks for resident interests based effective practice.

Engineers and other technical staff employed for managing maintenance of housing estates are too often by training background mainly oriented towards new construction; maintenance is always perceived as direct extension of the original construction process that should and could be carried out by professional building staff. Therefore several housing maintenance organisations are often subsidiaries for construction companies with good technical competence and equipment, but far away from the estates and targeted to doing works on the sites rather than providing residents targeted services. Maintenance has to deal with the existing buildings and with the needs of the households living there; accordingly many routine maintenance activities absolutely do not require technical skills rather human understanding. Therefore, in addition to educating the owners also professionally skilled maintenance managers are required.

5. Acknowledgements

The author of the paper as the Project Leader of the ‘Developing professionalism for housing maintenance management in the Baltic States’ project is thankful to the Nordic Council of Ministers for funding this housing maintenance mission. In parallel acknowledgements are extended to Estonian Science Foundation for supporting the academic research done in relation to cost-studies of buildings dependant on the actors’ behaviour.

Abstract

Managing construction projects and life cycles of built objects including their dynamics, and the inevitable changing circumstances and environmental context has proven to be difficult. However, procurement and supply strategies in construction are often based on a static approach: fixing briefs and contracts at the beginning of construction projects, when many issues are obviously still unknown or unresolved, many parties are not yet involved in the process, and change orders through the project and the life cycle are not yet known. This paradox calls for a shift from static to dynamic control of projects and life cycles, towards a "living building" paradigm of construction. This means introduction of new models, methods and contracts enabling to cope with the dynamics of construction projects and life cycles, and assuring that value is delivered and maintained adequately under changing circumstances.

In this paper a concept is presented to develop a "living building" paradigm for construction. The concept addresses two basic problems that currently exist in design and construction processes, leading to many conflicts between demand and supply. The inefficiency and ineffectiveness between demand and supply is caused perception of demands and solutions, combined with process statics and fragmentation in time. The development of the concept is based on a dynamic and interrelated approach to the demand and the delivery of built services. The concept implies new principles for procurement and supply strategies, process management and alliances between stakeholders involved in construction projects. The next step in the development of the concept is the extension of the new paradigm through the entire life cycle. This includes the formation of stakeholder alliances for the life cycle aimed at the maintenance of the long-term functionality and serviceability of built objects. Ultimately, this must lead to a shift of the construction industry as a whole from a project delivery industry towards a built service sector.

Keywords: construction projects, life cycle value, dynamic control, price development, process statics.

1. Introduction

In construction, demand and supply of value can be a complex undertaking, particularly for large construction projects involving many parties and long lead-times. The main problem identified is the intrinsically dynamic character of the process, and the changing and often diverging perceptions of parties of the outcome of the process, versus the static approach to the control of the process, because of formal arrangements between parties. What is needed for the effective control of construction is an aggregate and comprehensive model to be able to dynamically and effectively control and adapt demand (clients' value) and supply (delivery) in an integrated manner through the entire process, and idealistically through the whole life cycle of built facilities. Such a "big picture" model or "master plan" method has not been common in construction, but is essential to be able to control the complexity of building.

The concept presented in this paper represents an abstract, "sociological", or even "philosophical" view on building and built services. The concept is called the "living building" concept to indicate the dynamic approach to built services, the construction project, and the life cycle. In the concept presented the basic economic parameters value, price and costs are defined and interlinked on a high abstraction level representing the performance of the built service. The basic premise is the dynamic character of the connection between value and costs, price and performance, and therefore should be controlled dynamically; so no prescription of output against a fixed price, but rather defining a dynamic connection between performance and price. The concept is representing a further development of the concept of dynamic control, which has been introduced by the authors in previous papers [1] [2] [3]. The concept is based on the essential notion that the world is changing. Second construction is a social activity: Construction implies complex product development in a changing context, involving many parties, delivering products with value to society, pulling high levels of resources from the economy. Construction projects often take long time, and the life cycles of built services are long. During the construction process, the level of information and knowledge grow, by both the client and the supplier. Demand and supply influence one another. So requirements of buildings change constantly. Demand must be adaptable and supply must grow along. Procurement and supply strategies as well as project and life cycle management arrangements must be able to cope with these dynamic mechanisms. This calls for a reconceptualisation of the demand, delivery and life cycle management of built services.

2. The "living building" concept in construction

2.1 The problem of perception

The basic reason and rationale of a "living building" concept in construction is based on two underlying problems in construction: perception and process statics. These problems start with the demand and the fact that the first demand is basically always incorrect or incomplete, while it is impossible to demand before knowing what is available and possible, nor is supplying without knowing on a basic level what is wanted. So demand and supply are intrinsically connected, and this should be reflected in the process towards delivery of built services. However in current construction practice, this is often not the case. Demand and supply are relatively disconnected. Consequences are extra work and creation of extra value after establishing what had to be delivered after all, or work or value delivered in vain when finding out what not had to be delivered. This is basically the result of the tension between value and costs, i.e. the interest of clients' value versus suppliers' profits.

2.2 Construction process statics

The ideas and expectations of a successful project are often subjective, implicit and contradictory. For whatever reason there is always a need for change during process, so there is a need for a dynamic approach. This is particularly true in construction, where there are often no formal rules, no strict hierarchy, no fixed product, variable projects, many parties involved, unsynchronised involvement, absence of one party who has complete overview and authority. Traditionally, the "natural response" in construction is to try and fix and isolate various aspects as much as possible, including fixing the price and the design early in the process, which leads to quasi-certainty, process statics and disproportional additional transaction costs. Due to the fragmented and delegated control, and long demand and supply chains, changes come often too late to be able to effectively and systematically deal with. Change orders take lots of effort to follow up, and are often compensated through extensive rework or claims [4] [5].

2.3 Need for a dynamic approach to construction

The problems of perception and process statics and the paradox between static control and dynamics of construction life cycles call for a dynamic interrelated and long term approach to the demand and supply of built facilities aimed at systematic and adaptive maximisation of the total life cycle benefit (total value minus total costs) of built services. Value and costs are time dependent, thus the dynamic process must be aimed at the continued maximum benefit. When the total value could be interconnected qualitatively and quantitatively to the total costs of a built service, and parties would agree on the algorithm between value and costs, then the collective of demanding and supplying parties can aim the process at achieving the highest possible benefit to the mutual advantage of both demanding and supplying parties.

The contract will then not prescribe an absolute performance output against a fixed price but rather define an agreed-upon performance-price balance, i.e. value-costs balance. Within a "performance related partnering" arrangement the process can then be dynamically controlled, i.e. clients can alter their initial demand and calculate the impact on the initial price, and vice versa supplying parties are enabled to come up with new solutions that may reduce costs, or deliver additional performance output increasing client value. The initial price will grow within this dynamic process in a controlled way to a final price that may be higher or lower than the initial price for the initially planned performance. Instead of enforcing the initial planned performance against a fixed price calculated in the first phase of the process, the price is based on the actually delivered performance at the end of the process. The final price goes up to the maximum of the initially set maximum guaranteed price, not exceeding the planned budget of the client. The range between initial price and maximum budget can be considered as the client’s “control budget” for dealing with problems of perception and additional value delivered through the process. Because of the transparency of the process, on the supply side, contractors and other parties are enabled to reserve budget too for extra investments to reduce costs or increase value. This approach can be defined for the project scope only, but can be extended to the whole life and the facility management of built facilities, and be implemented to a variety of contract formats from build-only contracts to more inclusive “DBFMOT” kinds of contracts.

3. Principles of the “living building” concept

3.1 Procurement strategy principles

The client’s budget needs to include a buffer for dynamic control by the client. The supplier (e.g. contractor) sets an initial price for a basic solution to meet the client’s initial wishes. The buffer between the budget and the price is used for unforeseen changes and change orders; changing demands, requirements, regulations, standards, technology, finance etc. The following procurement process is based on a continued process of “price development”: it starts with an initial price for initial design, through a final price for actually measured additional output at the moment of delivery, and next constant measurement of delivery of life cycle value (figure 1). This process can be capped, e.g. by means of a guaranteed maximum price [6]. Thus the lowest price is must not necessarily be the client’s main selection criterion and driver. Rather it is necessary to realise that costs have to be related to the value delivered in a constant manner, and value for money has to identified, to assure that clients get the best possible life cycle value from suppliers (contractors etc.) [7]. However, in current practice, criteria for selection and bid evaluation of contractors are often still aimed at mere project delivery capabilities. For the “living building” concept, a wider range of criteria is needed to evaluate suppliers’ capabilities against the needs of clients and other stakeholders [8]. Thus the procurement system must be linked to the client’s priorities. The priorities and the procurement system are influencing the team selection, and thus the project outcome and performance level [9]. The use of “sound” selection criteria and application of a “best value based contractor selection framework” are essential to achieve the desired project outcome and “best value” [10].

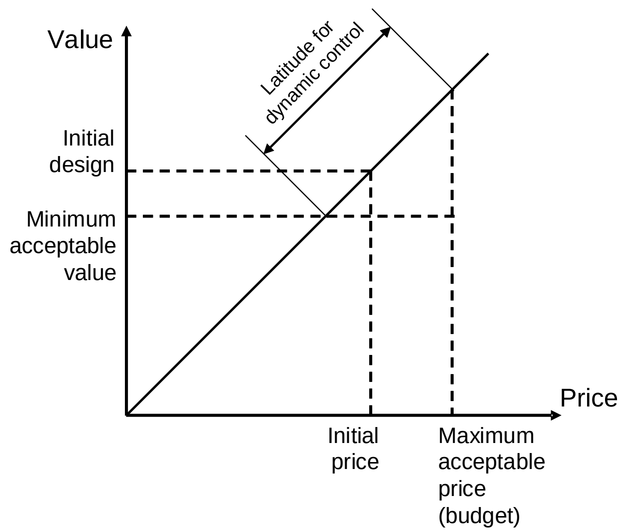

Figure 1: Principle of dynamic control

The ultimate goal is to find the best solution for clients and other stakeholders, as well as the contractor and suppliers, i.e. best value for the client at minimal costs for the supplier. This maximises the benefit; value minus costs. Client and supplier share the benefit by finding a right price in the middle. The goal specificity is influenced by value specificity and the client's requirements. Higher levels of value specificity and observing life cycle value rather than project delivery improve the final project outcome and the starting point for the rest of the life cycle of the built service [11]. In order to specify all stakeholders' values and project priorities, value engineering must be a structural component of the procurement process. Analogously to the procurement process, the value engineering must be performance based, not price based. This implies measuring and rewarding performance delivery, minimizing adversarial relationships and collaborative decision making leading to "best client value" [12]. Besides "value optimization" value engineering must be aimed at target costing, in order to increase and maximise the gap between value and costs, i.e. maximising the total benefit for client and supplier [13]. This kind of "value for money" approach has the largest potential in the early stages of the project, i.e. the briefing phase, when strategic decisions are made, together with application of integrated life cycle contract types [14] [15]. During the value engineering both client and supplier must be committed to invest and use extra budget to develop the design collaboratively based on life cycle incentives within an alliance or partnering arrangement [16].

Negotiation and collaboration have been advocated rather than competition and relying on market mechanisms to achieve best value for money. However, it has also been argued that competitive procurement methods achieve better value for money than negotiated procurement methods [17]. Clients tend towards competitive tendering to get value for money. Contractors tend towards negotiation and longer term contacts to strive for delivering value for money for a longer in the life cycle [18]. Strategic procurement methods, like framework contracts, have been observed to be more effective in particular sectors of construction, where longer term contracts offer specific benefits [19]. Reengineering procurement methods towards more from adversarial relationships to more co-operative and partnering relationships, need to be combined with fully integrated and coordinated design, integrated supply chain management, and efficient managerial control of the whole design and construction process, leading to benefits to all parties [20].

3.2 Supply strategy principles

Current supply strategies in construction are in most cases restricted to project delivery only. Future supply strategies must be extended beyond project delivery, including facility management, maintenance and refurbishment, to assure the functionality and serviceability of the built service. This implies “continuous value delivery” or “life cycle value delivery”, instead of project delivery. This approach requires dynamic control capabilities of the whole life cycle by suppliers of built services. The industry needs to broaden its approach to value delivery, and apply the concept of value delivery proactively vis-à-vis construction clients [21]. In general, the “living building” concept requires that the industry moves from a delivery system within a price based environment towards higher level of “performance based competition” [22].

Industry partners must adopt the use of integral value management through the supply chain to facilitate collaborative working and increased inter-organisational collaboration for resolving current industry inadequacies regarding design, construction and facility management [23]. Integration of the team to the client’s value system is essential to capture client value from the beginning of the project and informing further decision making during the project, and continued value delivery through the value chain [24]. Therefore, contractors and other suppliers in construction must develop and improve their pricing strategies, their costing capabilities and their financial risk management [25].

3.3 Integrated process principles

The “living building” concept must result in the integration of the design, construction and facility management of built services. Based on the awareness that perception and increasing knowledge will influence and affect demand as well as possible solutions during the process, clients and suppliers team up to develop and deliver the built service, based on a common understanding of the demanded value, performance, and how to define value, costs and price dynamically. Both clients and suppliers are no single entities, but often complex configurations of stakeholders, with different value assumptions, interests, investments, particularly in large construction projects, sometimes within a complex political social, economic context. This calls for extended stakeholder identification and involvement to define best value (demand) and deliver best value (supply) [26].

Operation costs of a built service over the life cycle are a multiple of the initial construction costs. Decisions in the briefing stage and the design process influence life cycle costs [27]. To improve the delivery of client best value the contactor gains more control over design and construction, in order to be able to assure the continued value delivery thought the life cycle. Therefore life cycle costs data and evaluation techniques must be linked to design development tools [28]. Then process control can be based on dynamic performance information and continuous output measurement, aimed at total costs minimisation and life cycle value maximisation [29]. For the cost evaluation of choices made through the life cycle, a comprehensive framework for decision-making is needed; ‘a continuum which links the life cycle cost across different stages of the life cycle’ [30].

4. The “living building” future of construction

4.1 From performance specification to output measurement

The “living building” concept advocates the shift from performance specification to output measurement. In current practice, clients often define the performance in the brief at the start of the project and use change orders to alter their demand during the process, even still in the construction phase. Change orders are often regarded as a phenomenon occurring outside the briefing rather than integrated part of the briefing process. Previous authors have proposed the application of “dynamic brief development”; a process to develop the brief allowing change orders until the brief and the price is fixed after a certain period of time during the first phase of the project [4]. The “living building” concept implies a dynamic approach to the brief that goes beyond this in two respects: the brief is kept dynamic until the project is delivered allowing changes from both clients and contractors/suppliers aimed at further improvement of the value and cost level; the price forming process is kept open based on the dynamic brief. The price is established eventually at the end of the project based on output measurement according to formulas that have been agreed upon by client and suppliers.

4.2 From static to dynamic process control

In the “living building” concept, the dynamic briefing approach is extended from the early briefing stage of a project through the design and construction process. This implies that the entire process is managed by dynamic control. To enable integrated dynamic control of the entire process and the supply chain, the interfaces in the design and the team are conceptualised by means of a systems approach that allows to design and evaluate the design holistically, and to monitor and take collective action after things change. In this way, the dynamic briefing process is extended throughout the entire project process. The project brief is the dynamic basis for continually developing and adapting in an integrated manner design and further technical development and realisation of the built service. This requires a control mechanism for development and feedback that incorporates all aspects of the value delivery process and connects all actions by participants to project priorities, and supports information sharing and informed decision-making [5].

4.3 From a project towards a life cycle perspective

The ultimate step of the “living building” concept is the extension of the dynamic approach after project delivery, through the entire life cycle. Clients and users, and contractors and suppliers continue their involvement in maintaining the functionality and serviceability of the built service. The team is involved through a long term contract to take action based on new demands and insights from clients and users, and make alterations and changes to the built service based on new knowledge that improve the usability or cost levels. The performance of the built service is evaluated continually, and decisions to take action are made through the continued measurement of value and cost levels. This implies life cycle alliances to assure the continued involvement of parties and stakeholders during the life cycle. This is particularly complex while after project delivery, alterations and changes to the built service imply reconstruction and refurbishments, which are part of the use and facility management of the service, involving users and facility managers and other parties that have not been involved in the project before. In addition, changes of users and owners through the life cycle make this even more complex.

4.4 Dynamic control for different types of contract

In a certain way, dynamic control is applied in current practice: Suppliers ask a price for the construction of the project as specified by the client. In order to cope with unforeseen events and the associated consequences, additional work due to perception is measured as additional quantities of materials related to the initial design. When multiplied by unit prices these quantities are the basis for supplier’s financial compensation for additional work. This simple measuring system can not used for integrated contracts such as DBMOT, BOT, DBFMOT, as quantities can not be measured due to the absence of a fully specified design of the building. For these types of contracts, the changed value should be measured in another way. For DBM kinds of contracts the changed value due to perception can be measured in performance of the building expressed in measurable aspects such as form (e.g. aesthetics), function (e.g. capacities), technical quality (e.g. energy consumption). For DBMOT kinds of contracts, the changed value due to perception can be measured at a high level by the net present value of the life cycle value. With a fixed relation between the measured value and the price to be paid, dynamic control leads to large benefit for the client and large profit for the supplier. The price development for the three different contract types is shown in figure 2.

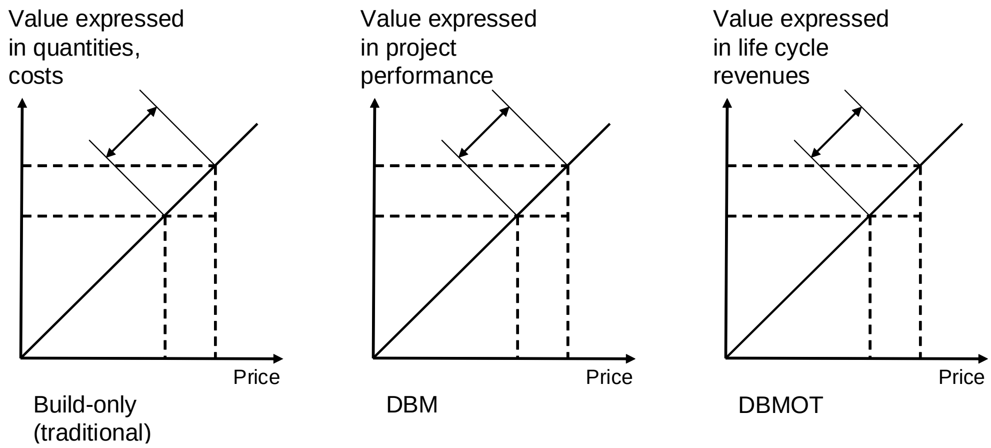

Figure 2: Price development for different contract types

5. Discussion and conclusion

The "living building" concept represents a new and comprehensive approach to demand and delivery of built services, based on a dynamic approach to the construction process and the life cycle. It solves problems of perception and process statics. It offers great potential advantages to demanding parties (clients, users etc.) as well as supplying parties (contractor, suppliers etc.). Particularly the continued dynamic approach, performance measurement and involvement of parties through the life cycle imply a great endeavour for clients as well as suppliers.

6. Further research and developments in practice

Further research and current developments in practice in the Netherlands have been aimed at at the development of the "living building" concept and life cycle contracts, particularly for road infrastructure. Few contracts have already been implemented by the Ministry of Transport, Public Works and Water Management for some roads. These contracts include the maintenance and facility management for a long period of time. The performance is predefined as much as possible, leaving open how the contractor/facility manager takes care of this operationally and technically, but only predefining cost levels and minimum performance specifications. The contractual and operational arrangements of adaptations that may have to be done to the roads in time, and proper corresponding financial arrangements still pose quite some difficulty. Delft University of Technology and TNO Built Environment and Geosciences have been doing and planning research projects aimed at these issues, as part of the national research and innovation programme for the Dutch construction industry PSIB. The research is aimed at the further development of contracts and procurement methods that include effective arrangements for adaptations of built facilities (i.e. roads) during the life cycle as a result of changing circumstances, demands and knowledge, including the definition of corresponding contractual financial mechanisms based on dynamic value-cost calculations and life cycle performance measurements. Results of these research projects will follow in subsequent papers.

e-Construction – finally taking off?

Jakob Munk Nielsen
Manager, Rambøll Management (email: Jamn@r-m.com)

Abstract

Various pilot projects on the use of advanced ICTs in the construction sector has demonstrated that stimulating digital integration is a key measure to improve quality and increase the productivity in the construction sector. Especially applications aiming at collaborative working are seen as promising, i.e. software to facilitate cooperation between designers, suppliers, engineers, software developers etc. [4, 5, 6]

Traditionally, the construction sector has been a slow mover in the field of ICT [1] [8], but a number of drivers challenge this conservatism, including increased competition in the internal market, increasingly complex project management and industrialisation. Thus, it could be expected that construction companies adopts a more pro-active approach in this field.

This symposium presents the 2005-results of the largest survey in Europe on the use of ICT in the construction sector. This presentation will explore:

- Recent developments of the use of ICT in the construction sector
- The impact of e-business on the European construction sector
- Comparison of the development with other sectors
- Implications of e-business on construction companies, including SMEs

Keywords: e-Construction, E-business, E-procurement, e-Collaboration, e-Invoicing, Productivity, Integrated IT-solutions

1. The e-Business W@tch

1.1 Overview

As part of the so-called EU Commission initiative e-Business W@tch, Construction has been selected as one of ten sectors to be analysed. The presentation on the symposium will be based on the analysis of the Construction sector conducted within this framework.

Brief presentation of the e-Business W@tch

The eEurope 2002 Action plan provided the basis for targeted actions to stimulate the use of the Internet for accelerating e-commerce, acknowledging that "electronic commerce is already developing dynamically in inter-business trading [...]" and that "it is important for SMEs not to be left behind in this process [...]." The eEurope 2005 Action Plan, endorsed by the Seville European Council in June 2002, confirmed and built further upon these objectives with Action 3.1.2. "A dynamic e-business environment", which defined the goal "to promote take-up of e-business with the aim of increasing the competitiveness of European enterprises and raising productivity and growth through investment in information and communication technologies, human resources (notably e-skills) and new business models".

It is against this background that the European Commission, Enterprise Directorate General, launched the e-Business W@tch in late 2001, with the objective to provide sectoral analysis based on sound empirical research, including annual enterprise surveys in all countries of the enlarged European Union. Special emphasis is placed on the implications for SMEs. [1]

Since its launching, the e-Business W@tch has published e-Business Sector Studies on 17 sectors of the European economy, synthesis reports about the status of electronic business in the European Union, statistical pocketbooks and further resources (newsletters, presentations, special issue reports). These are all available on this website: http://www.ebusiness-watch.org/

1.2 Introduction

The European construction sector includes more than 2 million enterprises of which the majority are small companies with fewer than 20 employees [2]. The construction sector is the biggest industrial employer in the European Union, with a GPD contribution on approximately 10%, an overall employment rate of 7% of European workforce and 28% of the industrial employment [3].

The European construction sector is characterised by a few large design and engineering companies and a large number of small sub-contractors. The role of the large construction companies are changing from pure contracting towards a greater focus on project management. Moreover, they increasingly outsource work to small companies and concentrate to a greater extent on running the projects.

Various pilot projects on the use of advanced ICTs in the construction sector has demonstrated that stimulating digital integration is a key measure to improve quality and increase the productivity in the sector. Especially applications aiming at collaborative working are seen as promising, i.e. software to facilitate cooperation between designers, suppliers, engineers, software developers etc. [4] [5] [6]

The symposium explore to what extent ICT is used today in the sector, where the development is heading and if potentially promising technologies are adopted in the sector. Some of the key issues related to the use of ICT in the sector are:

- Productivity: ICT aimed at controlling projects with marginal profit are important. To what extent are ICT used for project planning, budgeting, controlling of projects etc.? Will ICT increase productivity in the construction sector similarly to other industrial sectors?
- Integration: Integrated IT-solutions, which supports project management and tunes companies to an increasingly competitive market, is an important issue in the sector. Which problems related to IT-interfaces and standards are facing construction companies when integrating working processes horizontally and vertically?
- Cooperation: Production processes are changing internally due to new mobile/wireless solutions and externally due to collaborative software. Which new forms of internal and external organisation are emerging as a result of new ICTs? Are new technologies likely to catalyse a restructuring of the sector?
- European market: Systems for e-procurement and e-invoicing are evaluated and implemented in larger construction companies at the moment. Does e-business stimulate the cross-border consolidation of the sector? Does it promote the establishment of a single European market for construction services?

1.3 Findings

The construction sector today is characterised by a large degree of fragmentation in IT usage. [2] [8]

- A multitude in standards, technical specifications, labels, and certification marks as well as diversity in local, regional and national legislation and regulations.
- A low adoption and integration of relevant ITC in most business processes – especially with SMEs that are often characterized by communication and knowledge sharing based on personal contact or telephone.
- High sensitivity to changes of economical conditions in market and society.
- Companies are typically either organized around projects and project flows or suppliers to project managed companies.

The following trends also set the stage for further uptake of ICTs in the sector:

- Increasing pressure for consolidation
- Industrialisation based on new concepts, e.g. pre-fabricated houses
- Outsourcing and specialization

- Internationalisation including new market opportunities and increased competition from foreign players

<u>E-business activity</u>

The attitudes towards ICT in the sector have traditionally been of a conservative nature. Apprehensions towards ICT investments are still strong and most companies are re-active rather than pro-active in the usage of ICT as a tool for competitiveness. [2] [4] [5]

Four topics can be recognised as important drivers for the development of electronic business in the Construction sector. These are productivity, integration, collaboration and the European market:

Productivity in the building and construction industry has yet to show the same level of productivity improvements as other industries including production. This has to do with the line of work and the type of production involved in construction processes but it also has to do with a slow ICT uptake in a sector dominated by small and medium sized players. Large enterprises in the industry as well as new sector entrants have adopted ICT based production improvements, but there is still un-used potential for ICT uptake in the area of productivity, e.g. with production planning systems, ERP-systems with financials, MRP system, Inventory management systems, CRM-systems, SCM-systems and Mobile solutions.

Integration is an important driver for developing ICT in the Construction sector. Many companies have a low degree of integration of both internal and external business processes as most companies in the Construction sector organise work around unique construction projects leading to fragmented business processes supported by "home made" ICT systems that do not integrate across the basic ICT landscape of the company.

SMEs in the sector are especially behind on system integration – also compared to other sectors. However, new sector specific solutions for smaller companies are being developed and ICT vendors take a growing interest in the market.

Collaborative systems are important as the construction industry is characterized by bringing together many different organizations dependant on coordination and cooperation to complete a shared goal. Effective systems to distribute and share information are a critical precondition in order to raise productivity and manage resources and costs, and potential benefits and savings enabled by improving interoperability and implementation via digital solutions are extensive. But implementation of collaborative systems is hampered by a number of barriers ranging from form lack of shared standards for information exchange to technical limitations, social and cultural issues.

ICT as a means of creating a European market in the building and construction industry is limited by the location bound nature of construction. However, e-procurement (e-tendering and e-ordering) as well as e-collaboration (e-communication and e-SCM) can contribute to the creation of a European market by making the market more transparent and by facilitating communication and coordination across borders.

In the future new solutions and increased uptake can be expected in five areas:

- Platforms for collaboration between the many partners in consortia, mainly by project webs where drawings etc. are shared. This development will be facilitated by increased standardisation of information on building projects.
- Integrated ERP solutions will be developed further focusing on the main business processes of project management, risk management and resource management. As standard industry solutions become available at lower prices, more SMEs will begin to adopt such solutions.
- The large project driven firms (consortia leaders) will adopt e-procurement as a means of reducing costs
- The increased industrialisation driven by new concepts and increased internationalisation will be supported by e-SCM (systems for supply chain management)
- As reduced margins drive business models to focus on services, industry ERP-solutions will include management of services, e.g. facility management. Other construction companies will expand into project development (e.g. developing plots of land into housing and selling or letting the buildings instead of just building them) and look for IT-solutions that support this.

1.4 Methodology

As in the previous years, the e-Business W@tch 2004-2005 use internal as well as external sources to collect not only data and indicators but also background information about the sectors covered. The different types of sources and the information they deliver constitute the main input for the sector reports. These sources are complementary to each other. The nature of information to be extracted can be qualitative or quantitative. Qualitative information (e.g. from case studies, or as provided by industry associations) will mainly serve as context and have an explanatory function, while quantitative data gathered through primary research (mainly via the e-Business Survey 2005) will deliver the e-business indicators and the sector statistics for reports. [1]

- Desk research (secondary sources) will be used to identify business examples, background information about trends and e-business developments in the sectors, and as pointers to potential case studies which can be followed up.
- Primary research will be used in form of the e-Business Survey 2005 and for collecting new case studies on e-business.
- In addition, the e-Business W@tch will continue to use industry statistics obtained from the Eurostat New Cronos database. However, data from this secondary source will be

processed and refined as necessary in order to close gaps (for specific countries or years) as good as possible.

The e-Business Survey 2005 is a cornerstone to this initiative, as it is a key instrument to collect e-business data on sectoral level which are not otherwise available in this structure and coverage. The survey also represents an important cost position in the project. As in 2002 and 2003, the survey is carried out as a CATI survey and cover all 10 of the sectors selected. The survey provide aggregated data for the European Union as a whole.

The e-business indicators (questionnaire)

The questionnaires used in the e-Business Survey 2005 is based on a conceptual framework for the measurement of ICT adoption proposed by the OECD, namely to at "readiness, activity and impact".

"Readiness" translated into ICT infrastructure diffusion and the development of accompanying skills. "Activity" was defined as e-business processes between enterprises and their customers, suppliers and cooperation partners, as well as internal business processes that are conducted electronically. "Impact", which is still the most difficult area to be translated into survey questions that can be directly asked to interviewees, was dealt with by asking companies about the perceived consequences of their e-business activities. In addition, in 2003/04 the relationships between innovation activities of firms and the level of their e-business activity was investigated, which presents a more complex and sophisticated approach to look at possible implications and "impacts" of e-business.

Abstract

A smart control device with an additional tool box which includes educational and information kits, called forgiving technology, has been developed in the EU funded project EBOB (2002-2004). It is meant for personal computers of the office workers enabling sustainable office working environments based on user behaviour. Careful design of the new prototypes for smart control devices has been accomplished with usability studies in different working environments in Sweden and in the Netherlands.

Promising results of the effect of the forgiving technology on the end-user behaviour are expected, which can result in ever more sustainable office buildings in the future. The possible changes in the office workers behaviour, which improve energy-efficiency are discussed in the paper. They concern both new office buildings and renovation projects.

Keywords: Office buildings, building automation, forgiving technology, end user control, energy saving, motivation tool

1. Background

This paper is drawing much from the EU Fifth Framework project EBOB, Energy Efficient Behaviour In Office Buildings (NNE5-2001-0263). The key focus of the EBOB project (www.ebob-pro.com) is on the combination of the human and social perspective with advanced modern control and ICT (Information and Communication Technologies) solutions. This is done in order to make energy efficient behaviour natural, easy and intuitively understandable for the end-users, and at the same time to achieve the most energy efficient solutions while improving standards on indoor comfort in refurbished and new office buildings. The results gained due to this combining approach of human perspective and available new technology are called 'forgiving technology'.

The EBOB project creates new technical and socio-economic solutions to make energy efficient behaviour natural, easy and intuitively understandable for the end-users in refurbished and new offices. This will be achieved by starting from human perspective and use available and new technology (including ICT, smart control, user interfacing).

All energy use in a building interacts with each other in different ways. The focusing points in motivating the use of energy efficient solutions can be: information, user behaviour (end-user satisfaction, personal motivation), productivity, health aspects, indoor climate and tools (control systems and user interface). In this paper the building automation tools to be used to make the office space better regulated by the end-user and the end-user better informed of the influences of their acts are discussed. The more new knowledge is available the more productivity, health and indoor air aspects are talking for the need of flexible, adaptable and well regulated workplace and workspace. Furthermore, workers want to feel comfortable when working. The joy of work is gained out of empowerment, which forgiving technology allowing personal control is about. They are the basis for developing and using forgiving technology, but discussed in more detail in other context. First, this new way of controlling is introduced.

1.2 Definitions

Building automation is related to the phenomena of automated and intelligent buildings, which sometimes are mixed. There is no universal definition of intelligent buildings. However, certain consensus of the intelligent building concepts exists and efforts for agreement of the definition are available (cf. e.g. [4] and [18]). The latest of them is available of the automated buildings (Technology Roadmap for Intelligent Buildings, 2002). Also the ranking lists for the automated buildings are under development by the efforts of the CABA (Continental Automated Buildings Association, www.caba.org).

To differentiate intelligent buildings from other building concepts the forms of building intelligence[1] have been studied ([10], pp. 284-342). The forms of Building Intelligence (BI) are

[1] *Building-connectivity* (speaking and speech recognition including music and linguistics; user-connectivity and control: either personal or automatic or defined by the organisation in concern); *Building self-recognition* (building knows the state it is in; a kind of consciousness); *Spatiality* (a more conscious understanding of the spatial expression of the architecture, structures, interior design); *Building kinaesthetic* (a sense of change, active structures, moveable structures, furniture and equipment, adjustable technology or building services), and *Building logic* (embedded sensors to monitor the occupants' daily activities, combinativity).

derived from the forms of human intelligence[2] [11]. Automated or integrated buildings are intelligent buildings, where logic is the key attribute of the design, and the human ability of mathematical and logic intelligence is the motor for the solutions. Building automation is the leading application for this form of building intelligence. The other forms of building intelligence assist in making the building logic work for the benefit of the building occupants and occupant companies. Such assisting factors of intelligent buildings are (1) inter-connectivity by user interface (cf. also [12]), (2) building recognition which means that the building is aware of the status of building services and occupant activities, (3) spatiality which is related to the right locations of the building automation control units, and (4) the existence of active structures which make the building control come true.

Sustainability covers both the ecological issues and the human welfare. That is why the EBOB project and the development of forgiving technology have much to do with the Green building concept, which is also lacking a universal definition. Green buildings are according to the U.S. Green Building Council (USGBC), buildings that are environmentally responsible, profitable, and healthy places to live and work in (http://www.usgbc.org/). Furthermore, there is the concept of Healthy buildings, which is the continuation of the research of Sick buildings. The Sick building syndrome has been a concept to study phenomena of indoor air quality which affect people in a negative way causing syndromes such as back or head ache, irritation in throat or nose, difficulties with vision, etc. In healthy buildings indoor air is supportive to human health condition, abilities and activities.

1.2 State-of-the-art of Office Building Control

The need for energy renovation is urgent in such older office buildings where not only the envelope and the structures need repair, but also the control of HVAC systems is lacking. The change of the end-user behaviour can be an alternative strategy for reaching energy savings and still avoid high renovation costs. In the new office buildings that have been built by following the latest knowledge of the energy efficient and sustainable building technology and with the latest control technology, the correct energy efficient end-user behaviour is the only way of letting the technology prove its efficiency.

The end-user behaviour can be changed even without technology by informing and motivating. The automated control technology saves trouble caused by manual operations. However, still

[2] Seven forms of human intelligence by Gardner (1983 in [8], pp. 120–123, 1991 in [8], pp. 345–352, 1993 in [21], pp. 107–110, 1993 in [7], p. 28) are: Logical-mathematical, musical, linguistic, interpersonal, intrapersonal, visual-spatial and bodily-kinaesthetic.

personal involvement might be needed for special occasions or for personal needs differing from the standard norms of indoor climate.

1.3 Need of Personal Control

It is common knowledge among facilities managers that the possibility to influence one's work environment is one of the most important factors of the workspace design. A second one is the feeling that problems are taken care of, in one manner or another like change, repair, etc.

According to "What Office Tenants Want, the 1999 BUMA/ULI Office Tenant Survey Report" only 56 percent of all respondents are located in buildings with any of the intelligent features listed in the survey[3]. The questionnaire was sent to approximately 20,000 office tenants throughout the USA and Canada. Slightly more than 1,800 responses were received, primarily from principals or owners, executives, office managers, or department managers of the responding companies. Intelligent building features are much more prevalent in owner-occupied buildings ([24], p. 50).

In tenants' rating of the importance of intelligent building features to their business, but not currently available in their building no single intelligent building feature stands out, but six features are consistently among tenants' top three: high-tech and energy-efficient HVAC system, wiring for Internet access, wiring for high speed networks, LAN and WAN connectivity, fibre-optics capability, conduits for power/data/voice cabling ([24], p. 42). Automatic on/off sensor in the lighting system was not among the top six. The priority of the features changes when the tenants were asked to indicate whether they would be willing to pay additional rent to have those features: computer-related features, high-tech and energy-efficient HVAC system, security systems, telecommunications capability, and redundant power source ([24], p. 44).

The relatively high ranking of HVAC systems in this corroborates the importance tenants place on having a comfortable temperature in their office and having control over the office temperature ([24], p. 43).

[3] Fiber-optics capability, built-in wiring for Internet access, wiring for high speed networks, LAN and WAN connectivity, satellite accessibility, ISDN, redundant power source, conduits for power/data/voice cabling, high-tech and energy-efficient HVAC system, automatic on/off sensor in the lighting system, smart elevators that group passengers by floor designation, automatic sensor installed in faucets/toilets, compurized or interactive building directory

- According the IBs Survey, carried out in Finland in the Helsinki metropolitan area in twelve office buildings, the possibilities to control room temperature and lighting were not particularly good. They were evaluated with no high rates; room temperature with mean rate 6.2 (n[4]=455) and lighting with mean rate 6.7 (n=455) ([10], pp. 242-243). The index was from 4 to 10, which was the best. In general the building and office automation was rated with 7.9 (n=286) in the intelligent buildings and with 7.5 (n=182) in the other high quality office buildings used as reference buildings to the intelligent ones ([10], p. 208). The respondents' evaluation was based on the effect of the building feature to the working efficiency. In this Finnish survey, there was found a statistically significant difference in the quality of technology between intelligent and other types of office buildings in whole, when all rates were summarised. However, this correlation was not found on controlling possibilities. The control was not better in the IBs than in other office buildings, although in some cases good personal control possibilities of indoor air had been in focus in the design of IBs.

The IBs Survey proved the work environmental control possibilities important, while those who had the chance to participate in design of their work environment evaluated the quality of it better than whose who could not, or had difficulties in influencing the design ([10], pp. 264-267). Besides, the majority of the respondents (60.4 per cent) could not even participate in the design.

Wyon (1999) states that no improvements in sustainability will occur unless users are provided with insight, information and influence. Insight includes an understanding of the context in which the behaviour and its consequences occur. Information includes feedback on current conditions such as room temperature and energy use. Influence includes providing means of affecting the relevant variables such as a user friendly, intuitively understandable user interface enabling users control of indoor climate parameters on the office room level.

The office workers and the facility management have to be involved for effective use of technology. Commitment and encouragement of the office workers and facilities managers to promote sustainability, and prevention of misbehaviour in use of technology are seen among other benefits yielded from technology as a new potential for even better energy efficiency in commercial buildings. It is not even enough to provide motivation in the form of rewards or sanctions. Occupants must also be empowered to adapt modified behaviour.

[4] number of respondents

2. Forgiving technology

Practice shows that many technical solutions for energy saving exist and are installed in many office buildings, but the real energy saving effects are not there. Reasons for these deviations can be found from: wrong combinations of building and installation technology; misinterpretation of operational staff; misunderstanding and energy inefficient behaviour of the office occupants [5]. The overall aim in the EBOB project is to save energy by:

- Integration of and interaction between behaviour aspects of office workers and energy saving technologies
- Prevent wrong combinations of building and installation technology
- Prevent misinterpretation of operational staff
- Prevent misunderstanding of office users
- Prevent energy inefficient behaviour of office users
- Produce (energy saving) systems, that seduce people to participate in energy saving behaviour
- To guide the design process towards energy saving solutions that considers human behaviour.
- Design guidelines.

2.1 Need of End-user Involvement

The work done in the EBOB project has resulted in the conclusion that a major factor explaining the bad energy saving results in office buildings is that users are misunderstanding how the HVAC systems work, e.g. not seeing the relationship between lowering temperature and raised energy use during Summer conditions and on the other hand the relationship between high indoor temperatures and raised energy use in Winter. Information of the effect of personal behaviour on the energy use of the building where the end-user is working is expected to result in less energy use.

Also, office workers are not always aware of the correct use of the control equipment, which causes energy losses. A user-friendly technology with informative control alternatives – the forgiving technology created by the EBOB project - could solve this problem (Figure 1).

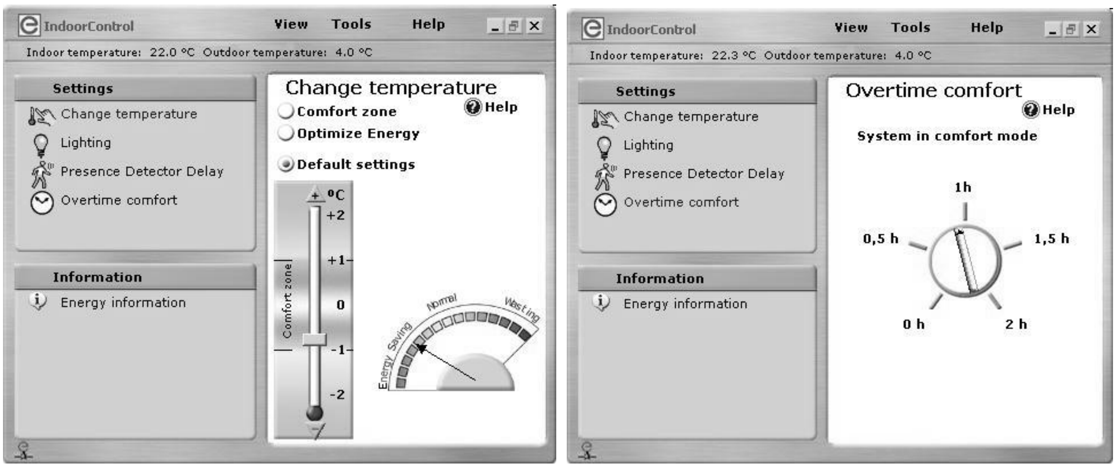

Figure 1: The control unit for forgiving technology. (TAC)

2.2 Technology

To allow the lowest energy consumption it is necessary that the building permits energy saving. A good starting point for energy optimisation of a building is that the building in itself is designed in an energy efficient manner.

In the modern office indoor environment the control of the room temperature, lighting and office automation equipment affect the energy consumption the most. In the EBOB project the work has been concentrated on the temperature and lighting regulation, and their co-operation. The temperature control involves heating and cooling and the lighting control includes the control of Venetian blinds. The system is generic and adaptable for other solutions in the future. The office automation as well as lighting is becoming energy-efficient. The energy losses from them or the use of free energy out of them will be reduced in the future.

Workers are a source of free energy. The occupancy of the office spaces varies during the working day. Working culture and the line of business influence the occupancy too. Occupancy has been discovered to be rather low for example in Northern American and English working cultures and higher for example in Finland. In England the occupancy can be as low as 45 % ([25] in [17], pp. 25) and in USA 33 % ([9] in [17], pp. 25). The occupancy of executives and executive assistants is 30 % and that of secretaries 60 % according to the British workplace consultants of DEWG [6]. However, Brill and Weidemann report higher occupancies in USA; managers 78 %, professionals 82 %, engineers and technical 80% and administrative 86 % (2001). According to the IBs Survey the occupancy of the Helsinki metropolitan offices is 87 % (62 % of the working time is spent at personal workspaces and 25 % in other spaces in the building) ([10], pp. 213, 228-231), and the occupancy of 67 % was found by Nissinen in Finland (2003, pp. 66). On the other hand, in the Netherlands the occupancies have been discovered to be low; 60 % of the office workers are in the office, and 35 % present at their personal workspaces [20]. The presence detection is the tool to take the occupancy into account also in the EBOB project in addition to the end-user motivation to prevent energy losses to reduce unnecessary heating and lighting of empty spaces.

The indoor air quality is out of the scope of EBOB project, although the standard of it might have influence on the need of energy for ventilation. However, the regulation of the heating and air-condition systems done for keeping up the comfortable indoor air temperature affect also the indoor air quality; odours, particles, etc.

A set of EBOB rules for installations have been defined including the temperature control set points, heating and cooling operation times, etc. They are based on the data of the most effective heating and cooling periods of office buildings around the clock, use of heat recovery, new theories of the use of outdoor air temperature for dimensioning, etc.

The building manager chooses the buildings' temperature set point value. This set point can vary during the seasons and should be easy to change. It can also vary how much flexibility the building manager want to give to the users in the aspect of how many degrees of centigrades they should be able to change the temperature. The set-up of the steps a user should be able to change has to be done as well.

The EBOB solutions may include equipment with specified functionality and performance. It is important that these requirements are made clear so that the right type of equipment is actually purchased by the subcontractors, and not replaced by lower functionality or lower performance products. E.g. the contractors should be educated in these questions after signing the contract.

2.3 User Motivation

Influencing the behaviour of the actors can be done by; a) investment in energy efficient equipment (e.g. insulation, energy efficient equipment), b) more efficient management (e.g. thermostat setback when the office-worker leaves her/his room) and c) curtailment of needs or comfort. The multidisciplinary approach to workspace design and energy-efficiency is needed, because only rarely one idea alone is strong enough to solve several problems at the same time. Also the humble ideas of not knowing all – or even the possibility of not ever being able to cope with all phenomena of energy efficient workspace design – might be useful in design, in particular in the era of demand driven knowledge workplace design. For successful implementation of forgiving technology a supportive energy-efficiency of the building environment in the terms of the life-cycle of the building is needed.

Control is about possibilities and limitations [22]. The limitations of control can be classified in two main categories: external limitations and internal limitations. When actors experience that they have external limitations they can believe for example that they cannot regulate the energy consumption of their room. External limitations are:

- The action is under the control (or responsibility) of other actors
- Economical limitations
- Limitations of social or work-related roles
- Time limitations
- There is no (realistic, good) alternative
- Lack of tools available
- Lack of information available.

When actors experience that they have internal limitations, they believe that their behaviour is not under their free will but under the control of an internal force. They are:

- Psychological aspects (personality, addiction, habit, lack of motivation)
- Cognitive aspects (lack of knowledge, biased mental models, lack of skill, has not thought about the issue before).

Motivation is based on the human tendency to use intelligence for the benefit of oneself and for satisfaction of one's needs, which can be described by the Maslow's Hierarchy of Needs according to his latest work [13]. A good environmental design cannot forget details that can clinch on the success or the fiasco of any solution, and an energy efficient forgiving technology respects the human needs, either separately each of them or in relevant combinations. There are a few interesting phenomena influencing the R&D work of products, which can be derived from the hierarchy of needs [12]:

- The human desire to easiness allows the automated functions.
- Variety of lifestyles makes the possibility to switch on manual mode necessary.
- Because of the need to know, occupants want to know what the automation is responsible for and what happens when a certain sound is heard or other activities take place.
- Such a human need as self-actualisation in the modern times goes hand in hand with the growing individualism influencing the design and research and technical development.
- Everybody wants to be good. A desired product provides the client with such an added value, which makes it possible.

To involve the service technicians, they need to be engaged in the creation of a new system. The main part of the life-cycle of a system is during the services and maintenance, after an installation is made. Often developers forget this and adapt the system to be easy to install but not to maintain. We can see the system as a combination of different modules and each module needs to be administrated and maintained.

By choosing this method of working we will get continuous feedback also from the service technicians on how the functions work and if they are easy to maintain or change. Good input can be given by them since they are used to work with different user interfaces and can pick the best pieces from each.

Commissioning of the installation system when the building is first used is a very important factor that can influence the energy use and comfort. It is important that the service technicians receive sufficient and correct information and training. The user interface should therefore be intuitive to minimise training.

Still, the knowledge of the state-of-the-art of building is valuable for those in charge of the energy costs and the comfort level of end users is valuable information for the human resources departments of the occupants companies, and the future design of the control systems. The possibility to transfer that information further to those in need is a mean of improving motivation among FM personnel.

The motivation of the building owners and providers emerge from such company goals as [14]:

- the matter of interest in developing the relatively traditional building sector with acceptance and understanding of knowledge and means how to embed new and radical technology
- to polish the image of the companies working in the fields of building automation and building parts and products with a sustainable or energy-efficient technology
- the understanding of the business of buildings as a form of advantages input to the core process of a the occupant companies
- the interest in gathering end-user feedback (cf. e.g. [16]), and the consideration of the satisfaction of the user needs as the best business opportunity, because the problems of the client are solved
- correct information of the cost competitiveness of intelligent energy-efficient products without over estimating the R&D costs, etc.

2.4 User Interface

The control unit of the forgiving technology of the EBOB project has been designed using expertise in psychology, usability, industrial design and functionality (Figure 1). It resembles the manual control panels for heating and ventilation, but it is run on the screen of a personal computer. In addition to the user friendliness of the control activities the forgiving technology is developed to give information to office workers to make them more aware of sustainability and motivated to behave energy-efficiently. Given information are of three kinds:

- General tips and knowledge
- Specific characteristics for this building
- Real-time feedback in the user interface.

Such factors that are related to the thermal comfort as clothing, so called climatisation[5] during longer warmer or colder periods or due to seasons will be taken into account with the information which will be given to the occupants via the user interface, as well as by education, energy saving campaigns and the EBOB toolbox.

Information and knowledge is only of real value in the process of decision making if it is Just in Time and Tailored to the demands of the end user. Most information systems fail because of the end user gets too much or irrelevant information. This means that the user has to be clear what his interest really is and for which purpose he or she needs information. In the EBOB InfoDoc, this will be solved by a users profile to be filled in before the request of information. Information about the person, interest, professional role, building phase and the organisation and the building will be required.

Such motivators can be mentioned [22] as:

- Comparisons with other's energy usage
- To see one's status compared to the average usage is useful
- To see one's status compared to one's earlier usage
- To display the usage in a graphical or in another easy-to-understand format,
- To display the energy usage in comparable terms which are easy to understand i.e. number of trees that can be saved by the energy savings etc.

Information and notes about energy usage should be short, practical but not too obvious. There also should be a link to further background information (e.g. scientific validity information). The energy related information should be shown already on the page where the users set the temperature so that it is up to the user to decide if he wants to perform the action or not (and not after doing it).

---

[5] with climatisation is meant the process while human body adapts to warmer or colder climatic condition either when moving to a warmer or colder climate or during spring and autumn

The system has to be able to give each type of user the appropriate information and steering option based on situation, role and authorisation. E.g., the office user will only see a certain portion of the information relevant to them in the "Information System" while the technician will be able to go deeper into the information, even read the manuals for the hardware etc.

3. implementation

The forgiving technology has been tested in a lab-environment at TNO in Delft in the Netherlands and in an office building of Kärnfastigheter in Helsingborg in Sweden. The rooms with and without forgiving technology are tested and compared (Figure 2). The evaluation of the tests has given feedback to the development of the prototypes of the forgiving technology.

The test results are also input to the activities of a simulation model and calculations which predict the success of the new technology under development. The calculation instrument of the energy consumption in one office building includes all kinds of influences such as sun, outdoor climate, design of the building, installations etc. The user of the instrument can define packages of all kinds of energy reduction measures.

Figure 2: The test room installations. For the end-users' convenience the control of the heating fan coils and the lighting and their different combinations are in focus in the design and testing of forgiving technology.

The classification of the problems implemented [23]:

- Catastrophic: Can lead to a situation where the user has to suspend the use of the product. The problem is catastrophic when it prevents the user from completing his task, causes distortion of information or when it is related to a crucial function. Has to be eliminated.

- Severe: Significantly disrupts the efficient use of the product or slows it down remarkably. Prevents the learning of its functions. Should be corrected.
- Major: Moderately disturbs the efficient use of the product or prevents the efficient use of a limited part of the product. Recommended to be corrected.
- Minor: Disturbs the efficient or fluent use of the product to some extent, generally however within a quite restricted situation. Worth correcting if it is not too difficult.
- Cosmetic: Doesn't directly affect the use of the product, but it might affect the user's experience about the reliability and convenience of the product.
- Technical Problem: A feature of the prototype or a programming- or functional error discovered during the usability assessment, which affects the usability of the product. Is likely to have to be corrected before the implementation of the product.
- User Expectation: User's wish for something generally to be added, but isn't really a usability problem.

In an ideal situation, the occupant's role in controlling energy use and indoor climate is overridden by the system in all aspects except for those in which they need to have the control. It is ideal because it would optimise the comfort and energy use, and at the same time the users do not have to worry about issues they do not want to be concerned with. Expert knowledge gives as an example of this the occupants disability to perceive or not wish to influence normal changes on humidity or air quality parameters as carbon dioxide levels.

However, there are some parameters or installation aspects that cannot be completely automated, parameters that the users want and need to control at least in some aspects [23]. These are:

- Indoor temperature (in a range of a few degrees),
- Lighting (can be partly automated),
- Being able to keep doors and (and in some cases) windows open and
- Shutting down the computer (can be automated in some cases).

In conclusion, these above mentioned situations are the most important cases where the incorrect uses are relevant [23]:

Misuse of temperature controls; four main reasons why the temperature is not always good enough:

- The temperature controllers are too difficult to use and understand.
- The natural feedback (the actual change in temperature) is delayed.
- People have wrong mental models about good indoor temperatures.

- The space is shared (e.g. open office space or a meeting room)
- Incorrect use of lighting, doors and windows, and the personal computer.

The common wrong mental models about the indoor temperatures and air quality are typically the following [23]:

- Most of the people seem to think that a good indoor temperature is always the same independently of other conditions (e.g. season).
- Some occupants think that comfortable indoor temperature is higher in the Winter than during the Summer (which is completely opposite of the reality).
- Many people think that a good temperature is always somewhere between 19-21 degrees of Celsius, which is often uncomfortably cool during the Summer times.
- The users want to change the temperature, or maintain it constant, it may be difficult if they have a door or a window opened.
- The outdoor air quality is also some times worse than the filtered indoor air, which is not always understood by many occupants.

The problem of shared spaces is inherently very tough issue to solve, because all individual preferences and differences cannot be matched. However, the problem is bigger, if there are temperature controllers available. This can produce constantly changing temperatures, if different occupants are often trying to change the temperature according to their own preferences. This kind of situation is uncomfortable for all occupants. It is probably recommendable that in shared spaces the temperature is automated according to the average preferences. In that case at least the majority of the occupants are not complaining. The rest of the occupants might be educated to control their thermal comfort by clothing.

Similar arguments can be found from lighting control as well as myths about computers and energy consumption 1[23]:

- One typical myth is that putting the light off and on too often consumes more energy than it saves.
- It is quite misleading to believe that shutting down the computer shortens the life span of the hard disks in general or shortens the life of the common hard disks.

The potential of computer energy saving settings depends on the computers and on the software used. The existing potentials are not often used because of a lack of time, knowledge or interest.

4. DISCUSSION

It is only recently that smart control technology for better indoor air quality took place, and now it is there for both better indoor air quality and better energy efficiency in buildings. In addition many papers claim that well being and productivity are related to indoor comfort and individual controllability if only without any exact measurements of the effect of them over productivity ([1], Farshchi and Fisher in [3], p. 60, [10], p. 264-268.).

The IBs Survey shows that the office workers (in 1994) wanted to have a building manager to help with facilities management rather than building automation systems (Table 1.).This is challenging for the R&D and testing of forgiving technology. Is current building automation technology able to please the customer needs in the office work environment?

The EBOB forgiving technology is an interactive system with several optional control possibilities, which are very different from fully automated systems dominating the end-user. Unknown in this phase of work when the last year of the three year project is left, is if the interaction between the end-user and the control technology can be used in the indoor air and lighting control satisfactory enough in the end-user point of view.

Table 1:. Man or machine the IBs Survey by VTT in 1994 [15].

Percentages of the respondents, n=514 (office workers)	**Favouring manual operation**	**Favouring automated operation**	**Both**
Text editing by secretary or text editing programs	27	71	2
Copying by a service or from personal computer	37	61	2
Information transfer in meetings or by phone, by emails and via video-conferencing	37	54	9
Image handling by draftsman or image handling programs	37	57	6
Information service by informaticians or from databases	42	51	7
Secretary answers the phone or use of answering machine	70	28	2
Education by personally attending seminars or by interactive multimedia	84	11	6
Building management by building managers or by building automation	**92**	5	3

5. Conclusions

For the time being the conclusions regarding the development and testing of the forgiving technology is based on the first version of the prototype. New software is now running in the test sites and the user feedback from the second prototype of forgiving technology is expected in summer 2004 for more evidence and indications. So far the results are very promising and the belief of the project participants is that the empowerment of the end-users with forgiving technology as developed in the project gives substantial benefits both in terms of savings of energy and more motivated and productive users.

6. ACKNOWLEDGEMENTS

Several partners contributed to this paper with material. The partners of the EBOB project are: NCC AB (Sweden, coordinator), TAC AB (Sweden), Kärnfastigheter (Sweden), VTT (Finland), RETI (Finland), Helsinki University of Technology (Finland), TNO (the Netherlands), Kropman B.V. (the Netherlands), WHC (the Netherlands), PERIGEE S.A (France), IAA (Italy).

Evaluation of proposals for PPP-projects from the perspective of the rational consumer

Wisa Majamaa,
YIT Construction Ltd
Helsinki, Finland (email: wisa.majamaa@yit.fi)

Abstract

This article analyses the evaluation process of public–private-partnership (PPP) projects from the perspective of a group of rational consumers. This is done by analysing a specific case study and examining how the evaluation process acts and how it affects the criteria, when public private provision is changed from the purchaser/provider model to the community service model so that the focus of the service is on the end-users instead of the relationship between purchaser and provider. The result of this article is the framework of the evaluation criteria of proposals for PPP projects, based on the advantage of the end-user. The proposed framework offers both the public sector in its role of purchaser and the private sector in the role of provider a new perspective for developing PPP-projects that are more valuable and innovative for both parties.

Keywords: Public Private Partnership, PPP, BOT, evaluation process, evaluation criteria, rational consumers, end-users, value for money.

1 Introduction

Viewing public services from the perspective of the end-user has received too little attention. One tool for improving this situation is the public private partnership (PPP). Traditionally, analysing the development and research work related to the mutual efforts of the private and the public sectors to provide public private service has been based on the purchaser/provider model. The purchaser/provider model is particularly evident in the building and real estate industry and research related to this field. In the purchaser/provider model, the end-users, independent consumer groups and associations have been acting in the role of “watchdog”, to protect the public’s interests [1]. Nowadays customer-orientation is widely considered to be the key to improving the quality and efficiency for ensuring and modernising the provision of welfare services. This means shifting away from the producer and administration-orientated thinking and from the purchaser/provider model towards a process of public services that is customer-orientated in their provision and organization. [2]

The aim of this article is examine how the method of evaluation works when the procedure for public private provision is changed from the purchaser/provider model to the community service model, and the focus of the service is the end-users instead of the relationship between purchaser and provider. The goal is to answer the question; what are the elements of the evaluation criteria to be considered when the PPP-model service production is assessed from the perspective of the end-user?

This article is based on a theoretical framework that reflects the end-user perspective of public services, i.e. the community of individual consumers in PPP projects. An evaluation process in action is considered with a case study of a PPP-project, where the focus of analysis is on tendering documents and evaluation criteria.

Chapters 2 and 3 are elaborated on the basis of the author's previous studies presented in, e.g., the Finnish article "Julkis-yksityinen yhteistyö rationaalisen kuluttajayhteisön näkökulmasta" [3].

2 Consumer community as a customer and end-user

The objective of a public-private-partnership is a cooperative arrangement between the public and private sectors to mutually produce services to a third party – the end-user. The public sector is responsible, amongst other obligations, for providing statutory services to the nationals of the state [4]. As the government in Finland is responsible for the entire public policy of the state, local and regional authorities (municipalities) have traditionally been considered to be in the best position to ensure that the statutory-service objectives were met at the local and regional levels of government [5]. Whether the participation of the public sector in service provision is based on law or voluntary action, the provision of services is dictated by current obligations, and benefits of the society constitute the market of public services for members of the society. Within this market, the consumer is expected to act as in the private market, where the consumer aims to fulfil his needs through consuming.

In the past, public service provision has been closely linked to decommodification [6], in other words, equal service provision for all members of the community [7]. This has led to a situation in which the consumer community was considered as a homogeneous (X=Y=Z) group of end-users whose needs have been viewed as consistent. Today's post-modern thinking, however, promotes individualism which recognizes the diverging needs of individual members of the community. As Bauman says, the changing needs and lifestyles of individual consumers affect the formation of one's identity, which is strengthened through consuming [8]. In accordance with this thinking, the community of end-users is actually a far looser heterogeneous (X≠Y≠Z) group of consumers with different needs. The purpose of the public sector is not to directly monitor psychological changes in consumers or to predict their future needs, but to meet the existing demand. It is, however, in the interests of the consumer community if the public sector takes advantage of service provision models which can, with optimal flexibility, adjust service provision to reflect the changing demand.

The following figure illustrates public private service provision in a process based on the purchaser/provider and the community service model.

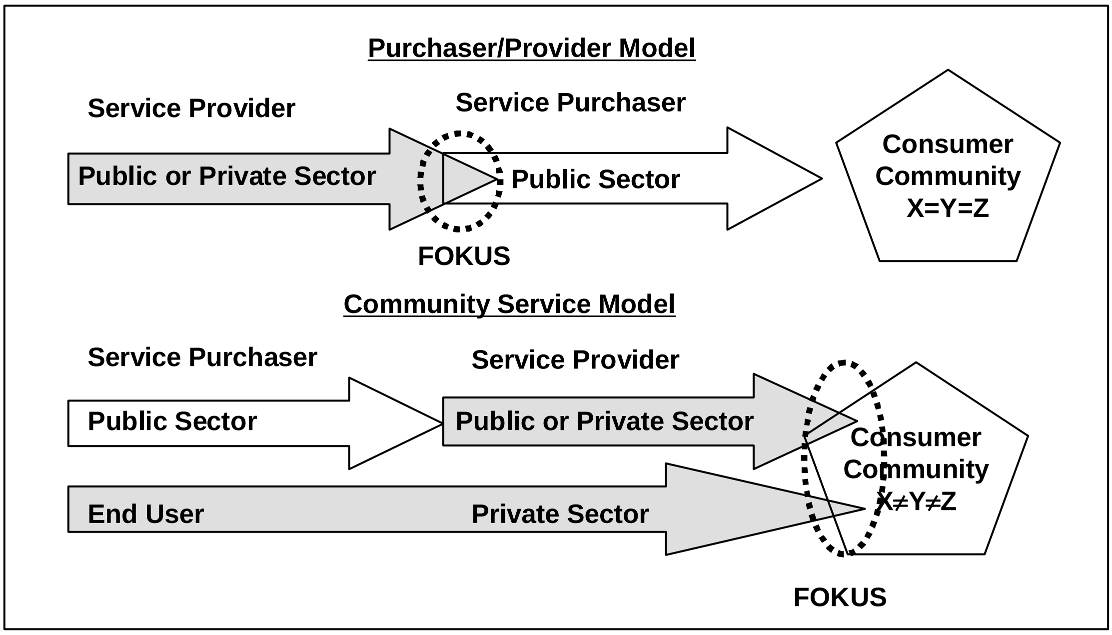

Figure 1: The community as the customer in a Public Private Partnership.

The focus of the purchaser/provider approach, previously used with relation to the PPPs, is on the interface between the provider and the purchaser. Less attention is given to the end-users, who are seen as a homogeneous community of consumers. In the purchaser/provider model, the provider can be a public sector unit or a private body. The purchaser is a public sector unit, representing the end-users. No actual customer relationship is formed between the service provider and the end-user, as the end-user cannot influence the content or scope of the service.

Service provision that utilizes the community service model is carried out through a private or a public unit or through the cooperation of the two. The purchaser of the services is the public sector or a member of the community, the end-user directly. When the purchaser is the end-user and the provider the private sector, the public sector has no role in the process. The customer, and thus the end-user of the services, is always a member of the consumer community, a resident of the local or regional authority or a national of the state. The focus of service provision is on the interface between the heterogeneous group of end-users and the service provider, where the customer relationship is also formed. In service provision models that are based on the community service approach, the possibilities of reacting to changes in the needs of consumers are better than they are in the purchaser/provider model, thanks to the direct customer relationship. Creating a true customer relationship is also an important step in shifting from the earlier provider and administration-orientated approach or the purchaser/provider model towards customer-orientated service provision.

3 Framework for Public Private Service Provision

The theoretical framework for service provision from the perspective of the consumer community is based on a process of the aforementioned community being the customer and the principle of maximising the benefit for the rational consumer community [9]. In considering the community as the customer, the focus of service provision was illustrated in terms of a public private service provision based both on the purchaser/provider model and the community service model. What is essential here is the creation of the customer relationship between the service provider and the end-user of the services, the rational consumer community, that becomes possible only within the community service model.

In addition to the basic presumptions included in the theory of consumer choice, this article presumes that a rational consumer monitors the use of tax revenue collected from the consumer. Therefore he expects efficiency and a high level of quality in the provision of services that are maintained through tax revenue. This presumption is also included in the *Value for Money* principle, which has a central role in promoting the development of public service provision through public-private-partnerships. In addition, a rational consumer is expected to prefer a wider selection of services and therefore to maximise the type and number of different alternatives available and to value the opportunity to make individual choices. The consumer's ability to make individual choices and his capability to compare and choose are also included in the basic presumptions of the theory of consumer choice [10,11,12].

In this article, the assessment of public private service provision from the perspective of a group of rational consumers is founded on the following three presumptions on the basis of which a rational consumer maximises his benefits:

1. **The Value for Money principle** both in an individual's personal decisions and his behaviour as a part of the community as well as his expectation that the representative leadership of the community also adheres to the principle.
2. **Appreciation for diversity in selection** and the resultant ability to make choices between different alternatives.
3. **Independent choices** and expectation of having the possibility to make free choices based on personal preferences.

The following figure illustrates the process of assessing public private service provision, which is based on the above presumptions and which is conducted from the perspective of the rational consumer community. It also highlights the theoretical framework that can be produced from the assessment.

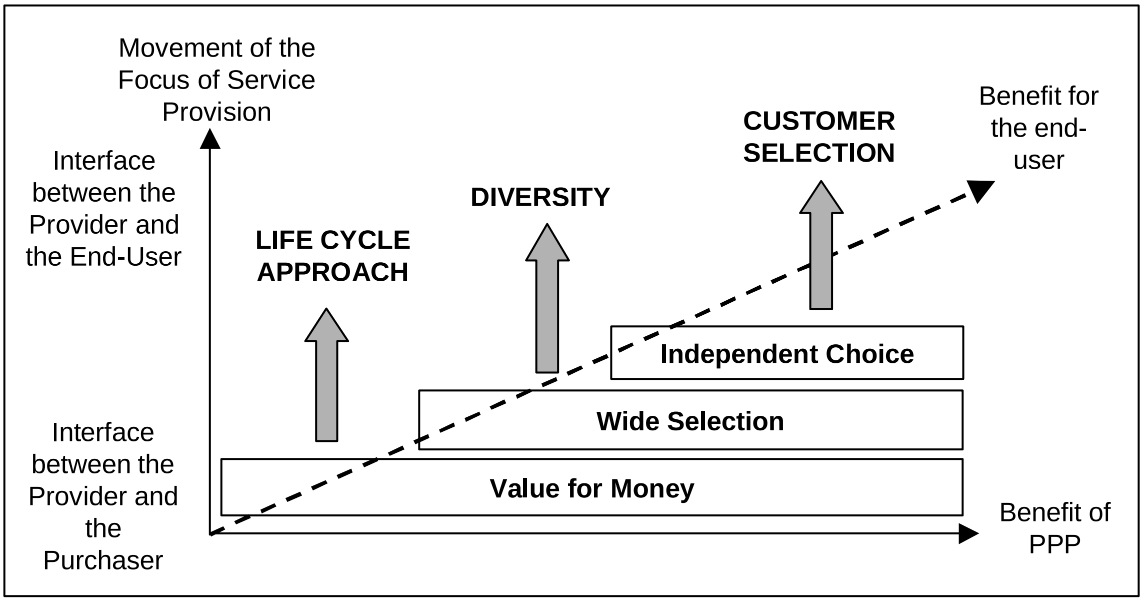

Figure 2: Benefit of public private service provision from the perspective of the rational consumer community.

The examination of public private service provision has been conducted in terms of the focus of service provision and maximisation of benefits. The vertical axis illustrates the movement of the focus of service provision from the interface between the provider and the purchaser to the interface between the provider and the rational consumer community as per the community service model. The horizontal axis illustrates the benefits of PPP in general. The dotted arrow illustrates the increase in the benefit to the end-user from public private service provision that is based on the preferences of the rational consumer community. From the perspective of the rational consumer community, the *Value for Money* principle is fulfilled through the life cycle approach. In addition, the diversity pre-requisite fulfils the wide-selection preference for the rational consumer community. Furthermore the maximisation of benefit is achieved through customer selection and, as a result, the possibility for independent choice is also fulfilled.

Examination of public private service provision from the perspective of the rational consumer community covers the structure of service provision and the scope and content of that provision. PPP, which is part of the life cycle approach, mainly concerns the investment and maintenance services that are connected to the structures of service provision and that involve its operational environment, for example. In terms of diversity, the examination focuses on the structure of service provision as well as its scope. This means an operational environment providing multiple purposes within the available resources as well as optimally diverse and versatile service provision. In terms of customer selection, the examination also involves the content of the service provision and the ability of the rational consumer to make independent choices between available forms of services. It is important to observe that from the perspective of the rational consumer community, it is irrelevant whether the service is provided by the public or the private sector or how the distribution of work is allocated between the two in relation to public private service provision. The relevant issues are the fulfilment of the life cycle approach, diversity and customer selection in public private service provision.

4 The case-study of a PPP-model for a High school and Leisure centre project

4.1 The Overview of the case

The first and only PPP-project in Finland that includes both construction and wide service supply at substance and support services is the Kaivomestari High school and Leisure centre in Espoo. The project was between BOT (build-own-transfer) and a leasing model. The private partner was responsible for the planning, construction and providing the service, exclusive of the educational element. The real estate has been funded through a leasing contract. The partners of the project company, Arandur Ltd., were NCC (the construction partner), YIT (the maintenance partner) and Sodexho (the service partner).

4.2 Evaluation criteria and evaluation process of the case

The evaluation process was based on procurement negotiations and began with a public notification on 2.6.2000 [13]. The information bulletin and pre-qualification requirements were announced in a public meeting on 15.6.2000. After the pre-qualification procedure, the call for bids for the PPP project and 25 year-concession agreement was sent in October 2000 to the three candidates (project groups lead by the construction companies YIT, Skanska and NCC). Detailed standards for technical requirements and services were articulated in the call for bids. The evaluation criteria also reflected the focus on technical and economical points [14]. The bids were then evaluated against the public comparator. The preliminary evaluation between the bids and the public comparator was conducted only from the economical perspective. As all the tendered PPP solutions were feasible against the public comparator, all three candidates were invited for negotiations in the spring of 2001. The second round of negotiations was set up only with the YIT and NCC, at which stage the candidates made their bids public. Based on the technical and economical points, the NCC group won the contract, and the school was ready to start operations in the autumn of 2003.

As this was the first PPP project of its kind, it was feasible to use a negotiating procurement procedure. In addition, all the candidates were asked to take part in a research program of possible PPP solutions in Finland which could lead this project. As was outlined in the call for bids announcement, the project also served to collect data and experience from the PPP model as an alternative to the traditional method of offering public services [15].

4.3 Case-study analyse

4.3.1 Evaluation criteria

As the article is based on a theoretical framework that reflects the end-user perspective of public services and the aim is examine the requirements of a new evaluation criterion, existing criteria should also be reviewed. This is done with a case-study, where the main criterion is the benefit to be gained with the public private service provision, as analysed from the perspective of the end user. The requirements given in the pre-qualification material and in the tendering and selection documents have been divided into three categories: Life cycle approach, Diversity and Customer selection. In each evaluation stage the given criteria are considered in greater detail.

Table 1: Evaluation of proposals from the perspective of the end-user. Criteria and weighting are based on tendering and selection documents [16,17].

CRITERIA CATEGORY	**EVALUATION STAGE**		
	Pre-qualification	**Tendering documents**	**Weighting in Selection**
Life cycle approach			
Economical factors and risk management and risk sharing	Economical requirements for tenders	Value for money principle and risk sharing mechanism from the provider's perspective	30%
Quality and technical factors related to design and construction	Technical requirements for tender	Functionality, architecture, technical usability, materials etc. from the providers perspective	40%
Quality of required services	Organisational requirements for tenders	Detailed services for the school and sport authorities from provider's perspective	10%
Project control and certainty of service performance	Organisational requirements for tenders	Detailed services during construction phase and during service –delivery time from the perspective of provider	10%
Risk sharing and economical points in concession agreement	–	Legal factors in approved concession agreement from the perspective of provider	10%
Diversity	–	Extra services identified and included in value for money principle. Economical view from the perspective of provider.	–
Customer selection	–	Private cash flow from extra services included in value for money principle. Economical view from the perspective of provider.	–

4.4 Results

4.4.1 Evaluation criteria

In the pre-qualification process the municipality of Espoo stipulated the technical and economical requirements for the tenders. At that time, the main interest was to estimate the potentiality of interested tenders on the basis of technical, economical and organisational factors. Only technical and economical requirements were made public, no evaluation criteria were given. The purpose of the pre-qualification phase was to short-list at least three, and no more than four, candidates for the ordinary tendering process.

The weighting of the evaluation criteria in selection indicated that the focus was on technical and financial points. The municipality of Espoo, as provider, tried to secure the service on behalf of its educational and sports authorities. The call for bids did not pre-exclude innovative solutions which would include some services and private cash flow. The main interest was in public services and the evaluation criteria were set up on this basis. The breakdown of the required services was specified in great detail, and the call for bids did not encourage tenders to innovate, develop extra services or to extend the service supply to end-users.

Evaluation was made from the public provider's perspective. There were no factors at all which would have necessitated a direct link between the purchaser and the end-user. All the criteria were founded on managing the interface between the purchaser and the provider. The end-users of the public services, eg., students and users of the leisure centre, were considered as a homogenous consumer group. The innovative services and diversity of the project were evaluated only on the basis of the life cycle approach and against the V*alue for money* principle.

4.4.2 Public comparator

The public sector comparative is a financial model for service delivery through the utilization of the public sector only. It provides a benchmark for evaluating the PPP alternatives [18]. In the case-study, the public comparator could not offer an all-encompassing alternative and the municipality of Espoo has difficulties in collecting the data for the comparator because all the information was not available from their own system. If the public comparator is not a noteworthy alternative, the comparison should made only for the purpose of assessing the costs of the PPP model solution against the traditional delivery of public service.

4.4.3 Evaluation group

The evaluation group was identified in the call for bids and all its eight members represented the municipality of Espoo, with representation from each of the various technical, financial, educational and legal departments [19]. The end-users had no direct representation. When the evaluation group is based only on representatives from the public sector, there is a risk that the group focuses only on the interface between purchaser and provider, and no one oversees the advantage of the end-users.

5 The evaluation of proposals from the perspective of the end-user

5.1 Framework of evaluation

Previously, the focus has been on the technical and economical values and the risk-sharing element between the purchaser and provider [20]. *Value for money* has been a primary objective in maintaining public interest and projects have been evaluated according to the cost-efficiency point of view [21,22]. These criteria have applied in PPP projects, for instance, in an evaluation method based on decision analyse, where the vital part is the regulation of evaluation: must criteria, want criteria and evaluation matrix & analysis [23,24]. As we note from the case study, the advantage of the end-user has been secondary and is evident only through the services supplied by the municipality.

When we consider that composition of the consumer group is heterogeneous, it is not important to try to make universal and unambiguous evaluation criteria for all types of PPP projects. The evaluation criteria must reflect - and be made specifically suited to - the nature of the project. It is essential that all the agreed criteria be observed from the perspective of the end-user; this can be ascertained by recognizing the advantage of the end-user as a main criterion.

Table 2: Framework of customer based evaluation criteria for PPP project and its benefits for public sector and end-user.

CRITERIA CATEGORY	BENEFITS	
	FOR PUBLIC SECTOR	FOR END USER
Criteria of Life cycle approach in substance and support services and investments and maintenances linked to them	Value for money Risk sharing and risk management	Value for money
Criteria of Diversity in substance and support services and in services directly to end-user	Increase in substance services through combining their provision or/and expanding the support services	Diversity of services
Criteria of Customer selection in substance and support service	Innovations and continuous development Confidence from security to surpass the minimum standards Value for money through private cash flow and lower yields	Possibility to make independent choices

During the first criteria, Life cycle approach, end-users expect that the PPP-model construction project or service production be evaluated as *Value for money* based in its whole life cycle. Because the end-user, through taxation, is directly or indirectly the only sponsor for public services, the *Value for money* concept is relevant for them. The *Value for money* concept has also been the primary advantage of PPP projects. The life cycle approach and *Value for money* assessment comprise two key elements [25]:

1. Monetary comparison – comparison of the cost of the proposals, expressed in term of discounted cash flows over the life of the PPP contract
2. Non-monetary comparison – comparison of all the factors that are difficult to quantify in monetary terms, but their value to government and the wider public is significant. Examples include speed of project delivery, quality of service, and security of supply.

Evaluation of bidders based only on quantitative criteria (monetary comparison) is irrelevant for large, complex projects. On the other hand, a selection process that focuses solely on qualitative (non monetary comparison) criteria may lead to subjective appreciation. It is also important that the procedure is governed by transparency of criteria. The evaluation should be based upon a combination of relevant realistic quantitative and qualitative criteria conducted through a process that is transparent and fair to all parties, including the public comparator. [26]

Diversity of services by increasing substance services through combining their provision or/and expanding the support services is the second criteria. The main idea for PPP should be how to offer more and better services for the end-user. The third criteria, customer selection, forces the purchaser to develop the concept in an open, market-based environment. From the perspective of an end-user, customer selection is the opportunity to make independent choices by selecting the desired substance service freely amongst the selection of various service providers. The end-user can make its own choice between the public, public-private and private services. This stage anticipates that there is a wide selection of service providers, and real markets can develop. In some fields where public services have been in a dominant or monopolic position, it takes time to dismantle the production structure. Free competition speeds up the innovations and depresses the price of services. Strengthening entrepreneurship and improving its conditions in these fields is closely connected to the desired development of new service structures [27]. In Finland this has been done, for example, in telecommunications and the results have been encouraging.

If the criteria in Life cycle approach category are satisfied, this can made at less cost to the public system. Diversity and customer selection can also create new innovations and services to the end-users. In an optimum case public services can become a catalyst for building new and better services to the end-users. Another noteworthy point is the possible cash flow from private use of public facilities and the rise in the utilization rate of real estate facilities. Private cash flows help to reach the financial goals of projects and to insure the quality of the service to the public provider. This also supports the first criteria by increasing the interest of investors to ask lower yields from a multipurpose property when the residual value and rental value are higher. It is also almost impossible to create a concession agreement for 25 years without gaps in service quality. If a significant part of the purchaser’s income is derived from the private sector under free competition, the facilities and service must be competitive price- and quality-wise all the time. Market-based service production needs innovations, continuous development and the confidence due to security for surpassing the established minimum standards for public service.

5.2 Public comparator

If we consider the typical tendering process in PPP projects, there are two evaluation steps. The first step occurs when the PPP-bids are evaluated against each other, and the second step is the assessment of the PPP-model bid against the public comparator. Normally this second step is conducted between the preferred PPP tender and the traditional public sector procurement at the end of the tendering process. [28]

In considering the evaluation method from the perspective of the end-user, we need to examine how the evaluation works in this new situation. When public private provision is changed from the purchaser/provider model to the community service model and the focus of the service is on the end-users instead of the relationship between provider and purchaser, we find that it is not relevant to isolate the traditional public comparator from other competitors. Traditionally the main aims of the PPPs were to explore for innovative solutions and to search for cost efficiency. From the perspective of a group of rational consumers, more aims than just the value of money are involved, such as diversity and customer selection [29]. It is not self-evident that this kind of development can only be achieved by the private sector. Public sector can also be innovative; it should strive for development and attempt to make the best proposal. From the end-users' viewpoint, it is fundamental that the public comparator be treated in a manner similar to the private comparators.

5.3 Evaluation group

In evaluation no criteria are important without the know-how on how to use them. The problem from end-users perspective is how to give 'voice' to the opinion of the consumer communities in the evaluation process. This can be done by using criteria which accommodates the consumer community, for instance, using an independent party to audit these criteria would ensure adequate representation. In its capacity as the service purchaser and decision maker, the public sector needs to give consideration to a fair representation within the evaluation group, so that it reflects the end-users as well as secures the transparency of the assessment through an open evaluation process. The process varies within projects and it depends on the public purchaser, government or municipality concerned on how consumer opinion can be taken into account. One solution is via representative democracy and another is via independent consumers or consumers groups.

6 Conclusions

This article confirms the need for an end-user perspective in the evaluation process of PPP projects. The traditional purchaser/provider service model and its attendant evaluation criteria do not acknowledge the requirements of the end-users. Concentrating only on Life cycle approach and the interface between the purchaser and provider, the case analysed indicates the lack of recognition for end-user opinion in evaluation process and criteria. In the case-study analyse, it was also noted that the main purpose of the project was to seek for a new PPP-model solution where the municipality as a provider offers a traditional service portfolio to the inhabitants of the municipality via private purchaser. The tendering process did not prepare tenders to develop innovative and customer-orientated PPP solutions.

The review of a PPP-project must be done in the interface between purchaser and consumer community where the focus is in the community service model. From the perspective of the rational consumer group, the relevant elements behind the evaluation criteria are based on life cycle approach, diversity and customer selection. Using the advantage of the end-user as a primary goal, we can create suitable framework for the evaluation criteria of PPP-projects. In criteria-setting the focus should be on questions such as how the criterion creates value for money, diversity, or makes the customer selection possible for the end user.

The used two-step evaluation process where bids are first compared among themselves and then against the public comparator is not a fair and relevant method for the end-user. In the case-study project, this was improved, as all the bids were compared to the public comparator. The problem at issue was the fact that the public comparator was not a comparable bid and the comparison was done only on an economical basis. In customer selection, the end user evaluates the service provision only on the basis of the contents of the service provision. From the perspective of the end-user, the crucial element is therefore not the service provider but rather the contents of the service concept and the relationship between its cost and quality. It is not specifically stated that the public sector cannot also assume an innovative role to develop and make the best proposal itself. If the public sector cannot offer the required service, this will become openly apparent when the public comparator in the evaluation process is given the same treatment as the private competitors.

Designing buildings for a crime prevention strategy

R. M. Barboni,
Teacher of Criminology at 'C.Bo' University of Urbino, Italy
R. Montagna,
Professor of Building Technology at Polytechnical University of Marche, Ancona, Italy

Abstract

The problem of reducing the rate of crimes in towns is therefore an emergency in a great number of countries. Criminologists debate of reducing the rate of violation in towns trough a different design of buildings and of their aggregation. This also involves a change in users' behaviour in order to reach a site control according to the theory of the "community policing".

To reach this goal a cooperation between architetcts and criminologists is strenghtly recommended. One of the trends is of reducing the rate of crime in towns through a different design of buildings and of their aggregation.

This paper aims to define how to modify traditional building components and to identify which is the level of "crime performance" to assign to different types of components and to various design solutions. A standard of "crime safety" is to be defined for each building and a scale of values is also to be defined according with the recently issued European standards "prevention of crime by urban planning and building design"

Keywords: Criminology, town design, CPTED (Crime Prevention Through Environmental Design)

1. Introduction

From the oldest times, the first purpose of urbanization is getting an higher level of living standards for the urban society. Using design to foster security has its origins in the early history of the development of communities.

Early Sumerian codes (4,000 BC.) identified the importance of respect for property rights, while the Codes of Hammurabi (2,000 BC.) introduced the responsibilities of builders to their clients. Eighth century Chinese practitioners of Feng-Shui promoted the design of harmony in space from the size of the smallest rooms to the planning of cities. Native American cliff dwellers at the same time were developing hierarchies of family and community identity and protection through the design of living space, building impregnable living areas on the face of cliffs accessible only by ladders.

European cities with historical defensive walls are a further and well known example of the historical consciousness of the problem.

Now-days, the rate of violence in towns is a relevant item of criminology in most of the industrialized countries. The problem of reducing the rate of crimes in towns is therefore an emergency in a great number of countries.

The concept of "Crime Prevention Through Environmental Design" (CPTED) has emerged world-wide as one of the most promising and currently effective approaches to reducing the opportunity for crime. Good results have been achieved in most environmental settings ranging from small stores to entire residential communities. Much is known about the relationships and causal links between street design, traffic control and behavior management. How space is designed and used directly affects profit, productivity and quality of life. CPTED concepts can be applied to an individual building as well as to an entire neighborhood.

CPTED is based on the theory that the proper design and effective use of the built environment can lead to a reduction in the fear and incidence of crime and an improvement in the quality of life.

This paper aims to define how to modify traditional building components and to identify which is the level of “crime performance” to assign to different types of components and to various design solutions. A standard of “crime safety” is to be defined for each building and a scale of values is also to be defined according with the recently issued European standards “prevention of crime by urban planning and building design”

2. Criminological tasks

One of the trends is of reducing the rate of crime in towns through a different design of buildings and of their aggregation. To reach this goal a cooperation between architetcts and criminologists is strenghtly recommended.

In the last thirty years criminologists debate of reducing the rate of violation in towns trough a different design of buildings and of their aggregation. Many criminologists believe that people who commit crimes often do so out of rational motives: that is, they want something and they consider the best/easiest way of getting it, but they will not take action unless the benefits outweigh the risks.

Under this cost/benefit model, if you make it harder or riskier for a person to commit a crime, you will reduce the amount of crime that occurs, opportunities for crime and, hopefully, crime itself.

A professional burglar, for example, will weigh the risks costs and benefits of breaking into two different houses. If one has locks and is easily visible from the street, while the other has concealing shrubbery and no defences, a widow left open, the burglar will naturally choose is likely to choose the second house. A non-professional burglar may only decide to break into a house if he or she notices an 'easy mark'. Changing the environment so that it is harder or riskier for someone to commit a crime is known as situational crime prevention. This term also includes removing the rewards for crime in order to reduce the benefit side of the cost/benefit formula.

'Situational crime prevention is directed at highly specific types of crime that involve the management, design or manipulation of the immediate environment in as systematic and permanent a way as possible so as to increase the effort and risks of crime and reduce the rewards as perceived by a wide range of offenders.'1

Some types of crime respond well to situational measures, such as graffiti, vandalism, assault, break and enter, theft, trespassing, motor vehicle theft, and computer-based fraud, etc.

Other types of crime, which are not motivated by greed but by other emotions such as hatred, fear or anger, etc., are not strongly affected by situational control's measures: domestic violence is a good example, as is serial rape, child abuse, elder abuse, and terrorism.

This program is not only a technical item, but it involves, and needs, to be effective, a change in users' behaviour in order to reach a site control according to the theory of the "community policing".

Most of people live the urban criminality emergency in an emotional way, automatically increasing the use of mechanical defence devices (such as armour-plated doors, unbreakable glasses, alarm systems etc) and accepting restrictions in their life style and in the social behaviour (less social events in the night, no use of high value wares such as jewellery, watches, nice cars etc).

---

[1] Clarke, Ronald V., ed., 'Situational Crime Prevention: Successful Case Studies' sub-committee add full reference please, p. 4.

Moreover the "fear of crime" leads to prepare self defence organizations, similar to a private police organization, that may degenerate and cause acts of intolerance or violence toward people suspected as criminal groups (such as immigrants, drug addicts, prostitutes etc..), this causing further crime acts and making hardier the already difficult cohabitation of these social and ethnic groups.

In historical times everybody was conscious of his role for the care of his house and external areas; this involved not only jobs for maintenance and ornament, but also a real engagement for a strict surveillance on the areas. The result was a signal, for ill-intentioned persons, of a site well cared, guarded, thus hardly accessible.

In the last decennia the reduced level of social relations of people living in the same neighbourhood or even in the same buildings had the consequence of less of connection with the territory. The same consequence follows from the stereotyped buildings and town design and organisation.

The actual resident behaviour is to exclude from his own care the common parts of buildings and town and to refuge himself inside his private areas.

Neglected areas thus become "no-man's lands" whose maintenance and care is committed to external agencies.

Criminologist suggest to modify this type of behaviour by means of information to the residents leading to a social conscioueness: the final result aimed is to reach a site control according to the theory of the "community policing".2

Of course the better strategies involve some differences when employed for existing or new quarters. The common method is that an everyday control must be carried out by the residents who must be encouraged to find out again this important role in the social organization.

The goal is to take again under residents' care the common areas by means of reducing the extension of each of them. It is thus necessary to increase their number and to personalize them for a reduced number of users in order to increase the attachment of each of them to that particular area.

Suggested solutions are to relocate gathering areas to locations that provide natural surveillance and access control, as opposed to locations away from the view of would-be offenders. For

---

2 R. M. Barboni "Perspectives of crime prevention involved by building design" IAHS world congress, Lubiana, 2001

example, all play areas should be located within the central common area of the building with as many units as possible able to glance or actively watch children at play.

Further suggestion is to place activities in locations where the natural surveillance of these activities will increase the perception of safety for legitimate users and risk for offenders. For example, well-used common areas (safe) may overlook a parking area (unsafe) to provide additional security for the parking area.

And again, placing activities in locations to overcome vulnerability of these activities with natural surveillance and access control of the safe area. For instance, common toilet facilities and laundry rooms should not be located in a remote corner of the site or at the end of a long nameless hallway. Locate these facilities (unsafe) adjacent to the entry or location where there is normally high foot traffic (safe). It is also advised to redesign or revamp existing spaces to increase the perception, or reality, of natural surveillance.

A result of this method is to create half-private areas where people can recognize each other and easily detect incoming persons. In the meantime a potential criminal should be discouraged by the possibility of being identified.

The “community policing” also involves the idea of greater transparency in buildings (Newmann 1972, Stollard 1991).; it means that staircases, entrance doors, common areas must be transparent, the purpose is to allow a person entering into a building to know in advance what and who he shall meet inside the building.

Transparency must, of course, coexist with high level antintrusion properties of building components (windows, doors, glasses, etc) and this involves a better knowledge of technical solutions and a new specialization of architects.

Outside areas, and especially the entrance area should be under visual control from the apartments; better if from living rooms and/or kitchens. Surveillance facility must be provided also for external areas such as parking areas, gardens, play grounds etc... The idea is to portion greater spaces into smaller easily controlled areas and clearly mark transitional zones that indicate movement from public to semiprivate to private space. For example, the sidewalk represents public space and the main path into a residential development is semiprivate, and a path that branches to an individual unit(s) becomes semiprivate and the interior of the unit becomes private space.

Three relevant case studies are described at Lawlink Crime Prevention Division of New South Wales Government, Australia (www.lawlink.nsw.gov.au)

Case study: Delta City

A quiet suburban community was being disrupted by high levels of malicious damage and house burglaries. Enforcement-style Police operations were unsuccessful. An analysis was performed of the pattern of crimes: they surrounded an old walkway, which joined a baseball field to a shopping centre. The walkway went between backyards and had poor natural surveillance with relatively easy access to private property

The walkway was closed, while pedestrian traffic was diverted to the streets. The problems stopped immediately.

Case study: Park Safety, Calgary, Canada

A park in Calgary was the site of a number of assaults and sexual attacks. The trees of the heavily wooded park had top-to-bottom foliage which reduced opportunities for natural surveillance from nearby streets. The trees were removed and replaced with high canopy trees with low level shrubbery. This not only significantly increased natural surveillance of the park from nearby streets, but also enhanced its attractiveness so that use of the park increased considerably. The number of assaults and sexual attacks decreased significantly. The cost of the project was kept to a minimum through service organisations and community groups working with the local authority to carry out the work

Case study: Kirkholt Housing Estate

A housing estate in the UK, Kirkholt had a very high rate of burglary (one in four dwellings in 1985). The local authority, Police and the residents of the estate co-operated in setting up a program to reduce burglary rates. Information was gathered from victims, neighbours and known burglars. The chance of a second burglary was four times as high as the first burglary (note that Australian statistics support this pattern).

Dwellings which had been broken into were given security upgrades by the town's Housing Department and some changes to utility connections were made (for example, removing coin-fed electricity systems). A watchful 'cocoon' of near neighbours was asked to keep an eye on the house – this program was highly publicised. The program went on to set up a school-based crime prevention program, groups for offenders from the area to address their problems, a cheap saving and loan scheme for the estate residents, experienced probation officers and an increase in resources to the local court.

Results: The program was intended to prevent re victimisation of burglary targets. It succeeded in this and in reducing burglary rates by 75% for the whole estate. There was no evidence of displacement

From a statistical point of view, it can be difficult to evaluate a multi-pronged strategy in that it may be difficult to isolate the effects of individual strategies on reducing crime. This is the case of CPTED programs where it is common to operate at different and integrated levels.

While individual strategies may have specific performance indicators, the group of strategies which are aimed at a particular crime problem should share a major indicator or Key Result Area – that of decreasing the incidence and/or effects of that particular crime.

Any agencies which contribute to these strategies, therefore, should agree to the overall indicator as a measure of success for their programs

3. Buildings typology related to crime prevention

In addition to a development of the site control, buildings with specialized characters are requested to increase the protection level.

The problem is to identify which parts of the building play a relevant role in crime prevention and to give to each part an evaluation of its level of efficiency, facing the proposed item.

A first step is to find out which is the type of crime that can be related to a specific building component, a second step is to classify the right solutions and the wrong solutions. This is a long work that requires an exam of all the types of components and of their way of realization and leads to large archives; an example is given in fig. 2 referred to the balconies.

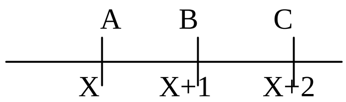
The tabulation leads to a first level of classification: the nominal scale that is based on the direct comparison of the possible solution to an assigned problem; the scale values are yes or not, this makes possible to affirm if a solution is correct or not, but does not affirm which is the value among correct (or incorrect) solutions. At this point we can say nothing between solution 4b and 2b.

A second level of classification is the ordinal scale that is based on three level comparison:3

$$\begin{array}{c} A > B \\ A = B \\ A < B \end{array} \qquad (1)$$

the (1) allows to create a sequence; so we can introduce a criterium to compare different solutions that can be better or worse than others and to find out a continuous scale where to ordinate the solutions

[3] L. Predabissi, A. Trotta, S. Soresi, "Appunti di teorie e tecniche dei test", Erip edit. Milano, 1996



(2)

and to attribute to each one a numeric value that is the measure of the difference of their efficiency. At the moment we cannot point a zero for this scale, but this is a minor problem, because we are only interested to the difference of values.

The problem is how to evaluate the efficiency of a specific solution for an assigned type of criminal attack.

	3	3	4	5
Level of potential risk ↑	2	2	3	4
	1	1	2	3
		1	2	3

Level of potential significance →

Figure B.1 – Matrix used to determine the level of protection required

Figure 1: Matrix used to determine the level of protection required.

Building Component	Type of risk	*Wrong solution*	**Right solution**
BALCONY	At a lower level the criminal enters with the help of an accomplice or any support	**1 a** 	**1 b** 	The criminal enters the balcony with the help of the waterspout	**2 a** 	**2 b** 	The criminal enters from the gallery	**3 a** 	**3 b** 	The criminal enters from the adiacent balcony	**4 a** 	**4 b** 	The balcony prevents to look at the entrance door	**5 a** 	**5 b** 
Figure 2: Example of an archive of solutions referred to a building component (balconies)

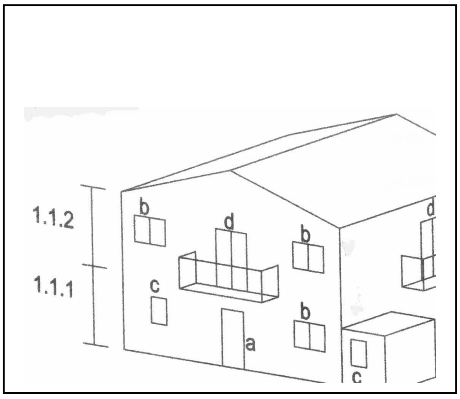
The recent european code CEN TS 14383-3 adopts the shown correlation between the risk and the protection required. The correlation is built on the basis of a model with three steps level of risk and of significance, but models with greater number of steps are allowed, and sometimes useful.

A further step of resarch is a typological analysis of buildings in order to define which component must be related to a stated level of risk. This analysis is of course depending on the type of building, its position in the town, the dimension of the town, the relation with other buildings and so on, here following an example is shown for new buildings in a middle town (80-150.000 inhabitants)

Residential housing	Group 1.1	Villas (isolated building)
	“	Serial houses
	Group 1.2	Block of flats
Commercial buildings	Group 2.1	Shops in town centre
	“	Shops in commercial centres
	Group 2.2	Larger commercial centres
	Group 2.3	Private offices
	Group 2.4	Hotels, restaurants, pubs etc.
Public buildings	Group 3.1	Hospitals
	Group 3.2	Schools
	Group 3.3	Sports centres
	Group 3.4	Theaters & cinemas
	Group 3.5	Stations, airports etc
	Group 3.6	Public & government offices

Group 1.1	1. ground floor	**a** Entrance door
		b Rooms windows
		c Bath-room & service windows
		d French windows
	Upper floors	**e** Rooms windows
		f Bath-room & service windows
		g French windows

Group 1.2	1. ground floor	**a** Entrance door
		b Rooms windows
		c Bath-room & service windows
		d French windows
	Upper floors	**e** Rooms windows
		f Bath-room & service windows
		g French windows



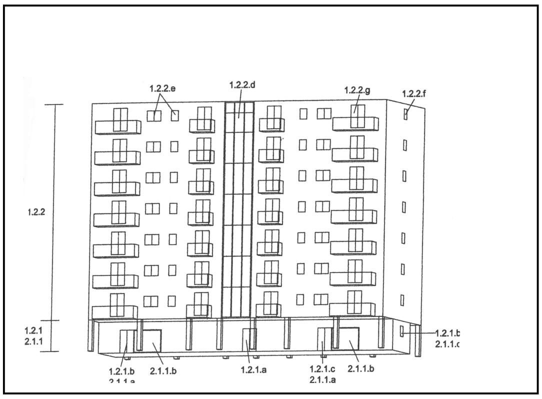


Figure 3: Typological analysis in order to assign risk and protection values to each window of a fixed building; from a research of Polytecnical University of Marche, Ancona Italy

In the example the risk level was assigned following the EU code prEN14383 which has 5 levels :

very low - low - medium - high - very high

the problem was to assign a numeric value to different components paying a role as in crime protection and to chose an algorithm that could lead to a synthetic value to be reported into the above shown risk scale

The building components that play a role come from various aspects such as the type of the area, the typology of the street, the level of the floor, and so on. As a general purpose the algorithm will be of the kind:

$$\textit{global risk level} \quad \mathbf{RL = (\Sigma\ Ri)\ \gamma\ \delta}$$

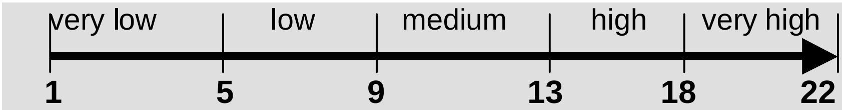
where Ri is the risk level under a specific point of view (level of floor f.i.), γ and δ are coefficients that take on count the “weight” of that point of view. The following example will make the process clear.

Tab A		
Area in the town	Suburbs	5 pt
	Semi-peripheral	3 pt
	Central	1 pt
Typology of street	One way	5 pt
	Double way secondary street	3 pt
	Double way main street	1 pt
Level of floor	Lower floor (1-2)	5 pt
	Intermediate (2 –to 6)	3 pt
	Higher (over 6)	1 pt

Figure 4 Tab A shows values of risk related to different components; tab B shows correcting coefficients related to the situation of the building.

Tab B	γ		δ
village	0,7	Well lighted area	0,5
Middle town	1	Commonly lighted	1
city	1,2	Poorly lighted area	1,3

Both tab A and B may be built up with a greater number of levels and with different values for the single items, anyway the above algorithm is valid and will show a numeric value that leads to the scale of risks provided from CEN codes. The final operation is to compare the scale of numeric values to the five steps of the CEN prEN14383; in the case of the above example this is as follows



in the case of a window at the 4th floor of a block of flats in a middle town , in a well lighted main street

$$(\Sigma \mathbf{Ri})\ \gamma\ \delta = 4{,}9$$

that means a risk level **very low**;

a window of the same building and level, but facing a one way poorly lighted street, will get

$$(\Sigma \mathbf{Ri})\ \gamma\ \delta = 10{,}8$$

that means a risk level **medium**

Once the risk level defined, the protection level required to the specific building component follows as a natural consequence (at a low risk follows low protection, at a very high risk follows a very high protection) and requirements to the component follow as well:

4. Perspectives of research

The research we are developing aims to analyse, inside a specific town, which may the correlation between crime and town design and, for an assigned building which is the level of efficiency of the building components and the adopted architectural solutions.

A first step is defining a typological organisation of the existing buildings in order to evaluate the role, and the "weight", of the typical architectural solutions.

This data organisation leads to an archive whose access is possible by building typologies (single houses, dwellings, commercial etc.) or by building components (entrances, garages, stairs

SAFETY REFERRED TO BUILDING TYPOLOGIES : **APARTMENT BUILDINGS**					
TYPE OF LAYOUT	TYPE OF FACADE	TYPE OF FLOOR	PARKING AREAS	GREEN AREAS	LIGHTING

STAIRS & LIFTS	***GARAGES***	***ESTERNAL STAIRS***	***PEDESTRIAN WAYS***
GATES	***TECHNICAL INST.***	***ENTRANCES***	**OUTSIDE FENCING**

Entrances must not create dark areas or offer the possibility to hide a criminal person.

There is a large variety of solutions in building practice: at street level, at higher level, covered by arcades, pilotis, etc.
This card shows the type and number of entrances for apartment buildings.

§ ***Linear building with single entrance***

pro: with a single entrance the criminal must cross it twice coming in and out increasing the probability of being noticed

con: with a single entrance the number of people crossing it becomes greater and the fact can induce a lower level of attention for visitors

* ***Linear building with several entrances***

pro: the increase of number of entrances helps the sense of property of each of them for the reduced number of inhabitants served thus increasing the level of surveillance

con: criminal persons have a larger choise to enter the building and of coming out from a different entrance.

Figure. 5 example of an archive of the expert system developed to analyse the influence of building components related to crime prevention

and lifts, balconies, arcades etc.) or by type of crime (burglary, violence etc.) and so on. A clever use of "links" (Fig 5) let us analyse the problem at the change of the selected item (type of aggregation, type of facade, type and level of lightning, type of pedestrian ways etc).

In this way we could build up an "expert system" where, by means of informatics, it is easy to find out the influence of the single variables.

This "expert system" needs, of course, the identification of the basic archives for each building component, in order of being sure to consider the whole range of possible solutions; an example of archive is shown in fig. 6 referred to windows in external walls

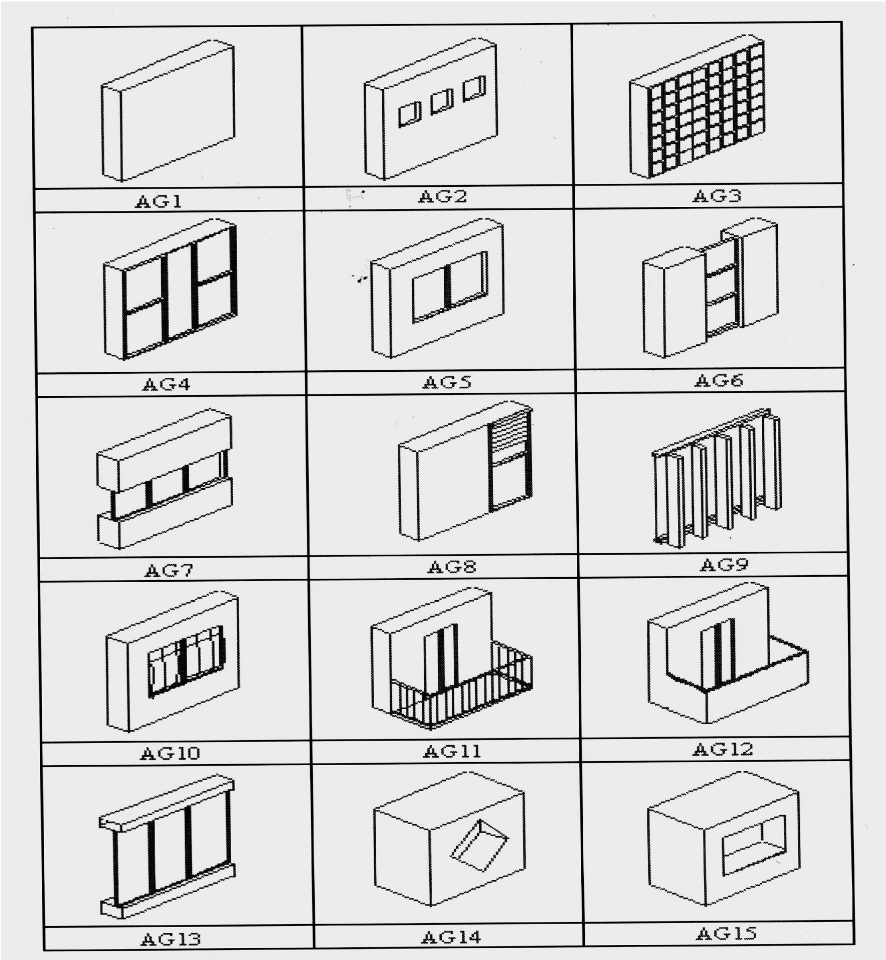

Figure 6: Shows an example of archive of typologies referred to windows in external walls, similar archives are built up for each component in order to evaluate the aptitude of the single solution to prevent crime.

5. Conclusions

It is well known to criminologists that people who commit crimes often do so on the basis of rational motives: that is, they want something and they consider the best/easiest way of getting it, but they will not take action unless the benefits outweigh the risks.

Under this cost/benefit model, if you make it harder or riskier for a person to commit a crime, you will reduce the amount of crime that occurs, opportunities for crime and, hopefully, crime itself.

A professional burglar, for example, will weigh the risks costs and benefits of breaking into two different houses. If one has locks and is easily visible from the street, while the other has concealing shrubbery and no defences, a widow left open, the burglar will naturally choose is likely to choose the second house..

Changing the environment so that it is harder or riskier for someone to commit a crime is known as situational crime prevention. This term also includes removing the rewards for crime in order to reduce the benefit side of the cost/benefit formula.

Not all types of crime are sensitive to situational measures (fraud, for instance, isn't), but the most common crimes such as vandalism, assault, break and enter, theft, trespassing, graffiti , etc. are sensitive.

The research shows how architectural design has a relevant role in situational crime prevention and that a correct design may outcome an effective crime prevention device in town design.

The basic idea of increasing residents' watch as a crime prevention method, can be realised in a plenty of different ways depending both on the ability of the architetcts, and on the level of risk for the area, but as a first step a perfect knowledge of the correlations between building components and of their weight in crime prevention is of basic importance.

The following step is assigning to each component (or architectural solution) a numeric value related to its efficiency in preventing crimes (or a specific crime). The said value can be modified (increased) in two different ways: by changing the design, or by adopting an higher level of protection for relevant parts of the component.

For instance, the use of breaking-safe glasses instead of common thermal glasses can improve housebreaking resistance without modifying the aesthetics of the building; the same level of improvement can be obtained by means of the use of metallic gratings or railings, but with a change in the exterior aspect of the building. To the architect, or to the owner, the choose, but finally based on a well know (numerically identified) level of efficiency.

Of course improvement in crime prevention is based on strict cooperation among architects, criminologists, and public institutions, but also on the evolution of the cultural an social background of residents, and, last but not least, on the budget.

Abstract

This paper discusses research at the University of Glamorgan which focuses upon personal safety on the university campus, its immediate environments and access routes. The issue of personal safety is significant because of the design and layout of many university campuses and facilities. Campuses are often large open spaces and lack systematic access control, which may lead to a higher propensity for campus users to experience victimisation and fear. In addition, previous research has shown that university students are more at risk of being victimised than the general population. The primary objectives of the research were to identify areas of the campus that posed possible threat and vulnerability to campus users and to identify solutions in the form of design and management modifications that were based on users' perceptions of their personal safety. This user-led approach produced a number of cost-effective and achievable recommendations for modifications so that all users could feel safer, as well as a generic, evidence-based model for comparable universities to emulate. The initial research determined the most common routes around campus used by three discrete user groups: staff, students and visitors. From this analysis representative routes were selected for each user group. A digital camera was used to take a number of 360° panoramas at key points along the routes which were then 'knitted together' using QuickTime software to produce a 2-dimensional virtual representation of the routes. These 'virtual reality' walk-through scenes of the routes were presented to focus groups where perceptions of personal safety were discussed. Possible solutions to personal safety concerns were considered in the form of the design and maintenance of existing facilities. Key findings from the preliminary research have identified a hierarchy of concerns and some practical recommendations that would improve campus safety. These were concerned with improving visibility, the issue of empty spaces and the need for more effective security measures. The methodology forms a cost-effective, versatile and insightful research tool that can be used to explore personal safety concerns in relation to the facilities of any organisation or environment.

Keywords: personal safety, university campuses, perceptions, virtual-reality.

1. Assessing personal safety on campuses

1.1 Introduction

This research focuses on a comprehensive exploration of how campus users perceive their personal safety on and around university campuses with particular emphasis on the physical characteristics of the campus environment. The salience of this research topic has been highlighted by a recent UK Government Home Office study that showed that a third of university students suffered some form of victimisation in the previous year [1]. Students are particularly likely to experience crime and personal safety incidents because they are young and vulnerable and because of the propensity of campuses to have specific crime and personal safety concerns linked to their design and physical layout. Sloan et al [2] observed that “campuses are typically park-like and easily accessible day and night. This openness may create high levels of fear and perceived risk of victimization among members of the campus community.” Universities can also have difficulty reconciling their traditional ‘open access’ philosophy with a safe environment and this inevitably has incidental consequences for the personal safety of campus users.

The University of Glamorgan was used as a case study for the research, and a comparative study will be undertaken at Loughborough University. The methodology used to elicit users’ perceptions on the two campuses was based on the ‘Virtual Reality (VR) Panorama Tool’. Quick Time software was used to develop a two-dimensional virtual representation of routes across campus which were presented to participants in focus groups. This perceptual approach offered profound insights into how the physical environment of the university correlated with feelings of personal safety. This instrument has been successfully used by the SLTRI in a study for a local train operating company, Valley Lines, which explored how station environments were perceived in terms of personal safety. The study by Cozens et al [3] led to a range of modifications to the design of the station environments, including transparent shelters and removal of overgrown vegetation.

The campus study has so far led to the identification of a range of cost-effective, practical and user-led solutions to promote the personal safety of campus users. Initial findings from the research are encouraging and point to the overall portrait of a relatively safe campus during the day. However, the physical environment was decoded differently at night and this had a significant impact on concerns over personal safety. Issues that users identified as influencing their personal safety included lighting levels, landscape, security equipment, the campus perimeter and the institutional open access philosophy.

2. Campus safety and the physical environment

2.1 Previous research

US research into campus crime and student victimisation spans four decades and several studies have explored the prevalence and nature of victimisation risk to students, focusing considerably on their demographic profile and characteristics of the campus environment as possible causes of increased risk. Much of this research is grounded in criminological theory, which centres on attempts to deconstruct why crime occurs and to suggest possible ways as to reduce or prevent crime from occurring. In the UK, such campus research is limited although there has recently been recognition of the salience of the topic [1, 4, 5]. Having established the particular risks to students, the UK Governmental studies have clearly triggered interest in this area. However, it remains that responses to issues of concern on UK campuses are usually reactive rather than proactive.

One of the most convincing criminological theories for explaining campus crime and risk of victimisation is the routine activities theoretical framework. This contends that three critical factors have a decisive effect on the likelihood of a crime taking place: a "motivated offender, a suitable target or victim and the absence of a capable guardian," as devised by Cohen and Felson [6]. It is suggested [7, 8] that on university campuses these critical elements are particularly significant owing to students' characteristics and the nature of the campus environment. The 'problem analysis triangle' is a useful crime reduction framework derived from this [9]. This maintains that any crime requires a victim, an offender and a location and that a crime can be averted by eliminating or adapting one of these key elements. This thesis highlights the crucial importance of location or environment in determining the probability of a crime occurring and it is this latter element that underpins this paper.

Research shows that fear of crime on university campuses can be influenced by different features of the physical environment. Nasar et al [10] argued that students felt less safe in areas with a high number of trees and dense vegetation, which provided locations for potential offenders to conceal themselves, while Robinson and Mullen [11] maintained that areas such as car parks and alleyways, specifically those which were secluded and had little 'human traffic', fostered fear. This stance is given greater credence by extensive supporting research from the criminological literature that correlates crime with the design of the physical environment. This is encapsulated neatly by Nasar et al [10] who suggest that reducing levels of fear on campus may be achieved through changes to the physical environment. An example of campus research that concentrated on ways of redesigning the physical environment was a study by Rengert et al [12]. Using high definition Geographic Information Systems (GIS) they located 'hot-spots' of victimisation on campus by analysing campus crime data and introduced appropriate situational crime prevention measures to improve safety. 'Situational crime prevention' (SCP) is a crime prevention approach that addresses specific ways of altering the physical environment to reduce the likelihood of crime. Examples include improved street lighting, increased natural surveillance by establishing, for example, Neighbourhood Watch groups and modified building design. The main criticism levied at situational crime prevention measures is that they can result in the displacement of crime from one area to another. However, there is also a considerable literature that supports the effectiveness of this approach, such as the work cited by Clarke [13].

2.2 Critique of previous campus research

The main criticism levied at the previous research into campus crime and student victimisation is that most of it uses recorded crime statistics and are underpinned by typically quantitative methodologies. This raises important questions about the accuracy of such data in reflecting reality and their validity in being the basis for underpinning crime prevention strategies and personal safety responses. Understanding crime by using recorded crime data is questionable because it has been found to systematically underestimate real levels of crime. Maguire [14] encapsulates the concern for the 'dark figure' of crime, which refers to unreported and unrecorded crime. Using official statistics as indicators of crime risk give limited indications of the social and situational context of the criminal offences, or the propensity for certain people to be more vulnerable than others [14]. It is therefore arguable whether objective approaches provide a fully representative portrait of victimisation, its causes and effects and accurate insights into possible focal points for campus improvements. For example, Rengert et al [12] sought students' perceptions of safety using quantifiable attitude responses which arguably provided an inadequate and superficial understanding of safety concerns.

In response to these concerns, this research sought to adopt a more rigorous and focused exploration of campus safety. In order to conduct more meaningful research a multi-method approach was adopted that encompassed both a perceptual approach and a statistical approach. Perceptions are arguably a more realistic portrayal of users' concerns than statistical approaches allow for and can lead to environmental improvements that more accurately reflect the needs of end-users. The importance of perceptions has been highlighted in relation to studies of crime and safety by Skogan and Maxfield [15], who found that users' perceptions are a more accurate indicator of safety concerns than simply using objective crime data. Pain [16], meanwhile, suggests that "qualitative and humanistic methods offer the most enlightening prospects of investigating the interactions between identity, social relations and place". This research sought to translate both forms of data into tangible improvements that objective indicators of risk on their own could not accurately record.

3. Defining personal safety

Having established that personal safety on University campuses is a pertinent research area, a thorough exploration of the literature was undertaken in order to gain an understanding of the concept. However, despite 'personal safety' being a term that is frequently and intuitively used in daily life, it is a widely misinterpreted term and lacks clarity. This was confirmed in a review of the literature, which revealed that no studies explicitly defined the term ‘personal safety’. Although Maurice et al [17] defined the more generic term ‘safety’, and Schroeder & Anderson, [18] Bilsky et al, [19] Burckhardt & Anderson [20] specifically used the term ‘personal safety’ in their research, none of these studies provided a lucid definition of the term ‘personal safety’. A review of the criminological literature, however, established a clear link between personal safety and crime. The notion of safety is firmly embedded in the criminology literature and there is a proliferation of the word ‘safety’, sometimes ‘personal safety’ and often ‘security’. Cozens et al [3], Lund & Hovden [21] and Barker and Page [22] all refer to personal safety as the focus of their research yet none defines what this elusive term means. Significantly, however, Austin et al [23] found in their study of neighbourhood conditions on perceptions of safety that “although fear of crime and perceptions of safety were separate concepts, they had significant theoretical and empirical commonalities”, which serves to acknowledge and document the relationship between crime and personal safety and suggests that some established theories of crime may be applicable to personal safety.

In response to the lack of definition, and prior to a campus assessment being conducted, it was necessary to produce a robust and academically useful definition of the term ‘personal safety’, as reported by Waters et al [24]. The Delphi Method was selected as the appropriate technique to attain a definition. The resulting definition of personal safety can be crystallised as relating to *intentionally motivated harm against the individual, their property or their personal effects.* Personal safety was found to be a complex composite of three causal converging determinants - physical, social and personal factors - which interact as an individual’s environment changes; personal safety is thus a transient phenomena. This framework provided further support for the commonalities between personal safety and crime; Pain [16] highlighted the tripartite relationship between individuality, social relations and the physical environment to explain what can cause fear of crime. There are thus clear parallels to be made between personal safety and the fear and risk of harm and the fear and risk of crime. Critically, this study established that personal safety is not a single dimension issue; *perceptions* of personal safety, in addition to *actual* personal safety, were both found to be crucial components of an individual’s personal safety. It was therefore imperative that the methodology for the campus research was designed so as to focus considerably on subjective perceptions because of their ability to reveal how people construct their personal safety in line with changes in the social and physical environment.

4. Methodology for the campus study

The University of Glamorgan was used as a case study for this research, with a smaller scale comparative study being undertaken at Loughborough University. The rigorous multi-method approach consists of three key components. **Questionnaires** asked for respondents overall perceptions of security on campus, whether, where and when they fear for their safety on campus and whether they have been harmed on campus. They were also asked to identify their three most common pedestrian routes across campus on a map. Analysis of these routes determined which routes would be filmed for presentation to the focus group. The **VR Panorama Tool** was used to film representative routes identified from the questionnaires. A digital camera was used to take

16 digital still images at key points (nodes) along the route. These 16 images were ‘knitted together’ using QuickTime software to produce a fluid 360° panorama, which were then ‘knitted’ to the other nodal panoramas, resulting in a 2-dimensional virtual representation of the route. This standardisation of the route ensured that participants responded and reacted to a consistent stimulus. These ‘virtual reality’ walk-through scenes of the routes were used as the stimuli in **focus groups** where perceptions of personal safety were explored. The technology allows for participants to move backwards and forwards through a route as requested, proving a more accurate representation of reality than static photographs. This approach explored how personal safety is influenced by the physical conditions on campus and identified any ‘trouble spots’ that exist. The study has so far consisted of a pilot focus group consisting of 12 undergraduate students, which explored a day-time and night-time route on and near campus and the analysis of 46 questionnaires (out of 120 distributed) with the following breakdown from each user group: 21 staff; 17 students; 8 visitors.

5. Key findings

Analysis of the questionnaire and focus group data led to the identification of key characteristics of the campus environment that influenced users’ perceptions of personal safety along with some possible situational solutions to improve personal safety on campus.

Table 1: Those campus features that invoked concern for personal safety and some suggested solutions for improving personal safety

Risk factor:	Risk caused by:	Possible safety solution:	Risk potentially reduced by:
Low lighting levels and state of darkness	Reduced visibility and reduction in social presence	More street lighting	Street lighting improves visibility and boosts confidence
Landscape concerns such as tall and dense vegetation	Opportunities for potential offenders to conceal themselves	Less dense vegetation	Providing more visibility and reducing opportunities for offenders to come on campus unnoticed
Insufficient security equipment	Lack of help response if victimised	More CCTV	Reassurance that individuals and their property are being protected and, if an individual is victimised, it will be noticed and help will arrive.
Problem of leaving campus and entering local community	Less protection when in local community	Improved lighting Security guards patrolling key routes off campus	Better visibility Security guards provide social reassurance
Open-access ethos of universities	Unable to monitor who comes on campus and enters buildings	ID cards, electronic swipe cards	More control over who uses the campus and easier to identify individuals who aren't on campus for valid reasons

6. Discussion

This discussion involves an exploration and critical evaluation of the five main risk factors relating to the physical characteristics of the campus and the effectiveness of possible situational solutions in reducing fear and increasing personal safety on campus.

Lighting levels

Personal safety concerns were considerably lower during the day, due mainly to high levels of visibility and high numbers of people to provide social reassurance. However, such perceptions changed dramatically at night as light conditions (and subsequent social conditions) changed. The state of 'darkness', it seemed, and what this signified in terms of reduced visibility and a corresponding reduction in the number of people in the vicinity as standard university hours ended, fundamentally changed the dynamics between people and their environment. The campus users generally thought the daytime route would be a lot less safe at night and the lack of illumination (natural and artificial) dramatically increased perceived risk. Some comments from the focus group included:

Participant 11: "Feel less safe at night – darker."

Participant 7: "Lighting is a big issue with making you feel safe."

In the main study questionnaires, 47% of all campus users thought that there was adequate lighting on campus. However, improved lighting was often cited in the questionnaires and focus groups as one possible way of improving personal safety on campus during the *state* of darkness. It would seem that such a security measure works by boosting self-assurance and personal safety levels by improving intervisibility of the immediate vicinity. However, it is generally accepted that improved street lighting only partially improves personal safety. This is supported in the criminological literature by Nair et al [25] who found that improved street lighting can considerably reduce fears and improve *perceived* safety, while Atkins et al [26] concluded that while this is true, the introduction of improved street lighting does not reduce actual risk (in terms of reported crime). Thus such measures to promote personal safety should ideally be implemented as part of a package of solutions.

Landscape

The other principal factor influencing personal safety was the physical environment – natural and built - of the campus. In particular, enclosed, quiet and remote spaces on campus, such as stairs enclosed by dense vegetation, the car park and the smoking shelters, which could present as hiding places for potential offenders, figured highly in respondents' fears and concerns for their personal safety. One location mentioned frequently in the questionnaires as being an unsafe place was the tunnel end of the main car park, which was decoded as being poorly lit at night, surrounded by high vegetation and enclosed on three sides. Some remarks from the focus group included:

Participant 1 "Car park is dark, bushes all around."

Participant 12 "No-one can see anything that goes on so if you are accosted or something bad happens at that point no one can see you because of the trees."

Analysis of the night-time route data showed that the physical environment was perceived to impact on senses of personal safety. A key entrance gate onto campus was perceived as dark and threatening as were back lanes adjacent to the entrance; most students in the focus group would avoid walking down these lanes at night and sometimes even during the day. These insights about the impact of the design and layout of the physical environment are echoed by Fisher and Nasar [27], who discussed how certain physical characteristics of the university campus environment, such as 'blind-spots' and places of concealment, can increase vulnerability and feelings of fear.

Security equipment

The lack of physical security equipment was a concern cited in the questionnaires and in the focus group. There was a degree of cynicism aimed at the current use of CCTV on campus, with some respondents intimating that it is useful only when it is being constantly monitored. However, 24% of users thought there was inadequate CCTV and many focus group participants cited CCTV as one possible solution to personal safety concerns on campus. The lack of security such as CCTV and lighting on the night time route, particularly off campus en route to the local train station, was a primary concern.

> *Participant 1 claimed her personal safety would be improved: "If you had CCTV there knowing that someone's sitting in an office watching the screens."*

CCTV can be effective in increasing perceptions of personal safety because it acts as a deterrent to potential offenders and it provides reassurance that such surveillance, if used appropriately, can immediately alert security personnel if threatening situations arise. This is supported by research carried out by Ditton et al [28], who found that 79% of people questioned thought that they would be less likely to become victims of crime in areas with street cameras. However, Campbell and Bryceland [4] proclaim that "CCTV alone will not reduce crime but …. if properly managed and monitored it will have a lasting effect on crime reduction and community safety." The findings suggest that inadequate lighting and CCTV both play a key role in making campus users feel less safe on the campus and contribute to the sense of a more sinister night-time environment.

Campus boundary

Routes within the campus boundary provided an almost intrinsic safety, a sense that users were better protected on university facilities than in the surrounding local environment. This was particularly an issue as users left the campus via a key entrance gate and entered the local neighbourhood. When participants left the perceived safety of the campus environment they claimed that they experienced different perceptions of personal safety as they entered the local community.

> *Participant 10 claimed that: "If you leave the campus it's a different thing all together – you are outside there and parts of that were very dimly lit and hardly any people. I wouldn't be happy or have a safe feeling at all."*

This relates in part to the issue of control. As Donnelly [29] observed, a common factor that plays a role in influencing fear of crime is the sense of control. Experiencing feelings of loss of control, for example over one's environment, can result in heightened fears and concerns. It could therefore be suggested that users feel they have more control over their environment on the university campus, thereby prompting an increased sense of personal safety on campus. A possible solution is to have security guards patrolling the key routes off campus.

Institutional open access philosophy

While the open access policy of the university can be equated to the lack of literal physical restrictions that prevent people from accessing an environment, it is the consequent impact that this has on the social presence that is perhaps most significant. The result of this is that 'anyone' can come on and off campus unchecked, regardless of whether they are there for reasons connected to university business or not. This was a concern particularly at night, when there were less people available to provide natural surveillance.

> *Participant 1 claimed that: "Anyone can get on and off the campus easily enough regardless of who you are and I wouldn't feel any safer walking around here than around Pontypridd (the local town), I don't suppose."*

However, this is a complex issue since the very ethos of an open access educational environment underpins the whole principle of a welcoming, accessible and creative learning environment which would be dramatically altered if a fortress image was adopted. However, perhaps some compromises have to be sought to try to reconcile the historical and philosophical rights of universities to retain some semblance of an open access ethos with the need to provide effective security on campus that maximises personal safety. Campbell and Bryceland [4] suggest that "the foundation on which to build a safe and secure environment is a tried and tested access control policy." The introduction of ID cards, perhaps initially limited only to certain areas of the campus, is one possible method of monitoring the rightful use of campus facilities without suppressing accessibility for valid campus users.

7. Conclusions

The study has supplied some intriguing preliminary findings that give an interesting indication of perceptions of personal safety on the University of Glamorgan campus and indicated what physical attributes of the campus need to be explored to promote personal safety for users. This provided opportunities for developing solutions that are grounded in users' every-day beliefs, actions and perceptions. The findings encouragingly suggest that the campus is a safe place during the day and there is probably only a limited number of actions that can be taken to improve it during daylight hours. Naturally occurring conditions as a direct result of the university environment such as institutional responsibility, high social presence and, of course, daylight, denote that personal safety is almost inherent to the university during the day. However, perceptions of safety noticeably decrease at night, and this is exacerbated by certain features of the physical environment. Recommendations for possible situational solutions to improve personal safety and reduce the risk of victimisation were therefore mainly in terms of tackling the negative effects of darkness and included upgraded lighting and CCTV, which would provide reassurance to some extent by improving visibility and reducing users' fears. The caveat is that although such measures are often cited as reducing fear, their actual effectiveness in terms of reducing victimisation is uncertain and should therefore form part of a package of solutions rather than stand-alone solutions. Another useful intervention would be to have an increased security presence patrolling the campus, *and* the immediate local environs, to strengthen the image and relationship of security staff with university users and to clarify security guards' roles on campus. Such situational crime prevention measures implemented to improve personal safety should not be viewed as a panacea to all personal safety concerns; rather, they should be integrated into a comprehensive package of solutions that together maximise personal safety on campus.

Beyond its utility in assessing and improving personal safety on university campuses, the methodology developed has considerable industrial relevance. It forms a versatile, insightful and transferable research tool that can be used to explore users' perceptions of personal safety in relation to the environmental facilities of any organisation or environment, including transport nodes, hospitals, schools, recreational services, hotels, banks and retail establishments. The methodology also translates into a sustainable applied research capability that is cost-effective and based on the premise that user groups can be effectively used in decision-making processes. It can also be used to explore issues such as aesthetic preferences and the architectural and design requirements of different user groups. For example, it can be used to explore the relatively unexplored issue of how the disadvantaged and minority groups perceive their environments and their specific needs and how this in turn affects how they use facilities and environmental spaces.

Developing a New Framework for Infrastructure Asset Management

Masayuki Kurihara,
National Institute for Land and Infrastructure Management, Japan
(email: kurihara@nilim.go.jp)
Kazuhiro Nishikawa,
Public Works Research Institute, Japan (email: nisi awa@pwri.go.jp)

Abstract

Maintaining the infrastructure asset is an important issue. In Japan, there is a large amount of the infrastructure stock constructed during its modernization era and they are getting older year by year. The local authorities who manage the most portion of the infrastructures do not have technical and financial background enough to perform periodic inspection and preventive maintenance of their infrastructure asset. They do not well maintain their infrastructure and are facing the crisis of losing the function of their asset. However, the existing technologies such as bridge management systems require detailed inspection data and high operation cost. So we propose a new framework of asset management which enables the authorities to conduct the asset management with limited technology and financial background. This framework allows the authorities to undertake the asset management and to realize the sustainable infrastructure services.

Keywords: Infrastructure, maintenance, management system, asset management

1. Introduction

Japan has a large amount of infrastructure stock constructed during its modernization era in 20th century. The considerable amount of structures such as bridges and tunnels were formed during 1960s and 1970s so they are getting older year by year. The most portion of the infrastructure is managed by local governments. For example, Japan has a 1,177,000km road network and the 98 percent in length is managed by prefectural and municipal governments. The budgets of them are not enough for the expenditure required for the maintenance and they are facing the shortage of the budget for the maintenance of their asset. It means that they do not well maintain their asset. Furthermore, we cannot expect that in future, the efforts to secure funding for the repair or maintenance of the road structures will be easily provided.

Table 1: Road network system and the expenditures for road maintenance in Japan

Road Type	Length (km)		Expenditures for Maintenance	Expenditure per km
National Highways (Class-A)	6,851	0.6 %	703,267	32.2
National Highways (Class-B)	21,828	1.9 %	178,153	5.6
Prefectural Roads (Regional)	32,028	2.7 %	256,564	4.5
Prefectural Roads (General)	128,409	10.9 %	213,491	3.0
Municipal Roads	982,521	83.9 %	583,297	0.6
Total	1,171,647	100 %	1,934,772	1.7

Unit: JPY Million

2. Issues of Asset Management in Japan

2.1 Overview

The stringent financial situations in recent years have forced the authorities to limit the budget for infrastructure, and it has been becoming increasingly difficult to allocate the funds as desired. In other words, as budgets has become to be allocated for specific, higher priority expenditures, it has become increasingly difficult to allocate enough funds for maintenance. Such a situation is severer especially in the local governments. According to the survey held by Japan Society of Civil Engineers (JSCE) on Japanese local governments, the issues of their asset management are summarized as follows.

(1) Issues of Asset Strategy
Only a few local governments have asset strategy. So most of them cannot create the alternatives based on life cycle cost nor environmental effects.

(2) Technical Issues
Only a few local governments perform periodic inspection of their structures and facilities. So most of them do not collect the data of the condition of their facilities including inspection results. They do not have technology for deterioration prediction and maintenance planning.

(3) Financial Issues
In Japan, the funds have been concentrated on new construction, replacement and improvement because the importance of maintenance has not been well understood. The financing system such as subsidies and bonds guaranteed by central government targeted on capital investments may distort the optimal choice of alternatives.

So the infrastructure management authorities in particular local governments need the methods and tools to establish and conduct their asset management and to realize the accountability to citizens, local assemblies and financial authorities.

2.2 Technical Issues on Asset Management

Now there are established methods for routine, standardized inspections and tools to provide the understanding of the condition of the structures and the facilities. There are also the systems for network-level management which assist maintenance and repair planning. For example, the United States has PONTIS system used by highway management authorities inside and outside the US. Japan is now developing management systems proposed by the Ministry of Land, Infrastructure and Transport (MLIT), Public Works Research Institute (PWRI), Hokkaido Civil Engineering Research Institute (CERI) and so on. However most of them are not applicable to authorities like Japanese local governments because the systems require periodical inspection data in detail and considerable operation cost. Therefore the local governments cannot undertake their asset management with the existing management tools. It is required to solve the issues to establish the asset management responding to the era of maintenance.

3. A New Framework for Infrastructure Management

3.1 Objectives

As the solution to the issues of the infrastructure management in Japan, the authorities need the methods and tools of asset management which can be applied under the condition with limited data and low operation allowance. So we propose a new framework of asset management which is applicable to authorities like Japanese local governments considering the following requirements.

The requirement for the framework are as follows:

-The management framework can be applied under situations with limited data which are inadequate for existing management systems.

-The management framework can be easily understood by executives who do not have engineering background and are not familiar with the sites of infrastructure such as citizens, local assemblies and financial authorities.

-The management framework can utilize the existing asset management technologies for maximum regarding strict financial condition.

Therefore, we reviewed the decision making process of the authorities in the management and maintenance, then designed the framework because the existing systems do not necessarily agree with the decision making process.

3.2 Concept

We can state that there are essentially two aspects in the asset management of the infrastructure. One aspect includes the inspections of individual structures, and the repair and maintenance activities. The other aspect is to formulate plans and allocate budgets for maintaining them in the most desirable way considering the overall infrastructure such as road networks and structure groups.

The former is conducted by the local field offices responsible for the operation and maintenance of structures and facilities at site and the latter is conducted by the headquarters responsible for the infrastructure as a whole. In terms of budgets and funding, the most important aspect of the former is securing the funds needed to maintain their structures and facilities in good condition. The responsibility of the latter is determining the optimal allocation of funds regarding the entire asset inventory under the charge of the authorities considering other policies such as capital investments etc.

Different information is required for each aspect of management. While the former requires detailed information of individual structures (degree of deterioration of the structures and their parts and members), the latter needs to know whether the structural conditions are improving or deteriorating as a whole, or whether there is any imbalance between districts or routes. It is not reasonable to consider the degree of deterioration of each structure for the purposes of determining nationwide budget allocation.

Therefore we propose the framework of asset management should include individual facility management and network (or a group) level management as shown in Figure 1.

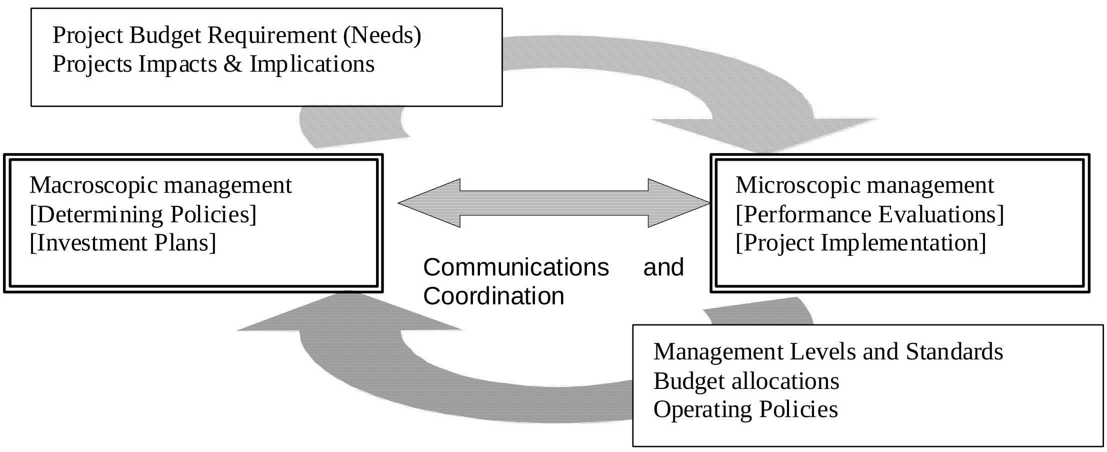

Figure 1: Structure of the new framework of the infrastructure asset management

The concept of the framework is as follows.

- -The management framework is composed of two components, individual facility management and network (or group) level management. We name them the microscopic management and the macroscopic management.
- -Both management components intend to the optimal management within their own scopes. The former is primarily responsible for operation and maintenance of individual structures at site. The latter is responsible for the management of the overall asset inventory, including total management planning and budget allocation.
- -Both management components communicate, cooperate and exchange information interactively, so they form the management cycle to realize the asset management in the most effective way.

3.2.1 Microscopic Management

The objectives of the microscopic management are providing appropriate maintenance and management to each individual structure, for proper structural functions in the face of deterioration and damage due to aging.

The microscopic management process is conducted with two types of indicators, indicator of the health and safety of each individual structure (Health Index) and indicator of the level of deterioration or damage of the parts and members (Damage Degree) of the structure applying deterioration scenarios.

(1) Health Index

The health index indicator reflects the safety of individual structures. It generally refers to how weakened structural functions may have become due to deterioration by aging or other factors. The indicator is expressed either as a percentage against a perfect score of 100 where no deterioration is noted, or five-levels definition.

The structures are composed of parts and members. Therefore, it is assumed that accumulated damage (damage degree) for each parts and members impacts the overall health index of the structure as a whole. With this assumption, for the more damage to parts and members, the lower the health index will be indicated. The health index is calculated with the following formula.

$$\text{Health Index} = (AX+BY+CZ+\ldots) / (A+B+C+\ldots)$$

Here, X, Y, Z…:numerical value of damage degree of each part or member as 'the lower degree of damage gives the higher numerical value'.

A, B, C… :weight coefficient of each parts and members

(2) Damage Degree

The damage degree is a quantitative indicator defined for each type of damage affecting parts and members of the structures. According to the severity and extent, the damage degree can be expressed in levels as shown in Table 3. The damage degree is used to ascertain the conditions of deterioration of the parts and members, and consequently, for the selection of repair works. The damage degree is also used for calculation of the health index shown above.

The damage degree as shown here is similar to the definition in the guidelines now in use for bridge inspections in MLIT but other measurement rules can be used in accordance with the inspection and deterioration evaluation standard of the authorities.

Table 3: Damage degree of individual structures (example for road bridges)

Damage Degree	Meaning of the Damage Degree	Index*
V(OK)	No problem, not shown below	100
IV	Points requiring attention, damages to similar structures, environmental factors (damage caused by salt), heavy traffic volume, aged.	80
III	Identified as Damages, subject to preventive maintenance measures.	60
II	Survey for Repairs required	40
I	Danger, urgent repair required.	20

* Numeric scale used for calculation of the health index

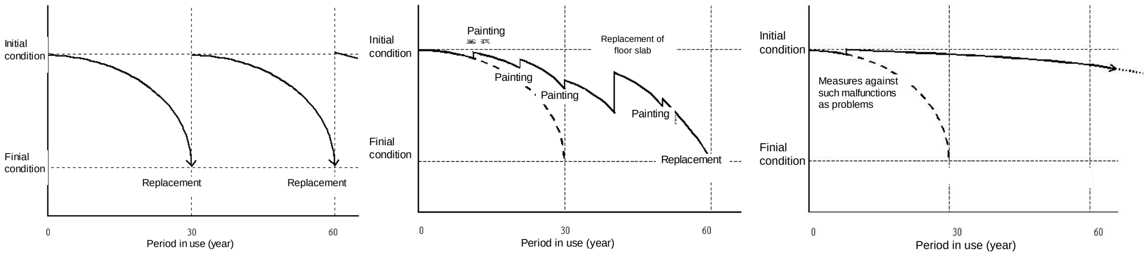
(3) Deterioration Scenarios

In managing structures, it is required to consider that the health index will change due to aging. Therefore, we have introduced the following deterioration scenarios.

It is the progress of damage to each parts and members that determines the health index. However, there is no clear understanding of the deterioration mechanism. So we assume the following three scenarios to predict deterioration patterns. These scenarios are based on expected management patterns and the period of usable life and are to be applied to each structural unit.

- Non maintenance (Disposable) scenario: a scenario to be left without maintenance and repair (30 years usable life)
- Repair when broken (Symptomatic treatment) scenario: a scenario to be repaired when damage becomes severe (60 years usable life)
- Troubleshooting scenario: a scenario in which preventive measures applied, defects completely fixed in early stages, and lifespan extended by new technology. (120 years usable life)

These scenarios enable to predict the usable life of each structure as well as estimate costs for maintenance and repair over the mid- and long-term. The scenarios introduced here are based on a survey on replacements of highway bridges held by the Public Works Research Institute and the Road Bureau of the Ministry of Construction. The survey revealed that relatively many bridges were replaced when they reached either 30 or 60 years of life. According to the more reliable data from inspections and surveys that will be accumulated in future, the scenarios will be adjusted accordingly to make the predictions more precise.



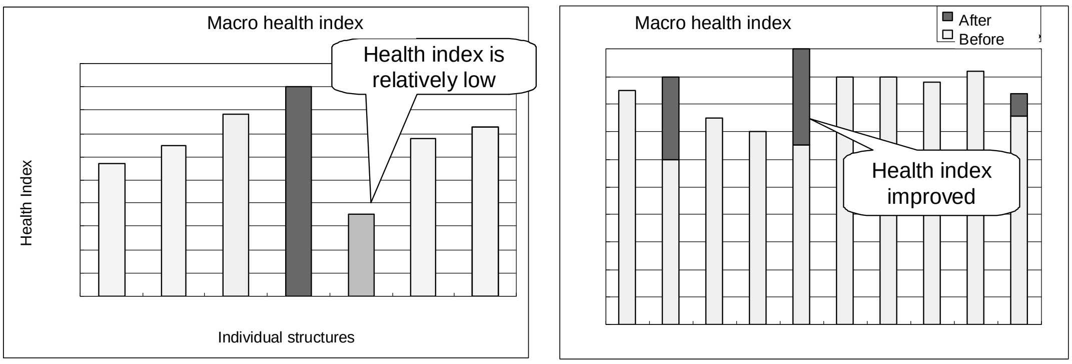
[Non-maintenance scenario] [Repair when broken scenario] [Troubleshooting scenario]

Figure 2: Deterioration scenarios applied in the asset management framework

3.2.2 Macroscopic Management

The objective of the macroscopic management is assisting the headquarters of the authorities responsible for the management of the overall asset inventory, drawing up the plans of maintenance and management, and budget appropriation.

Macroscopic management is conducted using the indicators that reflect the health of the overall asset, calculated by the health index of individual structures. In some cases, indicators express the health index of structural stock by routes or regions. The weighted average value of the

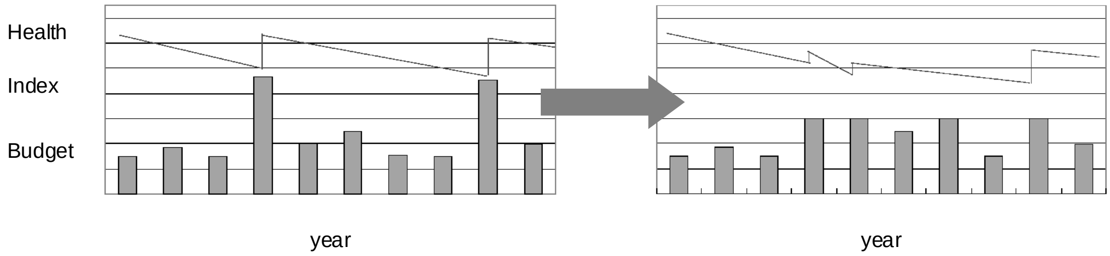


health index can be used as an indicator.

[Evaluation of structure groups] [Ex post evaluation of repair]

Figure 3: Utilisation of macro health index on the group or network management.

What is required in the macroscopic management is to set middle to long term goals based on awareness of the health index of the complete asset inventory, to enhance or maintain the health index of the overall asset, and to make decisions such as whether or not to prioritize routes and regions with lower ratings in allocating budgets.



[Sum-up of individual structures] [Equating of yearly budgets]

Figure 4: Utilisation of macro health index on yearly budget allocation

3.2.3 Communication between both Managements

The microscopic management conducts the inspection and records damage degree then makes up draft plan for maintenance and repair. It also calculates the health index. After that the budget request and data of condition including health index are transferred to the macroscopic management.

The macroscopic management evaluates priority regarding total budget allowance and asset condition shown by health index and other indicators. Then it allocates budget to the microscopic managements.

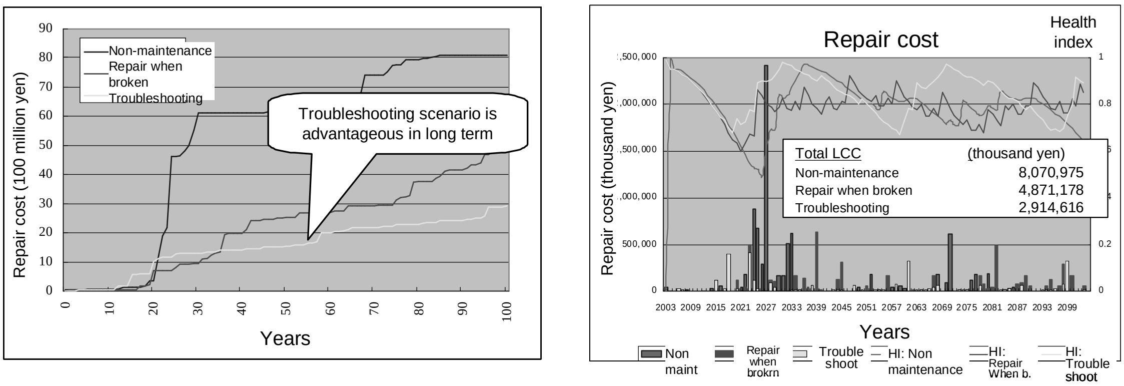
The microscopic managements revise the draft plan according to the budget allocated by the macroscopic management and carry out the maintenance and repair works. The microscopic managements conduct its activities in compliance with a set of certain rules fixed in advance. The results of the maintenance and repair are supposed to be reflected in changes in the damage degree, and further, in an improved health index. The management cycle formed by the two components works in this way.

3.3 Case Study

To show the possibility of the framework, we conducted a case study including the simulation on the data storage, the proceeding of the two management components and the data exchange between them referring the existing inspection data of national highway bridges in Hokkaido region of Japan.

3.3.1 Microscopic Management

At first we simulated the life cycle cost of individual structures applying three scenarios. In long term (over 35 years), the troubleshooting scenario becomes more advantageous than other scenarios on the life-cycle cost. As structure group, the concentration of budget requirement in several years is considerably high in two scenarios other than troubleshooting scenario. This result shows the need for the structure group management.

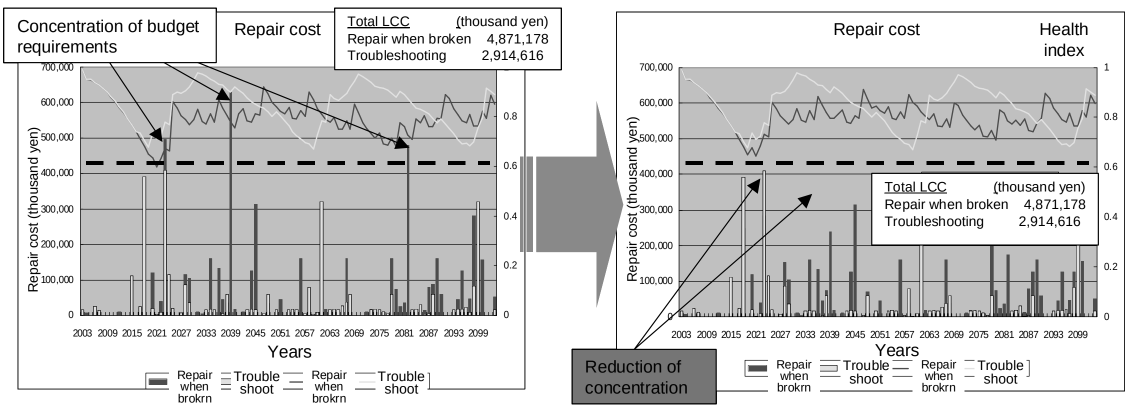


[LCC simulation of individual structure] [LCC and HI simulation of structure group]

Figure 5: Case study on the Microscopic Management

3.3.2 Macroscopic Management

We simulated the yearly budget control for the structure group by changing the scenario of individual structures which are managed according the ‘repair when broken (symptomatic treatment) scenario’ regarding the health index. The concentration of budget requirement has been reduced and the total health index has been improved after changing the scenario of several bridges. This result shows the effect of the structure group management.



[Sum-up of individual structures] [Macroscopic management applied]

Figure 6: Case study on the Macroscopic Management

4. Conclusions

Responding to the issues of the asset management of the infrastructure in Japan, we have built up a new framework of asset management composed of individual facility management and network (or group) management regarding the decision making process of the authorities in charge of infrastructure management. Then we simulated the framework with the inspection data of bridges of national highways in Japan. The simulation contains the choice of management scenarios with lifecycle cost evaluation and the optimization of long–term management including health index prediction and financial analysis.

The result of the simulation on the individual facility management showed the effectiveness of preventive maintenance and group management. These results were similar to that of simulation by existing bridge management system. So we came to the conclusion that the possibility and effectiveness of the framework have been confirmed. We will make more detailed simulations including decision of the priority between several infrastructure groups and then will make up a guideline of infrastructure asset management for the local governments of Japan.

The combined framework of the macroscopic and microscopic management introduced in this paper is based on some assumptions made for civil structures in the absence of clear information on the deterioration mechanism and it will be applicable to other infrastructure including buildings.

We expect this framework will assist the authorities in undertaking their asset management and securing the sustainable infrastructure services.

Creating a User Performance Brief: An Action Research Study

Jim Smith,
Faculty of Architecture, Building and Planning, The University of Melbourne, Australia
(e-mail: smithjj@unimelb.edu.au)

Abstract

Pre-design processes and activities are being instituted that work through client strategic and organisational issues, needs and requirements before the design team is involved. The participation of stakeholders in pre-design workshops is a common feature of these project inception approaches. These approaches prepare a clear and workable statement of the project requirements in performance terms that the client and user groups have committed themselves to. This strategic brief (or definition of the business case of the organization) can then provide a sound basis for the documentation of the needs and provide a sound basis for the development of the design. One approach to these early stages of the project is *strategic needs analysis.* This approach uses a workshop setting to focus stakeholder involvement in proposing and identifying a range of strategic options for the proposed project. An action research study of strategic needs analysis involving a new library with community facilities is presented. The process involved with the development of organizational strategic options with the stakeholders is described. The creation and identification of user performance indicators to guide the design development process is illustrated.

Keywords: briefing, strategic needs analysis, performance indicators.

1. Introduction

A number of approaches have been and are still being developed that aim to assist in creating alternative strategies during the development of policy in the early stages of project inception (Best and de Valence, 1999). These techniques aspire to develop a process that converts the organisational strategy into property investment decisions or corporate real estate that support them. Indeed, Green (1992), Latham (1994) and Egan (1998) have highlighted the need for skilled specialist practitioners to bridge the gap between corporate strategy and the development of building projects to realize their strategy.

The literature (Latham, 1994; Egan, 1998; Smith, 1998) has noted an established gap between the design process and the construction activities further down the development process or supply chain as the more recent literature terms it. However, this research focuses on the second gap between the strategic management in an organisation and the subsequent design development activities. A number of authors (Gray and Hughes, 2000 and Walker, 2002) have indicated that there is a gap between the pre-design activities and the design stages.

So, in contemporary terms the supply-chain exhibits discontinuity at two critical points: firstly, when a project passes from the strategic decision to build to the design stage and secondly, when it is translated from a design *model* into its built form at the construction stage. These gaps are illustrated in Figure 1. The emerging solutions to greater integration between design and construction are noted together with the focus of this work, the potential approaches and techniques that are being developed to close the gap between strategic management and the definition of a project for the design stages.

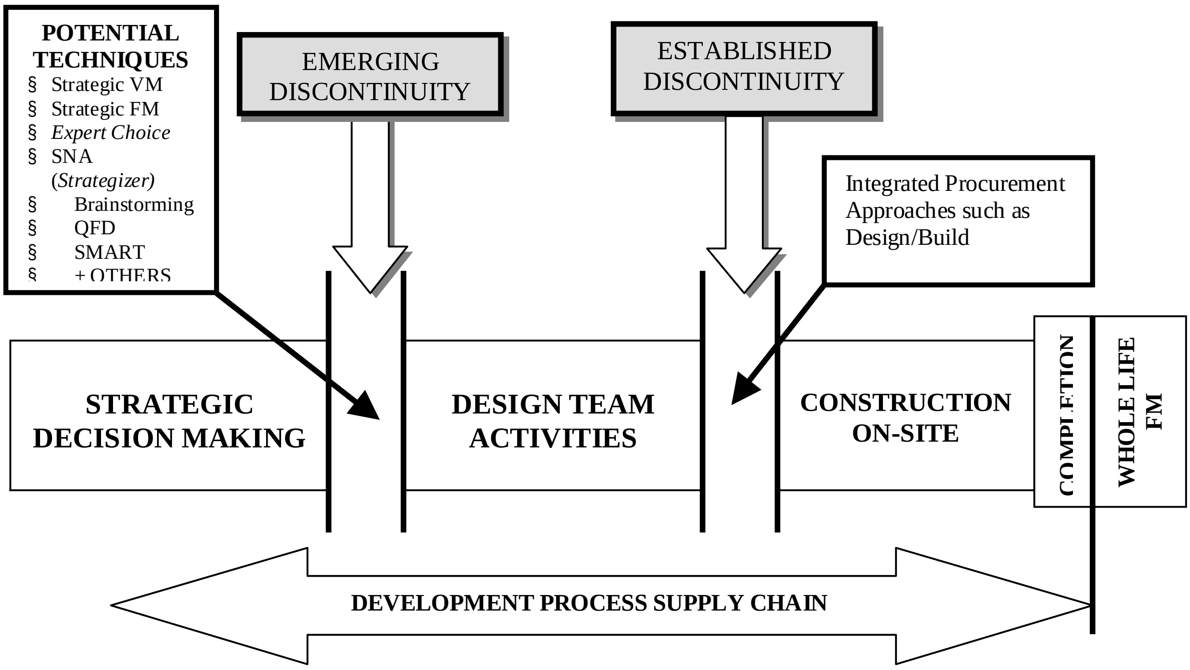

Figure 1: Discontinuity in the Development Process Supply Chain

The consequences of this first gap, between the strategic and design, after the decision to build has been taken at the strategic level, is that this decision may not be informed or supported by senior management or from a broad a range of ideas and views from stakeholders (users) as is possible. The possible insular approach adopted by the senior managers could result in an administratively easy or convenient decision that is not necessarily the best one. It seems to be more difficult for senior management when stakeholders are genuinely involved giving their ideas, views and suggestions for developing alternative strategic options. Senior management often are left with the freedom to make a decision to build, but it is likely to be a decision lacking comprehensiveness, clarity and authority. The design team naturally fills any information voids and makes its own assumptions to provide the necessary performance and user characteristics. So, when the decision passes to the design team it may result in a project decision that exists in a vacuum. It may be convenient for the design team to begin the process with a *clean sheet*, but the alternative view is that to disregard the strategic and stakeholder issues and information that contributes to the design team being poorly briefed and informed on all the factors influencing the project.

The closing of the gap or reduction in discontinuity should be achieved by adopting some of the recommended action for the strategic and stakeholder category attributes for the project inception process given in Figure 1.

A process is needed that can make a valuable contribution to the strategic stages in project inception. The process should confirm and extend the decision to build (new-build, extend, renovate, upgrade, remodel). It must reflect the environment of the organisation by being sensitive to the strategic direction identified in the strategic management process by capturing the mission, vision and values expressed by the organisation (Woodhead and Smith, 2002). These must guide the process of considering alternatives to satisfy the strategic direction already determined. The process must also be useful, flexible, well organised, sensitive to client and *stakeholder* needs and objectives and designed to provide more effective, efficient, innovative and better solutions (Karma and Anumba, 2001). Some notable attempts have been made to import existing techniques such as the *SMART* methodology (Green, 1990), *Expert Choice* or the analytical hierarchy process (Saaty, 1990a, 1990b; Yang and Lee, 1997), Quality Function Deployment (Akao, 1990; Kamara, et al, 1999), AdePT (Austin, et al, 2000) and value management (Thiry, 1997).

2. Strategic Needs Analysis

A number of approaches are listed in Figure 1 and these are expanding as new techniques are being developed. A model termed, *Strategic Needs Analysis* (SNA) was developed and adopted. SNA was designed with the characteristics noted above in mind and with the aim of making a positive contribution to the inception of a project. It also starts with the premise that the solution delivered will be the most appropriate to satisfy the stakeholder's strategic needs and this is likely to be, but may not always be assumed to be a construction project. Strategic Needs Analysis is designed to make a valuable contribution to this important formative stage of a project. It reflects and is sensitive to the strategic direction identified in the strategic management process and so overlaps it. Indeed, strategic management (Thompson and Strickland, 1995 and David, 1997) and problem solving approaches (Ackoff, 1978) have greatly influenced the development of this approach and it is designed specifically for the concept or project inception stages of a project.

The author used the SNA approach as a means of assisting in closing the gap between strategic decision-making and design team activities. However, from the author's research (Smith and Jackson, 2000, 2003 and Smith and Love, 2004) progress can only be achieved with the cooperation of the senior management that makes and implements the decision to build. A proposed solution to provide greater integration of the strategic with the project inception activities using SNA is shown in concept form in Figure 2. This Figure brings together the disparate elements of decision-making within an organisation at the various levels and attempts to integrate it into a framework that recognizes the decision to build is part of the strategic and operational (and facilities management) environment.

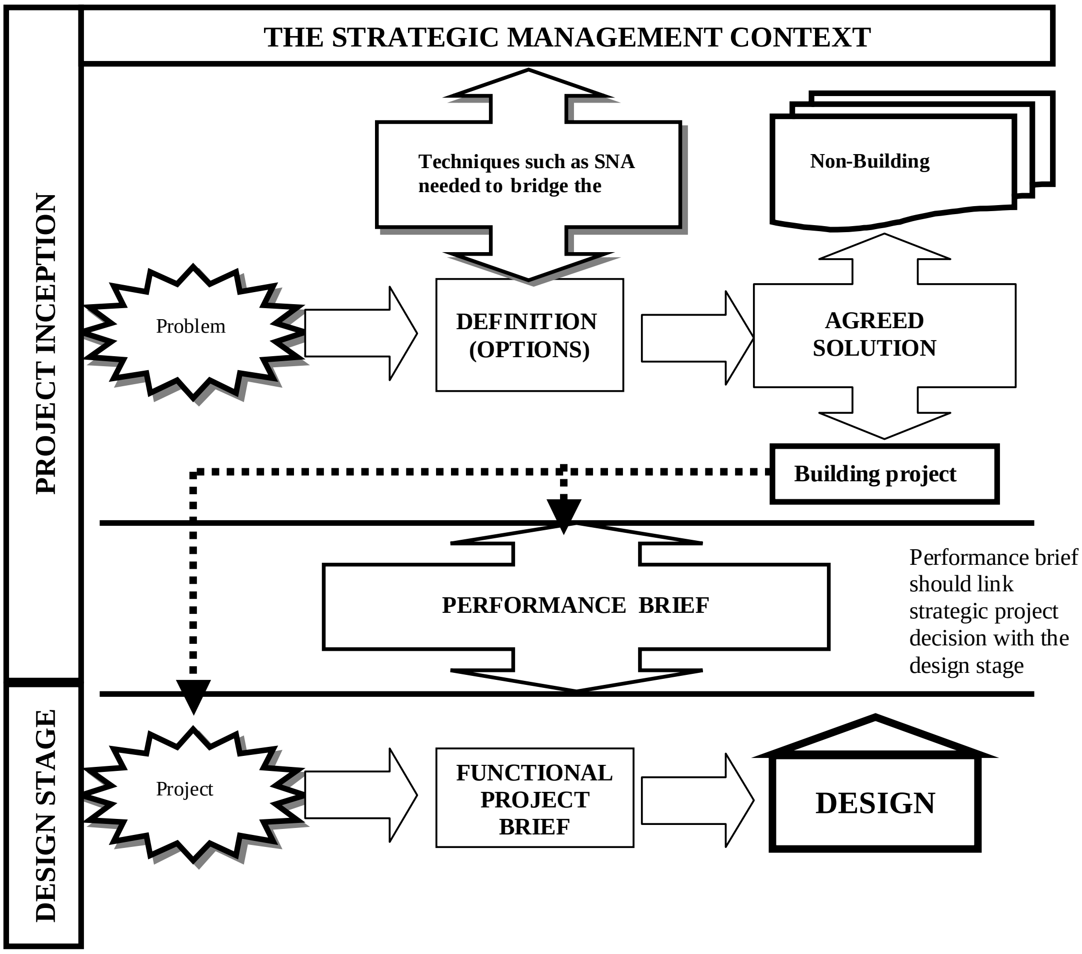

Figure 2: Linking the Strategic to Project Inception

Naturally, after its development and testing the author believes that SNA in conjunction with *Strategizer* can deliver a better way of defining client and stakeholder requirements. These can be captured in a performance brief that properly describes the client group needs and requirements in a form to give direction to the design team, but does not hinder their creativity nor their ability to explore alternative ways to satisfy the strategic performance requirements documented more explicitly by SNA.

3. The Study

This study was based on the analysis of the feedback from the evaluation surveys, the test analysis and personal observations about the process gained from five previous action research studies. (It is beyond the scope of this paper to describe action research in detail. For details of the action research approach see Barton-Cunningham, 1993 and Babbie, 1992). These earlier studies provided the means and the vehicle for the testing and development of SNA and guidance for making changes to the organisation of the SNA workshops and use of the *Strategizer* software in this study.

In this test study the author decided to test and gain assistance from an additional computer software program, *Situation Structuring*. From informal author test trials this software appeared to have the potential to assemble, or cluster, seemingly disparate characteristics and performance requirements (called elements in the software) into related groupings after interrogating participants on their views of these characteristics. The designer of *Situation Structuring* is Dickey (1995) and the software is described in Wyatt (1999). Diverse elements of a problem (people, places, objects) are combined into coherent groups. This enables these simpler and more manageable groups to be considered one at a time. By carrying out such an analysis the process provides a trade-off between simplicity and homogeneity (Dickey, 1995).

The software has been designed for generic problem-solving environments and this author believed that such a process could assist in the grouping of the range of participant identified themes from the workshop brainstorming session. These groupings would then form the basis of an agreed range of options for scoring by *Strategizer* at the end of the first workshop. *Situation Structuring* software could thereby provide the important link and technical structure to the critical process of options development and agreement.

3.1 Project Context

The Corporate Assets Manager of a local government council located in an eastern middle suburb of Melbourne (around 10 kilometres from the CBD) contacted the author. He felt that a SNA would be a useful process in identifying the nature of a proposed Library-Community complex with its potential uses involving a range of stakeholders who may be able to identify new opportunities for the new Centre at this critical stage in the planning and development stage of the project.

3.2 Aim

The aim was to develop a strategy that would take into account the needs and opportunities available from developing a site in a declining neighbourhood shopping area (known as an Urban Village). The wide ranging review required by SNA would involve a number of stakeholders from which the Corporate Assets Division (in conjunction with the author) could eventually prepare a performance brief for the agreed strategy.

3.3 Stakeholders

The Corporate Assets Manager organized the number and type of participants invited to attend the workshops. There were 15 participants in workshop one and 13 in workshop two. No external stakeholders (that is, outside Council employees or representatives) were invited or included in these activities. Four divisions within the Council were represented in each workshop; Corporate Assets, City Development, Business Development and Human Services.

4. Workshop One Summary

This workshop took place in a meeting room at the Council Offices. The process in workshop one is summarized in Figure 3. The participants were encouraged to identify the characteristics and their concerns about the project. No attempt was made at this early stage to limit the concerns. Once the full list of stakeholder concerns were identified and described they were then reviewed and discussed by the group. This produced a more refined and redefined list of concerns with fewer overlaps and repetition of the same concept. The refined list reduced the stakeholder concerns from 17 to 15 in number. These were summarised and are listed in Table1.

The fifteen refined stakeholder concerns above were measured and analysed by the group within the *Situation Structuring* software (Dickey, 1995; Wyatt, 1999). This analysis produced three groups of linked or related concerns. The features of these three common groupings were discussed and eventually placed under working titles chosen by the author to reflect their common approach or relationship. The titles, keyword descriptions and characteristics agreed by the participants under the common groupings are summarised in Table 2.

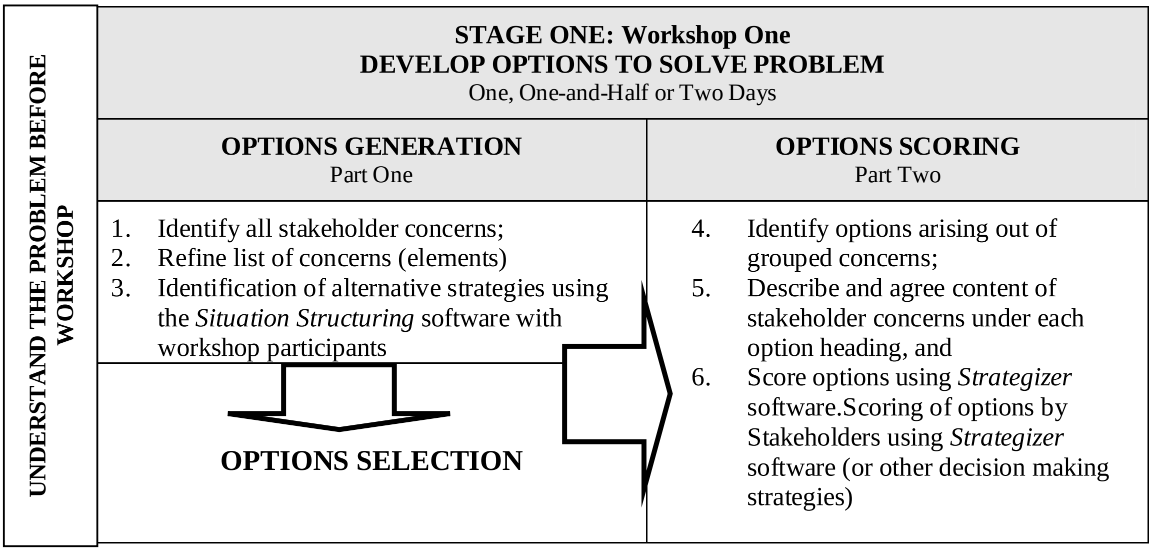

Figure 3: Workshop One Activities

Table 1: Stakeholder Concerns Defined and Refined

Identified Concerns	Refined List of Concerns
• Provide a sense of ownership	1. Interrelationships between uses
• Efficient / effective facility	2. Profile of council
• Adaptable/flexible facility	3. Service delivery
• Civic presence	4. Extent of commercial uses
• Recognition/local context	5. Commercial viability
• Satisfy community needs	6. Council viability
• Help create a sense of community	7. Sensitivity
• Enhance service delivery	8. Community ownership
• Improve/redevelop neighbourhood appearance	9. Accessibility
• Enhance economic viability of village	10. Flexibility
• Improve access	11. Effectiveness of individual service
• Distinctive sustainable environment	12. Sustainability
• Emphasis on people	13. Environmental efficiency
• Expand space for uses	14. Security
• Replace under performing/obsolete facilities	15. Diversity
• Reflect diversity of community	
• Change/grow to reflect community	

The participants concentrated on each stakeholder concern in turn. Details of the content of each concern was discussed, agreed and documented during the workshop using an electronic whiteboard. The finally agreed content of each concern is given under the appropriate option heading in Table 4. The three options (Workable, Council Perspectives and Community Satisfaction) group the stakeholder concerns as noted by the group and listed above in Table 4 were agreed by the participants.

Table 2: Details of Options

OPTION 1 **Workable**	**OPTION 2** **Council perspectives**	**OPTION 3** **Community satisfaction**
Efficient, Effective, Pragmatic	*Building Statement, Civic Presence, Best Practice*	*Integration, Belonging*
• Service delivery	• Profile	• Sensitivity
• Flexibility	• Extent of commercial uses	• Community ownership
• Sustainability	• Council viability	• Accessibility
• Security	• Environmental efficiency	• Diversity
• Interrelationship between uses	• Commercial viability	• Interrelationship between uses
• Effectiveness of individual service		

The participants also believed that in the first section, *Workable*, under the category of *service delivery* there should be further elaboration of uses into of existing uses and of potential uses that should be considered in the development of the new facilities. These were developed, agreed and are shown in Table 3.

Table 3: Service Delivery: Identification of Existing and Potential Uses

EXISTING	**POTENTIAL**	
§ library	§ service centre	§ immunisation
§ youth services	§ business/commercial use	§ information on council
§ playgroup	§ meeting space	§ library administration
§ three-year old activity	§ maternal and child health (outreach)	§ toy library
§ neighbourhood program	§ education training rooms	§ display area
§ senior citizens	§ business *incubator*	§ council adult learning centre
§ open space	§ library program and events	§ coffee shop
	§ residential accommodation	§ internet café
	§ visiting services	§ post office

The Workshop also discussed the inclusion of a number of *wildcard* options to test the demand for a non-conventional approach. A *Do-Nothing* option was rejected because it was agreed that from the ideas and commitment of the group that such an option would serve no useful purpose in the analysis in this situation. The four wild-card options suggested were; Outdoor performance space, Leisure Activities centre, High Rise Approach (with potential for more high density residential apartments) and Transportation Hub (linked with buses and railway station).

After a brief discussion it was decided that the final two options only (High Rise and Transportation Hub) would be included in the final list of options. The *Outdoor performing Space* was deleted by the participants as it was felt not to be a comparable option to the others. All the five options noted include the provision of the library, but with distinctive emphases in the joint development. The final list of options scored by all workshop participants in the *Strategizer* software at the end of the workshop were; WORKABLE, COUNCIL PERSPECTIVES, COMMUNITY SATISFACTION, HIGH RISE and TRANSPORTATION HUB.

Participants then scored each of the five options privately and individually on the *Strategizer* software. The scoring process brought workshop one to an end.

5. Workshop Two Summary

After a short break of five days workshop two was convened to finalise the SNA process. The steps required to complete the SNA in workshop two and to complete the performance brief are summarised in Figure 4. A major activity was to decide on a preferred strategy after the results of the scoring of the options was presented by the workshop facilitator (the author).

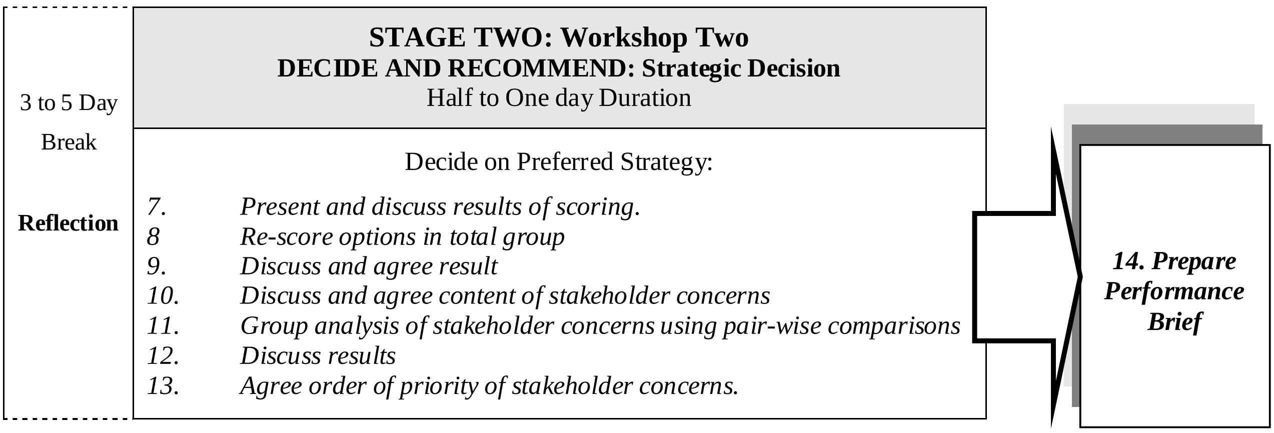

Figure 4: Workshop Two Activities

4.1 Options Scoring

When the Options' scores of all participants were analysed they showed the following results for the five options. See Table 4 for details of the scoring for each option.

Table 4: Options' Scores: All Participants

OPTIONS	WORKABLE	CIVIC	COMMUNITY	HIGH RISE	TRANSPORT HUB
AGGREGATE	3.8	3.5	3.8	-2.5	-1.6

A review of Table 4 indicates that the late entrant options, "High Rise' and 'Transport hub' did not fare well in the scoring. They have high negative scores and compared to the other three options (with positive scores) and so were not considered as serious options in the final analysis.

The participants in the workshop decided that the results were not conclusive enough to favour any single option. All three options were so close it was agreed that the characteristics or concerns from each option should be blended into the final performance brief for the project. The selection of a single option from the ones developed was, therefore, not considered. The workshop agreed to concentrate on first of all, refining the stakeholder concerns developed in workshop one.

The workshop group reviewed the list of fifteen stakeholder concerns and decided to prioritise these to provide the design team with guidance about their strength of feeling towards each one. The group then made a paired comparison of each concern scoring one concern against the others in turn on a ten-point scale running from, *overwhelmingly more* (9) to *overwhelmingly less* (0).

The workshop group then discussed and reviewed the final analysis based on the pair-wise comparison and agreed that it fairly represented the group's order of priorities in their stakeholder concerns. The group then agreed that the listing of stakeholder concerns provided a sound basis for developing the *Performance Criteria* for the proposed project. Rather than give each of the criteria a single priority it was decided to group the criteria into three levels of priority. These are given in Table 6 below with the individual criteria listed against each level.

Table 6: Priority Levels and Performance Criteria

PRIORITY	CRITERIA
1. Key Performance Criteria: PRIORITY ONE	Service Delivery Accessibility Security Council Viability Effectiveness of Individual Service
2. Essential Performance Criteria: PRIORITY TWO	Interrelationship between Uses Flexibility Community Ownership Sensitivity of Urban Design
3. Significant Performance Criteria: PRIORITY THREE	Diversity Sustainability Environmental Efficiency Commercial Viability Profile of Building Extent of Commercial Uses

6. Outcome

A Performance Brief was prepared based on these criteria. The brief was prepared within one week of the completion of the workshops and sent to the client for any additional Council and service department detail to be provided by the participants. The detail on each criterion provided by participants in the workshop provided the basis for the detail included in this performance brief.

The library project reached a hiatus soon after completion of the SNA. The draft performance brief was reviewed by the Corporate Assets Division and few minor changes and additions were made. This brief was then approved by Council a few months later and the agreed performance brief then formed the basis of calling tenders for design consultants. Consultant architects were appointed and outline proposal drawings for the scheme were completed in October 2002. Final documentation of the project was completed in September 2003 after more consultations with the community and delays in the compulsory acquisition of adjoining properties. The tenders were called in early 2004 and construction work started in June 2004. The project is expected to be completed in mid-2005. The activities and interactions following the completion of the performance brief were monitored and analysed by Heywood. A summary of the total process (now identified as the *Glen Eira model)* is given in a companion paper by Heywood and Smith (2004).

Abstract

The Facilities Management (FM) literature has identified that bridging the gap between expectations and delivery of service (performance) is crucial in successful Facilities Management that meets client needs. This gap between expectations and evaluations of service delivery contains an implicit assumption that both sides of the gap are objective and measurable. However, assessments of service delivery and the facilities themselves are not wholly objective. Assessments contain substantial subjective components, which are frequently labelled ‘perceptions’. The existence of subjectivity makes bridging the gap difficult for FM practitioners when relying solely on objective measures.

New facilities frequently catalyse expectations and perceptions. The research examines the pre-construction phase of the provision of a new local government library-community centre facility in Victoria, Australia. This paper aims to identify the psychological basis of subjective assessments that Facility Managers meet in their practice, and thereby provide a more comprehensive understanding of the basis of performance evaluations in Facilities Management.

The research used a case study based qualitative methodology. Within the methodology a psychologically classified lexicon was used to analyse the case’s data. A variety of data sources was used, including project documents and interview transcripts. This paper concentrates on data pertaining to briefing related activities.

The study’s findings furnish detailed evidence of the affectively based subjective components that exist in assessments of this facility; be that expectations of the facility or evaluations of how it will perform through meeting the brief. These results do show the subjective basis of expectations and evaluations of facilities, and in doing so, provides the comprehensiveness of understanding sought.

While specific to local government, the study is of interest to Facilities Management practice generally where meeting user expectations are key parts of assessing the performance of facilities and their management processes. In addition, the analytic framework used in this study provides a means for analysis to reveal the foundational basis of assessments of facility performance, thereby enabling a bridging of the gap between expectations and subjective evaluations of performance.

Keywords: Expectations; local government; perceptions; performance; psychology,

1. Introduction and positioning the problem

The following statements are probably familiar to many facility, or corporate property managers.

> 'It doesn't matter what facts you give them, the decision-makers decide using their own perceptions with who knows what criteria. The same could be said of our facility users.'
>
> 'In local government perceptions are everything.'[1]

These comments describe informal, subjective evaluations which, from a facility manager's perspective, often usurp their arguments for any given facility management decision. As such, they starkly illustrate the difficulty of bridging the gap between expectations and such evaluations of performance from facilities and their management. The Facilities Management (FM) literature has identified that bridging the gap between expectation and delivery of service is crucial in establishing successful FM that meets client needs and notes the importance of communication in that process [1] but contains an unstated assumption that achieving the service will satisfy. Delivery may constitute either FM service or the facility itself. This paper discusses the delivery, or provision, of a facility but could equally apply to other aspects. Little FM literature has been identified addressing differences in expectations. Hinks and McNay [2] is a notable exception. Means by which expectations are utilised in bridging the expectation-perception gap has been found in other service-based fields, for example Sawin [3].

It is an assumption that that both sides of the expectation-service delivery gap are objective and measurable. The use of management tools such as goals, aims, Key Performance Indicators, and even strategic management are indicative of attempts to objectify business outcomes [4]. FM research and practice has expended much effort in attempting to derive measures of facility and FM performance (Amaratunga [5] is fairly comprehensive as is Hinks and McNay [2]). However, definitiveness remains elusive, especially in light of observations regarding the number of new FM services introduced in a recent year, which is probably not atypical of other years [6].

Expectations and evaluations of performance are rarely wholly objective, as evidenced by the introductory comments, being, at times, quasi-subjective. In such circumstances, reliance on objective measures as proof of performance will invariably fail to completely satisfy evaluators of performance conducting formal or informal evaluations. Furthermore, objective measures of performance count for little if they are evaluated through subjective lenses. In addition, expectations and evaluations of performance exist, not so much as opposite ends of a process but with experience from previous evaluations contributing to expectations carried into future evaluations. To complicate it further the literature shows that professional and lay evaluations differ markedly [7, 8].

---

[1] These paraphrase comments made by this research's local government industry partner and are probably not peculiar to local government.

Previous research by the authors has shown the *affective* (emotional) basis to such heated facility evaluations as the 'Not in my Back Yard' (NIMBY) phenomenon [9]. For professionals, these are difficult responses to facility matters and often labelled 'irrational', or 'subjective' [10], or may be thought of as 'too hard', variable and unreliable for use [11]. In FM's case the basis of this thinking may be attributed to the operational and technical origins of the profession [12]; the technical-rational bases of many professions [13]; and the reliance on often financial measures in order to appear business-like [14]. The foundation of such categorisation as irrationality is undermined by Nussbaum [15] suggesting that *affective* (she uses emotional) responses are reasonable, direct indicators of, or responses to, threats to human well-being, or flourishing. For providers of facilities to support well-being, such as local government [16], such responses should be of interest.

The subjectivity of both expectations and evaluations of performance (perceptions) is due to their involving psychologically formed attitudes and beliefs, in addition to the role of psychological functions in processing environmental stimuli. Environmental psychology has worked extensively on evaluations of physical environments, but considerations of environmental management (such as Facilities Management) are largely contained to such issues of 'green' or recycling behaviour. A tripartite basis of psychological functions is well established in social psychology [17]. The three functions are – *Cognition*, *Affect* (or emotion) and *Behaviou*r (or conation). These same three functions have also been shown to be constitutive of attitudes and beliefs [18].

Furthermore, psychological processes do not operate autonomously but intervene on each other. For instance, mere exposure to something has been shown to induce *affective* responses (liking) which alters *cognitive* evaluations [19]. Also, *behaviour* based psychological therapies operate on the basis of changes to *behaviour* induce corresponding changes to attitudes and cognitive processes, for example [20]. In addition, the psychological functions show longer-term frames of mind, or more transient states and state-like conditions [21, 22].

2. Aim

New facilities frequently catalyse expectations and provide evaluative situations. This paper examines the psychological basis of subjective assessments within the provision of a new local government library facility in Victoria, Australia. The paper aims to show how *affect* is present on both sides of the expectation-evaluation gap providing an understanding of the foundational basis of performance assessment in Facilities Management.

3. Method

The study's methodology is a psychological based orientational qualitative enquiry [23]. Case study is the principle research method as this is most suitable for context embedded research such as this [24]. The case is from an inner to middle suburban Melbourne municipality, and is a current construction project. Within the case study a variety of data gathering methods are used – documentary analysis of Council's public statements and Council management documents; interactions with the research industry partner; participant observation in consultation meetings; time as a municipal resident; and interviews with Council service delivery and project management staff (including the external design team).

Coding methods are used to analyse the resulting textual data [25] with QSR's qualitative software *nVivo* used to assist coding activities. An *Affective Lexicon* [21, 22], based on the psychological typological classification in Figure 1, below, was used the basis of coding the *affective* content of language data (text). The *Lexicon* was formed from words the literature considered to be emotions. Text was analysed on the basis that the text acts as a record of emotion, in the absence of emotion's visual, neurological, or olfactory detection. The lexical structure includes categories for *affective evaluations*, the psychological functions (conditions) as *frames-of-mind* (longer-term dispositions), *states* (brief, temporally bounded), and *state-like* (similar to but not explicitly states) conditions. Inter-linked conditions, such as *affective-cognitive conditions*, are also provided.

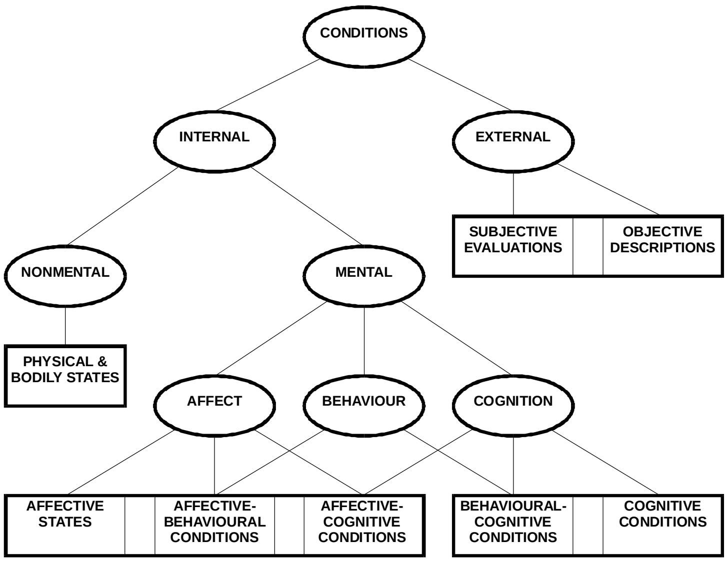

Figure 1: Psychological typological classification (after [21])

Additional categories such as *non-affective evaluations*, *Other cognitive*, and *Other behaviour*, have been added during the course of this research as they are absent from, but are consistent with the lexical structure. In the text below, words from the *Lexicon* are **bolded** while the typological classification is shown in *italics*.

Results for all three stages are tabulated together in *Appendix 1* but they are referred to throughout the paper.

4. Empirical study

The case studied is a new municipal Library-Community Centre to be constructed within a municipal 'Urban Village'. The client, as represented in the facility management function, may be considered a 'Secondary constructor' of a moderately 'Experienced' type (Walker [11] citing Masterman and Gameson [26]).[2]

The facility has, at least, two user-client types with Council service departments (primarily, library and local child services) consisting one, and community groups relocating into it, the second. As the introductory comments indicate the municipal Property Management was aware from previous experience that 'perceptual issues' exist in providing this facility. To address and manage the perceptual issues a two-stage facility provision process was adopted.[3&4]

Construction is not complete at the time of writing, therefore this paper only reports pre-construction processes contained within Briefing activities. These consist of three stages – the project's *Performance Brief*, the developing of that *Brief* with additional information from brief-building consultations with project stakeholders, and thirdly, reporting to stakeholders of how the building design met the brief from both Stages 1 and 2. The three stages capture expectations in the first two stages and, in the third, an evaluation of how they have been addressed. Incidentally, the third stage, also, contributes to the sum total of expectations that will be met in the post-completion evaluations, be they formal Post-Occupancy Evaluations or the 'informal' human assessments that are of interest to this research. Post-completion evaluations are beyond the scope of this paper.

4.1 Stage 1 – Council officer (client) expectations & developing the brief

In the first briefing stage the facility proposal was studied using pre-briefing Strategic Needs Analysis (SNA) methods [27]. Workshops with participants from stakeholder groups within Council administration responsible for possible tenants, or Council's strategic interest groups (such as municipal Business Development) lead to the development of three options with clustered strategic priorities – Option 1: Workable; Option 2: Council Perspectives; and Option 3: Community

---

[2] This classification system [26] is useful in understanding this municipality & local government generally. Local government falls towards the extremity of being 'Secondary constructors' (with this classification becoming known as Corporate Real Estate in recent years) but the level of the experience may vary and will frequently be linked to the level of experience of individual managers – both asset and service delivery. An issue for local government, and the factor that moves it away from the 'Experienced' end of the spectrum, is that individuals in local government Corporate Real Estate management may be experienced constructors but with limited experience of each type of local government facility, as each is built infrequently. It is feasible that local government 'Constructors' may then over-estimate their experience and assume that they do not need to acquire the experience by type also. This was not the case for the project studied.

[3] Linder and Peters [30] state the selection of such instruments may be traced to the perceptions of individuals in a position to choose about instrumental performance, regardless of its empirical record (similarly to previous discussion).

[4] It must be noted that this process was preceded by previous Urban Village consultations at two levels – overall concept and land use planning changes, so awareness of the facility proposal was at large in the municipality.

Satisfaction [27, 28]. These were then developed into a Performance Brief [29] subsequently adopted by the municipality in briefing the architectural design team for the new facility.

The Council officers, in providing a *Performance Brief* containing these strategic priorities options,' are providing both the performance parameters against which the facility may be assessed, or tested, and documenting their expectations of what the facility will provide for their municipality by way of function and as the embodiment of values. Analysis of these priorities using the *Affective Lexicon* reveals the psychological content of those expectations. Approximately 30% of the terms have *affective* content (Table 2, Appendix 1) Very few terms are psychologically based (Table 4, Appendix 1) but three-quarters of the *affective* terms are *affective objective descriptions* (Table 5, Appendix 1). These are statements that are resolvable by reference to facts [21].

Some of the priority expressions have complex content and have multiple connections with the classification categories. Typical of this is **Security**, which has two *affective* senses. In the first instance, **Security** relates to the sense of keeping something **safe** or providing safety. '**Safe**/safety' is an *affective objective description*. For a facility, the facts of safety may be tested or ascertained with questions such as:

- Does it have doors? Are they lockable? Where are the locked doors located relative to entrances?

These are all questions are all answerable in a factual form.

In the second sense, **Secure** is an *affective-cognitive state-like* phenomenon being an *internal mental (psychological) condition*. It is *affective* in that it has immediacy and value. It is *cognition*, being a way of thinking and the two conjoin in an 'emotionally toned way of thinking' [31]. The sense here for facilities relates to the psychological sense of **security** engendered by the environment, similar to the notion of *Defensible Space* [32].

4.2 Stage 2 – Developing the brief

The second Briefing stage added further input from Council internal stakeholders and groups outside Council – user tenant groups, adjoining residents, and shop-traders. Records of expectations and evaluations in this second stage are harder to find. Memos that record the results of consultation with non-Council stakeholders, by and large, appear to record factual material useful for establishing physical parameters for design. An impression aided in its formation by their introductory paragraphs that states, in part:

'The discussions were directed to focus on the layout and design issues of the facility .This memo is concerned only with those aspects that translate to design and layout.' [33]

However, the introductory paragraph opens with:

The discussions were led around patterns of use and nature of visits to the facility and the adjoining shopping centre; aspects valued about the existing facility, aspects considered able to be improved or **dislikes**, and features considered **desirable** to be included in the new facility [33].

dislike (*affective state-like condition*), **desirable** (*affective-cognitive state*)

Thereby, flagging the *affective* basis of the memo's content.

These memos constitute the record of user expectations, because having been specifically asked it is reasonable for them to expect the needs will be met in the new facility, unless negotiated otherwise.

Analysis of the memos yielded 153 connections between the Brief-building consultation data and psychological categorisation of which 51.0% have *affective* content (Table 2, Appendix 1). This is surprising given the stated purpose as records of matters of fact for design and initial reading as being very 'matter-of-fact' in presentation. Of the statements 32.7% have *affective external condition* content of which the vast majority are *affective objective descriptions* (Table 5, Appendix 1). This conforms to the documents acting as records of facts to be incorporated during design processes. This is augmented by an additional 31.4% that are *non-affective external conditions*. The expressions that relate to *internal mental conditions*, those with psychological content, (31.4%) the majority (18.3%) are *affective* expressions compared with 13.1% *non-affective* expressions.

4.3 Communicating meeting the brief

The third stage of the Briefing process provided data from participant observation notes taken during verbal presentations to stakeholders at the end of tender documentation. The content of those presentations, which the notes record, consisted largely of descriptions of the building made while presenting the project drawings. These constitute the project consultant's evaluation of what the building will be like and how it meets the brief.[5] Analysis of this data provides 143 connections between the descriptions of the building, or a building element, and the categories of the *Affective Lexicon*. The descriptions contain both a descriptor (an adjective) and a described object, which were then coded. In most instances the descriptor was most influential in coding.

The data is almost evenly split between *affective* and *non-affective* categorisations (Table 2, Appendix 1). A few (1.4% of total) *physical and bodily states* exist but have a minor effect on the 50:50 split between the two categories. In this aspect of the Briefing event the vast majority of the *affective* statements are *external conditions* (90.0%) (Table 5, Appendix 1). This is the highest level of *affective subjective evaluation* seen in any of the three stages constituting 90.0% of the *affective*, though in Stage 1 was 84.8% of the *affective* content (Table 5, Appendix 1). Of the *affective external conditions* the majority (28.0%) are *affective subjective evaluations*.

4.4 Affect across the assessments

Examples of *affect* in assessments were introduced in discussion of classification categories in Section 4.1. Exemplifying this across the three Briefing stages illustrates *affect* on both sides of the expectation-evaluation gap. The following example (Table 1) is illustrative.

---

[5] It is possible to interpret this exercise as 'selling' the design, but given that the presentation observed was the last in a sequence throughout the pre-construction period it is reasonable to state that the design had been 'sold' well before this point.

Table 1: Affective assessments across the expectation-evaluation gap

Stage 1	**Stage 2**	**Stage 3**
Sensitivity Two appearances in the lexicon	**Soften** the visual appearance of building towards neighbours (being considerate)	Domestic (building appearance and scale) Not in the *Lexicon* but usually used in the **Sensitivity (considerate)** sense in environmental descriptions
Sensitive (easily hurt) (*affective-cognitive frame of mind*)	**Comfortable (physically)** (*physical and bodily state*) for the many aged users and occupants (The design is considerate)	**Friendly** to the community (and neighbours) (*cognitive-behavioural frame of mind*). Also a synonym of **Sensitivity (considerate)**
Sensitivity (considerate) (*cognitive-behavioural frame of mind*)	**Serenity** (in the décor) (*affective state*)	**Comfortable (physically)** (stair) for occupants (*physical and bodily state*) Not **offensive** (colour scheme) (a synonym of **bad** (*affective subjective evaluation*) **Serene** (colour scheme) (*affective state*) **Quiet** (environment) (*affective objective description*)

The Stage 1 strategic options **Sensitivity** was re-expressed in Stage 2 by stakeholders requesting the design be considerate of their needs as neighbours and users. The Stage 3 evaluation of the building responds to this expectation with a multi-pronged evaluation littered with *affective* terms.

5. Discussion

The psychological typology and its associated *Affective Lexicon* employed in this paper provides a means of analysing the basis of the formations of assessments – expectations and evaluations – recorded in the language of Facilities Management. Both textual and verbal language forms have been encountered in this research. While the *Lexicon* used in this analysis provides a list of words that are considered in the literature to be emotion words Clore and his co-authors show that not all are emotions but belong to the range of types described in the psychological typology. This *Lexicon* is useful as it enables the psychological basis of assessments expressed in words to be revealed. Some are factually based as *objective descriptions*, some are subject-based internal evaluations and some are mentally formed.

This paper has concentrated on *affect* for three reasons. *Affect* has explanatory value for the warmth (positive and negative) in assessments of facilities. It is useful as an indicator of threats to well-being (related in part to the first point). And, it has a role in pre-emptively altering other mental evaluations. This research demonstrates the presence of *affect* in Facilities Management in the many words that are used in forming and describing assessments.

It is possible that *affect* may be present in all communication but for language that purports to be objective, as in the documentation of expectations, the presence of high levels of *affective* content, in excess of 30% in one stage of expectations and over 50% in the other stage, is remarkable. Thirdly, evaluations or reports of how those expectations will be met in the new facility also have almost 50% *affective* content. This is evidence of the importance of this psychological function in considering human's personal and subjective assessments.

Pure emotion (an *affective state*) was not found to be extensive (Table 3, Appendix 1), yet an emotional basis remains because of the *affective* content in the language. Of the *affective* content the majority are *affective external conditions*, both *objective descriptions* and *subjective evaluations*. The description component is, in Stages 1 and 2, consistent with the factual basis of the expressed expectations. In the Briefing evaluation-reporting stage the level of *affective subjective evaluation* rises in comparison with earlier stages.

Affect can be tracked across the briefing process where an *affective*-based expectation, **sensitivity** in this case, is expressed by both Council officers and stakeholders. Presenting the building design evaluations of how the building meets those expectations contain a range of *affectively*-based descriptions that are a direct response by the designers to the received expectations.

The endpoint in evaluations, to this point in the project, is that the Council officers responsible for delivering the project have assessed that these stakeholders are satisfied and happy (both *affective states*) with the design and the management processes employed thus far. It is this last point that most explicitly of the *affective* basis of human assessments of facilities. This goes towards answering the implied question in the *Introduction* as to why people use their perceptions and that is to achieve a personal *affective state* with regard to the facility.

The paper provides a more comprehensive understanding of the basis of expectations and evaluations, other than just labelling them subjective, through identifying their objective-subjective-psychological bases. These bases have been shown to exist on both sides of the expectation-evaluation gap. Where assessments are *objective descriptive* in form providing facts should support such assessments, and this research has found that many assessments are of this form. But *objective descriptions* may still have value as exemplified by something assessed as **important** (synonym of **unimportant** (*affective objective description*). Where assessments are subjective then the bridge will need to be individually relevant. To achieve this might require consideration of what an individual considers important (see above) or makes them happy (*affective state*). Where assessments are psychologically formed then processes to increase understanding (*cognition*) or **approval-of** (*affective-cognitive state*) facility proposals are likely to be typical of the bridge forms required.

6. Conclusions

This research originated in local government because it is susceptible to parochial politics which influences individual assessments. However, it is of interest generally to Facilities Management practice as meeting user or client expectations has been identified as being an important part of successful FM service. The discipline has struggled with addressing the gap between expectations and evaluations; be they of service delivery or the facility itself because attempts to bridge the gap have tended to rely on objective measures or on attempting to make measures objective. However, this paper has demonstrated the foundational basis of these expectation and evaluation assessments, particularly their psychological (*affective*) basis. Rather than labelling non-objective measures difficult or irrational and therefore opaque, this paper shows how they may be made visible. Such analysis reveals where assessments are factual, where they are subjective, where they are *affective*, or of some other psychological form; thereby beginning to illustrate the form that bridges may be required to have in order to span across the expectation-evaluation gap.

7. Future research

As this paper reports on facility provision up to the end of tender documentation it represents 'Work-in-progress.' Further research is required to examine assessments on facility completion. As this paper is concerned with facility provision processes consideration of the role of *affect* in other aspects of managing facilities is warranted, if *affect* is as fundamental to assessments as this research indicates.

8. Acknowledgements

The authors wish to acknowledge the Australian Research Council, and the City of Glen Eira for their financial and strategic support for this project.

Unpacking Performance Measurements of Operational Building Assets – An Integrated Model.

Danny Shiem-shin Then,
The Hong Kong Polytechnic University
Chi-kwan Chau,
The Hong Kong Polytechnic University

Abstract

Performance benchmarking and performance indicators are currently 'hot topics' in conversations within professional circles of both private and public sector organizations. The philosophy behind performance benchmarking is comparative analysis with the emphasis on analysis. The proper practice of performance measurement involves a careful analysis of processes and conscious selection of relevant performance indicators that are meaningful to the recipients who are then motivated to improving their processes and overall corporate performance.

This paper considers performance measurement of building assets as operating facilities. Operational buildings are at the same time, a physical asset, a functional facility, as well as a business resource. Literature on the subject suggests a wide range of views which tended to polarize towards either the measurement of the physical (technical) performance or the financial (cost) performance. Contemporary resource management supports the view that building assets are an essential resource just as human resource, technology; finance and knowledge are business resources needed to achieve corporate objectives. An integrated resource management approach views an optimum real estate or facility solution as one which is derived from consideration of all corporate resources to meet business needs. In this respect, the prime focus in measuring operational building performance must be viewed in the context of the relationship of building assets and their contributions to business outcomes. This is the premise upon which an integrated asset performance framework for performance of operational buildings has been developed. The content is process-focused in that it will unpack the components needed for performance monitoring of operational buildings and discuss some of the key issues that need to be resolved internally by an organization before the process of external benchmarking can be of value. Through a thorough literature review and brainstorming sessions with research collaborators, a framework for considering asset performance of operational buildings is developed and validated through two focused-group workshops in Hong Kong and Australia.

Keywords: Performance Measurements, Building Assets, Model.

1. Introduction

One of the key business performance issues for both business and government is the ability to leverage maximum performance from resources and drive effective management of resources for long term sustainability. Building facilities or assets are business resources in the same manner as technology, people and business capital. Increasingly, the dynamics of modern businesses demand solutions that optimize the utilisation of all these resources in the most effective manner. Hence the performance of building assets as a business resource is increasingly becoming a focus for management in both the private and public sectors.

Competitive pressures and tight economic conditions are driving the search for competitive advantage beyond a focus on costs and budgets alone. Business and government need to develop an informed view of what customers and end-users of services value and the level of performance expectations. These business drivers have a direct influence on the need to explore with a more searching attitude, more effective management of business resources, namely, the key resources supporting the business - people, property and technology [1]. The need and desire to monitor the performance of operational buildings as a class of assets deserves management attention because of a number of unique attributes:

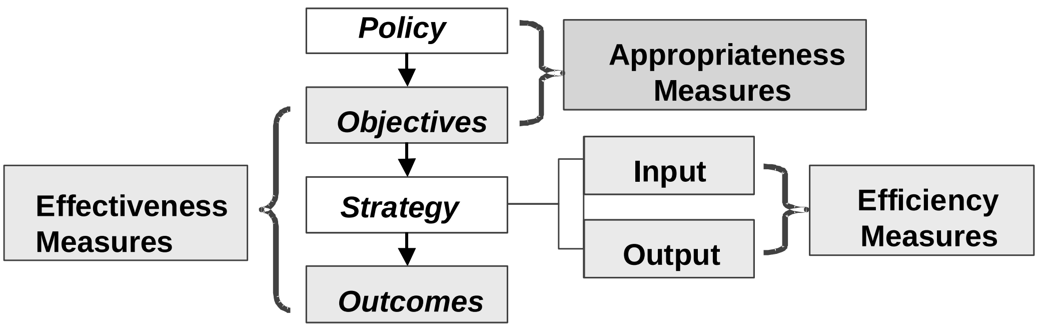
- the capital intensive nature of building assets (usually worth many millions of dollars which could potentially be applied more profitably elsewhere);
- their durable nature (often lasting up to 20-50 years or more);
- their relative inflexibility in responding to changes in business directions and technology;
- the significant accompanying stream of recurrent expenditure burden associated with maintaining and operating them at a desired service standard;
- the potential liabilities due to deterioration and depreciation over time;
- their impact on productivity and business performance; and
- their exposure to a wide range of legal requirements and risks.

The importance of performance measurement as a tool for effective management of such an important business resource is a key driver in the search for an effective performance measurement regime for building assets [2]. However, the practical implementation of a performance measurement regime that delivers the desired management outcomes efficiently and effectively is more problematic [3]. A wide range of methods and frameworks for performance measurement of building assets have been proposed [4]. They range from the detailed technical assessments of physical aspects of buildings to surveys of user satisfaction with the occupied space and quality of the internal environment. Despite this, there appears to be no commonly adopted framework for buildings against which performance measures of operational assets can be established to meet the particular needs of corporate management requirements and user expectations. This paper proposes an integrated framework for assessing building performance [5] and reports on the results of two validation workshops held in Hong Kong and Australia.

2. An Integrated Asset Performance Model

2.1 The Theory

The starting point of performance measurement is a conceptual model that can be applied as a framework for identifying and developing the necessary performance indicators that meet the objectives of any performance measurement effort. As a broad principle, performance measures can generally be divided into effectiveness measures, efficiency measures, and appropriateness measures (Figure 1).



Source: Adapted from Parker, W.C. (1993) *Performance Measurement in the Public Sector* and ANAO. *Best Practice Principles for Performance Information*. pp.8 [6]

Figure 1: Principles of a Performance Measurement System

Figure 1 highlights the need to clearly understand the purpose of performance measurement. Choosing the right measures for the right purpose is fundamental to any performance monitoring system.

2.2 The Need

The development of a conceptual framework for performance evaluation of operational building assets must recognise at least three important characteristics of buildings as a product, and as a business resource:

- Buildings have a much longer life than most other assets in business. A building represents a special class of durable assets requiring high initial capital investment and subsequent running costs and reinvestment – i.e. a regime of life cycle management is required to optimise its efficient operation;

- A building's value is represented by its effectiveness as a supporting resource in the overall value chain of an organisation's productive process. Its role as an enabling resource is increasingly seen as crucial in raising staff productivity – i.e. an integrated resource management approach incorporating the delivery of an enabling workplace environment must be acknowledged; and
- Buildings involve a number of stakeholders: owners, managers, service providers and users throughout their operational lives. Existing buildings are also being changed and renovated more often in response to new owners, organisational changes, and new occupant requirements – i.e. buildings as dynamic entities which must be managed proactively in order to respond to changing users' expectation and rapid technological development.

Evidence from the literature reviewed suggests that building performance monitoring is an amalgam of at least four aspects of facilities provision and their ongoing servicing as functional facilities:

- The appropriateness of the current asset base in meeting business objectives;
- The provision of a satisfactory working environment for occupants and customers;
- The minimisation of operating and maintenance costs by managing the condition of the existing facilities,
- The performance of the facilities as functional, operational assets supporting business processes.

In optimising the performance of building assets, an organisation must balance the interdependent and, often competing, outcomes of the above four aspects of asset performance in order to achieve their optimum service potential.

2.3 The EPFS Model

Taking the above constraints into consideration, Then and Tan [7, 3 & 5] proposed that asset performance indicators used by organisations from both the public and private sectors can be grouped under five broad facets of performance measures:

- **Economic measures -** The *Economic* facet of asset performance is concerned with decisions at a strategic level that optimises on value for money from property resources. Economic asset management requirements are governed by the need to relate physical facilities provision to longer-term business plans. The objective of measurement here is to ensure optimum resource allocation and affordable and economic provision of property resources in line with market offerings and business plans.

- **Functional measures -** The *Functional* facet of asset performance is concerned with management decisions that relate to the creation of the desired working environment in line with the preferred organisational culture and workplace standards. The objective of measurement here is to ensure continuous alignment of supply of appropriate functional space to anticipated service demands as far as possible. Fitness of purpose for property resource in meeting business requirements may be measured in terms of locational distribution, type, form and size of buildings.

- **Physical measures -** The *Physical* facet of asset performance is concerned with efficient and effective management of operational aspects of ongoing asset management. The objectives of measurement here are driven by the need to preserve asset value, ensure asset condition does not lead to unnecessary operational risks and liabilities, and to ensure occupancy costs are reasonable.

- **Service measures.-** The *Service* facet of asset performance is concerned with decisions and actions relating to quality perception by end users and quality of service delivery by service providers. The objective of measurement here is to ensure that the business context and organisational culture are appropriately reflected in aspects of service delivery and are aligned with core business requirements. Measures in this facet of asset performance are generally surrogate, often subjective indicators of performance derived from clients' and end users' perceptions of corporate facilities and support services.

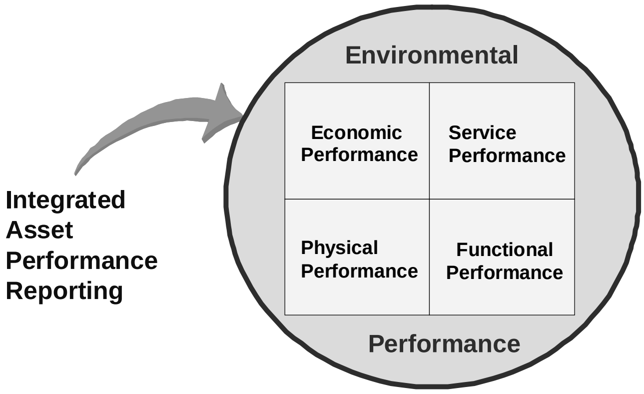


Figure 2: Integrated Asset Performance Reporting (Then & Tan, 2002)

- **Environmental measures -** The *Environmental* facet of asset performance is concerned with the role of building assets and their impact on facilities users, the community and the ecological environment. Measures in this facet are likely to involve monitoring against prescribed sustainability targets at project / state /national levels.

The premise taken is that any integrated asset performance reporting must incorporate these five facets of measurement in order to obtain a balanced view of the contribution of building assets as an operating resource, as illustrated in Figure 2. However, this paper only reports on four of the five facets of asset performance measurement. The Environment facet is the subject of another study.

The above five facets of performance measures form the cornerstones of an integrated asset performance concept that can be applied to:

- Fulfil specific stakeholder perspectives of asset performance;
- Guide selection of appropriate key performance indicators;
- Assist in defining data requirements for specified key performance indicators; and
- Provide a balanced view of asset performance.

Table 1 summarises the key management focus of the five facets of asset performance measures. Each facet of asset performance is governed by a different set of variables with its associated key performance indicators. The proposed model provides a structured approach for considering the many dimensions of built assets performance and critically reviewing the suitability of currently available measures.

Table 1: Asset performance facets and management focus

Performance Facets	Management focus	Focus of performance monitoring
Economic	Value for money	Efficiency in allocation of resources
Functional	Fit for purpose	Effectiveness in utilisation of resources
Physical	Operational risk and liability	Appropriateness in type and condition
Service	Customer satisfaction	User/client's Quality perception
Environmental	Workplace & environmental sustainability	Meeting prescribed targets at project / state / national levels

Then, S.S. & Tan, T.H. [5]

The necessity for a conceptual framework is supported by the need to explain, communicate and justify the need for data collection and analysis. A logical and consistent framework facilitates the process of focusing data collection on the asset performance parameters that are currently deficient or lacking from asset information systems.

Having a performance concept is only the first step in the implementation of an asset performance framework that is useful and cost-effective. There are a number of further steps which have to be navigated before full realization of a credible and sustainable asset performance measurement system [3]. Figure 3 illustrates the parameters within an organisational setting in which an asset performance measurement system must take into consideration. They are the factors that will influence the practice of asset performance management within an organizational setting. (modified from Then & Tan, [5]).

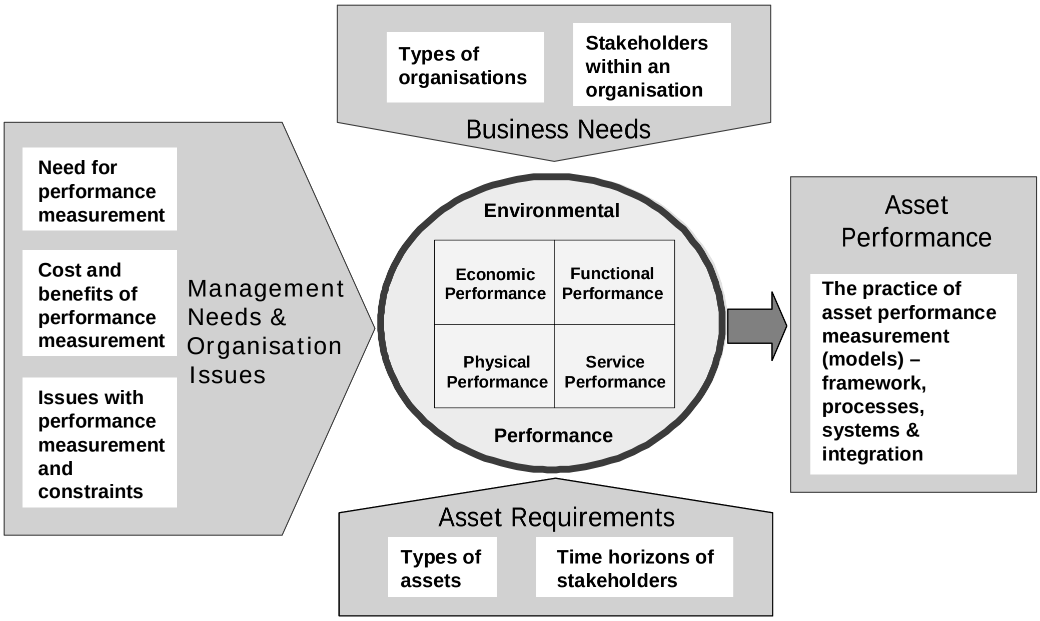

Figure 3: Factors influencing the Practice of Asset Performance Management

2.4 The EPFS Model – Variables and KPIs

Through a series of brainstorming sessions with research collaborators, it was decided that a structured approach is required to identify the appropriate key asset performance indicators. The alternative is a linear approach which has the potential disadvantages of being almost a random selection of measures or a selection that is technically driven by professional inclination.

The structured approach adopted comprised of a two-stage analysis. Stage one involved the identification of all possible variables associated with each of the four facets (i.e. Economic, Physical, Functional and Service performance). These are illustrated in Figure 4. Stage two involved identification of possible performance indicators that are measures of each of the variables identified. A total of 35 Asset Performance Variables and 95 Key Performance Indicators (KPIs) were selected for validation by two focus groups workshops held in Hong Kong (July 2004) and Brisbane (August 2004). The sample of the Hong Kong focus group (N=20) consisted of middle/senior managers with responsibilities for property and facilities services representing commercial buildings, airports, universities and banks. The sample of the Brisbane focus group (N=21) consisted of middle/senior managers with responsibilities for property and facilities services representing public sector facilities. In both locations, initial contacts were made via telephone and email, explaining the purpose of the workshop and who from the organisation should participate.

The deliberation of each validation workshop followed a structured format that comprised the following:

Session 1 – Introduction, background and purpose of workshop - 10-15 minutes,

Session 2 – Concept Validation:

a. EPFS Model Presentation by research collaborators – 30 minutes including questions,
b. Validation of EPFS Model by respondents via structured questionnaire – 30 minutes,
c. Validation of EPFS Variables via structured questionnaire – 30 minutes.

Session 3 – Practice Validation:

a. KPIs Presentation by research collaborators – 10 minutes including questions,
b. Validation of KPIs for each Variable via structured questionnaire – 60 minutes

Session 4 – Summary and Feedback.

In summary, both the workshops were well received by the participants who expressed keen interest in the outcomes of the research and analysis from the workshop questionnaires. A summary of the results of the research were provided as feedback to participants of the validation workshops.

3. Results of Analysis of Responses from Validation Workshops

3.1 Concept Validation of EPFS Model

The concept validation comprises a two-part analysis. Table 1 shows the results of the attributes validation of the combined sample of both sets of respondents from Hong Kong (N=20) and Australia (N=21). Respondents were requested to evaluate the EPFS model on five different attributes, each against a 5-point Likert scale. The model was highly rated against the attributes of *Completeness, Robustness, Importance* and *Practical Relevance,* scoring more than 4.0 on a 5-point Likert scale, with degrees of variation between 4.0 and 4.6.

Table1: Concept Evaluation of EPFS Model

Attributes	Mean	S.D.	Rank
Completeness – Degree of completeness in coverage of elements of asset performance	4.585	0.4988	1
Robustness – Degree of robustness in concept and practice of asset performance	4.439	0.5024	1
Usefulness – Degree of usefulness in making more informed decision on issues in asset performance	4.317	0.7563	1
Importance –Degree of importance in asset management practice.	4.317	0.7563	1
Practical Relevance –Degree of relevance in the practice of asset performance.	4.049	0.669	2

A pairwise analysis was also conducted to evaluate the respondents' opinions on the relative importance of the four different facets of asset performance: *Economic*, *Functional, Performance*, and *Service*. Six pair-wise importance questions with a nine-point linguistic scale were used [8 & 9].

The individual respondents' results on each individual pairwise question were aggregated using the geometric mean method before inputting into the necessary computation matrices. The final relative importance weightings of the four different facets of asset performance are shown in Table 2. No significant differences in the perceived importance of the four facets of the EPFS model were found for both groups of respondents in Hong Kong and Australia. A check on the consistency of responses was also performed to ensure the validity of the computed results. A consistency ratio of 0.0067 (<0.1) was obtained from the analyzed responses, which indicated that the responses given by all the respondents were quite consistent.

Table 2: Relative Importance Weightings of the four Asset Performance Facets

Asset Performance Facet	Relative Importance Weight
Economic	0.236
Physical	0.182
Functional	0.319
Service	0.262

3.2 Validation of Asset Performance Variables

For each of the asset performance facets, their potential asset performance variables were identified via a combination of literature review and brain storming sessions by the research collaborators. A total of thirty-five asset performance variables were identified for validation by respondents. A 5-point Likert scale type questions with '1' indicating *not relevant* and '5' indicating *very relevant*, for each of the asset performance variables was included in a questionnaire for the workshop respondents. Figure 4 illustrates the asset performance variables associated with each of the asset performance facets, together with mean relevant values and standard deviations. An asset variable is considered to be relevant if it has a mean value greater than 3.5.

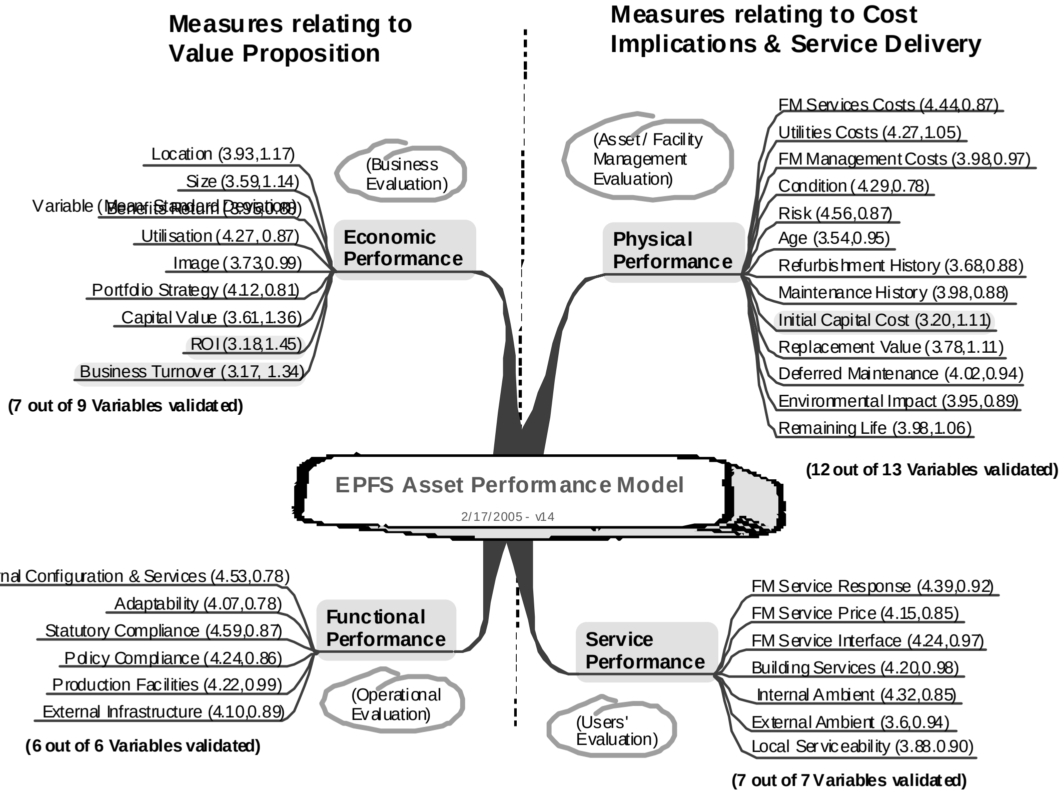

Figure 4: EPFS Model showing Asset Performance Facets and associated Variables

3.3 Validation of Asset Performance Indicators

For each of the asset performance facets, and their corresponding asset performance variables, a set of Key Performance Indicators (KPIs) were identified via literature review and brain storming sessions by the research collaborators. A total of 95 KPIs were selected and workshop respondents were requested to rate their relevance via a series of dichotomous questions with 'Yes' and 'No' options. An indicator is considered to be relevant if the percentage of respondents choosing 'Yes' is greater than 75%. A total of 68 KPIs were validated by the respondents. Figure 5 lists the selected KPIs against each asset performance variable and the corresponding asset performance facet. The sample size for the combined respondents from Hong Kong and Australia is 41 (i.e. N=41).

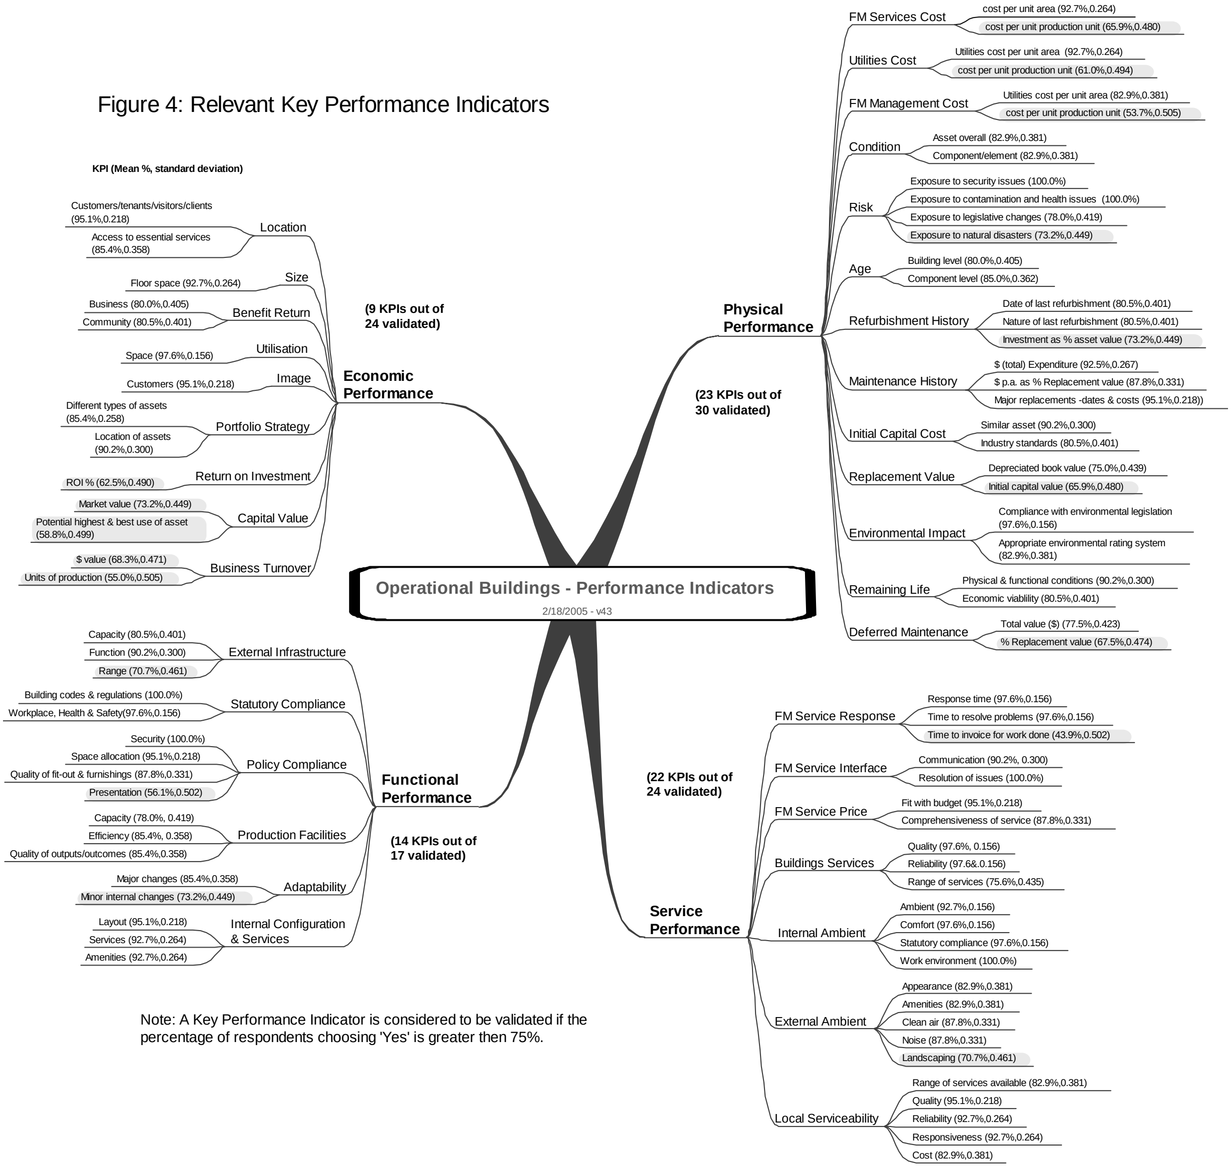

Figure 5: Relevant Key Performance Indicators against each Asset Performance Variable and associated Asset Performance Facet. (Note: Shaded KPIs <75%)

4. Conclusions

The quality of an asset performance measurement regime is subject to the proper definition, selection and organization of KPIs to provide relevant and reliable information for management decisions and actions. An unstructured and haphazard selection of KPIs is likely to lead to a waste of time and effort in data collection and incomplete or misleading performance information. This paper proposes a structured and logical framework for the development and selection of key performance measures. The EPFS Model provides a rationale and robust methodology for the organization of the KPIs selected and justification for the data requirement. Overall, the proposed EPFS model can be considered to be statistically validated relative to the sample of respondents in Hong Kong and Australia. The exercise has opened the doors for further development for practical use of the concepts underlying the evaluation of asset performance and the implementation of asset performance measurement towards best practice. It is anticipated that the EPFS Model will be further developed and refined through detailed case studies. The valuable assistance of the participants in the validation workshops in Hong Kong and Brisbane is gratefully acknowledged by the research collaborators.

Abstract

Part of a Nordic productivity study is reported here with focus on the owner and end-user and the correlation of price and quality of buildings. A product and a value model were tested on Swedish and Danish cases, which covered both new block of flats, renewal and laboratory. Differences in cost and reduction of deviations between cases are discussed. In the conclusion a structure is given for national or Nordic systems for benchmarking and key-figures and a number of supporting initiatives are presented.

Keywords: Building parts, quality, owner, end user, benchmarking and productivity.

1. Introduction

In 2004 five Nordic research institutes finished a joint study on productivity and benchmarking funded by Nordic Innovation. Through case studies, primarily on new blocks of flats, experiences and models for analysing productivity were discussed from two different angles – those of the construction company and the owner. The Swedish and Danish study is aimed at the owner and end-user, and shows how buildings of different locations, functions, sizes and standards can be compared.

1.1 The Nordic Productivity Studies

The Nordic Productivity Studies [1] was funded by Nordic Innovation (www.nordicinnovation.net), the former Nordic Industrial Foundation, according to the application submitted by the Norwegian Building Research Institute in the autumn of 2000 on behalf of five research institutes: Norwegian Building Research Institute (Norway), VTT Building and Transport (Finland), Icelandic Building Research Institute (Iceland), Danish Building Research Institute, (Denmark) and Swedish National Testing and Research Institute (Sweden).

The application included both building and infrastructure in the project. Early discussions showed that it was impossible to cover the whole area, and it was decided to base the research on case studies of housing and new blocks of flats. Another ambition was to discover common Nordic methods for data collection and comparison of cases based on the national experience. The first presentations of national cases outlined two opposite trends or two different target groups for the methods. One focused on construction companies, the production process on site and studies carried out on a comprehensive and detail level. The other focused on real estate from the end-user's, the building owner's and the customer's points of view, and the approach to the study had a broader and more general perspective. Each participant weighted these two tracks differently.

1.2 Activities in the Nordic countries

The building and construction sector can be divided into two supporting segments and three core businesses. The supported segments or the framework are public regulations (Regulation market) and research and education (Knowledge market). The core business is the three main segments along the value chain: The product market and the production industry; the construction market designing and constructing the building; and the real estate market where the owner, the developer and their advisers run the building as an envelope for the end-user for housing, work and institution (Figure 1).

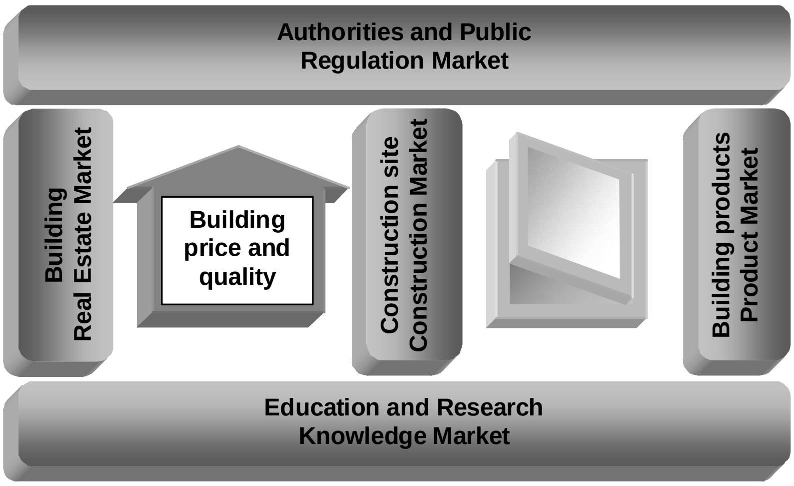

Figure 1: The building and construction (B&C) sector can be divided into five different markets and into two main types of 'products' – the building and building products.

Like in most industrial countries, the building and construction (B&C) in the Nordic countries is a major part of the GNP. In the European countries the B&C typically lies between 5 to 15 % depending on the market situation and on how the B&C sector is defined. The effectiveness of the B&C sector has an important influence on other sectors, the national economy and our well being and health. And the money invested and the capital tied up in real estate for housing, production and services are enormous.

Table 1: Construction companies (CC) in Nordic countries, 2002 (National statistics).

CC and part of total	Finland	Sweden	Norway	Denmark	Iceland
Turnover in CC in mill. EUR	139,700	312,340	190,091	156,590	8,952
Part of national total	14 %	7 %	10 %	5 %	7 %
Number of CC	224,847	842,000	429,910	297,706	8,184
Part of national total	13 %	7 %	9 %	9 %	8 %
Employees in CC in thousand	2,372	4,272	2,055	2,692	157
Part of national total	6 %	6 %	7 %	6 %	8 %

Table 2: Construction market (CM) in Nordic countries, 2002 (Euroconstruct).

CM in billion EUR			Finland	Sweden	Norway	Denmark	Iceland
Residential	New		3.6	2.2	3.3	3.0	0.4
	Renovation		3.2	4.3	3.7	3.2	
		Total	6.8	6.5	7.0	6.2	
Non-residential	New		5.3	2.2	4.3	4.0	0.3
	Renovation		3.4	4.6	3.7	2.6	
		Total	8.7	6.8	8.0	6.6	
Total			15.5	13.3	15.0	12.8	

1.3 Challenges for benchmarking productivity

The data collection and use of data seems to be similar in the Nordic countries, but the published data varies from one country to another depending of tradition. Statistical knowledge about the building and construction sector is in general based on national statistics. Most of the available data are macro economical, which means that the pictures given are rough and not very suitable for control and decision-making at company level. Nevertheless, the information is useful for the industry as general background. But when it comes to measuring productivity, the need for project level data is crucial.

The building processes in the five Nordic countries have a great deal of similarities. This should ease the benchmarking activities; if all other conditions of investigation were taken care of. Only few major research and development works have been carried out wit respect to measuring productivity, efficiency, value and quality. There is a need for productivity information in Nordic building and construction sectors on the micro level like in other sectors. To achieve similar statistical information about the B&C sector, the condition is to make project data available for common statistical studies. Till now this resource demanding challenge has not been taken. Instead there have been carried out local price- and costs studies to simply follow the change and 'explain' it in plain words.

2. Models for the Swedish and Danish study

The Swedish and Danish study focused the owner and his balanced communication with the end-user and the construction market from the early planning stage through the whole construction period into use and renewal. Based on experiences from different case studies a model was established for benchmarking the building more detailed than price per square metre. First level in the model is to make a comparison between buildings at different locations and building time – **the space model**. Second level is to analyse the deviations in price according to the different size, form, content and functions of the building – **the product model**. The third level is the correlation of differences in standard and quality including aesthetics and comfort – **the value model**. The fourth level is the differences between companies in industrialisation and level of changes, defects and claims – **the process model**. In the study focus was put on the product model and the value model.

2.1 The product model

In the product model the building is divided into different rooms, functions and building parts that are comparable across locations, type of building and the lifecycle of the building. The product model is a hierarchic of objects which build a bridge between real estate, the total building and the detail building product, and price and quality (the value model) can be connected to each object in the product model. Real estate is first divided into ‘The ground and site’ and ‘Building and rooms’. For each type of real estate a limited number of rooms and functions are defined (Table 3). In the next level the building is subdivided into ‘Building construction’, ‘Installation in building’, ‘Furnishing and equipment’ and ‘Common activities’. The last includes common activities for the building and construction process. VAT is separate in a single entry.

Table 3: The product model divides real estate in levels of objects in a hierarchic system, which builds a bright to building products and is visible for the end-user.

The real estate	**1. Ground and site**	**3. Building construction**
- Block of flats		
- Single family house	**2. Building and rooms**	**4. Installations in building**
- Office building	- Kitchen	
- Production	- Bathroom	**5. Furnishing and equipment**
- School	- Living room	
- Other examples	- Office	**6. Common activities**
	- Laboratory	
	- Other examples	**7. Value added tax (VAT)**

Each of three main building parts can further been divided into subparts (Table 4), and each of these can in turn be subdivided into different types if it is required. These subparts are directly related to the international classification systems for construction parts and materials, and real estate is related to the methodology in international statistic.

Table 4. Each main building part (here 3, 4 and 6) is divided into subparts, which can be common for all buildings and connected to the international classification systems.

3. Building construction	**4. Installations in building**	**6. Common activities**
- Foundation and ground floor	- Drain installation	- Construction site
- Exterior walls	- Water installation	- Design and planning
- Windows and exterior doors	- Heating installation	- Construction control
- Internal walls with doors	- Gas installation	- Project administration
- Story separations	- Ventilation	- Insurance of the project
- Roof and roof construction	- Electric installation	- Financing of the project
- Balcony	- Communication	- Other examples
- Other examples	- Other examples	

2.2 The value model

Building and constructions are normally benchmarked by comparing price per square metre gross area of the total building. In the value model price and quantity are connected in a unified price for each of the building parts and rooms described in the product model above. In addition the value model also describes the aesthetics, functions, standards and qualities as well as the delivery conditions. The main structure of the hierarchic value model is shown in Table 5.

Table 5. The main parameters in the value model. They can be divided into sup-parameters and connected to the actual objects in the product model.

Economy	Price, cost, profit and life cycle cost
Quantity	Unit, number, size, length, area and volume
Aesthetic	Design, form, texture, colour and appearance
Standard and quality	Function and applications of building and rooms
	Technical standards on constructions and installations
Delivery	Conditions on where, when and how each object is delivered

The first level is to measured price in relation to the quantity for each building, room and building parts in the product model. The unified price parameter can be calculated and used as a comparable key figure for benchmarking. Next level is to correct the unified price in relation to differences in technical standard, function, quality, aesthetics and delivery conditions. Measurable number, classification or a short description can be used to specify the value and explain the deviations between key figures or correct the key figures. An example of three typical rooms in housing is given in Table 6.

Table 6: Example of key figures and unit price on three types of rooms in new terrace houses for housing built in 1994 in Denmark [2].

Room	Standard and quality		Units	Unit price	Price
Habitable room	Paint ceiling and walls. Inner walls of 100 mm gas concrete. Floors of solid beech wood.	2,367	m^2 floor area	629	1.5 mill. DKK
Kitchen	Standard HTH kitchen. 10 m^2 floor area per kitchen.	400	m^2 floor area	1,765	0.7 mill. DKK
		40	Kitchens	17,647	
Bathroom	4 m^2 floor area per room. Tiles on the walls and quarry tiles on the floor. Normal standard of inventory.	160	m^2 floor area	6,272	1.0 mill. t DKK
		40	Bathrooms	25,089	

3. The Swedish case study

The Swedish case study included 32 different building projects of blocks of flats in Sweden. Twenty-seven of the projects came from a report from Boverket [3]. The cost data were given in applications for environmental subvention funding (‘Eko-bidrag’), and the data were collected before the buildings were finished. The projects therefore do not represent typical Swedish buildings. The next four projects came from the national committee report [4], and the last project was from the Svedala project [5]. The data from the last five projects were all final cost after the building was finished.

3.1 Distribution of different type of costs

Five of the projects were small student flats and one was located in the centre of Stockholm. All six differed in use, location and costs from the other 26 projects and were therefore removed from the case study. The rest of the projects were built in the period from 1998 to 2003, and a correction was made of the cost using 2002 as a reference. From statistical data it was found that the average price was increasing by 7 % per year. Each project was described by type of building, size, time and cost as given in Table 7.

Table 7: Type of data collected on each of the 26 Swedish cases.

- Type of building as name and community or town where the building is located.
- Size of building as number of flats, heated area (total gross area, BRA m^2) and useful area (gross area for flats excluding common area, BOA m^2).
- Time and date of starting and ending of building time.
- Production costs divided into 1) cost of site, 2) fees and taxes (not VAT), 3) financial costs, 4) building owner costs, 5) consulting costs, 6) contractor costs, 7) value added tax (VAT) and 8) total production costs.

The average size of flat in useful area for the 26 projects was calculated to be 72 m^2, and the smallest and largest flat were respectively 43 m^2 and 119 m^2. The average production cost per area was calculated to be 14,443 SEK/m^2, and the lowest and highest total cost were 9,658 SEK/m^2 and 20,139 SEK/m^{2,} respectively. The average production cost per flat was calculated to 1.05 mill. SEK per flat, and the lowest and highest total cost were 0.58 mill. SEK per flat and 2.01 mill. SEK per flat, respectively.

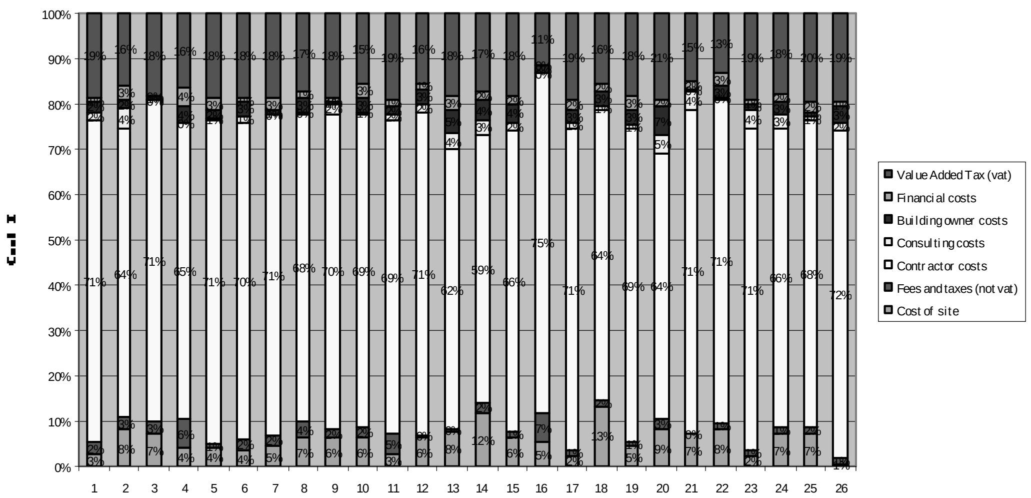

Figure 2: The distribution of seven different costs in % of the total cost for the 26 cases.

Table 8: Average value for the different costs.

Type of cost	***Cost in %***
1) Cost of site	6 %
2) Fees and taxes (not VAT)	2 %
3) Financial costs	2 %
4) Building owner costs	3 %
5) Consulting costs	2 %
6) Contractor costs	68 %
7) Value added tax (VAT)	17 %
8) Total production costs	100 %

As seen in Figure 2, the distribution of the different costs varies a lot from case to case. For instance, cost of site varies from 1 % to 13 %, fees and taxes from 0 % to 7 % and construction costs from 64 % to 75 %. The average value for the costs is in Table 8.

3.2 Benchmarking total costs

The next step in benchmarking building projects is to compare the total cost or the contractors cost per heated area (BRA). Normally a Salter diagram is used. Here (Figure 3) the columns are sorted in increasing cost per square meter heated area and the width of the column is the number of flats for the specific case. In Figure 3 it does not look like larger projects are cheaper, and we can see that the lowest price is 9,658 SEK/m^2. The Salter diagram can also use cost per flat and other values for the height of the columns and total cost as width of the column.

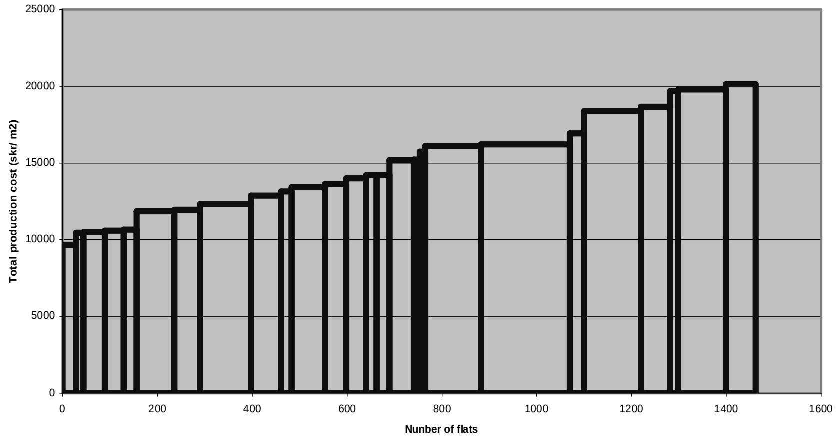

Figure 3: Salter diagram in increasing total costs in relation to number of flats.

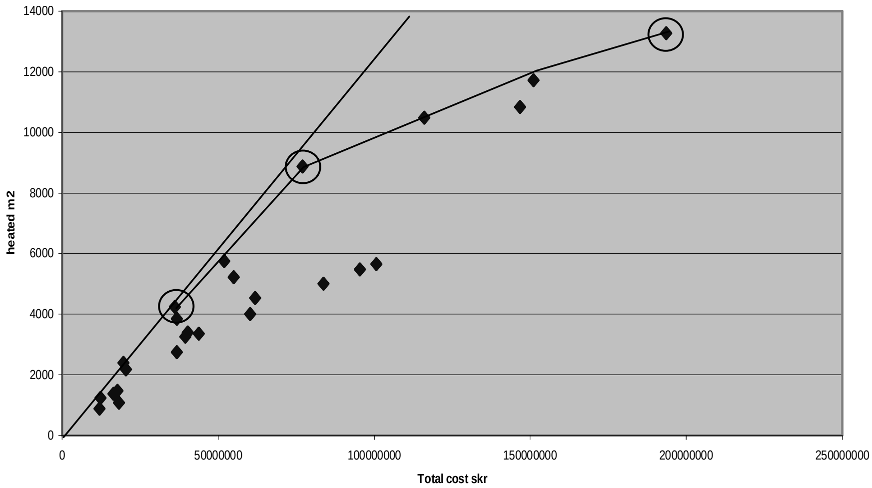

Figure :. Data Envelopment Analyse (DEA) for the 26 Swedish cases. Input is total cost in SEK and output is heated area, and the upper boundary is marking the best practice.

We can also use a Data Envelopment Analyse (DEA) [6] of the cases, where the production result (output) is analysed against the resources used (input), and the best practice is found as the upper boundary of the analysed cases. In the DEA of the 26 Swedish cases the output is the total heated area and the input is the total cost in SEK. As seen in figure 4 the upper curve is forming a boundary of best practice, and the following 3 cases (36.1 mill. SEK, 4,239 m^2), (77.0 mill. SEK, 8,873 m^2) and (193.5 mill. SEK, 13,269 m^2) are all representative of the best practice boundary.

4. The Danish case study

Experience gained from several studies shows that it is difficult to compare productivity between buildings because they differ in function and content. It is also evident that the variation in price per square metre indicates more than dissimilarity in productivity. Another cause is the difference in quality and value for the end-user, which moreover is difficult to measure and evaluate. When we compare buildings in cities with buildings in the country, we also find a marked influence from the location. In the Danish study the models are tested against these parameters on different type of cases in the search for a simple structure which fits international standards and the national opportunities.

4.1 Benchmarking against national statistic

Table 9: Benchmarking new terrace house against public statistics on housing. The benchmark is the median February 2003 and all costs include 25 % VAT.

Building parts and main accounts	Benchmark		Danish case 1		Comparison	
	Cost per gross area DKK/m^2	Part of total	Cost per gross area DKK/m^2	Part of total	Absolute Difference DKK/m^2	Benchmark index
Foundation	643	5,0 %	354	3,1 %	-290	55,0 %
External walls	1,231	9,6 %	1,262	11,0 %	30	102,5 %
Internal walls	1,260	9,8 %	830	9,8 %	-430	65,9 %
Ground and site	3,224	25,0 %	2,266	19,7 %	-958	70,3 %
Construction total	7,775	60,4%	6,898	59,9%	-877	88,7%
Common costs	1,874	14,6 %	2,345	20,4 %	466	124,8 %
Total costs	12,878	100 %	11,509	100 %	-1,369	89,4 %

Every six months the National Agency for Enterprise and Construction (Erhvervs- og Byggestyrelsen) publishes updated key figures on publicly supported housing on www.ebst.dk/-Boligmarked/Nøgletal. The statistics are divided into four different locations, five different functions and types of occupants and three different types of building. The cost per square metre gross area is distributed on 55 different accounts under the three main accounts: Ground and site costs, construction cost and common costs. Each of these 55 accounts is specified by lower quarter, median and upper quarter.

The first case is a study on a new terrace house and cost and gross area are compared with public statistical data on non-profit family housing in a municipality with a population below 50,000. Table 9 gives an example from the benchmarking of the three main accounts, the total cost and three different building parts. It is seen from the last column that the foundation is 55.0 % of the benchmark, the external walls are 102.5 % of benchmark, the ground and site cost is 70.3 % of the benchmark and the common cost is 124.8 % of the benchmark.

4.2 Comparing renewal of block of flats

The second case is a comparison of 88 different cases of renewal of a block of flats in Copenhagen. Data were collected on costs and units on 20 different building parts or common accounts. For each building part the type and renovation level was described and the average value for cost per unit and the corresponding standard deviation were calculated for similar types of renewal. For most building parts no change was found in cost over a period of 8 years and the standard deviation was as high as 25 % to 50 %. But renewal of windows showed another interesting profile.

Of the 88 cases 78 had had new windows installed and the total cost per installed window had decreased by 30 % from 1987 to 1994. In Table 10 the figures show a cost reduction from 624 DKK/m2 to 436 DKK/m2 gross areas. In the same period the standard deviation was reduced from 25 % to 17 %. It was concluded that the improved productivity was caused by industrialisation of both the window and assembly on site. Normally the cost figures are divided by the total gross area as shown in Table 10, but if we want to compare for instance the cost of renewal of the roof it is better to use the unit 'cost per m2 of covered roof area'. In Table 11 one project is benchmarked against the rest.

Table 10: Cost of new windows for three periods in the renewal of block of flats in Copenhagen. The costs are in July 1995 prices (DK index 138) without VAT.

Type of renewal	Cases		Cost per unit	Standard deviation
New windows 1987-90	27	31 %	624 DKK/m^2	25 %
New windows 1991-92	31	35 %	500 DKK/m^2	21 %
New windows 1993-94	20	23 %	436 DKK/m^2	17 %

Table 11: Four building parts in the project 'Oehlenschlægersgade 40' benchmarked against 88 renewal of the block of flats in Copenhagen (same index as table 10).

Building parts	**Benchmark**		**Oehlenschlæger..**	**Oehlen.. per benchmark**
	Cost per unit	St.dev	Cost per unit	
New bathroom	52,198 DKK/room	31 %	62,011 DKK/room	119 %
New kitchen	40,050 DKK/room	37 %	34,489 DKK/room	86 %
New heating system	423 DKK/m^2 gross	26 %	676 DKK/m^2 gross	160 %
New roof construction	2,759 DKK/m^2 roof	33 %	5,412 DKK/m^2 roof	196 %

4.3 University building and 3D visualisation

The third case is to determine key figures on different building parts on university buildings. The value model covering price, unit and level of standard is connected to the product model in 30 different building parts and accounts. Key figures are found on each building part and subparts as shown in Table 12 for external walls and windows.

In addition tests have been made on using a simple 3D visualisation in the communication in the early planning process with the end user. The 3D model was based on the collected key figures and colours showing different type and standard of rooms and building parts. Area, volume, total price and cost on the individual building parts were automatically calculated, and it was possible to replace building parts with other levels of quality and see directly the impact on the total price. The 3D visualisation has also been tested with success on new and renewal of block of flats **together** with the occupants.

Table 12. Key figures for different types (a to e) and the average price of external walls and windows on a new pharmaceutical university in Copenhagen built in 2002.

Standard and quality	**Units**		**Unit price**	**Price**
a) Walls and end walls of concrete covered with Swedish limestone.	1,045	m^2 facade	4,202	4.4 mill. DKK
b) Walls and end walls in concrete covered with blue subdued brick tiles.	845	m^2 facade	2,373	2.0 mill. DKK
c) Facade sections in steel and aluminium with sunscreens.	895	m^2 facade	4,828	4.3 mill. DKK
d) Walls and end walls in penthouse in steel with blue subdued brick tiles.	570	m^2 facade	4,909	2.8 mill. DKK
e) Walls in the basement in cast concrete on site and heat insulated.	900	m^2 walls	1,400	1.3 mill. DKK
Concrete walls, insulated and covered with bricks and tiles. Windows and glass sections of steel and aluminium.	4,255	m^2 facade	3,472	14.8 mill. DKK

5. Conclusions

The first rough benchmarking showed a deviation of 25 % to 50 %, and it could not be explained by differences in productivity alone. It was demonstrated that it was possible to split up the building in building parts and type of building parts, which could be compared between types of buildings. Connecting the individual object in the product model with values of cost, quantity, standard and quality the deviation could be reduced to more than 20 %. Based on the study it is recommended that a system should be improved if the deviation exceeds 25 % or smaller if the process is industrialised.

It is clear from the Nordic studies that it is difficult to introduce a common benchmarking system which covers the major part of the marked, different types of buildings and more countries and in addition can be accepted by the owner and construction companies. If an open system is preferred, it could be difficult to get information from contractors, and a system based on the owner must be preferred. Through the Nordic studies we formed a basis for future benchmarking systems which should have time and support to develop.

More international co-operation tailored to national options is proposed, and more research and innovation should emphasise: Simple 3D visualisation of the product and value model, methods for measuring standard and quality on different building parts, classification of type of rooms and building parts, which fits the purpose of the owner and end user, definition of units and key figures of rooms and building parts and network for exchanging experiences on benchmark system and use of key figures.

Partnering with user participation – as a means of better functionality

Ib Steen Olsen,
National Agency for Enterprise and Construction, Denmark, (email: iso@ebst.dk)

Abstract

The construction industry provides society with physical products not only in the form of finished buildings. It also provides the background for a number of basic living conditions and experiences in modern society such as forms of living, urban space, commercial centres, cultural activities, work places and transport facilities. This goes for new buildings as well as renovation of existing buildings.

Thus the building industry is a key factor in the efforts to create better living conditions. This was emphasised in a recent report to the EU regarding future research and development of building, cf. European Network for Construction Research (E-CORE) (1).

To accomplish this task it will be necessary for the enterprises of the building industry to develop new forms of planning which facilitate working on the basis of the interaction of the building with the activities that the building is to serve - during its whole service life. In this work users and their values could play a crucial role.

In Denmark a basis has been developed for improving collaboration – partnering – in a building project. This basis also opens for the possibility of involving the users far more constructively than has been the case up till now.

Keywords: Partnering, users, collaboration, service life

1 Clients create values

1.1 Overview

'Clients create values' is a development programme running for four years from 2002 – 2006 which at present includes 35 clients and experimental building projects organised in a network.

Elements that can improve collaboration are tested in each single building project. Examples of such elements are the use of workshops, elaboration of common objectives for the participants in the building project, common economic incentives, rules for conflict management, selection of participants/partners on the basis of competencies and budgeting based on open books. Altogether there are up to 15 elements that can be adjusted to fit the individual building project.

In 2004 the network submitted a proposal for a procedure for partnering based on reports on finalised experimental buildings projects (12). The proposal has received the general backing of the Danish building industry and the Government now demands that in every new building project the clients of public building projects should carefully consider whether partnering would be suitable for the project in question.

Guidelines have been elaborated that give directions and summarise the experimental results.

1.2 Industrial relevance

Based on the experimental building projects and the evaluations, the following picture of the advantages can be drawn:

- Collaboration promotes the possibilities of uniting architectural quality with buildability
- The close collaboration provides a better opportunity for involving the users and the values connected with the use of the building
- The transition between design and execution can be implemented with fewer misunderstandings, with more buildable project documents and more time to plan execution and cooperation on site
- Efficient control of economy/quality, survey of risks and improved conflict management are promoted for the whole process

2.What is partnering

2.1 Focus on dialogue

In practice partnering can be organised in a number of ways, but its core characteristics are reflected in the Danish *definition* which has found a general backing from clients and the organisations of the building industry:

”The concept of ’partnering’ is used to describe a form of collaboration in a building project and is based on dialogue, confidence, openness and with early involvement of all parties. The project is implemented with common objectives formulated by common activities and based on shared economic interests” (2) and (3).

In a preamble it is added: " Partnering should be established as a minimum between client, consultant and contractor".

The Danish Association of Construction Clients stresses "project optimisation in the programme and project phase with a view to create a better starting point for the building process and consequently a better product" as being a primary target (4).

2.2 Common characteristics and tools

In practice the definition provides the possibility of choosing between a number of procedures with some determining common characteristics such as:

- -An active client who decides to implement collaboration with partnering and who participates in a dialogue with selected enterprises about the design of the building project.
- -Dialogue and interplay where the contractors' knowledge is incorporated in the design. Economy, extent and quality are optimised in this open process between client, consulting and construction companies.
- -A partnering agreement, which includes a description of the common objectives of the parties, determines the framework for the collaboration and describes the tools that have been chosen for following up on the collaboration. This could be the establishment of a steering group, use of incentives and/or key figures, arrangement of workshops and methods for conflict management.

Partnering can therefore be described as a **number of tools**, which can be used to establish an individual procedure that matches the conditions and preferences in the individual project.

Here tools are mentioned in the form of keywords like: elaboration of *common values and objectives*, specification of the parties' *success criteria,* establishment of a common *steering group,* development of *competencies* before and during collaboration, agreements about the use of *incentives and incentive earnings,* follow-up through visible results and *benchmarking,* use of *open calculations* and books, arrangement of *workshops,* design with *participation* of construction companies, rules for *conflict management,* establishment of cooperation *on site* and keeping key persons.

The basis for the implementation of the building project is the traditionally used contractual agreements, cf. Section 6.

3. Focus on users' values

3.1 Value-based collaboration

Value-based collaboration has already for several years been used as a management form in business enterprises. The use of values in now spreading also to the building industry.

The client is the pivotal point when a building project should be developed that satisfies the users' needs. The client gets a new tool for planning by formulating the users' needs as the values credited with importance in the daily use of the building.

It is a tool that gives everyone involved in the building project – users as well as companies – better opportunities for communicating than traditional means like drawings or descriptions. Therefore dialogue and the formulation of values is the way ahead if new building projects are to be developed that provide higher satisfaction for all involved parties.

An issue for example might be whether it is open space , a good indoor climate, a low noise level, good daylight or other conditions that are the most important, and how they should be prioritised if it should become necessary – which it usually does. And during implementation of the project – is the most important value respect, punctual information, responsibility or other conditions, or all of them?

3.2 Different user groups

All relevant users should be involved. Examples are staff or persons with special skills. If the staff is not known, knowledge and experience from corresponding organisations can be obtained. Skilled persons can be persons with specialist knowledge of technical conditions. Finally users who only spend a short time in the building should be mentioned.

The organisation of user participation should be carefully considered in consultation with the users who could be represented by individuals or groups – and the framework of their work should be known.

The parties – not least the client of course – must beforehand consider well their own value base as well as wishes to the common values (5). Next they should jointly assess what benchmarks would be suitable for follow-up and for showing that the project is heading in the right direction. And finally, the desired level of ambition to be achieved.

The values should be understandable, meaningful and determining for decisions as well as social relations.

4. What competencies are needed?

4.1 The need for competencies

It is a necessary precondition for a successful collaboration in connection with partnering that the client and the enterprises possess basic technical and economic competencies. However, they should be applied in other ways in partnering, for example by letting designers work in a more interrelated way with the construction companies than is the case in traditional collaboration.

Moreover, collaboration in connection with partnering implies that a need exists for special supplementary competencies that can support and promote the collaboration. Especially for the tools previously mentioned under the characteristics of partnering (6).

At the same time it is crucial for a successful collaboration that the entire group functions well as a team intent on implementing the actual building project as “Project Partnering Inc.”

4.2 Pivotal role of the client

The client should begin by assessing whether the client organisation possesses the competencies necessary for its daily operation in relation to collaboration in openness and confidence. It is also important that the organisation has an overview of which methods and tools that can promote collaboration in partnering.

The client can choose to supplement his organisation with a consultant with knowledge of the practical organising of partnering and tools for supporting the collaboration.

A distinction could be made between three forms of competencies in connection with partnering: *managerial, technical and personal*. The client – and the client’s consultants – are in a central position to ensure that the competencies necessary for the implementation of the building project are available.

4.3 Selection of partners

Through the selection of design and construction companies, the client can see to it that persons with basic competencies participate. And later *during collaboration,* for example in a dialogue with the partners and in workshops, the client can initiate a survey on a more detailed level to establish the need for competencies and establish agreements about development or incorporation of lacking competencies, if it is considered necessary.

In practice the client can at first *select* the companies through prequalification that are considered suitable due to their general – basic – references. At the same time the client signals that the tender documents will include a closer description of the need for competencies at the implementation of the actual building project.

When *awarding* the design task and subsequently the task of executing the construction work, or both at the same time, the client could as a next step let the description of persons participating in the collaboration, which has been prepared by the companies, form part of the assessment to select the companies.

In a large building project, the sub-criterion for organisation was given the weight 20 % and based on the CVs of key persons. It was further subdivided into design, execution and sub-contractors, each with 1/3 and marked on a scale from 0 to 13.

5.Establishing a collaboration

5.1 Tendering at partnering

It is important that the client as a **first step** at an early stage - before or during the brief – assesses whether partnering will be a suitable procedure for the actual project. By early assessment it will be possible to choose between several procedures, in particular between early or late partnering, cf. below.

The client's assessments must be made within the framework conditions in force. The most important for public clients are the EU Directive on Tendering and the Danish Act on Tendering. In 2004 the EU adopted two new directives. The Danish Act on Tendering is expected to be revised in 2005 (7) and (8).

Overall these changes support the possibility of partnering and specify some conditions in connection with tendering like the use of sub-criteria.

5.2 Early or late partnering?

When the client has chosen partnering as the form of collaboration for a building project, the **next step** is to find a partner. The basis for the tender (selection of partner(s)) could be the brief**,** outline proposal or scheme design.

A distinction can be made between early involvement of the construction companies, meaning before the scheme design (”early partnering”) or later for example after the client has had an outline proposal prepared (“late partnering”).

The client should decide which form is the more suitable for the individual building project. At the outset “early” cannot be considered better than “late”.

At present early partnering is used in approximately 60 % of building projects and late partnering in approximately 40 % according to one survey (9). For early partnering, design and build contractors are typically used, while for late partnering for example smain contractors or trade contractors are used.

In the background material for the tender the client must describe the demands and wishes to the collaboration, for example in the form of a proposal for a partnering agreement which includes requirements to competencies, cf. above. The client can choose to request the tenderers to provide proposals for items in the agreement and let the proposals be incorporated in the assessment of the tenders and thereby the award.

The **third step** is to enter into a partnering agreement, which will remain in force until tender and contract – and as a rule form part of the contract.

6 Partnering agreement

6.1 Traditional contractual arrangments

It is normal practice – and it is recommended – that collaboration aims to use one of the traditional contractual arrangements. There are no examples of joint and several liability that also include consultants/contractors. But it can be included in a partnering agreement that a later contract should include specific provisions for the cooperation with consultants in connection with the implementation of the contract like for example contact to the client.

The partnering agreement can involve the users and as a minimum it contains a description of how the users’ knowledge and values should be included in the planning.

It is recommended that the partnering agreement runs until handover. And it should for example include the socalled lean production, which could involve foreman and workers in the collaboration.

The agreement will also need to include an agreement on how to manage possible conflicts. Known methods are a bottom-up process for solving disputes, dispute Review Board, pre-emptive conflict management and mediation.

6.2 Main items of the agreement

Main items of the partnering agreement will typically be: a description of the *parties* and *the purpose* of the collaboration, a concrete outline of the collaboration with the establishment of some *success criteria*, the framework for the *economy* and the time schedule, a *programme* for the future building project with an indication of targets for quality and the environment, the *basis* for the collaboration and the contribution to the partnering of the parties, conflict management and possibilities for *cancelling* the agreement, the basis for the contract(s) and possible contracts concerning incentives/incentive earnings (10).

There are different views of where the partnering agreements should be placed in relation to the actual contracts regarding its implementation. One way is first to make the agreement with a description of the conditions for its implementation. This is a conditional agreement, which will be continued in a contract if the conditions are met. Another way is to make the agreement in connection with the contract. The agreement should decide the possibilities and conditions for termination of the collaboration.

7. Implemention of the collaboration

7.1 How to create a good collaboration?

The basis for the implementation of collaboration is the partnering agreement, which has decided the objectives and framework for the collaboration together with the tools will be used by the parties.

The collaboration can be organised in different ways with regard to the structure of the brief, time schedule for workshops, user participation, utilisation of competencies and establishment of groups.

7.2 Steering group

Large building projects should establish a steering group with the overall responsibility that the objectives of the agreement are met with regard to the design of the future building project as well as for daily collaboration. The steering group could be seen as the ‘board’ of ‘Project Partnering Inc.’

The steering group should be a non-executive body and strike a balance between being a controlling and an inspiring factor for the collaboration. The steering group should function during the whole building project.

In the previous section on ‘Characteristics of partnering’, keywords are used to indicate a number of tools that can be used to support the collaboration. It should be assessed from one project to the next, which of the tools are relevant just as the actual wording should be agreed between the parties.

7.3 Tools in practice

The three tools most frequently used are: *elaboration of common objectives, shared economic interests and common activities*, including workshops. These are used in nine our of ten building projects (3) and (9).

Common objectives have been agreed in approximately 85 % of building projects. In less than 10 % of the projects, they were agreed before consultants and contractors became involved.

In 65 % of building projects consultant and contractors are paid a fixed price. Here *incentives* are used such as keeping the time schedule, budget. In just under 70 % of the agreements with contractors and approximately half of the agrements with consultants this is used.

Regarding *conflict management* the most applied method is the bottom-up process for solving disputes/level model, where disputes as a starting point should be solved at the ‘lowest possible’ level. This method is used for seven out of ten building projects.

A particular characteristic of the partnering agreement is that it involves collaboration during execution on site. There are several experimental building projects, for example where lean construction is applied and a number of common activities are carried out as well, not least regarding safety and health.

7.4 Utilising experiences

During the whole course of the collaboration – from the client’s considerations concerning the future building project via the tender to handover – the parties will be gaining experience. Most will be continuously utilised, but a status after finalisation of the building project can make the experiences of a more general nature stand out and can therefore benefit the partners’ participation in a future building project – with new parties.

This could be effected through a workshop – maybe several for large projects – arranged when the building project has become operational, for example three months later (11).

8. Conclusions

The building industry provides the background for a number of basic living conditions and experiences in modern society. The interaction of a building with its users and their values during its whole service life will therefore become increasingly important in coming years.

In order to accomplish this task, it is necessary to develop forms of collaboration that ensure that the users' values are incorporated and their knowledge utilised. A first step has been taken in Denmark with a new form of collaboration called partnering.

A number of tools or elements are being developed, but already a picture of this form of collaboration is taking shape. The most important characteristics are an active client, dialogue and interplay between the parties of the building project and a partnering agreement including objectives for the collaboration, elements to ensure the collaboration and the contribution of the parties to the collaboration.

Abstract

Clients with focus on end-users expect buildings to facilitate their business objectives. The increasing importance of end-users satisfaction creates the need for a performance based approach as to allow the management on end-results, and to provide a language they can understand. With such an approach the match between the clients' business objectives and the buildings will be facilitated and as a consequence buildings can be treated as factors of business rather than a capital asset only. A holistic approach is helpful in monitoring and assessing the output during all phases of the process, from project initiation to use and facility management.

In many countries all over the world programmes are ongoing with the aim for more or less radical reforms in the building and construction sector, and procurement appears to be a key factor for improvement in delivering added value for clients. A significant future trend is recognised in an explicite role of clients and focus on end-users, and consequently, the need for best value procurement of the built asset as a whole is apparent. This, in turn, calls for innovation through more co-operation, because such an approach drives prime attention towards whole building performance rather than to technology of parts and components. In doing so, managing added value should be addressed explicitely in the interrelation of product, process, and people.

When best value procurement is the leading ambition, the price-quality ratio of the output should be in the selection criteria rather than the focus on lowest price of tender only. Clients should approach industry in a way that stimulate the vendors to launch their best professional performers for the job required, which in turn requires a professional outsourcing client attitude. This will stimulate the development of instruments that allow monitoring and improvement of the output over the lifetime of a building, and consequently enhance building and construction process innovation.

Key-words: Clients, End-users, Best value procurement, Performance-based approach, Reform

1. Introduction

The need for reform in building and construction is recognised worldwide. In particular the public client is a very significant client for construction and it is therefore essential that public sector procurement practices reflect the objectives of reform. If the large public principals, and also the large private principals set the trend, the rest will follow. These large organisations have buying power, and they can take advantage of that.

From the clients perspective, a building can provide substantial return on the investment, but to enhance this return the building must be seen as an asset that exists to facilitate the client's objectives with focus on end-users. Value is a crucial concept in the procurement of a building and is difficult to measure in numbers, means or technical solutions. A performance-based approach may be helpful because it focuses on end results with regard to the asset rather than on means with regard to the technology of parts and components.

It is crucial to identify the stakeholderships of the construction client in its diversity from real estate investors to property managers and principals on to 'once-in-a-lifetime-clients', in order to treat the role of 'the client' in best value procurement. Value creation should be enhanced for both client and industry, and a shared vision from the perspectives of clients, industry, and government may be developed on added value of building and construction. Such a vision can be implemented through the development of a method of performance based briefing, that can explicitely be related to best value procurement.

2. Procurement is key-factor for improvement

Procurement practices are of crucial significance in building and construction reform. Traditionally, procurement has been based on price. The introduction of 'non-price' factors and best value procurement in the award of contracts and of 'value for money' criteria and innovative approaches to tendering can have major impact. The central place of procurement in reform leads naturally to much greater focus on client requirements and on the need to raise the capabilities of construction clients [1].

2.1 An international trend

The Proceedings of the 1st Revaluing Construction Conference in Manchester UK 2003 [7] revealed an international trend towards more value and quality driven competition, and also public client leadership in procurement. Meanwhile interesting construction reform initiatives are found abroad, many of those taking a lead with the UK Rethinking Construction Programme. A Dutch programme 'PSIBouw' (Process and System Innovation in Building and Construction), designed to encourage innovation in the construction industry, is currently mobilising all those involved within the building and construction sector [1]. This research programme has secured substantial funding of approximately € 43 million from both government and industry for a 4 year period.

The first PSIBouw project was an inventory of international reforms in construction, including a study tour to Australia, Denmark, Finland, Hong Kong, Norway and Singapore. In total, around 75 meetings were held with key individuals and representative bodies in these countries, and the lessons learned revealed major findings on the fields of procurement, the role of the clients with end-user focus, and the need for an integrated approach in building and construction.

The international trend shows a consistent move towards non-price and value-based procurement, away from focusing on lowest price only. Examples from Australia and Norway revealed the advantage of qualifying and selecting parties on their competence in co-operation in high performance teams. Life cycle costing is an item of topical interest in the Norwegian building industry, and indirectly it does enhance value-based procurement, in particular because LCC assessment is now mandatory for all public buildings, following a Norwegian standard.

2.2 Best value and non-price factors

New procurement processes were developed in Australia, Hong Kong, and Singapore, with greater emphasis on past performances and introducing best value and non-price factors in tender evaluations [1].

The National Museum of Australia was constructed using alliancing principles in which risks were shared between the client and the supply side, and a trust and no-blame culture was promoted. Major infrastructure projects, like the extension of the Hong Kong Kowloon Canton Raiway Corporation have similarly been constructed under partnering arrangements, allowing close liaisons between demand and supply sides.

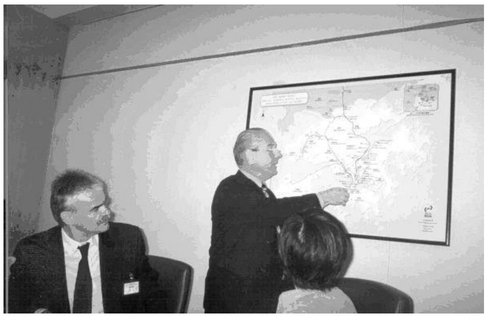

Figure 1: National Museum of Australia (left) and CEO Hong Kong KCRC Ian Thoms

The role of public procurement is evident in all countries visited, and public sector procurement practices reflect the objectives of reform. Some programmes, for example in New South Wales Australia, focused on the power of public sector procurement in developing a Code of Practice and a Code of Tendering, both applied in pre-qualification procedures.

The Department of Public Works in Queensland Australia improved the value for money effect by introducing rigorous pre-qualification standards, and new forms of contracts like non-adversarial, alliancing, and keeping regular dialogue with the industry. Leading private sector clients in Hong Kong and Singapore have adopted the same procurement principles as the public sector and so reinforced the reform process.

3. Clients with end-user focus

A significant future trend is the increasing role of clients with end-user focus.

The increasing importance of end-users satisfaction creates the need for a performance-based approach as to allow the management on end-results, and to provide a language they can understand. With such an approach the match between the clients' business objectives and the buildings will be facilitated and as a consequence buildings can be treated as factors of business rather than a capital asset only. There are good practices with the ASTM functional and serviceability requirements developed in Canada [5].

3.1 Construction Client Associations

In order to empower the position of the client in enhancing innovative construction practice effectively, clients should be properly identified and organised. In doing so a diversity of client systems related to types of clients, such as end-users, 'once-in-a-lifetime' clients, and professional clients may be distinguished. The so called 'intermediate' client – operating between client/end-user and industry – is particularly characteristic for the work of government building agencies. There are successful practices with Construction Client Associations in Denmark, Sweden, and Australia, all focusing on end-users, principals, and owners [2].

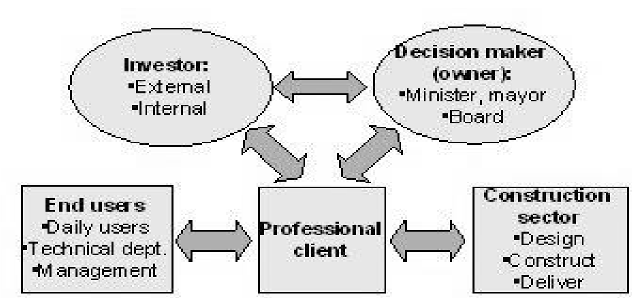

Figure 2: Professional client relationships – CEO Danish Construction Client Association Henrik Bang

These client associations, enhancing professionalism in clients, are currently developing as powerful driving forces for reform within the sector. Representing the majority of large construction clients, they have a sound impact on the development of improvements of products, process and services of the building and construction sector.

Demand driven research programmes are pushed by these client associations in Sweden, while acting as a Change Agent in construction, and professionalising their members, funded by the Swedish Research Council for Environment, Agricultural Sciences and Spatial Planning [6].

The associations membership ranges from every leading institutional investor, pension fund, property trust to private investors and developers, and as such, these associations can strongly influence the process of policymaking in procurement.

3.2 Client briefing methods

In order to facilitate understanding in client briefing methods, it is proposed to agree on an appropriate context that covers all the stages in the sequence of a building and construction process. This context is determined by three characteristics (Figure 1):

Firstly, briefing is manifest in all phases of the building and construction process, from project initiation on to use and facility management. It is in the nature of this process that alterations do occur all the way from the start to the hand-over of the built asset. Secondly, core competences affecting demand, production, and use and facility management are distinguished, and in doing so, domains of competences can be determined accordingly. For instance, demand competences are manifest within the phases of project initiation and definition, while product competences generally are in the phases of design, design documents, and construction on site, followed by the phases and competences of use/facility management.Thirdly, there is this continuous process of learning and ever improving expertise by effectuating the benefits from the process'life cycle, and as a matter of fact, the briefing process should start with the evaluation of the existing housing situation.

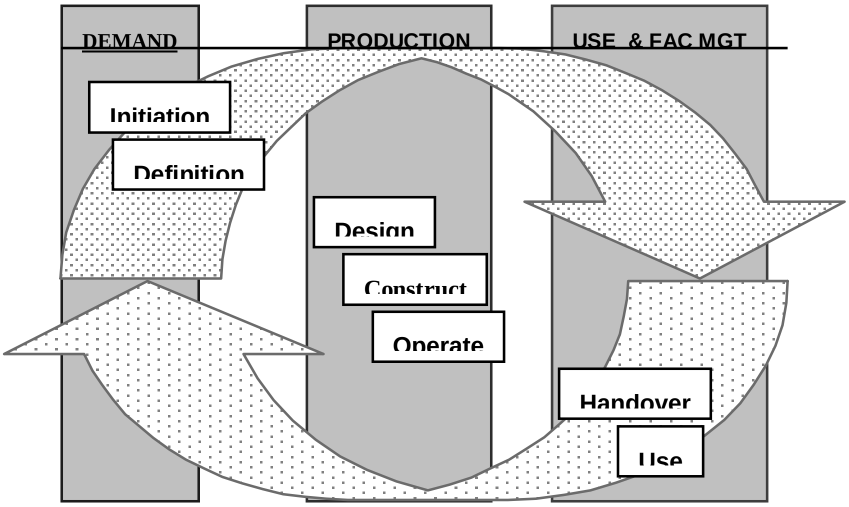

Figure 3: An appropriate context for the briefing process

Within this context new ways of briefing are developed using modelling techniques that provide client-organisation based functional outputspecifications, and can link these systematically to service quality, facility management, design, and costs [8]. The brief is converted into a digital model, that provide performance criteria in terms of organisational goals and ambitions, functional requirements, performance specifications, verification methods, and references of acceptable solutions. The method is applied in practice in behalf of the Dutch Treasury in the Hague, a € 200 million project, to be tendered in a concession form of PPP (Figure 4):

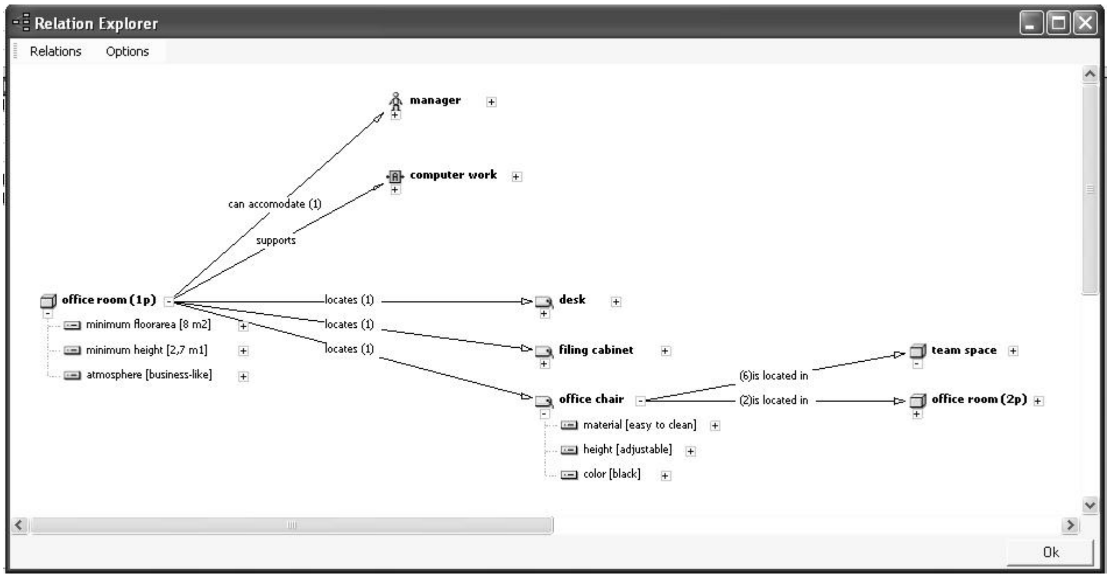

Figure 4: Modelling outputspecifications with focus on service quality [8]

3.3 Client assessment methods

Within the building and construction process from design on to hand-over, specific moments of risk for client dissatisfaction occur at the moments of transaction from one phase to the next one. One reason for failing causes is that the quality control traditionally relies on explicite assessment of technology of building parts and components (which not directly affect the clients expectations of performance), while the quality of the built asset as a whole (which indeed affects the client's organisational, economic and functional performance expectations) is being assessed 'pretty implicitely' beyond proper control, causing client dissatisfaction [9].

As a consequence, moments of risk are determined when matching assessment between the client brief and design, between design and construction documents, between desgn documents and construction on site, and finally, between hand-over and use within the so called domain of production competences, mentioned in 3.2 'Client briefing models'.

Each match is characterised by a different way of expressing (total) building asset performance, and in the traditional design and construction process it is definitely difficult to make sure that the constructed result matches the performance, that was initially expected by the client [3].

There are two causes to this situation: the lack of a systematic approach to the subject as an end result during the design stage, and the absence of a defined party that should be responsible for its implementation [10].

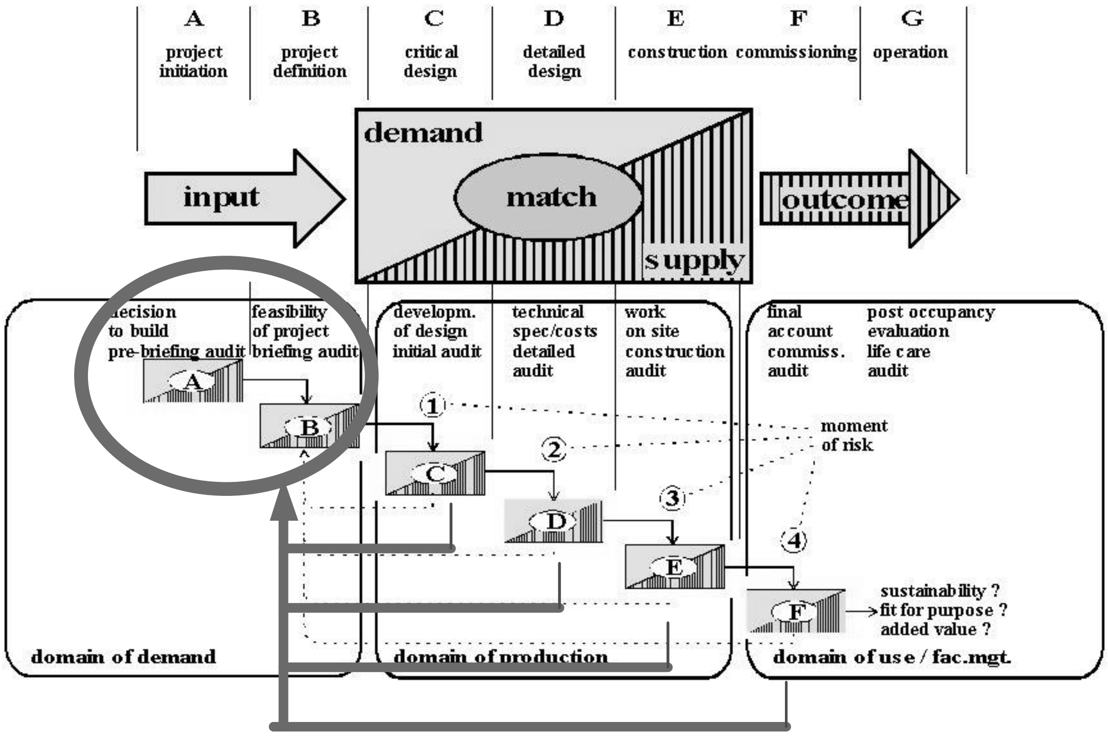

Figure 5: The moments of risk and assessment of brief [3, 4]

Therefore it is suggested to monitor and assess at all transaction moments between the phases during the process of production, and to focus all assessment, no matter in which phase, with reference to the initial perfomances required in the client brief rather than to the results of the result of the previous phase (Figure 5). The application of such a process enhances a systematic approach to the end result during the process of production, and it also stimulates the commissioning of a defined entity responsible for its implementation.

4. Best value procurement

Central to best value procurement is successfully recruiting the high performers in the design and construction industry. This way of recruiting is based on the Information Management Theory (IMT), followed by the Performance Information Procurement System (PIPS) and the application of the Six Sigma Model in construction [11].

If clients keep selecting vendors on lowest price only, these will consequently launch their cheap in-hired low performers, as to keep in business. But if clients act as ‘professional outsourcing clients’and select on inventiveness, creativity and sustainability, vendors will launch their high performers in order to keep in business.

4.1 Procurement strategies

From the viewpoint of the construction client, it may be obvious that procurement strategies start considering which services and activities to keep and to outsource when purchasing a built asset. Central to the clients'view may be the value for the end-user, and how to purchase this in best value procurement:

Clients may want value for money from their buildings by achieving a clear focus on meeting business needs; their immediate priorities are to reduce capital costs and improve the quality of the built asset by the right procurement strategy. A longer term, and more important, issue is reducing running costs and improving the standard of eventual existing buildings.

A specific trend is that best value procurement seems to be the leading ambition [2], and the price-quality ratio should be in the selection rather than the focus on lowest initial price only, because it will enhance product- and process innovation, and stimulate the development of instruments that allow monitoring and improvement of the output over the lifetime of a built asset.

These considerations are often part of the internal conditions of a projectspecific situation, and of course the market situation plays a substantial role in terms of external conditions prior to decide upon procurement strategies.

4.2 Decision support models

Recently in 2004, a projectspecific procurement decision support model was developed in co-operation between the Delft University and the Government Building Agency in the Netherlands, based on ex-post experiences and evaluation and ex-ante analysis of a few governmental real estate projects, i.e. the so called 'PAIR'model, which stand for Projectspecifieke Afweging Inkoop Rijkshuisvesting [12].

The model generates projectspecific recommendations for the strategy of procurement, as a result of an input of 11 procurement themes with an average of three procurement options each, considered within a projectspecific context of given project criteria (time, budget, organisation, quality expectations etc.), internal conditions (such as parties involved within the project, type and ambition of client in terms of involvement in the

project) and external conditions (such as the context of the project in terms of site, European regulations, market conditions etc.)

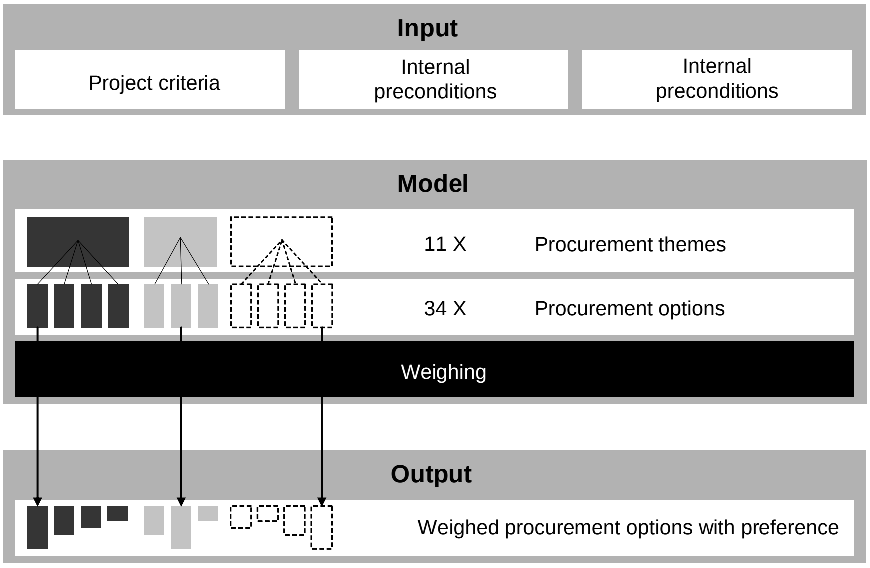

Figure 6: The 'PAIR-model', procurement decision support system [12]

The output of this PAIR model consists of weighting the projectspecifically selected procurement options within the 11 procurement themes, such as the division of project or process, number of vendors to co-op with, contractual relation between principal and vendor, design responsibility, risks and finance responsibility, criterion of selection, demand requirements, system of contracting, and reward sytem. In theory, there are 165.886 combinations of procurement options and strategies [12].

5. Conclusions

On the demand side, clients need to develop a greater ability to express the requirements and aspirations of end-users and society in a consistent and comprehensive way. Furthermore, they need to bring these requirements to the market in a way that challenges the supply side to produce solutions that maximise value for clients, while launching their high performers. Finally clients need to be able to assess the added value of different solutions. These changes may be summed up as the development of professionalism in clients. The creation of Construction Client Associations may promote more professional procurement. In some countries, existing organisations can form such associations, and in other countries, a special new initiative may be required.Training and educational courses can support dissemination of best practices and experience developed through these associations.

Procurement practices are of crucial significance in reform of the building and construction sector. They are the meeting point of demand and supply, through which the supply side responds dynamically to the demands of the clients side. Therefore, procurement processes need to encourage behaviour that is in line with aims for industry, placing emphasis on quality, performance, value, and the development of learning opportunities. To do so, however, implies a move away from traditional selection methods based on 'lowest price'. International experiences can provide a guide to the ways in which new procurement mechanisms may be introduced while maintaining proper safeguards against malpractice. Registration systems, together with transparent and accountable pre-qualification procedures, may play a major role in these new procurement processes.

Last but not least, there appears to be a large need for demand-driven research practices in order to support client professionality and innovation in best value procurement. A network of international knowledge, and experts, should be initiated on these fields, eventually by a starting initiative of the Dutch Knowledge Centre for Process Innovation in Building and Construction, CRC for Construction Innovation in Australia, Salford University, The Centre for Total Building Performance in Singapore, and VTT Finland.

Perceived Quality in Buildings: Human Factors in Global Quality Approach

Erminia Attaianese,
University Federico II of Naples - Dept DICATA (email: erminia.attaianese@unina.it)
Gabriella Duca,
University Federico II of Naples - Dept DICATA (email: duca@unina.it)

Abstract

To control integrated and complex dimension of building quality, we need to expand references to further cultural and scientific field, able to integrate technical aspects with human factors, in both design and management activities. Turning to human factors methodologies and tools we would be allowed to design and control global quality of building environment. The rising of user's expectancies level, the role of user's characteristics, and the variability joined to the specialization of activities, make so that an effective quality control must include human factors and user interaction with buildings.

Keywords: End users, Needs, User centred design

1. Introduction: a different approach to building quality

1.1 Overview

Observing the development of the idea of buildings quality from 70s up today, we notice that its control is moving towards systems more and more complex. In fact, we overcome a concept of quality as correspondence between performance and requirements applied of technical elements and we get to a new and more complex quality idea including the whole of building global performances, evaluated in relation to end user's needs. Users do tasks characterized by a rising involvedness, determining use models of architectural spaces even more specialized and composite, with a consequent increasing final quality demand. We can state that building quality is evolving in terms of all-in quality, even if user's expectancies are not clearly expressed in relation to the end-users perceptions. All that means that users expectations are referred to the human life-quality offered by buildings, also including behavioral, organizational and psycho-perceptive factors in human-building- interaction. At the present, quality aims coming from each specific field lead apparently to broken down and diverging visions, also because of the high-specialized competences and functions involved in building process.

1.2 The human centred approach

The new quality vision that comes out from most recent standards directions emphasizes the role of user's satisfaction. This point of view implies that quality has to be considered not only as a correspondence between building's performances to a set of predetermined requirements, but it results from the rate of motivation, support and gratification –in one word: satisfaction- felt using a specific system. Then, quality is anymore referable to the sum of all single performance, but is clearly related to the whole of combined effects of a system on its users, and so the quality has to be reported to the users' perception of system use. Moreover, the increasing relevance attributed to users' expectancies and their physical and behavioral characteristics, the variability of preferences and ways in everyday activities make so that an effective control of perceived quality should be based on human factors consideration and their interaction with built environment.

Methodologies and tools coming from human centred design provide an useful contribution to the built environment global quality. This approach, that requires competencies in ergonomics science, is able to improve all these field, today controlled separately one from the other, best fitting the current idea of building quality. In fact, ergonomics highlights relations among technical, organizational and human factors affecting -implicitly and/or explicitly- buildings' planning, design, fulfilment, fruition and management. User centred methodology founds on some basic steps:

- all users profiles definitions
- users goals in relation to each user's category
- task analysis of each user's activity
- definition of use requirements of product/service
- conversion of use requirements in technical requirements and details.

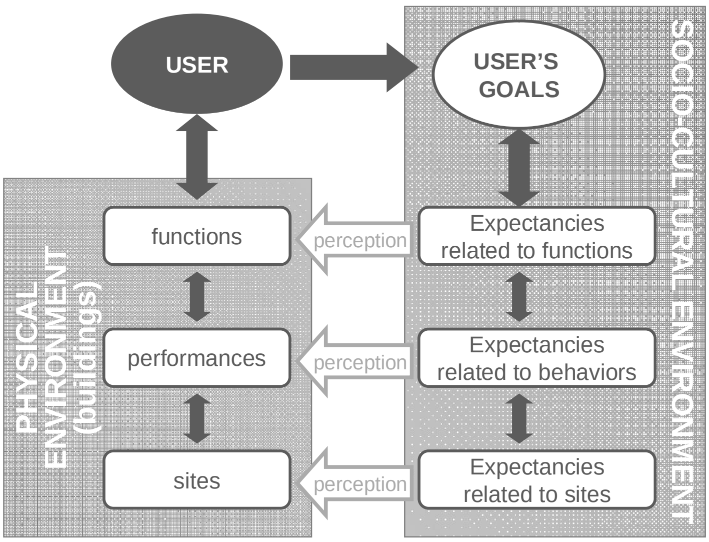

Figure 1: Relationships among context of use elements in built environment quality perception.

Operative techniques of User Centered Design produce many iterative processes in which users participate directly or indirectly to the design through simulations, interviews, observations, etc.

In fact, the user centered approach focuses the quality assessment on relationships establishing between systems and its users; then, following the user centered approach, quality means quality in use, appraisable through the usability measurements. Effectiveness, efficiency and satisfaction [1] are the three parameters allowing to define and measure specific markers for each observed system. Moreover, the wide variability of users' goals and characteristics make so that the usability or quality in use is not an intrinsic and absolute performance of a system, but it will depend on its different modality of fruition or, in other words, on the context of use [1].

2. Users and building quality

According the proposed approach the building quality topic is rather matching the building usability, that means the quality of interaction humans-built environment. The complexity characterizing a built system implies many multiple interaction levels, from a "sensorial" sphere to an "intentional" one, that is connected to goals pursued by users in buildings fruition. Following points are going to specify logical steps resulting from the user centred methodology applied to architectural design.

2.1 Users

First step is the definition of users' profiles. Already from this early stage, users' categories shall be defined considering the global use of buildings, therefore needs and expectancies of all users groups come up from the analyse of direct and indirect users, specific users (adults, older peoples, children, …), occasional users (cleaning or maintenance personnel, visitors, …). Each user's category is characterized by different physical and cognitive abilities or variables socio-cultural background that have to be taken into account when deciding building's technical requirements or evaluating its performances. For instance, we could think to diverse colours perception in aged peoples, to balance or orienting difficulties in children and elderly peoples but also to the potential way finding and orienting weakness in casual users of an environment [2].

2.2 Users' goals

Goals are explicitable according many different keys and can result differentiate and specifically oriented for each users' profile. For instance, we could look at some "cross goals", generally related to built environment; this kind of goals can be: adequate safety and security conditions, climate protection, pleasantness of spaces, environmental comfort, maintainability, etc. All these needs often are already considered in a traditional design process, but in a user centred approach they are enriched with many immaterial values and meanings. As an example we can quote the safety: user is not fully satisfied if its safety conditions are objectively assured by buildings, rather, in its opinion, the safety performance will result actually guaranteed only if user will feel safe and protected in a space.

Then, the quality control focused on users and their emotional and sensorial sphere affects perceived quality level and leads to rates diverging from a traditional evaluation measurement. Textures, orienting, wayfinding, identity of a places, are just some of aspects touching the actual level of user expectancies satisfaction that means the quality value according users [3].

About needs related to function hosted in a building, the user centred approach supplies some methodological tools able to highlight existing link between space-functional layout and organizational systems: in fact relationships and interferences among functions or actions and time, flows, rules can be clearly detected thanks to UCD. Therefore, a building quality meant as match between activities and living model is strongly supported by the UCD methodology that, on the other hand, stress the link existing between dwelling quality and the ability of building to support and make easier users activities (with reference to many useful concepts such as affordance, constraint lack, …).

2.3 Activities and tasks

From the task analysis of all users' categories is possible to understand their expectancies towards physical environment, strongly connected to their preferences and mode in tasks execution. In fact, through a tasks' analysis, a basic tool in usability field, designers can define what users need in term of actions or cognitive processes, to achieve their goals when interacting with any system. The task analysis consists in a task breakdown structure, where all actions are logically and hierarchically related to each other. Moreover, some specific analysis such as link or layout analysis, allow to observe modality of tasks carrying out and makes designers able to specify all that factors in built environment so that favour or hinder users life condition as regards to their goals [5, 6].

2.4 Use requirements

All data gathered and analysed in previous steps supply information on those characteristics of built environment necessary to satisfy the whole of users expectancies. So, general and technical requirements definition step become a strategic phase in building process because in this moment, and on the basis of all prior analysis, the quality process can assure that all actual users demands -and not those ones supposed by designers- will be transposed in technical requirements and building's detail characteristics. In fact, technical standards, designer experience, conventions and cultural references give to designers a "hybrid" model of users' needs, hardly controllable without a specifically user oriented design methodology [4].

3. Managing the building process through perceived quality

Building process in characterized by a plurality of involved actors, expressing different and, sometimes, opposite quality aims. In fact, in end use phase, quality perceived by end user coincides with the life quality offered by buildings, but during design and construction stages the different subjects have priority, and then quality aims, very dissimilar to end users' ones. This intersection and overlapping of dissimilar quality aims, joined to the process complexity, make so that each subject recourses to its own control criteria and evaluation system, from which could come contrasting solutions. Instead, the user centred approach, thanks to the possibility to recognize and relate needs and expectancies according more point of view, is an useful support to an unitary management of building process.

It seems now useful to report how ergonomic competencies support each process actor, contributing to improve the all-in process efficiency. First of all we have to consider that user oriented analysis is very helpful for customers, because they can better express they needs and, then, formulate in a more appropriate and not generic way their requests; moreover, if customer is not end user (i.e. the case of public buildings) UCD techniques allow the respect of end user "mental model" [7] for spaces rather a stereotyped or unreal one. Finally, the initial clarity about needs makes plain and effective the communications among customers and other involved subjects, reducing mistakes and ongoing modifications.

On the other hand, designers' activities are facilitated by UCD because this approach supplies a well defined set of needs and requirements. This condition allows to save time and resources carrying out planning activities, thanks to the high quality and quantity of input data; besides the user centred approach focuses the choice among many spatial or technical alternatives respecting not only management aspects (durability, maintainability, …) but also fruition ones (layout flexibility, psychological effect of environment, …).

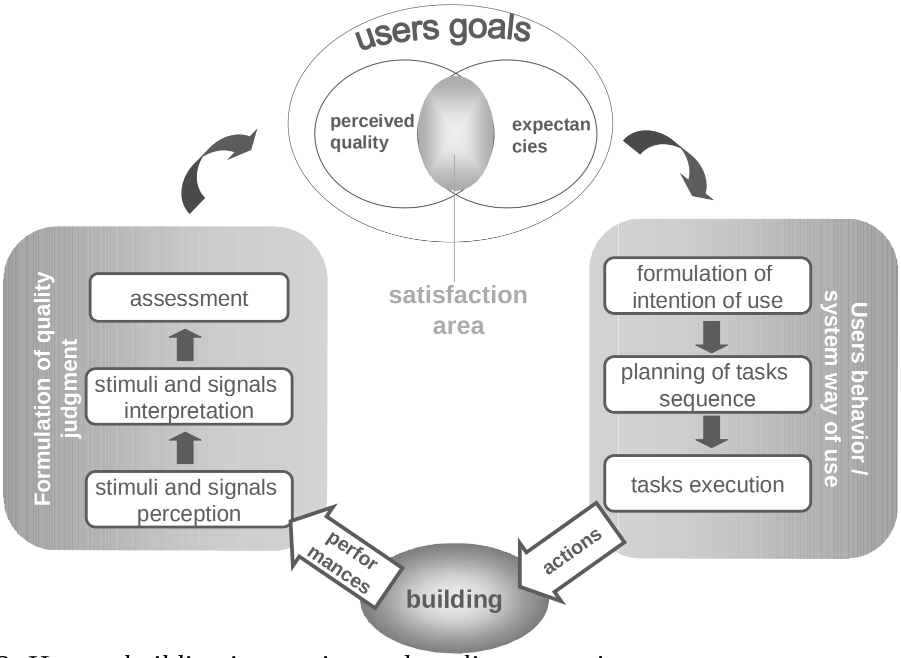

Figure 2: Human-building interaction and quality perception

4. Conclusions

Contribution of ergonomics to each step or function in building process allows to highlight relationships between human, technical and organizational aspects establishing in planning and design of buildings, benefiting and managing of real estate. Therefore, basing the building quality control on quality or qualities actually perceived by users is a strategy to improve building quality in either its aspects: formal and substantial ones. In fact, to the increase of efficiency levels in building process can correspond also a life quality improvement for direct and indirect users. This approach is tangent the TQM one and offers operative tools and theoretical references able to control the relations setting among many variables of building system and, finally, allowing to reach a global quality.

Abstract

The National Health Service (NHS) sector in the UK will be undergoing dramatic changes in the next few years. This is due in part to changing service user requirements and the implementation of the Agenda for Change programme, Department of Health [1]. Many healthcare providers within the NHS have lost track of the true needs of their service users and are trapped in outdated views of what healthcare delivery is all about. This is evidenced in the report by Nigel Crisp (NHS chief executive) in October 2002, published by the Department of Health. This report [2] clearly stated that the NHS needs to refocus its management efforts, engage with patients, staff and the public and build momentum to manage for excellence.

This paper describes a post-graduate research study into service user experience as a key element of service excellence in Primary Care Trusts (PCTs) in the NHS; and the notion of user-based 'healthscape'. The study employed the use of literature review and a case study approach to the collation of data. Analysis was primarily undertaken through content analysis.

The paper presents the results of a thorough examination of the impressions of the users through the entire healthcare experience identified through a survey of healthcare users in the case study trust, and a review of the current measurement techniques in the PCTs, which suggest that the current system is not representative of user experience. It also suggests how to move forward in capturing and measuring user experience in the pursuit of service excellence.

Keywords: Service User Experience; Healthscape; Service Excellence.

1. Introduction

1.2 Aims and Objectives

The aim of this paper is to investigate the construct of user experience as an integral part of service excellence within the NHS healthscape. Its objectives are to recognise and scrutinise the methodologies currently used within PCTs in the NHS to measure user experience in pursuit of service excellence; and recommend more effective ways of measuring user experience.

1.2 Overview

It is not so clearly accepted within the NHS that user experience is a critical indicator reflecting the strength of healthcare delivery. This is evident in the findings of Hwang *et al*, [3] who attributes these deficiencies to the lack of clarity and consistency in understanding the determinants of user approval. While service excellence assessments based on user experience is a useful guide, it is important to continue to strive for improvements which reflect the changing marketplace. Against this backdrop it is important to continue to reassess user experience.

Given the central role that service users can play in the excellence of any organisation in general and in the NHS in particular it is, perhaps, surprising that the current state of knowledge regarding user experience seems somewhat limited. There is no consensus on the definition of user experience or what it constitutes. This ambiguity also extends to its role within the evaluation process of service excellence, conceptualised as driven by the user experience. Users do form impressions about a range of service excellence constructs and these impressions vary across service providers and individual users. What is not clear is the extent to which these impressions are used, if at all, once the service has been experienced in a user's evaluation of service excellence.

2. User Experience

2.1 What is User Experience?

User experience is a journey through which the user senses the core benefits and the pleasurable performance of the service transaction in finding and approaching the service, interacting with other users in the right environment and departing from it, Abusaid & Alexander [4]. This definition implies that in order for users to experience the service, they have to go through a multifaceted cycle. This cycle starts from the moment that the user seeks to approach the service, makes a connection through the telephone/ internet and goes all the way through until the service is actually experienced and the user leaves the 'servicescape'.

According to the Oxford Advanced Learners` Dictionary [5] a user is "*a person or thing that uses something*", whilst experience is "*an event or activity that affects some one in some way: enjoyable, exciting, unusual or unforgettable*". Experiences can be classified into four categories, Pine II and Gilmore [6]:

Entertaining experience - a passive way to engage a customer and attract an audience of shoppers.

Educational experience - where the customer immerses in the event developing before him. This type of experience requires an active participation of the customer in the event to increase his knowledge and skill.

Escapist experience - where the customer is completely immersed and actively involved in shaping the experience.

Aesthetic experience - where the customer is immersed in an environment but has little or no effect on it, leaving it untouched.

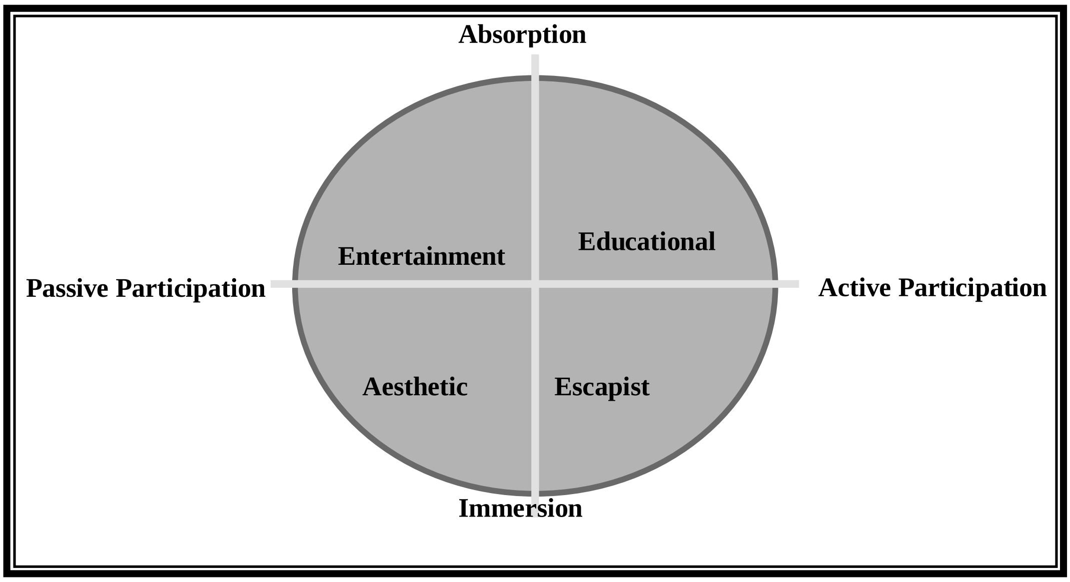

Figure 1: The Experience Realms, Pine II and Gilmore [6]

The escapist experience is the type of experience that should be promoted and encouraged within the NHS, because the user is completely absorbed and actively caught up in influencing the experience.

2.2 How does user experience differ from user satisfaction?

The NHS in the UK has witnessed the introduction of numerous quality initiatives over the past decade; driven by the realisation that patients were not satisfied with the health care delivery, and the necessity for the NHS to restructure in order to better respond to patient demands. The general consensus is that there are too many initiatives following on one after the other. Furthermore, most of these initiatives seem to lack two important features: relationship with each other, and the integration of all aspects of the organisation's activities into focused action on continuous improvement and customer desires, Stahr [7].

User satisfaction within the UK NHS tends to be based on assumptions about users needs from the NHS perspective. Many approaches deployed to measure user satisfaction neglected the impact that the process of healthcare delivery may have on the user satisfaction.

User experience differs from satisfaction in the sense that it allows the user’s own interpretations to be discovered. Research to date has been regarded by the researchers as questionable because it does not address issues that directly matter to the service users. Furthermore, the researchers identified that most established methods of measuring user experience are within the secondary healthcare sector, which has a different role to PCTs. In addition, the current measurement system imposes issues that are of concern from an NHS perspective, and not from the user perspective. It was felt that this was an issue of concern for the rigour and reliability of the measurement of user experience in the primary care setting.

2.3 Factors affecting user experience

Rowley [8], [9] applies factors that contribute to the user experience to liberalities and museums. These factors are: speed of service delivery, convenience, age, choice, life style, discounting, value adding, customer service, technology and quality (see table1 for further details).

Table 1: Users impressions of PCT healthscape

Healthcare Provider		Impressions of Service	Impressions of Environment
GP	Single-handed ( )		
	Group practice ( )		
Practice Nurse	Single handed ( )		
	Group practice ( )		
Dentist's Practice	NHS ( )		
	Private ( )		
Chemist's Shop	Incorporated ( )		
	Not incorporated( )		
Opticians	NHS ( )		
	Private ( )		
PCT: physiotherapy, paediatric, district nurse, out of hour, health visitor, minor surgeries, speech & language therapy, contraceptives			

Some of these factors may not necessarily apply to all organisations, although there are some common factors that can be shared. For example, discounting can be more influential in profit driven organisations and less so in non profit making organisations such as the NHS. Furthermore, organisations that rely on handcraft work would be less affected by technology than those that are heavily dependent on technology such as the NHS.

2.4 A typical user experience within NHS PCT

As mentioned earlier**,** user experience is defined as a journey, which implies that the user will go through a sequential process. This process varies depending on the type of healthcare provider and also on circumstances that a user may experience (see figure 2). The user journey according to the figure 2 consists of eight sequential phases. Phase one is initial contact where the user will contact the doctor's surgery either by telephone or the Internet to make an appointment. The second phase involves the way in which the user will get there for the appointment. This involves physical appearance at the surgery either by walking or by any other means of transport. The third phase is entering the surgery. This phase is important because the user starts to engage with both the service and the 'servicescape' at this point.

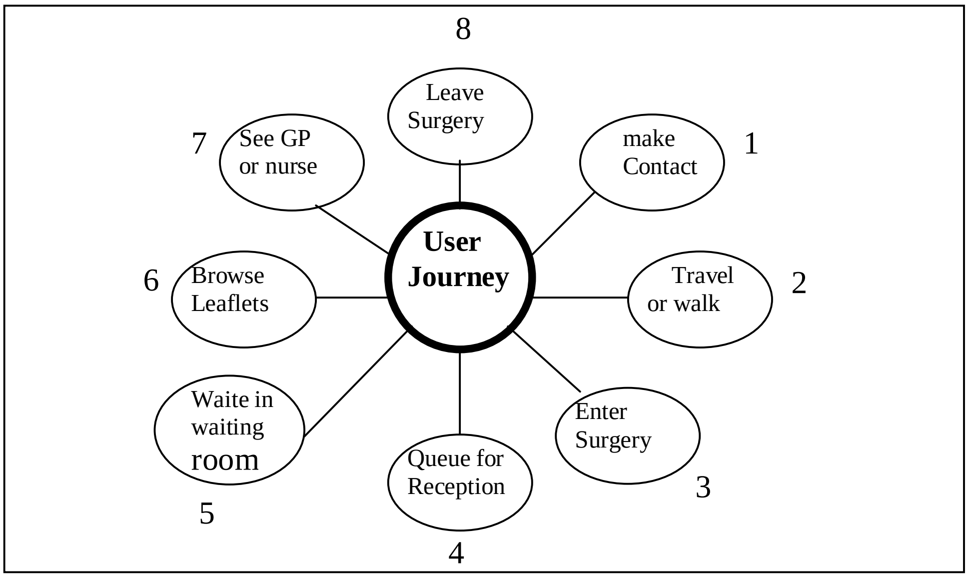

Figure 2: A typical user journey to a doctor's surgery

Having walked into the surgery, the user will interface with the receptionist. This can take the user a while until they are attended to because of the queue. At stage five, the user is asked to take a seat in the waiting room to be seen by either the GP or practice nurse. Once the user secures a seat, they then tend to wander around, usually looking for something to keep them occupied such as browsing through the surgery leaflets or a magazine. The user will then be seen either by the GP or practice nurse and departs the surgery either with a positive experience or otherwise depending not only on the quality of care received but also on the quality of process of accessing and exiting the 'servicescape'.

2.5 How do PCTs measure user experience?

The key role of a PCT within the NHS is the development, administration, provision and delivery of healthcare to the local community, in conjunction with its partners. Improving the health of the community is not simply about providing the best health care services, but also about delivering the right mix of health promotion activities and social care services. This differs from the key role denoted to other trusts such as acute and mental, which is the treatment and curing of illnesses, rather than the initial prevention, Salford PCT [10].

A review of PCT services to make them fit for purpose for staff and patients, rather than systems, has led inevitably to a radical rethink in the way that the PCTs' healthcare services are provided. This new way of thinking about primary healthcare has affected almost every area of the PCTs activities, as health and wellbeing cannot be separated from housing, employment, the environment and a thriving local economy.

An examination of previous work carried out on behalf of the Commission for Health Improvement (CHI) and Patient Environment Action Team (PEAT) has shown that the basis on which patient experience was interpreted cannot be traced back to their roots. From a research perspective, an understanding of the basis is important to ensure the reliability and validity of the outcomes. Many questions currently remain unanswered which impact on the reliability of current measures.

CHI identifies five domains for measuring patient experience [10], namely:

- Access and waiting;
- Safe, high quality, coordinated care;
- Better information, more choice;
- Building relationships;
- Clean, comfortable, friendly place to be.

Their definition of patient experience is based on the following:

- Preliminary discussion with stakeholders in the NHS and Department of Health (DoH) about issues to address in the surveys;
- Review of the existing literature and surveys;
- Focus groups with Acute Trusts' users to identify what matters to them; and
- Drafting, testing and piloting the questionnaire for 2003/2004 carried out with patients who recently experienced Acute Trust services.

Further investigations indicated that the development of the questionnaire used by CHI to assess user experience within PCTs has followed the same developmental process as for other NHS Trusts. This process is regarded by the researchers as highly alarming, because it does not address issues that directly matter to the service users in PCTs.

3. Research Methodology

3.1 Methodology

The purpose of this study was to explore how NHS PCTs service users experience 'healthscape' in pursuit of service excellence. A mixed (phenomenological and positivist) approach was used, allowing the user's own interpretations to be discovered. Further, this study sought to explore key impressions of service user experience as an integral part of service excellence in NHS PCTs, initially through a pilot study, and subsequently through a questionnaire-based study. Hence the mixed approach involving a combination of both qualitative and quantitative methods has been used for this research. Qualitative and quantitative methods can be seen as complementary, with different emphases in different disciplines, but sharing a heritage of logical thought and empiricism, Preece [11].

Case studies have been employed as a part of the research strategy embedded in a positivist and phenomenological framework, Yin [12], which does not show a concrete use of single or multiple case studies, but rather the whole research process as the case. By using multiple approaches, the researchers were able to triangulate the data gathered in order to generate better judgement on their interpretation. Yin *et al*, [13] supports this view stating that the case studies that adopt such methods are rated more highly than those that rely only on a single source of data. In addition, the case study approach as Yin [12)] suggests, is the preferred strategy when 'what', 'how' or 'why' questions are being posed, and when the focus is on a contemporary phenomenon within a real life context.

Five methods of enquiry are employed for data collection, and as a means of examining customer (service user) experience and views in pursuit of service excellence within the case study organisation. These are: literature survey, pilot study, focus groups, questionnaire and workshop.

3.2 Literature survey

The literature survey was based on text books, historical research and refereed journals on a number of relevant topics including performance management, service quality, customer satisfaction and service excellence. Literature review of existing and publicly available reports and documents regarding current user satisfaction measurement was also undertaken. This represented the first phase of the research and` set the background for future work.

3.3 Pilot study

Pilot studies refer to either a mini-version of a full-scale study, or a specific pre-testing of a research tool or method, van Teijlingen and Hundley [14]. The aim of this pilot was to identify service user experience. The study required an exploratory case study to be undertaken.

Preliminary data was acquired through face-to-face semi-structured interviews with eighty residents in the catchment area of Salford. This provided an opportunity to explore and gain insights into, and clarification of how impressions of 'healthscape' experiences were formed.

The semi-structured interviews consisted of two parts. The first part compiled general information such as local gender, age, employment, home ownership, ethnic background, disabilities and the use of PCT facilities (doctors' surgeries, dentists, chemists opticians, other) in the last six months.

The second part addressed the users' overall impressions of PCT 'healthscapes' in Salford. It addressed issues related to both their impressions of the service as well as of the environment in which services are delivered (see table 2).

Table2: Key impressions of service user experience

Issue	Service	Frequency	Environment	Frequency
Politeness of receptionist	√	78/80		
Waiting Time	√	77/80		
Friendliness of receptionist	√	67/80		
Understanding of receptionist	√	65/80		
Helpfulness of receptionist	√	62/80		
Quality of care	√	57/80		
Comfortable Waiting area			√	49/80
Appropriate furniture			√	41/80
Children play area			√	37/80
Quantity of care	√	35/80		
Choice	√	34/80		
Cleanliness			√	36/80
Up to date magazines and news papers			√	33/80
Car parking			√	29/80
Lighting			√	27/80
Communication			√	20/80
Colour			√	25/80
Security			√	18/80
Disabled facilities			√	10/80
Access			√	07/80
Signage			√	03/80

3.4 Focus groups

The next phase of the research would be based on a number of focus group sessions facilitated with users of Salford PCT 'healthscape'. This is deemed to be crucial for the rigor and reliability of the measuring instrument. According to Miles and Huberman, [15] the best way to improve credibility and acceptance is through the improvement and the rigor of techniques for data collation and analysis.

3.5 Questionnaire

The fourth phase involves the use of postal questionnaires to measure customer (service user) experience in Salford PCT, based on issues identified in the interviews and focus groups. Postal surveys are a powerful, effective, and efficient alternative to the telephone survey and personal interview. The postal survey was deemed appropriate as it enables easy access to population samples. Respondents are more likely to provide honest answers than they do to other interviewing methods, ASA Series [16]. Writers perceive that the biggest disadvantage to postal surveys is a low response rate, ASA Series [16], which is not necessarily true. Good planning can lead to response rates as high as those obtained in telephone or face-to-face distribution techniques, ASA Series [16].

3.6 Workshop

The final phase of the research would involve the validation of the findings through a workshop with a panel of experts and participating PCTs. A major benefit to be derived from this will be to gain an understanding of what has already been done, what needs to be done, and where potential opportunities and/or barriers may lie. It would also assist with the verification of data, and help generate a rich picture of FM service excellence practices and the impact that they may have on the user experience in NHS PCTs.

4. Case study

4.1 Case Study Organisation

Salford is the fourth most deprived local authority area in the North West of England, and 28th nationally. The city has considerable health inequalities as a consequence of lower educational attainment and unemployment, access to services and huge differences in lifestyle.

Salford PCT serves a population of around 234,000 people who are cared for via 61 GP and 41 dentist practices. Children born and raised in families of lower socio-economic groups are more likely to experience declining health later in life, and Salford residents have a life expectancy almost three years below the national average for men and almost two years below for women.

The PCT is a key participant in Britain’s biggest ever project to improve frontline health and social care facilities and services and has been driving forward radical plans for new health and social care centres, funded via the Manchester Salford and Trafford Local Improvement Finance Trust (LIFT).

4.2 Research Findings

The interview schedule took place between June until September 2004. The lead researcher visited each venue, and the duration of the interviews varied depending on the number of users at the different venues. In order to ensure complete and accurate records of interviews, hand written answers were taken. Each user was asked for the details of their impressions formed about the healthcare delivery and the environment in which it took place. Several key issues were identified, and the users were asked for more details wherever necessary. After the interview schedule, all the notes were transcribed to analyse the interview findings. These were compiled in table 2, and highlight the fact that user impressions reveal important facts as to whether the PCT is responding to the needs and desires of the healthcare service users, and helping to facilitate the provision of 'healthscape'.

However, as with any investigative process, there are always potential difficulties to be encountered somewhere along the line. Therefore an evaluation was made by the lead researcher to identify any difficult elements to the study that could hamper the progress and successful outcome of the research. It was found that some of the service related elements detailed above may be difficult to determine because of the subjectiveness of some of the measurement criteria. For example, in determining how polite and friendly the receptionist is, it may be difficult to analyse real-life scenarios and quantify how much politeness and friendliness have been dedicated by the receptionist.

The next step in this research was therefore to identify and prioritise the demands of the service users of healthcare delivery within Salford PCT through a questionnaire, based on the outcomes of the pilot study. From this basic mapping (table 2), and the data set that underpin it, it was possible to prioritise and show the service delivery related impressions in terms of importance.

As table 2 demonstrates, out of eighty service users interviewed, politeness of receptionist was the most highly cited occurring seventy eight times. Waiting time came second with seventy seven citations, friendliness of receptionist scored sixty seven citations, and so on. Quality of care came sixth with fifty seven citations, and choice came eight with thirty four citations. This highlights that an improvement in the politeness of receptionist, will greatly improve the perception of healthcare services in the PCT.

On the other hand, an analysis of key environment-related impressions (table 2) shows that a comfortable waiting area was most important with forty nine citations. This along with appropriate furniture (forty one), children's play area (thirty seven) and cleanliness (thirty six) were more important to healthcare service users than choice (thirty four).

5. Conclusion

Although changes in healthcare performance measurement in the NHS are currently in the process of being implemented, the earlier findings of this study still apply in terms of the relevance and reliability of previous measurement tools in use for measuring PCT performance. Previous measurement criteria did not truly reflect user needs and requirements to ensure the measurement of user experience or service excellence.

The mixed approach adopted by this study has enabled the in-depth exploration of user experience in the Salford PCT using a variety of research tools. These highlighted the fact that users found the highly subjective areas of politeness, friendliness and comfort very important. These have never been previously measured in determining user experience.

From a Facilities Management (FM) point of view, the emergence of FM related issues from seventh position down on the grid (table 2), with the exception of choice, may be taken in two ways. The first is that they are not as important to users of PCT services as the people and quality and of care issues. However if we consider the fact they represent thirteen out of the top twenty-one citations for user experience, we begin to see the importance and contribution of the FM function to user experience in this sector.

Another emerging concept is that of the healthscape, i.e. viewing the delivery of healthcare services in the user's perception of enjoyment of consumption. This forms the basis of future work to be undertaken in this research. It also represents for Salford PCT, the first step from delivering a quality service towards service excellence.

Abstract

Global Engineering and Manufacturing in Enterprise Networks, GLOBEMEN, is a three-year (January 2000- January 2003) research project with an estimated effort of 1000 person-months. It is part of the global Intelligent Manufacturing Systems (IMS) program and the project consortium has 19 participant organisations dispersed across different IMS regions ....

Experience from several hospitals indicates challenges according to usability of hospital buildings, associated with the rapid and continuous changes in the hospital organization and use of technology. Experience also shows that the hospitals are having difficulties in adapting existing buildings due to new requirements and user needs. The quality of hospital buildings depends on the buildings ability to absorb organizational, operational and technical changes.

Usability is defined as the *"….effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment"* (ISO 9241-11, 1998). According to this definition, a product's usability is determined by 3 key factors:
Effectiveness – whether users can achieve what they want to do with the product.
Efficiency – how long it takes them to achieve it
Satisfaction – their feelings and attitude towards the product

Hospital buildings are characterized by major complexity, and hospital operation are affected by rapid changes and trends. Planning and design of hospital buildings reflect a view of society, humanity and patients at all levels, from the location, overall concept and urban plan, down to the architecture and design in the immediate surroundings of the patients and staff. In recent years there has been a changing trend in cultural and ideological aspects due to hospital operation, and an increased focus at the patient, patient's rights and participation in the treatment situation.

Will this ideological change affect usability of hospital buildings? This paper is discussing some of those challenges arising according to the relationship between usability of buildings and a patient focused hospital, and is discussing whether patient focus is leading to usability of the

hospital buildings. These issues are discussed in relation to planning and design of the St. Olav’s Hospital in Trondheim.

Keywords: Building performance, hospital, patient focus, usability.

1. Challenges in hospital buildings regarding technical and functional aspects

Hospital buildings are characterized by major complexity, and hospital operation are affected by rapid changes and trends. In accordance to Jonassen et al. [1] the supply of health and care are continually changing world over, and the speed of change is ever accelerating. In the last decades the hospital sector has been influenced by a tremendous development within ICT and medical technology. This has led to more focus on adaptability of existing buildings.

Planning and design of hospital buildings are on all levels reflecting a perspective on the society, human beings and the patients, from localization, concept and town planning, down to architecture in patients and hospital employees close surroundings. A brief summary of hospital organization and design in the different eras is given below, based on how changes in this perspective have affected organization and physical surroundings within the hospital.

In recent years there has been a changing trend in cultural and ideological aspects due to hospital operation, and an increased focus at the patient, patient’s rights and participation in the treatment situation. This paper is focusing how ideological changes due to patient focus is affecting usability of hospital buildings. Will a stronger patient focus in the planning, design and daily hospital operation lead to greater usability of buildings? We will discuss some challenges in handling the relationship between usability of the buildings as physical surroundings, and whether a stronger patient focus is leading to usability of the hospital building. In the paper we will use the case St. Olav’s Hospital in Trondheim, and the planning and design of this project. St. Olav’s Hospital is a large ongoing redevelopment project of the old regional hospital in Trondheim, and the project has a pronounced objective of a high degree of patient focus in the hospital development.

Our studies are based on literature studies, the theoretical framework developed by CIB TG51 “Usability of buildings” [2], and studies of project documents and interviews from the St. Olav’s Hospital project. This is a preliminary study, where we develop the research questions for a following PhD-study.

1.1 A brief historical summary

In the 18th century a demographic growth in the population, wars and epidemics resulted in establishing institutions with a diffuse distinction between treatment, detention and penalty.

Gradually the treatment aspect appears more and more clearly, foundation of medical science gains greater scientific understanding, and hospitals arise as separate institutions [3].

The physical surroundings in hospitals were a large problem in the public health service in the 19th century. Florence Nightingale wrote in her “Notes on Hospitals” (1859) that the death rate at the largest hospitals in town was considerably exceeding that of patients suffering from the same diseases, treated other places. In her “Introductory Notes on Laying-in-Institutions” (1871), she pointed at several cases of illness caused by physical surroundings, and referred to design, light, air and ventilation as important elements in hospital buildings [4].

The development within the hospital sector in recent decades has gone from the pavilion hospital, via the block hospital, to the “neighbourhood hospital”, representing the hospital model of today. This has happened based on the development in medical technology, and the changes in main nursing philosophy have been the driving forces behind this development.

The pavilion hospital emerged as a consequence of the problems at the 19th century, and was focusing daylight, air, ventilation to offer satisfying hygiene for the patients. The hospital buildings were divided into separate pavilions, which were gradually connected with glass corridors, to simplify the work for the employees and transportation of the patients.

The major hospital development in Norway has taken place periodically, being at its maximum in the 1950ies and the 1970ies [5]. There was a large expansion in the health sector in the 1950ies, and the planners adopted organizational models from the industry aiming to increase the efficiency and productivity in the hospital sector. The nursing philosophy was based upon specialization, hierarchy, centralization and top management, and this hindered communication between the patients and the employees. Satisfying the patients’ physical needs was in focus, and little attention was shown the psychological, social and spiritual needs of the patients. The block hospital was developed as a response to the quantitative objectives related to efficiency and requirements due to the technological development at that time. This was also the dominating trend internationally, among others in Germany, where “medicine in focus” was the leading ideology. In the 1960ies and 70ies the functionalism was the predominant style in the hospital architecture. Hospitals were designed and built as “nursing factories” in high-rise blocks, focusing quantity and centralization of the hospital activity. Esthetical quality was not given priority.

In the 1970ies a critical debate related to the hospitals as “nursing factories” arose, and the basic attitude towards hospital planning started to change. Bad working conditions and mechanical treatment of the patients was focused in the media, and the centralization and the de-humanifying due to the physical surroundings in the hospital was strongly criticized. This lead to a search for new operational models in the hospital, and a development towards hospital projects of smaller scale, decentralization, and a higher degree of intimacy and tighter contact between the employees and the patients [6].

1.2 Patient focused hospital

As mentioned above, in recent years there has been a changing trend in cultural and ideological aspects due to hospital operation, and increased focus at the patient, patient's rights and participation in the treatment situation [7]. Hospitals have moved from being focusing efficient treatment to a higher degree of patient focus. The patient is no longer regarded merely as a "product" being in hospital to get "fixed", and respect of the patient is in a higher degree ensured in the hospitals of today. Besides scarce economical frames has been leading to further focusing efficient examination and treatment, a high exploitation of the resources and productivity, and this is changing the way the hospital is being operated.

An option of freely choosing hospital for treatment, competition from private actors within the hospital sector, together with the threat of outsourcing of services, affects the requirements of change within the public hospital sector. On this basis, the hospitals planned and built today give the expression of being founded on another fundamental attitude towards health and care than the traditional, by putting the patient in focus.

The organization and design of several projects is based on the Planetree philosophy, which is a philosophy especially focusing the patient and seeks to improve the medical treatment seen from the patient's point of view [8]. The fundamental values of the Planetree philosophy is trust, intimacy, dignity, security and confidence, holistic care and treatment, information, participation in decision-making, health promoting physical surroundings, and network support. The philosophy emphasizes to personalize and humanize the hospital treatment, and make it less unfamiliar both for patients and relatives. The Planetree philosophy is besides representing a value based and holistic patient perspective.

1.3 Usability of hospital buildings

Experience indicates challenges according to usability of hospital buildings, associated with the rapid and continuous changes in the hospital organization and use of technology. Experience also shows that the hospitals are having difficulties in adapting existing buildings due to new requirements and user needs.

The quality of hospital buildings depends on the buildings ability to absorb organizational, operational and technical changes. To meet these changes it is necessary to design buildings with an appropriate physical and organizational adaptability over a time period. Hospital projects are characterized by an extensive planning and construction period, often lasting 10 – 15 years. During this period the project assumptions and the user organizations needs are changed, due to rapid development in technology, organizational changes and treatment methods. Not seldom we experience a mismatch between the user organization and the building at the completion time, resulting in continual building changes.

2. Operationalizing the concepts

Both the terms usability and patient focus are hard to make operational, and are according to this often difficult to measure and evaluate in a completed hospital building.

2.1 Usability of buildings –theoretical framework

Until lately it is written and done little research on usability in buildings. Several research projects are done due to aspects concerning this concept, but few are studying the connection and dependence between the aspects. The term is vague and little tangible. The concept of "usability" is widely known in relation to applications within product design, information technology and web-design, related to user friendliness and user interface of the system.

A CIB Task Group 51 "Usability of buildings" has been created to apply concepts of usability, to provide a better understanding of the user experience of buildings and workplaces. Usability is here defined as the *"….effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment"* [9]. According to this definition, a product's usability is determined by 3 key factors:

Effectiveness – whether users can achieve what they want to do with the product
Efficiency – how long it takes them to achieve it
Satisfaction – their feelings and attitude towards the product

Usability means that systems are easy and fast to learn, efficient to use, easy to remember, allow rapid recovery from errors and offer a high degree of user satisfaction. It also means bringing the user perspective into focus. The term usability describes whether or not a product is fit for a specific purpose [10]. Usability, or functionality in use, is concerning the buildings ability of supporting the user organizations economical and professional objectives.

The concept of usability of buildings can be approached in four ways [11];

1. Criterions and parameters affecting usability
2. Usability from different stakeholder's point of view
3. The time perspective
4. Workplace and context

According to the patient in focus it is especially interesting to discuss the second approach, usability from different stakeholder's point of view.

2.2 The patient in focus

The organization and design of several projects is based on the Planetree philosophy. The last project in this development is new St. Olav's Hospital in Trondheim, a project designed in accordance with the hospital ideals of today. According to Dilani [12] no hospitals has so far been implementing the Planetree philosophy as extensive as this project. The architectural competition for the project, accomplished in 1995, was based on treatment, nursing and care to be done with the patient in focus. The term “patient in focus” is defined as a holistic view of the patient and a production oriented view on the organizational structure in the hospital. The solution for St. Olav’s Hospital is a decentralized hospital with smaller, partly autonomous units in separate buildings; integrated centres in independent blocks. The fundamental idea is that the patients needs and wishes is the basis for all planning. Emphasis is made on dignity and participation of the individual patient. Through a patient focused treatment the patient is to experience continuity and connection during the treatment.

The staff is brought together around the patient, as opposed to earlier, when the patients were transported from department to department to receive the necessary treatment. The patient needs to deal with less people, giving a more humane atmosphere. Every building unit is of a smaller scale than a traditional centralized hospital complex.

2.3 Case: St. Olav’s Hospital

St. Olav’s Hospital is based upon a transformation of the existing buildings at the original site. 80% of the existing buildings are being demolished, and the remaining is rebuilt. The project contains 197 500 sqm new buildings. Rehabilitation and new building is done step by step over a period at 11 years.

The main objective of the project is to create an efficient and professional hospital. The development plan for the project [13] states “the patient in focus” as a main objective, and is also describing seven other objectives for the completed hospital [14], among them flexibility, which can be related to usability. The hospital is based upon a decentralized centre model, where each centre is representing self sufficient units. Necessary changes are assumed to be solved within the centre, giving few effects and consequences for the rest of the hospital.

Several concepts are affecting usability and patient focus in the hospital project [15];

- Area flexibility (possible extension and addition of buildings)
- Generality (standard design solutions)
- General centre (basic principles for building structure, communication, organizing, functional division, volumes, exterior facades, use of materials)
- Structural flexibility (focusing possible rebuilding and functional changes)
- Technical flexibility (possible changes in capacity)

In this context it is especially interesting to describe and discuss the topics *generality* and *general centre*, due to patient focused hospitals.

2.3.1 Ideas for developing patient focused design solutions, with the bed cluster as an example

The bed cluster (“sengetun” in Norwegian) is a physical and organizational model representing one way to organize patients’ rooms in the wards. According to the principal architect in The St.

Olav's Hospital Development Project, part of the challenge in planning and design of the new hospital is to transform an existing physical and organizational structure into a modern hospital according to the objectives for efficient operation and patient focused care.

The holistic model "Human and material resources" (figure 1), is developed to discuss, together with other aspects, generality in physical solutions. According to this model, hospitals can be divided into two sectors which have different sets of resources. One sector is based on human resources, and the other sector is based on material resources (buildings and equipment). Achieving value in hospital planning and operation can similarly be described in two ways. One sector describes quantifiable objectives, such as the number of health services delivered, while the other sector is based on values associated with the human experience of quality, including user satisfaction.

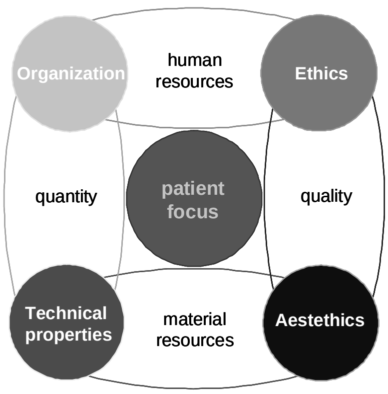

Figure 1: The holistic model "Human and material resources" [16].

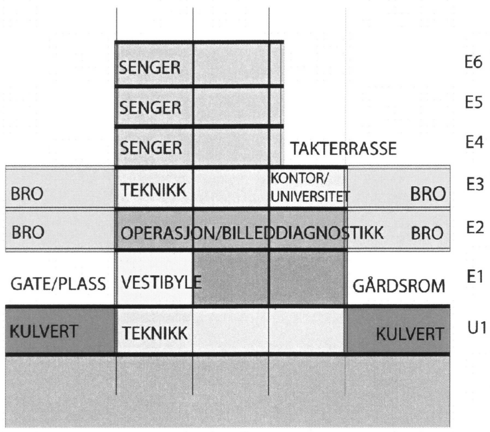
The hospital organization can be placed in the intersection between the human resources and the quantitative resources. In St. Olav's Hospital one of the goals are to build up an organization for best possible use of the combined resources of human capacity and competence in the hospital. In the intersection between the human resources and the qualitative values, we find ethics, where visions about attitudes and the human perspective must be defined. This is, among other philosophies, put into system by the Planetree organization. In the intersection between the quantitative and the material, we find the technical properties, defined as functionality and technical quality of buildings and equipment. In the intersection between the qualitative and the material resources aesthetics are created.

This holistic model describes various aspects of the hospital organism, and shows how various aspects affect each other in a development process. According to the principal architect, the development process will include all the aspects, whether they are taken into account or not. Objectives and visions for developing the hospital organism are placed in the centre of the model, so that all the secondary aspects are directed at a common focus. In St. Olav's Hospital, the vision has been defined as operational efficiency (production focus) and patient focus (customer orientation). This involves awareness of both quantitative and qualitative values, and the whole model is activated.

The bed cluster design provides, according to the principal architect, an opportunity to develop a more practical, social and building-related environment for patients and staff. The patients' rooms are grouped around stores for supplies and workstations for the staff which care for the patients. At St. Olav's Hospital there are 6 – 8 patient rooms per bed cluster, and the clusters are placed in series with common supporting rooms in between.

2.3.2 General centre

The concept "general centre" is developed as a part of the hospital project. The target of this has been to develop a model to take care of common qualities and solutions in the project, general for all centres, corresponding with the superior objectives. "General centre" includes basic principles for building structure, communication, organizing, functional division, volumes, exterior facades, use of materials and so on, to assure superior structure, character and totality. The concept introduces guidelines for physical design, and is meant to be a "prototype" for the development and design of each centre. This is considered to be an important feature in gaining flexibility (figure 2).



3rd - 5th floor;	*wards*
2nd floor;	*mezzanine level for technical services over medical functions requiring technology*
1st floor;	*connecting bridge, theatre, radiology, recovery*
ground floor;	*policlinics, day areas, cafeteria, kitchen for the centre, auditoria, rented areas*
Basement;	*underground passages between centres, technical functions, bed equipment stores, locker rooms and cleaning unit.*

Figure 2: General centre [17].

The concept of general centre comprises the following principles;

- identical localization of functions on the floor plans (figure 2)
- functions belonging to one centre can easily be expanded into the adjacent centre
- logistics due to transverse function is improved
- concentration of activity at inconvenient time
- a continuous surgery area at the 1st floor
- a continuous university area at the 2nd floor

3. THE BUILDING VERSUS THE EFFECT OF THE BUILDING

The relationship between usability of a building and a user focus is discussed in a case study draft report [18], carried out as the Swedish part of the CIB TG51's work in 2003. In the report, which is a work in progress, it is expressed that *"We can define functionality as a property given to an artefact in order to create a practical effect. An important effect can be described as usability. (…) We all know that functionality alone does not make a certain artefact usable. The technical and physical properties of the artefact and its theoretical potential to deliver a certain effect do not automatically make it usable in the real world."*

The same aspect is discussed by Granath [19]. According to Granath the Swedish society traditionally are based upon production of goods. The rationalist way of thinking is the dominating, and it is focusing at what theoretically should happen if the product is produced in a specific way, rather than focusing the result of what is done. There is however also another knowledge, even if it often is secondary. In state of being a user, we confirm how the products are working for us, whether we like them or not, in what way they are affecting our lives, and whether we think they are beautiful or ugly and so on.

Granath says that in the first perspective we are talking about buildings and products (the artifact in figure 3), in the other perspective people doing things (the effect of the artifact). We are measuring and evaluating the shape, quality and quantity of the product, but should rather be talking about how the product is meeting the users needs and requirements. We are focusing functionality believing this will lead to what really is crucial, being usability. We believe that the problems are solved when we succeed to develop tools for solving them, and think that the effect always is the desired. In figure 3 these two perspectives are visualized;

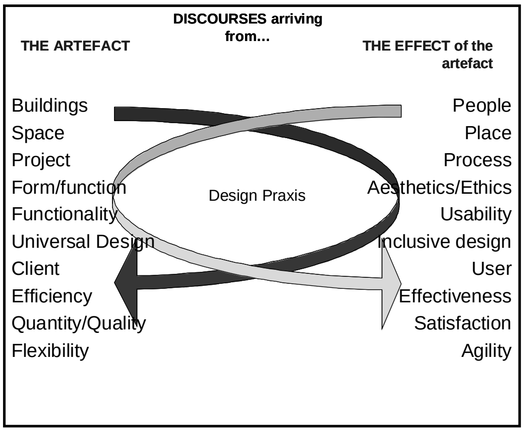


Figure 3: The artifact versus the effect of the artifact. [19]

The traditional way of thinking is visualized by the dark arrow in the figure, where the range of ideas is based on the product, and where the conclusion is a technical solution to a humanistic problem. The new and needed way of thinking is that there always is, in both new buildings and in a buildings phase of use, a need for developing knowledge starting on the right side of the figure, based on the core organization, and further to use tools and techniques on the left side of the figure to develop relevant solutions judged based on the thinking of the right side in the figure. This new way of thinking is represented by the light gray arrow in the figure. To achieve this, a change of attitude is crucial.

The model in figure 3 gives a good picture of the traditional versus the new way of planning and operating a hospital. Traditionally it has been usual to develop hospital projects in line with the red arrow, and focusing “the nursing factory” and “the medicine in focus”. St. Olav’s hospital is based upon a fundamental reorganization of the hospital activity. As we see in section 2, the planning and development of this project is based on the right side of figure 3, in a higher degree than most of the other hospital projects the latest years, by emphasizing the patient focus in the degree that is done. This can however cause some challenges related to the traditional way of building a hospital and organizing the hospital activity [20].

3.2 Possible challenges that might arise

3.2.1 Different actors – different perspectives on usability of the buildings

There are several approaches to the concept of usability. In the paper *“Usability of buildings. Theoretical framework for understanding and exploring usability of buildings” [21] four approaches to the concept are described. The second approach describes how different stakeholders and organizational levels have different perspectives considering usability of buildings; “The terms usability, effectiveness, efficiency and satisfaction is interpreted and understood in different ways. Productivity and effectiveness are generally emphasized as a strategic management issue, while individual workers are engaged with user satisfaction and practical aspects in their daily working situation.”*

In a hospital project “the users” consist of several actors, both hospital employees, patients, primary health service and so on. It is impossible to involve all these actors directly in the planning of the project in a high degree, and the user involvement in the project is due to this often based mainly on participation from the hospital employees.

The planning process in St. Olav’s Hospital is accomplished with extensive user participation, consisting of mainly hospital employees. As mentioned earlier patient focus is emphasized as crucial in the new project, and the challenge is therefore whether the hospital employees and the architects designing the project have the necessary knowledge and ability to take the patients’ perspective in the process of planning a patient focused hospital. Do the actors represented in the planning phase manage to represent other actors’ perspectives in a good way, so that the new hospital buildings are usable for the patients? Interviews done in 1999 indicates that several actors are sceptical to whether this is sufficient to gain a patient focus, because of the medical employees being mostly engaged in focusing their own medical discipline and specialization; *“The hospital employees think they are patient focused, but they are too close to the patient to see that they are not really patient focused.”* [22].

The Örebro case study, accomplished as the Swedish part of the CIB Task Group 51 work, still points at the value of user participation in the process, and concludes that *"From this case we might conclude that participation has a large value for performance and satisfaction in the near future after the move in."* The results of the case study confirm the importance in longer terms of user participation in these kinds of building projects; *"Örebro County has a long tradition of involving the users in the design of places for work. It is a natural part of the culture and is not regarded as an event. It is interesting to discuss how this culture of participation has an impact on trust between employees and employer and how that in turn makes it possible to impose even more drastic changes like the change of technology in the radiology department."*

3.2.2 Involvement of the users in the planning – leading to usable buildings?

We have seen that rather extensive user participation is used as a mean to implement the concept of patient focus in the new St. Olav's Hospital. Some actors are questioning the user participation in the project, and whether this is contributing to tailor made buildings rather than flexibility and usability in a long time perspective. In an evaluation of the project done in 2003 [23], it is concluded that the experience so far is that the users not are sufficiently farsighted. They are mainly concerned about their situation and activities ongoing today, and relate their own transferring of information to this, instead of being visionary and future oriented. The result is often too much focus at reaching solutions, at the sacrifice of focusing functional claims. An important challenge is therefore to balance the individual users need for tailor made solutions with a more superior need for long-term future solutions.

Via the evaluation project some actors also express that the concept "general centre" has had too little validity in the first phase of the building project. It has been too easy to do changes and exceptions from this standard, and this has resulted in different solutions in different centres. This might be an indication on that the guidance developed due to generality and general centre have been influencing the design of each individual centre in a less degree than desired

3.2.3 Is the patient focus affecting the traditional hierarchy in hospitals?

The interviews unveil a disagreement related to fully base the new hospital project on a patient focused ideology, due to the organizational changes needed to be done. Professional arguments are used against this ideology, and it seems like a number of hospital employees, especially within the medical profession, experience the increased patient involvement and openness in the hospital organization as a threat against their own professional integrity and expertise. It is expressed that a hospital organization according to patient focused thinking will cause a fragmentation of specialist environments and offer jobs being less professionally attractive.

Accentuating patient focus as something new and revolutionary is comprehended as provocative by the medical profession; *"The patient focus is not something new. We have done this all the time!". "It is a provocation to the doctors to say that they so far not have been doing patient focused work."*

The patient focused thinking is assuming increased communication and cooperation between the different professional disciplines than earlier. This will be crucial to develop common knowledge beneficial to the patient. The hospital is traditionally based on disciplinary development of knowledge, because it is this that gives professional status. Some actors within the medical profession are afraid this transdisciplinarity will fragment existing specialist environments, and establish interdisciplinary areas in competition to the existing specialist environments.

Implementing a patient focused thinking and the Planetree philosophy in the hospital assumes development of a socially robust knowledge within the organization. Patients and relatives must perceive the knowledge developed in the hospital as credible and functional, and an assumption for this is increased openness, access, participation and involvement than the traditional.

A change in the hospital organization considering patient participation and involvement in the treatment situation promises that it is necessary with a general change in attitude in the hospital organization, according to the traditional view of the patient as an object or a "product". These kind of changes seems to feel like a threat for the traditional hospital organization, since the existing organization is needed to be questioned critically.

4. CONCLUSIONS

In this paper we discuss some of the challenges for planning, design and operation of patient focused hospitals. Usability forms the basis for this discussion. We are using a theoretical framework for exploring usability presently under development by CIB Task Group 51 and the Planetree philosophy regarding patient focused hospitals. The theoretical discussion is related to the new university hospital project in Trondheim, where the project organization has an expressive goal of achieving both a greater efficiency and a more patient focused hospital.

Usability is defined as the "*….effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment*" (ISO 9241-11, 1998). According to this definition, a product's usability is determined by 3 key factors:

Effectiveness – whether users can achieve what they want to do with the product
Efficiency – how long it takes them to achieve it
Satisfaction – their feelings and attitude towards the product

In this paper we have discussed some aspects considering how these 3 key factors are connected to a patient focused ideology. The dominating discussion is related to user satisfaction, as an important element of gaining usability of a building. Evaluations show an immediate relationship between a stronger patient focus and satisfied patients. Implementing a patient focused ideology might however cause some challenges related to usability of the building, and thus both the hospital building and organization;

- Different actors have different perspectives on usability of buildings. The planning process in hospital projects is often accomplished with extensive user participation, but this is consisting of mainly hospital employees. The question is due to this whether the hospital employees and the architects have the necessary knowledge and ability to take the patients' perspective in the process of planning a patient focused hospital.
- Will involvement of the users in the planning lead to usable buildings? We have seen that rather extensive user participation is used as a mean to implement the concept of patient focus in the new St. Olav's Hospital. Some actors are questioning the user participation in the project, and whether this is contributing to tailor made buildings rather than flexibility and usability in a long time perspective.
- Another question that is important to emphasize is the relationship between efficiency and a patient focused ideology, and whether these are incompatible. Parts of the medical profession fears that founding the new St. Olav's Hospital on a patient focused ideology will result in a fragmenting of specialist environments, and that this will cause a decrease in efficiency.

These questions and topics will be taken further as part of a PhD-study at the university. This PhD-study will be focusing usability of buildings related to a stronger patient focus, and will be discussing the relationship between efficiency at the one side, and a patient focused ideology on the other side.

Exploring tenants' perceptions of their homes in the UK social housing sector

Ritsuko Ozaki
Tanaka Business School, Imperial College London, UK
(e-mail: r.ozaki@imperial.ac.uk)

Abstract

In recent years, many researchers in marketing have stressed the importance of the need for satisfying customers. They believe that a better understanding of customer requirements leads to successful business. In 1998, the Egan report identified key drivers which needed to be addressed if the UK construction industry was to benefit from the radical change experienced in other industries. The UK housebuilding industry has long had difficulties in satisfying its customers and has now been put under pressure to make strenuous efforts to modernise itself. Egan specifically considered social housing as an area where significant improvements could be achieved. In reviewing the sector, the potential to lead change in housing via the social housebuilding programme was highlighted. As part of this initiative, a set of 12 key performance indicators were identified, and one of them was customer satisfaction.

In this context, a four-year research project began in 2001. The project includes 12 registered social landlords, which have formed a consortium, and one of the objectives is to achieve higher customer satisfaction through using a new procurement system. In order to investigate the satisfaction level of those who lived in the consortium's schemes a post-occupancy questionnaire survey was designed. Five themes for the customer satisfaction KPI were identified prior to the project: space and facilities, ventilation, sound insulation, ease of use, and after-care. These themes form the main part of the questionnaire. The questionnaire also contains questions as to general satisfaction and satisfaction with service provision/decision-making participation.

This paper first presents the survey results. The survey was conducted in two stages in 2003 and 2004, with 3 RSLs and with a total of 8 schemes that reached the end of the 12-month Defect Liability Period. Ninety-five questionnaires were sent out and 34 were returned (the 35.8 per cent response rate). The findings will be fed back to the consortium to improve the products and performances. Then, the present paper discusses organisational problems in terms of the management of the survey. There has been difficulty in conducting the survey across the housing associations. In order to understand the nature of the problems, informal discussions were carried out with relevant officers in these housing associations. It has become clear that there has been a lack of understanding between the consortium and the member housing associations. An analysis of organisational problems will help the consortium to act more efficiently.

Keywords: Post-occupancy evaluation, tenant satisfaction, housing quality, communication

1. Introduction – background

In recent years, many researchers in marketing have stressed the importance of the need for satisfying customers. They believe that a better and deeper understanding of customer requirements leads to successful business. This is because it is more profitable to keep the same customers than to do one-time sales with different customers. Customer satisfaction leads to a higher customer intention of returning to the same provider and of making positive referrals; and such customer loyalty and referral lead to an increase in company profits. Customer retention, therefore, ensures a steady stream of future cash flow. Conversely, dissatisfied customer may switch providers and be a source of negative advertisement. In this regard, an analysis of 'defectors' and their views on the company provides useful information to improve the business [1, 2]. There is, however, one aspect that should not be forgotten in this 'satisfaction – loyalty' formula: some people are forced to remain as customers because they have no or little choice. This concept of *false loyalty* tells us that we should not neglect investigating customer satisfaction even though they remain with the company [1, 3].

So, what makes customers satisfied? There are several elements that underpin customer satisfaction: customers' perception/evaluation of tangible service performance, such as staff's willingness to help and provide information, attentiveness, friendliness and ability to understand customer needs [4]; employees' satisfaction because it affects their responsiveness to customers [5]; and problem resolution [6]. Therefore, a good understanding of the significance of customer satisfaction is crucial to success in any business organisation. The housebuilding industry is no exception.

This concept of 'customer focus' is an approach that the service industry has been applying for some time, and these customer-oriented attitudes offer lessons for the housebuilding industry. This is a new idea for the industry, but as Normann [7] puts it, companies that used to think of themselves as mere manufacturing firms have to see themselves as service organisations and to accept the consequences of this new view. The step that they should take will be a shift towards a service, and therefore, customer orientation.

In 1998, the Egan report [8] identified key drivers which needed to be addressed if the UK construction industry was to benefit from the radical change experienced in other industries. Whilst these drivers were considered applicable to all sectors of the construction industry, Egan specifically considered the social housebuilding sector as an area where significant improvements in performance could be achieved. In reviewing the housebuilding sector, the potential to lead change in housing via the social housebuilding programme was highlighted, and the Housing Forum was established for this task as a government-funded body. Its objectives included: agreement on targets for improvement and performance indicators, simplification of procurement processes and standardisation of component linkages, encouragement of long-term partnering arrangements. A set of 12 key performance indicators (KPIs) were accordingly identified; one of them was customer satisfaction.

The UK housebuilding industry has long had an image problem, but its difficulties in satisfying its customers are now being exposed to greater public scrutiny than at any other time. The industry has now been put under pressure to make strenuous efforts to modernise itself [9]. Consequently, improving the ‘customer focus’ of the industry has become something of a holy grail for housebuilders [10]. Research conducted so far in the context of housebuilding has indicated that there are gaps between what customers expect and what housebuilders offer in three main areas: the quality of workmanship, service provision, and house design; and these gaps suggest that customers are not satisfied with the products and service provided [11].

In order to bridge such gaps, and consequently to make the customers more satisfied, it is crucial for housing providers to communicate with the customers. Customers’ views must not be neglected and a feedback chain of information should be incorporated into the business process. Feedback from customers, such as comments and complaints, helps the company to know when something goes wrong [12]. Thus, communication has to be dialogue, not monologue: not only does the company talk to customers, but it should also listen to their opinions. This is how the relationship between the company and the customers can be built. This relationship is particularly important in the competitive market. In order to survive the turbulent changes in the market, the company has to develop relationships with end-customers, as well as with suppliers and distributors. As customer requirements influence the market, the feedback from the customers is essential in adapting to changes in the market. Everyone in the business process has to take part in this ‘relationship-marketing’ [13].

In these contexts, a four-year research project began in 2001 to evaluate the social housing sector’s performance [14]. This paper reports on the outcomes of the post-occupancy tenant satisfaction survey that was carried out as part of the project. The present paper deals with two issues: the result of the questionnaire survey, and an analysis of organisational problems that were encountered in conducting the survey.

2. Benchmarking performances

The present research project includes 12 registered social landlords (RSLs; i.e. housing groups/associations) in the UK, which have formed a consortium. The consortium aims to improve the quality in terms of amenity and performance for the residents and to eliminate defects, in line with the government policies and associated initiatives within the industry described above. In order to achieve these, the consortium introduces lean production methods to housebuilding, with the following objectives:

(a) To try out a new construction method (using factory made pre-fabricated timber-frame, as opposed to the traditional brick and block method);

(b) To work on the ‘partnering’ agreement (as opposed to tendering, through which a contractor is traditionally assigned for a project) between the consortium and a particular housebuilder/off-site manufacturer; and consequently,

(c) To achieve higher customer satisfaction.

As part of the research project, a questionnaire survey was designed to investigate the level of satisfaction of tenants who lived in the consortium’s schemes which had been built with the new procurement system. Five themes were identified for the customer satisfaction KPI in the benchmarking workshops held by academic researchers, consultants and the consortium at the beginning of the project. These five themes form the main part of the questionnaire: (1) space and facilities, (2) ventilation, (3) sound insulation, (4) ease of use, and (5) after-care.

The questionnaire also contains questions as to:
(6) general satisfaction to see if participants are basically happy with their homes; and, (7) satisfaction with overall service provision by the landlord and opportunities for participation in decision-making.

These questions are called Best Value questions, set by the Housing Corporation (the funder for RSLs) to be included in any tenant satisfaction surveys.

3. The survey results

The survey was conducted in two stages – in June 2003 and in January and February 2004 – with 3 RSLs and with a total of 8 schemes which reached the end of the 12-month DLP (Defect Liability Period). Ninety-five questionnaires were sent out and 34 were returned (the 35.8 per cent response rate). Seventy-one percent of the participants were female. Forty-four percent were aged between 18 and 35, 21 per cent were between 36 and 50, and the rest were over 50.

3.1. General satisfaction with the home

Participants are satisfied with their homes and generally think that their new homes are better than the last ones (Table 1).

Table 1: General satisfaction with the home

		Frequencies	%
Satisfaction with the home	Very satisfied	18	52.9
	Fairly satisfied	14	41.2
	Neither	1	2.9
	Fairly satisfied	1	2.9
	Very dissatisfied	0	
Compared to the last home	Better than	28	84.8
	Worse than	2	6.1
	No opinion	3	9.1

Disable participants seem to be pleased with the adaptation that the housing provider made for them:

> ‘Being disabled, [I find that] this house has made life a lot easer for me due to the space of rooms, hand railing and a downstairs shower.’

Indeed, more flexible internal design is possible because of the timber-frame method which does not rely on walls to support the weight of the house. The use of this new building method could enhance the flexibility in the internal plan for different users with different needs [15].

3.2. Satisfaction with space and facilities in the home

Questions about satisfaction with space and facilities in the home were asked by using a 1-10 scale (10 = very satisfied and 1 = very dissatisfied). Table 2 shows participants' satisfaction levels with different features in their homes.

Table 2. Satisfaction with space and facilities in the home

	Mean score	**Frequencies of low scores (4 or below)**	**%**
Space in the kitchen	7.12	8	23.5
Kitchen fittings	7.94	5	14.7
Space in the bathroom	8.03	3	8.8
Bathroom fittings	7.65	5	14.7
Space in the living room	7.94	5	14.7
Space in bedrooms	7.94	3	8.8
The no. and location of electrical sockets	8.45	3	9.1
Internal doors	8.06	3	9.1
External doors	7.36	5	15.2
Windows	7.25	7	21.9
Internal storage space	6.33	9	27.3
External storage space	7.29	4	12.9

Participants are generally satisfied with space and facilities in their homes with some exceptions. Typical reasons for dissatisfaction are:

- Lack of storage space (mainly internal, but also external),
- The small size of the kitchen,
- Poor fittings and finishes (doors, windows, door handles, showers, etc.),
- External design and maintenance (landscape, garden, parking, etc.).

These negative comments are valuable. Social housing customers tend to have little choice in their housing situations. In order to avoid false loyalty from the customers, it is important to analyse the customers' negative views. Furthermore, it is useful to analyse the discrepancies between customer expectations and the management's perception of their customers' expectations, and between the managements' perceptions and the translation of those perceptions into specifications. By identifying differences in views, a housebuilder can reduce guess-work and improve value to its customers (Winch et al., 1998).

3.3. Satisfaction with ventilation

Three-quarters of the participants feel warm in their homes on a cold day, and most of them find it easy to keep their homes sufficiently ventilated (Table 3). The typical reasons for disagreement are: draught from doors and windows, and temperature varied within the home. In addition, participants claim that the running costs for their new homes were about the same as they had expected.

Table 3: Perceptions of ventilation

		Frequencies	**%**
Feeling warm on a cold day	Yes	26	78.8
	No	7	21.2
Easy to keep the home ventilated	Yes	32	97.0
	No	1	3.0

3.4. Satisfaction with sound insulation

The majority of the participants say that they are bothered by noise from outside (e.g. traffic and children playing), and about one-third say that they are bothered by noise coming through the wall from next-door neighbours. Noise between rooms and floors, as well as squeaky floors, also appears to be a little problematic, for about 40 per cent of the participants mention that they are bothered by noise within the home (Table 4).

Table 4: Perception of sound insulation

		Frequencies	%
From outside	Often	14	42.4
	Sometimes	11	33.3
	Rarely	6	18.2
	Not at all	2	6.1
From internal communal space (e.g. staircase and corridor)	Often	1	3.3
	Sometimes	2	6.7
	Rarely	4	13.3
	Not at all	13	43.4
	N/A	10	33.3
Through the wall from next-door	Often	6	18.8
	Sometimes	6	18.8
	Rarely	9	28.1
	Not at all	11	34.4
From flats upstairs	Often	3	10.0
	Sometimes	1	3.3
	Rarely	0	
	Not at all	4	13.3
	N/A	22	73.3
From flats downstairs	Often	0	
	Sometimes	2	7.4
	Rarely	0	
	Not at all	6	22.2
	N/A	19	70.4
Between rooms within the home	Often	6	18.8
	Sometimes	8	25.0
	Rarely	3	9.4
	Not at all	14	43.8
	N/A	1	3.1
Between floors within the home	Often	4	13.3
	Sometimes	8	26.7
	Rarely	3	10.0
	Not at all	9	30.0
	N/A	6	20.0
Squeaky floor boards	Often	12	36.4
	Sometimes	4	12.1
	Rarely	5	15.2
	Not at all	10	30.3
	N/A	2	6.1

3.5. Satisfaction with ease of use

With regard to ease of use of the home, although most participants say that it is easy or relatively easy to clean the home, to garden and to use the heating/hot water systems, there are a few who find it difficult to use those systems and to garden (Table 5). There are also some detailed features that participants find inconvenient, such as the location of the hot water and/or central heating switches.

Table 5: Ease of use

		Frequencies	%
Running cost of the home	More than expected	6	20.0
	About the same	21	70.0
	Less than expected	3	10.0
Easy to clean	Easy	27	79.4
	Relatively easy	4	11.8
	Relatively difficult	3	8.8
	Difficult	0	
Easy to garden	Easy	18	56.3
	Relatively easy	11	34.4
	Relatively difficult	0	
	Difficult	3	9.4
Easy to use the heating system	Easy	23	67.6
	Relatively easy	8	23.5
	Relatively difficult	2	5.9
	Difficult	1	2.9
Easy to use the hot water system	Easy	24	70.6
	Relatively easy	8	23.5
	Relatively difficult	1	2.9
	Difficult	1	2.9

3.6. Satisfaction with after-care services

Participants generally give high scores to after-care services (a 1-10 scale; 10 = very satisfied and 1 = very dissatisfied), except to speed of responses to queries (Table 6). As the following comments show, there are some dissatisfied tenants in terms of repair works. When problems are not promptly resolved, the level of dissatisfaction of customers become high [6]. So, this is a warning sign:

§ I have been waiting for a repair work for months. I have phoned twice and supposedly had it logged both times.

§ Any repair works that have been done are broken again.

§ Contractors in some circumstances have been very poor in response time and completion. I had a loose roof tile on my property for two months, which could have blown off and injured someone at any time.

§ [Contractors] don't come out within time, don't knock or ring bell. They put paper in door and walk away. Contractors can be blunt.

Table 6: Perceptions of after-care

	Mean score	Frequencies of low scores (4 and under)	%
Ease of contact with the landlord	8.00	3	9.1
Helpfulness of the staff	7.94	3	9.4
Speed of response to queries	6.76	7	21.2
Information the landlord provides	8.16	3	9.7
The time period repair works carried out	7.28	5	15.6
Contractors' attitudes	7.64	5	15.2
The quality of repair works	7.91	5	15.6

3.7. General satisfaction with services provided by the landlord

Participants are satisfied with overall services provided by their landlord and are not dissatisfied with opportunities for participating in decision making (Table 7).

Table 7. Satisfaction with overall services

		Frequencies	%
Overall services	Very satisfied	17	50.0
	Fairly satisfied	13	38.2
	Neither	3	8.8
	Fairly satisfied	0	
	Very dissatisfied	1	2.9
Opportunities for participation	Very satisfied	9	29.0
	Fairly satisfied	11	35.5
	Neither	5	16.1
	Fairly satisfied	2	6.5
	Very dissatisfied	1	3.2
	No opinion	3	9.7

3.8. Summary

Overall, the participants are satisfied with their homes and the services provided. However, there is more housing providers can do, as residents would like better quality workmanship and design than currently offered. For example, high-quality off-site manufacturing should be able to cope better with quality problems, such as draught and noise. Also, although some attributes and features (e.g. the provision of storage space, the design/location of central heating/hot water switches and the maintenance of the garden) cannot be controlled by off-site manufacturing, they need to be considered in the design stage. In order to improve features that are currently seen as negative in the next generation of design, good communication between customers, housing associations and building contractors is necessary. Also important is the staff's attitudes towards, and attentiveness to, the problems that the residents are facing. Prompt problem resolution is very important to achieve customer satisfaction. People want to feel being looked after by the house provider; and satisfactory 'looking-after' leads to customer satisfaction [11, 17].

4. The management of the survey

There was some difficulty in conducting the tenant survey across the housing associations. In this survey, there were three housing associations involved. ‘A’ Housing Group is based in Kent and consists of several housing associations according to the nature of business. ‘H’ Housing Group, based South East London, has also a number of housing associations according the regions they cover. ‘B’ Housing Association is a single entity, based in Norfolk. Each organisation presented different attitudes towards the survey initiated by the consortium.

In order to understand the nature of the difficulty experienced, informal discussions were carried out with relevant officers in the three RSLs that carried out the tenant satisfaction survey (a meeting and discussions over e-mail with A and H Housing Groups respectively, and a telephone interview with B Housing Association). It then became clear that there was lack of understanding about the aims of the survey and of the consortium by the participating RSLs.

Firstly, the complex organisational structure has turned out to be a problem in this particular survey exercise. The questions to be asked in the questionnaire were agreed by representatives from several RSLs and academic researchers after a number of meetings. However, as A Housing Group has several housing associations under its umbrella, it seemed more difficult for the housing director who had attended the meetings to get consensus on the content of the questionnaire from different sections of his organisation:

> ‘I needed agreement from colleagues before writing to tenants, and they [the colleagues] were seeking to meddle.’ (Housing Director, A Housing Group)

It is understandable that, if a RSL is going to carry out a questionnaire survey, they would also like to include the questions that they want to ask the tenants, as they know that their tenants do not like to receive too many questionnaires. The issue here is that the purpose of this particular survey was not really understood within the housing group in question. The questionnaire survey had a specific aim to find out the tenant satisfaction level in relation to the finished products constructed by the new procurement procedure as well as to the services provision. But this message was not communicated.

B Housing Association, on the other hand, was a straightforward case. The development support officer took full responsibility for carrying out the survey and no one questioned her within the organisation as she had been in charge of all the tenant surveys in the organisation. She understood that it was a decision made by the consortium which her organisation was part of and followed the order, sending out the questionnaire to relevant tenants.

Lastly, There was misunderstanding about the survey procedure, rather than its purpose. The development director instructed some of the agreed questions to be included in their own tenant survey to cover the 5 themes mentioned above. Although the dates for the survey had been agreed between the customer manager who was going to conduct the survey and the project researchers, this misunderstanding delayed the whole exercise for two months:

> I was told that I did not have to conduct your survey. The director said that they had included most of your questions in our satisfaction survey. (Customer Manager, H Housing Group)

These examples show the importance of communication between the consortium and participating RSLs, as well as within the RSL. It is especially difficult to achieve an understanding when an organisation has a complex organisational structure, involving a number of different housing associations that have different issues and agendas. A better understanding of such organisational problems would help a group of RSLs to conduct cross-organisational surveys more efficiently.

Currently, the consortium is withholding its activities. When the consortium originally started, there were 22 RSLs participating, but the number of the member RSLs became 12 by the time this research project started. The reason why it has not worked well is still to be investigated, but the different agendas that the participating RSLs and their internal sections have seem to have contributed to its failure. Furthermore, for those who actually do surveys, there is little difference between their own surveys and the consortium's surveys. The latter is just additional work for them and more surveys for their customers. Unless the idea of being part of the consortium is disseminated and understood within and across the organisational boundaries, even a joint survey appears to be difficult to carry out.

5. Conclusion

This is a small-scale study and the results cannot be generalised. However, it has identified tenants' perceptions of the quality of their homes and of the services provided, indicating some problems. Firstly, regarding the physical quality of the homes, the timber-frame construction method, off-site manufacturing and on-site assembly seem to have succeeded in providing a better building design and quality to some extent. Nonetheless, there are still a few problems to be sorted out (e.g. storage space, draught and sound insulation), which should be taken into consideration in the design of the next generation.

Secondly, on the quality of services, although the satisfaction level is generally high, there is still room to improve. As seen above, customer satisfaction is determined by employees' performance. Customers want attentive responses to their problems. Thus, responsiveness to enquiries and repair works, for example, do affect the way in which customers feel about the service provider and its services.

Lastly, with regard to the management of the survey, it has become clear that there has been lack of understanding about the aims of the survey and of the consortium among the participating RSLs. Furthermore, the importance of communication between the management and the front-line employees who actually carry out the survey has also been shown. These organisational issues need to be taken into account when a similar cross-organisational survey or project is conducted.

An innovative procurement system (i.e. the use of pre-fabricated timber-frame method, and partnering agreement with a single contractor/off-site manufacturer) that this group of housing associations employed, still has room to improve. The above findings – the survey results and the analysis of organisational problems – will be fed back to the consortium, so that the member RSLs can understand their strengths and weaknesses and improve their products and performances. It is also hoped that the findings provide any social housing providers with a lesson to learn in order to achieve higher customer satisfaction and consequently successful business.

6. Acknowledgement

We are grateful to the EPSRC-DETR LINK scheme for supporting this research under its 'Meeting Customer Needs Through Standardisation' programme. The work was carried out as part of a project on benchmarking Egan compliance, in conjunction with the University of Greenwich, and the Palmer Partnership. We would like to thank our industrial partners and the residents who kindly responded to our survey.

Abstract

This paper describes the main results of a multiple case study concerned with client requirements management in the product development process (PDP) of seven low-income house-building projects, carried out in the South of Brazil. These projects were developed in two different forms of Brazilian housing provision: four in the Residential Leasing Program (*Programa de Arrendamento Residencial – PAR*) and three in the first phase of the City Entrance Integrated Program

(*Programa Integrado Entrada da Cidade - PIEC*). Both are new forms of housing provision in Brazil and have created different client relationships, which have never been experienced in Brazil before. The main objective was the comprehension of the PDP of both forms of housing provision as well as the identification of a potential client requirements management in public instances, in order to improve the quality of these products without raising costs. This investigation was based on the analysis of design, production control and legal documents, semi-structured interviews carried out with design and production professionals, as well as the evaluation of user's satisfaction. The main contributions of the study are concerned with the understanding of the relationship between the PDP improvements and the product performance according to the perception of the various clients (users, construction companies, design and budget professionals, financial agents, as well as Municipal and Federal Government professionals) involved in the PDP. The four case studies presented in this paper are part of a larger research project, which is being developed in a network of six Universities in Brazil. The main objective of this larger research project is to propose guidelines for client requirements management in the PDP of low-income house-building projects.

Keywords: Client requirements management, value generation, product development process, low-income house-building projects

1. Client Requirements Management in the Product Development Process

1.1 Overview

The design process can be understood as a sequence of steps and activities that make the construction of a building possible. Design and construction can be analyzed as a product development process (PDP) because it describes the activities needed for the development of a determined product, for example, a building. The main benefit of analyzing design and construction as a PDP is that it gives a more integrated view of the whole process. In manufacturing, the PDP is understood as a sequence of steps or activities necessary for the conception, design and commercialization of a product. According to Ulrich and Eppinger [1], the PDP is a series of activities needed for the conception and design of a product, from the identification of a market opportunity to its delivery for the final client. When compared, the necessary steps for the development of a product in construction and manufacturing, many similar points stand out: the importance of client requirements capture and the translation of these requirements into design specifications [2, 3]; the product is developed by teams of various areas, therefore, there is a considerable variety of people with different abilities and knowledge involved in the process; the main phases of the process are similar, as identifies in the work of Kagioglou et al. [4] and Ulrich & Eppinger [5]; there is a great amount of information, information flow and trade-offs during the process [6, 7]; and many uncertainties in the process.

But many different point are also identified between the development of a product in construction and manufacturing, such as: in manufacturing, a prototype is made during the development o the product's concept [5]; for a building, each productive cycle involves a new piece a land [8], therefore, a new location, what makes a prototyping not as useful as in manufacturing [9]. Among the various types of building, a house building is destined specifically for a basic need: residence. For this reason, the house building is a product that has attributes that commonly generate a more complex consumer behavior, because it is a more expensive product with unique characteristics and considered as a product of long-term use [10]. On the other hand, manufacturing products have a shorter life-term than a building.

For the points that make the development of a construction and manufacturing product similar or different, the analysis of the design and construction processes are here considered in a wider context, which is the PDP. A wider view of the PDP is a necessary prerequisite to systematically consider the needs of the various clients involved in the process.

In the construction industry, due to the long use time of the constructed facilities, the client has no prior expertise [9]. Therefore, the outward orientation should be given more attention, in order to obtain more information from the final client. The expression of the needs of a client in a form that describes the facility that he/she desires involves "processing" to ensure that the information is presented in a format that enhances adequate understanding of what the client desires, and which facilitates their implementation by designers [11].

The systematic management of information on client requirements consists of finding the knowledge applicable to a problem situation and formulating it in project objectives and constraints. The client requirements management consists of the identification, analysis, prioritization and availability of information about the client's necessities and preferences. Such tasks can potentially result in a better definition of possible design solutions, consequently increasing the perceived value by the client. Concurrently, a great challenge for a designer is to define the best solution to meet the client's needs [12].

According to Kalay [13], the need for collaboration arises when the limits of their abilities prevent individuals from completing a given task on their own (due to the lack of knowledge or power), or when collaboration can help them to complete the task more quickly and efficiently. Therefore, the communication is a prerequisite to collaboration, being a means by which the intents, goals and actions of each one of the participants are made known to the other participants in the collaborative effort, thereby forming the basis of their own actions [13]. This poses new demands on communication and cooperation in design practice [14].

The collaborative group must, therefore, establish a definition of the team, identify their outcomes, ensure there is a purpose of the collaboration and clarify the interdependencies of the members [15]. Therefore, collaborative work is not the only mechanism to generate value, but it can make the team more capable of better managing client requirements in the product development process (PDP).

1.2 Low-income house building in Brazil

According to the Brazilian Federal Government's Cities Ministry [16], the Brazilian social debt related to the housing deficit is impressive. Over 7 million families need new homes and over 10 million homes have basic infrastructure problems. The social differences and income concentration, characteristics of the Brazilian society, are manifested physically in the segregated spaces of the cities in the country. In these, the housing needs constitute a greater problem: the lack of decent homes for the poorer citizens represent 91.6% of the total Brazilian housing deficit [16]. Besides being concentrated among the population that has the lowest monthly income, the housing needs are also increasingly concentrated in urban areas.

According to the Fundação João Pinheiro [17], the housing needs include the deficit and housing inadequacy. For this same institution, deficit is understood as the need for the construction of new homes, because of both the replacement and increment of the housing stock. All of these complex housing needs have lead, in the last decades, to a change in the Brazilian Government's role in offering low-income housing. Nowadays, there is greater interaction between public and private sectors. This has lead to growing financial, regulatory, environmental, social and technical complexity, which has made the construction process of low-income house buildings highly decentralized in Brazil. A great number of professionals are involved, resulting in requirement conflicts and in the need to manage trade-offs.

This situation is even graver when it comes to the complete housing provision. The term housing provision is understood as the group of specific actions developed by various governmental and non-governmental agents, that result in one or many types of dwelling units [18]. Moreover, the same authors define complete housing provision as a set of actions, developed by various agents, understood as the supplying of a dwelling unit in an area with urban infrastructure, giving complete inhabitance conditions. Also, the provision of a complete dwelling unit demands the involvement of many agents and created different forms of relationships among them.

The Residential Leasing Program (*Programa de Arrendamento Residencial – PAR*) and the City Entrance Integrated Program (*Programa Integrado Entrada da Cidade – PIEC*) illustrate two representative forms of housing provision in Brazil. They were selected for this research project because they focus on a population with a monthly income that represents the largest part of the Brazilian housing deficit, as shown below in table 1. The PIEC concentrates a population with a family monthly income of zero to three minimum wages and PAR, a population with a family monthly income of three to five minimum wages. The sum of both represents the poorer citizens (91.6%) of the total Brazilian housing deficit, according to the Brazilian Cities Ministry.

Table 1: Brazilian Urban Housing Deficit [17]

Region	**Urban Housing Deficit**	**0-3 Min. wages (%)**	**3-5 Min. wages (%)**	**5-10 Min. wages (%)**	**Over 10 Min. wages (%)**
North	411,600	84.0	7.2	6.9	1.6
Northeast	1,729,100	91.3	5.1	2.1	0.7
Southeast	2,257,500	77.6	11.0	7.1	3.0
South	589,100	80.9	9.4	6.7	2.5
Center-west	427,600	82.9	7.8	6.5	2.0
Brasil	5,414,900	83.2	8.4	5.4	2.0

2. Reserch method

2.1 Overview

This paper describes the main results of a multiple case study concerned with client requirements management in the PDP of seven low-income house-building projects, carried out in the South of Brazil. These studies are part of the Requirements Management and Quality Improvement in

Social Housing (REQUALI)[1] Project, which is still in its early stages. This investigation was based on the analysis of design, production control and legal documents, semi-structured interviews carried out with conception, design, production and financial agency professionals for the PAR and PIEC projects.

For the PAR projects, four house-building projects were analyzed: Alta Vista, Guerreiro, Marcílio Dias and Sul América. The first three are located in the city of Pelotas and the fourth, in Porto Alegre. For the comprehension of the PDP of PAR projects, 8 interviews were carried out with professionals from design and construction companies, as well as from public institutions, such as the Brazilian Public Savings Bank (*Caixa Econômica Federal)*. Other sources of evidence include: evaluation of user's satisfaction in the four PAR projects studied, in which the research team conducted interviews in 20% of the dwelling units, using multiple sources of evidence, such as: open questions (critical incident technique) and closed questions (level of satisfaction), photography and drawing, characterizing this evaluation as predominantly qualitative.

For the PIEC projects, three housing allotments were analyzed: Vila Tecnológica, Pôr-do-Sol and Progresso. All of them are located in the city of Porto Alegre. In order to comprehend the PDP of these projects, 16 interviews were carried out with professionals from various areas and institutions, such as: Brazilian Public Savings Bank, all the eight secretariats that comprehend the Municipal Executive Unit, part of Porto Alegre's City Hall. Other sources of evidence were: designs and reports supplied by the City Hall for the Bank, visits to the informal settlements and new allotments and photographical registers.

2.2 Brief description of two housing programs in Brazil

2.2.1 Residential Leasing Program

The PAR exists in Brazil since 2001 and has been bringing benefits to families with a total monthly income of two to six minimum wages. The program is destined for the construction or refurbishment of buildings in metropolitan areas, capitals and urban centers, with a population of, at least, 100,000 inhabitants. This program is managed by the Cities Ministry of the Federal Government of Brazil and is carried out by the Brazilian Public Savings along with the participation of construction companies, which design and construct these projects. The

---

[1] The REQUALI Project started in 2003 and its conclusion is previewed for 2006. It is being carried out by a network of six Brazilian universities in the states of Rio Grande do Sul (Federal University of Rio Grande do Sul, Federal University of Pelotas), Ceará (Federal University of Ceará, Ceará State University), Paraná (Londrina State University) and Bahia (Feira de Santana State University). The main objective of the REQUALI project consists of establishing criteria and directives for client requirements management in low-income house building projects, aiming at the improvement of these projects' quality. The studies are focuses on existing programs in Brazil, such as PAR and PIEC.

Residential Leasing Program (PAR) is one of the most important programs for low-cost housing provision in Brazil. This program is a new form of housing provision and requires innovative roles for both public and private organizations in product development, and a new form of relationship with the final user, which has never been experienced in Brazil before.

It is important to point out that the main client is the Bank, since it plays a major role in the conception of projects. Its technical staff is responsible for establishing the main parameters for the product (cost yardstick, design parameters, criteria for choosing technologies, etc.), design evaluation, final user selection. Moreover, the Bank owns the dwellings for a minimum period of 15 years. The users have an incipient participation in the process, being selected only during the production phase, when the design has already been concluded. This characteristic might cause future conflicts, during the 15-year leasing period, since the Bank prohibits any irreversible change in the dwelling unit. In this sense, it is essential to identify the user's requirements in order to minimize these conflicts and raise the product's value, since they can become the owners after the leasing period.

In the state of Rio Grande do Sul, 58 PAR projects are either already in the use phase or in the production phase. Only in the year of 2004, 3.4 thousand dwellings were built in 11 cities: Bagé, Cachoeirinha, Novo Hamburgo, Parobé, Passo Fundo, Pelotas, Portão, Porto Alegre, Rio Grande, Santa Maria e Sapiranga. Of these 11 cities, two of them stand out: Pelotas (with 12 projects) and Porto Alegre (with 9 projects, including 4 refurbishments). Because these two cities in the state of Rio Grande do Sul present the largest number of PAR projects, they were chosen for the development of this research. Four projects were selected, three in the city of Pelotas (projects Alta Vista, Guerreiro and Marcílio Dias) and one in downtown Porto Alegre (project Sul América).

2.2.2 City Entrance Integrated Program

The City Entrance Integrated Program (*PIEC*), which was started in 2002 in Porto Alegre, in the state of Rio Grande do Sul, has been bringing benefits to families with a total monthly income of zero to three minimum wages. When totally concluded, the PIEC will benefit 3,775 families, who live precariously in 22 informal settlements. In the first phase of PIEC, that has already been concluded, 413 families received new dwellings in three allotments: Vila Tecnológica, Pôr-do-Sol and Progesso.

The PIEC is integrated by four projects: road infrastructure, landscape valorization, housing and social work. Besides the importance of the housing provision, that program also represents the restructuring a significant urban area, especially because of the road system upgrading and environmental recovery. Another difference from that program to PAR is the development of the social work, which aims at the inclusion of those people in the formal city by means of work and income generation, besides community participation in some phases of the development of house building projects.

The program's conception was a complex process that lasted about 6 years. The intervention area is of three neighborhoods in the city of Porto Alegre (Humaitá, Farrapos and Navegantes). The selection of this area was made according to the life quality indicator, which was very low for this area, and the community needs that live in 22 irregular settlements.

Besides, the evolution of the PIEC is linked to demands of the process of the Participatory Budget (*Orçamento Participativo - OP*), which was initiated in the beginning of the 1990s in Porto Alegre. According to Fruet [19] the need to solve urban problems (lack of urban services, secure tenure, transportation, education and health services) has motivated people to organize and adhere to this new space of participation. In this sense, the OP and other mechanisms previewed in the Master Plan, such as the integrated projects and the Special Social Interest Areas, allied to international finance agent's demands and to the experience of the City hall in housing provision, which resulted in a new format for low-income housing provision in Porto Alegre.

PIEC is different than PAR because its main client is the population to be served, aiming at the inclusion of the people who live in the 22 irregular settlements in the formal Porto Alegre. The social project involved, among others, a detailed register and, through the area identification in the city, the City Hall's priority was to serve all of the registered families. Another important client in PIEC is the City Hall itself, because of its involvement in the conception and development of the entire program and in the future management of the settlements.

3. Results of the multiple case study

3.1 Results related to PAR´s case studies

Initially, the product development process for PAR projects was analyzed, with the identification of the main phases, activities, clients, as well as the products that separate each phase in order to better identify problems and opportunities for client requirements management. Four main opportunities for client requirements capture were identified in the process, one in the first phase (concept and design phase), two in the second (production phase) and one in the last phase (use and occupancy phase). They are: initial registration of interested families, selection of registered families, social project and evaluation of user satisfaction. Also, some positive and negative characteristics were identified in this program, in the main phases in with client requirements management can be developed.

3.1.1 Positive and negative characteristics in conception

The product development starts with the search for a terrain, which is analyzed by the Bank's technical staff. The terrains must be located in urban areas, close to services and public transportation. This is one of the main positive characteristics of PAR projects. In the case of the PAR refurbishment, the location is an even greater positive point, because the refurbished buildings are located in city centers. Another important point is that the program is an opportunity for low-income families to obtain their house after the 15-year leasing period, which represents an important asset in a country with a history of unstable economics.

An improvement opportunity identified in the program is that the registered families are only selected after the project has been designed, during the production phase. These families requirements are, therefore, not captured and used in the design process and the construction company, which designs and builds the projects, do not know who they are designing for. Another negative point identified for PAR refurbishments is the environmental and sound pollution existent in city centers, contrasting the fact that these buildings are very well located when it comes to services and public transportation.

3.1.2 Positive and negative characteristics in design

In the design of the common areas, an important point identified is the leisure areas, playground, sports court, community center, with are normally only present in middle-class projects. The families also feel safer in this pleasant environment with 24-hour security guards, which are not common, not even in middle-class condominiums. The dwelling units are small, around 39 m², but are considered better than other dwelling units in the local construction market.

The negative points identified in the design were mainly in the dwelling unit. The users considered the laundry room too small, with no area for hanging and drying clothes. This might be a regional characteristic, since the humidity level is very high in the South of Brazil. The users also pointed out the integration between the kitchen and the living room as a negative point. About 40% already have or wish to separate the kitchen from the living room. In PAR Sul América, about 25% of the dwelling units are studios and most have been vacant for almost three years (the entire use phase). This demonstrates that the Bank did not know who their final client was before the design phase. In PAR Sul América, the lack of open areas for leisure, especially for children, leads to a smaller number of families (29%) with children interested in this project. In the projects in Pelotas (two-bedroom apartments), there are 48.6% of families with children.

3.1.3 Positive and negative characteristics in use

In the use phase, the main positive point identified if the community life that the program makes possible for the families. Most of them did not know what it was like to live in a condominium before, with common leisure areas. Also, because these projects are well located, they loose less time commuting from home to work, therefore having more time to spend with their families and friends.

The main problem is the maintenance of these projects. The Bank contracts a building administration company, which manages the contracts, common areas and dwelling units. This company has created a barrier between the users and the Bank. In some cases, such as in PAR Sul América, the maintenance tax has already equaled the leasing tax, probably because this building has two elevators, with high maintenance cost.

3.2 Results related to PIEC's case study

Initially, the main characteristics of the program were identified, especially the one that points out the differences between this program and other existing Brazilian housing provision programs, especially PAR. In this sense, the main points identified in the PIEC were: extent of the program, integrated program and social project.

3.2.1 Positive and negative characteristics in the program's extent

One of the main characteristics of this program is its extent. The large sum of money invested (55 million dollars) reflects on the number of families that is served. The PIEC represented the first opportunity for a complete register of a large area in the city's urban space. All of the infrastructure conditions were surveyed, as well as a detailed profile of the population in the 22 settlements. Moreover, viability studies were developed for new investments capable of absorbing workers in the region, surveying the companies in the region, identifying their needs. In this sense, the program's extent is a stimulus to partnership among the City Hall and NGOs (non-governmental organizations), universities, associations, public institutions and private initiative.

On the other hand, in relation to the negative characteristics there are many aspects to be considered because of the high complexity of investment of heavy resources that result in: slow conception (around 6 years, according the professionals of the City Hall), difficulties for development and execution, difficulties to control and plan. Another important point is a great contrast between the slow development of a formal housing program and the reality of the life dynamics of registered communities. The families change very quickly, the birth rate is very high and the new necessities grow very fast.

3.2.2 Positive and negative characteristics in the integrated program

In order to make this thorough intervention viable, there is the need to integrate in the City Hall the various secretariats and professionals that participate in the development of a project as big as this one. In search of integration, a multidisciplinary approach was used among secretariats and, especially inside the Municipal Department of Housing (DEMHAB). The need for this integration is explicit by the projects overlapping in the territorial space: infrastructure, road structure, sanitation, housing, work and income generation equipments.

On the other hand, in relation to the negative characteristics there are many aspects to be considered related to alternating program coordination among City Hall secretariats. This results in fragmentation of the process view by professionals involved, late creation of the Municipal Executive Unit and difficulties for attending the priorities of the program and fragmentation in some actions, for example contracting of outside professionals. The program demands a new form of working that breaks the organizational structure of the City Hall leading to difficulties in DEMHAB projects to be approved by another secretariat in the same City Hall.

3.2.3 Positive and negative Characteristics in the Social Project

The social project deserves special highlight in this program because it represents an important opportunity for client requirements management. Besides, it is a project that tries to guarantee an effective social inclusion of the served communities. PIEC was the first program with specific resources for the social project in the city of Porto Alegre. This resulted in the first application of a social-economic register which permitted a more detailed knowledge of the community's reality (income, educational level, activities, relationship with animals, handicapped people).

On the other hand, demands of too many reports by HBB take too much time for the professionals. Also, the requirements of communities were incompletely identified, such as when they opened a computer course, not knowing that most of the population was illiterate. A specific challenge for the communities is changing the people's lives, giving them conditions to maintain themselves in this new life (paying accounts, taxes, living in a condominium, etc). In a few months of use, depredation was already noticed in these condominiums, because they steal community equipments in order to obtain money with their sale. Which demonstrated that the social project is not giving a fast answer to the social problems that this population faces. Also, there is the need to break pathological relationships present in these communities, such as sexual exploitation, slavery, oppression and drug trafficking.

The program is still small if compared to the urban housing deficit in Porto Alegre and the continuous flow of poor people to the capital. But it represents a new trend in Brazilian housing interventions, being more thorough when compared to traditional interventions.

4. Conclusions

The multiple case study for both forms of housing provision indicated that client requirements management must be considered from the initial phases of building projects. There are clear signs of client requirements capture for the PIEC projects during the social project, but these are not well processed during the PDP. On the other hand, in the PAR projects, there is no client requirements capture in the beginning of the process, leading to a design following the logic of mass production, not considering specific requirements of the final clients. The register of the families, carried out during the social project in the PIEC, is an example of client requirements capture that could be used for PAR projects. Nevertheless, the processing must be improved.

Also, a need for a more thorough view of the PDP as well as collaboration between the actors that develop the products and those that inspect them for both forms of housing provision is needed. For the PIEC projects, there should be a more intense collaboration between the Bank and the City Hall. Moreover, for the PAR projects, there should be a more intense information flow between the Bank and the construction companies that develop the products, avoiding re-work.

Among the agents that conceive the programs (the Bank for the PAR projects and the City Hall for the PIEC projects), an improvement opportunity was identified when it comes to the integration among the various sectors in these institutions. In both institutions, because of the traditional fragmented structure, the technicians have difficulty in viewing the entire PDP because they only work in parts of it. The development of an organizational structure that permits and enables conjoint actions can be reached through the use of training and approaches that can help these professionals to view the process as a whole. This integrated view of the processes is a pre-requisite for client requirements management. Besides this, the use of approaches to manage trade-offs and establish communication interfaces, as well as specific training for collaborative work, is needed for client requirements management and, consequently, value generation for the main clients involved in the processes.

Specially related to the communication interfaces, another negative point identified in the public institutions that conceive the products (the Bank and the City Hall) is the lack of integration between the databases and software used by the various sectors. In order to have a more intense information flow, the sectors should be more integrated through an efficient information system.

Finally, another important point in value generation is the participation of the final client in the development process. For the PIEC, there is an intense participation of the final client in the process, from conception phase, through the identification of their demands by the participatory budget. This participation goes through the development of the design, production until the management of use of these projects. On the other hand, in the PAR, the final clients have no effective participation in the process and the families are only selected in the end of the production phase, when the design has already been completed. Therefore, their requirements are not captures in the beginning of the process. The experiences from both forms housing provision could be used in order to improve them both, specially related to client requirements management, with the final objective of raising value from the user’s perspective.

5. Acknowledgements

Thanks to FINEP - Programa Habitare, CNPq and CAPES for the financial support and to public and private organisations that have been partners in the REQUALI research project (Requirements Management and Quality Improvement in Social Housing).

Abstract

Conventional approaches to building performance focus on technical, functional and operational aspect of their use. More recently, building performance appraisal has focused on functionality, serviceability and accessibility in an attempt to assess buildings-in-use. Post occupancy evaluation seeks to relate building performance to the design intentions. However, occupying organisations consider buildings from a different perspective, as workplace settings.

In contrast, usability is one of the most important, but most often neglected, aspects of buildings and workplaces. CIB task group (TG51) was created to apply concepts of usability, commonly used in the fields of IT and engineering, to provide a better understanding of the user experience of buildings and workplaces. Work to apply these concepts in building design, construction, management and use is in its infancy.

The work of the task group proceeds through a programme of action research, comprising an intensive series of case studies and workshops, in association with occupying organisations, to produce research findings within a 'business' timeframe, to satisfy a practice audience, and to identify the scope for further collaboration amongst research partners.

The paper introduces a theoretical framework, identifies key concepts and discusses methodological issues raised by this novel research approach, which aims to generate new knowledge for use in design and management in the built environment. The paper describes the selected cases, from five European countries, presents the results of a series of associated workshops and raises methodological issues arising out of the work. The cases consider the use of particular techniques for usability - community-based planning, design-for-all and facilities management. Final results of the two-year programme of work will be presented at the conference.

The work addresses a mixed audience of practitioners, researchers and academics and highlights the opportunities for collaboration in ‘new knowledge production’.

Keywords: sability, workplaces, appraisal, action research

1. Introduction

Usability is one of the most important, but most often neglected, aspects of building performance. Work to apply these concepts in building design, construction, management and use is in its infancy. A new CIB task group (TG51) has been created to apply concepts of usability, commonly used in the fields of IT and engineering, to provide a better understanding of the user experience of buildings.

The agreed objectives of the task group are:

- to conduct out a series of case studies and associated workshops, involving users, practitioners and researchers in a programme of action research
- to develop concepts of usability for application in practice
- to promote, develop and share methods, processes and techniques for the evaluation of buildings-in-use;

The task group has been formed with the commitment of the following research-based partners:

- Laboratoire Espace de Travail, La Villette, Paris, France
- Norwegian University of Science and Technology (NTNU), Trondheim, Norway
- Chalmers University, Gothenburg, Sweden
- University of Salford, Greater Manchester, UK
- VTT, Transport and Buildings, Helsinki, Finland

Each research-based partner facilitates the involvement of a cluster of ‘industrial partners’, representing different stakeholder perspectives as owners, occupiers and operators of buildings and workplaces.

The work of the task group proceeds through a programme of action research, comprising an intensive series of case studies and associated workshops, in association with occupying organisations, to produce research findings within a 'business' timeframe, to satisfy a practice audience, and to identify the scope for further collaboration amongst research partners.

This paper sets out the aims and objectives of the research, clarifies some of the key terms and concepts and describes the exploratory case study framework that has been created in two preparatory workshops held amongst the research partners. The programme of case studies and workshops that comprise the research will be completed and reported in the next six months and initial findings and conclusions will be available at the congress.

2. Usability

Usability has been described as the 'effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment' (ISO 9241, 1998).

There is a growing body of work on usability in related fields, particularly engineering (Neilson, 1993) and computing and web design (Cooper, 1999). Usability refers to the many aspects of human interaction with a man-made system. The user interface is everywhere where people have to use something: from process control systems to office software, from VCR's to ticket vending machines, from buildings to traffic systems.

User experience encompasses all aspects of the end-user's interaction with an organisation, its services, and its products (and its buildings and workplaces). The first requirement for an exemplary user experience is to meet the exact needs of the customer, without fuss or bother. Next comes simplicity and elegance that produce products that are a joy to own, a joy to use.

User experience goes far beyond giving customers what they say they want, or providing checklist features. In order to achieve high-quality user experience of an organisation, there must be a seamless merging of multiple service disciplines, including engineering, marketing, graphical and industrial design, and interface design.

Successful products have two key characteristics:

Functionality - the product will offer functions and features that users need to complete tasks.
Usability - these features will be used easily and efficiently during task completion.

A product's usability is determined by three key factors:

Effectiveness - whether users can achieve what they want to do with the product.

Efficiency - how long it takes them to achieve it.

Satisfaction - their feelings and attitude towards the product.

Usability means that systems are easy and fast to learn, efficient to use, easy to remember, allow rapid recovery from errors and offer a high degree of satisfaction for the user. Usability means bringing the usage perspective into focus, and facing the user.

A focus on usability can bring many important benefits: improved productivity, innovative designs, reduced risk of costly design errors, shorter development time and effort, high competitiveness and high customer satisfaction! Tools are being developed to represent, measure and evaluate usability and to demonstrate the value and benefits of improvement.

The task group will the share an understanding of the concepts of usability, assess applications in the built environment and evaluate available tools and techniques.

2.1 Usable buildings and workplaces

When these concepts are applied to facilities and buildings, there are important distinctions to be drawn between usability, functionality (International Centre for Facilities, 2003), serviceability (Davis et al, 1993) and accessibility (Travis, 2002).

Functionality has been defined as ‘performing or able to perform a regular function’ and is concerned with the functions and features of the product and has no bearing on whether users are able to use them or not. Increased functionality does not mean improved usability!

Serviceability focuses on 'the capability of a facility to provide a range of performances for which it is designed, used, or required to be used, over time' (International Center for Facilities), usability focuses on user perceptions of the ease and efficiency with which they can use the facility. The concepts can be seen as the 'flip sides of the same coin', serviceability from a supply perspective, usability from a demand perspective. Davis and Szigeti suggest that serviceability combines functionality with quality, which they define as the ‘totality of features and characteristics of a product or service that bear on its ability to satisfy stated and implied needs’.

Accessibility is a key dimension of usability. Travis has clarified the objectives of ‘accessibility’ audits, which concentrate on meeting the needs of disabled customers and a usability audit, to meet the needs of all customers. Travis argues that there is little point having an accessible (website) if it is unusable by both disabled and non-disabled people. By following a customer-centred approach, a usability audit can achieve both goals.

Research into ‘buildings-in-use’ has recognised that 'building users quickly recognise when things they need are absent - usually comfort, health and safety, ease of use and quickness of response when they want to change something. A lot of research and legislative effort goes into the first three, but much less for the last two - the essence of usability.' (Leaman, 2000)

Usability was however identified as a key concept in Facilities Management in the first issue of the International Journal of Facilities Management (Alexander, 1997).

Kernoghan et al (1997) used the development of guidance on building access and usability to describe well developed techniques for building evaluation. They suggested practical difficulties for structuring knowledge databases and address ways of making best use of hard won feedback. They presented facilities management as a dynamic process, requiring a dialogue between building providers and users, and building quality as a matter of ongoing negotiation.

The key role of facilities managers is to allow such negotiations to operate both openly and effectively.

Beech (1997) developed the theme of usability in the context of a 'virtual organisation', Reuters. He argued for enhanced teamwork and a more supportive style of leadership. The focus was on organisational culture - the artifacts, values, basic assumptions and normative practices which underlie organisational life. The new approach requires a non-hierarchical, non-judgemental team-working ethos, and a reward system that promotes collaborative working at all levels.

The task group will continue to explore the theoretical underpinning of usability concepts in an action learning approach that ensures practical relevance and applicability.

2.2 Changing the perspective

Applying the concept of usability implies a change from the traditional construction and property perspectives, which focus on the building as a project and a product, and consider technical and functional aspects of performance.

A clear example of these different perspectives is provided by the contrast and focus of the work in two separate centres of excellence at the Building Research Establishment in the United Kingdom, each with an interest in Facilities Management.

On the one hand, the Centre for Whole Life Performance focuses on the built asset and considers'the various issues surrounding facilities management, risk assessment, residual life assessment, functional performance and obsolescence - to ensure best value is achieved for a built asset'.

In contrast, the Centre for Productive Workplace focus on issues involved in evaluating the productive workplace, which cross a number of disciplines - engineers, architects and psychologists. This Centre offers help to organisations to 'get the most out of your workforce by an evaluation of the environmental and organisational aspects of workplace design and operation'.

In both cases the focus is on the capability of the building as an asset and it functional performance without direct reference to the end user. The working group on Usability seeks to redress this imbalance by promoting independent post-occupancy studies, with the direct involvement of users, and the management of feedback and feedforward.

2.3 Buildings as a factor of production

There is now much greater recognition of the need to consider buildings in the context of business, and from the perspective of end users. Buildings are a means to an organisational end and an instrument of use.

The workplace concept is used broadly to relate considerations of the physical setting in which work happens, to the services that support people in those settings and, perhaps most critically, the management processes that enable their effective use. These relationships need to be considered in the context of particular organisational contexts (culture) through cycles of time. The concept also embodies many types of work activity, not only the administrative and clerical work conventionally found in offices, but also health-care, education and industrial production, in a variety of settings and in dispersed locations.

There is considerable interest in the United Kingdom in establishing the links between the quality of the environment, health and well-being and productivity in the workplace. A number of practice-based research groups, eg Office Productivity Network, Workplace Forum, and Building Use Studies, are actively engaged in studies of buildings in use. The BRE has established a Centre for the Productive Workplace.

Similar work is also being undertaken in other European centres, including the Norwegian Building Research Institute, TU Delft, and Chalmers University and, in the United States, at Comell University and MIT.

Perhaps the best example from practice is provided by the work of Leaman and Building Use Studies. The aim is to 'help improve buildings, with hindsight from studies of past performance and foresight from well-considered strategies using simple but powerful tools to get useful results quickly'.

Building-in-use studies have created a usable buildings web-site as a resource for practitioners, managers, building owners, developers, students and anyone else who wants to make buildings more suitable for the people who use them, less damaging to the natural environment and a better long-term investment.

The task group will seek to identify and assimilate related research and to evaluate its application to case examples, in discussion with the industrial partners.

3. Research programme

The background provides a conceptual basis for developing and applying Usability concepts, but a concerted programme of activity is required to test their robustness and applicability in the context of organisations.

The programme of work for the CIB Task Group focuses on studies of the user experience of buildings and research on buildings-in-use and on the workplace, rather than on laboratory or theoretical studies, and will focus on concepts of usability and manageability.

The overall objective is to seek to improve buildings and workplaces through a better understanding of their performance in use, and more care with their design, construction and management. The working group will promote independent workplace appraisals and the management of feedback and feedforward and make the findings generally available where possible.

The task group has a limited two-year life, during which each research-based partner will host a workshop, involving all research-based and industrial partners, to present and discuss a usability case study.

4. Methodology

The project adapts and develops a methodology previously used in an EU research project entitled Workspace (EuroFM, 2000), by working through a series of interactive ‘best practice’ workshops to consider the results of case studies of buildings-in-use. The workshops involve the participation of organisations, organised as clusters of ‘stakeholders’ to represent the interests of owners, occupiers and operators of buildings. The clusters are organised as action learning sets, providing the opportunity to share learning and experience in the business context of the case study organisations.

The overall project uses a multiple case study approach. An initial set of four case studies will be carried out to test the adequacy of the framework, survey methods and to identify the overriding issues, which are of concern to different stakeholders. Material for the main case studies will then be gathered through interviews and analysis of documentation at different levels in each of the organisations involved. The data was being assessed at the level of holistic cases (projects), embedded cases (incidents within projects) and through cross-case comparisons at both of these levels.

A descriptive model will be developed for considering usability in the context of facilities management and business performance. Individual cases to be analysed using a standard framework to include:

- overall assessment of the usability of the workplace;
- assessment of the extent to which original business objectives have been met;
- assessment of changes to the business objectives, adaptation of the workplace;
- identification of the processes through which business objectives were translated into user requirements and usability criteria;
- comparison of design intentions and assumptions with the way buildings are being used;

The case studies focus on the processes by which the client organisation translates business objectives into process and operational performance requirements for the building, during the briefing development, commissioning and occupancy stages of a building. Initial business objectives, assumptions and design intentions will be compared with the buildings-in-use study. Evidence of changing business requirements, the consequences for usability and building performance, and resulting adaptation of the building will be collated to provide a longitudinal study of each case, and provide feedback to all stakeholders.

A 'best practice' workshop will be held in each host organisation to evaluate the cases and to draw out lessons and conclusions.

5. Case Studies

A usability case study framework has been devised, for the purposes of the research, comprising six inter-related dimensions of an organisational system and describing the context of the case study organisation in its business environment and the relationships amongst people, processes and settings, through time. The case study framework has also been related to an assessment for business excellence, the EFQM model, to facilitate discussion with business leaders and managers in the host organisations. The case study framework will be further developed during the project.

Three case studies have been selected and are being prepared, one each in the United Kingdom, Sweden and Finland and a fourth is planned in Norway. All four case studies and associated workshops will be completed in the initial programme of work to be completed by May 2003.

The UK case study focuses on the development of R & D facilities for NCR in Dundee, Scotland. Contribution to the Usability Task Group is demonstrated through the use of novel planning processes. Features of the project include the relocation and change process in such a tight timescale, Community Based Planning process, integration of Business Unit and Facilities Management as well as NCR 'Discovery Centre' being selected as one of the World Class FM practices.

Örebro University Hospital has been chosen as the Swedish case study and focuses on the users experience of functionality and usability of the surgery centre, built 1997, at Örebro University Hospital. Contribution to the Usability Task Group is demonstrated through the analysis of the planning process, the effects of incorporating new technology and new work processes as well analysis of the building configuration/layout. The case also enables a discussion on ongoing development of hospital work and its relationships to clients and premises.

The Finnish case study takes place in the area of Turku Science Park, which is the core of the innovative environment in Southwest Finland. In this area 'Old Mill' offers companies versatile services as well as functional and interesting premises with an atmosphere reminiscent of an old factory. There is a need to enlarge the functional and Old Mill 2 is in a planning phase. The case- study in Old Mill goals firstly to understand the elements of usability in refurbished environment and secondly to produce the elements for the use of planning process of Old Mill 2. The method used is a workplace survey for users of the building and database information about the requirements of the building. This data is analysed in order to find out the relevant components of usability.

The workshops provide the opportunity for participants to share their experience and for the presentation of similar cases. Other workshops are planned in Norway and later in France.

6. Usability processes

A particular focus of the case studies will be the processes by which the organisations ensure improved effectiveness and how successfully they manage organisational change associated with the workplace. These processes include usability planning, design and management and processes of workplace appraisal and audit.

The workshops will provide the opportunity of evaluating the application of particular processes and systems and tools for usability. Processes will include for example community-based planning (ref), universal design (Center for Universal Design, 1997), and particular tools for performance measurement, such as design quality indicators (Gann, 2003).

These tools will be assessed in the context of the organisations, from a facilities management perspective, with a particular interest in the manageability of the workplace (Alexander and Murphy, 1993).

7. New knowledge production

The task group will also reflect on the working of the task group, with particular attention to team working and collaboration.

Cooper (2002) has considered similar collaborative projects as examples of the ‘new production of knowledge’. He describes such production as ‘short-life inter-disciplinary teams collaborate by engaging in a dynamic form of research characterised by practical problem solving through negotiated and consensually produced knowledge.’

New knowledge production increasingly transcends discipline boundaries (Nowotny et al, 2001, Cooper, 2002). New means of knowledge production, mediated electronically over the Internet (Mansell et al., 1998; Cooper, 2002), will be able to unify the cross-disciplinary boundaries working in dispersed locations. Network based collaboration gives organisations the opportunity to share knowledge and hence allows the partners’ cooperation and team approaches to problem solving more quickly (Rifkin, 2000).

8. Conclusions

The results of the four case studies, reports of the associated workshops, and initial findings and conclusions will be presented at the congress. Key issues will be highlighted to generate an initial discussion about the application of usability concepts and techniques to assessing buildings and workplaces in use.

ABSTRACT

This paper presents a project management concept for programming and designing workplaces in relation to facility user's strategy and operations. The concept includes the target costing product model that defines the life cycle costs basing on spaces needed and workplace planning product model which links spaces to business operations. They enable the definition and costing of working environment in client activity level.

The strategic management of the organization investing in the spatial facilities expect that the investment will support the business idea. The facility user's require working environment with such performances that enables their operations. During programming the building as a solid object can not be predicted; the user activities, extent, mass and materials of the building are unknown. Problem is complex and inductive since there are several correct answers.

Initial information are the values of the customer; "what are the valuable activities for the strategy?", "do they require spatial resources?". Design deals with connections of activities, theme and mass with which the building is connected to built environment. Combining those orthogonal variables in decision making cause more iterations and can be called unnecessary complexity. When dealing with orthogonal, complex and temporally hierarchical information, the information flow in decision making should be one-way. Unnecessary complexity would be reduced if the valuable activities for strategy are defined first, the performances of the working environment for those activities are determined then and the design solutions are looked for after these decisions.

However, some information that is realized in construction–in-site would be crucially needed in programming, namely the life cycle costs that will be caused by decisions. When deciding whether an activity would deserve spatial investment, it would be worth to know if the activity can afford it. Power must be linked to accountability. Target costing principles such as define functional criteria, determine target cost, design to the targets fit perfectly to construction. But the methodologies from the client needs to target cost must then be solved.

Keywords: Project management, knowledge management, workplace planning, target costing, customer needs

1. Target costing in Finnish construction

In the 1980's in Finnish construction sector facility owners thought that there was a lack of concern for their needs on the part of architects and project managers. Building costs seemed to be out of control, unpredictable in relation to their functional needs. Yrjänä Haahtela was working in the National Board of Building, and he was in charge of developing cost economics theory for building construction projects. It was explored that the variance of building costs was big and it was caused by complex set of variables: functional requirements, conditions in site, fluctuations, regional factors and design solutions. The way the design solutions affected to final costs seemed to be partly random. The questions for further research were: "Is it possible to separate those variables in a practical steering model ?", "Is it possible to set a cost target for a building project basing in client's functional needs?", "Is it possible to steer the design solution to the target?" , "How does target costing and steering the design affect to architectural quality?". Haahtela published the theory of target costing for construction in 1980 [1]. In this theory the target cost is set by using the room program (list of rooms) the client requires. The practical method fir target costing and steering the design was published next year. In the 1990's it was completed also to use room performances as initial information. Target costing has been in use for two decades and he benefits of method has been proved indisputable.

In the 1990's Ari Pennanen of Haahtela Research group started to construct a theory to link the need of rooms to the client activities and client business strategy. In this research it became evident that but the geometrics of the functions, also temporal strains of the functions and operation degrees of the rooms are important variables. The conclusion was that client functions and temporal planning of the functions are possible to steer, and this steering process will produce the needed rooms and stakeholders commitment to the result. The theory was named "the theory of workplace planning" and it was published in 2004 [2].

At the moment the research is continued to combine Target Costing and Workplace Planning theories to enable activity based costing management, to trace life cycle costs of the spaces to the user activities.

2. Target costing in other references

Target costing has been in use in Japanese automotive industry since the 1960's. Target costing aims to influence to the product costs (investment costs or life cycle costs) during the design phase by cost planning and cost control. As conventional product development practice converts costs into design outcome, target costing prices rather the design criterion. Since target cost is set before design solution, the price is usually driven by the market [3], i.e. the price is for specified product functionality, which is determined from understanding the needs of the customer and the willingness of the customer to pay for each function. After the product is designed, estimated costs of production are compared with target cost. If the estimated costs are higher than target cost, cost planning is employed to help achieve the target; the Cardinal Rule of target costing is: "The target cost must never be exceeded" [3].

In the 1960's target costing aimed to reducing cost through continuous improvement, "cost kaizen". This is becoming relatively less important in automotive industry, because the efforts made throughout the company will inevitably lead to fewer opportunities to cut costs [4].

According to the study of seven Japanese companies, the target costing discipline has been structured into three sections [3].

- the company's long-term sales and profits objectives in current market conditions
- product level target costing
- to component level target costing, i.e. decomposing product level target to the major functions or subassemblies

3. Target costing suitability to construction

3.1 Needs of the client

The strategic management of the organization investing in the spatial facilities expect that the investment will support the business idea. The facility user's require functional environment with such performances that enables their operations. The client need should be derived from the customers business strategy and the customers operational requirements. There are numerous stakeholders and decision makers in building process. Therefore, in the initial stage of programming, there are a lot of specifications and wishes. Most of them can be considered "right" or "entitled to", many of them are in contradiction to each other and, when combined, they are generally in serious competition for the resources available. Programming is a complex system [2].

3.2 Functional criteria information versus design information

Information used in the programming deals with the values of the customer; "what are the valuable activities for the strategy?", "do the activity require spatial resources?", "does that spatial investment support the strategy?". During programming the building as a physical object can not be predicted. The activities that require spaces, extent of building and materials are unknown. Design deals with connections between needed activities and theme and mass of the building that connects it to the environment. Before construction-in-site the materials, equipment and details will be determined by design (of course, parts of building can be designed after construction has begun, but all the components are designed before their production).

If a problem "do we need to invest in an activity?" is dealt simultaneously with a question "where would it be located in a plan?", there are limitless possible alternatives. If we first answer "no" to the first question, there are no alternatives left. Does answer to question A: "Where will it be in a plan?" create more valuable information to the question B: "Do we need it?" It will not as the problem B is linked to business strategy and problem A to steering the design process. Combining orthogonal variables in decision making cause more iterations and can be called unnecessary complexity [2]. Both programming and design last long, months or years, and unnecessary complexity leads to loss of money and time and offers very little benefits. Design problems should not be mixed with programming problems, one should not seek for a solution while defining the needs. Differentiating needs definition from the design solution is supported also in Suh's axiomatic design concept. It states that good planning require reduction of information content. Therefore customer needs and functional requirements must be determined in a solution-neutral environment [5].

Target costing principles such as:

- define functional criteria
- determine target cost
- design to the targets

fit perfectly to construction. But the methodologies from the client needs to target cost must be solved.

4. Target costing criteria and construction

4.1 Client criteria in construction

In automotive production target costing is often used as a tool between manufacturer and its supplier (external or internal). The manufacturer defines the functional criteria and willingness to pay, supplier designs the product below the target price to ensure the profit. The product criteria can usually be described in measurable way, e.g. the engine must have certain dimensions, power, fuel consumption etc. In construction, when operating in component level target costing, similarities with automotive industry can be found, e.g. main switchboard must have certain dimensions, power, ability to distribution and air exhaust apparatus has to provide certain amount of air, it must heat, cool and filter the air etc.

When operating in product level target costing, when the whole building is a product, conversation with client can not be done with traditional construction language. The client do not want cooling beams, switchboard or columns. Instead the client may want a library for 15 000 volumes and good internal climate in rush hours. The buildings tend to be unique. If we name a building as “an office building”, we don’t know whether they park cars, make food, have conferences, have a library or do fitness exercise in a building. Client functionality description is a complex problem.

In construction there also are soft values that can not be described in measurable way. The building must “hath three conditions: firmness, commodity, and delight” as Vitruvius expressed.

4.2 Quantitative criteria and target costing

In construction most of the functional criteria can be described in measurable way. The customer needs can be defined as a path from customer activity need to workplace spatial needs and finally to performance requirement description like in following example [1,2]:

- customer activity needs: library for 15 000 volumes
- workplace spatial needs: shelving areas 125 m2, pc:s for inquiry 12 m2…
- performance requirement needs internal temperature within +- 2 degrees, load 10 kN/m2…

The target costing techniques to price quantitative functional values by market information can be solved as it will be shown later in this paper.

4.3 Non-quantitative criteria and target costing

There are soft values (e.g. beauty) that can not be controlled in a quantitative way. The non-quantitative values of building, such as pleasantness, beauty, etc. are culturally bound and evolution is essential to culture. People mirror concepts of beauty against their cultural background (their experience, reading, learning. etc.). The basis of European’s taste in music is in accordance with western cultural heritage, interval division and chord techniques. Cultural heritage makes it difficult for an European to find Arabic, Chinese or Indian music beautiful, even though this music, like western music, includes its own culturally specific notions of beauty. Personal judgments of beauty are in accordance with personal inclinations and levels of education. The media (the press, television etc.) usually concentrate on those areas, where the values of individuals concur (how beauty is generally conceptualized) [2].

Culture and pleasantness is a problematic combination, because cultural heritage is cumulative and changes over time. Impressionism in the arts at the end of the 19th century was for the most part considered incomprehensible by both critics and collectors, whereas currently both Monet and Renoir are widely regarded as masters. Many of the buildings currently regarded as beautiful (for example functionalistic) were once beautiful only to a small elite. On the other hand most of the buildings that are currently considered ugly, will, in the future, still be considered ugly, and we do not know the direction evolution will take. The Museum of Modern Arts in Helsinki by Steven Holl delighted many when it was finished, but at the same time many felt it ran counter to modern cultural evolution. Only time will tell if it will become part of the accepted cultural stratum [2] (14.9.2003 The museum of modern arts was voted one of the ten most remarkable buildings in Finland. It was also voted the most unattractive building. The poll was conducted by the Helsingin Sanomat newspaper).

How does target costing deal with soft values? To answer that question we have to find out what is the correlation of architectural quality and costs. Architect Niukkanen has studied the correlation of architectural quality and building costs [6]. The population of the study was design & build competitions in Helsinki City residential building production. The competitors competed with architectural design solutions and price tenders. The architectural quality (external beauty, internal comfort, habitability) was analyzed by a delphi-group and value analyze matrix. The result of the study can be seen in figure 1.

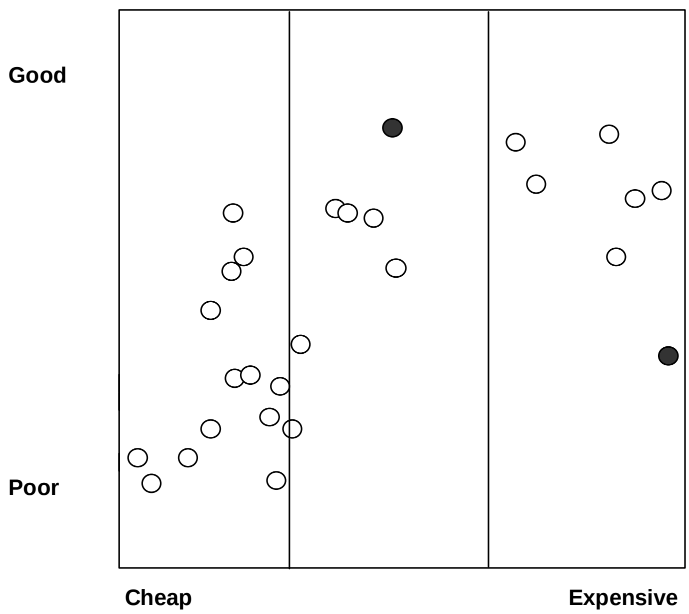

Figure 1: Architectural quality and building costs

If we aim at a minimum price, it might lead to poor quality. But very soon when moving to average price production, the correlation between quality and costs disappears. The most expensive design solution was quite poor in terms of quality and the best quality was achieved with a reasonable price (of course, high price did not prevent good quality). When moving from minimum to reasonable costs the architectural quality can not be assured by allocating more money to production, indeed, this may just as well lead to a poor quality solution as a high quality one. It seems that architectural quality is linked to creativity and artistry of the design group in interpreting our culture and it's changes rather than to money [2]. If we operate within reasonable cost area the building cost don't affect to architectural quality and information from possible future design solutions is not necessary to pay regard to in programming.

If we have methodologies to set the target cost by using quantitative criteria and set target cost in a reasonable area, then the costs can be considered as a fixed variable (a criteria among the others) and the architectural quality is the variable that is managed.

5. Target costing management and project management in construction

In simple "manufacturer and its subcontractor" situation the target cost is defined by market and by target profit. If negotiations are successful, agreement can be done and subcontractor starts design. This also can be done in component level target costing in construction. But acting in this way with "client – contractor" relationship is quite seldom in Europe. Because the client needs are complex and because there are soft values in design, the client don't normally want to lose his power in programming and design. The concern is that the contractor would add his profit by giving up the values that can not be described in measurable way. It is normal in Europe that programming and design is carried out by client's consultant.

Instead of observing customer – supplier relationship, target costing has been used in Finland to make project management more effective by observing internal customer relationships in production. The rest of the production can be considered as a customer of the programming process. The next internal customer would be design. Vague requirements of the stakeholders harm design (and production) [2]. By target costing the client can test fast several requirement combinations and finally commit to one specification and one target cost. It is design's duty then to achieve requirements and target cost. Target costing management is very widely used technique of project management to handle client – design relationship in Finland.

In Japanese automotive industry target costing has been used to reducing cost through continuous improvement. As it can be seen in figure 1, there is potential to cut costs in construction. But total effectiveness in reducing costs might lead to poor architectural quality. Target costing can also be used to prevent expensive solutions and to ensure resources to the best quality.

6. Target Costing Application

Target costing management require reliable methodologies to describe customer needs and to price customer needs. The methodologies must be descriptive in customer language and tested with market information. The Target Costing Application [1] has been developed in Haahtela Group project management. At the moment it is widely used among project managers, contractors and facility owners in Finland. The Target Costing Application calculates the life cycle costs of a project based on the rooms and the requirements for those rooms. The Target Costing Application is a mathematical model that creates the link between the requirements the client sets on the rooms and the possible distribution of elements + use of resources connected to running costs (energy, cleaning…). The budget can then be addressed back to the activities by tracing paths back in the Workplace Planning Procedure.

Target costing must be based in market information, not design information [1,3]. It is easy in component-level target pricing (e.g. air exhaust apparatus) but somewhat difficult in product-level as the buildings tend to be unique and complex in regard to client needs. Suh’s Axiomatic Design concept [5] states an axiom: “A good design is made up of design parameters that result in the independence of the functional requirements from each other”. It means that unnecessary complexity can be reduced if each design components satisfy only one functional requirement. Let’s have a look at two requirements for internal climate: CO2 content and air cooling. They both can be controlled by

- variable air volume system (VAV) or
- CO2 content can be handled by constant air volume (CAV) system and the air temperature by water circulation system and cooling beams.

Suh’s axiom argues that latter solution reduces complexity of whole system. Haahtela’s Target Costing Application have similarities to Suh’s axiom. It is modeled to link one widely used design solution, “reference solution”, for each client requirement, as far as possible. By that means it has been possible to price each requirement by market information. This kind of modeling can describe the cost differences between the client requirements, but not the cost level as whole. It is hard to describe the entity by means of little pieces and on the other hand, the contractor’s tenders are influenced, but by the costs of components, also by their current situation in the markets. Therefore Target Costing Application used also black box modeling [9]: differences between the client requirements are modeled by reference solutions, the level of target cost is calibrated by comparing continuously the modeled result to the actualized tenders. If these two results act regular, the difference is stored in black box. If not, model has to be improved.

■ TOTAL RENT ON ROOM SCHEDULE

Sec.	User	RoomN	Function area	m2	Capital (8%) €/m²/a	Maintenance €/m²/a	Total rent €/m²/a
A			Clinical treatment	60	126	86	286
A			Operating theatre	35	306	261	861
A			Martins room	15	93	43	143
A			Car parking hall	3 000	27	7	42

Figure 2 : Sample of output data of life cycle costs, expressed as a rent of a room.

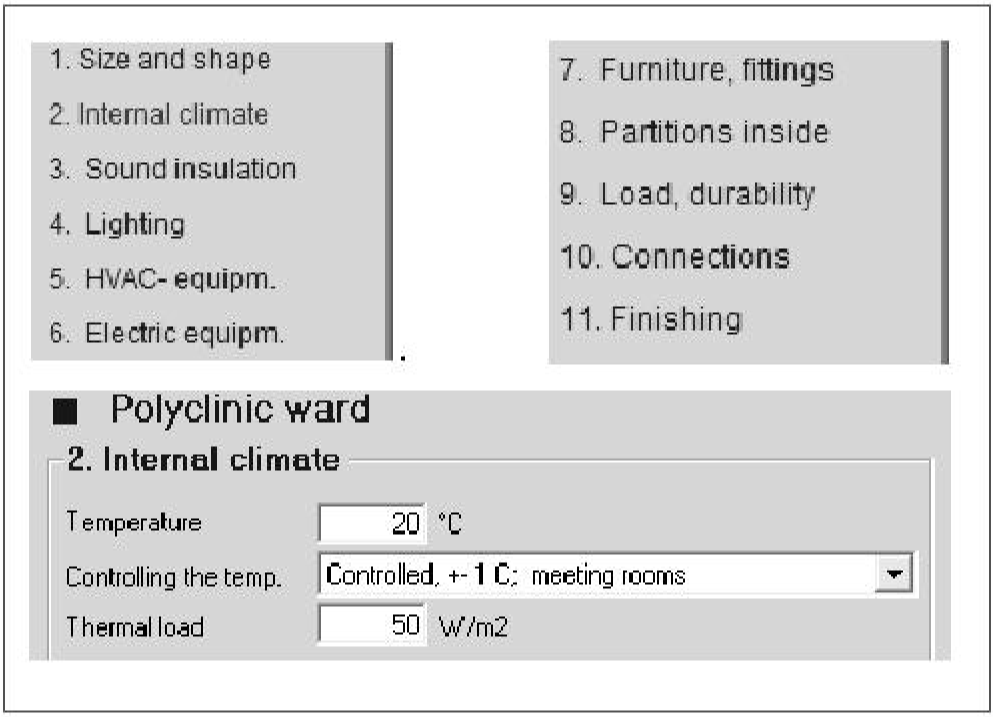

Figure 3: Classification of criteria of the application and sample criteria for internal climate.

7. Workplace planning application

Workplace Planning Application is based on the Workplace Planning concept that was developed in Haahtela Group project management in the 1990's [2]. The concept uses TFV- production theories [7] and ABC –management concepts [8] to construct a workplace planning theory. The Concept of Workplace Planning links workplace production to client's production. A spatial investment in an operation competes for the same recourses as the other investments in the operations. Workplace planning brings spatial investments and the values of the spaces into line with the other factors of client's production. Workplace planning is a process where valuable requirements for workplace production are determined through observing and evaluating the values of stakeholders against the organization's strategy.

The size of a space is determined by the operations taking place within that space (working at table, sleeping, teaching, playing tennis…). Spaces are a scene of temporal flow of operations and non-use time. The number of spaces is determined by the temporal utilization of the spaces. The concept of workplace planning defines value adding spatial investment (or here: no-value-adding) as follows:

- Investment to the operations' time is value adding and the non-use time is non-value adding with regard to the strategy
- Spatial investments in operations that are not needed for the organization's strategy are not value-adding.

The Workplace Planning application describes spatial environment:

- for strategic management as activities that require spatial resources
- for operative management as working environment for operations

Application computes the spatial need and their temporal utilization degrees basing on the factors shown in the table 1.

As the application uses only client activity information as initial input, and the spaces and utilization degrees are the outcome, the project manager knows who or what activities use a certain space, why they use, why it is that size and is there temporal resources left in a space. This information enables Activity Based Costing, if the costs of the spaces are known (previous chapter: target costing application). The application is continuously tested in market. Performance results are tested, but against reference books, against reference buildings. Outcome utilization degrees are tested by post occupancy evaluation. Space lists are tested to already made buildings.

Table 1. Space Quantification Example

Quantification Factor	Description	Example of Education Institution
The total volume of the sector.	No. of Customers or Products.	Two hundred design students.
The activity bill programmed for the sector.	Core Activities Supporting Activities	Teaching & Research. Administrative activities. Dining.
The temporal strain of functions and goals for the use of time in the space i.e. utilization degree.	Temporal Strain. Operating Degree.	Teaching Design Theory 4 credits, 30 h/ credit equals 120 h temporal strain/ student during 3 years. Facility management sets a 75 % utilization degree target for learning environment spaces.
The people working and the geometrics of the objects to be placed in the space.	Each function requires space expressed as a performance result.	Lecturing requires 10sq. Meters of lecture area. Students require standard seating and 1,2 sq. meter workspace. Material shelving require…
Regulations.	Regulatory society defines the quantification of space.	A basketball court have certain dimensions

Workplace planning operates in a complex area. It does not aim for an optimum because an optimum does not exist in a complex system. There are numerous working environment solutions that can be considered acceptable. It aims for a "good" solution. Once the workplace planner has presented the workplace measurements, the facility owner develops an understanding of the present or desired state of the system; i.e., what kind of working environment the owner groups need and value, and what the subsequent consequences will be to their resources. The information presentation allows transparency in that the client stakeholder can trace organizational activities to their origin.

If waste of space for unneeded operations and waste of non-use-time can be reduced, more resources will be available to the other investments for operations, spatial or non-spatial. Seeking for alternatives in value generation is an allocation process. Allocation deal with the questions

- can activities be combined within the same environment?
- is the activity really needed ? Compared to the others ? Are other activities needed ?

What is the criteria that differentiates the chosen solution from the bad ones and from the other good ones? It is the commitment of the participants to something achieved. The product of workplace planning for the rest of production is the stakeholders commitment. Indeed, stakeholders' commitment to the common values and requirements is an absolute necessity in all production to enable value generation. Thus it is a crucial part of the production.

8. Conclusions

Target costing and Workplace planning applications have been made to clarify and intensify internal customer relationship management, particularly between programming and designing. Target costing application enables pricing the rooms needed. Workplace planning application enables the definition of needed rooms on the basis of client activities. When combined, the enable target costing in client activity level.

Target costing application has been widely in use for two decades. It has been proved that it is possible to price the requirements the client sets on the room before design, and it is possible to steer the design to targets.

Workplace Planning application combined with Target Costing has been in use for five years, and the results have been encouraging. In recent cases the building costs have been reduced during the process without losing important activities. In Cygneaeus high school case and Jyväskylä Polytechnics case the "traditional programming" had already been done when the customer asked for workplace planning process. In both cases costs were reduced more than 15 %, decisions were made both by operative and strategic management and stakeholders committed to the result. In Cygnaeus case the process led to so low costs that operative management could add spatial investments. They did not add anything that was removed during the process; discovered waste remained waste. Both the cases has been designed to the targets [2].

Workplace planning and target costing have been used to wide range of lines of business; offices, hospitals, churches, assembly halls, universities, day care centres etc. The concepts have been universal. Better understanding of client values and costing them have not prevented good architectural quality as it has been shown in Synapsia- rehabilitation centre case [2]. The building was named "one of the best pieces of Finnish architecture during 1998…2002" [10]. It is possible to deal with values, money and activities during workplace planning and target costing and to create the best architectural quality

Usability Walkthrough in Workplaces – What, how, why and when?

Suvi Nenonen,
Turku Polytechnic, Finland (email: suvi.nenonen@turkuamk.fi)
Kari Nissinen,
VTT –Technical Research Centre of Finland (email: kari.nissinen@vtt.fi)

Abstract

The usability of workplaces is a challenge – how then does one investigate it? Usability walkthrough as a method in general can be cognitive or pluralistic. Cognitive walkthrough is a task oriented usability inspection method. Cognitive walkthrough is based on a theory of learning by exploration according to which users try to infer what to do next using cues that the system provides. Pluralistic usability walk through is a method, which combines elements from a usability test and usability inspection.

This paper concentrates on the usability walkthrough methods in the context of a workplace as a system. A pluralistic usability walk-through session involves participants from three groups: group of users representatives, architects and usability professionals from facilities management. Together the participants gather information about the workplace usability by inspecting it. At the end of the session the whole group discusses the findings they have made. The application of cognitive walkthrough is also significant for development and evaluation of workplaces – there exist many components, which are relevant to test from the perspective of continuous learning. The technique is suggested as a tool for a process to evaluate workplaces, identify the gaps between the original design concepts and the current use, and to provide a platform for different parties to communicate.

The paper presents a case study from the business park for IT-companies in Finland. The process of usability walkthrough is described and conclusions include the proposal for developing the method further.

Keywords: usability walkthrough, workplace, usability profile

1. Introduction

The easy use of workplace is one of the main tasks for customer-orientated facilities management. The user of the workplace and his or her experience differ from the experiences of designers, architects and construction teams. There is no use to ignore this diversity but however there is an interesting challenge to develop ways to get benefit out of this diversity. This multidisciplinary approach in practice might be difficult to achieve but it this effort is worth to do.

There are challenges in the method and processes of usability walkthrough and one of them is the shared language and common understanding. The understanding of customer's or end-user's need sounds like different languages even though the focus is on the same object, workplace. The second challenge is the timing in the building process. The third challenge is: who is finally responsible of the usability?

These challenges have been a matter of interest in the research project of Usability of Workplaces. The Usability of Workplaces as a research project of CIB51 Task group includes five different case studies in five countries: England, Sweden, France, Norway and Finland. The Finnish case study focused on the elements of usability in a refurbished working environment of Old Mill Business Park. The Old Mill is located in Turku Science Park area and offers services as well as premises with an atmosphere of an old factory for ICT companies.

The Finnish case study among others developed the method of the usability walk- through. Besides the European research project there are several case studies conducted as part of the studies of facilities management in Turku Polytechnic. The paper aims to create an overview for the usability walkthrough as a method.

2. What is Usability Walkthrough?

2.1 Usability

Beyond all definitions, office usability is about the usage phase and end-users of the office. According to ISO 9241 [1]. "A system can be said to be usable when specified users in specified circumstances with specified goals, can use it with effectiveness, efficiency and satisfaction." Effectiveness means the accuracy and completeness with which users achieve specified goals. Efficiency is described as the resources expended in relation to the accuracy and completeness with which users achieve goals. Thirdly the satisfaction is the comfort and acceptability of use. To make it simpler the effectiveness means doing right things, the efficiency means doing this right and satisfaction is the level of comfort and pleasure in doing things.

According to Nissinen (2004) the high quality working environment is not only functional but also usable. It is well known fact that the costs of office environment constitute only a small part of the total costs of a typical organization. [2]. However, the importance of working environment quality is essential for any organization due to several reasons, for instance: High quality working environment enables the office workers – the most important resource of the organization - to do their best every working day and every working hour according to today's business challenge: to do more, faster and better, with less time. For any company a high quality working environment is an important advantage when competing for the best and satisfied workers.

The methods to evaluate and measure the workplaces from the usability point of view include more than only a survey of customer satisfaction. The effort is to find out the quality and content of the user experience of the usability.

2.2 Usability walkthrough

Pluralistic usability walk through is a method, which combines elements from a usability test and usability inspection. A pluralistic usability walk-through session involves participants from three groups: the users (present or potential) of the workplace, system developers like architects, designers and constructors and usability professionals. Together the participants gather information about the usability by inspecting the workplace. All users who try to accomplish given tasks participating the usability analysis. In the end of the session the whole group discusses the findings they have made.

Cognitive walkthrough is a task oriented usability inspection method. Its focus is on ease of learning. Cognitive walkthrough is based on a theory of learning by exploration according to which users try to infer what to do next using cues that the system provides. Users do not read manual or want any formal instructions before they start to use new systems. Instead users learn by doing and exploring. The method is applied in ICT field. [3, 4, 5, 6, 7]

Riihiaho (2000) describes the usability walkthrough as the method, which guides the analysts to consider users' mental processes in detail instead of evaluating the characteristics of the actual interface. The method can be used very early in the design process to evaluate designers' preliminary design ideas and hence no running version of the systems required. On the other hand the context of the tasks and the users' characteristics must be well specified so that the analysts are able to consider the users' mental processes. [3]

In the walkthrough, the analysts comment on the sequence of actions that the users should execute to accomplish their tasks. The walk-through should always follow the right sequence of actions, that is the sequence that the designer has planned the user to follow. If problems arise in this sequence, they are recorded but the analysis's continued as if the problem did not exist. [3]

3. Why to make Usability Walkthrough?

The usability walk through can serve several purposes. It can indicate the components of usability of the workplace. It is essential to point out the factors, which are causing the high or low usability in order to improve it. Secondly it is important to get information about the factors, which are significant for usability. Thirdly the factors of usability and evaluation of them seems to be a source for interesting process of understanding and discussing about the workplace. According to Horelli (1992) the human beings are very adaptive to the environment [8]. This explains why the usability is not self evidently the elements which people demand in the workplaces. The tendency is to take the workplace as granted instead of demanding the high usability. But the increase of the awareness around usability of the workplace is a change to get into the learning process both in individual and organizational level. The process will lead to the improved usability and at its best, the process is continuous learning and evaluation cycle and an important part of organization's functions. The usability walkthrough technique is suggested as a tool to evaluate the workplaces, identify the gaps between the original design concepts and the current use, and to provide a platform for different parties to communicate.

The object of the usability walk through varies in different situation. It can focus on the use of the new workplace. It can be done in the workplace, which has been long in use or it can goal to the refurbishment of the workplace. In all these settings it is a way to investigate the relationship between the workplace and the workplace behavior and human cognitive maps. The logic in environment is a component of vital environment [8].

4. How to make Usability Walkthrough?

4.1 Usability Walkthrough in case study

This Chapter presents a case study where the usability walkthrough was used. The usability walkthrough was a challenge in the case study target, which was the Old Mill business park, which is located in the Kupittaa area of Turku close to three universities, the polytechnic, the railway station and the increasing Turku Science Park. The building itself is an old ceramic factory renovated for the use of ICT-companies. In Turku the area development strategy includes an important center for ICT-business. Consequently, the decision was taken to renovate the old factory as a modern center for ICT-companies The interior of the building has been left exposed in the renovation giving the estate its unique feeling combining modern technology with the building's historical features.

The Old Mill includes a number of additional services alongside its functional and interesting office space. The building is equipped with latest data network connections to provide the best setting possible for the ICT-companies in the estate. Tenants also have access to a number of meeting rooms as well as an auditorium for their use. Sodexho manages a restaurant in the building providing the perfect setting for business as well as private functions. Petrasol Business Centre oversees the running of the Old Mill's reception area, switchboard, as well as the building's Intranet.

The building of the Old Mill presents the imago and brand in a similar way as the name, slogans or logo. The Old Mill has its own profile and identity, which differs from the surroundings and manages to provide something unique for the companies. The expression in www-pages "From a ceramic factory to a technology center – a glance into Old Mill’s history” and **“**New technology in an old factory “ make the brand of the building exciting, unique and valuing tradition

The usability walkthrough was thought carefully and some framing was done. The interesting character of business parks encouraged concentrating in the usability walkthrough fully in shared, common and public parts of the building instead of the individual workstations. In order to clarify the objectives of the usability walk through the diagnosis of high and low usability was made by the survey for user’s of the building.

In usability walkthrough itself the end users, on various levels, evaluated those objectives, which had scored with high or low usability in the diagnosis survey. The balance of the participants is important. The team for usability walk through included

- The architect of the present structure in Old Mill
- The service provider of help desk services
- The service provider of catering services
- The facility manager
- The end user
- The usability researchers

Using the former data from the diagnosis phase the route for usability walkthrough was identified. The results were described briefly and the participants have had the chance to prepare. They got some guiding questions beforehand.

Participants were encouraged to reflect their views on the facilities and open-ended questions were asked to collate different point of views. Discussions were tape-recorded. During the walk through, the participants observed the facilities and began to discuss the causes and effects of use of spaces. Participants were encouraged to give feed back according to their own experiences on predetermined milestones:

- The entrance space
- The restaurant
- The meeting room
- The parking area

Table 1 Usability walkthrough results

VIEW	FACT	RECOMMENDATION AND FINDINGS
The entrance space	The entrance space is large and the reception/ help desk is located on the other end of it. As the desk is relatively distant from the entrance itself, it is not immediately noticeable when you enter the building. This sometimes causes confusion for visitors. *"We often need to catch visitors attention, because they don't notice us"* – reception	Make the help desk service visible. Hospitality (of reception staff) increases usability – service is an intangible attractor.
	It is assumed that visitors approach the help-desk/reception first in order to provide security (limited access to offices). Therefore there is a limited amount of signs and guidance.	People should be encouraged to **learn** to use the help desk. Host should inform the visitor about norms.
	The "lobby-area" is in low use *"People are not familiar with using such a open entrance spaces"* - architect People are not utilising this space for other purposes (multi-use), such as meeting, displaying products, events etc. *"People don't want to be seen to sit in a lobby as this means you are lazy"*'- FM	To provide information about multiuse possibilities The attractors: vending machines and touchdown desks The furniture solution - Encourage for communication and interaction (greeting and informal meeting) - Should the space be divided to provide more privacy? - Focal point to the entrance (
	The design of the space creates a "wow"-effect. *"I chose to work here because I was impressed with the design of the building"* - user	A lively and dynamic atmosphere should be created to sustain the positive and attractive impression. (From the first impression to the total experience – "wow, here is a pulse"-effect) Maintaining the 'wow' effect throughout the building -
The restaurant	*"The layout of the lunch buffet is illogical - wrong way round"* – service provider	Use the towards the clockwise Arrangements Change the location of the cashier
	The lack of information about "traffic" rules	Signs

	Limited use of two meeting rooms after the restaurant closing time	Information Room booking arrangements
	On-peak time queuing is time consuming and frustrating *"I sometimes turn back when I see the queue and come back later" - user*	Encouraging people to have their lunch on off-peak times – rewards (free coffee and dessert etc.)
The meeting room	The light and ventilation switches are illogical: Red light indicates that the ventilation is switched on – confusing message (red = danger) To control the level of light you need to press rather than turn the switch – Delay in the change of the level of light - difficult to achieve desired level. *"It is embarrassing when the lights turn off in the middle of a important customer meeting"* - user	Guidance for, and information about, efficient use.
	As a consequence after combining two smaller meeting rooms, the light and ventilation switches are not next to the new main door (having to find the switches in the dark)	Investigate new solutions (Remote control etc.)
	It is difficult to serve food and beverages in the two small meeting rooms.	Consideration of furniture solutions
	The need for larger meeting spaces has increased – more training sessions	Use of entrance space?
	ICT system and security – the same phone line for two rooms. *"We need an absolute confidentiality also during the tele-meetings"* - user	Under assessment.
The Parking area	Not enough parking space for customers. *"I sometimes have to go and re-park our customers' cars because the allowed parking time is only 2 hours – less than most of the meetings. " –* user	Help desk service can be developed

The status of usability Old Mill is quite high, but some areas of improvement have been identified. The aims for improvements include:

- Customer orientation in the car parking area. (Serviceability)
- Smarter' (multiple) use of the entrance hall - focus on different options and communication of these to the users. This encourages them to use this space more efficiently. (Usability)
- Efficient use of the restaurant lunch buffet by improving the logic of the layout.can be improved (Learnability)
- Better guidance of the ways the meeting rooms are used. The amount of information for the use of meeting rooms. (Functionality) [9]

4.2 Learning points for developing the usability walkthrough method

The usability walkthrough in the public and shared places in the business park kind of setting gave interesting results. Anyhow it caused several questions, which are worth to consider further. The user's experience of the public areas are always linked to the context of the workplace as a whole setting. The whole setting in usability walkthrough could give different results from the perspective of the user. On the other hand the group of service providers as end-users in the business park is an important group within a usability investigation.

The second issue is about the targets of usability. To the usability walkthrough in the presented case study the targets based on the results of the survey. The targets should be based on the user's experience of usability. Because the experience has its soft kind of nature it might be worth to explore if the usability attributes created by Keinonen (2000) could be a matter to apply. [10]

Keinonen (2000) has developed a model of usability for consumer products but many of the attributes he defines are also relevant with workplaces. The usability attributes are:

•Functionality (FNC)
•Logicality (LOG)
•Information presentation (PRE)
•User manual, documentation (DOC)
•Usefulness (USE)
•Ease of use (EoU)
•Affect on emotions (AFF).

The attributes described are connected to either personal preferences of the consumer, or directly to the product, or to its functionality. The first level of usability has to do with how the user perceives the concrete characteristics of the user interface of the product (LOG, PRE, DOC, and FNC. [10]

The two other attributes documentation and functionality have a lot to do with the instructions and their achievement according to the functional properties of the building. The use of lightning, regulation of room temperature, the air-conditioning – how do their function, how they can be used and how the use of them is informed. These are essential points of views of usability of workplaces.

The next level of usability evaluation contains the consumer's feeling about the quality of the interaction between her and the product (USE, EoU) [10]. In addition it might be relevant to mention two more criteria for vital environment by Horelli [8]. Besides earlier mentioned logic of the environment the vitality included the feeling that the workplace can offer an exit from daily rush, disturbances and mental requirements –it is refreshing environment. As well it offers the sense of belonging for the user – it helps a person to include oneself to the organisation, profession and goals of the work. Nevertheless it is attractive. This comes close the third level of usability, which is also the most common in use when usability is evaluated, is the interactions general effectiveness on users' emotions. This level is emphasised by consumers' personal aesthetic and value based criteria (AFF). [10]

Instead of the objects like entrance hall or meeting room it could be possible to concentrate more in the description of the qualitative aspect of the usability experience. This approach can then end up to concrete objects as indicators and visible artefacts for the usability experience.

5 Conclusions

The usability walkthrough is a relevant way to approach usability, its evaluation and development. The existence of diversity in participants characteristics and needs in relation to usability walkthrough has all the potential to impose significant challenges. Two questions still remain: whose responsibility is usability? and secondly how to attract usability experts to the organization to share usability experiences?

The method of collecting and disseminating information about usability of work places is one issue that requires further investigation. Such investigation would make it possible to build a usability profiles for workplaces. This profile can illustrate the characteristics, which make the workplace suitable for doing right things in right way and with the ease and satisfaction. The usability profiles from different workplaces could together produce interesting material to compare and classify further the elements of usability.

One other difficulty with investigating usability at workplaces is that it is impossible to create a controlled environment within which usability data can be collected. Usually usability walkthrough is carried in a workplace environment and is quite different from a designed environment on a smaller scale. This is largely because of the impracticability of designing such physical smaller scale usability environment. However there are possibilities for simulation especially in the virtual environment. This is an area that has not yet been fully explored or applied. Such usability lab is possible given the existence of supporting technologies and requires more investigation.

The usability, based on the experience of the user, is one element in the discussion about the workplaces, which support the total well being of the user. The effectiveness, efficiency and satisfaction in the workplace increase the productivity of the user – not only as a ratio between input and output but also as a quality of the work performance.

The Impact of Hi-tech learning Environments on Pupils' Interactions

Túlio Tibúrcio,
The University of Reading, Reading, UK, (email: t.m.d.s.tiburcio@rdg.ac.uk)
Edward F. Finch,
The University of Reading, Reading, UK (email: e.f.finch@rdg.ac.uk)

Abstract

This study focuses on the intelligent 'classroom of the future' which characteristically make extensive use of information technology and flexible environments. The UK Government has recognised the need for radical changes to classroom environments and their facilities in order to improve learning. As an outcome of these new ideas, proposals are being developed and implemented through the UK's "Classrooms of the Future" project [1]. The behavioural analysis method described in this is used to critically examine the efficacy of the "Schools of the Future" concept.

Research suggests that students are positively disposed to new technology in the classroom environment [2]. One study has used behavioural mapping to analyze the effect of the classroom environment on the practice of teachers [3]. The purpose of this research is to determine whether these novel intelligent classrooms will affect the behaviour of children in their new learning environments. Behavioural mapping was used to observe and monitor the classroom environment and analyse usage. Two new classrooms designed by INTEGER (Intelligent and Green) in two different UK schools provided the case study environments to determine whether intelligent learning environments can enhance learning experiences.

Keywords: Learning environment, classroom environment, intelligent classrooms, behaviour, behavioural mapping.

1. Introduction

1.1 A Hi-Tech Learning Environment

The discussion about learning environments extends beyond the boundaries of a single room to a variety of settings. Learning can occur in numerous environments. Information and communication technology (ICT) are integral to this learning experience and the flexibility it affords. The measurement of successful learning can be a very complex task to accomplish. [4].

The classroom is also a complex space [2]. He states that “the classroom environment is a complex environment which poses a number on methodological problems for any researcher” [page 22]. However, observing and understanding a space can provide an indication of how well learning resources and interactions are being explored.

Figure 1 A technology-based flexible classroom

This study focuses upon new technology-based classrooms (see Figure 1), referred to as intelligent classrooms. It aims to investigate the impacts of these new environments on pupils and whether pupils’ behaviour is affected by the change of environment. Methods from environmental psychology underpin the research.

The UK government is seeking improvements in education both in terms of learning acquisition and school facilities. New learning spaces have been built or renovated. In UK about 31 new classrooms of the future were designed and are being built around the country [1]. However, some fundamental questions remain to be answered. What are schools of the future going to be like? What will be the impact of technology in early education? What changes are needed in the learning environment? Annesley et al. [5] argues that the design of a school affects the way pupils and staff interact, their motivation and self-esteem – this in turn has an effect on learning.

In this study the focus will be restricted to single classroom spaces, although it is acknowledged that other issues such as grounds and circulation areas may also play a significant role. The study explores key factors that seem to have some influence in this process: the flexibility of the space, the mobility of the teacher and the use of new-technology. New technology enables flexibility and mobility, both of which are analysed in the study. In addition, human interactions in the classroom are analysed in order to find out if technology-based classrooms enhance learning.

1.2 An intelligent classroom

Study by Underwood [2] already indicates that students are willing to accept information and communication technologies (ICT) in the classroom environment. Dudek [6] argues that schools and their educational needs are changing and that information and communications technologies are expected to transform the classroom. School facilities, including the classroom, are already facing changes to meet the needs of the ‘communications age’. Figure 2 shows the use of information and communication technology in one classroom took as case study.

Figure 2 A n intelligent classroom environment

There is a belief that "in the classroom of the future the learning environment will look and feel different" [1, page 79]. The intelligent classroom, in this research, considers two aspects: technological (or technology-based) and sustainable. The technological aspect looks at the building as a product that: **a.)** makes extensive use of information and communication technologies such as wireless computing, video-conferencing, interactive whiteboards, that enable individual and group work as well as electronic links to other schools and facilities; **b.)** has flexibility as a central theme to enable a variety of different learning environments; **c.)** provides movable, attractive and adjustable furniture suitable for a wide range of ages and sizes facilitating use of the new learning technology.

The other aspect of the intelligent classroom concept is linked to sustainability or green buildings. According to Edwards [7] "sustainability is increasingly seen as the only legitimate architectural design issue for the 21st century" [page 83]. He also tries to establish a link among productivity, technology and sustainability and states that these three factors "are quickly being recognized as an important package of interactions, especially in working environments" [page 83]. Environmental (green) issues in the workplace are also discussed by McGregor and Then [8]. They argue that both providers and occupiers of buildings are realizing, increasingly, "that workspaces need to be provided in an environmentally responsible way" [page 121]. This research investigates these sustainable workplace ideas by looking at school environments which were conceived as intelligent *and* green buildings.

2. Multi-Method Approach

A multi-method approach was employed in the research in order to avoid bias (as advocated by Zeisel [9]), who argues that using several methods to attack one problem achieves higher-quality research, suggesting that "the appropriate mix of methods will be the one that enables you to achieve your ends with the greatest control over side effects" [page 229].

This research is based on comparative case studies of two new classrooms and two traditional classrooms at different schools. Two main methods were used: behavioural mapping (through class observation) and questionnaires. In addition, two other tools were used to elicit information: interviews were carried out in the beginning of the field work and a feedback box was set up in the studied environment.

2.1 Behavioural mapping

Rivlin and Rothenberg [10] define behavioural mapping as a naturalistic time-sample technique for describing patterns of activities and the use of physical space. Zeisel [9] describes similar technique named as behavioural plan annotation in which information about the relation between the environment and behaviour is recorded.

Horne [3] explored the behavioural mapping technique in her observations in classrooms. She argues behavioural mapping is an efficient tool to get a clear understanding of the classroom environment. It is generally believed that behaviour is affected by the environment and the environment in turn is changed or adapted to accommodate different behaviour.

Behavioural mapping was chosen since it allows several graphic maps to be produced during an observation session. Every 5 minutes a map of the physical space or physical settings (as defined by Proshansky [11]) was produced and information was registered. Ittleson *et al* [12] suggested time intervals of 15 minutes, but variation is possible. The observations were mapped on floor plans of the classroom, annotating layout, teacher's movement, interactions among users and with the environment, record of activities and their duration.

2.2 The Constructs and Terminologies

Various constructs were developed by Horne [3] to help class observation techniques. Some of them are described here. *Lesson profile, flexibility of the classroom, mobility of the teacher,* and *density* are constructs being used in this research. Another factor, *interaction*, was added and is being investigated in order to check the relation of the new learning environment with possible interactions among users. This factor has also been used before by Horne, but from the teacher's perspective. In this research the focus is on pupils.

Some constructs and terminologies described in this session were used in the research and originate from Horne [13] with some adaptations: **a) Lesson profile** is a column that identifies the clusters of activities (introduction, teacher teaching, pupils on task, transition, and conclusion; identified to describe the different activities that occur in the classroom. **b) Flexibility factor** of the classroom "is the total area in each room that allows change to be made by the teacher with varying degrees of effort" [page 143]. **c) Mobility factor** of the teacher is the total area covered by the teacher during the lesson in relation to the total area of the room. **d) Density** is the amount of space per pupil in a classroom measured in square meters per pupil**; e) Interactions** mean relationship between users and the new learning environment. These interactions were classified in 5 categories in order to be quantified and to investigate if there is any relationship with the other factors. As the focus of this study is the pupils, the possible interactions were identified: 1. pupil-to-pupil, 2. pupil-to-teacher, 3. pupil-to-equipment, 4. group interaction, 5. no interaction; **f) New-Technology** is introduced to refer to leading information and communication technology (ICT) which includes interactive whiteboards, laptops, web-tablets, video-conference, scanners, printers, and digital cameras. This equipment is available for pupils and teachers alike and can be used to support both group and individual working.

2.3 Physical Settings

Two new classrooms designed by INTEGER-Intelligent and Green as part of UK Government project named "The Classroom of the Future" provided the case studies for this research. The goal of this government project is to enhance learning acquisition through innovation in the school environment. Several such classrooms have been designed and built around the country. Telford and Wrekin Local Education Authority (LEA) has these two new classrooms in two different schools: The Lord Silkin (secondary school) and Wrockwardine Wood Church of England Junior (primary school). Two locations were used for class observation in this research. In addition, pupils were observed in both traditional and new classrooms to provide a control.

Table 1: Summary of the school classes studied.

Case Study	***School***	***No. of pupils***			***Age group***	***Stage****	***Year***
		Male	*female*	*Total*			
01	Wrockwardine Wood Church of England Junior School	15	14	29	7 - 9	Key Stage 2	Year 3 and Year 4
02	The Lord Silkin School	20	17	37	15 - 16	Key Stage 4	Year 11

* Related to DfES (Department of Education and Skills) [14]

Location 1 Wrockwardine Wood Church of England Junior School is a primary school attended by pupils at Key Stage 2 with 10 classes from Year 3 to 6. The classroom of the future built in this school was in use by all school pupils. One class of 29 pupils who were 7-9 years of age was chosen for class observations (Table 1). This choice was based on the convenience of matching the schedule of the secondary school observations. Students were observed in the new learning environment and in the traditional classroom (see Figures 3). The same group of pupils, the same teacher and the same subject were observed in both environments.

Location 2 The Lord Silkin School is a secondary school built in Telford and Wrekin Local Education Authority. This school is now applying to become a specialist school in business. The classroom of the future built in this school has been used by these business students. It is the same original design with slight differences in terms of cladding, decoration and different external deck. One single class of 37 pupils, 15-16 years of age (Table 1) was chosen as the second case study. Students were observed in this new classroom and in the traditional learning environment (Figure 4). Again, the same group of pupils, the same teacher and the same subject in this school being observed in two different environments.

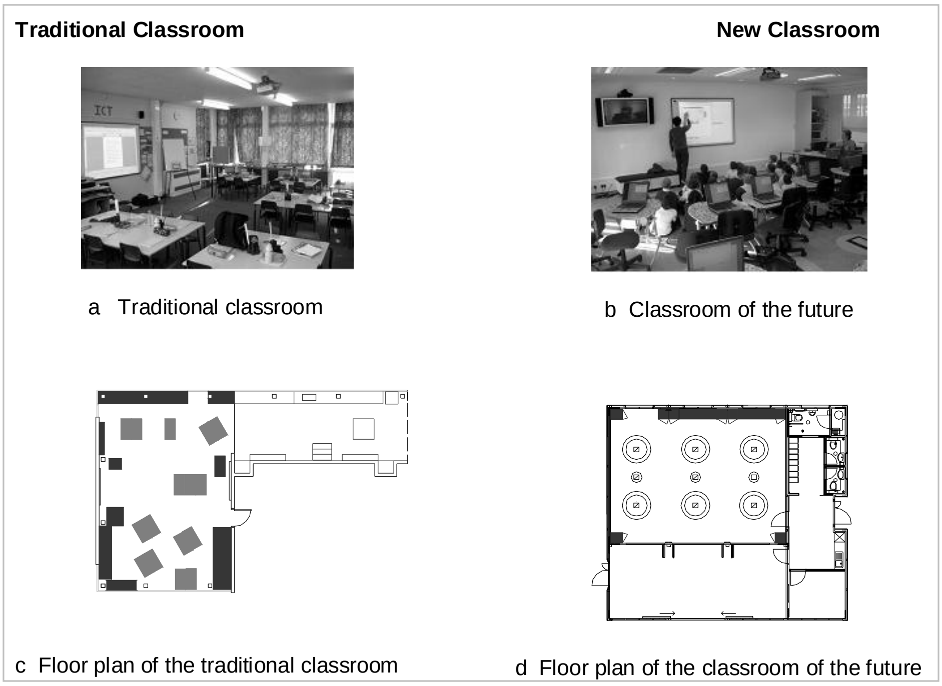

Figure 3 The two physical settings at Wrockwardine School

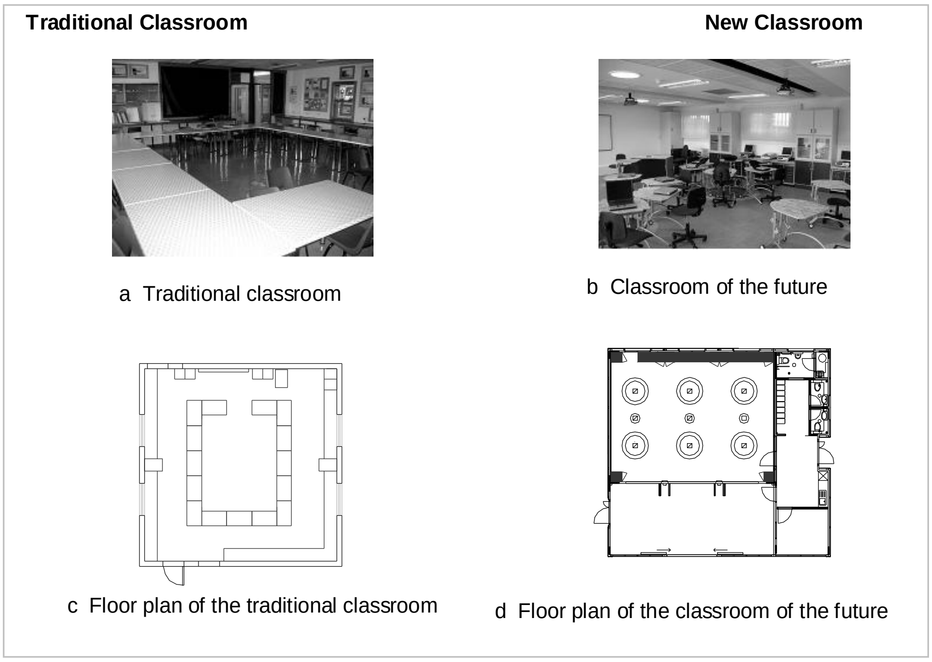

Figure 4 The two physical settings at Lord Silkin School

2.4 Methodology

Interviews were carried out a few months after the launching of the classrooms which occurred last September 2003. Data gathering was structured based on the case studies described above.

A total of 64 class observations were planned. Pupils and teachers were observed in the new and in the traditional classroom for comparison purposes. In this way the sample has 4 physical settings (4 classrooms: 2 “classrooms of the future” and 2 ‘traditional’ ones) in two different schools. Each lesson observed would generate 10 behavioural maps in a total of 640 maps, considering that it could be reduced due to school dynamics.

Questionnaires were also used in the study. Considering a classroom a space where behaviour is an important observable factor, the behavioural mapping technique allows information to be gathered about this learning environment. However, observation in turn relies on interpretation of what was observed. Swetnam [15] argues that case studies are often classified as qualitative by definition. “Observation is essentially observer-oriented” [16,, page 9] having thus a degree of subjectivity. It means observation has limitations and information can be missed by the observer. Zeisel [9] states that it is crucial that the observer be aware of what he is looking for and what needs to be observed.

With research focus on teachers, Horne [3] used interviews to validate the data originating from observation. In this research, another technique was used since the focus is on the pupils. The use of questionnaire at the end of the observation process allowed the validation of the data collected from observations. The focus of the questionnaires was the users’ views of their experiences in the new environment. All pupils in the classes were given a questionnaire. The sample size for questionnaire in a qualitative study, as suggested by Allison et al.[16], needs to be only large enough to ensure a wide variety of answers. It was agreed with teachers that questionnaire would be a class activity, which produced a large number of responses.

Other tools were used to get feedback from users of the classroom of the future in both schools. A feedback box was set in each ‘Classroom of the Future’ and open-style forms were made available for users to give their feedback about the new environment. These boxes were collected at the end of the academic year. Interviews were also undertaken. Some teachers and pupils were interviewed at the pilot study stage to get impressions and expectations about the space.

3. Results and Discussion

3.1 Findings

Only initial findings were available at the time of writing. However the study has already shown some preliminary results that seem to support the hypothesis that ‘intelligent learning environments can enhance learning experiences’.

Figure 5 illustrates how some of these factors have been observed and recorded. Interactions were mapped graphically. Each five-minute map has tracked the teacher's movement and by overlapping them it is possible to calculate teacher's mobility. Furniture movements were measured to allow for calculation of the flexibility of the classroom.

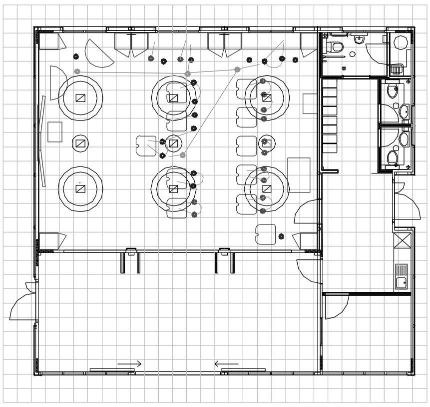

Figure 5 An example of a 5-minute map showing interactions in various categories, the layout for that lesson and teacher's tracking

Initial analysis of the behavioural maps has shown that interactions occurred more frequently in the classroom of the future as shown in Figure 6. This figure represents two observation sessions of the same group of pupils (secondary school) involving the same teacher and the same lesson subject in the two different learning environments: the traditional classroom and the classroom of the future. Four major factors that relate to interactions and their relationship have been identified: (1) interactions, (2) flexibility, (3) mobility, (4) technology.

The flexibility of the space in the classroom of the future is much higher (93%) than the traditional classroom (85%), encouraging more mobility from the teacher. Although the traditional classroom has a sizeable flexibility factor it has not been made use of.

Also the new technology in the classroom of the future has permitted the teacher to move around the classroom much more in the new environment (66% mobility). In the traditional classroom, where technology is limited, the teacher tends to be less mobile (15% mobility). Both use of technology and mobility seems to generate more interactions to occur in the new environment.

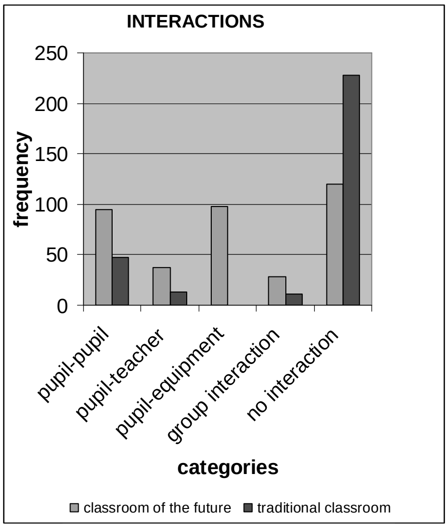

Figure 6: Interactions observed during 2 sessions in the secondary school

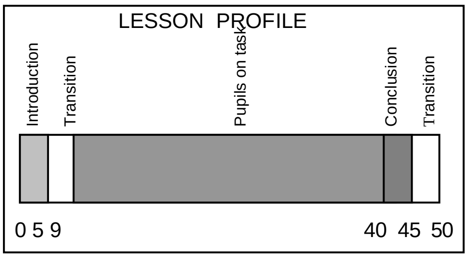

Figure 7: Lesson profile in traditional classroom at Lord Silkin School

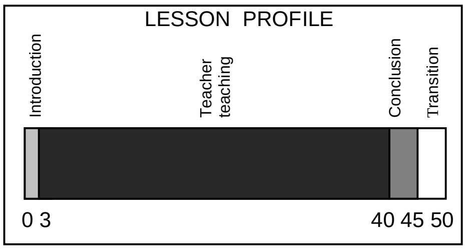

Figure 8: Lesson profile in classroom of the future at Lord Silkin School

Another important finding from the maps is the lesson profiles. They indicate that, in the classroom of the future, there is a tendency to have a more child-centred lesson as can be seen in the lesson profile in Figure 7. Pupils spend more time on tasks. In the traditional classroom the lesson profile (Figure 8) shows that the teacher spends most of the time teaching in the context of a teacher-centred lesson.

3.2 Relationships

Findings from the observations indicate that relationships exist between factors being investigated in this research. These relationships suggest that more interaction is stimulated by the new technology-based classroom.

Mobility and Flexibility The observations showed that flexibility seems to be directly linked to the mobility of the teacher. By comparing teacher movement in the traditional and new classroom it is possible to identify greater support for mobility in the new classroom. Furniture layout is routinely rearranged and equipment is relocated.

Mobility and Technology The new classroom has more equipment (laptops, web tablets, printers, interactive whiteboard, video-conference equipment) available for pupils to use (each student can have one piece of equipment for his own if necessary)

and evidence suggested that it was being used. The teacher was significantly more mobile in the new environment. Pupils only use the technology if the teacher invited them to do so. Only the teacher was tracked and mapped in terms of movement, but through observation it was possible to identify that there was also more movement of pupils in the new classroom due to new technology available.

Mobility and Interactions It was found that the more mobility the teacher had, the more interaction occurred amongst pupils. This was most obvious in the secondary school. In the traditional classroom the teacher spent most of the time teaching in front of the classroom while in the new one the teacher moved around interacting with individuals or groups. This was also apparent in the primary school. Observations indicated that the layout also influences the likelihood of interaction.

Interactions and Technology The technology available in the classroom of the future allows more teacher-pupils and pupil-pupil interactions. There was a belief at the beginning of this research that interaction may drop off when students used their own individual equipment. However, observations indicated that interactions seem to increase. The teacher was inclined to move around to teach and help pupils with the equipment. Pupils also interact more with each other and often worked in groups to help each other with the equipment.

Interactions and Flexibility By comparing the layout in the traditional and new classrooms (mainly in the secondary school) it is possible to state that the flexibility allowed by the new classroom has encouraged meaningful interactions. The traditional classroom in the secondary school has a horse-shoe shape layout that encourages the teacher to stay in the front of the room and the students to sit quietly around the horse-shoe shape desks arrangement. It produces few interactions. Most of the interactions that occur are teacher-group or one-to-one. In the new classroom a more flexible space has allowed more interactions as the teacher has more mobility. Pupils also have greater opportunity to interact with each other and in groups.

Flexibility and Technology A relationship was observed between 'flexibility' and 'technology' found with wireless technology together with movable furniture creating more flexibility in the observed classroom.

All these relationships can be summarized in a diagram as illustrated in Figure 9. It indicates that the use of new technology, flexibility and mobility all allow more interactions to occur.

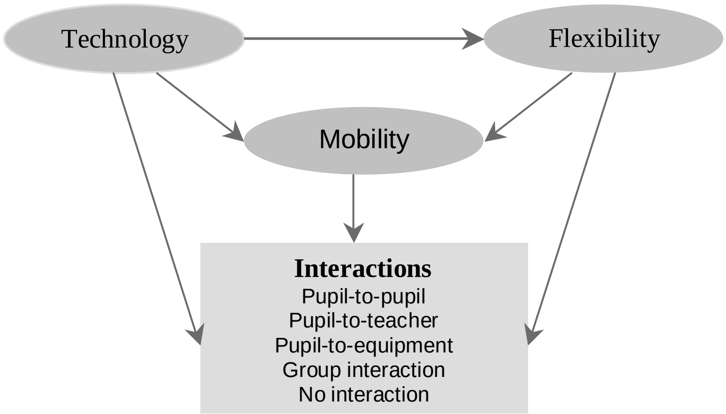

Figure 9: Relationship among key factors

4. Conclusions

This research sought to investigate the impact of new classroom environments on pupils and whether pupils' behaviour is affected by the change of environment. The research also shows a new way of examining the classroom environment with the focus on pupils.

The study has shown that developments in classroom design needs to consider technology as a key factor. Pupils are comfortable and become familiar with the use of new equipments and technology. Teachers are being trained and encouraged in the use of technology in their classes. The use of new technology-based environments seems to have positive effect on the learning process, in the delivery, interpretation and reuse of information. Pupils' behaviour was observed to improve in these environments. The pupils seemed stimulated by the new technology and also by the appeal of the classroom spaces. Teachers also felt pupils were stimulated by these new learning environments. Interactions seemed to increase as discussed previously due to factors such as flexibility, mobility and technology. This confirms flexibility as another important issue in building design and workspace design.

Further studies in this research will investigate productive interactions as suggested by Littleton [17]. It is expected that it will allow some understanding of whether learning acquisition has any relationship with interaction levels. The assumption that high levels of interaction are necessarily 'good' needs further analysis.

It seems to be clear that an intelligent classroom will demand more investment, maintenance and management. It becomes a more complex environment and needs to be well planned and designed in order to attend to the demands of teachers, pupils and the community at large.

Intelligent classrooms present a new approach for learning environments. These environments seem to be a new way of stimulating pupils’ curiosity, initiative and autonomous learning. The flexibility existent in these classrooms facilitates interaction and it seems to help group and independent learning. The accessibility to and use of information, made easier through technology, introduces new practices in the classroom. A new way of learning is brought about by the intelligent classroom. In order to discriminate between effective and ineffective innovations in such environments, analytical tools such as that described in this paper should be adopted.

Architectural design as an enabling resource for end users in K-12 schools

Erland Flygt, MArch,
KTH Syd Campus Haninge, Dep. for Design, Work environment, Safety and Health
Marinens väg 30, 13640 Haninge, Sweden. erland.flygt@syd.kth.se

Abstract

This paper discusses architectural design as an enabling resource for end users in K-12 schools. It also presents work in progress and preliminary results from a doctoral program project that investigates the relationship between architectural design and educational outcomes. The main focus lies on a case study concerning a K-12 school built in the late 1960s and situated in a socioeconomically deprived and mainly immigrant catchment area in Sweden. There is surprisingly little research done in this field so far. The author argues that there is potentially valuable knowledge to be gained through this research for all actors involved in school design, development and maintenance. The proposed research would focus on client and end user perspective through continuous evaluation of the fit between organizational goals and results, end user experience and architectural design. Prior to the doctoral program the author had been working with development of ICT environments and applied ICT projects for higher education, research and development since graduation in1997.

Keywords: Architecture, Design, Evaluation, School buildings, Educational outcomes

1. Introduction

1.1. Industrial relevance

The industrial relevance of having access to scientific research about the relationship between architectural design and learning environment is imagined as follows:

- The development and application of ICT is one of the major drivers for change in societies all over the world. Good educational systems becomes a strategic asset as we move into a global knowledge society with a knowledge-based economy demanding life-long learning [1].
- There is a rising demand for international benchmarking and national school quality assessments. This demand constitutes a new incentive for clients, such as local authorities, to try to connect the cost of facilities and activities to educational outcomes [2]. Facilities may get a new role in adding value (or the opposite) to learning activities for the client responsible for educational facilities. At the same time globalization and increased interdependence, such

as within the EU, create an international marketplace for the construction industry. The industrial contender who has the best understanding of the evolving end user needs and expectations down to the local level will then gain competitive edge.

– Educational reform in Sweden increasingly put the individual learner in focus. Learning is perceived as taking place in a socio-cultural context where interaction and communication is essential [3]. At the same time educational activities are to be adjusted to meet individual needs and thus calls for various modes of tuition and self-studies. The bulk of existing schools however was not designed to meet this need and does not always offer the necessary flexibility.
– As ICT becomes more and more integrated into building systems on all levels it is safe to say that professional architects and builders will have to learn more about how end users interact with and benefit from ICT application in real-life contexts.

1.2. Research horizon

1.2.1. Molecular level research

Many scientific research studies have been done on a molecular level about how factors in the physical school environment affect prerequisites for learning and health. Standards and recommendations regarding environmental factors such as noise levels, air-quality, temperature and lighting have emerged. Still there seem to be difficulties in the application of the very same standards and best practice. For example, in 2001 ventilation was still the single most common object for complaints in Swedish educational facilities, as it had been for 10 years, according to a study in by the Swedish Work Environment Authority [4].

1.2.2. Molar level research

Hitherto there has been very little architectural research about educational facilities at all in Sweden [5] [6]. The most well-known example is probably a study by Skantze from 1990 about how children view their school work environment [7]. Another more recent example is a PhD thesis in architecture by Patrik Bjurström on modern Swedish school buildings, their meaning and the ideas behind them studied through a series of case studies. Unfortunately there is even less scientific research done about how architectural design relates to educational outcomes in formal learning environments.

In a study initiated by The Swedish Association of Local Authorities the question was: “Does better facilities give better educational quality?” [8]. An initial survey with questionnaires was distributed to pupils, teachers and principals in about 100 compulsory schools in Sweden. According to the study nearly 25% of the schools had good facilities, but in general the facilities were unsatisfactory. For the statistical analysis they created an educational quality index to which various factors were tied and related to educational outcome in terms of results. The authors point out that it was difficult to find appropriate measurements for educational outcomes in Sweden and that they had to settle with grades in year 9. The four factors that had the greatest importance to explain variations in the index was, in falling order: 1) management and organisation, 2) teacher competence, 3) the physical school environment and 4) textbooks and teaching aids. Even if the physical environment does have an effect on variations in this index, the conclusion in the study is that it is of little use spending more resources on facilities in order to improve educational outcomes. Despite being a promising initiative the study is problematic for several reasons. One is that the resulting report included a quality development tool targeted at politicians and employees in local authorities responsible for education. The text in the report might persuade readers to actually believe that by following the model to allocate resources you will improve school quality (and thus educational outcomes) accordingly with an accuracy down to two decimals. This seems particularly problematic since the study only used questionnaires to establish casual relationships about a complex real-life situation. Facilities are treated in very general terms and the study does not, and cannot, describe differences between different schools in any detail. This paper argues that research about the relationship between architectural design and educational outcomes need a combination of methods, both quantitative and qualitative, and perspectives to be of practical use for school development.

In the USA an interesting approach to studying the relationship between architectural design and educational outcomes have developed over the last couple of decades. It is a design patterns concept that stems back to the investigations by Christopher Alexander and his colleagues in the 1960s and 70s [9] [10] [11]. Basically the idea is that to any well-defined design problem it is possible to create a design pattern that captures the essence of the solution to the problem. It should then be described in such a way, through text and diagrams, that the pattern will be generic and practically useful. Lackney and Moore (architectural researcher and behavioural scientist respectively) have developed sets of design patterns and design guidelines for educational facilities that they suggest promote learning [12]. These patterns are primarily based on meta-analysis of scientific studies and best practice literature within behavioural science, pedagogy and architecture as well as on their own empirical studies. The patterns that Lackney and Moore considered the most strongly supported were used as a starting point for items in the initial survey among principals as part of the doctoral program project that this paper describes.

Evaluation research of school buildings has been around for some time, but is still not very common. As early as in the late 1960s the Building Performance Research Unit (BPUR) at the University of Strathclyde, Scotland carried out post occupation evaluations of some 50 comprehensive schools in Scotland. Later the POE concept was developed, primarily in the USA, into handbooks through the work of researchers like Preiser, Rabinowitz and White [13]. Different versions of POEs are now in use for evaluation of buildings all over the USA. According to Lackney there were still very few POEs conducted on educational facilities in 2001. A promising way forward for POEs in educational settings seems to be through institutionalisation, as proposed by Zimring in 1988 [14]. POEs become a standard operating procedure for local authorities, such as the New York City School Construction Authority

[15]. In his paper Lackney also mentions the State of California and their Department of General Services (DGS) as an example where state policy has potential of institutionalise the POE in educational design practise. In 2002 the California DGS have named their own POE version FPE, or Facilities Performance Evaluation (see http://www.poe.dgs.ca.gov/default.htm).

1.3. Approach and methods

1.3.1. Applied research approach

This case study is part of a doctoral program project that also has a practical, or applied, purpose. It might therefore be considered applied research. This purpose is: to contribute to the knowledge of local authorities and schools in general, and one specific municipality and school in particular, with recommendations for application in development of formal learning environments; and to contribute to the knowledge of practitioners / architects with recommendations for design of formal learning environments. It is common practise for architects to take a holistic stance to the design problem at hand and try to merge technical, economical, functional and other aspects into an aesthetic whole. The author also takes a holistic stance in approaching the case in order to investigate the research question from several angles.

1.3.2. The case study research strategy

Given the applied research approach and the opportunity to investigate the research question in a real-life context a case study research approach seem feasible. Robert Yin is an authority within case study research and his handbook is widely used [16]. In his view the method is what characterize a case study. His approach includes both qualitative and quantitative methods but with an emphasis on quantitative analysis. The focus is on the instrumental case study and deductive theory testing. In this particular case the objective is to try to learn as much as possible about, and from, the case in itself, not necessarily to strive for universal generalizations. That makes Robert Stakes approach to case study research relevant as a complement to Yin's. In Stakes view the case itself is what characterize a case study [17]. Compared with Yin, Stake is an advocate for a more qualitative focus, but does not exclude quantitative methods. His model of thought is based on hermeneutics, on abduction and induction through grounded theory, striving to create a whole picture. In terms of generalizations Stake uses the term "Petite generalizations" to mark the kind of generalizations that you can do within the specific case. Outside of the case it is possible to make Naturalistic generalizations according to Stake. Every practitioner builds a repertoire of cases that can be referred to in problem solving. This notion is also supported by Donald Schön in his work on reflection-in-action [18]. Stake claim that the repertoire of cases can consist of conclusions made from personal real-life experience, but also of stories about cases that are so well told that it feels as if you had experienced it yourself. Stake prefers the story as the format for reporting on the case study.

This case study primarily makes use of Stakes approach, as it fits the background, purpose and context of the case with regards to the research question. Stake works with issue questions for negotiating the study. Etic issues that the researcher brings in from the outside, and emic issues that emerge from the case and the people inside the case. As the work develops these issues are restated and transformed into tentative assertions that take form of the Petite generalization. These may in turn develop into Naturalistic generalizations made by the readers of the report themselves. Stake use the term progressive focusing to describe how the researcher moves through the issues during the study. At this time the issues relevant for the paper will be divided in two categories: initial issues and issues under development.

1.3.3. Data collection

- 10 interviews, including one group interview, have been recorded in digital audio format and transcribed for coding.
- Each interviewee filled out a questionnaire identical to that of an initial survey among the K-12 principals in the municipality. Each questionnaire was completed in the presence of the researcher who could answer questions about the items, definitions etc.
- Data from the end users were also gathered on three occasions through the walk-through evaluation method called “Gåtur”, described by Ambrose and DeLaval [19] [20]. In this particular case the Gåtur consisted of eight stopping points on the premises that the researcher found considered as key locations for understanding the case. Two was done with faculty and staff and one with pupils. The material from protocols, notes and recordings will be coded for an aggregated data analysis.
- Observation notes were taken both from classroom sessions and walking around the school.
- Protocols have been made with notes from various conversations and improvised interviews.
- Some 500 digital images were taken of the facilities. A photo album with comments from the construction period in the late 1960s is borrowed from the principal.
- A large number of documents have been collected from both the school and the local authorities. These include for example: drawings, diagrams, statistics, rules and regulations, instructions for teachers, internal reports and protocols.

2. An empiric example

2.1. Main context

2.1.1. Background for the study

The study referred to in this paper has both an intrinsic and an instrumental character. It is intrinsic in that the main object of study, the K-12 school, was given beforehand due to an agreement between the university and the local authorities to make a joint effort in a local, real-life context. This particular school was chosen for several reasons. One reason was the fact that it has a tough setting, situated in a socio-economically deprived and mainly immigrant catchment area. The school was also considered by the local authorities to be worn down after 35 years. The Swedish National Agency for Education specifically called for improvement in terms of educational outcomes in this municipality. The study is therefore instrumental in the respect that the issue of the importance of the physical environment as a prerequisite for the learning activities can be studied.

2.1.2. The case study school

The main building was built in the late sixties and complemented in the 70s with a separate pavilion to house additional classrooms. The pavilion is still there, even if it had to be demolished and rebuilt due to health hazards in the 1980s. Today there are about 350 pupils from kindergarten to year 5 and about 80 adults in faculty and staff. The main building layout has an E-shaped plan where classrooms are located in the wings. Each classroom is connected to a small lobby/group space/corridor section with a door to the outside. In between each wing is a small yard mainly covered with asphalt. But there are also small patches of grass with a couple of young trees, a few large sandpits and a climbing structure. The predominant features of the exterior are the low one-storey profile and long rows of windows on all sides. In recent years the kitchen has been renovated and expanded and a ventilation system has been installed that slightly breaks silhouette of the roof.

2.1.3. Surroundings

The site is flat and has modernist residential building complexes from the late 1960s on three sides. The location towards the periphery of the small community put the school only a couple of hundred meters to the forest. Some teachers pointed out in the interviews that the relative close proximity was a major, if not the major, asset of the schools physical environment. The teachers enjoyed taking their pupils to the forest on excursions. The local community where the school is located has a small modernist centre with a few shops and basic service.

2.2. Initial issues in the case study

Initially there were a number of larger and smaller etic issues in the study and the following still seem relevant for this paper:

- How does architectural design affect the prerequisites for learning in this K-12 school?
- How can architectural design be an enabling resource for learning?
- How do the end users react to malfunctions in the physical environment?
- How does the design matter according to the principals in the municipality?
- How does design matter according to teachers and staff in the case study?

- Which of the supposedly supportive American design patterns can be identified in this case?
- Are these design patterns a relevant concept for developing architectural design that work as an enabling resource for learning in K-12 schools?
- What expectations do the staff and faculty have about the importance of ICT for their future learning activities and physical learning environment?
- Which design factors seem the most important to the end users?
- Which are the specific end user needs and expectations in this K-12 school?

3. Preliminary results

The case study format lends itself rather badly to account for results before the final report exists. Aggregation of data is underway through coding of transcribed interviews that, at the time of writing, only can be analysed through direct interpretation. Also the data has not yet been studied enough for deciding the necessary data source triangulation and method triangulation. In the following sections the "preliminary results" comprise of issues under development.

3.1. Issues under development

- So far there is no evidence in the data that the facilities are part of the school quality assessment. A tentative assertion from the interviews is that a strong incentive for design evaluation of municipal K-12 schools has been missing until now.
- Analysis of interviews done in connection with the initial survey among principals suggest that potential health hazards are their most powerful argument for change in the physical environment. How would design evaluations in relation to added value for the learning environment affect the argumentation?
- Crowding seems to be a substantial problem to some teachers. In interviews and conversations members of staff and faculty express the notion that disturbing noise levels among the pupils are a direct result from crowding, but also a result of the catchment area characteristics with a lot of anxiety among the children. The integration of pre-school activities and classes that is now taking place at the school is also related to this issue.
- At the moment of writing it can be noted that the protocols contain a total of 209 negative observations and 119 positive observations in total. There are also 127 suggestions for change. The pupils' observations will have to be complemented by analysis of the sound recording since they did not always use their protocols.
- Why does the individual fail to notice things that actually work well? It is not until something actually malfunctions that some end users seem to notice the physical environment.

- The end user expectations seem to be somewhat restrained by a general notion of cut back economic resources for municipal schools over the years and the specific notion that the school is in low esteem due to its history and current situation with a socio-economically deprived mainly immigrant catchment area. This observation gets some support in a book from 1999 about planning school buildings in Sweden. There the architect Lena Dranger Isfält claim that within Swedish school traditions there is an attitude towards facilities and furniture that it is something that is provided for you, and that it is something you yourself cannot do anything about [21].
- Even if some teachers express that they have given up hope for improvements of their physical work environment, they still have the feeling that it should be in another way. Many teachers have experience form other situations and schools that serve as references when thinking about the current situation.
- Data from interviews and walk-trough evaluations suggests that some end users finally give up. They stop taking initiatives to do the little things they actually can do by themselves to improve the situation. As committed professionals they have been adapting and trying to overcome the limitations of the physical environment. They say “Well, I am the kind of person who always try to make the best of the situation, but…” In essence they claim that it takes to much resources (time and stamina) away from their teaching and learning activities. It is no use making small efforts since the school needs substantial improvement and they feel that they really cannot do anything about that.
- Future educational facilities are likely to include a mix of real, augmented and virtual environments for learning activities. How can ICT be used to expand the use of educational facilities?
- There seem to be conflicting views on the approach towards the children in carrying out the schoolwork. Some people would like to give the children more freedom to choose for themselves and more responsibility while others stress the importance of keeping a “short leach” in order to create a safe and sound environment that minimize the level of anxiety and unrest among the children who are considered (by all interviewees) as being more lively and out-acting than average. How does the attitude towards the children regarding their need for regularity and rules affect the way the facilities are being used?
- Interviews indicate that, just like medicine, teachers must act in the right conditions to have the desired effect. They must have a chance to set the scene and interact with the children in a way they consider appropriate for the situation and task at hand. If the current faculty cannot work efficiently due to a cramped space situation, would adding yet more qualified teachers have the desired effect?
- ICT equals a PC and an Internet connection according to the interviews and the conversations. The notion of for example interactive thin displays on furniture and/or building parts in their learning environment is a very distant thought for most interviewees.
- Why is it that even though everybody seems to agree on that the need for substantial renovation and redesign has been around for a long time, nothing has happened?

- The canteen, as well as other common and worn down spaces, seem to provoke negative emotions and frustration among the interviewees. The colours are ugly, the lighting is bad, the acoustics are bad, the general layout is not functioning well etc. The same description would apply to several other places, such as their own classrooms, but it does not seem to provoke the same emotional response. Could it be related to a feeling of responsibility – or guilt? That in “your own” room you are somehow more to blame for every shortcoming in the environment, while in the shared spaces no one seems to take the full responsibility?
- So far no data in this case study contradicts the notion that the local authorities do not have access to reliable and updated information about the building performance in relation to the needs and expectations of the end users. How do those responsible to make informed decisions with respect to quality go about to prioritize in the educational facility budget without seemingly necessary information? Some people in the study claimed that it was due to the fact that the school is in a mainly immigrant catchment area, but the school do receive extra resources in terms of teachers for the same reason.

4. Discussion

In economic terms municipal schools does not have the purpose to generate money. The goals are described in the national curriculum that changes over time. The activities aim at letting young people obtain valuable knowledge and know-how, but also to give them the opportunity to develop as individuals in a social setting that prepares them for adult life. Therefore it is safe to say that the output of school activities is complex and difficult to measure. In terms of results there are some variables that can be measured, such as; academic achievement through test results, grades and the amount of pupils that obtain results that meet minimum requirements.

A protracted design phase, or a continuous design cycle, means smaller interventions and more often. There might be a market for flexible design solutions with multiple utility spaces that can expand and contract smoothly. In some cases it might be a matter of organization and co-habitation of clients/end users. In other cases the solution might involve ICT for tele-presence and virtual reality (or virtual space rather)

Most POEs (and other facilities evaluations in Sweden) still seem to focus on “hard” technical issues of building performance. The focus on the technical issues brings forward easily measurable variables. This might obscure more complex issues and variables concerning the activities and interaction that also have substantial impact as a prerequisite for learning in formal learning environments. I suggest the added value that Ang, Wyatt and Hermans discuss within the domain of use and facility management should also apply in the municipal context, even if the “business process” are somewhat different [22].

Preliminary results indicate that there are a lot to be learned from studying the problem out in the field and collecting data first-hand. Design solutions and interventions benefit from knowledge about the actual end user. Every country and possibly every municipality down to the single school will have slightly different prerequisites concerning all variables that are thought to affect educational outcomes. From a pragmatic viewpoint it would make good sense to address the issue of design and evaluation on the lowest possible level and to assemble all relevant data in databases for cross-case analysis and reference.

Minor changes in maintenance do not seem to be a big issue or matter that much in the whole. However, many small changes made in a patchwork manner will affect the whole. Each little alteration might be perfectly rational in the short term. The long-term consequences will risk getting out of our control unless there is continuous and updated documentation and evaluation available for analysis. On one hand there are serious ethical problems building schools as scientific experiments. On the other hand, building and running schools without employing scientific knowledge or evaluation is also a kind of experiment with the end users life in the workplace. It is just not stated as such. Continuous design might be one strategy to deal with changing prerequisites and to achieve better fit between design and end users needs and expectations. Perhaps not all economic resources need to be spent at once. Some resources could be put in a redesign fund for each school. Every space in a novel building might not have to be "finished" or furnished to the highest standard at once, but could retain a slightly more rough or robust character.

There might be other ways of improving the fit between design and learning. The initial analysis of interviews and conversations also suggests that clients and end users would benefit from having access to an "expert end user" or, perhaps better formulated, an "environmental coach" who would assist and coach the clients and end users in the possibilities and limitations of the physical environment of their school. Another approach would, in line with the notion of continuous design, be to use a "learning solutions designer" who could access a municipal best practise reference database and provide each school with individual solutions while keeping track on previous alterations.

Finally it is striking how teachers and staff were pleased with someone asking them for their experience, what they think about their physical work environment and what they would change if they had the opportunity. In several cases the interviewees stated that this research was important and that it was about time someone looked into the matter. The interviews indicate that talking about the physical environment also provided a good starting point for discussing a wide range of other issues related to organization, identity, values and culture.

5. Conclusions

As mentioned in the results section it is rather a awkward business trying to extract traditional results, or conclusions, from a case study of this kind before a final report exists. Still, it is important and valuable to share reflections and assertions above in relevant forums, even if the format is not ideal. The conclusions at this stage would be that there seem to be a need for research about architectural design of formal learning environments in relation to educational outcomes. As for the direction of future research the issue of incentives for evaluation seems most important, but that it is necessary to look for the criteria in the local context. The question of accounting for added value, or how well the facilities support learning processes, in the eye of clients and end users may well be a key to future success for both architects and the construction industry.

Abstract

Organizations are often forced to modify their physical environment and relocate employees in response to new business strategies. However, the impact of these changes on employees is rarely considered. Many organisations are acutely aware of the costs associated with high staff turnover, staff alienation and recruitment. Recent innovations in workplace design such as hot-desking have further undermined our sense of belonging. This research considers the attachment employees have for their established work place. It is argued that this attachment may influence people's response to the new environment and the move process. Issues of place attachment, personal expectations and perceptions can affect a person's response to a changed environment, which may be at odds with a strong organisational imperative for a move. To date, however, our understanding of how these factors relate to each other is limited. This study seeks to expose the gaps in our understanding of 'attachment' as a phenomenon. It describes the methodology that will be used for a subsequent case study, which attempts to quantify and qualify the phenomenon of place attachment in the workplace. In particular it suggests how design elements can be introduced that nurture a sense of belonging in an organisation.

Keywords: Change Management; Place Attachment; Relocation; Sense of Belonging; Workplace Design

1. The Research on Workplace Attachment

1.1 Overview

Change has become a way of life for organizations, as the business environment has become increasingly dynamic. Many organizations are being forced to re-examine every way in which they can improve their performance. Workplace redesign and relocation has been used as a catalyst by many organisations to introduce many elements of organisational change. However such change can have a significantly undermine performance and can cause long term damage to work relations. For this reason, thought needs to be given to the ways such changes are perceived by employees, and the consequences of such changes [1].

Despite the best efforts of corporate managers, 25 per cent of major change initiatives fail because employees are fearful of and resistant to change [2].Most changes fail because the soft aspects of change are not properly managed. Employee resistance can pose significant obstacles to the planning and development of office space relocation, particularly for projects that attempt to change the way people work.

Office renovations and relocations are one of the most challenging aspects of a facility professional's job to resolve growth and space constraint problems in organisations. Yet, to employees, the change can be seen as threat, disturbing and emotionally alienating. These placements can have serious negative and emotion-laden consequences when seen from the point of view of environmental deprivation [1].

Many organisations are acutely aware of the costs associated with high staff turnover, staff alienation, and recruitment. The cost of not overcoming the resistance to change can be enormous [3]. The negative attitude can affect the bottom line. The Bureau of Labor Statistics estimates that U.S. companies lose $3 billion a year to the effects of negative attitudes and behaviours [4].

The research is particularly focused on the concept of place attachment to understand better the person's response to a changed environment. In particular it suggests possible mechanisms for using the work environment as a way of accelerating our sense of belonging in the new workplace. In order to combine place attachment theory with practice, the research will undertake a case study analysis in which the research quantifies and qualifies the phenomenon of employee place attachment.

1.2 The Relevance of the Research

Psychologists and others concerned with work behaviour have long been interested in employees' feelings in terms of outcomes such as satisfaction, stress and fatigue. In contrast to research on the expression of emotion, research on the experience of emotion is relatively underdeveloped [5]. Even though recent interest on affectors in the workplace has been intense, ignorance regarding the emotional significance of the physical environment remain.

Routinized interactions in a given location typically result in place attachment. An emotional bond is formed by an individual with a physical site. Having developed a 'secure' place attachment, the loss of such an attachment creates a stressful period of disruption. The move is often a ‘loss experience’ for employees. Employees place attachments often go unrecognised by management involved in such transition processes [6]. Ignoring the emotional charge given by these employees has the potential to undermine the success of the move project and the organisation itself. The focus of this research is to expose the current gaps in our understanding of 'attachment' to previous workplaces as a phenomenon.

However today, social theorists are often skeptical about the importance of place and place attachment, as people seem to be increasingly mobile, and their social relations and other experiences become disembodied from physical location [7]. Far from reducing the importance paid to physical space, the focus on knowledge work and increasing productivity in the new economy lead to more increased emphasis on creating the “right” working spaces. Although technologies have the potential to enable people to work anywhere, people still need to choose to work somewhere [8].

Much of the previous research about psychology in work environments is largely defined by the outcomes and facets of the physical environment. For the individual employee, such research has focused on the outcomes of satisfaction and performance and their association with the ambient environment. For interpersonal relationships, it has focused on the outcomes of communication and group formation, cohesion, as well as their relationship with features of the workspaces and layout. For the organisation, the focus has been on organisational effectiveness and its association with the features and layout of buildings [9].

These studies with their behaviourist approach assume that change is best achieved by considering “external” factors. For example a change agent working on these assumptions would look for those reinforcements which are producing the current behaviour. Having specified the new behaviour precisely, the object would be to set up a schedule of reinforcement to encourage the necessary change [10].On the other hand the cognitive approach is based on the belief that behaviour is controlled by “internal” factors, such as the individual’s beliefs, assumptions and theories about the situation. To change behaviour, therefore you have to change these internal theories [10].

This research is concerned with the cognitive, affective and behavioural processes which contribute to a person’s attachment with a place. Issues of place attachment, personal expectations and perceptions have a significant bearing on a person’s response to a changed environment, even when a move provides a path for economic improvement. To date, however, our understanding of how these factors relate to each other and place attachment is rather limited in move projects in organisations.

After describing the aims and objectives, the paper will reconsider previous work done on place attachment phenomenon. Empirical research findings are drawn from a broad-ranging literature review. The resulting research model will be applied to the proposed case study and the validity of this model assessed.

1.3 Aims and Objectives of the Study

Change and transition recur in the lives of people and are part of human development. Although for some people change is positive, for others it is difficult to accomplish without disruption and distress [11].

The main aim of the study is to determine the impact of place attachment in employees' perception of change. It seeks to describe the socio-psychological and behavioural effects of changes in the physical environment on employees.

The second aim of this study is to explore the meanings such adjustments hold for employees exposed to changing environments over time. And discover how these meanings influence to adopt new environment.

The third aim is to examine the extent of employees' place attachment in old and new environments. This involves isolating aspects of the person–place transactions which have affected their ability to detach from the old environment and attach to the new.

The objectives of the study are:

- To expose the current gaps in our understanding of "attachment" as a phenomenon
- To investigate human reaction to change in the environment
- To measure the significance of this reaction to business performance
- To obtain tools for communicating concepts of change management.

There are pragmatic and facilities management implications arising from the phenomenon of place attachment. Further investigation of the affective relationships that all employees have with their workplace will aid in appropriately designing and managing facilities.

2. Previous Research on Place Attachment

2.1 What is place attachment?

The psychology of place is an emerging area of research that explores the association between individuals and their immediate environment-setting. The psychology of place assumes that individuals require a “good enough” environment in which to live. People are linked to that environment through three key psychological processes: (1) attachment; (2) familiarity, and (3) identity. Displacement breaks these emotional connections. The ensuing disorientation, nostalgia, and alienation may undermine the sense of belonging and mental health in general [12].

Familiarity refers to the processes by which people develop detailed cognitive knowledge of their environs. Place identity is concerned with the extraction of a sense of self, based on the places in which one occupies in life [12].

Place attachment is the pattern of reactions that a setting stimulates for a person. These reactions are a product of both features of setting (what settings are) and personal processes (what the people bring to it) (Figure 1) [31].

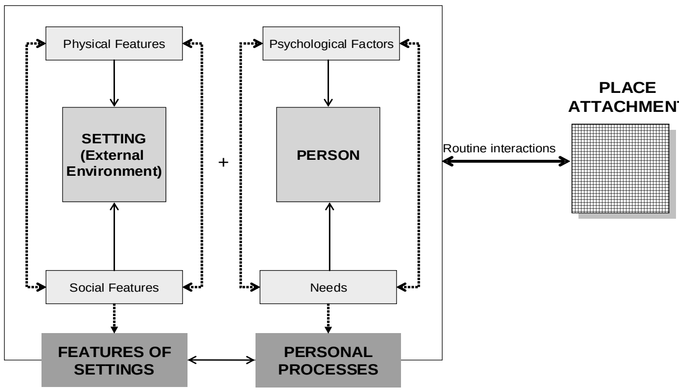

Figure 1: Place Attachment, the link of features of setting and personal processes (adapted from Steele F., 1981)

Milligan (1995) defines place attachment as “the emotional link formed by an individual to a setting that has been given meaning through interaction, comprised of two interwoven components: the interactional past and the interactional potential of the setting” [13].

The *interactional past* refers to past experiences: in other words “memories” associated with a setting. Places have the power to recall emotions and stir memories that have been dormant while the person was away from the place. *Interactional* potential refers to the future experiences imagined and anticipated to be possible in a setting, or in other words “expectations”. An individual’s experiences within and in relation to a specific setting, result in a set of expectations for future interactions in the setting.

In forming people–place interactions, what people bring to their setting is as important as the place itself. A particular setting becomes a place to an individual specifically because of the activities that have occurred within its boundaries, which then come to be associated with the setting. A history develops that is tied to the experiences of people that have occurred within the setting. At the same time, specific features of the setting shape, constrain and influence the people's perceptions and expectations for evaluating new settings [6].

Setting acts as also as a facilitator of needs. Place is important in the extent to which it satisfies a need. Stokols and Shumaker (1981) suggested that the degree to which a particular setting satisfies the needs and goals of an individual determines his or her judgement of its quality [14]. This quality judgement regulates the attachment to a place.

Within the past few years, place attachment has been studied by scholars from several disciplines such as: anthropology; architecture; family and consumer studies; folklore, gerontology; landscape architecture; leisure and recreational studies; marketing; psychology; sociology; social ecology; and urban planning. This diverse research is bringing to bear different philosophical approaches, theoretical formulations, and research methodologies. Perhaps, the most important challenge for researchers in this area of inquiry is to integrate different viewpoints and approaches [15].

Giuliani et al. (1993) group the differences in the researchers' definitions of place attachment according to several characteristics [16]:

- the content of the bond: affective, cognitive, and/or symbolic
- the valence of the bond: positive or negative
- the specificity of the bond. Some researchers choose to consider attachment as a broad concept, a super-ordinate category whereby affects are designated as part of an entire system such as 'set of feelings'. Others seem to consider attachment a specific affect that is distinct from other kinds of affects which are part of the same system.

Problems arise if we accept a broadened definition of place attachment. Such definitions of the phenomenon become so general that they fail to explicate the nature of the cognitions and affects that characterise psychological bonds, linkages, ties, and so forth with places. It also obscures the conceptual distinctions between different affective bonds and their dynamics.

As a result, the role of place in people's lives is more complex than we understand. Attachment can be viewed as a multilevel person–place bond that evolves from specifiable conditions of place and characteristics of people. This fact has implications for the attitudes and behaviours of individuals toward their socio-physical environments [17].

2.2 The Process of Place Attachment

Place attachment operates in the background of awareness. It is difficult to assess. Shock of disruption helps to clarify what has been disrupted. A study of place attachment starts with an understanding of disruptions of place attachment.

Repeated interactions in specific settings including organisational locations typically result in place attachment. An emotional bond forms between an individual and a physical site. After the development of secure place attachments, the loss of normal attachments creates a stressful period of disruption followed by a post-disruption phase of coping with lost attachments, followed by the creation of new ones [18].There are discernible patterns across the phases of attachment and disruption (Figure 2).

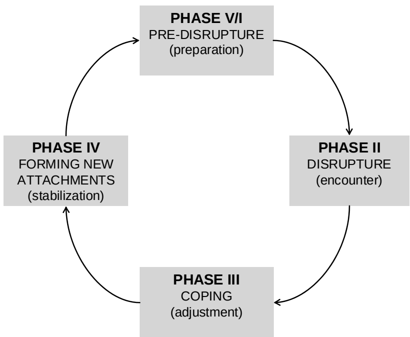

Figure 2: The transition cycle (adopted from Nigel Nicholson (1990)
