F13: Financial failure of client (Owner)	*0.413*	*26*	*0.613*	*22*	*0.253*	*24*
F07: Cost of legal processes	*0.443*	*25*	*0.570*	*26*	*0.252*	*25*
F15: Indemnification and hold harmless	*0.468*	*24*	*0.536*	*27*	*0.251*	*26*
F04: Changes in codes & regulations	*0.388*	*27*	*0.608*	*24*	*0.236*	*27*
F16: Inflation and exchange rates	*0.383*	*28*	*0.525*	*28*	*0.201*	*28*

A further examination indicates that the degree of criticality (i.e. rank of SI) is less likely to have any strong relationship with the degree of 'expected shared risk'. For example, a few risk items have the same or closer ranks in both category: unforeseen site conditions' and 'site access' rank 5 and 19 respectively, in both category. 'Availability of materials' ranks 14 in SI, but ranks 15 in the other category. Some factors seem to be inversely related. For example, the three least ranked risk items in terms of SI tops the list in terms of expected shared risk. They are: indemnification and hold harmless, changes in codes and regulations, and inflation and exchange rate. Factors that may be loosely considered in this group are health & safety (ranks 1 and 24), workmanship (ranks 3 and 21), contractor competency (ranks 6 and 18), third party delays (ranks 16 and 12), acts of God (ranks 20 and 7), and permits and ordinances (ranks 23 and 6). The remaining risk items seem to form no clearly identifiable pattern.

5. Conclusions

This interim report on an ongoing study attempted to estimate the present and expected risk allocation profile, and was focused on construction clients. Both incorporated a provision for risk sharing, i.e. to identify the attitude towards a strategy for joint management of risks, possibly in a teamwork based collaborative manner. It is seen that the contracting parties had inherently different perceptions, and extremely opposite in most of the cases (i.e. 0% and 100%), of both present and expected allocation of risks, although they all work for public clients. Such diverse perception might have shaped from diverse individual experiences that may be bad or good. Nevertheless, they indicate the need for a cooperative learning. Interestingly, a markedly positive attitude towards shared management of risk was observed. Most of the respondents opted for risk sharing between 18% - 53% for all of the 28 risk items used in the survey. In doing so, respondents generally reduced the present risk liabilities of either one or both of the contracting parties (i.e. contractors and clients). This may be an indicator of the long awaited paradigm shift from the existing traditional construction industry environment towards a friendly and teamwork based culture. This result seems to support the argument that most of the risks need joint efforts of varying degrees from both contracting parties for their effective management.

This survey also identified the criticality of different risk items, which lacks to have any identifiable pattern of relationships with the degree of their sharing. All these are expected to help clients to better appreciate the impacts of different risk items and suitable approaches for their effective management. The next step of this study is to extend the survey to contractors and consultants, to tap their opinion in the first place, and then identifying a set of strategies for wider adoption of risk sharing in construction.

(hadikbas@medipol.edu.tr)

Abstract

While there seems to be a vast literature on the administration of construction contracts, we have yet to understand the complexities of extra contractual concerns and their contractual consequences, especially in the Near East. Pre-conceived biases, expectations and perceptions of obligations and intricate behavioural patterns are often the sources of confusion and poorly functioning contractual relationships.

The present paper will attempt to shed some light on some of these issues, drawing on observations of cases from Turkey and the Turkish contracting experience overseas. The method adopted can be best described as "participant observation" through the authors' intensive involvement with contractual claims as experts and consultants.

The main focus of the paper is the identification of reciprocal and one-sided patterns of contractual behaviour of Turkish employers and contractors operating in the Near East. Reciprocal patterns are those exhibited by both employers and contractors and include "honeymoon patterns" and obscure documentation practices. One sided patterns include employers' and contractors' practices, such as deliberate preservation of ambiguity in contracts and contractual behaviour, fears of violating public welfare, fears of being included in the "Black List", fears of challenging prominent main contractors and "face value" issues, resulting in complex adversarial relationships, complicated disputes and, occasionally unexpected outcomes. The paper discusses these patterns from a performance perspective and concludes with a set of recommendations for further research into contractual behaviour.

Keywords: Construction contracts, Near East, disputes, relational governance, survival

1. Introduction

The ENR Sourcebook is an annual publication that offers rankings of international contractors and design firms based on contracting revenues generated abroad. ENR Sourcebook's figures include prime contracts, subcontracts, design –build contracts, construction management-at-risk contracts and shares of joint ventures.

ENR's "The World's Top 250 International Contractors" list published in August 2015, based on 2014 figures, included 43 Turkish contractors. Turkey kept its second position in the list after China for the eighth year. The total revenues of the 43 Turkish companies placed on the ENR list increased by 43.4 percent to $29.3 billion in 2014 compared to the previous year. Thus, the total share of Turkish companies, which was 3.8 percent in 2013, increased to 5.6 percent in 2014 (The 2015 The Top 250 International Contractors 101-200, 2015).

Construction has played a significant role in the economic development of Turkey since the 70's , currently accounting for 5.9 % of GDP. The share of GDP attributable to construction may be as high as 30% if the impact of the construction sector on other sectors of the economy are taken into consideration according to a report by the European International Contractors (FIEC Construction Activity in Europe ,2015).

Turkish contractors undertook approximately 7500 projects in 103 countries between 1972-2014 (6 months). The total value of these projects is estimated around 285 billion USD (Türk Yurtdışı Müteahhitlik Hizmetleri, 2014).

The foregoing seems to be a success story. The realities of construction contracting are, of course, more complex. The sheer size of the overseas market is not an indicator of high performance by itself. Only one Turkish design firm took place in the ENR Top 100 International Design Firms list (ENR bases Top Design Firm rankings on total revenue of design services from projects within their region during the previous calendar year. Firms are also ranked by design specialties and disciplines)

Turkish construction projects are characterized by adversarial relationships, confrontational disputes, abandonment, early termination, contractual deadlocks, low satisfaction and other complex issues. The present paper shall not attempt to analyse the competitive advantage of Turkish construction firms, as this has been undertaken by many researchers (Giritli et, al., 1990, Günhan and Arditi, 2005, Özorhon et al. 2010, Batmaz et. al, 2010). Instead the paper shall try to identify patterns of behaviour prevailing in contractual relations in Turkey and the Near East, drawing on the authors' experiences as expert witnesses and claim consultants over a period of twenty years in the Turkish construction sector. In addition, the paper shall attempt to raise questions about best contract administration practices, firm survival and firm performance.

The cases examined were observed during the authors' involvement with construction claims over a period of twenty years. As such, the method approximates participant observation in the sense that the researchers have shared the activities of the parties.

The paper describes patterns of observed behaviour and provides a brief discussion of non-legal sanctions and rewards exercised by the parties. Raising questions of sustainability in the long run, the paper concludes with suggestions for further qualitative and longitudinal studies to offer insights into contractual behaviour.

2.Turkish Contractors in the Near East

2.1 Brief History

Most of the Turkish contractors moved into the Middle Eastern market in the late 70's as subcontractors following a recession. By the early 80's most were working as prime contractors. Between 1978 and 1987, about 60% of the value of work undertaken came from Libya and 31% from Saudi Arabia (Giritli et. al. p. 417). At that period, opportunities of work were created by several mechanisms, including soft loans (government to government loans), joint economic cooperation systems (such as the Turkish Libyan and Turkish –Iraqi Joint Economic Cooperation Agreements), barter agreements and military construction projects. Turkish contractors gained considerable competitive advantage through the operation of these mechanisms (Sözen, 1998).

The situation, however, started to change by mid-80s. There were several reasons behind the transition, including the saturation of the Saudi Arabian market, the influx of South Korean, Pakistani, Chinese and Bangladeshi firms with highly competitive labour costs and governmental supports (such as tax breaks), while the end of the barter agreements with Libya generated cash flow problems and the crisis that eventually led to the Gulf War created adverse conditions for Turkish contractor firms (Sözen, 1998).

The decline in the overseas market resulted in insolvency: 23 of the 50 contractor firms studied by Sözen in the years 1981-82 had closed down by 1992 (Sözen, 1992; Sözen, 1998).Risk taking and competitive firms had entered new markets, e.g. the Russian federation and the Turkic Republics, whereas firms that had put all their eggs in one basket (e.g. firms concentrating activities in Libya or the domestic market) were forced out of business.

Following the economic crisis of 2001, the volume of contractual activity overseas increased sharply. The explanatory factors offered were the following:

- The decline of domestic investments following the economic crisis in 2001 resulted in abnormally low offers
- Creation of opportunities overseas by booming oil prices
- Accumulation of overseas expertise and entrepreneurial learning

The leading markets since 2013 have been Turkmenistan, Russian Federation, Azerbaijan, Iraq, Kazakhstan, Algeria, Saudi Arabia, Angola, Libya and Kuwait.

2.2 Background

The authors' experiences as expert witnesses and claim consultants in the construction sector indicate that contractual relationships of Turkish contractors in the Near East are characterized by a lack of trust in the other party (employer or subcontractor) crystallizing in:

- Mistrust in the other party, confrontational attitudes, adversarial atmosphere;
- Deterioration of employer-main contractor/ main contractor-subcontractor working relationships;
- Disappointment and dissatisfaction with DAB decisions, arbitral awards and court decisions;
- Relinquishment of contractual rights because of insufficient or non-disclosable contract documentation;
- Inertia in pursuing claims because of "black list" exposure;
- Prolonged dispute resolution processes or contractual deadlocks;
- Dependence on foreign design and technological know-how in complex, multidisciplinary EPC projects.

Yet, the survival of Turkish firms in the Near Eastern market deserves an objective explanation. There are a number of rival theories about the survival of firms in organisation theory. "Liability of newness" and "liability of adolescence" models have found widespread empirical support (Freeman, Carroll et al., 1983; Bruderl, Preisendorfen et al.1992, Bruderl and Schussler, 1990).

Among models based on firm dynamics, the most influential is perhaps the passive learning theory by Jovanovich, who contends that the longer a firm operates in a market, the more it learns and the more efficient it becomes (Jovanovich, 1982). The basic assumption in the passive learning model is that firms learn without engaging in active learning effort, e.g. research and development.

Frankish et al (2007) offer an alternative but interesting explanation: It is possible that entrepreneurs do not learn:" *Here, even if business success is a chance event, an individual who continues to buy tickets for the lottery will enhance their probability of being successful at some point in time. It does not mean that they have 'learnt to play the lottery'. It merely means they have bought more tickets."* (Frankish et. al. 2007, p.4).

As to the role of unwritten codes of conduct that powerfully affect inter-firm behaviour Macaulay, in his classic article argues that "*Not only are contracts and contract law not needed in many situations, their use may have, or may be thought to have, undesirable consequences*." (Macaulay, 1963, p.64). Macaulay's argument has lent support to the relational governance literature associated with trust (Poppo, 2002). The underlying argument is that formal contractual relations and enforcement of contractual obligations undermine exchange relationships based on trust, whereas relational governance reduces friction between the parties, increasing flexibility and adaptability.

One of the most important questions that needs to be addressed is whether Turkish contractors have passively learned behavioural patterns that somehow fit with the contracting environment in the Near East despite active engagement in R&D and investment in trust. The answer to this question is not simple and certainly deserves empirical investigation. Even then, this is a shaky foundation and there would be problems of measurement in an empirical investigation.

3. Observed Patterns of Behaviour

The following section shall attempt to identify observed reciprocal and one sided patterns in contract performance. Reciprocal patterns are those shared by employers and contractors. One sided patterns seem peculiar to employers or contractors.

3.3 Reciprocal Patterns

Honeymoons

Like any social relationship, the contractual relationship is likely to experience a honeymoon period during the early phases of contract performance. This period is typically characterized by leniency in contractual enforcements, goodwill, trust and tolerance of contractual breaches.

Almost all contracts set out obligations and responsibilities of the parties relative to performance and claim notices. Claim notice provisions describe procedures that must be strictly followed in notifying the other party before claims can be pursued. Likewise these provisions typically include deadlines for notification, known as time bars.

Similarly contracts contain provisions that any changes made to a contract are ineffective unless made in writing and signed by or on behalf of both parties. This is known as the variation clause and aims to prevent oral variations

At the honeymoon stage, however, both parties are disinclined to require strict compliance with contractual provisions: time bars are often overlooked and oral change orders are executed. This is a widely observed behavioural pattern and is interpreted by both parties as an exhibition of mutual goodwill. There is nothing inherently wrong with this approach as long as the relationship endures within an amicable atmosphere. However, the honeymoons typically do not last long and mutual goodwill eventually evolves into “constructive acceptance”.

During the execution of a large scale infrastructure project under FIDIC Silver Book in Istanbul, time bars were ignored by the contractor and late submission of notices was accepted by the public authority employer during the initial stages of contract performance. At a late stage when the relationship between the parties deteriorated into an antagonistic one, the employer refused a late notice by the contractor based on employer’s rights under clause 20.1, which stipulated that any claim to time or money would be lost if there was no notice within the specified time limit. The contractor took the employer’s determination to the Dispute Adjudication Board, with supporting evidence that previous late notices had been accepted by the employer earlier. The DAB interpreted this as constructive acceptance against the employer.

Duplicate or non-disclosable documentation

Most projects produce duplicate documentation. The reason for this anomaly is the difficulty in obtaining approval of authorities having jurisdiction over the design documents or frequent changes in legislation. The basic intention of the parties is to comply with existing codes, while reserving the potential to make alterations to a scheme after it has been granted planning approval. In a majority of cases duplicate drawings are preserved, one official, the other non-official. In a potential claim situation, however, submission of documents can present a problem, since only official documentation may be submitted to a court or an arbitral tribunal. Duplicate documentation poses difficulties in filing claims, as a party can only claim what she/he can demonstrate transparently.

In a recent case, a contractor was barred from claiming site office and head office overheads for a standby period of 9 months because of non-disclosable documentation.

Another case demonstrates the impasse reached by the parties .A widely used contractual arrangement in Turkey is financing of construction costs by sharing independent units between the employer and the contractor. During the construction of high rise a mixed-used luxury building located close to the centre of Istanbul under a similar arrangement, the landowner/employer and the contractor had a disagreement about the appropriation of areas and spatial arrangements. There were considerable discrepancies between the official projects that had obtained planning consents and the actual drawings. The actual drawings included alterations beyond the scope of permission. This incongruity presented a major obstacle in taking the disagreement to court and the disagreement still remains unsolved.

3.4 Employer’s Patterns

Ambiguity

Aoki and Allison (2005) argue that it may not always be desirable for all parties to a social relationship to account precisely and accurately for actions. The authors use the term ambiguity in its sense of admitting multiple interpretations. Thus, ambiguity is created to provide personal space in social relationships.

Creation of ambiguity is a pervasive pattern in contractual relations. The employer usually refrains from approving contractual documents to provide “contractual space” in a reflex action that functions to reserve future defences.

During the performance of a large scale project under FIDIC Silver Book in Istanbul, the employer never officially approved the work programme submitted by the contractor. Thus, there was no baseline schedule that is typically intended to measure and control project activities. The absence of a baseline became a major problem during the resolution of a major time extension claim.

Public welfare concerns

Liability for public welfare offences is a major determinant of contractual behaviour for the public employer in Turkey. The public authority is particularly sensitive to cost claims filed by the contractor, while granting extension of time is not a major issue. Cost claims in compensable delay cases can be a serious cause of concern for public employers.

The proliferation of DAB referrals by the contractor was a phenomenon that took us years to understand. Ultimately it turned out that the contractor was encouraged by the employer to take money claims to the Dispute Boards, as complying with a Board decision was less risky for the employer than granting entitlement to cost through an employer's determination.

In one particular case, where the contractor proposed a value engineering solution that reduced cost at the expense of quality, the proposal had to be accepted by the contracting public authority. In the final account, protection of the public fisc mattered in a government audit. The regulatory government audit mind set is difficult to understand and accountability for costs can be interpreted as a public welfare offence.

Grossly one sided contracts

Employers (clients and main contractors) tend to drive the contractor/subcontractor into a corner by means of grossly one-sided contracts that minimize employer risks while imposing onerous terms on the contractor. These contracts are characterized by exclusions of damages, disclaimers for the owner and limitations of remedies for contractors. The question is, of course, why a contractor/subcontractor would ever sign such a a burdensome contract. Surprisingly, both parties are of the opinion that (unstructured interviews of the authors) that nothing eventually happens because when the contractor fails to strictly comply with a particular provision of a contract, the employer often delays its attempts to enforce such provision. The employer is well aware that severe losses may force a contractor out of business, resulting in a failure to complete the work, with the inevitable delays, and the attendant delays, high monetary and non-monetary costs on the parties.

3.5 Contractor's Patterns

Black List concerns

Contractors working with the public employer or powerful private employers are generally disinclined to file or pursue claims in fearful anticipation of being included in the "black list" which implies serious problems in securing future contracts. In compensable delay situations, time extension claims are fairly well tolerated by the employer, whereas money claims are risky for the procurement of future projects from the same employer.

A Turkish contractor working for a Middle Eastern employer under FIDIC was terminated for convenience. Under FIDIC conditions, the employer is not allowed to terminate the contract in order to execute the works himself or to arrange for the works to be executed by another contractor. In this particular case, however, the employer did outsource the remaining works to another contractor. The reaction of the terminated contractor was “to remain silent”. Eventually, the terminated contractor was awarded another contract by the employer.

In another case where an eminent Turkish main contractor and a Turkish subcontractor were working on a project in Azerbaijan, the main contractor breached the subcontract repeatedly. The subcontractor refrained from raising claims for a considerable amount of time. Finally when it did bring the matter to international arbitration, there were problems in finding experts to provide an expert report in favour of the subcontractor. The subcontractor sought amicable settlement and the matter eventually faded off.

Saving “face”

Contractors and subcontractors alike display ambivalent attitudes toward powerful clients. Contract administration manuals generally provide templates for different kinds of claims, such as: “ *We hereby give notice in accordance with Sub-Clause ....of the Conditions, that during the execution of our Works, we have encountered adverse physical conditions in the form of …………………. located …………………….. which in our opinion was Unforeseeable because……………………….. We will be maintaining such contemporary records as we believe necessary or may be required by you, to substantiate our additional costs/and support our request for an extension of time pursuant to Sub-Clause....”.* However, the standard claim template is too aggressive for the Turkish contractor.

Notices served under contracts have to be worded carefully in order to refrain from offending the employer. As a result, the standard claim letter is unassertive and maintains a degree of ambiguity as to the consequences of the claim.

“*The employer’s representative is offended and turns his head when we meet on the site just because we filed a claim against the employer although we were fully entitled to do so*” ,complained a contractor once while admitting that he had similarly been outraged by a subcontractor filing a (rightful) claim and never awarded a subcontract to the same firm again.

4. Discussion

The motive for the present paper was the authors’ failure to understand and interpret the results of contractual actions or inactions of the parties and to draw straightforward conclusions from them.

The foregoing observations certainly do not depict best practices in contract administration. Yet the survival of Turkish contractor firms in the international market deserves attention and empirical investigation.

The observations suggest that relational governance and contractual enforcements do not always complement each other. It is true that Turkish contractors and employers frequently call upon or depend upon non-legal sanctions (black list threats) and rewards (securing future contracts by remaining silent in potential claim situations).This may be interpreted as "passive learning" and probably has contributed to the building of stable market ties in the Near East, but the question is whether reliance on non-legal sanctions or rewards is a sustainable behavioural pattern in the long run.

Many key questions remain unanswered. For instance why is the formal execution of contracts been substituted by relational governance without the expected positive effects on exchange performance and cooperation? Or put more simply, why do the parties rely on non-legal sanctions or rewards in the absence of trust? What then is good performance in the administration of construction contracts if the intended benefits are not realised? Or have the Turkish contractors have simply bought more tickets in a lottery?

Cognitive biases of the parties are affected by the environment in which they occur. This is why interactions and influences of organisational culture and climate also need to be taken into account.

5. Conclusions

In this paper, we have sought to raise a number of research questions related to how contractual relations are understood and performed in the working practice of Turkish contractors at home and in the Near Eastern market. Obviously, the paper is based on non- systematic observations of the authors and as such, has important limitations that imply caution in generalizing the findings. In this sense, although the study falls short of developing a formal diagnostic tool it draws a picture of a complex situation. The study, being of an exploratory and interpretive nature, raises a number of opportunities for future research, both in terms of theory development and interpretation of contractual relations.

Further work is clearly needed to explore the relationship among the features of governance that support contractual relations. Further research can thus shed light on the dynamics of interfirm behaviour, sharing and exchange in the construction sector. Qualitative and longitudinal studies carried out could offer insights into these complex mechanisms. Understanding of organisational cultures could also provide great insights into why certain behaviours do and do not emerge.

Abstract

In the UK over the last 50 years, legal developments in relation to extensions of time and/or monetary compensation for delays in construction and engineering projects, have been both cautious and incremental. In order to contend with the practical difficulties inherent in these industries, the courts have established various common law concepts and principles. The efficacy of many of those principles remains to a degree intractable, perhaps none more so than those relating to concurrent delays. Abstracted from wider doctoral research into how extension of time and/or monetary claims are dealt with in the UK courts, this paper explores the concept of concurrent delays and explains (through analysis of case law and legal commentary) how recent court decisions have, in effect, confirmed a doctrinal split between English and Scots Law. The paper also identifies the reasons for those differences, and poses further questions which require to be investigated and addressed, in order to move towards a more satisfactory and consistent approach as to how the UK courts deal with concurrent delay. Unless and until more is done to stabilise the common law concepts and principles relating to concurrent delay, such as arriving at a definitive working definition, determine conclusively the ratio for adopting the dominant cause test (or otherwise), adequately clarify why the prevention principle should (or should not) prevail, elaborate on critical path methodologies and justify which approach to causation to apply and why, then confusion over how concurrent delay will be dealt with by the judiciary will remain unsettled. Perhaps the most expeditious and pragmatic way to settle issues relating to concurrent delay should, in the first instance, be dealt with in the various standard forms of contract. This is justified as a reliance on common law principles to provide an equitable solution to concurrent delays, has had limited success. Indeed the current approach has witnessed UK judges struggling to harmonise their decisions, given under differing contract conditions and compounded by often opaque evidential constraints on projects which are factually complex. It is suggested that until concurrent delay clauses are incorporated into the standard forms, the current approach engendered by the courts, will be susceptible to imprecise, unreliable and incorrect judgements, which may not reflect the original contractual intentions of the parties.

Keywords: Construction law, prevention principle, **c**oncurrency, apportionment

1. Introduction

Complex building and engineering projects are susceptible to delays. In 2008 the Chartered Institute of Building conducted a survey of more than two thousand schemes and found that over two thirds, were delayed beyond the original completion date, and around a fifth of those projects were late by over 3 months[1]. There are a myriad of reasons why construction projects are delayed such as: labour shortages, contractor errors, poor management, employer variations to the original work scope, unforeseen ground conditions, design delays/omissions and adverse weather conditions. The list is interminable.

In construction and engineering projects, delays can be divided into both excusable delays (either with or without compensation), or culpable or non-excusable delays. Excusable delays are the contractual responsibility of the employer and entitle the contractor to an extension of time, and/or compensation depending on the event and the specific contract terms. Culpable or non-excusable delays are the contractual responsibility of the contractor, and do not entitle the contractor to an extension of time or any compensation.

Where excusable delays are identified, the standard forms of construction and engineering contracts such as the JCT, NEC and FIDIC suites, entitle the contractor, under certain criteria and conditions, a right to an extension of time and/or compensation. By definition, an extension of time clause revises the original contract completion date set out in the contract, which has been affected by delaying events which are the contractual responsibility of the employer.

Extension of time clauses protect and provide, a benefit to both the contractor and the employer. They are primarily regarded as being a benefit to the employer in that *"it establishes a new contract completion date, and prevents time for completion of the works becoming 'at large"*[2]. They are also a benefit to the contractor as they *"relieve the contractor of liability for damages for delay (usually LD's)"*[3]

Notwithstanding the standard forms attempts to provide the parties with cohesive guidance and clear obligations with respect to the management of delays and/or the associated compensation, unfortunately they are often unable to deal effectively with many of the inherent complexities which exist in construction and engineering projects of scale. In consequence, there have been various common law interventions, where the courts have been compelled to establish various dicta and principles and formulate dicta, necessitated by the limitations of the standard forms. An area where both the standard forms of contract, and the common law have struggled to provide unanimity, is in relation to concurrent delay[4] (hereinafter referred to as 'concurrency').

Recent jurisprudential developments in the UK have revealed a steady departure in how the English and Scottish courts deal with concurrency. Indeed in 2012, Mr Justice Akenhead took the opportunity to review the relevant body of precedent on this matter and provided an obiter commentary, as to the English courts approach to concurrency, and how it now departs from the Scottish courts approach:-

"The two schools of thought, which currently might be described as the English and the Scottish schools, are the English approach that the Contractor is entitled to a full extension of time for the delay caused by the two or more events (provided that one of them is a Relevant Event) and the Scottish approach which is that the Contractor only gets a reasonably apportioned part of the concurrently caused delay.[5]*"*

2. Concurrency, a moveable feast?

In the UK, despite a wealth of judicial and professional commentary on the subject, a definitive and workable definition of what constitutes concurrent delay in construction and engineering projects and how it is measured in practice, remains elusive[6]. Learned debate centres on whether concurrency exists where delay events begin at the same time in the project, begin and end at the same time, overlap at the same time, or, as it has been suggested, *"…need not involve delays felt at the same time"*[7]. Indeed the last 15 years or so have seen many and varied definitions from both the courts and legal commentators alike, none of which have been universally accepted[8]. The difficulty in arriving at a definitive definition has not, however, been a barrier to the courts commenting upon issues of concurrency.

Current literature identifies, at a somewhat summary level, the jurisprudential reasoning as to the underlying reasons why the English and Scottish courts have arrived at their requisite positions[9]. However it is suggested that more should and could be done to challenge the common law principles / concepts relied upon, such as Prevention, Dominant Cause, The Malmaison Approach, Apportionment and Causation, and in particular how those principles interplay with one another in practical terms.

It is important to note that the key common law developments in the UK, in relation to concurrency, have in general, been based on various iterations of the Joint Council Tribunal

('JCT') Standard Forms of Contract[10]. Therefore, it is worth reiterating John Marrin QC's guidance on common law approaches to concurrency when he said:

"….there is one truth which can scarcely be over-emphasised. The answers to the questions raised will depend on the terms of the contract which governs the relationship between the parties."[11]

Finally, it is also significant that, despite a plethora of literature and obiter commentary, the Scottish case of City Inn v Shepherd[12] is somewhat remarkably, the only reported construction case where concurrency was actually found to exist.

3. Concurrency in the English Courts: The Current Position

Perhaps the most widely accepted definition of concurrency in England, first proposed by John Marrin QC, in 2002[13], referred to in Keating on Construction Contracts[14] and echoed in the case of Adyard Abu Dhabi v SD Marine Services[15], is as follows:

"the expression 'concurrent delay' is used to denote a period of project overrun which is caused by two or more effective causes of delay which are of approximately equal causative potency"

There are three important points that can be derived from this definition:-

- The *"two or more effective causes of delay",* must relate to both employer[16] and contractor events for concurrency to exist[17];
- The causes do not have to be concurrent in time; and
- Where on examination, the effective causes of delay are not of "*approximate equal causative potency"*, i.e. one is effective and the other is not, the minor cause will be treated as not causative[18]. Where an event has greater causative potency, notwithstanding it may be co-critical[19], it has sometimes been referred to as the dominant event or cause. Whether the use of the 'dominant cause' to separate causes, which do not have equal

[19]Co-critical – both delay events are identified on the critical path and have the same effect on the completion date when either one is omitted, often calculated using Critical Path Analysis Techniques.

causative potency, but could still be deemed effective causes of the delay, is still good law in England has been subject to increasing debate[20].

The genesis of the current English approach to concurrency was first established in 1999, in the case of Henry Boot v Malmaison, where Mr Justice Dyson J (as he was then) stated:-

"… it is agreed that if there are two concurrent causes of delay, one of which is a relevant event, and the other is not, then the contractor is entitled to an extension of time for the period of delay caused by the relevant event notwithstanding the concurrent effect of the other event."[21]

This approach, commonly referred to as the 'Malmaison Approach', has been adopted in subsequent English cases[22], culminating in what can be considered the most recent decision in the UK courts, Walter Lilley v McKay, where Mr Justice Akenhead said, *obiter* [23]:

"…I am clearly of the view that, where there is an extension of time clause such as that agreed upon in this case and where delay is caused by two or more effective causes, one of which entitles the Contractor to an extension of time as being a Relevant Event, the Contractor is entitled to a full extension of time. Part of the logic of this is that many of the Relevant Events would otherwise amount to acts of prevention and that it would be wrong in principle to construe Clause 25 on the basis that the Contractor should be denied a full extension of time in those circumstances. More importantly however, there is a straight contractual interpretation of Clause 25 which points very strongly in favour of the view that, provided that the Relevant Events can be shown to have delayed the Works, the Contractor is entitled to an extension of time for the whole period of delay caused by the Relevant Events in question…The fact that the Architect has to award a "fair and reasonable" extension does not imply that there should be some apportionment in the case of concurrent delays. The test is primarily a causation one.[24]

Therefore in terms of *'delay'* to the works, where concurrency is deemed to exist, the contractor will be entitled to an extension of time to completion for that period, notwithstanding his own delays which may also have delayed completion of the works by the same period.

[24] Walter Lilly, note 5, para 370

How the contractor's *'loss and expense'* associated with concurrent delay, is to be dealt with by the English courts, was clarified in De Beers V Atos Origin, where Mr Justice Edwards-Stuart said:

"The general rule in construction and engineering cases is that where there is concurrent delay to completion caused by matters for which both employer and contractor are responsible, the contractor is entitled to an extension of time but he cannot recover in respect of the loss caused by the delay." [25] [emphasis added]

Taking precedent into consideration, the following statements can be concluded as to how the English courts will deal with concurrent delay and the associated loss and expense:

- Where there are two or more effective causes of delay which are the contractual responsibility of both the employer and the contractor, but have unequal causative potency the dominant cause may prevail. Marrin QC, however argues that the lack of judicial support, among other things, may provide room for doubt as to whether the dominant cause approach would be adopted by the English Courts[26].
- Where there are two or more effective causes of delay, which are the contractual responsibility of both the employer and the contractor, and have equal causative potency, then the contractor will be awarded an extension of time for the concurrent delay. The reasoning behind Mr Justice Akenhead's decision is two-fold:-
    - Firstly, that to deny the contractor an extension of time would amount to an act of prevention[27]; and
    - Secondly, the contract expressly provides that the contractor is entitled to an extension of time, for a Relevant Event[28]. There is nothing in the contract, which states that the contractor will be denied an extension of time, should he be responsible for a concurrent delaying event.
- Where there are two or more effective causes of delay, which are the contractual responsibility of both the employer and the contractor, and have equal causative potency, then the contractor will not be entitled to claim loss and expense for that period[29]. The logic here is that the contractor cannot recover damages, because he would have suffered the same loss and expense due to the delays for which he is responsible[30]. Loss and expense in this instance would generally take the form of prolongation costs, such as site management, site accommodation, transportation and the like.

[26] Marrin note 12 p. 13.
[27] See p. 5 above – Mr Justice Akenhead's decision in Walter Lilly – note 24 refers..
[28] Relevant Events are risk events which are the contractual responsibility of the employer, and depending on the circumstances, allow the contractor extensions of time, and or monetary compensation. The specific term 'Relevant Event' is particular to the JCT Standard Forms of Contract, but can and often is, understood in a similar manner, in any of the standard forms, where events/actions are the contractual responsibility of the employer.
[29]This is relevant if the contractor cannot satisfy the "but-for test" of causation that his losses would not have occurred in any event during the concurrent period. Keating on Contracts, Section 5, para 9-062.
[30] De Beers, note 25 para 178.

4. Concurrency in the Scottish Courts: The Current Position

In light of recent case law, it is considered that the closest current definition of concurrency as it is understood in Scotland defined in the case of City Inn, is as follows: "*true concurrency between a relevant event and a contractor default, in the sense that both existed simultaneously, regardless of which started first…*"[31]. However in the appeal to the Inner House to this decision, Lord Osbourne widened the definition of "true concurrency" by saying: "*the focus of attention has moved, rightly in my opinion, from events themselves and their points and durations in time to their consequence upon the completion of the works*".[32]

Until 2004, there was no material inconsistency in how the Scottish and English courts dealt with concurrent delay and/or the associated loss and expense. However Lord Drummond Young's judgement in John Doyle Construction v Laing Management (Scotland) began what is now seen, as a departure between the Scottish and English courts.[33] Although predominantly known as a case concerning global claims, the learned judge had some interesting and diverging opinions on losses incurred due to concurrent delay: "*…even if it cannot be said that events for which the employer is responsible are the dominant cause of the loss, it may be possible to apportion the loss between the causes for which the employer is responsible and other causes.*"[34][emphasis added]

In England, at that time, in light of the Malmaison decision, the contractor was deemed disentitled to any loss or expense associated with events which were concurrent. It was not until 2007, in the seminal case of City Inn v Shepherd Construction, that a Scottish court was clear that it was taking a different approach from that in the English courts. Lord Drummond Young (now a pivotal figure on this matter) had some difficulties in agreeing with the English courts view on how concurrency should be dealt with[35], both in terms of loss and expense and extension of time claims. Considering mostly English precedent and taking some guidance from the US courts, he said:

In terms of dominance: "*I agree that it may be possible to show that either a relevant event or a contractor's risk event is the dominant cause of that delay, and in such a case that event should be treated as the cause of the delay*"[36]

---

[31] City Inn, note 12, para 18.
[32] City Inn, note 8, para 52
[33] *John Doyle Construction Ltd v Laing Management (Scotland)* Ltd [2004] S.C.L.R. 872 B.L.R. 295
[34] ibid, para 16.
[35] His difficulties were based on Judge Richard Seymour QC's decision in *Royal Brompton Hospital NHS Trust v Hammond* (No.7), (2001) 76 Con LR 148 at paragraph 31, where he had suggested that should a contractor already be in culpable delay, and an employer's Relevant Event arises (such a inclement weather), is concurrent for a period of time, but does not affect completion, then the Relevant Event should not be considered. Lord Drummond Young, said *"It should not matter whether the shortage of labour developed, for example, two days before or two days after the start of a substantial period of inclement weather, in either case the two matters operate concurrently to delay completion of the works."*
[36] City Inn, note 12, para 21. His support for the dominant cause approach is found in Leyland Shipping Company Ltd v Norwich Union Fire Insurance Society Ltd [1918] AC 350.

In terms of delay: *"Where true concurrency between a relevant event and a contractor default, in the sense that both existed simultaneously, regardless of which started first, it may be appropriate to apportion responsibility for the delay between the two causes, obviously, however, the basis for such apportionment must be fair and reasonable"* [37]

In terms of loss and expense[38]: *"In this respect the decision in John Doyle Construction Ltd v Laing Management (Scotland) Ltd, supra, may be relevant. In that case it is recognised at paragraphs [16]-[18] that in an appropriate case where loss is caused by both events for which the employer is responsible and events for which the contractor is responsible it is possible to apportion the loss between the two causes. In my opinion that should be done in the present case."*[39]

His judgement was affirmed by a majority in the Inner House of the Court of Session[40], notwithstanding a dissenting view from Lord Carloway.

Taking current precedent into consideration, the following statements can be concluded as to how the Scottish courts will deal with concurrency, both from a delay, and loss and expense perspective[41]:-

- Where there are two or more effective causes of delay, which are the contractual responsibility of both the employer and the contractor, and have <u>unequal</u> causative potency, the dominant cause <u>will</u> prevail.
- Where there are two or more effective causes of delay, which are the contractual responsibility of both the employer and the contractor, and have <u>equal</u> causative potency, again the dominant cause will prevail and it <u>may</u> be appropriate that the delays will be apportioned between the parties. On analysis of Lord Drummond Young's decision, the reasoning behind his position is as follows:-
    - Contrary to Judge Seymour QC's view in Royal Brompton, the employer event and the contractor event, do not have to happen simultaneously and both should be treated as concurrent causes whichever happened first[42].
    - The architect should exercise his judgement to determine what has delayed the works, on a fair and reasonable basis[43]. Precisely what is fair and reasonable must turn on the facts and circumstances of the case. [44]
    - Apportionment is supported by US law[45,] where he referred to a Board of Contract Appeals case which stated:- *"Where a contractor finishes late partly*

---

[37] City Inn, note 12 para 18.
[38] In this instance, prolongation costs.
[39] City Inn, note 12 para 166.
[40] City Inn, note 8.
[41] Note to facilitate a comparison, the phrasing of concurrency in this instance has been chosen, to be consistent with the conclusions drawn from the English courts.
[42] City Inn, note 12.
[43] Lord Drummond Young attaches "”considerable importance to these words", see note 12, para 20.
[44] City Inn, note 12, para 18. The *"fair and reasonable"* approach is taken from clause 25 of the JCT Conditions, (Private Conditions with Quantities) (1980 edition), with amendments.
[45] *Chas. I. Cunningham Co*, IBCA 60, 57-2 BCA P1541 (1957) the Board of Contract Appeals.

because of a cause that is excusable under this provision and partly because of a cause that is not, it is the duty of the contracting officer to make, if at all feasible, a fair apportionment of the extent to which completion of the job was delayed by each of the two causes, and to grant an extension of time commensurate with his determination of the extent to which the failure to finish on time was attributable to the excusable one."

- Causation in practise works in a complex manner, in ways that does not permit the easy separation of causes, meaning the Architect or court must apply judgement, which can take the form of apportionment.[46]
- When an apportionment exercise for delay is carried out, the methodology is similar to that found in contributory negligence among joint wrongdoers.[47]
- Contrary to significant emphasis being placed from the English courts, he does not consider the principle of prevention in any meaningful detail.

- Where there are two or more effective causes of delay, which are the contractual responsibility of both the employer and the contractor, and have equal causative potency, then the losses may be apportioned between the parties[48]. The logic being similar to that adopted for concurrent delays.

5. Discussion

Taking the foregoing into consideration, it is evident that there are inconsistencies in how the Scottish and English Courts approach the matter of concurrency. In order to find a more consistent and satisfactory direction for both jurisdictions, requires further research and discussion into the following areas:

- **Definitions:** Unless and until a definitive definition of concurrency can be commonly understood by both the English or Scottish courts, then it is likely that difficulties in relation to concurrent delay will prevail. For example, it is still to be understood in practice whether *"true concurrency"*[49] i.e. employer and contractor delay events which overlap in time, as defined in City Inn, will be dealt with any differently to employer and contractor delay events which do not overlap in time, neither of which is dominant, but act together to delay the completion date. If the employer and contractor events are deemed concurrent because they do not overlap in time, but in *effect* cause delay to the completion date, why are these not merely delay events that are calculated as part of the delay analysis. Furthermore, why would they be deemed *"concurrent"* at all?
- **Dominant Cause v Effective Cause:** The advancement of the "*effective cause*" approach in England, may suggest the demise of the dominant cause test, although this remains unconfirmed. It is suggested however, that it is possible in many instances for experienced construction professionals and the courts, to identify the dominant cause

---

[46] City Inn, note 12, para 22.
[47] City Inn, note 12, para 158.
[48] Although Lord Drummond Young stated that prolongation *costs "need not automatically follow success in a claim for extension of time"*, note 12, para 166
[49] City Inn, note 8 para 50.

between two events which may appear to have approximate equal causative potency, and appear co-critical in the programme. It is important to maintain a differentiation, because if dominance can be established, then it may be the parties could have chosen alternative mitigation strategies, to avoid their delays impacting the completion date. If that is the case, it is suggested that there is no reason, why the dominant cause approach is not adopted in the first instance. It is also respectfully suggested, that the term *"effective cause"*, is too general in description, which may only confuse matters when applied practically. Concurrency should only exist, it is suggested, once dominance cannot be established.

- **Prevention Principle:** In England, prevention is the first of two ratios in support of the Malmaison Approach; however there are conflicting judgments as to whether prevention actually exists in relation to concurrent delays[50]. In Scotland, there is ongoing debate as to whether the judge's ability to apportion concurrent delay and/or loss actually offends this principle in any event?
- **Express terms of the Contract:** In England the second and main ratio, in support of the Malmaison Approach centres on a literal interpretation of the contract (at least a JCT contract), which expressly allows an extension of time for employers Relevant Events. However, it must be explored as to why the architect or contract administrator should be precluded from taking other events (not expressly stated) into consideration, which also have an impact on the completion date. One must consider the original intention of the parties, and what would the outcome be for standard forms of contract, other than the JCT suite, which requires the architect to act fairly and reasonably? In Scotland it would appear that in evaluating concurrent delay and its effects on the completion date, the architect should do what is fair and reasonable, taking into consideration Relevant Events and events which are not expressly stated in the contract.
- **Causation:** The standard causation criteria, commonly referred to as *"but for analysis"* is suspended adopting the Malmaison Approach in England, and is also suspended in Scotland if the dominant cause approach is accepted. It must be asked, have the courts decided suspend the standard criteria for causation as a matter of Policy, if so on what basis?
- **Contributory Negligence:** The apportionment of concurrency in Scotland has been likened to contributory negligence between (joint wrongdoers (tortfeasors)[51]. There are conflicting arguments as to why a similar approach cannot be adopted in the law of Contract, which require further analysis?
- **Obiter commentary:** As mentioned previously, apart from one reported construction case, both English and Scottish courts commentary on concurrency has been given in obiter dicta. Indeed in City Inn, the judge merely suggested that apportionment *"may"* be appropriate. It is obvious therefore that the issue of concurrency is far from settled, and divergence between the English and Scottish courts may not be as immobile as is generally considered?

[50] *Jerram Falkus Construction Ltd v Fenice Investments Inc* (No 4) [2011] EWHC 1935 (TCC), [2011] BLR 644, 138 Con LR 21, [2011] CILL 3072.
[51] City Inn, note 12, para 158.

- **CPA: Programme Analysis / CPA**. It is inadequate to consider the legal understanding and application of concurrency without considering the forms of delay analysis which may be adopted to evidence same. It is imperative that more should be done to align how the legal principles will actually work in practise.
- **Redrafting of the Standard Forms:** Workable definitions could and should be provided by the standard forms of contract, such as JCT, NEC3 or FIDIC suites[52]. Admittedly, it is possible that the definitions of concurrency when included in the standard forms may be different[53], but at least the parties would have more certainty on what terms they were entering into. Furthermore it would be helpful if the delay analysis methodology was outlined, because it is an integral and perhaps inseparable element in analysing delays to completion.
- **Policy considerations:** Given the relatively low profit margins of contractors of scale, it may be of benefit to acquire a deeper understanding of whether in matters of concurrency, is it fairer to award time, but no money, or apportion both time and money. For example in general, liquidated damages would be considerably higher than prolongation costs, should that influence the decision making process?
- **Hybrid Solution:** Considering all of the above, is there a viable argument to suggest that the contractor is entitled to an extension of time, but only a proportion of the money for concurrent delays? This is significant because, by way of example, if a project overruns because of a number of employer events, but only one contractor event, then there is no incentive or control for the contractor to mitigate his delays, if he is in the knowledge that he will not be able to recover or reduce his prolongation costs in any event, due to delays caused by concurrent employer events. A form of pacing delay which brings its own complexities.

6. Conclusions

This paper has identified the jurisprudential differences between the English and Scottish Courts, and how they may deal with concurrent delay in construction and engineering projects in the future, and how these differences manifest themselves in the decision making process.

It is essential that first and foremost the parties involved in construction and engineering projects, must refer to the particular terms of their contract, to understand their immediate rights and obligations in relation to how concurrency is to be administered. More often than not, the parties will have contracted using one of the standard forms, which are in general silent on how concurrency is to be dealt with. In consequence, divergences in how the English and Scottish courts deal with concurrency, will prevail and common law solutions will have limited efficacy. It is suggested that unless and until the aforementioned considerations are addressed, it is likely that problems articulating and measuring concurrency will persist for the foreseeable future.

[52] Currently the only standard form of contract to define concurrency is found in the CIOB Complex Contract Conditions, 2013.

[53] Indeed the current common law differences on concurrency between the Scottish and English Courts may require a departure between the JCT suite in England and its SBCC equivalent in Scotland.

Abstract

Delays in construction projects may seem to be easy to analyze, however, in many cases, the process is complex and difficult. As a result, many methods were developed for analysing project delays. With projects varying in nature and complexity and the availability of several delay analysis methods (DAMs) that produce different results for the same project and set of facts, conflicts started arising in projects over which DAM should be used and why. This paper examines the commonly used DAMs in construction projects and the factors that could influence the decision as to the selection of the appropriate delay analysis method adopted by Contractors.

The analysis of five case studies found that there is agreement on what is considered acceptable framework of performing delay analysis by Contractors. The research found support for using the Time Impact Analysis (TIA) Method, as this was considered the most reliable and acceptable method to Contractors in UAE. The main factors affecting the selection of the DAM were the attitude of the opponent party, experience of the delay analyst, complexity of the project, stage of the project at the time of performing the analysis, and the available time and cost for performing the analysis.

Keywords: Delay analysis, extension of time, claims, selection factors, time impact analysis

1. Introduction

Delays are commonly in many construction projects and researchers. Braimah and Ndekugri, (2008) argued that it is rare that a project finishes without time overruns. Delay analysis methods (DAMs) are essential tools for assessing the effect/impact of a delay, particularly in complex projects. While there is an agreement over the possible approaches to analyze the delay, there appears to be a disagreement over which DAM is the most appropriate or preferred, if any. Researchers have concluded that there is no one DAM than can be universally applied (Arditi & Pattanakitchamroon, 2006).

Researchers identified multiple factors affecting the selection of the DAMs. The most recognized work in relation to delay and disruption are that of the Society of Construction Law (SCL) delay and disruption protocol (SCL, 2002) and the American Institute of Advancement of Cost Engineering International (AACEI) recommended practice 29R-03 (AACEI, 2011). Both documents provide invaluable information as to delay analysis types and selection factors. However, they do not provide sufficient guidance as to how such factors influence the selection and application of the DAMs. D'Onofrio (2015) reviewed the work of both SCL and AACEI and concluded that the preferred DAM is the Time Impact Analysis (TIA). This view, however, was undermined by the issue of Rider 1 to the SCL delay and disruption protocol (SCL, 2015), which excluded the preference of the TIA method and encouraged the utilization of the factual based methods, particularly for analyzing delays at a time distant from the event.

The aim of this research is to investigate the most appreciate DAM, if any, and the relevant influencing factors for selection and acceptance. The research main objectives are to identify the main factors influencing the selection process, the commonly used and most acceptable DAM(s).

2. Delay Analysis and DAMs

One of the early decisions the delay analysts have to make before selecting a DAM is whether to perform a forward perspective or backward retrospective path calculations. This decision is influenced by initial factors such as the timing of performing the analysis and its purpose (Kao and Yang, 2009) which in turn would influence the decision of whether to follow an observational or a modelling approach of the delay (SCL, 2002).

Some methods, such as the TIA are categorized as complex while some others, such as the Impacted As Planned (IAP) are considered as simple methods. Complex in this context means requiring analysts to have certain level of experience, the necessary records and willingness to invest significant effort into the exercise (Braimah & Ndekugri , 2008). Therefore, each of the DAMs can be performed to a different level of detail; such detail level is influenced by the availability of the records as well as the time, money and resources available to perform the analysis (Braimah & Ndekugri, 2008).

There are various types of DAMs that are commonly used in the construction industry.The name and type of the DAM does not really matter as long as the delay analysts explain and justify their selection and performance technique (D'Onofrio, 2015). Yang and Kao (2012) note that none of the existing DAMs are perfect as they all require assumptions and contains theoretical forecasts and subjective assessments.

SCL (2002) and Arditi and Pattanakitchamroon (2006) suggested that four methods are the most common in the construction industry which are the As Planned vs. As built Windows Analysis (APvAB), Impacted as Planned (IAP), collapsed as Built (CAB) and the Time Impact Analysis (TIA) method. *APvAB* compares the planned activities (Baseline) with the as built activities. Yusuwan and Adnan (2013) describe it as the most preferred method as it is simple and produces fair and reasonable results. SCL (2015) recommends using this method when performing the analysis distant from the event. Its main features are that it does not present a complex analysis, rely on the baseline network, or require any computerised software, however, it is based on heavy subjective views and assumptions. While this method is relatively easy to perform, it requires analysts to have relevant experience and it may not be sufficient to deal with concurrent delays or the dynamic nature of critical path (Braimah and Ndekugri, 2008). The APvAB method requires a baseline and an as-built schedule or as-built records. It might be suitable for simple and complex cases. SCL (2015) also refers to the Longest Path Analysis method as something similar, but different in that it requires as built schedule and looks at the delay at one point whereas the APvAP may utilise any available as built records and can be performed in window periods.

IAP method simply influences all delay events on the baseline schedule in a prospective way on the assumption that the baseline logic, sequence and durations have not changed (Arditi & Pattanakitchamroon, 2006). IAP may be sufficient to predict future delays but it will not give adequate results when analysing on-going or completed projects (Braimah & Ndekugri, 2008). Kao and Yang (2009) suggested alternative names for the IAP method: 'as planned', 'what-if', impacted baseline schedule', 'as planned plus delay analysis' and the 'affected baseline schedule' methods. The IAP method requires a baseline schedule and knowledge of the delay events and it is not recommended for complex cases and completed projects.

Collapsed/'But for' As-Built Analysis method analyses the delay using the final as built schedule or creating one including all network logic along with all delay events and their impacts and then start excluding the impact of the delay events to see what would have been the case but for such delay events (Braimah and Ndekugri, 2008). This method is moderately complex and requires an as-built schedule and knowledge of the delay events. It is suitable for complex cases but cannot deal with concurrency issues and the changing nature of the critical path.

TIA is a dynamic method that allows for initially creating a separate sub-network for each of the events, which can be agreed between the parties, and then these subnets can be inserted into the project-updated schedules in each relevant time-period. In the final time-period, there will be a fully impacted schedule containing all delay events and considering all as built data (SCL, 2002). SCL (2002) considers TIA as the preferred method but not when the case of analysis is distant from the events (SCL, 2015). It considers project delays regardless of the originator or the type of the delay and encourages the parties to keep good records and to update the project schedule on regular basis. However, is that the method requires complex analysis and effort and a substantial time to perform. As such, its use will be highly depended on the availability and the quality of the project records (Arditi & Pattanakitchamroon, 2006). Williams (2003) described three other methods in a way similar to the TIA, which are the windows analysis, snapshot analysis and the time impact technique. They are effectively the same but with different ways of looking at the delay events, delay effect, window periods and project progress. The TIA, however, differs from the Contemporaneous Windows Analysis method in that the latter is observational method that does not require modelling or impacting the delay events as it follows the "effect and cause" approach rather than the "Cause and effect" approach. In summary, the review of the literature recommendations (table 1) supports the use of TIA except when projects have poor records or when there are limitations on time and budget for the analysis.

Table 1: Summary of delay analysis methods

Nr.	Method	Brief Description
1	As-Planned vs. As-Built APvAB)	Observation of the difference between an as-planned and an as built schedule
2	Impact As-Planned (IAP)	It is based on the theory that the completion date can be determined by adding the delays into the as-planned schedule.
3	Collapsed As-Built (CAP)	Effects of delays are ''subtracted'' from an as-built schedule to determine what would have occurred but for the delay events.
4	Time Impact Analysis (TIA)	Assumes that delay impacts to a project can be assessed by running a series of analyses on schedule updates.

3. Main Selection Factors

Before selecting a DAM, questions should be asked as to which DAM can produce the desired outcome and whether the project circumstances are suitable for performing such method (Williams, 2003). Braimah and Ndekugri (2008), SCL (2002) and AACEI (2011) identified several factors affecting the selection of the appropriate DAM by delay analysts.

Data, Information and Records Available focus attention on the type and level of available project data that could heavily affect the selection and application of a DAM. However, the reliance on the project records varies between the DAMs. Records may include correspondence, progress reports, meeting minutes, site inspection records, transmittal sheets, videos, photos and others (Braimah & Ndekugri, 2008). None of the DAMs would give valid results if the project records were incorrect or invalid. Not surprising that more than 70% of the delay analysis effort is usually exerted in gathering and organizing the information (Arditi & Pattanakitchamroon, 2006). ***Baseline, Availability Quality and Features*** is the second in importance after the availability of proper records. Having a proper baseline schedule reflecting the original intentions of how and when to perform the works is essential to perform the delay analysis, regardless of the selected method (Arditi & Pattanakitchamroon, 2006). ***Contractual Obligations and the Attitude of the Opponent Party****;* a DAM might be specified in the Contract documents or agreed by the parties. It may also be influenced by the applicable legislation. This may limit the analyst choices as to the section of the DAM (Braimah & Ndekugri, 2008 and SCL, 2002). The attitude of the opponent party may not affect the application of the DAM, but it must be considered by delay analysts before selecting a DAM. If the opponent party, for example Is willing to accept liability, a fair and simple method maybe sufficient (Braimah & Ndekugri, 2008). ***Project Nature, Complexity and Circumstances;*** the characteristics of the projects such as the size, design, duration, cost and complexity will heavily influence the selection of the DAM. However, the effect in two different ways. Complex and large projects may require a complex DAM to be able to analyse the delays. However, in some cases, the project might be too complex or has unnecessary complex information which may require a less sophisticated method to analyse the delay (Braimah & Ndekugri, 2008). ***Nature, Type and Number of the Delay Events***; Delays are usually categorised based on liability to Compensable, Excusable and non-excusable delays. The type of project delay affects the selection of the DAM as some methods are unable to analyse multiple liability events (SCL, 2002). ***Skills of the Analysts*** and abilities could influence the selection of the DAM as some methods require complex analysis and certain level of experience, particularly when it comes to making reasonable assumptions, subjective views, interpretations and understandings (SCL 2002; 2014, AACEI, 2011). ***Time, cost and Resource Constrains for Performing the Analysis***; claims are usually governed by certain resources, budget, time and milestones. This must be taken into account before selecting the DAM. There is a huge variance on the level effort required to perform each of the DAMs Cost proportionality should be considered when selecting the DAM. The more complex the DAM is, the more effort is required and the more expensive it will be. (Arditi & Pattanakitchamroon, 2006). ***Capabilities, Shortcomings and Strength Points of the Method***; depending on the project circumstances, the analysis will have to choose a Dam that is capable of producing the desired results. For example, the IAP method cannot deal with concurrency issues while the TIA can (Arditi & Pattanakitchamroon, 2006). ***Status of Project and Point of Time;*** delay analysis can be performed at any point of time before, during or after completion of the project. However, this will heavily influence the section of the DAM. For example, if a forecast of a prospective delay is required, then the IAP method may be appropriate. However, if a retrospective analysis is required and the as built data is available then the other methods such as the CAP or the ABvAP methods would more appropriate. In cases where the project is still running and a real time delay analysis is required, then the TIA method may be the best (SCL, 2015). ***Concurrent delays, Disruption and Acceleration Issues; w***hen multiple delay events with multiple potential liabilities for the delay exist in a project, complex analysis might be required. This would affect the analyst's selection of the DAM as, for example, simple methods such as the IAP cannot delay with such complex issues (Williams, 2003). ***Purpose and Reasons for Delay Analysis;*** Braimah and Ndekugri (2008) note that the purpose of the delay analysis will influence the selection of the delay analysis methodologies. Purposes of analysis are usually extension of time, prolongation cost, and acceleration and disruption entitlements. Depending on each method capabilities, the selection should then be made. For example, if acceleration entitlement is the purpose of the analysis, methods such as the impacted as planned or the collapsed as built may not serve the purpose. However, methods such as the TIA may effectively present the acceleration measures. ***Ownership of the Float, Software Used and Scheduling Settings;*** the ownership of the project float affects the criticality of the activities. While the float is commonly owned by the project, sometimes this is not the case. It is therefore essential that the delay analysis gets this cleared out and even try to get the consent of the parties on the ownership of the project float before selecting the DAM (Arditi & Pattanakitchamroon, 2006). Various scheduling software programmes in the market allow for scheduling large number of tasks and activities using the CPM logic. Such software contains various options that affect the calculation and determination of the critical path. Specific attention to software settings such as the scheduling options: retained logic and progress override is needed. In-progress updates, such scheduling option would make huge difference on the critical path as it would allow activities to schedule out of sequence (Arditi & Pattanakitchamroon, 2006).

4. Research Method

The research analyzed five case studies of construction projects in UAE. The decision to use case studies approach is driven by the need to engage the key actors, mainly delay analysists, and develop a detail understanding of the dynamics of the decision making process that determines the method as well as the process adopted for delay analysis. The projects were selected using the researcher contacts to ensure cooperation and overcome sensitivity about disclosing details of what many organizations consider confidential. A wide range of similarities and differences were identified between the analyzed case studies. The case studies were driven by three main questions; how the decision was made on the method to assess delays, what were the key factors that have influenced this choice and in what way has the selected method enabled or impeded the effort to assess delays more effectively and achieve the desired results. Table 2 is a brief summary of the case studies, interviewees and the used DAM.

Table 2: Summary of case studies

Project	Interviewee	Used Method(s)
A (5 Stars Hotel)(65M US$)	A1 (Project Planner)	IAP
	A2 (External Consultant)	Float Mapping
	A3 (External Consultant)	TIA
B (International High School) (120M US$)	B1 (Project Planner)	IAP
	B2 (Project Planner)	TIA
C (Highway Road) (113M US$)	C1 (Project Planner)	TIA
D (Sewage Treatment Plant) (1.5B US$)	D1 (External Consultant)	ABvAP
E (Residential Tower) (25M US$)	F1(Project Planner)	IAP

In terms of the common DAMs, the TIA method is more common in the sample. The interesting fact is that the IAP method, although criticized by the researchers, according to the case studies, it is still commonly used. The float mapping method was used in one of the projects but did not deliver the desired results due to its over-complexity and lack of ability to deal with concurrent delays. Similarly, the As Built vs As Planned method was used in one of the case studies and, exactly as suggested by Arditi and Pattanakitchamroon (2006), was not successful because it is not yet popular and clients seems to have doubts about its abilities and results.

Figure 1, shows the research developed selection process for the DAMs. The process is dependent on the selection of a delay analyst having the appropriate experience which would influence the choice DAM. The process addresses all the relevant factors and the potential effects of such factors; however, it does not provide specific instruction for the selection of the DAM as such decision requires the analyst’s subjective view.

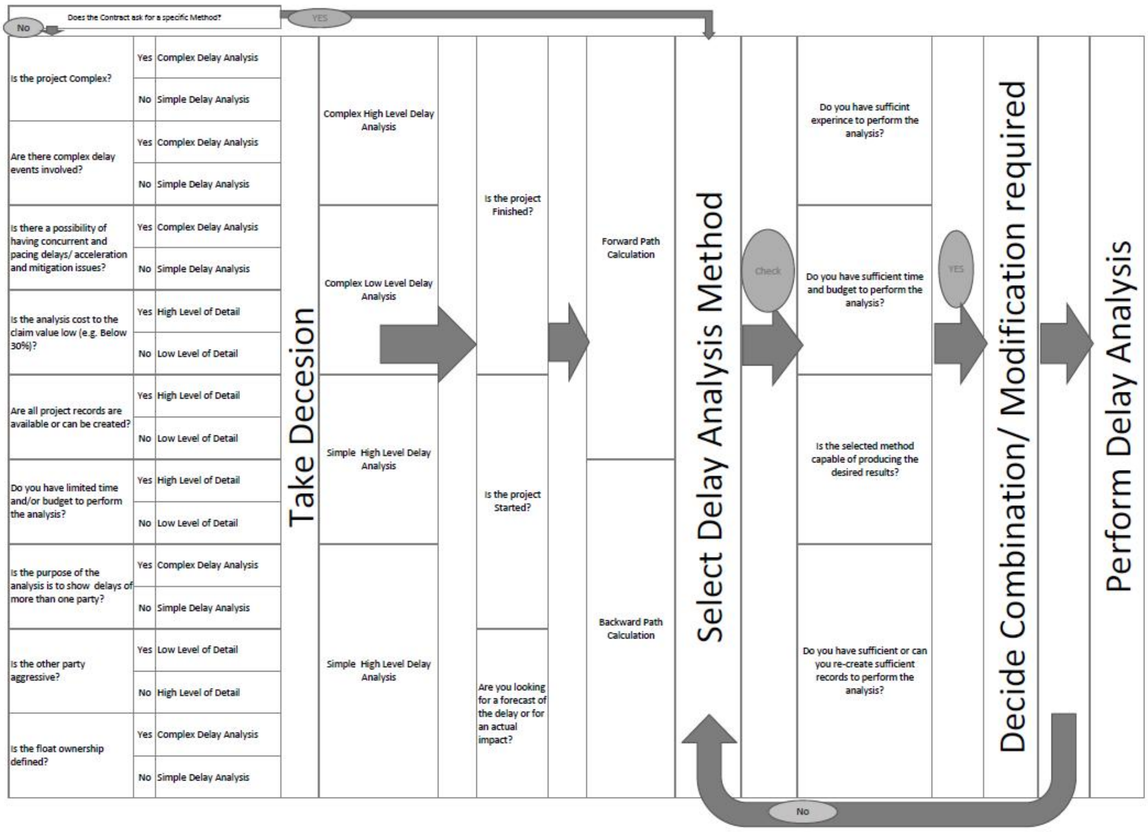

Figure 1: Selection process of delay analysis methods

5. Analysis and Discussion

The analysis of the case studies has shown that the main factors influencing selection of DAMs were the availability of records, the time available to perform the analysis, the attitude of the other party, the contractual requirements and the actual status of the project at the time of performing the analysis. The main factors that were found to be influencing the acceptance of the method were the attitude of opponent party and the purpose of the delay analysis which were highlighted by Braimah and Ndekugri (2008). An important finding however was that the selection of the method itself is a subjective decision of analysts based on their own understanding, interpretation and appreciation of the various factors. Interestingly, the reputation and the impartiality of delay analysts were found to be the main driver for accepting the delay analysis. Such factor was not directly addressed in the literature review although clients seem to be strongly influenced by such factor when making their decision.

There is an agreement that the first factor to check is that if the contract documents specify which DAM should be used. Although SCL (2002) suggests that new forms of contract nowadays specify the DAM, this was not the case in any of the projects examined in this study. The primary factors for the selection of the DAM were the availability of project records, the time available for performing the analysis and the point of time of time of the analysis. The interviewees also viewed the availability of an adequate baseline schedule, as part of the project records, as an essential element for performing the delay analysis.

Only one of the interviewees gave great importance to the experience of the delay analyst while others viewed it as a secondary factor. This could be because he was performing the float mapping method which is not a common method and may require special experience. SCL (2002)) emphasize on the importance of this factor as it may affect both the decision of selection of the method and the results of the analysis. Cost and time limitations are viewed as a constraint for both the selection of the delay analysis method and the level of detail of the analysis. Contractors seem to tend to utilize IAP Method, not only because it gives them favorable results, but also because it requires the least time and effort. Although SCL (2015) notes that the actual status of the project and the time of performing the analysis are the main factors, it appears that in practice they are secondary. Table 3 below, however, provides a summary recommendations, based on the reviewed literature and conducted interviews, that may assist delay analysts while deciding which DAM to utilize.

Table 3: Summary of recommendations (1-2)

Factor	*Conditions/ Circumstances*	*Recommended Method(s), listed on priority basis*
Records availability, accessibility and Quality	Baseline only	IAP
	As Built only	CAB
	Baseline and As Built	CAB OR ABvAP
	Baseline, periodic updates and As	TIA OR CAB OR ABvAP
Contractual Requirements	Specific Method	Specified Method OR Challenge with Justifications
Complexity of Project and Delay Events	Simple	TIA/ low level of detail (LD) OR Any Method/
	Complex	TIA/ High level of detail (HD) OR Complex Method/ HD
Skills of the Analyst	Expert	Perform Analysis
	Intermediate/Beginner	Get Support OR Refuse Job
The attitude of the opponent party	Lean	TIA/ LD OR Any Method/ LD
	Aggressive	TIA / HD OR Any Method/ HD
Time, Resource and Budget Constrains	High	TIA / LD OR Any Method/ LD OR Challenge Constrain(s)
	Law	TIA / HD OR Any Method/HD
	Complex	Complex/ HD

Factor	*Conditions/ Circumstances*	*Recommended Method(s), listed on priority basis*
Capabilities of the	Simple	Simple/ LD
Time of Performing Analysis	Before Start	IAP OR forward calculation method
	During Construction	TIA OR dynamic method
	After Completion	TIA OR CAB Or ABvAP OR dynamic
Concurrency, disruption and	Present	TIA OR Factual Based / HD
	Not Present	TIA /LD OR other simple method
Purpose of the Delay Analysis	Complex	TIA /HD OR modified version
	Simple	TIA /LD OR other simple method
Ownership of Project Float	Disagreed/Complex Apportionment	TIA /HD OR any complex method
	Agreed/Simple Apportionment	TIA / LD OR other simple method
Scheduling Settings	Special Settings/Constrains	TIA /HD OR complex method
	Common Settings/Constrains	TIA/LD OR other simple method

6. Conclusions

The challenge that most construction projects face is to deal with delays when they appear efficiently and effectively to be able to put the project back on track. This research reviewed the key literature on the topic and set case studies of the projects in the UAE to examine how the decisions to select a DAM and the factors influencing such a decision. The main finding of the research is that two DAMs, IAP and TIA, are dominant in the UAE construction industry with evidence that TIA is the most favoured by Clients. The availability of project records, the availability and quality of the baseline schedule, the actual status of the project and the time of performing the analysis are the primary factors that analysts consider when selecting a DAM. The results also showed that the selection of the DAM is subjective influenced by the delay analyst experience, knowledge and understanding. This is a new factor that can be aligned with the ‘skills of the analyst’ factor. Time and budget limitation are important factors. That would limit the work of the delay analyst who will have resist the pressure to compromise on quality and details as this may affect the accuracy, fairness and reasonableness of the delay analysis results. In summary, the research demonstrated that although the advantages and disadvantages of each of the DAMs are clear, the appropriateness of using any method remains influenced by the analysists personal views and judgment of the project events and their understanding of the appropriateness of the different DAMS.

The ability of the research to generalize its findings may be argued to be limited to the selected case studies. However, the depth of analysis and established trust between the researcher and the interviewees would give credit to the findings that provide a useful insight in such important and sensitive issues.

Statutory Adjudication of Payment Claim Disputes in Australia Affected by On-Going Scrutiny by Courts and Changes to the Legislation

Abstract

The object of statutory adjudication in NSW and Queensland is to ensure that a party, who performed construction work for another party, is able to recover payment. It is intended that payment would be made on an interim basis, pending final resolution. However, the NSW Supreme Court has viewed adjudicators as tribunals, proceeded to judicially review adjudication determinations and provided relief in the nature of *certiorari* to quash an adjudication determination where there has been jurisdictional error. This power to quash an adjudication determination was initially rejected but subsequently re-confirmed by the NSW Court of Appeal.

The recent amendments of the NSW and Queensland security of payment legislation have significantly modified the operation of the adjudication process. The main purpose of the amendments in NSW was to put in place an orderly regime of cash flow from principals, through to head contractors and subcontractors, and to create retention trusts in high value projects, to improve security of payment to parties who carry out construction work. In contrast, the purpose of the Queensland amendments was firstly to improve efficiency of distributing adjudication applications to qualified adjudicators through an office of the Adjudication Registrar of the Queensland Building and Construction Commission (QBCC) and secondly, to correct the perceived bias that adjudication of large payment claims within the short statutory time lines, disadvantaged respondents. To that end, the amendments introduced a two tier adjudication process for 'simple' claims of $750,000.00 or less and for 'complex' claims of over $750,000.00. Respondents are now able to raise further reasons for withholding payment during the adjudication process and the parties to an adjudication have more time to make submissions to the adjudicator.

The main objective of this paper is to critically assess, based on the published information, the case law, and the data obtained from the QBCC Registrar, the NSW Government and the Adjudication Research and Reporting Unit (ARRU) of the University of NSW, the performance of the recent amendments of the NSW and Queensland security of payment legislation.

Keywords: Adjudication, payment claims, amendments, NSW, Queensland

1. Introduction

In the first part of this paper, the brief history of the security of payment legislation in the Australian construction industry will be outlined, with a particular emphasis placed on the NSW Act, in relation to the evolution of the adjudication law. In the following parts, the recent amendments to the NSW and Queensland Acts will be outlined and the authors will attempt to assess the impact of the amendments on the performance of the adjudication process.

2. History of statutory adjudication in Australia

The *Building and Construction Industry Security of Payment Act 1999,* which commenced in New South Wales on 26 March 2000 (the NSW Act or the Act), was an outcome of the Cole Royal Commission into the conduct and practice of the construction industry in the late 1990's. The objective of the Cole Royal Commission was to review the conduct and practices employed in the Australian construction industry in view of a high rate of insolvencies, particularly among subcontractors, who are the main source of labour and who undertake work, which represents 75% of the total project value (Cole, 2003).

The NSW Act was the first legislation in Australia, which aimed at providing security of payment for parties who carry out construction work or supply related goods and services under a construction contract by way of a rapid statutory adjudication process. It followed the introduction of the *Housing Grants, Construction and Regeneration Act 1996* (UK) (the UK model) but it adopted a different path to the UK model. The NSW Act was taken up by Victoria in its *Building and Construction Industry Security of Payment Act 2002*. Significant amendments were made to the NSW and the Victorian Acts in 2002 and 2007 respectively to remove the option of respondents providing security in lieu of paying the adjudicated amount. Under the amended Victorian Act, claims for damages and delay damages are expressly excluded as are some disputed variations.

Queensland, in 2004, and South Australia, Tasmania and Australian Capital Territory, in 2009, adopted the amended NSW Act with minor changes. This became known as the eastern model as it generally operates in the eastern States of Australia. The eastern model is characterised by the rapid adjudication of payment claim disputes, where only a party (a claimant), who carried out construction work, may apply for adjudication.

Western Australia and the Northern Territory introduced their own security of payment legislation under *Construction Contracts Act 2004* and *Construction Contracts (Security of Payments) Act 2004* respectively. These Acts were based on the UK model and are commonly referred to as the western model, under which either party to a dispute may apply for adjudication. Timelines for submissions are longer than in the eastern model. The reason for narrowing down the scope of this paper to the eastern model and in particular, to the recently amended legislation in NSW and Queensland, is that data on the performance of the adjudication process in these two States is more readily available.

The intent of the original NSW Act was to ensure that a party, who carried out construction work or supplied related goods and services under a construction contract, received payment by way of a rapid adjudication process, pending the final resolution of the dispute by arbitration or litigation. However, the Act was found not to provide security of payment, as intended, as the respondent, instead of making payment of the adjudicated amount, could provide security for payment in the form of a bank guarantee or a deposit into a trust account pending the final resolution of the dispute. The outcome of this was that despite being successful in adjudication, the subcontractor received no payment and its cash flow was adversely affected.

The amendments introduced in 2002 re-affirmed the original intent of the Act and made it much more effective in providing security of payment by:

- empowering Authorised Nominating Authorities (ANAs), who collect adjudication applications and appoint adjudicators, to issue an adjudication certificate, which, when filed in a Court of competent jurisdiction, becomes an enforceable judgment for debt;
- preventing the respondent, in challenging an adjudication determination in a Court, to raise any cross-claims or any defence in relation to matters arising under the construction contract; and
- requiring the respondent to pay the adjudicated amount.

The effectiveness of the amendments was reflected in a sharp increase in a number of adjudication application, as reported by Uher & Brand (2005a). However, this period is also characterised by an increase in challenges to adjudication determinations in the NSW Supreme Court. In *Musico & Ors v Davenport & Ors* [2003] NSWSC 977 (‘*Musico*’), McDougall J viewed the adjudicator as a tribunal with power to make determinations that, although not final, are binding on the parties. On that basis, in paragraph [54] in *Musico*, McDougall J held that the Court had power under s.69 of the *Supreme Court Act 1970* to provide relief in the nature of *certiorari* to quash an adjudication determination where jurisdictional error is shown. This was contrary to the object of the Act in that the intended role of an adjudicator was that of a mere certifier.

Subsequently, in *Brodyn Pty Ltd trading as Time Cost and Quality v Philip Davenport & Ors* [2004] NSWCA 394 (‘*Brodyn’*) the Court of Appeal reversed the decision in *Musico,* to the extent that relief in the nature of *certiorari* to quash an adjudication determination that is not void, is not available, and that the only relief available was by declaration and injunction if a determination is void. The Court of Appeal provided guidelines as to the basic and essential requirements for a valid adjudication determination. These were: the existence of a construction contract, valid service of a payment claim and an adjudication application, and the adjudicator determining the adjudication application in accordance with the Act. The Court of Appeal held that a determination is void where the adjudicator acts outside its jurisdiction, including where the adjudicator does not exercise its power under the Act in a ‘bona fide’ manner and where it denies natural justice to a party.

The period post *Brodyn* is characterised by a further increase in the number of adjudication applications as reported by Uher & Brand (2005a), which reached the peak in or around 2005. This is verified by empirical studies by Brand & Uher (2004) and Uher & Brand (2005b), and by reports issued by the NSW Government and the ARRU. While generally complying with the principles decided in *Brodyn*, the Courts set aside many determinations for a variety of jurisdiction related reasons including denial of natural justice, abuse of process, issue estoppel, a payment claim being related to multiple contracts, not satisfying the contract pre-conditions of payment or not being referrable to a valid reference date, invalid service of documents and an adjudicator failing to apply an active process of intellectual engagement.

In *Chase Oyster Bar v Hamo Industries* [2010] NSWCA 190 [*Chase Oyster Bar*], the NSW Court of Appeal revised the decision in *Brodyn*. The Court, found that the adjudicator was a tribunal, and the NSW Supreme Court had power to provide relief in the nature of *certiorari* to quash an adjudication determination. As the laws now stands, adjudication determinations may be quashed by the NSW Supreme Court, where there has been a jurisdictional error of law and where an adjudicator denies natural justice to a party. However, this decision did not change the finding in *Musico* that judicial review of an adjudicator's decision is not available on basis of non-jurisdictional error of law.

The decisions of the NSW Courts have, to a large extent, been persuasive in Queensland Courts, nevertheless, the Queensland Supreme Court and the Court of Appeal have, in some instances, handed out decisions, which are contrary to the decisions of the NSW Courts.

3. The 2010 Amendments of the NSW Act and their impact on the operation of the Act

Upon a review of the operation of the Act, in 2010 the NSW Government inserted a new Division 2A into the Act to give greater protection to subcontractors. Prior to this amendment, a claimant (a subcontractor), upon filing an adjudication certificate in a Court, could request the Court to issue a debt certificate under s.7(1A) of the *Contractors' Debts Act*. If served upon the principal, the principal would be required to action the debt certificate by deducting an adjudicated amount from payment to the respondent (a head contractor). The shortcoming of this mechanism was that upon the conclusion of an adjudication process, the principal may have already paid the respondent the full amount of its entitlement so the debt certificate was of no utility.

The new Division 2A of the Act provided, in sections 26A–26F, that a claimant (a subcontractor), who has made an adjudication application, may serve a 'payment withholding request' upon the principal. The principal is then required to retain sufficient money due to the respondent (a head contractor) to cover the claimant's payment claim. This new mechanism, while allowing a subcontractor to issue a payment withholding notice much earlier than under the *Contractors' Debts Act*, does not guarantee payment to the subcontractor in circumstances where the principal has already paid the respondent its payment entitlement. This may well be the reason, why subcontractors, in the authors' personal experience as adjudicators, only infrequently rely upon sections 26A–26F of the Act.

4. The 2013 Amendments of the NSW Act and their impact on the operation of the Act

4.1 Introduction to 2013 amendments

On 9 August 2012, the NSW Government established an inquiry into Construction Industry Insolvency in NSW, headed by Bruce Collins, a Queens Counsel. The impetus was the financial collapse of a number of established building/construction companies. The purpose of the inquiry was to recommend measures to better protect subcontractors from the effects of insolvency of head contractors.

The Final Report was published on 28 January 2013 (Collins, 2003). It made a number of recommendations, some of which were adopted by the NSW Government as the 2013 Amendments of the Act. The most notable amendments will now be briefly discussed.

4.2 Definition of subcontractor, head contractor and principal

Superseded section 4 of the Act provided definitions of various terms including the definition of *claimant* and *respondent*. Amended section 4 introduces, for the first time, definitions of *subcontractor*, *head contractor* and *principal*. This was necessary for the proper interpretation of a new regime for the due date for payment outlined in amended sections 11(1A–1C), trust accounts for retention in section 12A and the supporting statement in section 13(9) of the Act.

A *head contractor* is defined as "*the person who is to carry out construction work or supply related goods and services for the principal under a construction contract (the main contract) and for whom construction work is to be carried out or related goods and services supplied under a construction contract as part of or incidental to the work or goods and services carried out or supplied under the main contract*".

It emerges from this definition that a party cannot be a *head contractor* unless the party enters a construction contract that requires another party to carry out part of the *head contractor's* obligations under the main contract. A *head contractor* must also have at least two construction contracts, one with the *principal* and one with a *subcontractor*. A *head contractor*, whose construction contract bars sub-letting of any part of the contract works, is not a *head contractor* but a *subcontractor*.

While there will always be a subcontractor, given the varied nature of contractual arrangements associated with building/construction projects and the varied nature of roles played by participants to construction contract, Davenport (2014, pp. 2–4) observed that "*in the course of a contract, a* *principal can mutate and cease to be a principal and a subcontractor can mutate and become a head contractor. On any day, you may not know whether a party to a construction contract is a principal, a head contractor, a subcontractor or something else*".

In circumstances, where a subcontractor or a head contractor can both be a claimant, the parties' failure to correctly identify their status could lead to confusion as to whether the claimant is a subcontractor or a head contractor and whether the respondent is a principal, a head contractor or a subcontractor. Although the authors are unaware of any adjudication application falling over due to the failure to properly identify the status of the parties in relation to a construction contract, as noted by Davenport [2014], Rippon & Smiley [2014] and Davenport at el (2015), these new definitions may bring about a real problem for adjudicators to interpret the proper status of the parties.

4.3 Due date for payment

Prior to the 2013 Amendments, the due date for payment was, according to section 11 of the Act, 10 business days after a payment claim was made if a construction contract made no express provision thereof.

The amended section 11 now differentiates between payment by a principal to a head contractor and payment to a subcontractor. Under s.11(1A), the maximum period for payment to a head contractor is 15 business days after a payment claim is made and under s.11(1B), the maximum period for payment to a subcontractor is 30 business days after a payment claim is made.

The rationale for mandating the maximum period of 15 business days for payment to a head contractor is to improve the flow of cash from top of the contractual chain down through the supply chain. This amendment clearly benefits head contractors' cash flow but it may impair the principals' ability to source funds from lenders within the prescribed time frame.

The statutory maximum period of 30 business days for payment to subcontractors is likely to adversely affect the cash flow of subcontractors involved in small value subcontracts, who often enter into subcontracts with no express terms of payment. Prior to the 2013 Amendments, payment was, in those circumstances, due within 10 business days of the date of service of a payment claim. Under the amended section 11(1B), payment is now due some 20 business days later. This amendment may also compel subcontractors to rely on other than the adjudication process to recover payments. While no statistical data is available from either the NSW Government or the ARRU on the impact of this amendment on subcontractors and the adjudication process, the information obtained from one ANA indicates that in the period after the amendment to June 2015, the number of adjudication applications declined by 28%. However, whether this is entirely related to the amendment or to some other factors, is not clear.

Only subcontractors, who may benefit from the amendment, are those, involved in high value subcontracts, where they traditionally receive payment well after the new mandatory period of 30 business days.

4.4 Removal of a notice that a payment claim is made under the Act

Prior to the 2013 Amendments, a payment claim required to be endorsed as a claim under the Act. This ensured that the Act only applied to such endorsed payment claims.

Under the 2013 Amendments, a payment claim under a construction (non-residential) contract is no longer required to state that it is made under the Act.

Facts Sheet 4 (2014), issued by the NSW Government, explains the rationale for this change by asserting that the mandatory endorsement of a payment claim as a claim under the Act, made subcontractors reluctant to use the adjudication process for fear of losing future work. This issue was identified by Brand & Uher (2004) and Uher & Brand (2005b), in analysing the performance of the Act in the first few years, as a potential problem for subcontractors. However, contrary to Facts Sheet 4 (2014), there is no evidence whatsoever that in the past 10 or more years, the endorsement requirement had the effect of intimidating subcontractors.

An unintended side effect of this amendment is that any document may be a valid payment claim under the Act if it satisfies the requirements of section 13(2) of the Act. This will require a respondent to be vigilant and issue a payment schedule in respect of each document, which may be or may appear to be a valid payment claim and which is referrable to a reference date. The failure to do so may expose the respondent to the risk that the claimant would proceed to recover payment as a debt due in any court of competent jurisdiction.

This amendment could also cause a problem for a claimant. This is demonstrated in the following example. In a day to day communication with a respondent, the claimant may issue an email in which it identifies construction work and indicates the amount that the claimant claims to be due. The respondent may construe this email to be a payment claim. Prior to issuing a payment schedule within 10 business days of receiving the email, the claimant issues a regular monthly payment claim. Provided the email satisfies the requirements of section 13(2) of the Act, it would be found to be a valid payment claim. Accordingly, a subsequent monthly payment claim could be a second payment claim referrable to the same reference date. As such, it would be invalid under the Act.

Although no statistical data is available on whether or not this amendment has caused adjudication applications to fall over, the authors have, in their practice as adjudicators, become aware of adjudication applications being found to be invalid due to this issue.

4.5 Mandatory head contractor statement

The 2013 Amendments include, in sections 13(7) and 13(9) of the Act and in section 10 of the Building and Construction Industry Security of Payment Regulation 2008 (amended on 1 May 2015), a new provision, which requires a head contractor to include, with a payment claim served upon the principal, a supporting statement in the form of a declaration to the effect that all subcontractors have been paid all amounts that have become due and payable in relation to the construction work the subject of the payment claim. No such requirement has been placed upon subcontractors making a payment claim against head contractors and no rational for this has been provided by the NSW Government.

This new provision has, according to Facts Sheet 3 (2014), issued by the NSW Government, further improved subcontractors' security of payment by requiring head contractors to make a required declaration of payment to subcontractors at the time of making a payment claim to the principal. Section 13(7) of the Act provides a maximum penalty of $22,000.00 for failure by a head contractor to provide a declaration with a payment claim. Section 13(8) of the Act provides a similar monetary penalty and/or 3 months imprisonment for knowingly providing false or misleading information in a declaration.

No statistics are available at present as to the impact of this new provision on the operation of the Act. However, the authors are of the view that while this provision may improve security of payment of subcontractors, it is less likely to improve the position of sub-subcontractors of a subcontractor who makes a payment claim on the head contractor.

4.5 Trust account for retention moneys

The 2013 Amendments include a new section 12A relating to retention money being held by a head contractor in trust for a subcontractor. It was enlivened by the proclamation on 1 May 2015 of the Building and Construction Industry Security of Payment Regulation 2008. The regulation in section 5 requires head contractors to hold retention money in a trust account for subcontractors, where the head contract value reaches a threshold of $20 million, either at the time when the head contractor entered into a main contract with the principal or when the original main contract value reaches the threshold.

The retention trust created in section 12A of the Act, is not the statutory construction trust recommended in the Collins Inquiry Final Report. The Final Report recommended that any payment by a principal to a head contractor, or by a head contractor to a subcontractor, or by a subcontractor to a sub-subcontractor, for work done or materials supplied by the head contractor, subcontractor or sub-subcontractor, be held on trust where the value of the building project exceeds $1,000,000. This recommendation was to ensure that in case of insolvency of a head contractor or subcontractor, money paid for work done or materials supplied would be protected. The NSW Government's reason for limiting the statutory trust to retention, managed by a head contractor for contracts greater than $20 million in value, is unclear.

This amendment was criticised by the Housing Industry Association (HIA, 2015) on many grounds, including that no reciprocal proposal has been created to quarantine head contractors' retentions held by principals, and that the trust creating, managing and reporting requirements are overly onerous and anticompetitive.

While this new amendment recognises the importance of protecting subcontractors' retention money, it only operates on projects with a value of at least $20 million and in any event, the only guarantee that the retained amount is secured in case of insolvency of a head contractor is that provided by the laws governing trusts. Subcontractors engaged on small value contracts will continue to have their retention money unprotected.

This new amendment has no impact on head contractors if the contract value does not reach $20 million. However, when it is reached, which could occur any time during the execution of the works, head contractors will assume an additional administrative burden in establishing and managing a trust fund in respect of subcontracts entered into after the threshold is reached, and in complying with the reporting requirements. It is likely that at least some head contractors will attempt to negate the impact of amended section 12A of the Act by moving away from cash retention in favour of a bank guarantee. While no empirical data is available at present to verify this, the authors have already experienced, as adjudicators, a shift away from cash retention to bank guarantees in high value contracts between head contractors and subcontractors.

5. Recent amendments to the Queensland Act and their impact on the adjudication process

5.1 Introduction to recent amendments

The intent of a discussion paper titled 'Payment dispute resolution in the Queensland building and construction industry', issued by the Queensland Government in December 2012, was to obtain feedback on the operation of the Building and Construction Industry Payment Act (the BCIPA Act or the Act). It resulted in the release of a Final Report, prepared by Andrew Wallace, on 24 May 2013 (Wallace, 2013). The main recommendations of the Final Report were accepted by the Queensland Government in the form of the 2014 Amendments of the Act. The two most prominent amendments will now be briefly discussed.

5.2 Appointments of adjudicators by the Adjudication Registrar only

Prior to the 2014 Amendments, claimants lodged adjudication applications with privately operated ANAs, who in turn referred the applications to adjudicators on their respective panels.

Under the 2014 Amendments, the responsibility for receiving adjudication applications and for appointing adjudicators now lies with the Adjudication Registrar of the QBCC. The 2014 Amendment in effect abolished the ANAs and centralised the administration of the Act within the

QBCC. This was intended to improve efficiency and effectiveness of the adjudication process, improve the quality of adjudicators through mandatory transitional training and through on-going professional development, and remove perception that some adjudicators and some ANAs were claimant friendly.

While the Wallace Final Report provided no verifiable evidence of inadequate training of adjudicators, the requirement for on-going professional development of adjudicators under the new regime must be viewed a step in the right direction.

It is commonly accepted that greater efficiency of public services can be realised through privatisation. In that context, the decision of the Queensland Government to abolish the ANAs and administer the Act through the QBCC, is a revolutionary step.

The Adjudication Registrar of the QBCC provides, on its website, comprehensive monthly statistics of adjudication applications submitted, adjudication decisions released, certificates issued and adjudication fees charged. In the period from July 2015 to November 2015, 44% of adjudication applications, made under the 2014 Amendments, did not proceed to adjudication for the reason of withdrawal due to invalidity of applications or settlement. In comparison to the same period under the original Act (from July 2014 to November 2014), 26% of adjudication applications did not proceed to adjudication. Whether this indicates that there are gaps in information that the Adjudication Registrar provides to claimants on how to prepare valid applications or the high rate of failed applications is a short term issue related to the transition from the original to the Amended Act, is not clear.

5.2 Dual system of adjudication

Perhaps the most significant change to the Act was the creation of a dual system of adjudication. A claimant must now identify in a payment claim whether the claim is a standard or a complex claim.

A standard claim is a claim with a monetary value of $750,000.00 or less. The time frame for providing a payment schedule and an adjudication application has not changed. However, the time frame for the lodgement of an adjudication response has doubled from 5 to 10 business days. Otherwise, adjudication of payment claims follows much the same path as under the original, unamended Act.

A complex claim is a claim with a monetary value of more than $750,000.00. It is worth noting that it is not necessarily a claim involving complex issues. The only parameter for a claim to be classified as a complex claim is its monetary value.

An adjudication response, issued in response to a complex claim, may include new reasons for withholding payment not previously included in the payment schedule and the claimant has a right of reply to such new reasons. In order to accommodate the claimant’s additional submission and by assuming that a complex claim is multifaceted and wide ranging, the amendment provides a significantly longer time lines for adjudicating a complex claim, which could be in the order of many months. In comparison, the time frame for adjudicating a standard claim is only 30 business days from the day of service of the claim.

Given the significantly different time lines between complex and standard claims, it is likely that claimants would prefer to make standard rather than complex claims in order to secure payment in the shortest possible period. The statistics provided by the Adjudication Registrar indicate that in the period from July 2015 to November 2015, only 12 complex claims or 7.1% of all claims, have been made. It is not possible to directly compare the number of complex claims of over $750,000.00, made under the Amended Act to the same value claims made under the original Act as the Adjudication Registrar's previous statistics classified large claims as claims in access of $500,000.00. Notwithstanding, it is to be noted that in the period from July 2014 to December 2014, just prior to the introduction of the Amended Act, there were 35 or 16.3% of all adjudication decisions related to claims in access of $500,000.00. While the value of some of these claims would have been below $750,000.00, the difference in the percentages is sufficiently large to suggest that high value claims had more frequently been made under the original Act than under the Amended Act.

6. Conclusions

Wide ranging amendments were made to the NSW Act in 2010 and 2013. New provisions were introduced in the form of a payment withholding request, a head contractor's statement and a retention trust to further enhance security of payment of subcontractors. Of these provisions, only a head contractor's statement is likely to achieve the desired objective as a payment withholding request would only provide security of payment in circumstances, where the principal is yet to make payment to the head contractor. The establishment of a retention trust will not enhance security of payment of small subcontractors or those engaged on a project of less than $20 million.

The impact of the amendments on the operation of the adjudication process is not possible to assess objectively for lack of statistical data. In the authors' view, while the amendments are likely to further improve security of payment of claimants and subcontractors in particular, compliance with the new provisions, such as a head contractor's statement and a retention trust, will increase the administration cost of construction contracts.

An unintentional consequence of the removal of the requirement to endorse payment claims as claims under the Act is that documents not intended to be payment claims may in fact qualify to be valid payment claims under the Act. This has already resulted in an intended payment claim being invalid as it was referrable to the same reference date as a valid but unintended payment claim.

The new maximum mandatory date for payment of subcontractors of 30 business days is contrary to the original intent of the Act to provide payment within 10 business days, unless a construction contract allowed for a longer period. This will impact adversely on the cash flow of subcontractors who enter contracts with no payment terms. The data available from one ANA indicates that this amendment may have caused the reduction in the number of adjudication applications made in the post-amendment period.

The 2014 Amendment of the Queensland Act, which abolished privately operated ANAs in favour of having adjudication applications submitted to the Adjudication Registrar of the QBCC, who in turn appoints adjudicators, runs contrary to an established trend of achieving greater efficiency through privatisation. It is much too early to draw conclusions as to whether or not this amendment has achieved any efficiency. The data provided by the Adjudication Registrar indicate that at least, in the short term, more adjudication applications have not proceeded to adjudication for the reasons of either being non-compliant or withdrawn. This may indicate that the Adjudication Registrar does not advise claimants on the process of making valid adjudication applications to the same extent as now abolished privately operated ANAs. Another significant 2014 Amendment of the Queensland Act was the creation of a dual system of adjudication, which provides for claims in excess of $750,000.00 to be adjudicated over a significantly extended period. This will undoubtedly result in an increased cost of adjudicating such claims. The present trend indicates that claimants are averse to making complex claims in excess of $750,000.00.

Abstract

In this paper we introduce the concept of Designing Project Management. On the basis of our earlier work, we suggest that there is still a gap between what is known from recent project management literature and what project managers can structurally help in the effectiveness of their work. Assuming that project management is a form of solving wicked problems, we propose a designerly way to solve these problems. To this end, we introduce the Project Design Cycle, consisting of the elements Awareness, Design, Performance and Reflection. This cycle has been studied in a purely exploratory study. Result of the study is that these elements are sometimes recognized, sometimes not, that the order of these elements has been hardly recognized, that the difference between Reflection-in-action and Reflection-after-Action has been recognized and a distinction seems to occur between a 'large' Project Design Cycle through the overall project management and a 'small' Project Design Cycle in the daily management. We finally conclude that more training in the cycle is necessary because this will possibly lead to a more effective project management.

Keywords: Project management theory, managing, designing, project management education

1. Introduction

In this paper we introduce the concept of Designing Project Management as a domain specific approach to the management of architectural design and construction projects in an ever changing environment. Much recent research points to the importance of understanding projects, and building projects in particular (Svejvig, 2015), as social systems in which there is a complex interplay and alignment of different goals, meanings, and perspectives (O'leary, 2013). This research suggests that it is important to take the personal, professional and business situations of project partners, commissioners and stakeholders into account when attempting to manage project teams [citation]. Many of the leaders in the rethinking project management (Cicmil, 2006; Hodgson, 2006; Morris, 2013) have come to the conclusion that as yet little of this research has led to significant advances in project management tools, practice, or education. Nor does the so-called classical approach address issues of daily practice or career development of project managers structurally do. In this we believe that current approaches to project management, while containing much essential material are not entirely adequate to the task of helping project managers to carry out their work (Heintz, 2015).

Our purpose is to refocus education from learning the systems of project management to learning how to be a project manager. To do this we propose an approach to project management that is based on the agency of the project manager rather than on the integrity of project management systems. It is not that we believe that the project management systems are irrelevant, but that we place the emphasis on the project manager's agency in selecting tools and actions from those systems and enacting courses of action using them. More specifically, we choose to see project management as a process of designing and enacting courses of action and "preferred situations". In doing so we are shifting attention from project management as an idea to project management "an ostensive (the idea) … [to] a performative (the enactment of the idea) dimension" (Carlgren, 2016).

We call this approach Designing Project Management. The research intention is as much to provide a lens through which to view project management action as to confirm the use of designerly approaches to problem solving by project managers. The educational intention is to offer a model for and an approach to training students in management of design and construction projects in how to enact the systems and theory of project management in the management of complex building projects. Further we believe that this approach will support young project managers in developing their professional capabilities.

This paper discusses the results of a preliminary explorative research project attempting to determine if the elements of the project design cycle can be recognised in the practice of project managers, and to what extent these elements function together as a cycle. The data consists of am interview based case study, and four semi-structured interviews of project managers. We found that the elements were observable, and that while not structured as a formal cycle, a regularity and interdependency between the elements could be observed.

2. Designing project management

2.1 Design in project management

By focussing on the action of the individual project manager we shift the interest from the validity and robustness of project management systems, many of which are aimed at monitoring and enforcement, to the interventions project managers make in steering projects towards successful completion. Such interventions occur at a range of scales from major problems such as development of project organizations to 'smaller' daily problems such as conflicts between project team members. Seen this way, project management is a form of problem solving (Ahern, 2014). These problems may be planning problems, or they may be problems requiring interventions in already ongoing events. Anticipating the current interest in design thinking Herbert Simon connected problem solving in areas such as management with design in areas such as architecture (Simon, 1969) He proposed that design was a approach to general problem solving across a wide range of fields, and defined design as itself "defin[ing] courses of action aimed at changing existing situations into preferred ones." (Simon, 1969) A more recent and more specific definition is: "A design can be defined as a model of an entity-to-be-realized, as an instruction for the next step in the creation process." (Aken, 2007). Indeed project management can be seen as a process of situated inquiry in which the project manager must interrogate the situation he or she finds themselves in, and through processes of sense-making arrive at judgements about, or design, what to do. (Lalonde, 2012)

The recent interest in the application of design thinking to management (Boland, 2004; Martin, 2009; Brown, 2008) has been based on the belief that because of its "liquid and open character" (Boland, 2004), design is an excellent way to approach the more general types of problems encountered in management. Although much of the literature on design thinking in management has drifted away from the earlier work on what Carlgren et al (2016) call designerly thinking, we believe that the distinction will be more limiting than empowering of research and practice in this area.

We therefore draw our inspiration from both the contemporary work on Design Thinking, and the older work on how designers think (Dorst, 1997; Cross, 2006; Lawson, 1997).

Design problems facing design and construction project managers include developing briefs and budgets, composing the design teams, specifying tendering approach and project organization, and creating construction schedules. However, design is also required in order to solve the day-to-day problems that face building project managers. Determining how cope with conflicts between stakeholders or actors, deciding how to bring a jury's deliberations to a close and choose the architect. In each case the project manager must inform him or herself about the current situation, and determine a course of action that is very likely to lead to the desired result. Both kinds of design problems, the mapping out of the future course of the project, and the resolution of day-to-day problems occur under a high level of uncertainty, and in dynamic situations where hidden and exogenous factors will likely play a significant role in driving the project off the current plan. Design thinking is required to find courses of action that will yield the desired results but will be robust across a large range of possible futures.

2.2 The Project Design Cycle

Design whether in the more generalized sense described by Simon, or in the more specific architectural sense, is a cyclical process. In the simplest sense this is a cycle of generate and test (Simon, 1969), but the design cycle also bears similarity to Deming's Plan-Do-Check-Act cycle (Deming, 1952) and the Kolb Learning Cycle: Concrete Experience – Reflective Observation – Abstract Conceptualization – Active Experimentation (Kolb, 2000). These similarities are not coincidental, design and management both rely on learning and feedback from the situation to arrive at better outcomes than might otherwise be realized. For the purposes of illuminating the role of design in building project management the following formulation of the cycle may be most helpful:

Awareness – Design – Performance – Reflection

2.2.1 Awareness

The cycle begins with establishing awareness of the current situation. This awareness encompasses not only the formal project as captured in so called "project information", but also, and importantly, the social situation (situational awareness), including the status and state of the various actors and stakeholders in the project. Awareness of what is going on, who is doing what, etc. Also of intentions, goals, and plans. Awareness also encompasses the determination that 'something needs to be done' i.e. deviation from the intended course of the project in some why. Awareness has a very significant component of sense-making.

2.2.2 Design

Out of awareness flows an understanding of both the current state, a need for change and perhaps a desired outcome. Having determined that action is required, design refers to the shaping of a course of action. Design thinking here is important in its open and free approach to generating alternatives and possibilities. But Design should include both generate and test. A designed course of action is also one that has been in some sense tested.

2.2.3 Performance

The designed course of action must be performed by the project manager. The choice of the word performance refers to the performative aspect of management. It is not just a matter of carrying out the design. A performance is required in that project management requires that one changes people's minds and actions. This requires that one reach them in the same way an actor does. Here we define performance as acting/ putting on a mask to change behaviour.

2.2.4 Reflection

Finally, there is a reflection upon the outcome, attempting to draw any lessons about the designed course of action or its performance that may be useful in the future. We use Reflection in two different senses. In the first sense reflection refers to reflecting in a separate moment after the performance is completed, reflection-after-action. This type of reflection is used by e.g. Deming's (quality) management cycle and Kolb's Experiential Learning cycle (Kolb, 2000). The second sense in which we use reflection is reflection while performing, referring to reflection-in-action, introduced by Schön and defined as thinking about doing something while doing it (Schön, 1983). It is precisely these two approaches of reflection-after-action like Deming and Kolb and reflection-in-action as described by Schön that seem to come forward in the next case.

3. Case: the Vondelpark Pavilion in Amsterdam

3.1 Introducing the case and methodology

The Vondelpark Pavilion is at a magnificent location in the Vondelpark in Amsterdam. Previously, the Pavilion housed a Film Museum, and a café (always packed in the summer), giving the location the reputation of 'a cultural media house', a platform where the creators of art and culture programmes could find a varied audience. The departure of the Film Museum meant that new tenants had to be found – and a second media organization agreed to lease the building. A new restaurant tenant was also found at this time. Due to the change in tenancy and a substantial backlog of maintenance issues, the building had to be substantially rebuilt. The new lease agreements left a very limited time for the renovation. The project management was in the hands of the Project Management Office of the municipality of Amsterdam and consisted of a project manager, assisted by an assistant and a quantity surveyor.

To explore to what extent the Project Design Cycle described above could be recognized in the daily practice of a project manager , a pilot interview covering the Vondelpark Pavilion project was held with the project manager. The data were analysed on four topics: 1. the identification of the elements of the Project Design Cycle, namely Awareness, Design, Performance and Reflection, 2. the sequencing of the elements of the cycle, 3. the difference between Reflection-after-action and Reflection-in-action and 4. the identification of large and small scale cycles during the project. The interviewee was already aware of our work, and for this reason a document was provided ahead of the interview clarifying our then current understanding of the project design cycle. The interview was conducted in Dutch, and translated by the authors.

3.2 Data and Findings

When asked if he could recognize the elements of the PDS in his work for the Vondelpark pavilion, he replied: 'the funny thing about the [PDS] model is that in the last few years with the complex projects I have managed, you start with setting up the project on a rather systemic way – I mean: the money should be okay, planning, organization etc. etc. – then you go along, and things prove to be quite different than you expected. This is not about, for example, whether the schedule is right, but it is about the peoples' perception, what their roles are, and whether they feel good about the objectives; because if [they do] not, they will object or start acting in complicated ways. In the latter case people just don't go along with you, do not act as agreed upon and then you must analyse, you must repair, you must change.'

In the Vondelpark project, at a certain moment different actors had different perceptions of the importance of keeping to the schedule. The schedule was accepted as such, but without sufficient commitment. It was only during the course of the project that the project manager became aware of this problem. Once he became aware of this issue, the project manager attempted several different approaches to getting the team to accept and implement the schedule. Including a 'hard line' strategy developed in consultation with the project manager's employer. All without success. Finally, the project manager determined to approach the issue by trying to understand what the schedule meant to the other actors, he spent two months in conversations between the various actors: *"my question remained; how do I get my team really involved in the plan? For a few months, at the start of a construction meeting, I began to ask every time: how are you? We were able to talk about our concerns, the opportunities we saw and the threats, about how the project was accepted in their organization. Further, a study of sense making[1] in the project seemed to start to bear fruit. People came as reborn out of the conversations that were held in the context of that research. In these conversations they had it made clear for themselves and others what this project was about. Hence they behaved differently during the regular project meetings and the schedule was actually no longer an issue."*

Reflective discussions by the group members during the regular meetings were uncomfortable, but there definitely was reflection during the 'sense making' conversations.

The episode outlined above displays the elements of the Project Design Cycle, but not in a clear sequence. There were Conscious moments of trying to make sense of the situation and then designing a course of action to remedy it. Also smaller cycles imbedded in a large cycle. Trial and error, but with intention. We see the project manager actively expanding his awareness, designing a strategy, trying, and then starting again. There was a 'large' Project Design Cycle from the fuzzy beginning, to the eventual implementation and confirmation of the overall schedule. But there were also 'small' daily

[1] This was a research project conducted by the second author, Louis Lousberg (Lousberg & Pikker, 2015)

cycles in, for example, meetings, in which following daily ‘surprises’ actions are planned, undertaken and given feedback to support the 'large' cycle.

The project manager had the awareness in advance that things could go wrong due to lack of clarity regarding the contract and designed an arrangement on this issue. In the everyday project management however, it seemed different: “*during the construction process, you're more reactive as manager, sometimes the phone rings and you have to solve a problem. However, you notice that there is not only a construction problem, but also from the angry call from the contractor that the structural engineer is not cooperating. And then when I check with the structural engineer it appears that he does not do so because he did not receive an order to do additional work. But, that's pretty standard, I have subsequently called the managing director of the structural engineer to have a coffee and asked him: why do you react so unprofessionally?*”

In this episode, the project manager saw *“no design here: it is a matter of just keep asking questions. Especially during the construction phase you can be direct, because there are simply agreements and everyone should keep them, so you can just say to someone: you’re not doing your job, why is that? It does not really require social skills, it's just being direct and directive. But sometimes you also have to be diplomatic, as in: how do we fix this?”* There appears to be a conscious dealing with problems on the one hand, but otherwise a fairly routine resolution is shown in which, at least not consciously, is designed and performed. It is, one might say, classical project management. Though there seems to be consciously reflecting-in-action.

This was completely different regarding a large ‘surprise’ in the project. *“The surprise with the hotel and catering industry entrepreneur was an exciting one. We had designed a kitchen with a catering consultant and tendered a hotel and catering entrepreneur as a tenant of the restaurant. After which this entrepreneur said: I can’t work in that kitchen. His design for the kitchen which cost not only a 100.000 euro’s more but also had all sorts of consequences for the rest of the construction work. I initially approached this in a hard way: ‘you pay it all by yourself, because you had to say this in the tender procedure’ but finally we settled it on each a half of that amount.”*

In this episode the project manager described his role as: “*first analysing what happens when we would accept this, what impact will this have not only on the building, but also on the costs on the basis of current contracts with e.g. the architect or the consequence for the penalty clause with the contractor at time overrun, in that sense it was complex. I eventually had to talk to the clients. Client B agreed because of the entrepreneurship and employment of this hotel and catering entrepreneur. But before that he summoned them to appear and informed them that this was the last time, otherwise he could leave. Client B picked this up beautifully: the entrepreneur sat shivering on his chair, because first the client made clear that this was the very last time and only finally he presented the deal.”* That was a moment of performance as we have defined in this paper.

Finally, we asked for moments of reflection e.g. at the end of the day. The project manager: *“I have a lot of those moments, especially when things have clashed. Then I ask myself: was this smart or tactical enough by me? I also discuss this often with my colleagues, of which the most important result is that you become aware of things and try out your thoughts. By talking about it, it becomes a kind of reality.”* With the observation that this turns out to be about Reflection-after-action the interview is closed.

4. Interviews with project managers

4.1 Introducing the interviews

After reviewing the pilot interview/case, semi-structured interviews were carried out with four project managers. For these interviews we did not explain the Project Management Design Cycle in advance. Nor were these interviews restricted to a single project. At the beginning of an interview we explained that the research was concerned with establishing what project managers actually do, that we had created a model on the basis of what is known in the literature and that we are now investigating whether the model is adequate. Also, we distinguish between strategic and daily management and that the model might be applicable to both. Interviewees were asked to tell us what they did. Questions followed where necessary to encourage the interviewee to address aspects of the PDS, but without using any of the terminology of the model. Extensive notes were taken from the recordings of the interviews, and the analysis based on these notes.

4.2 The four elements of the cycle

Our opening question at all four project managers was: "what do you do as a project manager?". One of them replied, *"I start with identifying … the program of requirements [including] the environmental factors i.e. stake-holders who can influence the project, feasibility studies, risk analysis, … and then I walk through all management elements. … [then] I start with a Plan of action."* Another project manager described his role as *"determining frames … My role in this is: making it a project. … I look at it from the point of view of project hygiene. My role is very much to agree, capture and make people stuck to their role. … I'm not going to start with a project if I don't have written my own project plan. You need to formulate your own assignment as it were. This includes explicit creation of what I do not. … First you focus the project on what do you want to achieve, then you need to set it up and then you go do."* Just like the project manager of the Vondelpark case, both project managers start with gaining awareness of the project and environment, and then create a Plan of action or determine and establish the frameworks within which the project can be carried out; the first steps in a large project design cycle.

Further, one of the project managers describes how she treats a 'surprise' in the daily work: *"I try to advise the client as well as possible, because in the end it is not my risk, but that of the client. I draw up scenarios, and the client then asks me ' what do you think? '. First, there is a problem signalled, that problem is extensively unravelled on what risks we actually have and there are possible measures (Design), where each choice has all kinds of consequences, up to and including the procurement strategy. So you will have to think about very well."* And another says about 'surprises': *"I manage decision making, by my client, but also by myself. However, if something happens, I always ask myself: 'is this bad, is it an issue? ', because what everyone does when something is an issue – especially in a meeting with techies – is to solve, without thinking at all whether it is necessary. I sharpen the problem in terms of consequences, I see that as my role compared to other team members."* To which another project manager adds: *"Actions such as letting clients choose where the paintings may hang – together with the architect – are deliberately designed [to create support for the project]."*

When asked to elaborate on acting out his role as project manager, one interviewee responded: *"I have been trained to think of yourself as a tool. That is, to be aware of what you can do and what you can't,* *also of how you look, what you're wearing, for example, a suit and sometimes a tie. The rule is that you never are underdressed. "* Another: *"Yes. I act absolutely. For instance, in a meeting where I enter and think about the place where I sit down, and meetings where I say nothing or only two things. What I'm going to do, mainly depends on the others."* And another: *"Sometimes you need some sort of decisiveness. This has to be called a form of bluff sometimes, because you still do not know exactly what's going on."*

Regarding Reflection one interviewee said: *"I think about work when I'm in bed at night. It's about responsibility. Whether did you do things well as a team, or did you have enough control …, did we do things well – you always doubt of course – did we make the right choice, could we have done it not better in another way?"* All four project managers said they think it's important to reflect with colleagues: *"Often this is in conversations with colleagues who were there. We discuss how it went, what the next steps are that we need to take, what those are in six weeks.* … It is sharing what you are going through, that mutual collegiality, that reflection is very important to be able to grow. That you should do as much as possible." Or: *"Moments of reflection are those in which I am away with my assistant on to or off from a meeting. We also here internally with colleagues do very much to exchange knowledge, both structurally at meetings every month as it happens to come across or look for each other, with us is that essential."*

In the interviews all four elements of the Project Design Cycle can be recognized both in large design cycles and in 'surprises' in everyday work. As in the Vondelpark case that they are not always seen by the interviewees to constitute a formal or explicit cycle.

4.3 Content and Support

In addition to the recognition of the PM Design Cycle, the analysis of the data from the four interviews resulted in two additional findings.

1. There seems to be an awareness of to distinct issues: content and support. All project managers report that they have a strategy or plan of action which they enact and against which they measure progress. This was often referred to as [project management] content. In addition to this, three of the interviewees emphasized their work on generating support or enthusiasm (*draagvlakt*) for the project: "For one of our projects we let the Board take a decision on our proposals for their wing. We have lots of support, since we have put a lot of time in it in recent months. So that decision will certainly succeed", as with the user" "Our added value is the creation of support [for the project]. By making people feel that they are heard, making them feel that something is done with the comments they make, even if you do nothing with it, explain why you do nothing, give feedback and as much as possible make them understand that it is going to work." For example let the architect have a say in the selection of technical advisers to have a good click because otherwise everyone sits on his small island" or "to make sure that everyone is heard, for example, despite differences in dominance in terms of personality. And I'm steering in the sense that I always say ' what are *we* going to do now, how will *we* approach this? (-) It is really people work, I'm aware of this increasingly." The latter is typical, there seems to be a dual consciousness in the way project managers look at their work. This dual consciousness seems to consist of content and support. Based on that Plans of approach are made (content) and captured (support) and meetings are led. "A junior project manager has in a great deal of difficulty in following the rhythm of a meeting. A senior project manager actually looks at what happens in a meeting, by which I mean how people respond, whether they are involved, or what they say, or not. A junior project manager has no time to think about how he should steer a meeting. … If it's in a meeting about an ICT-issue and the ICT-man says nothing, then you should think: 'That is not ok'. The way someone says something, or doesn’t say, is almost more important than what he or she says. "

2. That dual awareness has to do with the professional growth as a project manager. In the previous paragraph, a relation was established between the project managers focus on generation of support and the development of a project manager in his or her career. All four interviewees supported this relation. For example: "there comes a time in your career that you come out of the shadow of an experienced project manager into full exposure. … It is important that you gradually develop your soft skills more and more, that you observe how people are most effective." And: "you can be promoted from assistant manager to senior manager if you can look further than just facilitating, if you have an eye for the interests at stake. If you have a kind of independence, and are aware of the risks out there . … It also has to do with your attitude, you shouldn’t be an uncertain little mouse.” And again: "Self-reflection and feedback (Reflection) of your surroundings is an important part in order to grow. If you always make others responsible, you can’t grow. … You have to dare to experiment with management styles to see what work, therefor you need self-reflection.” Beside that dual awareness has to do with professional growth, the last quoted project manager seems to indicate that even in that there is a cycle.

4.4 Education

The interviewees were explicitly asked which characteristics or capabilities distinguished a senior project manager (capable of leading projects independently) form a junior project manager (capable only to assist a senior project manager). In addition to the dual awareness described in the previous section, they consistently identified two things that were key in this distinction 1) the ability to conceive of and enact courses of action independently, 2) the ability to lead or carry a team – to perform with authority. Thus, while the knowledge of project management systems is an important pre-requisite to working as a project manager, it seems to be that it is precisely those capabilities highlighted it in the Project Design Cycle which are key to career development and success as a fully fledged project manager. Indeed, many of the interviewees indicated that as a senior project manager they no longer concerned themselves with monitoring daily progress or operating project management systems.

This points to the importance of preparing young project managers not only for their immediate employment as junior project managers, but also to be able to successfully grow into more senior roles. To do this, we believe that project management education should address issues of design, performance and reflection as integral to project management. We do not necessarily think that project managers trained through the use of the PDS will always follow these steps in practice, rather that by incorporating the PDS into their practice, they will approach the issues of awareness, design, performance, and reflection in a more considered and professional manner.

5. Discussion

The results reported here are only exploratory, and both additional data and analysis will be required to put the findings on a surer footing. What we have tried to do, is determine if the elements of the project design cycle could be identified in the daily practice of project managers, and if these elements occurred in the expected cyclical pattern. This has been done by investigating a pilot case and four comparable interviews with project managers.

The interviews have yielded evidence of all four elements of the Project Design Cycle. However, the complete cycle itself was not observed. Rather groups of elements were reported together, and in the order described in the model, but not the whole cycle. These fragmentary cycles occurred at both large scales and smaller day-to-day scales. There is too little data to show more than the possibility of recognizing these elements and the possibility of consistent relationships between them. Further research will be needed to both firmly establish the ubiquity of the Project Design Cycle elements, their cyclic relationship, and the degree to which project managers use these elements as an explicit method. However, we might speculate that the Project Design Cycle will not be observable ‘in the wild’ as an explicit method. Rather we believe that further research will show that the Project Design Cycle is a formalization of habits of thought and action common among experienced project managers.

Both the literature upon which the Project Design Cycle was based, and the interview results here have suggested that the Project Design Cycle and the behaviour it attempts to capture and (eventually) reinforce are strongly related to a number of important areas of management research – sense-making, methodological pluralism, design thinking and leadership. Further research will be needed, both in the literature and in the field, to explore how each of these processes manifest themselves in the behaviour of project managers and in the Project Design Cycle.

6. Conclusions

In this paper a first exploratory research is conducted into the recognition of the Project Design Cycle in managing building projects. Drawing from literature, the proposed Project Design Cycle consists of Awareness, Design, Performance and Reflection. Subsequently, in an interview with the manager of a complex project followed by comparable interviews with four different project managers we looked for moments in the management of the project to which one or more elements of the cycle may be attributed. The research reveals that: 1) the elements sometimes are and sometimes are not recognized. 2) The sequencing of the elements is barely recognizable. 3) In some moments there is reflection-in-action and sometimes reflection-after-action. 4) In everyday work sometimes management can be described as elements of a 'small' Project Design Cycle and sometimes as elements of a 'large' Project Design Cycle. 5) There seems to be a dual awareness: content and support and 6 That dual awareness has to do with the professional growth as a project manager. Follow-up research will reveal to what extent this can be confirmed and deepened.

Stakeholder Management Practices to Boost Outcomes of Construction Projects

Florence Yean Yng Ling,
Department of Building, National University of Singapore
(email: bdglyy@nus.edu.sg)
Istilah Yanti,
Turner & Townsend Singapore
(email: Istilah.abali@turtown.com)

Abstract

The role of project managers (PMs) in stakeholder management to boost project outcomes is investigated, by examining the practices that PMs adopt which lead to effective stakeholder management and studying the extent to which effective stakeholder management contributes to better project outcomes. Based on the literature review, a questionnaire containing 39 practices were identified and grouped into 8 categories. Using a survey questionnaire, data were collected from PMs in Singapore's construction industry. Adopting 11 stakeholder management practices could significantly improve the level of effectiveness in managing clients, consultants and/or main contractors, especially those that take into account stakeholders' power. It is also found that managing project stakeholders effectively can improve time performance, quality performance and owner satisfaction. It is recommended that PMs need to set and communicate common goals and objectives, understand stakeholders' interests and consider their power and influence on the project. To manage clients better, PMs need to prioritize stakeholders and develop a stakeholder interest list. The study found that clients prefer to be the sole winner in project disputes, but PMs need to strive for a multi-win solution. PMs need to cultivate skills and methods in managing stakeholders so that conflicts can be resolved in a collaborative and constructive fashion.

Keywords: Project management, stakeholder management, project outcome, construction projects, Singapore

1. Introduction

In a construction project, the stakeholders include the owners and users of facilities, project managers (PMs), facilities managers, designers, shareholders, legal authorities, employees, subcontractors, suppliers, process and service providers, competitors, banks, insurance companies, media, community representatives, neighbours, general public, government establishments, visitors, customers, regional development agencies, the natural environment, the press, pressure groups and civic institutions (Smith and Love, 2004). Leung and Olomolaiye (2010) stated that internal stakeholders, mainly the client, consultants and contractors, are key decision makers who are linked via legal contracts. As stakeholders can influence a project either positively or negatively, their rights, needs and expectations must not be taken lightly (Carroll and Buchholtz, 2006). If stakeholder management is not in place, it may bring about uncertainty and unexpected problems, where stakeholders' disparate actions can harm the project outcome (Aladpoosh et al., 2012).

The aim of the research is to investigate the role of PMs in stakeholder management to boost construction project outcomes. The specific objectives are to: (i) investigate the extent to which PMs practise stakeholder management; (ii) study the extent to which PMs' effectiveness in stakeholder management contributes to better project outcomes; and (iii) examine the practices that PMs adopt which lead to effective stakeholder management.

The scope of research is limited to PMs who work for clients (either as employees or project management consultants) who have managed construction projects in Singapore. These PMs may be working for project clients, architectural, engineering or project management consultancy firms.

2. Brief literature review

Taking into consideration that internal stakeholders are the key decision makers, this research focuses on internal stakeholders that PMs need to manage, namely clients, consultants and main contractors. PMs' effectiveness in managing stakeholders in a construction project is operationalized into effectiveness level in managing clients (Y1); consultants (Y2); and main contractors (Y3). The aim of stakeholder management is to achieve a successful project outcome (McElroy and Mills, 2003). The following variables relating to project outcomes are operationalized following Ling et al. (2009): cost performance (Z1); time performance (Z2); quality performance (Z3); and owner satisfaction (Z4).

Based on the literature review, the possible actions of PMs (X variables, numbered as X1 to X39), and how projects are managed to achieve effective stakeholder management (Y1 to Y3) are identified. It also uses the instrumental approach to identify the connections that exist between the management of stakeholder groups (Y1 to Y3) and the achievement of project goals (Z1 to Z4). The relevant actions that PMs can take in stakeholder management include: defining project missions, goals and milestones (Jergeas et al., 2000); understanding stakeholders' characteristics and exploring their circumstances (Chinyio and Olomolaiye, 2010); assessing stakeholders' behaviour (Freeman et al., 2007); understanding stakeholders' power (Bourne and Walker, 2005); engaging stakeholders (Leung and Olomolaiye, 2010); managing conflicts (Ogunbayo, 2013); and managing corporate social responsibility (Yang et al., 2009).

The literature review has revealed many practices in stakeholder management. The gaps in knowledge are that it is hitherto not known if: PMs are managing stakeholders effectively; adopting certain practices would lead to more effective stakeholder management; and better stakeholder management leads to project success in terms of time, cost, quality and owner satisfaction.

3. Research method

The research design was based on a questionnaire survey. A structured questionnaire was designed as the primary data collection instrument. The questionnaire was divided into three sections. Section A comprised questions to find out the characteristics of the construction project and project outcomes. Cost performance (Z1) was rated on a 5-point scale, anchored as: 1 = overrun budget by > 5%; 3 = cost same as budget; 5 = below budget by > 5%. Time performance (Z2) was also rated on a 5-point scale, anchored as: 1 = late finish by > 5%; 3 = finish on time; and 5 = early finish by > 5%. Product/output quality (Z3) was measured on a 5-point scale, where 1 = expectations not met; 3 = expectations met; and 5 = exceed expectations. Owner satisfaction (Z4) was measured on the 5-point scale where 1 = very low; 3 = neutral and 5 = very high. Respondents were also required to evaluate their level of effectiveness in managing three main stakeholders (clients (Y1), consultants (Y2) and main contractors (Y3)) on a 5-point scale similar to Z4. Section B requested respondents to rate extent to which stakeholder management practices were implemented for the project identified in Section A. These were derived from the literature review on stakeholder management practices, and rated on a 5-point scale, where 1 = not adopted, 3 = adopted about half the time, and 5 = adopted almost all the time. Section C sought information on respondents and their firms.

The population comprised PMs working for clients, or as consultant PMs in project management, architectural or engineering consultancy firms. In Singapore, there is no national registry of PMs, so the size of the population is not known. Random sampling was used to identify PMs from architectural, engineering and project management consultancy firms registered with the Building and Construction Authority's Public Sector Panels of Consultants. A search was also done on GOV.sg and Asiabuilders.com to identify PMs in the government sector and developer firms respectively. To increase the sample size, convenience and snowball sampling methods were also employed. E-mails were sent to firms and individual PMs, with follow-up calls made to these companies requesting for relevant PMs to participate in the survey.

4. Results

A total of 352 surveys were sent out and 43 responses were received. 35 questionnaires were completed comprehensively and used for data analysis. The majority of the respondents are PMs and senior PMs from middle management. They have worked in the construction industry for between 1.5 and 28 years, with an average of 15 years. The majority have more than 15 years of practice. The PMs work in client (public and private) organizations and consultancy firms, with the majority working in the private sector. The PM-respondents reported mainly building projects. The projects range from 415 m^2 to 250,000 m^2, with the average at 44,377 m^2. The majority of the projects cost above S$50 million (S$1 ≈ US$0.72), with a mean of S$106.5 million. Most of the projects took more than two years to be completed. Table 1 shows the projects had significantly poor cost and time performance indicating budget and schedule overruns. The projects had significantly good quality performance (Z3) and owner satisfaction (Z4) In addition, the PMs reported that they were significantly effective in managing clients (Y1), consultants (Y2) and main contractors (Y3).

*Notes: ** $p<0.01$; *$p<0.05$. r_s is Correlation coefficient, and sig is 2-tail. Sig for t-test is 1-tail.*

Objective 1 was to investigate the extent to which PMs practised stakeholder management in construction projects. Statistical t-test of the mean was carried out to check whether the population would adopt the practices to a significant extent or otherwise. The t-test results in Table 2 show that among the 39 practices, 34 have been adopted by PMs to a significant extent (mean > 3; t-value positive; and $p< 0.05$), indicating that PMs do actively adopt stakeholder management.

Objective 2 was to study the extent to which PMs' effectiveness in stakeholder management (Y) contributes to better project outcomes (Z). Table 1 shows that time performance (Z2) is significantly correlated with the effectiveness level in managing clients (Y1). When clients are managed more effectively, the project is less likely to have schedule overrun. Table 1 also shows that the effectiveness levels of managing clients (Y1) and consultants (Y2) have significant positive correlations with the output quality of the project (Z3) and owner satisfaction (Z4). This suggests that when PMs manage clients and consultants more effectively, project quality and owner satisfaction may be higher. There are significant positive correlations between owner satisfaction (Z4) and the level of effectiveness in managing project client (Y1), project consultants (Y2) and project main contractor (Y3) (see Table 1). This suggests that by managing all stakeholders more effectively, owners will be more satisfied.

5. Discussion

Objective 3 was to examine the practices that lead to effective stakeholder management. The results in Table 2 show that there would be significantly more effective management of clients (Y1), consultants (Y2) and main contractors (Y3) when some of the practices are adopted to a higher extent respectively.

Results from Table 4 show that PMs setting common goals, objectives and priorities (X1) is significantly correlated with higher effectiveness in managing consultants (Y2) and main contractors (Y3). Clear indications and directions are necessary to ensure that consultants and main contractors fully understand project requirements, which will safeguard the quality and performance of project deliverables, and improve confidence among project stakeholders (Karlsen et al., 2008).

Table 4 shows a significant positive correlation between PMs gathering information about stakeholders (X5) and the level of effectiveness in managing main contractors (Y3). The result is consistent with Caroll and Buchholtz's (2006) finding on the importance of gathering information on stakeholders' background and role in the project. PMs should embark on aggressive information-gathering of stakeholders, such as their stake, power and influence on the project, as well as any opportunities, challenges and threats that the stakeholders face.

The t-test result in Table 4 shows that PMs do not conduct prioritization of stakeholders (X7) to a significant extent (mean = 2.257, t = -3.599 and p = 0.000), yet this activity is significantly correlated with effectiveness in managing clients (Y1). PMs may not have done this because they took for granted that the client should be given the highest priority, rather than other stakeholders. Taking the t-test and correlation results together, it is recommended that PMs conduct more systematic prioritization of stakeholders. This is important because it allows PMs to deal with the different stakeholders appropriately according to their power and interest in the project. By knowing which stakeholder takes priority, PMs will be able to closely manage those who possess high power and high interest (Kolk and Pinkse, 2006).

Developing a stakeholder interest list and going through it with team members (X8) is not adopted by PMs to a significant extent, yet it is significantly correlated with Y1 and Y3 (see Table 4). PMs may not have consistently carried out X8 because they assumed that stakeholders' interests are similar to project goals. Developing the stakeholder interest list at the early stage of the project will allow the potential impact of stakeholders' vested interests on the project to be identified (Arian and Low, 2005). It is recommended that PMs develop a stakeholder interest list so that they know which stakeholder to pay attention to.

Taking stakeholder interests into account in decision making and operations (X10) was significantly adopted, and X10 also has a significant positive correlation with the level of effectiveness in managing consultants (Y2) and main contractors (Y3). Without considering stakeholders' interests, PMs may make decisions purely based on achieving project objectives (timely completion, within budget and acceptable quality). However, this may frustrate stakeholders who may not cooperate because their interests are not safeguarded.

Exploring probable strategies that stakeholders could employ to realize their objectives (X14) is significantly adopted by PMs, and also have significant positive correlation with the level of effectiveness in managing consultants (Y2) and main contractors (Y3) (see Table 4). As stakeholders may adopt strategies that can help or obstruct an on-going project, it is important for PMs to predict stakeholders' actions as these may have both direct and indirect effect to aid or obstruct the development of a project (Orndoff, 2005).

The result shows that PMs do rate the impact of project strategies on each stakeholder (X16) and this has a significant positive correlation with the level of effectiveness in managing main contractors (Y3). This supports Chinyio and Olomolaiye's (2010) finding that in developing strategies to manage construction projects, PMs have to make assumptions regarding the stakeholders and how project strategies implemented by PMs can impact the level of interest, influence and support of these stakeholders. Stakeholders with higher impact ratings should be handled more carefully.

Understanding the urgency faced by stakeholders (X18) is positively correlated with the level of effectiveness in managing consultants (Y2). Urgency influences the manner and extent to which power is exercised in stakeholder management (Chinyio and Olmolaiye, 2010). When stakeholder claims are given immediate attention it shows that PMs are conscious of a project's time sensitivity in relation to stakeholders (Mitchell et al., 1997).

The practice of implementing strategies which depends on the demands of stakeholders (X35) is positively correlated with managing consultants (Y2) (Table 4). Certain stakeholders may assert their demands and claims, which may not be in the best interest of the project or in line with the client's vision. PMs must be able to handle these stakeholders within project constraints, and devise and implement appropriate strategies to engage and manage them (Leung and Olomolaiye, 2010).

The practice of taking into account stakeholder influence on the project before resolving conflicts (X26) is significantly correlated with the level of effectiveness in managing consultants (Y2) (Table 4). If PMs do not take into account varied stakeholder influence, they may not accord the correct response, and be unable to mitigate any negative stakeholder influence on the project (Aladpoosh et al., 2012).

Table 4 shows that identifying suitable conflict resolution strategies (X27) and implementing a multi-win solution (X28) are negatively correlated with the effectiveness of managing clients (Y1). The results indicate that if PMs identify suitable conflict resolution strategies and/or implement multi-win compromise solutions, clients are not managed effectively. This may be because finding the right conflict resolution strategy requires time, which is a luxury that most projects can ill afford. A multi-win solution can pose a challenge to the project team (Yang et al., 2009), and cause clients to incur additional costs or suffer project delays. Notwithstanding the results, it is recommended that PMs adopt appropriate conflict resolution strategies and resolve conflicts in a collaborative and constructive manner (Moura and Teixeira, 2010) so that the conflict does not escalate to a greater dispute and lawsuit (Ogunbayo, 2013).

Managing projects with a sense of duty and in accordance with the law (X38) is positively correlated with the level of effectiveness in managing consultants (Y2). The results echo Turner and Muller's (2005) emphasis that PMs actions and decisions should be based on rightfulness and integrity. To manage the legal aspect of construction projects effectively, PMs should be familiar with the relevant and most current legislations, and the contractual agreements made between stakeholders.

6. Conclusions

The findings show that when PMs manage clients more effectively, projects will have significantly better time and quality performance and owner satisfaction. Managing consultants and contractors more effectively leads to better owner satisfaction. This study contributes to knowledge by showing specific practices that PMs adopt which are significantly correlated with effective management of stakeholders (see Table 2). Among the many practices, those relating to assessing and taking into account stakeholders' power have the most instances of significant correlation with effective stakeholder management. It was found that consultants and contractors would be managed more effectively when PMs adopt these practices to a greater extent: set common goals, objectives and priorities; take stakeholders' interest into account in decision making; and explore probable strategies that stakeholders could employ to realize their objectives.

The implications of the findings are that PMs need to set clear goals, objectives and priorities so that all stakeholders have the same understanding throughout the whole life cycle of the construction project. As the interests of all stakeholders are of intrinsic value, it is important that the PM is able to reconcile the divergent interests of all stakeholders for the benefit of the project. To do this, PMs should endeavour to understand the different interests of stakeholders and what project success means to each stakeholder. Going through the stakeholder interest list with the project team allows all interests to be explored and understood, and should be done at the start of a project. Additionally, these interests should be well considered in decision making and operations throughout the life cycle of the construction project.

Another novel finding is that clients are perceived to be not well managed when PMs identified suitable conflict resolution strategies and implemented multi-win solutions. The finding suggests that clients prefer to be the sole winner in project disputes, thus putting PMs in a difficult position of having to manage other stakeholders and ensuring projects are completed successfully. Striving for a multi-win solution is challenging and PMs need to cultivate skills and methods in managing stakeholders so that conflicts can be resolved in a collaborative and constructive fashion. This is vital to ensure that any conflicts in the construction project will not be escalated.

Abstract

This contribution wants to examine the relationship between the role of the designer and the role of the safety coordinator in design and construction phase.

EU technical analysis say that the designer plays a key role in the design preparation stage, and is so important in preventing occupational risks on construction sites. In nationals codes the relationship between design and safety it is not so strong.

The chronological path of EU directives dealing with Health and Safety at work in temporary and mobile sites it is analysed, starting from 92/57/EEC till arriving to the later EEC communications on the subject. Contemporary, the national Italian legislation is analysed, from Decree 494/96 till Decree 81/08, with the specific aim to search the connection between the role of designer with respect to the safety in project development. This way it is possible to reconstruct the actual link among architectural design and safety design.

It is thus possible to individuate the weak points in this relationship that lead to a difficult safety management in construction phase; main finding is that the connection between design and safety has been transposed into national standards in very different ways and only through a cultural awareness of the designers on the issues of health and safety objectives of Directive 92/57/EEC will be reached.

Keywords: Safety, design, legislation

1. Introduction

Health and safety issue in construction industry has a great importance. The importance of the theme is ratified by the specific European health and safety on construction sites directives that dictate the guidelines for the state members regulations. All European states are then provided with health and safety legislation concerning construction sites that is related with the common European principles.

Therefore if we analyse the data of accidents in construction industry in the various Member States on the basis of annual Eurostat report, it is possible to note a particularly variable trend within the Member States. The data shared by all European countries is a general decline in accidents: between 2008 and 2012 (latest available consolidated data) accidents in the workplace, in construction industry, had a decrease of 46%. But the fact remains that the number of accidents in construction is considerably higher than that recorded in other economic activities

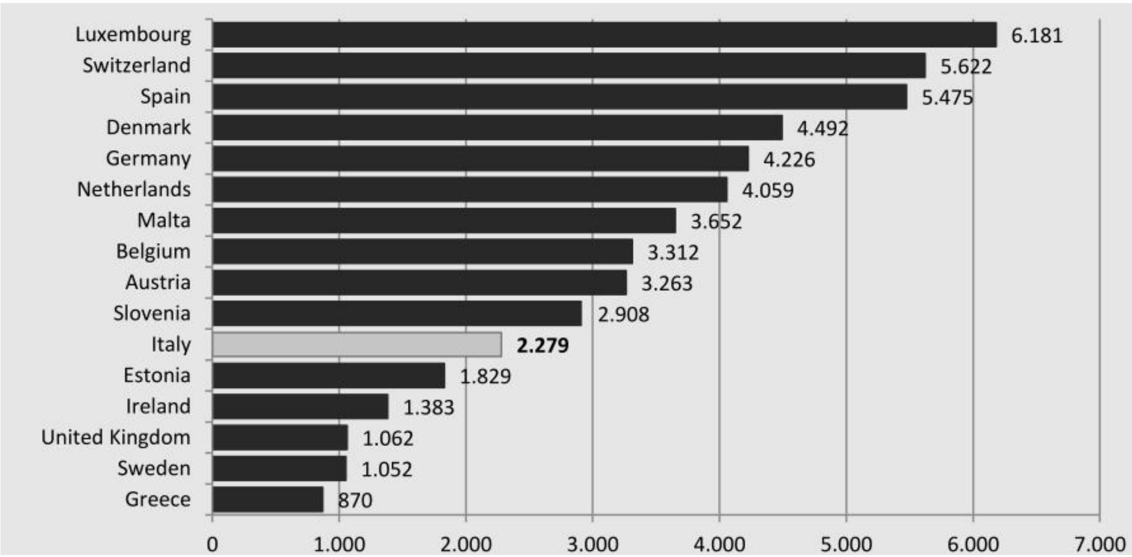

Figure 1: Accidents per 100.000 workers in construction in 2012 (Cresme Ricerche spa, 2014)

The international comparison shows that Italy, in 2012, was well below Germany (4,226) and Spain (5,475). However, considering the most serious accidents, i.e. fatal accidents, Italian ranking radically changes. This may partly be due to the vast spread of the informal economy and the specific entrepreneurial fabric (mainly made up of small and micro enterprises) can lead to under-reporting of less serious accidents.

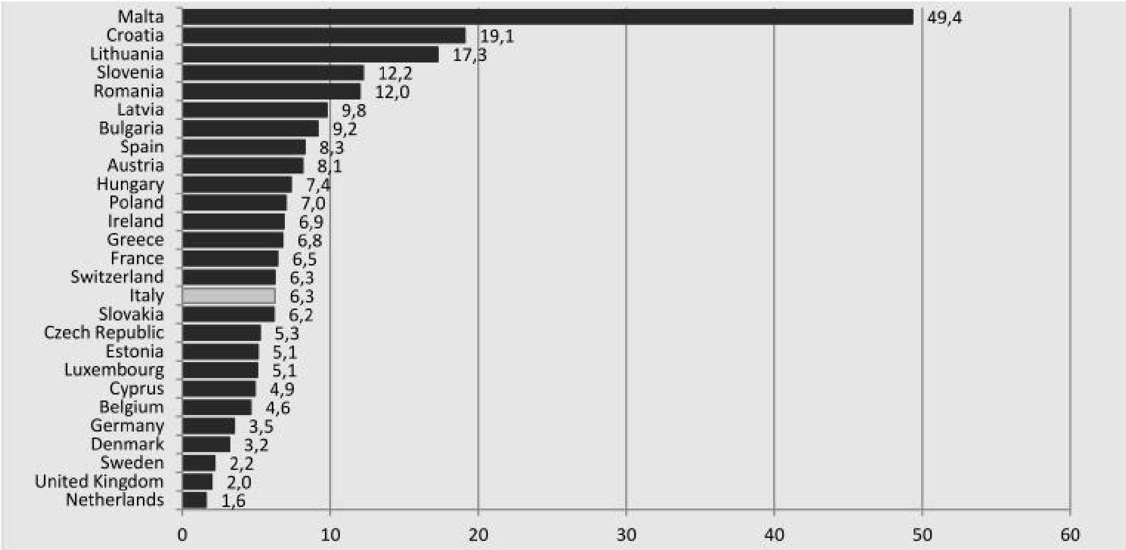

Figure 2: Deadly accidents per 100.000 workers in construction in 2012 (Cresme Ricerche spa, 2014)

The clear disparity in accidents that emerges from the European data, lead us to investigate the path that European directives have made at the moment of their implementation through national legislation. According to Capone et al. (2015), it is interesting to investigate how the European inspiring principles can be found in the texts of Member States laws.

In particular, the question we focus in this paper is on the relationship between the responsibility of the designers of the building and the project and health and safety management. This point of view comes from the importance that the European directives give to the design with respect to health and safety management in construction. EU directives clearly state the importance of the "safety awareness" during various stages of design and, for this reason, remark the Health ad Safety Coordinator involvement in the design phase. Despite of it, in some European countries (i.e. Italy) the involvement of Safety Coordinator in design process is weak, even if national laws theoretically agree with EU directives. For this reason we examine how much national laws are in complete concordance with EU principles basing our analysis on the duties of Designer and Health and Safety Coordinator in Design phase. With the comparison we try to understand possible reasons for such differences in national legislations.

2. EU directive 92/57/CEE and UE Communication 06/11/08

2.1 EU directive 92/57/CEE

Directive 92/57/EEC concerning the minimum safety and health requirements at temporary or mobile constructions sites, since the initial considerations expresses the centrality of architectural choices in determining the safety during construction:

“[…] Whereas unsatisfactory architectural and/or organizational options or poor planning of the works at the project preparation stage have played a role in more than half of the occupational accidents occurring on construction sites in the Community […] “

Right from the initial considerations, the Directive stipulates a direct relationship between the architectural choices and the occurrence of accidents in construction site. Stating that “*it is therefore necessary to improve coordination between the various parties concerned at the project preparation stage and also when the work is being carried out”*, it focuses on the design phase of the work.

Directive brings together again the connections between design and safety:
“Article 4 - Project preparation stage: general principles
The project supervisor, or where appropriate the client, shall take account of the general principles of prevention concerning safety and health […] during the various stages of designing and preparing the project, in particular:
— when architectural, technical and/or organizational aspects are being decided […]”.

The article 4 involves the client, empowering him, and asserts that he also must consider the principles of health and safety at the time of the architectural, technical and organizational choices. Complementing this, the article 5 stipulates the presence of specialized technicians in construction site safety (Health and Safety Coordinators), working since from the design stage.

All the European safety codes are therefore based on the above assumptions. It is interesting to investigate regulatory developments subsequent to 1992 to understand how the relationship between design and safety is inside in the current national standards.

2.2 EU Communication on the practical implementation of Health and Safety at Work Directives 92/57/EEC – 06/11/08

Communication is a European report about the practical implementation of Directive 92/57/EEC in the Member States; it is dated 06/11/08 and represents the state of the art 16 years after the enactment of the directive. Communication follows a Commission undertaking to assess the implementation of the regulatory framework with a view to improve it. It is based mainly on the national reports supplied by the Member States and an independent experts' report analysing implementation of the Directive 92/57/EEC.

The practical implementation of Directive 92/57/EEC

The implementation of the Directive is a complex issue in terms of technical and administrative staff. Member States regularly revise and update their legislation. This explains why in some States the directive has been transposed in a very fragmented of legislation that make it more difficult to assess. It is then revealed differences in national legislation deriving from the previous regulatory framework and from the fact that the Directive lays down minimum requirements and leaves the Member States free to maintain or establish higher levels of protection.

Since the Directive gives all those active on a construction site key roles in prevention, its implementation was therefore assessed in terms of the influence that each group has on prevention of and protection from occupational risks. While the Directive does not refer explicitly to architects, engineers or consultancy firms, this group was evaluated because the designer plays a key role in the project preparation stage, and is so important in preventing occupational risks on construction sites.

It is clear from the report that architects and engineers know the health and safety requirements but do not totally agree with the measures imposed. Some designers are not in favour of the client appointing a coordinator for the design stage as, in their view, this hampers their creative freedom.

While stressing, in some ways, a lack of safety culture in the designers, on the other side it also notes that, when architects and engineers act as coordinators at the design stage, the working conditions on construction sites considerably improve. A specific education in the field of building design is a condition of absolute advantage for the health and safety coordinators. Communication also underlines that preventive health and safety is often not integrated into the project at the design stage because safety conditions during construction and subsequent use and maintenance are not a major factor in design/architectural choices. The designers are thus not adequately involved in health and safety process from national codes.

"There is a long way to go in all the Member States before the culture of prevention effectively takes root at the design stage" (EU Communication 06/11/08).

According to the Communication, it is important in this context that the competent national authorities make an effort to train designers at schools and at university, making prevention a key part of the curriculum

Roles of Health and Safety Coordinators

The Directive does not define the competencies required to act as coordinator, so there are big differences from one Member State to another. Some states have defined the competences and/or skills of coordinators in great detail, sometimes even requiring that they have specific training or a combination of training and experience (i.e. in Italy). The competencies required of coordinators by the Member States to fulfil their duties differ greatly, and so the standard of coordination varies from one Member State to another.

EU communication states that, because project preparation does not take prevention of occupational risks into account before the design is finalised, the lack of planning for prevention has to be remedied at the execution stage. It is to hope a change of attitude in construction industry; if national legislation made it a requirement for prevention measures linked to the subject-matter of the contract to be systematically incorporated into the technical specifications for invitations to tender and in the contract performance clauses and quality contract management by the contracting authorities, this could help to change attitudes in this area.

The communication surveys that a lack of coordination in design affects the quality of the coordinator's work at the execution stage. The result is that on-site coordinators often encounter health and safety problems that are difficult to solve because they are generated from the design itself, because of its morphology and construction techniques. This underlines that safety should be considered a design property which affects itself.

3. European comparison

Here it might be helpful to tell briefly the theme of the relationship between design and safety in the European regulatory framework. The considerations, drawn from Bergagnin et al (2012 and 2013), resulted from a project of the Safety Commission of the Federation of Associations of Engineers of Emilia Romagna in 2012, then continued in 2013. Starting from the comparison between the various national laws transposing the Directive yards 92/57/EEC, aspects related to the main figures involved in the member states Germany, UK, Spain, France and Sweden (Aulin and Capone, 2010) have been analysed. Only these few European countries have been selected because in the academic detailed studies Sweden have been added to the work of Bergagnin et al (2012 and 2013).

Italy is our reference country since in the Italian construction system there is actually a weak position of the Health and Safety Coordinators with respect to the designer position in defining principal stages of the design. The study found that the role and requirements of professional technicians who deal with health and safety vary greatly in European countries. In particular, it was noted that while some EU countries have an approach to the issue very similar to the Italian one (i.e. Germany and Spain), other members (such as France and especially Britain) are significantly different, especially as concerns the design and construction management.

The research method was to deepen investigate the Italian legislation with respect to the EU directives, then, basing on literature studies (Bergagnin et al, Bragadin, Capone), other national legislations have been analysed in order to underline the research theme.

Italy

In Italy the first legislation on health and safety in construction sites declared after the EU directive 92/57/EEC was that the Decree 494/96. With subsequent amendments and additions it was in force until 2008, when it was replaced with Decree 81/08. Health and Safety Coordinator at the Design stage is central in the relationship between design and safety, bond never directly explained.

While in the European Directive are cultural recommendation related to the role and to the operative tools of the Health and Safety Coordinators in Design phase, in the national code specific legal duties and responsibility are assigned to Health and Safety Coordinator at the Design stage. This lead to a strength definition of the Health and Safety Coordinators role in the Decree 81/08 with respect to the EU Directive.

In the following there is a synthesis of the evolution of Italian laws related to the Health and Safety Coordinator at the Design stage:

- Decree 494/96: no substantial differences from the EU Directive about the Health and Safety Coordinator at the Design stage duties. It is important to underline that Health and Safety Coordinator at the Design stage intervention is postponed in the executive design phase.
- Decree 528/99, modify to the Decree 494/96: Health and Safety Coordinator at the Design stage intervene in the generic “design phase”.
- Decree 81/08: not sensible differences from the previous law, except for the coordination of architectural, technical and/or organizational aspects.

At the same time, contents of the Health and Safety Plan evolved; analysing the specific contents of these documents allows us to detect the real competences a Safety Coordinator in Design phase must have with respect to the design. According to Bragadin and Giusti (2015) Health and Safety Coordinator can be seen as a specialized Project Manager and it is important for him to have real designer skills in order to intervene in the whole project.

Article 98 of Decree 81/08 indicates the requirements to be a coordinator: university graduation is not the only requirement, also graduates (surveyor, industrial or agricultural) are in fact admitted to the profession of coordinator. We are so distant from the auspices of the 2008 EU communication in which explicitly refers, as described above, to the design skills of engineers and architects who can assume the role of Health and Safety Coordinator at the Design stage. The debate is as a technician can objectively, without specific design skills, participate in the design phase of the work in relation to the issues of health and safety.

In this context, the stronger link, extremely general and as such address the cultural, is in Article 22 of Decree 81/08, "Obligations of the designers": designers of workplaces should comply with the general principles of prevention in health and safety at the time of design choices. Read extensively, this reminder of the responsibility of the designers – both designers of the building and of the construction site as a workplace - is the strongest bond that the Italian code, only in 2008, re-established with the directive of European origin.

United Kingdom

First aspect of the peculiarity is seen in the great importance that is reserved by the UK Regulations to the concept of design in safety. British standards provide binding obligations of the designer with respect to the safety of the building. In practice, in the UK the designer is required to design the safety of the work for all the people who come in contact with it, by those who realize, the future users and to future maintainers, according to a concept of global security that extends the entire life of the work itself. UK legislation comes to accurately define some technical aspects that the designer has to consider in the design phase, such as the future maintenance of facilities and structures, or cleaning the windows or translucent walls, or how access to areas where there is the risk of falling.

The coordinator is responsible, on behalf of the client, to monitor the work of the designer, making sure that he complies with the safety provisions in order to receive full cooperation on the preparation of the Health and Safety File. The drafting of Health and Safety File, according to EU directives, is charged to the same coordinator.

Health and Safety Coordinator at the Design stage appointment comes even in the process of definition of the levels of design: once prepared the preliminary draft, is not allowed to proceed in the further steps of the design Health and Safety Coordinator at the Design stag is not appointed. Under these conditions, it is clear that the interaction between designer and coordinator proves effective and not fictitious.

Many clear differences are found between the United Kingdom legislation and other European countries including Italy, about the drafting of Health and Safety Plans. In Britain the customer directly provides information in a pre-construction stage, in order inform the designer, the principal contractor and the contracting companies, about the interesting elements regarding the future building, its construction and the construction site.

In UK Health and Safety Coordinator acts decisively and mainly managerial; he is in charge of ensuring the transfer of information between the various parties and the constant updating of proper documents relating to it. Recognizing the importance of the design in the future realization of the building, the UK code make the Health and Safety Coordinator at the Design stage to take a role of "safety consultant" designer and as such works with designer in a nearly equal ratio.

According Bragadin (2011), it can be said that countries like UK, with greater business culture and social sensitivity, while adopting apparently less strict rules have on their side a positive response statistical accident.

Germany

German legislation is very similar to the contents of Title IV of Italian Decree 81/08. On the design phase they are detected small differences from the provisions of Title IV, although it is clear more attention to the verification of the early interaction between the coordinator and designer, with a strong focus also on the contents of the technical dossier ("Document for Future Work").

France

In France there is an insurance system that is mandatory for public procurement and optional (but very useful) for private procurement; this is the so-called "ten year policy posthumously". Insurance institutions have their own technical specialists of the construction industry to grant the insurance. The insurance technics analyse the whole design and can request changes, improvements and any kind of depth, otherwise the denial of insurance coverage. The same procedure is applied to the technics (from design to construction and safety) that must all be covered by insurance. Once implemented, the insurance thus guaranteed the technical quality of the work.

Furthermore, Health and Safety Coordinator in France cannot carry out any other type of appointment within the same building process.

Spain

In Spain Health and Safety Coordinator at the Design stage is appointed only in the case where there are more designers who do not have corporate links between them, or more professionals, or more member firms, or engineering companies. In practice this implies that Health and Safety Coordinator at the Design stage is not almost appointed in the bigger works because often they are carried out by big engineering companies or professional offices.

This law determines an obvious latency in design and programming of safety, in sharp contrast with the objectives of the European Directive, which provides for a special attention to safety since the embryonic stages of the development of design. Since in many cases the Health and Safety Coordinator at the Design stage is not appointed, it is possible that health and safety of the construction is entirely in the hands of designers work.

Sweden

In Sweden Health and Safety Coordinator at the Design stage participates in the planning and lead the preparation and design of project. Health and Safety Coordinator at the Design stage coordinates the preparation and design of project with regard to health and safety to allow participants involved during this stage to take into consideration each other planning and solutions. The coordination should lead to the execution of different parts of the project together with the construction, installation and others that occurs at different time and stage of the project where the risk of ill-health and accident could arise. Health and Safety Coordinator at the Design stage draws up a Health and Safety Plan if it is required before the construction site is set-up.

In table 1 a synthetic comparison among the countries is reported; in the table can be found the Designer Role in Health and Safety in construction and the Health and safety Coordinator involvement in design stages, with respect to the EU principles.

Table 1: A synthetic comparison among the analysed national legislations.

Criterion / *Countries*	*Designer Role in Health and Safety in construction*	*Health and safety Coordinator involvement in design stages*
Italy	*weak, not specific duties or responsibility*	*quite strong but not efficient*
United Kingdom	*very strong*	*weak, only duties of control*
Germany	*weak*	*quite strong*
France	*weak, insurance system*	*weak, insurance system*
Spain	*weak*	*weak*
Sweden	*weak*	*strong*

4. Conclusions

It is clear in this discussion that, despite the common origin (Directive 92/57/EEC), the transposition of the European standard in the different countries was characterized by different hints and in some cases, UK among them, an approach substantially different.

A first objective fact that emerges from the research is the earlier and more intense involvement of the coordinator in the design stage during the project preparation; this takes place in the main European Union countries such as Germany and UK. Especially in UK, the function of Health and Safety Coordinator is purely managerial, having him responsible not only to draw up the Health and Safety Plan but also to control and monitor the activities of the designer. The designer is in fact the main subject invested from the obligation to respect the safety design choices and to provide all necessary information to the coordinator to compile the technical file (Health and Safety File).

An important consequence of the different approach to the safety of European countries, is found in the important role that Health and Safety Coordinator at the Design stage assumes: it has a guiding role to proper design of safety. The Health and Safety Coordinator at the Design stage is given this task with the knowledge that this will translate into lower cost of the work, both during its construction and during its future use.

The comparison shows another obvious fact: the diversity of skills that Health and Safety Coordinator at the Design stage must have. In the main countries is in fact required a high specialization of this figure and some of it expressly forbid to overlap the function of the coordinator with other positions within the same project or construction site. The main EU countries are in fact oriented towards the high specialization of Health and Safety Coordinator.

In conclusion we can say that, from the cross-reading of the rules of the Member States in relation to the European directive, the connection between design and safety has been transposed into national standards in very different ways. This is certainly due to the difference social reality of the construction industry, made by the technicians who work there and by the fabric of businesses, widely variable from state to state.

Starting from the same EU directives, in some countries relationship between duties of the Designers and the duties of Health and Safety Coordinator is strong, in some other is actually very weak. Sometimes the Designer is not even mentioned in the legislation.

In our view and in accordance with the European community indications, the solution to bring the design to the centre of the construction site safety system is to act on the education of the designers, rather than on that of safety specialists. Only through a cultural awareness of the designers on the issues of health and safety we will tend to the actual achievement of one of the objectives of Directive 92/57/EEC: the reduction of architectural and organizational inadequate choices as a cause of accidents on construction site.

Abstract

In this contribution, at first an approach to analyse safety in the construction process is proposed. This approach includes Building Design for Safety (BDS), a specific method to check both constructability and workers' safety of the critical phases in construction process. Safety management in design and construction phases is one of the essential components that can influence the actual achievement of the constructability goal. Compliance with costs and time, necessarily passes through the risk mitigation of the critical activities, this must be done in order to safeguard the quality of the building. Prefiguring the construction process from the design phase, allows us to manage both safety and constructability. We operate within a framework that has to be used in design phase. In the framework, making use of the construction management instruments, we can identify critical activities for the workers' safety during the future construction process. For critical activities characterized by overlapping of time and physical space of construction, the BDS tool is proposed. BDS makes a check both of constructability and safety of the critical construction activities in order to suggest technical and management solutions to mitigate risks. The tool allows the user to identify measures and procedures for risk prevention and protection, with respect to the constructability. BDS has to be performed during the design phase, in order to prefigure the construction process. This way, risk mitigation can be performed according to the constructability goal, safeguarding the building correspondence to the needs of the design. So far, the results achieved concern the BDS application in many real case studies. Future issue are related to the development of the instrument in BIM technology.

Keywords: Constructability, safety, design

1. Introduction

It is within the last fifty years that quantitative methods for project analysis and scheduling have been developed and documented, and particularly those supported with computerization.

Critical Path Method (CPM) has ever since been the dominant methodology for scheduling construction. (Baldwin, 2014)

In this paper a new approach based on the analysis of construction scheduling supported by a construction simulation is proposed and used in order to increase safety constructability in the phase of activities planning.

Such an approach provides a new tool for extending basic activity-based CPM logic adding workers' dimension and optimizing basic scheduling in function of workers' safety. Traditional CPM uses a single layer of logic which operates only between any two activities. Production occurring inside an activity is described only by duration, and there is no recognition of the worker's position in terms of working areas.

Until now the approach of Location-based management assumes that there is value in breaking a project down into smaller locations and using these to plan, analyze and control work as it flows through these locations.

The location-based planning system takes into account activities and tasks, where a task is made up of a sequence of activities in differing locations. Then it uses CPM external logic to define the logic or connection between different activities within locations wherever they occur. However, unlike CPM, the planning system also considers a task's own internal logic, by calculating durations based on quantities and allowing the planner to plan the location sequence and production rate to achieve continuous production.

Starting to carry out a review of the currents practice in the field of Location Based Management Systems (LBMS) a new approach is proposed which generates a logical relationship between working areas and activities and automatically, first, integrates this relationship in the CPM and then manages overlapping activities in terms of risk workers' risk reduction.

This approach comes from the consideration that in construction management, the health and safety is one of the most important element able to influence the entire process-management.

In this perspective it could be useful to remember the close relationship between safety and design (Capone et al., 2015). In safety management, EU Communications refer to architectural, technical and/or organizational choice in order to minimize professional risks. Such choices underline the cooperation needed between designer and safety coordinator at design stage: actually the main issue is related to the effectiveness in reaching the constructability goal.

2. Constructability, design and safety

As referenced by Capone et al. (2015), in the theoretical approach to Constructability the difficulty of designers to lead the construction phases during design phases was straight from the beginning. This opened up to a discussion about the aim to link design phase and construction phase: the results of building's quality are strictly related to the separation/integration between design and construction.

Together with Constructability the development of methods and tools aimed to manage this complex relationship, known as "Constructability", is a strategic resource for the field of Construction management and the progression of this concept shows that the aims could change throughout time depending on many factors such as incidental, environmental, social and economic (Gambatese 2007). According to Russel (1994), the construction time and cost could be depending on the way of running of the relationship between design and workers Healthy and Safety. The aim of directing such factor, according to the Constructability theories, means to find new design tools that aim to manage H&S during the design phase (Gambatese, 2009) (Creaser, 2008) (Taiebat, 2001).

The research line about Constructability has been carried out at two levels of analysis: one is overview level which focuses on the broad picture of Constructability and the other is the practical level, which investigates new tools, created ad hoc, to reach the research objectives. From the relationship between design and safety, the Building Design for Safety (BDS) method has been proposed by Capone (2014). This tool, better explained in Section 4 of the presented paper developed a construction simulation based by starting the activity simulation from the shop drawings. A 2D representation was used to visualize construction operations but the integration of this approach with a construction scheduling tools was not proposed. The presented work first develops a new tool for an automatic re-scheduling of CPM in function of workers' safety and when the tool is not enough proposes BDS as design solution in order to consider safety reasons before construction process starts.

3. Location Based Management System

Location-based management considers there is value in breaking a project down into smaller locations and using these to plan, analyse and control work as it flows through these locations. The location provides a container for project data at a scale which is easy to analyse.

Location-based planning is, in turn, concerned with the process of planning for work to protect production efficiency as work moves through locations. Specifically, the emphasis in location-based planning is to plan for productivity.

Location based methods extend basic activity-based CPM logic to yield an easy-to-use system which possesses the underlying analytic properties of CPM but specifically includes production estimation. This is reached by layered logic which is a simple process of automating the creation of a critical path network by using locations. Traditional CPM uses a single layer of logic while

Location-based planning introduces new layers of logic which add more detail to both the internal task production of the location-based task, and to the external links between tasks.

In this case all the analytic features of CPM are preserved when examining the logic between activities within locations, as activity sequencing is driven by normal CPM algorithms with familiar concepts such as precedence and lags.

In parallel, Location-based control assumes that planning has maximised productivity, found an optimal balance between risk and duration and is feasible to implement.

At least this approach aims to reach a better productivity level without considering how site and workers' conditions change due to overlapping activities and how safety risks increase in construction site.

For this reason the proposed WSiCPM framework, which is explained in section 6, aims to propose a novel approach which consider the integration of CPM with locations but assumes the planning as function of potential hazards which has been calculated using equations depending on different parameters. WSiCPM framework is integrated in a wider framework of design phase as explained in section 5.

4. The method Building Design for Safety (BDS)

The starting point is the idea that the visual simulation is not only a "passive" image of contents, but it is an " active" control in terms of built result. The aim was then to improve the contents of the representation to accentuate its "dynamism", implied in the project. The approach tents to re-elaborate project drawings to clearly express those construction processes implied in the drawings of the constructive details. The approach is to entrust to the design the role of harmonizing different parties. The chosen way is to assess “workers' safety” as the parameter to implement a new tool in order to obtain a safety realizable project. Starting from the representation of construction details, according to Building Design for Safety (BDS), it is possible to simulate the construction of them using the CAD 2D as graphical tool. This can be done through progressive drawings that express the breakdown in construction phases –one phase for each new building product-, chronologically processed and logically related. In these specific drawings are depicted all site facilities (temporary works, machineries and manpower) in order to simulate and verify the real conditions in which it will be the realization. BDS allows both the detailed assessment of safety conditions –by using a traditional risk analysis- for the realization of the item and the Constructability verify of the element itself. It is important that this happen before construction stage, when it is still possible to intervene, where appropriate, with amendments on the project itself. It is possible to find more details on the BDS method in (Capone et al. 2014). The picture below (Figure 2) shows the visual representation of the method.

5. Safety management approach for critical construction phases

In BDS method have been proposed and tested a simulation process of the construction operations, with the specific aim to correct and optimise shopping drawings in order to have a better performance of the building (Capone et al. 2015). After a lot of applications in different case studies, the necessity to consider the “time variable” has appeared, above all in managing interfering activities.

The question should be how to insert BDS method in a wider processual and operative framework, in order to make BDS free from the theoretical, episodic, uneconomical and unrealistic aspect that could have been attributed to it.

To reach this goal the first step was to define an approach that, using the construction management tools, could individuate the critical construction activities in the safety point of view. In professional practice, regarding interfering activities, the Health and Safety (H&S) Coordinator usually gives operative prescriptions to stagger in space and/or in time the interfering activities and gives the instructions to control the efficacy of such prescriptions.

If interfering risks still remain, the H&S Coordinator must determine preventive and protective measures in order to minimise risks.

Nevertheless there are a lot of situations in which is difficult to stagger in space and/or in time the interfering activities preserving together the workers’ safety and the Constructability requirements.

Usually the individuation of critical phases is performed by means of the classical construction management tools; with BDS method we have a closer analysis of the critical phases (Figure 2).

Searching for the applications in which the BDS method could be more effective, we investigated different theories linked with construction management and safety (Baldwin and Bordoli 2014).

The link between design and safety suggested us to improve and optimize visual representation of construction site issues, taking distances from the traditional site layouts in order to improve information and make designer tools more effective.

According to the aforesaid traditional theories, planning techniques such as critical path method (CPM) are useful for analyzing the logic of construction activities, identifying critical activities and producing a model form which it is possible to produce schedules for activities and identify milestone/completion events. From the literature review emerged that CPM helps to clearly identify key contractual dates for the start of the activities on site and completion of construction work. CPM confirms production deadlines and contractual obligation. However,

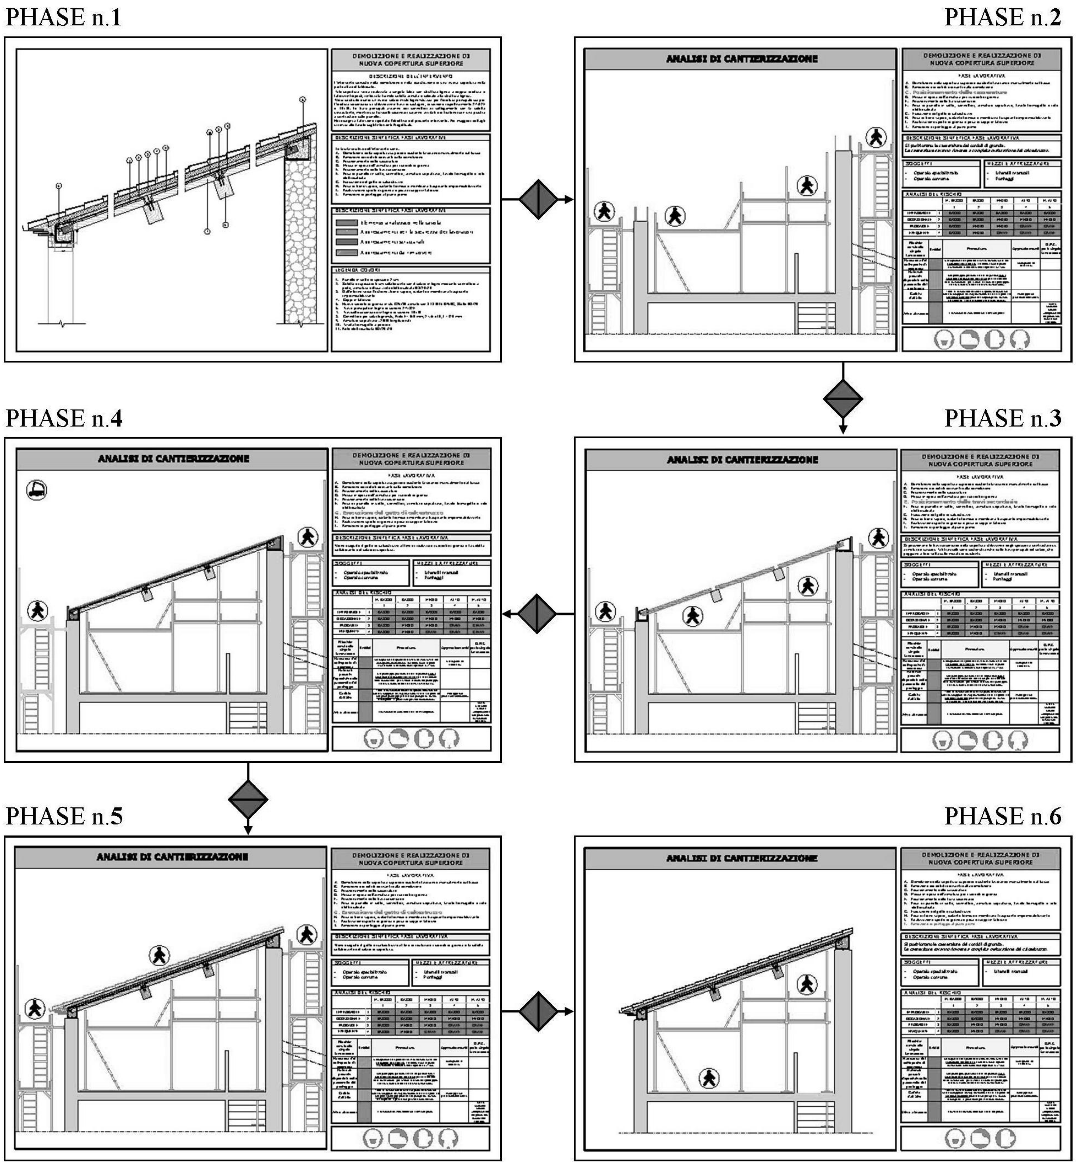

Figure 1: Operative Framework of the BDS procedure for a roof redevelopment (Capone et al. 2014)

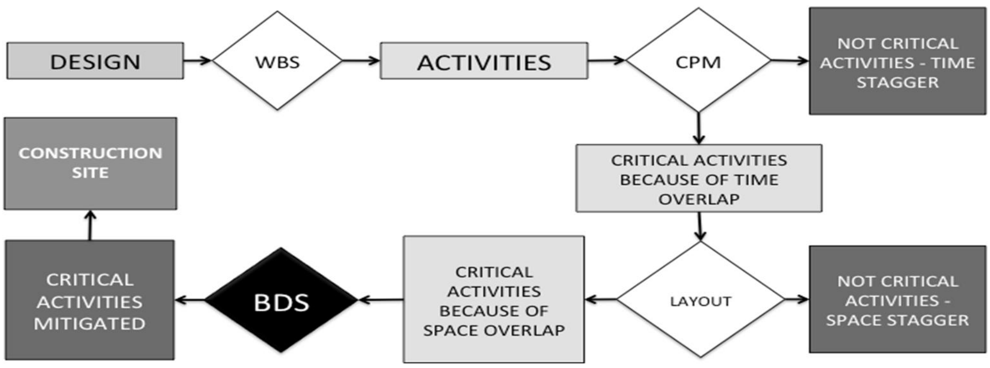

Figure 2: Graphical representation of the approach to safety management of critical construction phases (Capone et al. 2015)

CPM is not the best tools to direct production on site. The great deficiency is the luck of a direct connection between scheduling approach, used for the baseline schedule, and the real site condition. Only introducing the spatial dimension and workers' dimension, considered by BDS method as well, in the traditional construction tools and in CPM planning in this particular case, it could be possible to effectively manage the site conditions.

A step in this direction can be the WSiCPM framework, as in the following it is described.

6. The WSiCPM framework

6.1 The methodology of the WSiCPM framework

An attempt to create a methodology able to incorporate the workers' safety and the spatial dimension into the critical path method (CPM) has been done. Such methodology can be used as a supplemented tool in planning and design phases to identify and remove early the risk of accidents by means of BDS method. The methodology called WSiCPM (Workers Safety into CPM) has been developed to detect time-space-conflicts of activities in order to help health and safety risk assessment in construction management. In WSiCPM framework, a method for qualitative and quantitative risk assessment was programmed and implemented. Probability of potential hazards has been calculated using equations depending on parameters such as: overlapping duration, overlapping working area, number of workers in the observed pair of interfering activities and type of hazard. The severity of the hazard has been estimated analogously, with the compensation of a casualty by insurance companies (through this, the risk can be modified into a monetary value representing the predicted accident cost). Additionally, the framework proposes possible solutions for each pair of interfering activities. BDS has been linked with WSiCPM as a method useful to analyse and resolve health and safety risks in space-time conflicts activities. In figure 3 WSiCPM framework is depicted.

In the following steps the methodology is described using the information from a case study which includes a set of nine different site activities.

6.2 Step 1: Definition of the Overlapping Matrix

This step of the analysis sets out an overlapping matrix which is able to identify and control the *time-overlapping activities* in order to achieve the following aims:

- Organize the analysis of interference activities by way of a pairwise comparison, in order to discuss their interaction;
- To apply the mathematical concept of non-analogue relationship between the two activities of each pair;
- Calculate the overlapping duration of each pair of interfering activities.

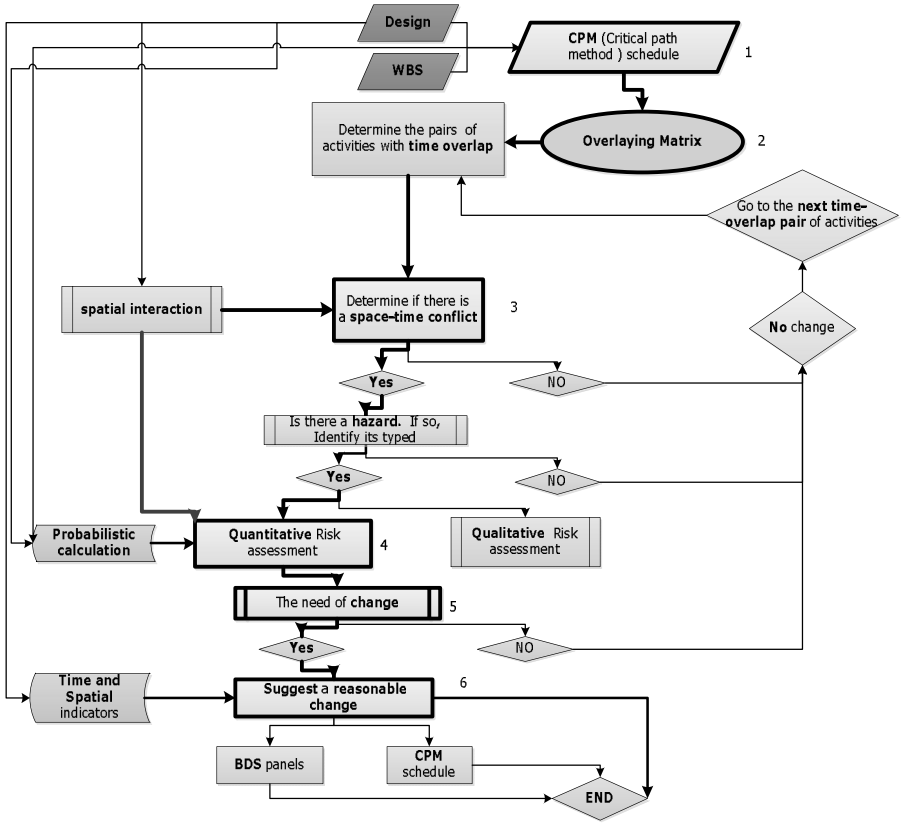

Figure 3: WSiCPM workflow

This is carried out exporting information about the activities' properties (name, duration, finish, dependencies, cost, …) from the baseline schedule CPM (Fig. 4), practically using MS Project Software, to a pre-set database, practically implemented in MS Access Software.

	WBS	Task Name	Duration	Start	Finish
1	1	stare	0 days	Mon 6/8/15	Mon 6/8/15
2	2	activity A	5 days	Tue 6/9/15	Mon 6/15/15
3	3	activity B	4 days	Fri 6/12/15	Wed 6/17/15
4	4	activity C	2 days	Tue 6/16/15	Wed 6/17/15
5	5	activity D	4 days	Thu 6/18/15	Tue 6/23/15
6	6	activity E	8 days	Tue 6/16/15	Thu 6/25/15
7	7	activity F	4 days	Wed 6/17/15	Mon 6/22/15
8	8	activity G	3 days	Wed 6/17/15	Fri 6/19/15
9	9	activity H	5 days	Wed 6/24/15	Tue 6/30/15
10	10	end	0 days	Tue 6/30/15	Tue 6/30/15

Figure 4: Example of the baseline schedule –CPM- taking into account nine activities by using MS PROJECT

The method automatically fills the matrix in using two type of overlapping scenario: "*No conflict*", "*Time interference*". The figure 5 shows the matrix for the proposed case study. After this analysis it's possible to pull the pairs of activities with a time overlap out from the aforesaid matrix.

APPROACH	APPLICATION TO THE CASE STUDY

	A	B	C	D	E	F	G	H
A		Time interfer-ence	No conflict	No conflict	No conflict	No conflict	No conflict	No conflict
B	Time interfer-ence		Time interfer-ence	No conflict	Time interfer-ence	Time interfer-ence	Time interfer-ence	No conflict
C	No conflict	Time interfer-ence		No conflict	Time interfer-ence	Time interfer-ence	Time interfer-ence	No conflict

Figure 5: Example of matrix of overlapping

6.3 Step 2: Determination of the space-time-conflicts

According to the framework, after determining the activities with a time overlap, each activity pairs should be processed in order to achieve a double-check: time interaction (as described in the step 1) and spatial interaction as described below, locate the "*space-time conflicts*".

This double-check aims to locate the "*space-time-conflicts*" which mean that there is a spatial interaction between the two activities, even if they are run in separated spaces, since the conflict could be present not only in the activity's work area but also in in the areas connected to each activities. For this reason, referring back to the designer, the method considers four different kind of areas related to each activity and check their interaction as shown in the Figure 6.

If the two activities run in different places without space interface, then space-time-conflict has not occurred as the Figure 6 shows.

6.4 Step 3: Determine the type of hazard and risk assessment

After determining the space-time-conflicts, it is important to know whether a hazard has been created by each space-time-conflict pair of activities. If so, once hazard has been identified, it is necessary to calculate the associated risk.

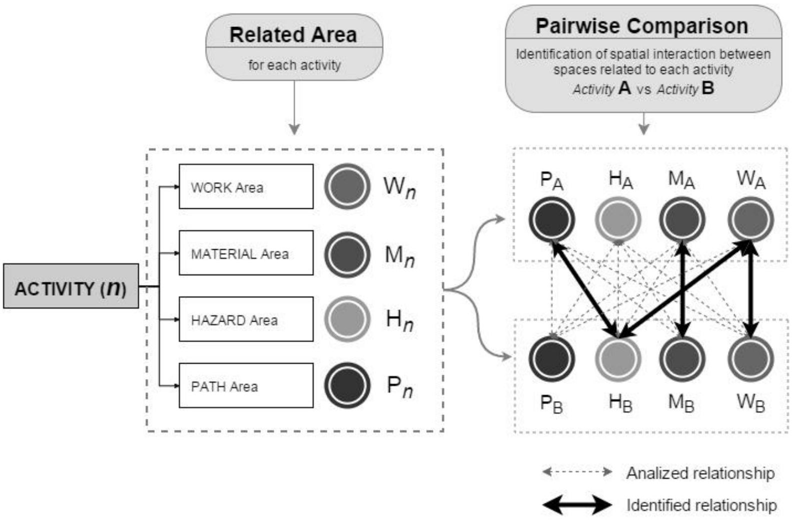

Figure 6: Example of space-time conflicts determination

In WSiCPM a specific quantitative risk assessment has been developed and the risk evaluation is generated by the framework. Inside WSiCPM the probability has been estimated with probabilistic calculation of the time and space probability with respect to the space overlapping areas and the number of workers. The severity of the accidents has been expressed using a method deriving form insurance (monetary quantification of the damage).

6.5 Step 4: Risk response and change request

The WSiCPM framework works like an expert system: the outputs of the quantitative risk assessment, in addition to spatial information and time information from CPM, are the input in this operation. For each space-time hazard conflict pair, the framework suggests a solution.

The framework provides four different kinds of suggestions in order to mitigate risks, helping the decision maker in resolving the conflict.

BDS will be use in WSiCPM to solve the risk situations that cannot be mitigated just with scheduling actions. BDS will be used in case if it would be necessary to have a deep H&S and constructability analysis, coming until the possibility to solve critical situation even by changing the design.

The solutions automatically proposed by WSiCPM are listed as follows.

1- Changing the path

This suggestion is given if there is interference between the hazard area of an activity and the path area of another.

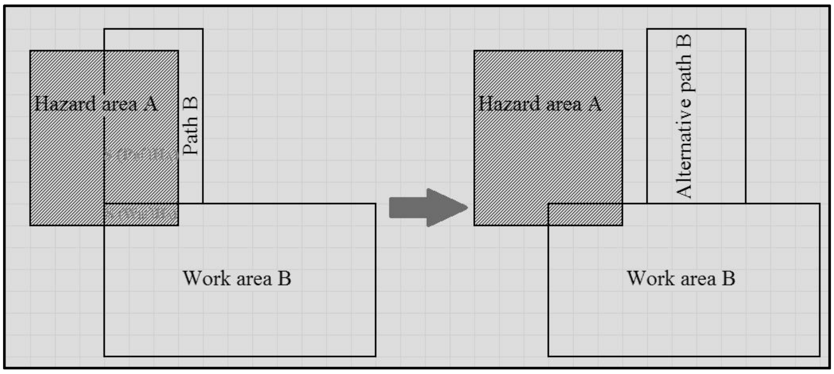

Figure 7: Example of path changing

2- Dividing the areas

This suggestion considers the interference of the hazard area of an activity with the work area of another activity. If this interference is minor with respect to the work area itself and the overlap time is less than the duration of the last activity, taking into account the ability of the last activity to be divided, then the framework will suggest to subdivide it.

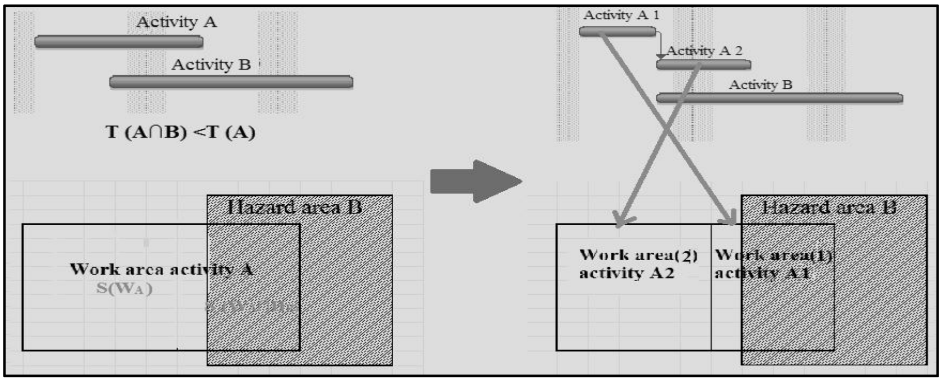

Figure 8: Example of dividing areas

2- Splitting the activity

This suggestion considers that, if the overlap-time is small in comparison with the duration of one of the activities, which can be achieved in two phases and it is not critical, the framework proposes to divide the workload. Thus, the work in the long activity is halted and later continues after the end of the hazard (time dividing).

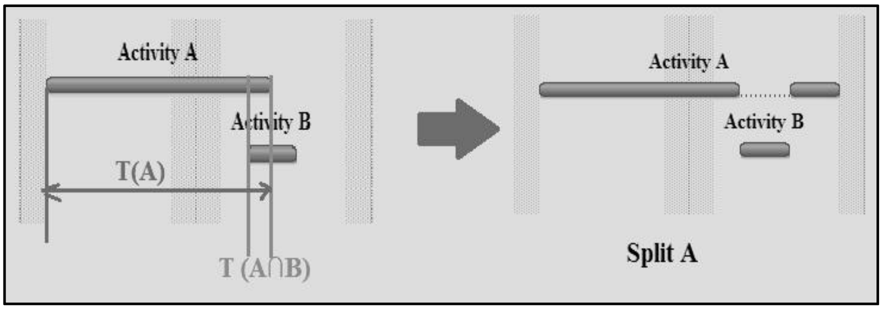

Figure 9: Example of splitting

2- Rescheduling

This suggestion considers that, when the risk is high and the interference of the space is substantial (the two activities take place almost in the same place), and the time overlap is equal to the duration of one of the two activities; re-scheduling the non-critical activities would be the main solution proposed by the framework.

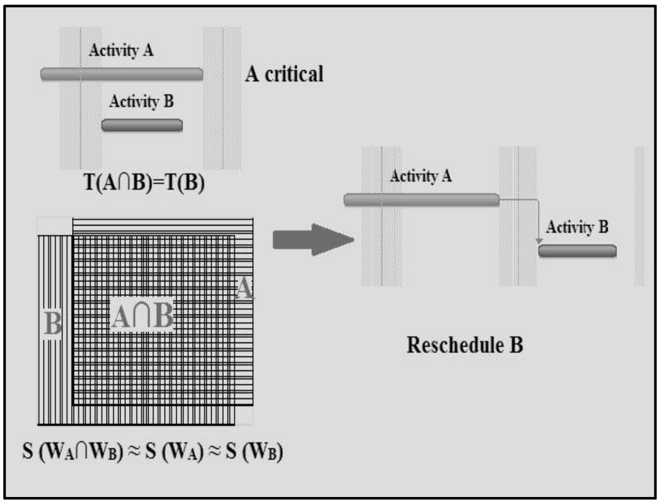

Figure 10: Example of re-scheduling

7. Conclusions

An attempt to propose a framework to analyse, evaluate and solve space-time conflicts with respect to health and safety risk mitigation has been made. If the automate solutions given by the WSiCPM are not suitable for the specific situation, BDS is suggested as the best method to solve the constructability issue mitigating health and safety risk for workers. This way, we tried to individuate acceptance criteria for critical activities overlapping, both in space and in time and then to quantify workers' safety risks.

The analysis, the assessment and the management of health and safety for workers in complex risky activities by using BDS, seems to push future developments in the direction of Building Information Modeling (BIM). In this perspective the research group is working on the implementation of site-analysis in a BIM-environment.

Abstract

Construction production is typically highly dependent upon space to move, store and fabricate materials and building components, and to perform transformation and assembling activities. Construction planning and scheduling goal is to provide a logical order for activities taking into account safety, space and logic requirements. Construction process scheduling should also incorporate specific features of work-flows of project activities through work spaces. The Location-Based Management System (LBMS) is a recent and innovative method that aims at planning and managing construction projects in a process-oriented way, taking into account activity locations on-site. In an on-going research an improved scheduling method for construction operations has been developed, based on a CPM - Precedence Network plotted on a Resource–Space chart. Space Units of the project work are identified by a Location Breakdown Structure (LBS) like in the LBM System, and project activities are identified by a two dimensions coordinate system based on Resources (i.e. construction crews) and working Spaces (e.g. floors of a multi-storey building). As the Precedence Network is plotted on a resource – space chart, Space Units can be characterized by a maximum resource capacity number for each activity type, thus defining the available space capacity of working crews. In this way project scheduler can verify the quality of the produced schedule during the planning and scheduling process, as dimensions of workspaces and their congestion limits, safety spaces and protection spaces can be easily verified. The method has been tested on a sample project. The proposed scheduling approach can help unexperienced project schedulers to identify specific resource requirements for spaces needed for activities, and to define locations of these spaces and resources on building site. The proposed approach can be useful especially in case of project acceleration and time-cost trade-off, helping the project team to produce an efficient construction schedule.

Keywords: Construction, project scheduling, resource management, precedence network, workspace management

1. Introduction

Construction projects are very specific industrial projects. One of the most important features of construction production is related to the building site. Building construction is an industrial activity in which workers build not only the product but also the working location, i.e. the building site. Therefore, space for construction activities, including materials, machines and fabrication stations, traffic routes, places of construction work and welfare facilities must be designed, organised and planned (Riley, Sanvido, 1997). Construction planning and scheduling has the objective of providing a logical order for activities taking into account safety, space and logic requirements. In particular, it is believed that a construction schedule should focus on space requirements as they can have very important effects on safety and production quality (Akinci, Fischer, Levitt, Carlson, 2002; Ciribini, Galimberti, 2005). Understanding the organization of the various materials, trades, and subcontractors in the project processes is an ability acquired only after years of study and experience. Construction workspace is, at the same time one of the main components and constraints of construction scheduling, due to production context and building product characteristics. So, workspaces are generally difficult to proactively plan and manage, because of the dynamic nature of construction production where site layout and work environment change continuously as processes progresses. Workspaces are key elements of the process model embodied in a schedule, and work-space conflicts prevention is an important feature of a construction schedule. As standard planning and scheduling of a construction project can be achieved through networking techniques, the space – related component of the schedule is difficult to model and to efficiently take into account by an unexperienced project scheduler. Thus, a method to understand schedule workflow and spaces during the scheduling process can be a valuable instrument to achieve project success.

2. Literature review

Many scheduling methods have been proposed in literature in order to improve construction project workspace management with a scheduling model. As crews perform activities from a space unit of the project to another one, it might be advantageous to arrange for such crews to work continuously, without interruptions, thereby preventing idle intervals of equipment and manpower (Selinger, 1980). Riley and Sanvido (1995 and 1997) observed that current space planning in multi-storey building construction is limited to site layout and logistics, and they propose a space planning method that provides a logical order and priority for activities related to their needed spaces. Effectively a construction planner need to: (1) identify the space needed for activities; (2) define locations for these spaces on building floors; (3) develop a sequence of work that defines the order spaces are occupied; (4) identify potential spatial conflicts. Kang et alii (2001) observed that in a multiple repetitive construction project, construction cost and duration are dependent on: number of work areas, proper crew grouping, size of work areas, frequency of repetition of each activity, and provided an heuristic approach to allow optimal construction planning. Yang and Ioannou (2001) proposed a scheduling method with focus on practical concerns in repetitive projects, and implemented in particular the pulling effect in the continuity relationship between activities.

Yi, Lee and Choi (2002) presented a heuristic method for network construction and development for repetitive units project, with the aim of minimizing total project duration by reducing idle time of resources and spaces. Actually the heuristic changes the sequence with which crews complete the scope of work encompassed in each repetitive activity. This approach and general formulation has been applied in earlier and more accurate models (El Rayes and Moselhi, 1998) which guarantee a global optimum solution. Guo (2002) proposed to integrate computer-aided design with scheduling software for the dynamic identification of space conflicts on the jobsite. Work-space types are identified and time-space conflicts are studied. The seminal work of Akinci, Fisher, Levitt and Carlson (2002) investigated the time-space conflicts in construction projects. Six type of spaces required by construction activities were detected and each construction activity requires at least one of these spaces. As activities can have time overlaps, i.e. they can be performed at the same time, time – space conflicts may occur. Ciribini and Galimberti (2005) observed that the H&S Management has widely to deal with working areas and space conflicts. A schedule model should indicate crew workflow directions, space requirements, and spatial buffers between activities. The optimization of the sequences of crews (workflows and production rates) can be done by scheduling work locations. Daewood and Mallasi (2006) and Mallasi (2006) observed that lack of execution pace planning may disrupt the progress of construction activities. Also, spatial congestion can severely reduce the productivity of workers sharing the same workspace, and may cause health and safety hazards to workers. A Critical Space-Time Analysis (CSA) approach is proposed to model and quantify workspace congestion and a computerized tool termed PECASO was developed for workspace management. The basic method suggested by researchers and practitioners for time – space project modeling is the linear scheduling method, flow line or linear planning, integrated with a network model (Kenley and Seppanen, 2010; Russell, Tran & Staub – French, 2014). Kenley and Seppänen (2009, 2010) observed that locations are important in construction because building can be seen as a discrete repetitive construction process, a series of physical locations in which work of variable type and quantity must be completed. They also observed that the location based methodology does not exclude Critical Path Method (CPM), in fact dependencies between activities in the various locations and between tasks (that are made up of activities of the same work item) are realized with CPM logic links. Construction projects are location – based projects (Kelley, Seppanen, 2010), where resources perform the same activity in different locations consecutively. Choy, Lee, Park et alii (2014), observe that current construction planning techniques have proven to be insufficient for work-space planning because they do not account for needed spaces of activities. So a framework for work-space planning is proposed categorizing activity spaces and including 4D Building Information Model (BIM) generation for space identification. Zhang, Teizer, Pradhananga and Eastman (2015) highlight safety and productivity poor performances of construction due to congested site conditions, and propose a method for automated visualization of workspace with BIM. Workspace modelling is based on five workspace sets and a conflict taxonomy.

In summary it is felt that there is a lack of structured planning and scheduling method for workspace management, at the design and schedule level of a construction projects. Workspace is an important concept and viewpoint for understanding characteristics of construction projects. The earlier research has covered already several important methodological characteristics of construction planning and scheduling with the site space on focus. Although not covered explicitly here some research has covered also computerized assistance for the generation of alternative plans and schedules – for example (Kahkonen, 1994; Märki et al, 2007). The research presented in the following aims at proposing a method to understand work-space characteristics of a construction project for planning and scheduling purposes, thus creating a process-oriented environment for construction schedule production, and enabling high quality scheduling.

3. Proposed Method

3.1 REPNET: Repetitive Networking technique

In an on-going research an improved scheduling method for construction operations has been developed, based on a CPM - Precedence Network plotted on a Resource–Space chart termed Repetitive Networking Technique (REPNET). Locations or Space Units of the project are identified by a Location Breakdown Structure (LBS) like in the LBM System, and project activities are identified by a two dimensions coordinate system based on Resources (i.e. construction crews) and working Spaces (e.g. floors of a multi-storey building) (Bragadin 2010, Bragadin, Kahkonen 2011). As construction projects activities are often performed in many different locations of the building site by the same crew, a basic component of construction process understanding is the modeling of this time – space related process. A project activity performed in different locations, with similar sub-products, is termed repetitive activity. It is important that repetitive activities are planned in such a way as to enable timely movement of crews from one unit to the next, avoiding crew idle time and space - conflicts with other construction activities. The REPNET heuristics provide optimized activity scheduling maintaining the work continuity constraint and also the As-Soon-As-Possible total project duration calculation.

3.2 Resource-flow tracking with a resource – space chart

A Precedence Diagram Network of the repetitive project is plotted on a resource – space chart, with the x-axis representing resources and the y – axis representing space units of the project. The two coordinates identify each network node representing an activity performed in a specific space unit: the first coordinate is the main resource performing the activity (construction crew) and the second coordinate is the work space in which the activity is to be performed. The procedure of plotting the network on a resource – space coordinates has been used by many researchers in the past. In particular Yi, Lee and Choi (2002) presented an heuristic method for network construction and development for repetitive units project, with the aim of minimizing total project duration by reducing idle time of resources and spaces. The heuristic plotted the activity network on a Resource – Space Chart. Resources in the x-axis of the chart were the work crews or the equipment that was intended to perform activities. Resources were grouped by work item i.e. masonry, plastering, floor concrete slab etc. Multiple resources, i.e. multiple crews, were allowed for the same work item in order to perform parallel repetitive activities in different locations of the same task. In this way in every column of the chart activities are grouped by resources (fig. 1). Space units of the project are plotted on the y-axis. Space units are the locations where only one crew can perform one activity at a time. In the proposed method the Location Breakdown Structure (LBS) can be displayed on the y-axis with a hierarchical decomposition of project locations (fig.3). An activity is defined as the set of construction operation performed by a specialized crew or equipment in a space unit of the construction project. In a repetitive construction project a set of activities, performed by the same crew in more than one space unit, is defined repetitive activity. Resources that perform a repetitive activity are identified by a j code. A task is defined as a set of repetitive activities performed by one or more than one crew for a work item, and is identified by the i code. So a resource path is completely identified as a repetitive activity by the ij code (ie resource path) and a single activity is identified by the ij-k code where k identifies the space unit where the activity is performed (i.e. space path, fig. 1). The k code is a unique alphanumeric character that identifies the operational space of the Location Breakdown Structure.

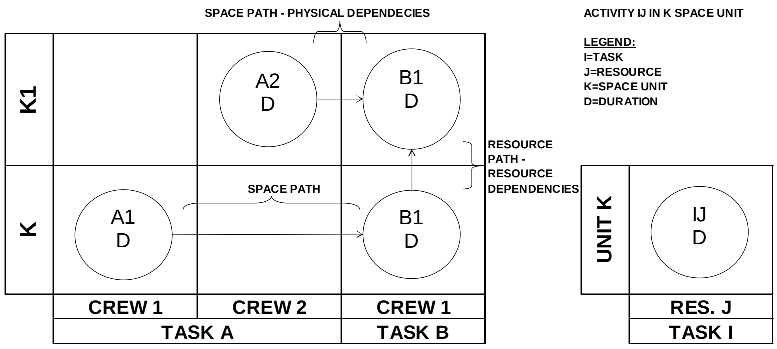

Figure 1: Network Diagram plotted on a Resource-Space Chart (adapted from Yi, Lee and Choi, 2002)

3.3 Space planning with the resource – space chart

The space identification for a construction schedule can be addressed by Location-Based Planning (Kenley and Seppänen, 2010). Location – Based management assumes that there is value in breaking a project down into smaller locations and using these to plan, to analyse and to control work as it flows through these locations. The location provides a container for project data at a scale which is easy to schedule and to control. The emphasis in location – based scheduling is to schedule the construction project achieving high level of productivity, quality and safety. The Location Breakdown Structure (LBS) is the backbone of this design process of on-site operations. Once the project is decomposed into various locations, or space units, understanding the interactions between activities and spaces is needed. In this phase the required spaces for each activity are detected and assigned to space units. Repetitive activities are decomposed into various activities to be performed into specific space units due to their production features, and single activities are allocated to specific spaces of the LBS. The sequence of activities is then generated using Precedence Diagramming Method (PDM). Activities are sequenced with network logic links and consecutive and concurrent work tasks are defined first for each space units and then for the complete building project. The prepared activity network can now be plotted in the Space – Resource chart. The allocation of activity on the resource – space chart can highlight possible time/space conflicts between activities. Conflict resolution can be performed and the optimized space-allocated schedule can be completed. The flow-chart of the proposed scheduling process can be found in figure 2.

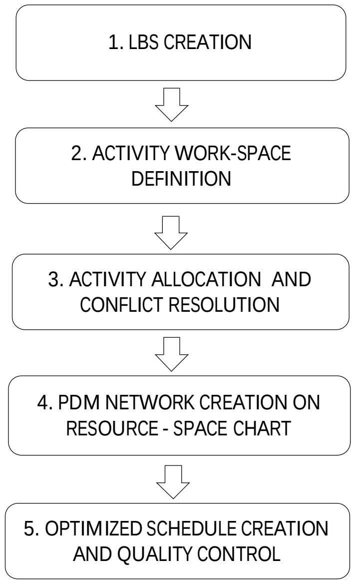

Figure 2: Proposed Scheduling Process

The seminal work of Akinci, Fisher, Levitt and Carlson (2002) investigated the time-space conflicts in construction projects. Six type of spaces required by construction activities were detected: building component space; labor crew space; equipment space; hazard space; protected space; temporary structure space. Each construction activity requires at least one of these spaces. As activities can have time overlaps, i.e. they can be performed at the same time, time – space conflicts may occur (Akinci et alii, 2002; Mallasi, 2006; Zhang et alii, 2015). Time – space conflicts have three characteristics:

- Temporal aspects of time-space conflicts: since activity space requirements change over time, time – space conflicts between activities only occur for certain periods of time.
- Multiple types of time – space conflicts: depending on the types of space conflicting and the quantity of interfering spaces, time – space conflicts can have many types: safety hazard; congestion; design conflict; damage conflict.
- Multiple conflicts can exist between a pair of conflicting activities.

In the proposed method, four types of conflicts are identified for project scheduling purposes:

- Time / space conflicts due to activities' time-space overlapping and consequent contemporary space usage;

- Congestion of space due to labor density. The maximum number of workers per site location should be limited. The increase of labor density can lead to productivity loss and safety hazards.
- Safety hazards due to hazard spaces created by an activity for labor crew spaces of other activities.
- Damage conflicts due to labor crew spaces, equipment space, temporary structure space, hazard space required by an activity conflicts with a protected space of another activity.

The proposed resource – space chart based method can help project planner and production managers to avoid conflicts in many ways. In fact, time-space conflicts can be avoided due to space allocation of activities in the resource-space chart. PDM activities plotted on the resource-space chart give a clear definition of the space used by labor crew for working. At the same time the layout space for each activity execution is identified on the chart, and it is easy to indicate the maximum number of workers per space units. Safety hazard spaces and protected spaces can be represented as unavailable spaces directly on the resource – space chart plotted for a specific time window. Basic limit of the proposed solution is the level of detail of the LBS, and the consequent space requirements for activities and representation of space conflicts between activities. The understanding of space conflicts needs a deep knowledge of the modelled construction process and proper level of detail of work packages.

4. Sample project

A sample project of construction of a small three storey residential building is presented. The created workflow model for the construction phase of the systems and interior finishing works is presented. The residential building of the sample project is composed by two edifices (A and B), joined by a covered corridor. Building A has three storeys while building B has only two storeys. The Location Breakdown Structure (LBS) is depicted in figure 3.

PROJECT	*FLOOR*	*BUILDING*	*SPACE UNIT DESCRIPTION*	*SPACE UNIT LBS CODE*
SAMPLE PROJECT - 1	2^F-SECOND FLOOR: 1.SF	BUILDING A 2^F: 1.SF.A	*FLAT-U6*	*1.SF.A.2*

		CORRIDOR: 1.GF.C	*CORRIDOR*	*1.GF.C.1*

Figure 3: Location Breakdown Structure of the sample project

After the LBS creation work spaces of each activity have been defined, and the maximum number of workers per space unit has been assigned. Labour density limits are set with the aim of satisfying technology and safety requirements. In figure 4 the maximum number of workers per space unit is shown. In this phase activity allocation on space units is performed with the aim of optimising construction processes in terms of work continuity of crews, safety issues, congestion avoidance due to contemporary space usage and protected spaces usage.

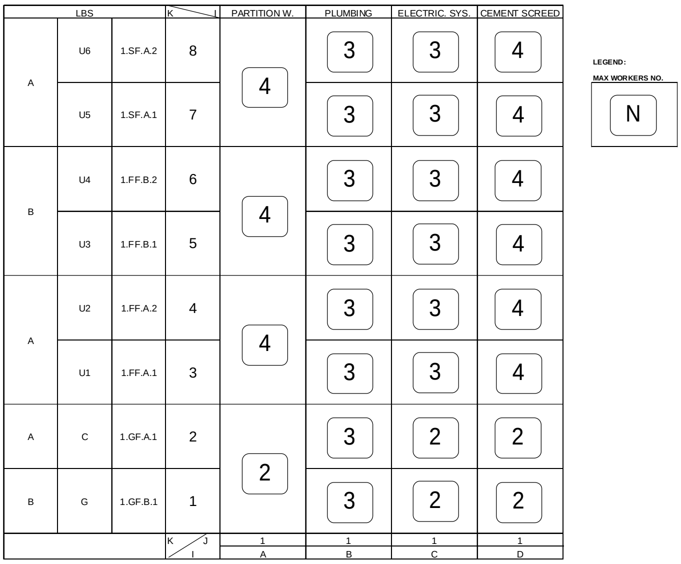

Figure 4: Labour density limits per space unit of the sample project

At the end of this phase activity durations can be computed, as shown in table 1.

Table 1: Sample project activity data

TASK [i]:	*A - PARTITION WALLS*			*B - PLUMBING*			*C - ELECTRICAL SYSTEM*			*D - CEMENT SCREED*		
SPACE UNIT [k]	*SPACE CAPA-CITY*	*No. Laborers*	*DUR. D*	*SPACE CAPA-CITY*	*No. Laborers*	*DUR. D*	*SPACE CAPA-CITY*	*No. Laborers*	*DUR. D*	*SPACE CAPA-CITY*	*No. Laborers*	*DUR. D*
1	*2*	*2*	*10*	*3*	*3*	*3*	*2*	*2*	*5*	*2*	*2*	*2*
2				*3*	*3*	*3*	*2*	*2*	*5*	*2*	*2*	*2*
3	*4*	*4*	*15*	*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*
4				*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*
5	*4*	*4*	*15*	*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*
6				*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*
7	*4*	*4*	*15*	*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*
8				*3*	*3*	*5*	*3*	*3*	*4*	*4*	*4*	*4*

The creation of PDM network on basis of the Resource – Space chart (fig. 5) is easy to perform as a following step, as it is only needed to add logic links on the previous pattern of activity allocation on the LBS (fig. 4). The REPNET heuristics (Bragadin, Kahkonen, 2011) is then performed and a workflow optimised schedule is developed. In figure 6 the flow-line chart of the sample project is depicted. Then the produced schedule needs to be controlled. Firstly it is easy to observe that for the sample project the work continuity requirements has been satisfied almost completely, with the exception of activity D in units no.1 and 2. Also no time – space conflicts are detected and labour density requirement is satisfied (as activity durations were computed with this constraint in table 1). For each working week the state of the project can be plotted, thus facilitating the controlling process through building site scheduled status representation. Completed and in progress activities are pointed out with successor spaces. Unavailable spaces because of cement screed hardening (after activity D implementation) are highlighted with different colour in the chart, to ease production management of successor construction processes (fig. 7).

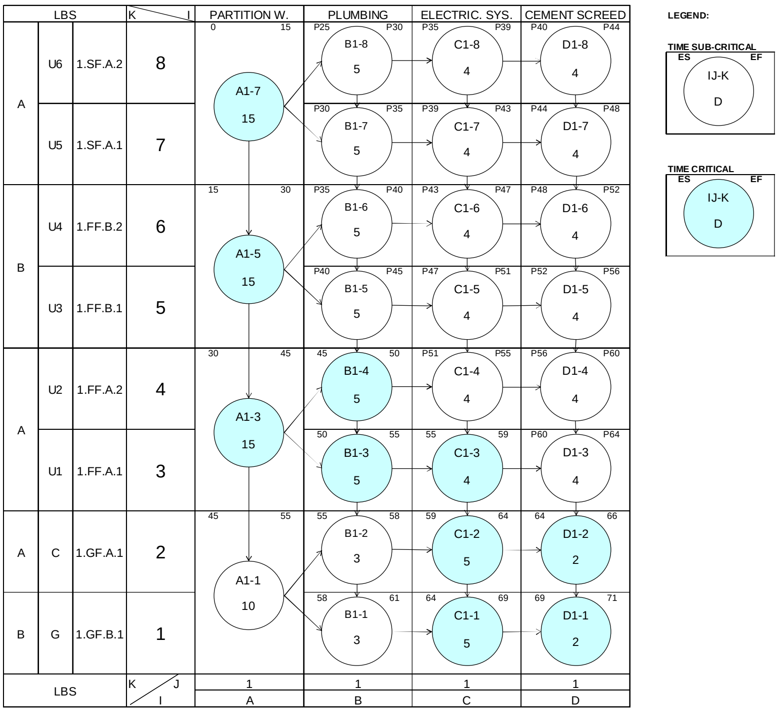

Figure 5: PDM network plotted on a resource – space chart - REPNET

5. Discussion

The proposed method for construction scheduling, is based on workspace management issues. It is considered that the proposed simple method that uses resource – space charts can be useful for preparing schedules of good quality, meaning with this that they are process oriented and easy to update and maintain. On the other hand, the proposed method needs a skilled scheduler especially at the beginning, when LBS is created and activities' work spaces are defined. The need of developing a good LBS is because of the proposed scheduling method structure, i.e. the sharpness of LBS directly affects the sharpness of activities, as project activities are allocated into space units created in the LBS since the beginning. Mistakes and incongruences in this phase can affect schedule development and conflict detection. Also activity allocation and conflict resolution need a good construction expertise for a sharp modelling, but it is believed that the creation of the resource-space chart helps logic thinking and prearranged problem solving. Linking the proposed method with BIM models capturing location details of end product is an interesting way to develop it further. This would mean capturing directly the location data of interest from BIM model to be used for scheduling purpose. With the known spatial needs of different activity types and their operational resources this can provide grounds for highly advanced and detailed scheduling solutions. As previously mentioned, limitations of the method can be found in the workspace modelling performed by the LBS and the two-dimensions resource-space chart. Detailed BIM models can be very effective for workspace conflict detection (Akinci et alii, 2002; Choi et alii, 2014; Ciribini, Galimberti, 2005; Dawood, Mallasi, 2006; Mallasi 2006; Zhang et alii, 2015), but it is also believed that a simple space modelling approach, as the one based on the LBS development, can be a quick and efficient method for workspace scheduling (Kenley, Seppanen, 2009, 2010; Russell, Tran, Staub-French, 2014).

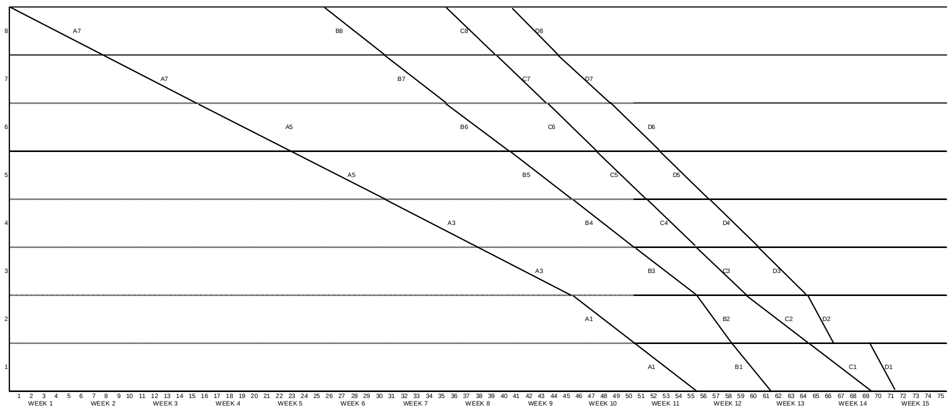

Figure 6: Sample project: flow-line diagram REPNET

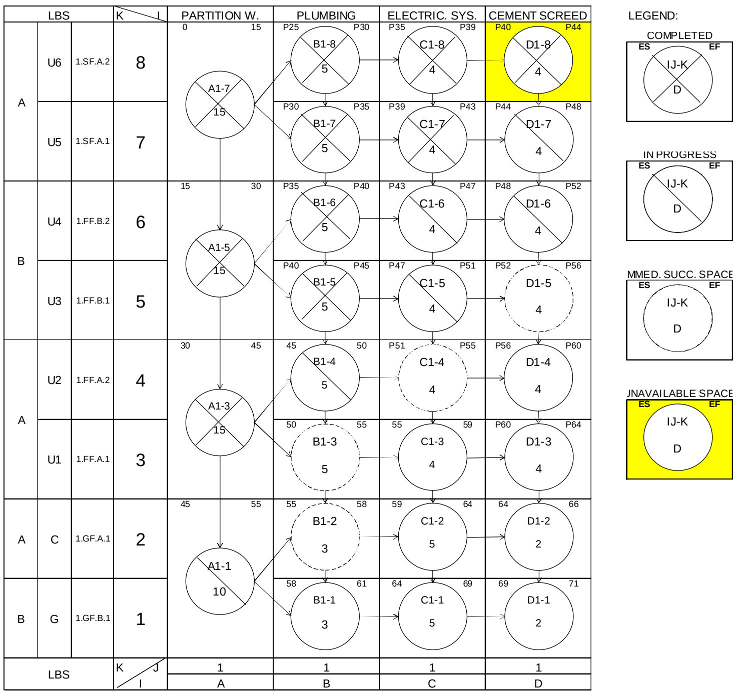

Figure 7. Sample project phase: week 10 plotted on a Resource – Space chart

6. Conclusions

The use of Resource-Space charts for construction workspace scheduling has been presented, since it is considered that explicit inclusion of spatial calculation is essential for preparing construction schedules of good quality. Many researchers and practitioners have highlighted the need of a workspace management system for construction process modelling, planning and scheduling. A Resource-Space chart, based on a Location Breakdown Structure, captures already main part of the logic of construction schedule. Thus, a PDM network can be easily prepared based on this. Accordingly project and production managers are creating process oriented project schedules where time – space conflicts of activities can be prevented, and congestion avoided due to the overall logic of the proposed scheduling method. The proposed method can be linked with BIM models for having direct access to spatial data.

Silvio Burrattino Melhado,
University of São Paulo
(email: silvio.melhado@usp.br)

Abstract

Unfortunately, delays are common in the construction industry. They create concerns for project performance and cause losses to project parties. These delays are caused by a number of factors.

The aim of paper is to analyse the main causes of delay in construction projects and to propose a preliminary and structured framework to improve the actual use of time planning tools and control instruments.

The framework is based on assumptions defined to optimise the techniques of tactical-operational planning currently adopted in the academic and professional environment, but reflecting on the Brazilian construction reality. It also assists early risk identification of non-compliance to scheduling and the best ways to compensate for delays.

Initially, a literature review was conducted to identify the main factors influencing the delay of construction projects. One of these surveys was emphasized because it compiled all these factors in a specific list.

Then, an analysis of data from 50 real estate construction projects in Brazilian cities (built in the last eight years) is also described, ordering the results in a frequency rank. This rank showed that the greatest concentration of causes of delay (over 60%) is related to inappropriate use of planning tools, team management and low productivity in the activities.

Using literature review again, this article identifies tools and assumptions to improve the control of project deadlines, thus avoiding the occurrence of various problems raised in the previous rank.

Finally, a time management framework is proposed. It consolidates the tools studied for better managing of time in construction projects. The performance of this preliminary model could be measured by its implementation in new researches, as described in the conclusions of the paper.

Keywords: Delay causes, planning, scheduling tools, construction project, time management

1. Introduction and justification

The execution of real estate projects in Brazil has always been a difficult activity because, historically, the country conditions do not stimulate Brazilian entrepreneurs, such as difficulty in financing, high interest rates, legal risks, defaults, complex regulations and non-qualified labour.

The market scenario started to change in the late 1990s and especially after 2005, with the IPO (Initial Public Offering) of large construction companies, improvement in the country economic conditions and more availability of credit for buyers. This scenario allowed a great market growth, but the sector was not prepared (technically or materially). Thus, despite this positive condition, there was an increase of delays, consumers' complaints and financial losses.

This would be a great opportunity for academic studies in the area. However, Brazilian structured researches about this theme were not found.

In recent years, the situation has been different, due to the global economic crisis and the Brazilian political situation. Even after technical adjustments and market restructuring, delays are still constantly verified. Even with less significant impact, as compared to those of the recent past, the question is what are the reasons why the construction projects are still delaying?

With all these doubts, the importance of academic studies into this subject was identified. This article can provide information and raise the interest of researchers and professionals in the sector.

Outside Brazil, in this period, many studies were observed to identify the most frequent causes of these delays, how they relate to each other and possible mitigation actions. To contribute to future research on the topic in Brazil, De Filippi and Melhado (2015) established a unified list of the most common papers, adapting items based on the Brazilian market scenario.

This article furthered this research, by increasing the number of projects surveyed and established what the main causes would be by studying a sample of companies in Brazil.

Finally, guidelines for a project management model in the construction sector were established, which could minimize the occurrence of the most important causes.

2. Research methodology

The methodology adopted includes some steps, starting from a literature review. The references studied by De Filippi and Melhado (2015) were increased and the new literature review searched not only causes of delay, but also tools to minimize these problems.

Then, using a list of 100 items compiled by De Filippi and Melhado (2015) as a research protocol on a field survey, the authors analysed which of these items influenced the delays of 50 Brazilian construction projects, in the last eight years. The sources of evidence for this analysis were interviews with those responsible for the projects planning and control, besides documents related to the project (plans, schedules, management reports, etc.).

The resulting data were also analysed and classified, resulting in a ranking about the Brazilian scenario.

Based on this ranking, the tools and guidelines by several authors were compared. This study supported guidelines generation to prevent the occurrence of the major causes.

These guidelines were structured as a proposal to improve time management. The application of these guidelines was discussed for developing a time management model (paths supporting the creation of structured methods to overcome the main causes of delay).

3. Literature review on studies into the delay in construction projects

3.1 Delay causes and interference with project time management

Recent researches, such as Fugar and Agyakwah-Baah (2010) in Ghana, Doloi *et al.* (2012) in India, Gunduz *et al.* (2013) in Turkey, Haseeb *et al.* (2011) in Pakistan, Marzouk and El-Rasas (2014) in Egypt and Mydin *et.al.* (2014) in Malaysia, identified the general causes of delay that occur in projects in their respective countries. A number of them allowed verifying different causes of delay and its importance (hierarquy). According to the authors, identifying the most impacting helps professionals and researchers to seek alternative solutions to mitigate delays.

Olawale and Sun (2010) presented an extensive survey on causes of delay with 250 construction companies in the UK, and listed a number of researches on the subject published in a 25-year period, by Ardini *et.al.* (1985 cited by Olawale and Sun, 2010) until the date of its publication.

Other papers discussed the main causes, such as El-Razek *et al.* (2008) in Egypt, which highlighted "financial issues" and "design changes", or Aibinu and Odeyinka (2006), in Nigeria, identifying some main causes, such as "actions and omissions of the project participants" and "external factors".

Assaf and Hejji (2006), in a study in Saudi Arabia, revealed that the most common cause of delay identified in their survey was "change in orders". Yang and Wei (2010) identified similar situations and described that "changes in customer demand" are the main causes of delays and these problems occur in the planning and design stages.

In Brazil, some authors not focused on construction, but who study project management in general, presented very interesting discussions that contributed to this article.

Elder (2006), using TOC (Theory of Constraints) concepts, presented by Goldratt and Fox (2002), established five reasons for projects not to achieve their results, especially the planned deadlines: (i) harmful multi-tasks (constantly changing priorities); (ii) Parkinson's Law (work expands to fill the time available). (iii) Student Syndrome (procrastination of work); (iv) dependency between tasks (probability of dependent events); (v) the termination of an activity does not mean that the other will be started immediately.

Other authors studied how these causes were related to other problems or practices in construction management. In a current survey in the USA, Russell *et al.* (2014) identified not only the causes of time variation in projects, but also the most serious reasons for adding time buffers for the durations of construction tasks.

Several authors, including Rogalska and Hejducki (2007) and La Garza *et al.* (2007) discussed the use of buffers as an improved programming tool and time control over projects.

Nepal *et al.* (2006) stated that accelerating a project can be rewarding but the consequences can be problematics when productivity and quality are sacrificed to keep ahead of schedule. Productivity directly affects the delays, according to Hanna *et al.* (2005), who studied the impacts of overtime with extended duration of the projects.

3.2 Actions to avoid delays and to improve time control

Many of the issues discussed by several authors established guidelines or tools to improve the methods used by managers in their projects.

One of the aspects studied by many authors regards the adequacy of classical planning tools to manage project deadlines. In Malaysia, Abdul-Rahman *et al.* (2006) described the importance of applying appropriate management to deal with the delays in the construction of developing countries.

Although one of the project features is its uniqueness, there is a great repeatability of tasks in construction projects. Different authors identified alternatives to organize the processes when there are repetitive activities or when the projects can be repeated with few changes.

Vanhoucke (2006) affirmed that in repetitive projects, a major goal of the planning is to maintain the continuity of the work and to minimize the downtime of resources.

Under these conditions, traditional tools such as CPM - Critical Path Method would be too complex or they would not add the value expected. In projects with this feature, several authors such as Mattila and Park (2003), Fan and Tserng (2006), Kallantzis *et al.* (2007), Lucko (2008), and Hegazy and Menesi (2010) studied the use of linear programming tools or a repetitive scheduling method, along with their limitations and risks.

Some authors analysed other CPM limitations. Kim and La Garza (2003) stated that a traditional schedule based on CPM is not realistic, because it assumes unlimited resources. Ibbs and Nguyen

(2007) described that the delay analysis without the resource allocation practice substantially affects the results. Some delay may cause the unrealistic allocation of resources in the subsequent service, which could further delay the project.

Yi *et al.* (2002) and Barraza (2011) declared that tools such as CPM constitute a logic established by intuition and human experience; therefore, it could mean that there is a variety of alternative networks and this can bring inconsistencies in planning.

Arditi *et al.* (2002) attempted to establish improvements in the use and representation of the line of balance tool, including the development of an algorithm that improves the project acceleration with efficiency, dealing with resource constraints and deadline milestones, and a new concept of criticality, including the learning curve effect.

Kim and La Garza (2005) advocated the use of the Critical Path Method with multiple calendars to effectively represent the various project conditions, such as site properties, the availability of resources, weather conditions, etc.

In Brazil, a survey conducted by Quelhas and Barcaui (2004), not for the construction market analogously to Elder (2006), described the concept of CCPM (Critical Chain Project Management) as the application of TOC (Theory of Constraints) to the project environment. The authors suggested how best actions: (i) reduction of safety margins per task; (ii) reduction of multitasking; (iii) use of dependencies also based on resources and not only on predecessors; (iv) use "later start dates" to the tasks; and (v) use of buffers at the end of the critical current (project buffer).

4. Classifications of causes of delay

The paper by De Filippi and Melhado (2015) brought a correlation of the main researches classifying the causes of delay. The authors sorted them into groups common to most authors[1], as can be seen in Table 1.

While there are several other studies related to project delays, we chose surveys that effectively brought qualitative descriptions and frequency as they appear in the construction projects in each of the countries where the surveys were conducted.

[1] the authors are references in the paper De Filippi and Melhado (2015)

Table 1: Classifications of causes of delay (De Filippi and Melhado, 2015)

Group	Authors[1] / Delay Causes	Abd El-Azek et al. (2008)	Aibinu & Odeyinka (2006)	Alwi & Hampson (2003)	Assaf & Al-Hejji (2006)	Chan & Kumaraswamy (1997)	Couto (2007)	Faridi & El-Sayegh (2006)	Fugar & Agyakwah (2010)	Gunduz et al. (2013)	Lo et al. 5. Field survey

For the field survey, an extended protocol was used, based on Table 1 items. The protocol aimed to ensure that all possible causes of the delays would be verified in all the projects, acting as a research guide.

Based on the monthly reports of each project, which described physical performance and the facts interfering with the schedule, it was possible to analyse when and why problems occurred along these projects and their impact on the deadline.

Complementing the analysis of the facts, interviews with the project professionals were made, mainly with the planning team. Interviews were able to recover some hidden problems in reports.

The sample sought elements from different economic realities. However, so that the results could be compared, it sought projects with some similar features such as:

- Residential or commercial real estate projects, in several different construction companies;
- Vertical buildings (towers) with more than 10 floors (where there is repeatability);
- Projects with at least 5% delay (which had clear problems in the schedule).

Based on these specifications, 50 projects were selected. They presented these characteristics:

- 15 different locations: projects in São Paulo City (33), projects in other cities in the State of São Paulo (12), projects in cities in other States (5);
- 24 constructors: small/local firms (12), medium/regional companies (7); large companies (5);
- Built-up areas: 8,140 to 80,750 sq. meters;
- Number of towers: one tower (25), two (11), three (7), four (5) and six (2);
- Project time foreseen: 13 to 35 months;

Using the history of each project throughout its execution phase, we performed a qualitative assessment of the facts that caused partial delays in scheduled activities and their sum resulted in significant final delays (more than three months, at least).

This survey did not identify which facts more significantly affected the final delay (those most affecting the critical path), but how often they occurred in the projects. Later, in a more comprehensive research, the classification of these impacts was also studied.

We identified in how many projects (of all the 50) each cause was found (in reports or interviews) and this result was characterized as the "frequency" of occurrence. In addition, to facilitate the analysis of the results, the frequency was ordered, creating a ranking as shown in Table 2.

Only the results above 40% of frequency in the rank were analysed, considering that the other items not were impactful or they were outside of the critical zone for future analysis.

Table 2: Rank of delay causes in construction projects

Cod.	*Description*	*Group*	*Frequency*
a	*Poor site management and supervision*	*5*	*68,0%*
b	*Sub-contractor's interference with the site operations*	*5*	*66,0%*
c	*Ineffective project planning and scheduling*	*5*	*60,0%*
d	*Low worker productivity*	*7*	*60,0%*
e	*Slow mobilization of labour*	*5*	*54,0%*
f	*Rework due to errors*	*5*	*54,0%*
g	*Late delivery of materials*	*6*	*48,0%*
h	*Labour work shortage*	*7*	*46,0%*
i	*Delays in internal production decisions*	*5*	*44,0%*
j	*Inappropriate physical reprogramming*	*5*	*42,0%*
k	*Conflicts over sub-contractors scheduling during project execution*	*5*	*42,0%*
l	*Poor procurement process or material delivery programming*	*6*	*42,0%*
m	*Unreal duration of original contract (too short)*	*1*	*42,0%*
…	*Delay in sub-contractors' activities / tasks*	*5*	*38,0%*
	Slowness in decision making by owner	*2*	*36,0%*
	Slow mobilization of equipment	*8*	*36,0%*
	Inadequate definition of project scope or construction product	*1*	*30,0%*
	Poor / inefficient sub-contractor supervision	*5*	*30,0%*
	Frequent change in subcontractors	*5*	*30,0%*
	Unfavourable weather conditions	*10*	*30,0%*
	…	…	…

In Table 2, group 05 (contractor) held the greatest concentration of delay causes. In almost 2/3 of the projects studied, there were problems related to inappropriate use of planning tools and to managing the work teams.

Low productivity problems also appeared with great frequency, the only featured item that was not in group 05.

Then, less highlight, but also important, procurement items were also listed in the survey, which included not only the buying process, but also "delivery delays" and "shortage of labour ".

6. Discussion

Based on the literature and experiences of this paper's authors, we sought to identify, several guidelines related to the focus of this study. It focused on minimizing problems, especially those related to Group 05 (team management in construction, correct planning, rework and reprogramming).

The actions can be grouped into just four groups, which are the most frequent causes in research results and coded as the first column of Table 3, as shown below:

Table 3: Guideline to treat the main causes of delay

Guideline Group	*Cause Code*
I. Planning of bold goals without the inclusion of random floats, but with realistic assumption of estimate;	*c,d,j,m*
II. Establishing the continuity of services, ensuring the end of the activity before starting the next task;	*b,d,f,g,h,k,l*
III. Constantly identifying operational constraints and their elimination with the deployment of simple systematic risk management	*a,d,e,f,j*
IV. Clear definition of hierarchy in decision and elimination of slowness or lateness in decisions affecting the critical path.	*a,e,i,k*

For each guideline, the authors suggest some activities that could be implemented in a structured way in each project. These will be later used as the basis of a management method. See Table 4.

These actions were based on recommendations of several authors, as presented in Section 3.2 or in the analysis of good current practices effectively observed in some of projects belonging to the sampling of the field survey described in Section 5 (but not were in this article).

7. Conclusions

As evidenced, the most significant causes of delay identified were relatively different from those presented by the authors surveyed. The main problems were more concerned with internal issues, organization of construction site or the management of the construction companies hired, than with external issues.

Thus, the authors of this paper identified the importance of investing in qualifying, systems or planning and control methodologies, even if they are simplified. A number of delays are verified to derive from external factors (rain, soil, market, customer, etc.) and the apologies to justify the delays are usually based on these aspects. Yet these factors were identified as less relevant.

Similarly, the results of this research can be useful to promote studies to identify causes of delay in different kinds of projects (such as horizontal constructions or in other regions of Brazil with different characteristics) or to establish more detailed actions or methods that help reduce the problems of delays.

This fact further motivates the studies into the theme showing that it is necessary to apply efforts to understand processes, tools, resources, and their relation to the project success.

Table 4: Actions for improving operational planning

Guide	Suggested practice	Actions suggested for improving operational planning
I. Realistic schedule and bold goals	Establishing "most likely" durations to define the project baseline	- Not accepting the most favorable scenario as a reference; - Establishing details of the inicial schedule (at least in the critical paths); - Validating schedule references identifying risks in task completion; - Separating the contractual dates and the target operational dates (realistic references vs. best scenario to target planning).
I. Realistic schedule and bold goals	No float in each task / controlling with safety buffers	- Avoiding Parkinson's Law (resource demand tends to expand to the total resourse offered) and the Student Syndrome (planned procrastination); - Include controlled buffers only in the critical path.
I. Realistic schedule and bold goals	Calendars differentiated by activity type	- Forecasting of rain days not worked (services affected); - Including regional characteristics, local restrictions; - Analysing seasonality, market realities or partners' restrictions.
II. Establishing continuity of services	Avoiding high productivity periods	- Stabilizing production (cadence of tasks); - Applying line of balance; - Prioritising the work teams maintenance.
II. Establishing continuity of services	Guarantee of task completion	- Not accepting rework of tasks; - Not anticipating activities that do not add value to project; - Incorporating learning curves in production estimative.
II. Establishing continuity of services	Anticipating procurement activities	- Validating previously the task quantitatives; - Placing material orders in advance (critical path items); - Defining compatible delivery schedules; - Transparency in negociating and in managing suppliers (fidelity); - Join into service orders both "easy activities" such as "hard works".
III. Management focusing on restriction identification and its elimination	Identifying and removing tasks restrictions	- Eliminating the programming restrictions previously; - Action plan for recovering unfulfilled items or avoiding reoccurrence; - Developing database with more common items (restrictions check-list).
III. Management focusing on restriction identification and its elimination	Identifying and monitoring the planning assumptions	- Establishing main services variables towards productivity control; - Formalising plan of attack with leaders and team workers - Defining detailed schedules for critical path services; - Develoingp contingency plans / anticipating alternatives to recovery.
III. Management focusing on restriction identification and its elimination	Managing risks of task completion	- Quantifying the risks to identify the critical ones; - Highlighting the critical path activities that will be carefully controled; - Checking the best moment of intervention (triggers); - Defining schedule milestones to control.
IV. No slowness of decisions	Identifying schedule priorities	- Identifying responsibility and decision deadlines with formal methods; - Establishing a priority list based on the impact on the critical path;
IV. No slowness of decisions	Proactive and immediate actions	- Knowing who is responsible for the activities and treating the problems directly with them and as soon as possible (war room concepts). - Applying the GEMBA concept, solving problems in the "real place" (production site, where value is created).

Abstract

Earthquakes are low probability, high consequence events which are known to cause significant damage. Small to medium-sized enterprises (SBEs) are particularly vulnerable to impacts arising from such disasters, including: business disruption, employee health and safety, financial strain, or even total loss of business. Owners of these SBEs can make a few key decisions to prepare their businesses for an earthquake, in order to ensure business continuity and the wellbeing of their employees. This study sought to examine the level of earthquake preparedness of SBEs located in high seismic risk regions by examining the extent of mitigation measures adopted five years post the Canterbury earthquake disaster. Using a mixed-methods research approach, combining both qualitative and quantitative data, the research findings revealed that a majority of SBEs operating in regions of high vulnerability to disaster are underprepared for a potential earthquake disaster, despite the general increased awareness of earthquake risks in New Zealand. Cost, time, insurance processes, and access to disaster mitigation information, were identified to be the most important and constraining factors in the overall decision-making process. The research findings will provide strategies to local authorities on how to assist SBEs in making better informed preparedness decisions, ultimately improving their resilience to earthquakes, and thus improving the resilience of the New Zealand community as a whole. How Prepared are Small Businesses for Another Earthquake Disaster in New Zealand?

Keywords: Small business enterprises (SBEs), earthquake, preparedness initiatives, New Zealand

1. Introduction

The severity of the recent 2010/2011 Canterbury earthquakes demonstrated the vulnerability of communities which are inadequately prepared for such disasters. These earthquakes created significant economic and social strains on the Christchurch region, as a result of a large drop in economic activities within the central business district (CBD) of the city, and generally on the New Zealand economy. Consequently, this resulted in a staggering 34.6% drop in the number of businesses operating (Statistics New Zealand 2012). Buildings which have insufficient seismic capacity – termed "earthquake-prone buildings" (EPBs) – have been found to contribute to major losses during an earthquake (Egbelakin, 2013). An EPB is considered to be a building that will have its ultimate structural performance capacity exceeded in a moderate earthquake, and would likely collapse causing injury or death to persons in the building or to persons in another property or damage to adjoining structures (Department of Building and Housing 2004). The definition of an EPB contained in the Act is the legislative expression of the New Zealand Government's policy objective to reduce the level of earthquake risks posed by EPBs to the public. These buildings are particularly vulnerable to impacts from an earthquake disaster, due to being built from inadequately strong construction materials, and prior to advancements in seismic design codes, specifically since 1976 (Egbelakin 2013).

The Ministry of Business, Innovation, and Employment define an SBE as one which consists of between 0 to 20 full-time employees (Ministry of Business & Innovation and Employment (MBIE) 2014). These enterprises are a prominent part of New Zealand's economy, collectively make up 99.0% of the nation's business population, and contribute to approximately 30% of the national GDP (Ministry of Business & Innovation and Employment (MBIE) 2014). The majority of SBEs reside in the CBD (Burgess 2008). It is common to find a large proportion of the city's old building stock in the CBD, which are likely to be earthquake-prone due to their age and construction materials. SBEs are the majority leaseholders of these EPBs due to attractive rent prices and greater accessibility to customer foot traffic whilst residing in the CBD (Murphy 2007). Due to inherent risks posed by residing in an EPB, these SBEs are highly vulnerable to damage and losses from a potential earthquake disaster, as evident in the Canterbury earthquakes.

The decision-making process a business owner follows in order to prepare for an earthquake is crucial for maintaining business operations, and post-earthquake continuity, as well as for ensuring employee health and safety. The business owners who are tenanted in these buildings are likely to make a few key decisions regarding earthquake risk mitigation: adopt appropriate risk mitigation measures; accept the risk and do nothing about it; or ignore the risk completely (Egbelakin, 2013). Despite the rising intensity of low probability and high magnitude earthquake disasters, there is a consistently low rate of earthquake preparedness generally in New Zealand. Moreover, earthquake preparedness of local businesses is vital for local communities, whose economic prosperity depends on the types of mitigation decisions made by the owners of SBEs. Mostly, collective losses of these businesses generally devastate the local economy (Yoshida and Deyle 2005). Thus, this has created a need for a study to evaluate the types of decisions and earthquake mitigation initiatives implemented by SBEs, in order to alleviate the damage caused by these disasters. Hence, this study sought to examine the level of earthquake preparedness of SBEs located in high seismic risk regions by examining the extent of mitigation measures adopted five years post the Canterbury earthquake disaster. The research findings will provide strategies to local authorities on how to assist SBEs in making better informed preparedness decisions, ultimately improving their resilience to earthquakes, and thus improving the resilience of the New Zealand community as a whole.

2. SBEs Disaster Preparedness

A plethora of research exists regarding businesses and their preparation for earthquakes. Studies into earthquake preparedness have been conducted predominantly internationally, and also in New Zealand, as a result of several earthquakes since 2007. Disaster preparedness can be regarded as any activity which is implemented in order to reduce damage caused by a natural disaster such as earthquake (Alesch, Holly et al. 2001). There are several of ways an SBE can mitigate risks posed by an earthquake disaster; these are termed earthquake risk mitigation measures or initiatives. Implementing these measures is vital for the resilience of an SBE, as they reduce the seismic risks that they can be exposed to, allowing them to thrive and find opportunities in times of distress (Stevenson, Seville et al. 2011). Several mitigation measures exist which are available for SBEs to implement. These comprise reasonably technical measures such as the purchase of earthquake insurance, and also less complicated low-effort measures such as employee disaster preparation. Despite the abundance of ways which an SBE can prepare for an earthquake, consistently low earthquake preparedness is reported by SBEs in New Zealand (Brown, Seville et al. 2013). Several factors have been identified in the literature to affect SBE owners' decisions to prepare for an earthquake and these are discussed in a subsequent section. The most significant ones will be outlined below.

2.1 Business Characteristics

The ability of an SBE to implement earthquake risk mitigation measures was found to be dependent on certain factors, which are inherent in the nature of the business and its physical operating environment. The size of the business, measured by the number of full-time employees, was consistently found to affect business' earthquake preparedness (Chang and Falit-Baiamonte 2002). According to Brown et al. (2013), small businesses are particularly vulnerable to the damage resulting from an earthquake due to a lack of resources; both in terms of finance and staffing that could be devoted to potential earthquake risk mitigation measures. Large businesses, on the other hand, are more readily able to raise finance due to their ease in accessing business reserves (Chang and Falit-Baiamonte 2002). They are more able to devote greater resources towards possible mitigation measures, and therefore exhibit a greater sense of preparedness compared with SBEs. Drabek (1991) found that businesses in operation longer than six years were involved with greater disaster planning. These older firms are more prominent, have greater financial resources, and more opportunities to consider earthquake planning in their daily business operations. Owning the building in which the business operates, as opposed to leasing, was found to be significant. Dahlhamer and D'Souza (1995) found that owners of the business property were more likely to adopt disaster preparedness measures than lease-holders. Webb, Tierney et al. (2000) explained that the owners of the building have more to lose than lease-holders in the event of an earthquake, which indicated they are more likely to be place greater importance on earthquake planning.

Many older buildings with the potential of being earthquake-prone located in the CBDs of many cities and towns in New Zealand are more likely to be impacted by a potential significant earthquake (Egbelakin 2013). Many SBEs are likely to be tenanted in these EPBs. These businesses are highly vulnerable to the damage dealt from earthquakes and business operations within the community in general, as was evident from the Canterbury earthquake (Brown, Seville et al. 2013). Also, whether a business is independently owned at a sole location, or if it is part of a franchise operating in multiple locations, plays a huge part in the overall decisions they make. Franchise firms have an ability to spread their risk across multiple locations (Dahlhamer and Tierney 1998). These firms have the added benefit of being at ease with regard to financing their capital and starting up costs, as they can be funded by the franchiser. Businesses operating in the insurance, finance and real estate sectors were generally better prepared for disasters (Yoshida and Deyle 2005). This is mainly due to the fact that these businesses have high regulations, and have greater awareness of risk due to the inherent nature of their work.

2.2 Behavioural Factors

Several behavioural factors could affect how owners or managers of SBEs make disaster preparedness decisions. Past experience in a disaster could intuitively enhance readiness for a disaster in the future (Egbelakin, Wilkinson et al. 2011). The decision-making process may require an individual to identify a risk, perceive and assess the risk, and through trade-offs between risks and rewards, come to a final decision on whether or not to mitigate the risk (Egbelakin, 2013). An individual's awareness of the risks they are subjected to, and how they perceive and respond to them, is critical in influencing the final decision carried out (Slovic 2001). Given that perception of risk is regarded to be the one of the most notable barriers to adopting earthquake preparedness measures (Egbelakin & Wilkinson, 2010), this facet is important to consider when studying the decision-making patterns of SBE owners. A study carried out by Egbelakin, Wilkinson et al. (2011) aimed to understand potential behavioural factors which hindered the decision-making process of seismic retrofitting in New Zealand found that many respondents have fatalistic mind-sets and were not concerned about the risks associated with an earthquake disaster, and were unlikely to implement mitigation measures in the future. Fatalistic mind-sets may be attributed to hazard anxiety, and consequently a denial of risk (Paton 2003). Moreover, Webb *et al.* (2000) emphasised that businesses which showed drastic improvements in their preparations were ones which had already prioritised planning, and had the resources to do so. This is further supported by the findings arising from the study conducted by Powell and Harding (2009), which explained that "the careful become more careful" and those who didn't have any mitigation measures in place before the disaster were less likely to employ more measures after.

Legislation plays a key role in earthquake risk mitigation in New Zealand. The Building Act 2004 contains provisions which address EPBs. TAs are required to implement an earthquake-prone building policy, to lessen the seismic risk from EPBs, such that a perceived level of safety is developed (Egbelakin, 2013). In addition, depending on the approach taken, the TAs requires building owners to have an engineer assess their buildings, if necessary, for potential seismic risk. This is vital for business owners, especially ones who are tenanted in an earthquake-prone building. Decisions revolving around seismic strengthening are beyond their grasp, and they must rely on their landlord (the building owner) to act. Knowledge and awareness of these practices is essential in the decision-making process.

2.3 Business Operations and Emergency Planning

The ability for a business to survive a major disaster depends on the organisational structure and operations systems in place (Seville et al., 2008). In New Zealand, prevention of harm to all persons at work and other persons in the vicinity is promoted by the Building Act (2004) and Health and Safety Act (2013). The Health and Safety Management Act was enacted to ensure that employers, and their representatives, adopt practicable steps are taken to ensure the safety of their staff while at work. It is expected that a procedure for dealing with emergencies that may arise during business hours is in place and that this information is readily accessible. Also, safety and emergency policy and practices adopted by the organisation should be known to all employees.

3. Research Methods

A mixed-methods research approach was adopted in this study, combining both qualitative and quantitative data, because of the nature of the research objective, and to overcome deficiencies intrinsic to a single research approach. The basis for this choice was due to the exploratory nature of this study, which was very similar to the study which Egbelakin (2013) conducted on building owners. An online survey was conducted using a questionnaire as the data collection instruments for the quantitative study, which mainly assesses the profile of the SBEs, decision-making processes and the factors that were significant to affect an SBE to implement mitigation measures. Semi-structured face-to-face interviews were undertaken for the qualitative study, in order to gauge a more in-depth understanding of respondents' behaviour. This type of interview allows the researcher to "probe" for in-depth information. In order to ascertain a sample for data collection, a database was formed using data provided by the Napier City Council. The information contained a list of the addresses of approximately 167 SBEs located in the Napier CBD, and mainly in EPBs. Napier was selected as a case study to represent a high seismic hazard region in New Zealand. The selection criteria were predominantly based on: a high seismic hazard factor, Z, of 0.38 (Standards New Zealand, 2004); and the occurrence of a previous significant earthquake disaster in the region in 1931 (Hawke's Bay Earthquake). This earthquake resulted in the emergence of a unique Art Deco architectural style for older buildings within Napier, which has attracted great interest from the local community and the tourism industry. There is a large heritage importance placed on these buildings by the community, and it is therefore necessary to enhance decisions made by SBEs operating in such buildings. Both questionnaire and interviews were administered in one of New Zealand regions susceptible to high earthquake risks; Napier. Care was taken to exclude the interview participants from the survey. Industry experts reviewed the findings for comments and confirmation in order to establish data validity. A total of 42 questionnaires were returned out of 167 sent out. Only 38 were usable surveys due to a large amount of missing responses, generating a response rate of 23%, which is expected for a study of this nature and is similar to that found in previous studies. The extent to which an SBE was prepared for an earthquake was measured by counting the amount of mitigation measures they had implemented as at the present time, out of a possible 21 measures. Potential disaster preparedness measures an SBE could have implemented are summarised in Table 2. A variety of mitigation measures are covered and grouped under four categories, namely knowledge enrichment, insurance and business continuity, business survival, and structural and non-structural mitigation (see Table 2 for details).

4. Results

4.1 Respondents Profile and Business Characteristics

The respondents' profiles and business characteristics are summarised in Table 1. The respondent comprises mainly micro and small businesses (90%).Therefore, the research results and findings results are limited to the research participants. Half of the respondents are business owners, and the rest were personnel acting on behalf of the owner. Sixty-three percent of respondents are above 40 years of age, and 42% of the predominant ownership comprised of female business owners (42%) and combined (male and female) ownership (42%). Seventy-four percent of these SBEs were micro-sized and 58% have been in business for at least 10 years. All SBEs were reported to be operating in the CBD, with 79% operating in the retail sector. Eighty-seven percent of SBEs are located on the building's ground floor level. More than half of the SBEs were operating in a sole location of a locally-owned business, and all were in a separate location for their business (i.e. not operating from home). A majority of the SBEs surveyed in this study leased the building in which they operate. Almost all respondents (95%) had experienced an earthquake in the past. It is interesting to note that only 29% of respondents had been in an earthquake causing physical building damage. Nearly all respondents reported no damage to their personal well-being or their business from the last earthquake they had experienced (86% and 92% respectively).

Table 1: Respondents' profiles and business characteristics

Respondents' Profiles		*Frequency*	*%*	*Business Characteristics*		*Frequency*	*%*
Type of Respondent	*Business Owner*	*19*	*50*	*Size of business / Number of full-time employees*	*1 - 5 (micro)*	*28*	*74*
	Director	*1*	*3*		*6 - 19 (small)*	*6*	*16*

4.2 Earthquake Mitigation Initiatives of SBEs located in High-Risk Regions

The extent to which an SBE was prepared for an earthquake was measured by counting the amount of mitigation measures they had implemented at the present time, out of a possible 21 measures. Table 2 provides a summary of disaster preparedness measures an SBE have implemented. A variety of mitigation measures are covered and include: knowledge enrichment, insurance and business continuity, business survival, and structural and non-structural mitigation. The respondent's sense of earthquake prepared was categorised based on the number of mitigation measures they had implemented, being: 0-5 (underprepared); 6-10 (somewhat prepared); 11-16 (prepared); and 17-21 (highly prepared). The research findings showed that SBEs were found to have mainly implemented low-effort, less technical mitigation measures, such as insurance, first aid kits, employee preparation, and data backup. These measures are generally easy to acquire and take less time compared to more complex measures such as the seismic retrofitting of buildings and implementation of business disaster continuity plans. Regarding insurance and business continuity plans, a majority of the SBEs had purchased business contents insurance (61%), and 55% had purchased business interruption insurance. In contrast, only three SBEs had developed a business continuity plan, while only one had a business relocation plan. Concerning the knowledge enrichment disaster preparedness activities, a majority of the respondents have discussed with their employees about what to do in the event of an earthquake (42%), while 32% have provided written information on earthquake preparedness to their employees, and 13% of the participants regularly conduct earthquake drills with their organisation. Sixty-three percent did not know whether their building was earthquake-prone or not, and about 50% of the respondents were not aware of the seismic assesSBEnt practice. Overall, the respondent's sense of earthquake prepared was categorised based on the number of mitigation measures they had implemented. The research findings showed that 66% of the SBEs are very underprepared for survival in the occurrence of another major earthquake in the region (see Figure 1).

Table 2: Earthquake risk mitigation measures initiatives adopted by SBEs

Earthquake risk mitigation measures initiated adopted by SBEs	*Frequency*	*%*
1. Knowledge Enrichment Disaster Preparedness Activities		
Talked with employees about what to do in the event of an earthquake	*16*	*42*
Have written information on earthquake preparedness	*12*	*32*
Attended a first aid course	*9*	*24*
Earthquake drills or exercises for your employees	*5*	*13*
Earthquake preparedness or training programs for your employees	*1*	*3*
2. Insurance and Business Continuity Plans		
Purchased business contents insurance	*23*	*61*
Purchased business interruption insurance	*21*	*55*
Purchased earthquake insurance to cover damage to building	*10*	*26*
Developed a business disaster recovery plan	*3*	*8*
Developed a business emergency plan for event of earthquake	*3*	*8*
3. Business Disaster Survival Actions		
Obtained first aid kit, extra medical supplies	*18*	*47*
Stored water and canned food	*6*	*16*
Stored extra fuel or batteries	*5*	*13*
Business relocation plan	*1*	*3*
Obtained an emergency generator for power failure	*0*	*0*

Earthquake risk mitigation measures initiated adopted by SBEs	*Frequency*	*%*
4. Structural and Non-Structural Measures Implemented		
Ensured computer and electronic data backup	*20*	*53*
Engineer conducted a seismic assesSBEnt	*12*	*32*
Secured shelves, cabinets or objects	*11*	*29*
Ensured heavy objects are stored on the floor	*10*	*26*
Secured business records and supplies	*6*	*16*
Retrofitted the building to higher seismic performance	*4*	*11*

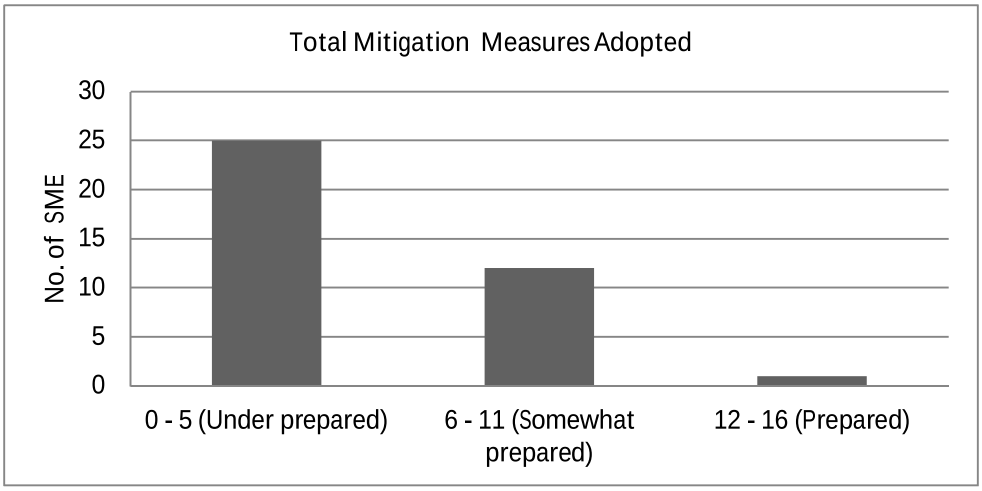

Figure 1: Summary of mitigation measures adopted by SBEs

5. Discussion of Findings

The capability of a business to implement earthquake risk mitigation measures was found to be dependent on certain factors, which are inherent in the nature and characteristics of the business, and its physical operating environment. SBEs in Napier were found to be underprepared for a potential earthquake disaster. Only five earthquake risk mitigation initiatives or measures were implemented, on average, out of a possible 21 options. This finding is similar to previous research conducted in the USA by Han and Nigg (2011). The low rate of preparedness is surprising given the region's high vulnerability to earthquake occurrence. Intuitively, a greater concern towards earthquakes would be expected due to Napier's location in a high seismic hazard zone, and its historical and cultural underpinning due to a past earthquake in 1931. Interestingly, 74% of respondents believed it was important to give consideration to earthquakes in relation to their business operations, yet a vast amount of the participating SBEs were inadequately prepared for a potential earthquake disaster. One of the respondents wrote that "Napier is making its tourist trade a little bit on the fact that it's been through an earthquake, and so I think the knowledge of earthquakes in Napier is pretty good". Due to the region's increased awareness of earthquakes, individuals may have become complacent when giving thought to earthquake preparation. Some business owners were reported to express a sense of optimistic bias and complacency in their approach to disaster preparedness initiatives.

In addition, the majority of respondents who took part in the questionnaire were greater than 40 years of age. The research findings revealed that concern for earthquakes decreased greatly as the age of an individual increased. This may be explained by a complacent or fatalistic attitude which manifests with greater age. When asked if there were specific factors which influenced their preparation for an earthquake, one interviewee mentioned that: "It's quite nice to think that you're a bit secure because you do have the earthquake proofing done up to a standard, but I'm a bit fatalistic to be honest". Many of the respondents demonstrated similar behaviour during the face-face data collection, strongly expressing that earthquakes were an inevitable event, and no amount of preparation would be useful. Due to the large number of older respondents, there may be a prevalence of a fatalistic attitude, resulting in a lesser perception of risks and mitigation measures. This is similar to the findings of Egbelakin, Wilkinson et al. (2011), and this therefore negatively impacts overall earthquake preparedness. This finding is intriguing as one would expect individuals residing in high seismic hazard regions to exhibit more concern about earthquakes.

The size of an SBE measured in terms of the number of full-time employees could be attributed to the number of mitigation initiatives or measures adopted. A majority of SBEs had less than five full-time employees, and hence could be less prepared for an earthquake due to lack of resources to devote to disaster preparedness, and therefore lack the ability to have access to staff, and experts, specialising in disaster mitigation. This may provide a possible explanation as to why such a low sense of earthquake preparedness was observed. In addition, SBEs normally have greater financial constraints than their larger counterparts. A firm's financial capabilities have been proven to be a potential impediment in the preparedness process from past literature. As expected, cost and time were identified in the survey to be the important and constraining factors in an SBE's earthquake preparedness decision. Furthermore, respondents were found to have a low awareness and knowledge of building seismic assesSBEnt procedures. This is interesting given Napier's history with a previous devastating earthquake; one would expect that the respondents would be more proactive in their understanding and knowledge of seismic risks regarding the building in which they operate their businesses. The low level of awareness and knowledge of the building seismic risks may explain the low preparedness in Napier. For those respondents who were aware of seismic assesSBEnt procedures, it was reported that there were issues in consistency. One interviewee stated that: *"What I've noticed is there doesn't appear to be a consistent application of the rules, or understanding of the policies and I think there's been a frustration in that, businesses have found that engineers say one thing, and then another engineer comes around and says 'what were they talking about?'"* These disparities create confusion for SBEs, and complicate the decision to adopt risk mitigation measures (Egbelakin, Wilkinson et al. 2011). A low perception of risk was observed by SBEs in Napier. As discussed above, given the region's history with a prior earthquake, one would expect a greater perception of risk. The low perception may be due to the fact that 71.1% of respondents had not been in an earthquake causing physical building damage. Past experience with an earthquake may affect an individual's perception of hazard exposure.

6. Conclusion

The objective of the study reported in this article is to examine whether SBEs located in regions of high vulnerability to seismic hazard are well prepared by adopting a range of earthquake preparedness initiatives. The research findings revealed that SBEs having less than 20 employees located in Napier were generally underprepared in the event of a potential earthquake disaster, and an average number of five mitigation initiatives or measures were observed out of a total of 21 initiatives. There is a general lack of knowledge and awareness of seismic assessments and risks posed by the building from which they operate, which could be due to the fatalistic attitudes, or a sense of complacency exhibited among the respondents. Cost, time, insurance processes, and access to mitigation information, were the most important and constraining factors for SBEs in preparing for an earthquake. SBEs need to be better informed about seismic assessment procedures. In particular, communication between TAs, building owners, and business owners must be enhanced. In addition, the local authority approach requires some form of increased consistency in building seismic risk assessment results, to allow a greater understanding of the potential risks for SBEs. SBEs need to have greater access and exposure to reliable and effective mitigation measures which have been proven to work. These must be provided by credible individuals or organisations, in order to motivate SBEs to become more active in earthquake planning procedures.

Achieving Incremental Cost Reduction via Kaizen Costing in the Nigerian Construction Industry

Temitope Omotayo,
School of the Built Environment, University of Salford
(t.omotayo@edu.salford.ac.uk)
Udayangani Kulatunga,
School of the Built Environment, University of Salford
(u.kulatunga@salford.ac.uk)

Abstract

Nigerian small and medium scale construction firms are facing challenges of cost and time overruns which have led to project abandonment and liquidation of some of these firms. This is also as a result of large scale dissatisfaction of clients. This study focuses on how to improve the post-contract cost management in Nigerian construction firms by using Kaizen costing. Kaizen presents a better solution to cost and time overruns, and client satisfactions. This method of managing post-contract cost had been proven to create more profit, quality, value and improved relations with the stakeholders involved in construction activities. Incremental cost reduction is the key element of Kaizen. The most critical activities which can influence kaizen costing implementation in the Nigerian construction industry are addressed in the paper.

This investigation identified eight crucial activities for continuous cost reduction from literature. Based on the existing literature, a Likert scale questionnaire was produced. Data was gathered from one hundred and thirty-five (135) cost and project managers in Lagos, Nigeria. The Kendall's coefficient of concordance was used to test the identified activities based on the agreement of the respondents. Important activities were ranked by respondents. The findings identified "overhead cost related to paying suppliers, sub-contractors and labourers can be reduced continually throughout the construction phase to keep the project cost within budget" as the most critical activity for continuous cost reduction during Kaizen costing. Assessing the essential procedures carried out during construction creates an avenue to implement Kaizen philosophy and Kaizen costing in a developing economy such as Nigeria. Therefore, the benefits of Kaizen are easily transferred for alleviating the challenges of cost and time overrun, effective post-contract cost controlling, profitability of small and medium scale construction firms and client satisfaction.

Keywords: Activities, cost reduction, incremental, Kaizen costing, Nigeria

1. Introduction

Construction cost management in many countries have been using the same conventional cost management systems since the 1920s from inception (Kern & Formoso, 2006; Owens, Burke, Krynovich, & Mance, 2007; Rad, 2002). Johnson and Kaplan, (1993) as cited by Kern and Formoso (2006) stated that the same cost management system which has been used in the 1920s is still in use in many construction firms. Ostrenga et al., (1998) as cited by Kern and Formoso (2006) noted that traditional cost management cannot provide the precise product cost and the system cost estimation does not include managerial decision making approach which eventually brings a positive impact on the project. Traditional cost management system is the conventional cost management system used since the 1920s. This term is used because of modern systems such as value management system and earned value management system which are operation in many construction firms around the world. However, systems such as the value management system, earned value management system, expert systems, benchmarking and building information modelling have emerged over the last sixty years to redefine the art and science of construction cost management. The enormity of negative factors influencing cost estimates at the pre-tender phase as stated by Ashworth (2010); Oyedele (2015) and Samphaongoen (2010), cost estimates always have latent errors which arises during the construction phase. Therefore, the need to focus more on post-contract cost control by project managers and cost managers during a contruction project is imperative.

Cost estimation in construction has set rules by the Royal Institute of Chartered Surveyors and other Quantity Surveyor bodies in the various countries when construction cost estimates are prepared. Nonetheless, the same problems of cost and time overruns, variations during construction, construction disputes have always plagued construction activities. Ashworth (2010) noted the factors which influence the accuracy of cost estimates as being difference in design information, market conditions, experience of the project manager, project complexity and historical data. In a developing economy such as Nigeria, the challenges facing cost estimation is peculiar.

2. Literature review

This section addresses the challenges facing the conventional cost estimating system in Nigeria, the importance of kaizen costing as an effective panacea to the prevailing cost management challenges and the justifications for this investigation.

2.1 Factors affecting traditional cost estimation in the Nigerian construction industry

The unique challenges facing most cost and project managers during estimate preparation are related to a number of factors. Oyedele (2015) highlighted the various influencing factors as:

a) Political situation: Most cost estimates are accurate during stable political times
b) Government policy: Influence of local content investment policies, importation policies, taxes, method of procurement, number of foreign contractors or expatriates are some of the policies which may affect accuracy of cost estimates at a point in time.
c) Economic condition such as inflation, monetary rate, interest rate on lending.

d) The construction season such as rainy season and dry season may affect on-going construction work
e) Geographical location of the project may also affect accuracy of estimates. In places such as the Niger Delta and Northern parts of Nigeria, the accuracy of estimates may be influenced by the topography, swamp or soil conditions
f) Risk emanating from security may also have a drastic effect on the accuracy of construction cost estimates, especially in the Northern parts of Nigeria where there is high level of Islamic insurgency.
g) Years which are close to the general elections in Nigeria have a lot of influence on the cost estimates because prices of building materials are lower and there are a lot of procurement activities and award of contracts.
h) Corruption is a factor which affects cost estimates in Nigeria. Most cases of kickback during procurement have led to inflated cost estimates.

These factors can mar a construction project during the execution phase if they are not addressed. Although, other construction cost management systems, methods and techniques such as earned value analysis, value management, building information modelling may have been applied to curb the excessive cost and time overruns.

2.2 What is Kaizen costing?

Kaizen costing is a continuous improvement technique which emanates from Kaizen, a product of the lean philosophy (Suárez-Barraza & Lingham, 2008; Suárez-Barraza & Miguel-Dávila, 2014; Suárez-Barraza, Ramis-Pujol, & Dahlgaard-Park, 2013). Kaizen costing mean continuous improvement of the cost of production, it was first introduced in the 1960s in Toyota (Arya & Jain, 2014; Brunet & New, 2003; Prošić, 2011; Puvanasvaran, Kerk, & Ismail, 2010). *Therefore, Kaizen costing is the cost management aspect of Kaizen which is usually utilized during the production phase.* The benefits of Kaizen has been transferred to other sectors such as manufacturing , business management, development of small and medium scale industries and construction (Arya & Jain, 2014; Berger, 1997; Puvanasvaran et al., 2010). Several case studies by (Puvanasvaran et al., 2010; Suárez-Barraza & Lingham, 2008; Suárez-Barraza, Ramis-Pujol, & Kerbache, 2011) concluded that Kaizen is very useful for improving manufacturers' profit in this instance contractors, enhancing the quality of products, providing more client satisfaction and encouraging better employee-employer relationship. This aspect of Kaizen is the continuous improvement in the work place. However, the costing aspect involved the process which stems from a Plan-Do-Check-Action (PCDA) process. This process is based on an incremental approach of maintaining and reducing production cost.

This process stands on standardized production. Imai (1997) noted that the three M's in Kaizen are muda (waste), Mura (irregularity) and muri (strain). These three words are the major check points of the Kaizen process. Wastes are identified during the course of construction and eliminated. This lean related concept ensures adequate stakeholders involvement in the overhead cost reduction process. A Kaizen costing team comprising the project manager, architect, cost manager and other relevant stakeholders take on the responsibility of identifying waste and elimination processes. Follow up activities are also carried out during this process for incremental cost reduction.

2.3 Activities for incremental cost reduction during construction

Post-contract cost control activities are based on techniques such as interim valuations, preparation of monthly statement of accounts, cash flow, variation management and monitoring of all activities related to the construction work. There is no technique for continuous cost maintenance and reduction. The traditional cost management technique available in most construction companies do not consider cost maintenance and reduction during construction. Kaizen costing during construction involves specific activities related to transportation, handling of materials on site, overhead cost monitoring and reduction, variations, equipment and plant cost, purchase orders, suppliers' and sub-contractors' cost, planning and preliminary items of work (IFS, 2010; Lin et al., 2001; Ashworth, 2010 $ Sanni and Hashim, 2013). These activities are very delicate and may lead to cost and time overrun if they are not monitored. In kaizen cosing, these activities are monitored for waste, irregularities and strain. The continuous cost redecution process are based on these activities. They are summarized in table 1 below.

Table 1: Cost reduction actitivities required for incremental cost reduction

S/N	COST REDUCTION ACTIVITY	REFERENCES
1	Continual reduction of plant and equipment depreciation overhead cost throughout the construction phase will keep the project cost within budget	Shang and Pheng, 2013; Granja et al., 2005; Suárez-Barrazaa and Lingham, 2008
2	Continual cost reduction of overhead cost of activities related to mobilization and equipment setup will keep the project cost within budget	Granja et al., 2005; Prošić, 2011
3	Continual reduction of activities related to drawing reviews and other variations or alterations will eliminate unnecessary cost thereby keeping the project cost within budget	Suárez-Barrazaa and Lingham, 2008; Granja et al., 2005; Martin, 1993; Kaur and Kaur, 2013
4	Ensuring activities related to construction variations are continually minimized will create more profit for the contractor	Ashworth, 2010; Dada and Jagboro 2007
5	Cost of activities related to purchase orders and material deliveries can be reduced continually throughout the construction phase to control the project cost for optimum profit	Lin et al., 2001; Mansuy, 2002
6	Overhead cost related to paying suppliers, sub-contractors and labourers can be reduced continually throughout the construction phase to keep the project cost within budget	Lin et al., 2001; Mansuy, 2002;
7	Continual reduction of overhead costs related to construction cost planning, general planning, resource planning and project reports will create more profit for the contractor	Sanni and Durodola, 2012, Sanni and Hashim, 2013; Lin et al., 2001; Granja et al, 2005
8	Continual reduction of overhead costs associated with preliminary items of work such as site office, storage, security, electricity, water supply, first aid and so on will	Sanni and Hashim, 2013; Sanni and Durodola, 2012; Lin et

	eventually help the creation of more profit and improve project delivery	*al., 2001; Granja et al, 2005*

The cost activities identified above were gathered from various articles related to important activities which are carried out during construction. They are also a product of the questionnaire designed for the data collection.

2.4 Research objective

The objective of this study is to assess the most critically important construction activities required for incremental cost reduction in the Nigerian construction industry. Having identified the objective of this paper, the following section discusses the research methodology adopted for this study.

3. Research Methodology

Data was obtained from one hundred and thirty-five cost and project managers in Lagos, Nigeria. The questionnaire was designed in a Likert scale format. The range was from 1 to 5, spanning from strongly agree to strongly disagree respectively. The questionnaire is based table 1. This survey questionnaire was aimed at assessing the attitude and beliefs of the respondents towards the costs that might be required to reduce during the construction stage. Therefore, the questionnaire is logically designed to fit the continual cost reduction objective through Kaizen costing.

Two hundred and fifty (250) questionnaires were distributed but only one hundred and thirty-five (135) could be retrieved. The respondents had work experience range of two (2) to forty years (40), this is illustrated in figure 1 below. Seventy-seven (77) cost managers and fifty-eight (58) project managers responded to the questionnaire. Some of these respondents are from the same construction company. However, a total of eighty-seven (87) companies responded to the questionnaire.

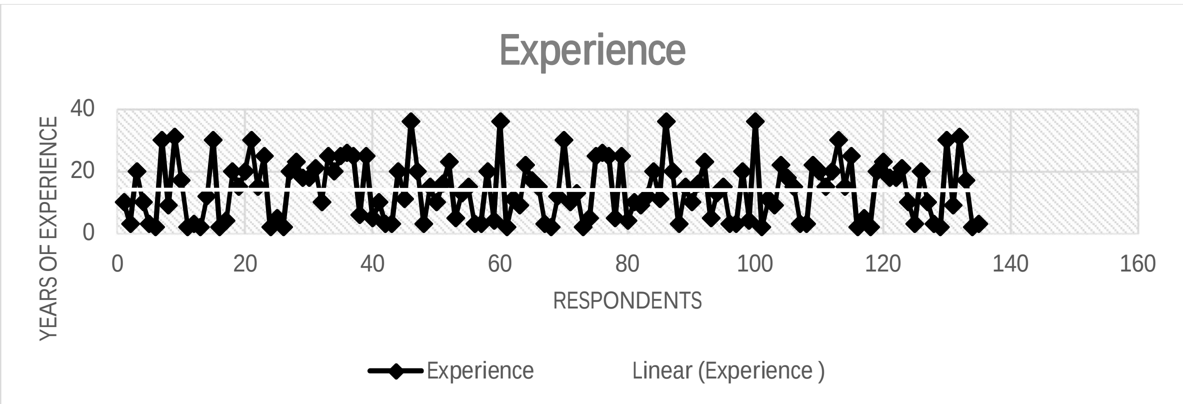

Figure 1: Years of experience of the respondents

In the graph above the linear years of experience for the respondents is fifteen (15). Very few respondents have experience above thirty years.

3.1 Investigating the presence of Kaizen costing

The presence of Kaizen costing in Nigeria was investigated. The questionnaire distributed was aimed at identifying the type of post-contract cost control method in use in Nigeria. It included the conventional cost management system in construction, earned value analysis, value engineering, activity based costing and Kaizen costing. The findings in figure 2 below show that ninety-eight (98) percent of the respondents are still using the traditional post-contract cost control method, while 1.2 percent are using earned value analysis.

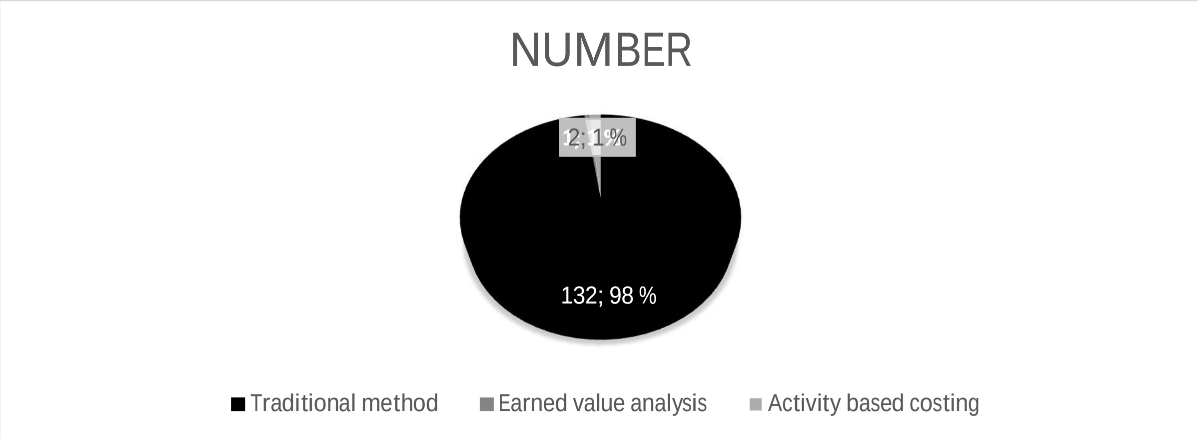

Figure 2: Pie chart showing the type of post contract cost control methods used

1.1 percent of the sample population made use of activity based costing. Kaizen costing is still very new to the construction industry in Nigeria.

3.2 Assessing the most critical post-contract cost control activities

This section addressed the key critical post-contract cost control activities which enables the researcher to evaluate the critical activities which will be required for continual cost reduction on site. This will be meant for small and medium scale construction firms in Lagos, Nigeria. The critical success factors are itemised below.

Table 2: Abbreviations for the activities

Abbreviation	***Meaning***
MESETUP	*Continual cost reduction of overhead cost of activities related to mobilization and equipment setup will keep the project cost within budget*
DRR	*Continual reduction of activities related to drawing reviews will eliminate unnecessary cost thereby keeping the project cost within budget*
PI	*Continual reduction of overhead costs associated with preliminary items of work such as site office, storage, security, electricity, water supply, first aid and so on will eventually help the creation of more profit and improve project delivery*

CGPG	*Continual reduction of overhead costs related to construction cost planning, general planning, resource planning and project reports will create more profit for the contractor*
CVMINI	*Ensuring activities related to construction variations are continually minimized will create more profit for the contractor*
PEOVER	*Continual reduction of plant and equipment depreciation overhead cost throughout the construction phase will keep the project cost within budget*
POM	*Cost of activities related to purchase orders and material deliveries can be reduced continually throughout the construction phase to control the project cost for optimum profit*
PSL	*Overhead cost related to paying suppliers, sub-contractors and labourers can be reduced continually throughout the construction phase to keep the project cost within budget*

The critical post-contract cost control activities were carefully selected from literature review, which highlights the key areas required for continuous cost reduction during construction. It covered monitoring material, plant, labour and overheads, elimination of unnecessary activities, planning and stakeholders.

Table 4: Kendall's W score for the most critical post-contract cost control activities

	PSL	*POM*	*PEOVER*	*CVMINI*	*CPGP*	*PI*	*DRR*	*MESETUP*
Kendall's W score	*5.02*	*4.70*	*4.64*	*4.52*	*4.50*	*4.39*	*4.30*	*3.99*

From table 4 above, PSL representing o*verhead cost related to paying suppliers, sub-contractors and labourers can be reduced continually throughout the construction phase to keep the project cost within budget.* This is ranked highest with a Kendall's W score of 5.02. POM which is *cost of activities related to purchase orders and material deliveries can be reduced continually throughout the construction phase to control the project cost for optimum profit* has a Kendall's W score of 4.70. The least critical activity is MESETUP which stands for *continual cost reduction of overhead cost of activities related to mobilization and equipment setup will keep the project cost within budget,* with a score of 3.93. The Kendall's W score for each of the critical activities for continual cost reduction highlighted the most important activities which cost and project managers have to focus on during construction. The activities were prioritized in order for cost and project managers in small and medium scale construction organizations to address the most important activities which would enable them reduce cost.

df	*7*
Asymp. Sig.	*.008*

In table 5, Kendall’s coefficient of concordance for this analysis is 0.02. This figure is very low and shows that there is almost no agreement between the respondents. Asymp. Sig. is $0.008<0.05$ hence, the respondents have a significant association with the critical success factors.

4. Discussion of results

Based on the findings in figure 2, it can be inferred that kaizen costing is a new concept to the construction industry in Nigeria. This may be the case for other construction industries around the world. Although Kaizen costing is used in the manufacturing industry in Nigeria (Olabisi, Sokenfun, & Oginni, 2012), the construction industry needs to adopt this method as major approach for cost maintenance and reduction. Granja, Picchi, and Robert (2005) noted that cost control is not enough during construction, cost has to be maintained on a daily basis and adequately evaluate for waste factors. An allowable cost in construction is the target price minus the target profit (Granja et al., 2005). Therefore, the cost manager has to ensure the allowable cost is maintained. In reality, the forces of demand and supply and other activities on site influence the cost of construction. This is why the major activities which may denigrate the contractor’s plans for the construction project have to be evaluated.

Activities on the construction sites were evaluated based on their level of criticality. Overhead cost related to paying suppliers, sub-contractors and labourers can be reduced continually throughout the construction phase to keep the project cost within budget has to be taken into consideration more than any other activity. Olawale and Sun (2013) revealed that the performance of nominated sub-contractor and suppliers affects the final cost of construction projects. The incremental reduction of overheads costs resulting from the activity of suppliers, sub-contractors and labourers will definitely create more profit and value for the contractor and project. In most cases, it is very difficult to monitor the activities of the suppliers because of certain forces in the Nigerian construction industry. Such forces include, collusion with a project team member to inflate the prices of the construction materials, kick back and other vices on the construction site. Inflation, foreign exchange rate and market forces also affect the supplier’s and sub-contractors’ cost.

Incremental reduction of activities related to purchase orders and material deliveries ranked second in the test. The Kaizen team can focus on this aspect to ensure that the wastage arising transportation of material to site and purchase orders are kept within an allowable cost limit. The cost limits allowed may have a profit and overhead of twenty-five percent plus (25 %+). Most cost managers who are mainly Quantity Surveyors in Nigeria also include this profit and overhead. In some construction companies it is a management function. However, focusing on actions relating to purchase orders and material deliveries will definitely assist the contractor in getting more value for money and client satisfaction.

For most complex projects, equipment and plants are required. "*Continual reduction of plant and equipment depreciation overhead cost throughout the construction phase will keep the project cost within budget*" was ranked third on the scale. The plants and equipment hiring cost, depreciation and maintenance cost is highly important. This aspect is very difficult to maintain and incrementally reduce cost. This aspect is very critical to the success of the project. The final account for the project depends on these factors. Therefore, the cost manager needs to address precise steps which pertain to plant and equipment hiring.

5. Conclusion and further research

The presence of kaizen philosophy is necessary for kaizen costing to be in place during construction. Although this study did not address the presence of kaizen in the management level, the findings revealed that Kaizen is non-existent in the Nigerian construction industry. Cost control during construction has to go beyond monitoring. Maintenance procedures is viewed as monitoring. However, identifying waste and gaps in cost during construction will invariably reduce the cost of construction. The critical activities identified in this paper has to do with external influences such as suppliers, sub-contractors, purchase orders, material handling, equipment and plant hire. These factors are very difficult to control and are critical to a project's success. Achieving a successful incremental reduction of cost during construction depends on these factors.

The involvement of other stakeholders such as the suppliers, sub-contractors and labourer may also facilitate continual cost maintenance and reduction. A research framework may be designed to provide guidelines for a successful Kaizen costing procedure in the Nigerian construction industry.

Abstract

Cost overrun on infrastructure projects is widespread and represents significant financial risks to stakeholders. The large number of possible causes makes the planning and management of projects challenging. A survey of 160 project managers of infrastructure projects in Saudi Arabia was conducted to elicit the cost overrun causes. After cluster analysis, the causes were reduced to four dimensions: scope changes, market and regulatory, inadequate planning and control, and unforeseen circumstances. These four dimensions were then used to develop a risk-based cost contingency estimation model (RBCCEM) to improve the accuracy of cost forecasting and then validated using a bootstrapping approach. The accuracy of cost estimation measures was used to compare RBCCEM with fixed cost contingency (10%), reference class forecasting (RCF P50 & P90), and hybrid (it is a combination of RBCCEM & RCF P50). The comparison suggested that the RBCCEM could be more accurate as the error decreased by 10%. Therefore, by considering the actual impact of cost risk of similar projects, the results show that cost contingency was improved and the model delivered a better result compared to RCF.

Keywords: Cost overrun, cost overrun causes, infrastructure projects, classification and cost contingency estimation

1. Introduction

A significant proportion of large infrastructure projects have experienced substantial cost overrun which has led to financial or fiscal distress to project stakeholders and resulted in the deferral or cancellation of other projects (Flyvbjerg, 2014). Cost overruns in infrastructure projects are common around the world, as identified by Flyvbjerg et al (2003). Controlling project cost within budget is important for most if not all projects. The focus on cost performance is even stronger for infrastructure projects because of their high costs. Therefore, it is critical that causes of cost overrun are identified and effectively managed to minimize cost overrun.

Studies have identified a wide range of factors that lead to cost overruns, with two main schools of thought on the causes of cost overrun: technical and strategic causes. Technical causes include mistakes in design, overall price fluctuations, inaccurate estimations, government regulations, project size, quality of the contractor management team, plan changes, priority on construction deadlines, completeness and the project information timelines, the lack of experience of the estimators, certain bidding conditions, project characteristics, and lack of past data on similar types of projects (Koehn et l., 1978; Shash and Al-Khaldi, 1992; Lowe and Skitmore, 1994; Al-Harbi et al., 1994; Flyvbjerg et al., 2002; Memon, et al., 2011). The strategic causes considered optimism bias, which encapsulates the systematic propensity of decision makers to be over-optimistic about the outcomes of planned actions, as the main culprit of cost overruns for infrastructure projects (Flyvbjerg et al., 2002). However, the rhetoric seems to have shifted towards strategic misrepresentation as the main cause of cost overrun, which refers the use of deceptive means in order to win the project or obtain project funding (Liu and Zhu, 2007).

One of the techniques of reducing the impact of project cost overruns is the use of project cost contingencies—usually as a fixed proportion of the project total estimated cost and most recently estimated produced using sophisticated approaches such as reference class forecasting (RCF) or risk-based estimating (RBE) (Liu et al., 2010), but each method has its limitations. By taking into consideration the actual impact of cost risk of similar projects this paper develops and validates a cost contingency estimation model. A cross-sectional survey was conducted in Saudi Arabia to identify the causes of cost overrun of infrastructure projects in Saudi Arabia and the causes identified form the basis of the new cost contingency estimation model.

The structure of the paper is as follows: literature on causes of cost overrun was reviewed and the research design was explained. Cluster analysis is used to classify the causes of cost overrun into clusters. Subsequently, a cost contingency estimation model was developed by regressing project cost overruns on the clusters of causes. The model was then validated using the split sample. Further validation was conducted by comparing the accuracy of RBCCEM with those produced by the fixed cost contingency (10%), RCF (P50 & P90) and hybrid method, respectively. Finally, implications were discussed, future research directions were outlined and conclusions were drawn.

2. Literature review

This section examines the concept of the classification of cost overrun causes. Then, cost contingency estimation in infrastructure projects was also reviewed, followed by a discussion on using a classification approach in a cost contingency estimation model to improve cost contingency estimation accuracy.

2.1. Classification of causes of cost overrun

Cost overrun occurs in infrastructure projects (Memon, et al., 2011), and the causes are various. Classifying or grouping the large number of causes of overrun that may share similar patterns of impact can help manage causes during planning and construction.

Based on a survey of project managers on high-rise construction projects in two Indonesian cities, (Kaming et al., 1997) grouped seven causes of cost overruns into three groups using factor analysis: inflationary increases in material cost, inaccurate material estimating and project complexity. In Vietnam, Le-Hoai et al. (2008) categorized 21 causes of cost and time overrun for the construction industry using factor analysis and identified seven groups of causes: slowness and lack of constraint, incompetence, design, market and estimates, financial capability, government and worker factors. In Malaysia, Abdul Rahman et al. (2013) modelled 35 causes of cost overrun in large construction projects with a partial least squares-structural equation modelling approach and categorized the cost overrun conceptually in seven groups: contractor's site management related factors, design and documentation related factors, financial management, information and communication, human resource, non-human resources, project management and contract administration. These classification attempts have shown that homogenous groups of causes of cost overrun exist which aggregate the effect of causes within the same dimension.

Flyvbjerg has published various widely cited papers on causes of cost overrun for infrastructure projects. Flyvbjerg (2006) proposed a conceptual categorisation of cost overrun based on four main types of explanations that are claimed to account for cost overrun: technical, economical, psychological and political. Flyvbjerg et al. (2003) and Flyvbjerg (2008) acknowledged the technical explanations for cost overrun such as project size and location, but they concluded that the political-economic explanation of strategic misrepresentation and the psychological explanation of optimism bias are the main causes of cost overrun.

In brief, many causes significantly overlap, with relationships between multiple causes contributing to the final cause of cost overruns. There is a need to understand how the diversity of causes share similar patterns and how these causes impact on cost overrun, how causes can be mitigated, and the techniques or tools to ameliorate or eliminate cost overrun.

2.2. Estimation of infrastructure project cost

Accurate cost estimation tools can help reduce or eliminate the uncertainties of cost overrun. Accurate cost forecasting of large project costs is based on the availability and the level of professional knowledge and the historical cost data quality (Liu and Zhu, 2007). Available information, however, might be limited in the early stage of a large project. This may mean the quantity surveyor must make assumptions about the design; a detail of a project that may not eventuate as the life cycle of the project evolves (Liu et al., 2010).

The most critical feature of effective cost estimation is its potential for accuracy. Classic cost estimates consist of a base estimate, accounting for all physical quantities of materials and labour, and an additional risk contingency quantifying the underlying levels of uncertainty associated with the base estimate (Liu et al., 2010). Accuracy in forecasting costs and risks is valuable for decision makers to make rational decisions. Research has shown that cost forecasting errors are not unique to any specific industry or to project type with estimate inaccuracy in transport (Flyvbjerg et al., 2002), roads (Odeck, 2004), general construction (Liu and Zhu, 2007) and industrial projects (Merrow and Yarossi, 1990). Many studies have found, however, that there has not been noticeable improvement in estimation accuracy despite continued research (Flyvbjerg et al., 2002; Liu and Zhu, 2007).

The dominant methods of cost contingency estimation used in infrastructure projects can be classified into three categories: conventional contingency approach, risk-based estimation (RBE) and reference class forecasting (RCF) (Liu et al., 2010). The conventional contingency approach is to add a percentage, such as 10%, to the most likely estimate of the known works (Burger, 2003) based on the estimator's experience, which may be prone to optimism biases and could lead to cost overrun (Yeo, 1990; Newton, 1992; Mok et al., 1997). The cost contingency technique is acceptable under stable conditions and simple projects, however, it is inappropriate for large and complex projects (Newton, 1992). As a result, it is a less evidence-based approach and a reason for many projects having cost overrun (Hartman, 2000).

The other two methods, RCF and RBE, have been shown to increase the accuracy of cost contingency estimation (Liu et al., 2010). The RBE model is the cost of individual components with base estimates and stochastic or random risk contingencies. Summing the stochastic cost components determines the distribution or probability of the overall project cost (Shaheen et al, 2007). The RBE method identifies inherent risks that directly relate to the internal behaviour of a project; as well as contingent risks derived from external events that may or may not occur (Aspinall and Trueman, 2006). It requires large amounts of expert time and expense (Liu et al., 2010) especially for large and complex projects.

RCF developed by Flyvbjerg, which only takes into account a project's class (the outcome of cost overrun), even when other project factors might impact upon estimate accuracy. RCF utilises a database of previous project performance, from which a subsample of similar projects is selected, and adds a contingency to the total project cost (Liu et al., 2010). As RCF's aim is to mitigate either optimism bias or strategic misrepresentation, it does not specifically address other causes of cost overrun such as technical causes and does not forecast events which may influence the project.

Since cost contingency accounts for the unforeseen cost risks, it is likely the estimating model based on the actual impact of cost risk of similar projects could produce more accurate cost contingency estimates. As a result, in the paper a risk based estimation method was adopted, by including 'cost overrun causes classification scheme', the accuracy of cost estimation could be improved. Supporting this proposal, (Liu et al., 2010) showed how RBE had excellent predictive validity as 90% projects having an actual cost within the range of the risk-based estimate in which they estimated the risk contingency of every single components of the project but they did include the cost overrun causes of similar projects. Therefore, this study designs and validates RBCCEM for infrastructure projects.

3. Research design

To develop the RBCCEM model, the survey data and the risk factors identified by the authors in a separate paper (Allahaim and Liu, 2015) is used to demonstrate development and validation process. First, the data collection and the identified causes of cost overrun for infrastructure projects in Saudi Arabia were summed up. Then, the use of cluster analysis to reduce the dimensionality of the risk factors was explained in preparation for the subsequent multiple regression analysis. The regression analysis derives the RBCCEM which was validated using bootstrapping analysis. Finally, the estimates produced by RBCCEM was compared those by alternative approaches such as the fixed cost contingency (10%), RCF (P50 & P90) and hybrid (RBCCEM & RCF P50) approaches.

4. Data collection

A survey of infrastructure project managers in Saudi Arabia was conducted to collect data from key infrastructure project professionals in three groups: owners exposed to project cost overrun, consultants supervising the projects, and contractors delivering the projects. The survey asked about the frequency of the 41 causes of cost overrun most frequently identified from 25 selected studies, as shown in Table 1. Respondents used five Likert-scale response anchors to assess the frequency of each cause in Saudi Arabia, based on their own professional experience. For more information about the data collection please refer to the survey data that conducted by the authors in a separate paper (Allahaim and Liu, 2015).

5. Data analysis and results

Based on the clusters identified, the scores for each cluster in each case was derived by aggregating the scores of each cause within each cluster. Subsequently, the cost overruns of projects were regressed on the four clusters identified to develop a risk-based cost contingency estimation model. R project software (version 3.0.2) and IBM SPSS 19 were used for statistical computing and graphics in the cluster analysis, model building and validation of the model.

5.1. Cluster analysis

Cluster analysis was used for dimension reduction (Everitt et al, 2011). The steps in cluster analysis of the data include preparing the data, determining the number of clusters, testing the cluster solution and finally validating clusters.

In Figure 1, there is an extreme “elbow” in the plot suggesting that solutions over four clusters do not have a substantial impact on the total SSE, which indicates that four clusters are appropriate. The next step tested hierarchical cluster analysis with the selected number of four clusters (Everitt et al, 2011). The Euclidean distance method was used to measure the dissimilarity distance based on the information values and the nature of the variables describing the objects to be clustered. Figure 2 shows the hierarchical cluster (tree) generated from R software, where the cause numbers (C1, C2... C41) refer to the causes listed in Table 1.

In the analysis, 10,000 bootstrap resamplings were used to reduce the error (Suzki and Shimodaira, 20016). In Figure 2, four rectangles have an AU *p*-value of 99 (0.99), therefore, for a cluster with AU p-value ≥95 (0.95), the hypothesis is rejected with significance level 0.01 for one cluster and 0.00 for three clusters, which indicates how strongly four clusters are appropriate as each cluster group contains objects which have a relationship with each other (Figure. 2).

5.1.1. Results – four cluster classification

The four cluster groups were defined based on causes of cost overrun and the literature as scope changes, market and regulatory uncertainty, inadequate planning and control and unforeseen circumstances. Table 1 shows how each of the 41 causes in Table 1 is allocated to one of the four clusters.

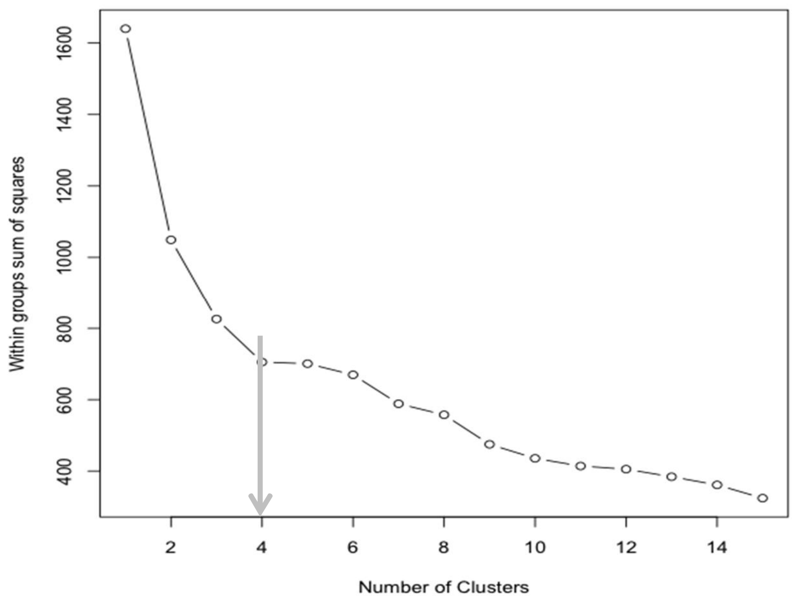

Figure 1: Elbow plot for the cluster determination

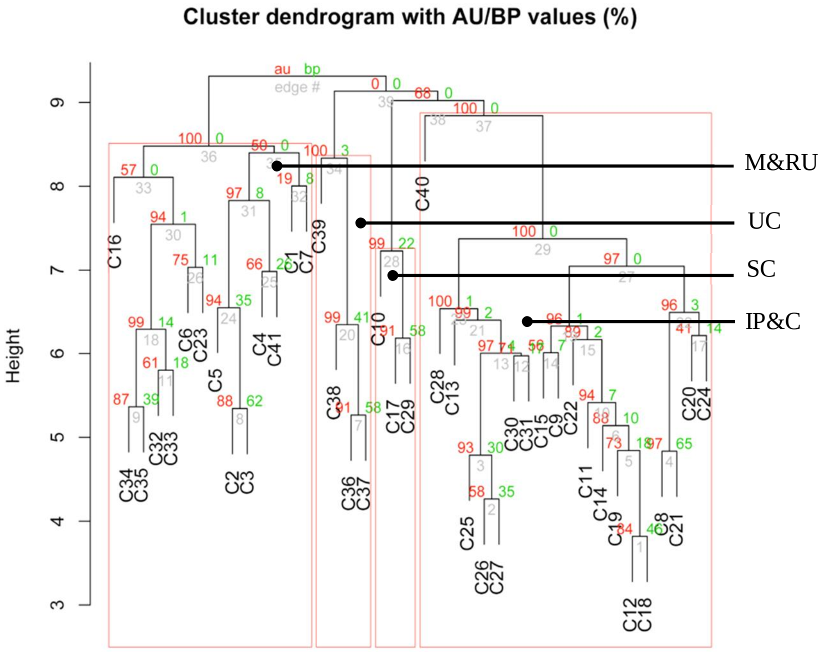

Note 1: Values at branches are AU p-values (left-red), BP values (right-green), and cluster labels (bottom). Clusters with AU ≥ 95 are indicated by the four red rectangles.
Note 2: Inadequate planning and control (IP&C), Market and regulatory uncertainty (M&RU), Scope changes (SC) and Unforeseen circumstance (UC).

Figure 2: Hierarchical clustering with four cluster solution

As shown in Table 1, the first cluster group is scope changes (SC), which represents the causes of cost overrun due to design changes, additional work and rework, and change in the scope of the project. The causes in this cluster are related to time, that is the urgency of the project, namely how much time there is to complete the job. Forcing the project team to take short-cuts or to work on tasks which clash with other tasks and working on concurrent tasks and projects are known to cause delays and cost overrun. The second cluster group is market and regulatory uncertainty (M&RU), which includes causes of cost overrun that relate to the chance or speculation changing costs, whether directly or indirectly. The third cluster group is inadequate planning and control (IP&C), it represents the causes of cost overrun which relate to project planning and control, which comprise the most critical causes of cost overrun in large projects in Saudi Arabia. Inadequate planning and control dimension is referring to the factors that could increase the complexity and thus difficulty of controlling the project cost. The last cluster group unforeseen circumstance (UC). The causes of this cluster relate to environment issues, as well as social and cultural impacts. These issues increase the pressure to find a solution to these problems associated with the project site. For example, the increase of environmental requirements has a significant impact on construction operations, which leads to technical uncertainty that relates to the physical difficulty of completing a project.

Table 1: Four-cluster classification scheme for causes of cost overrun

Classification clusters	Key	Causes of cost overrun	Relationship to cost overrun
Scope changes	C17	Design changes*	Unclear project scope forces project team to take short-cuts, crashing tasks, concurrent tasks/projects, which are known to cause delays and cost overrun (Shenhar and Dvir, 2007).
	C10	Additional work and rework*	
	C29	Change in the scope of the project*	
Market and regulatory uncertainty	C5	Market conditions (materials and labour)*	Increases the volatility of input costs and thus chances of overrun (Pindyck, 1993).
	C41	Practice of assigning the contract to the lowest bidder*	
	C4	Slow payment of completed works*	
	C3	Cash flow during construction	
	C33	Obstacles from government	
	C1	Inflation	
	C35	Laws and regulatory frameworks	
	C16	Failure to price in some risks	
	C2	Monthly payment difficulties from agencies (e.g. contractor, owner)	
	C34	Political complexities	
	C7	Deficiencies in cost estimates prepared by public agencies	
	C32	Fraudulent practices	
	C23	High interest rate charged by bankers on loans	
	C6	Fluctuation in money exchange rate	
Inadequate planning and control	C40	Delays (decision making, in approval of drawings, material delivery)*	Increases the complexity of coordination of parties and tasks, thus making it harder to meet present targets (Baccarini, 1996).
	C21	Design error*	
	C8	Deficiencies in the infrastructure*	
	C20	Changes in material specification and type*	
	C13	Shortage of site workers	
	C18	Incorrect planning and scheduling by contractors	
	C24	Inadequate specifications	
	C14	Unrealistic contract duration and requirements imposed	
	C11	Lack of experience of project manager (e.g. location, type)	
	C28	Lack of constructability	
	C15	Strategic misrepresentation	
	C22	Project size	
	C12	Contractor’s poor site management and supervision skills	
	C19	Late delivery of materials and equipment	
	C25	Waste on site	
	C9	Labour, insurance, work security or workers’ health problems	
	C27	Poor financial control on site	
	C26	Equipment availability and failure	
	C31	Optimism bias	
	C30	Inadequate modern equipment (technology)	
unforeseen circumstances	C37	Site constraints	Increases the uncertainty of tasks and
	C36	Weather conditions	

	C38	Social and culture impact (e.g. problems with neighbours)	outcome, thus making planning and estimating difficult (Ofori, 1992).
	C39	Heritage material discovery	

Note: (*) ranked in the top ten causes

5.2. Development of the risk-based cost contingency estimation model

To build the model using multiple linear regressions (MLR), as there are 160 cases and 41 causes, the data was randomly split into two data sets with two-thirds of the data as the training set (100 cases=62.5%) for model building and the remaining one-third (100 cases=37.5%) as the test set to ensure more reliable results and also to reduce bias in the validation (Kothari, 1985). For model validation, bootstrap resampling of multiple linear regressions was employed. Then, the estimates by RBCCEM were compared with those produced by alternative models such as fixed contingency and RCF. Error indices such as mean absolute error (MAE), mean absolute percentage error (MAPE), mean square error (MSE) and root mean square error (RMSE) were used to compare the accuracy of estimates produced (Han and Kamber 2006). Then, RBCCEM, fixed cost contingency (10%), RCF (P50 & P90) and hybrid (is a combination of two models which used to increase the accuracy of cost contingency estimation as Liu et al., (2010) identified) were compared based on the distribution of the means of adjusted cost overrun as the smallest dispersion with the shortest distance between the mode and median indicates the most accurate model (Rothwell, 2005; Lawrence, 2007).

5.2.1. Risk-based cost contingency estimation model building

The regression results using the training subsample are reported in Table 2. The results in Table 2 show all four clusters have significant impact on cost overrun. It is worth noting that Table 2 shows that the R-squared is 32% and adjusted R is 30%, which indicates that the four clusters explains about 30% of variance in cost overruns (Chambers, 1992). The interpretation here is that the observed variation in cost overrun is also explained by other factors beyond those captured in the equation. It is not the intention of this paper to delve into which other factors explain overrun, as it focused on the four clusters (p-value < 0.05) as all variations that were categorised based on 41 causes that are frequently identified in the literature are significant. Therefore, the RBCCEM is represented by the equation 1.

$$\boldsymbol{BCCEM} = \%\boldsymbol{Cost\ overrun} = \mathbf{0.652} + \mathbf{0.157}(\boldsymbol{scope\ changes}) + \mathbf{0.089}(\boldsymbol{market}\ \&\ \boldsymbol{regulatory\ uncertainty}) + \mathbf{0.047}(\boldsymbol{inadequate\ planning}\ \&\ \boldsymbol{control}) + \mathbf{0.024}(\boldsymbol{unforseen\ circumstnaces})$$

Equation 1

Note: the value of inadequate planning and control, market and regulatory uncertainty, scope changes and unforeseen circumstances ranges from 1-5 as 1 has low risk and 5 has major risk.

Table 2: Residuals, coefficients and p-values of regression analysis

Residuals	**Min**	**1Q**	**Median**	**3Q**	**Max**

5.2.2. Models validation

The bootstrapping method was used for validating the RBCCEM. 5,000 bootstrap samples were created to validate the predictive ability of the proposed RBCCEM (multi-linear regression (MLR) model). According to all three measures (Table 3), the coefficient was statistically significant (the default for boot.ci is a 95% confidence interval) as they are centred to the normal, which indicated the model was valid. As reported in Table 3, the mean values of the four regression coefficients estimates from the RBCCEM bootstrapping were close to the proposed RBCCEM (Tables 2 and 3). Also, the standard error values of the four-parameter estimates from the RBCCEM bootstrapping were close to the proposed RBCCEM (Tables 2 and 3). The similarity of estimates of the RBCCEM model from both split samples suggests that RBCCEM is valid and robust.

Table 3: RBCCEM bootstrapping

Note: Calculations and Intervals on Original Scale

5.2.3. Models evaluation using estimation accuracy measures

In the models evaluation we used two methods. The first method was by using estimation error (error indices). The second method was comparing the adjusted cost overrun percentage means by using independent samples t-test. The following section will discuss these two methods and the results are delivered.

5.2.3.1. Model evaluation using measures of forecast accuracy (error indices)

To further validate the model, the estimates produced by RBCCEM were compared with alternative methods such as RCF. RCF uses a database of actual performance of comparable past projects within a given reference class to provide an objective reference point for the cost forecast of a current project (Flyvbjerg, 2006). For a particular project, reference class forecasting requires the following three steps (Flyvbjerg, 2006, p. 8): (a) identifying a relevant reference class of past projects as the base, (b) establishing a probability distribution for the selected reference class and (c) comparing the specific project with the reference class distribution.

To compare the models, the accuracy of each model was measured. Forecast accuracy measurements were based on the distributions of absolute errors (|E|) or squared errors (E^2), taken over the number of observations (n), which are the most commonly used measures to compare the performance of predictive models (Hyndman and Koehler, 2006). These include mean absolute error (MAE), mean absolute percentage error (MAPE), mean square error (MSE) and root mean square error (RMSE) (Swanson et al., 2011). Table 4 presents MAPE MAE, MSE and RMSE where values of 0 indicate a perfect fit (Singh et al., 2013). Table 4 shows that the RBCCEM has comparable error indices to that of RBCCEM bootstrapping. In contrast, the error indices for RCF are much higher, suggesting RBCCEM is more accurate.

Table 4: The MAE, MAPE, MSE, and MAPE of MLR and error estimates of the four-clusters model: Proposed RBCCEM, RBCCEM bootstrapping and RCF model

	MAE	MAPE	MSE	RMSE	RMSE -MAE
Proposed RBCCEM	0.473786	15.78 %	0.426456	0.653036	0.18
RBCCEM bootstrapping (5,000 bootstrap of test data)	0.428924	14.68 %	0.358026	0.598353	0.17
RCF model	0.872376	25.19 %	1.190669	1.091178	0.22

5.2.3.2. Models evaluation by comparing the means of adjusted cost overrun percentage of the models

As discussed, β1 to β4 were estimated based on a sample of 100 and the model was validated using bootstrapping based on the 60 samples, which shows the model was valid and accuracy was improved compared with RCF. In this section, the mean of the adjusted cost overrun percentage of the RBCCEM was compared with those estimated using alternative approaches, such as RCF and fixed contingency (10%), using the split sample. The result in Tables 5 and 6 shows the adjusted cost over. The comparison results reported in Tables 5 and 6 showed that the adjusted cost overrun of RBCCEM results are significantly lower than adjusted cost overrun of fixed (10%) cost contingency, RCF and hybrid approach.

Table 6 shows that the means of adjusted cost overrun percentage using the fixed cost contingency, RBCCEM, RCF P50, RCF P90 and hybrid (RBCCEM + RCF P50), respectively, are all significantly different from each other (*p*-value <0.00). Considering the negative mean (under budget) in the adjusted cost overrun percentage mean of RBCCEM (-0.11451), the results suggested that the mean of adjusted cost overrun percentage using the RBCCEM approach is preferable to that using the RCF P50, RCF P90 and hybrid.

Moreover, Table 6 reports that the adjusted cost overrun using RCF reduce the overrun significantly (*p*-value <0.05) as the mean differences for P50 is (0.1049) and for P90 is (0.0140) (Table 5 and 6). Despite the fact that RCF P50 and RCF P90 have lower mean differences, it should be noted that the RCF estimates are subject to the acceptable risk of cost overrun which RBCCEM does not. In addition, the RBCCEM model tends to underrun budget while the RCF model tends to overrun budget. The dispersions of the RCFs are higher than RBCCEM (Figure 3) suggesting RBCCEM produces more consistent results. In sum, using estimates of contingencies by RBCCEM results in slight average cost underruns with more consistent and accurate estimates than that from RCF.

In addition, the variance of adjusted cost overrun percentage using the fixed cost contingency, RBCCEM, RCF P50, RCF P90 and hybrid, respectively, are significantly different (*p*-value <0.035) (Table 6). Considering that the variance of adjusted cost overrun percentage using the RBCCEM is lower than those using fixed cost contingency, RCF P50, RCF P90 and hybrid (Table 6), respectively, the results indicates RBCCEM produces the most consistent estimates for cost contingency Therefore, RBCCEM is the preferable method for estimating cost contingency for infrastructure projects.

Table 5: Descriptive statistics for mean of adjusted cost overrun of two models

	N	**Mean**	**Std. Deviation**	**Std. Error Mean**
Fixed cost contingency 10%	60	**0.3319**	0.22739	0.02935
RBCCEM	60	**– 0.1145^**	0.15616	0.02016
RCF uplift P50	60	**0.1049**	0.17155	0.02214
RCF uplift P90	60	**0.0140**	0.15604	0.02014
Hybrid of RBCCEM and RCF uplift P50	60	**–0.0096^**	0.32646	0.04215

Note: ^ A negative value denotes under and a positive figure indicates over budget.

Table 6: Test results for the equality of means and variances

	Leven's Test for Equality Variance		t-test for Equality of Means				
	f	**sig**	**t**	**df**	**Sig. (2-tailed)**	**Mean Difference**	**Std. Error Difference**
Fixed cost contingency 10% *vs.* RBCCEM	3.289	0.035	6.54	104.52	0.000***	0.44650	0.13561
Fixed cost contingency 10% *vs.* RCF uplift P50	7. 659	0.005	9.174	109.73	0.000***	0.23677	0.03117
Fixed cost contingency 10% *vs.* RCF uplift P90	7.394	0.006	8.931	104.48	0.000***	0.31795	0.04360
Fixed cost contingency 10% *vs.* Hybrid of RBCCEM and RCF uplift P95	6.616	0.010	6.650	105.342	0.000***	0.34157	0.05136

Note: Significance codes: p < 0 '***', p < 0.001 '**', p < 0.01 '*', p < 0.05 '.'

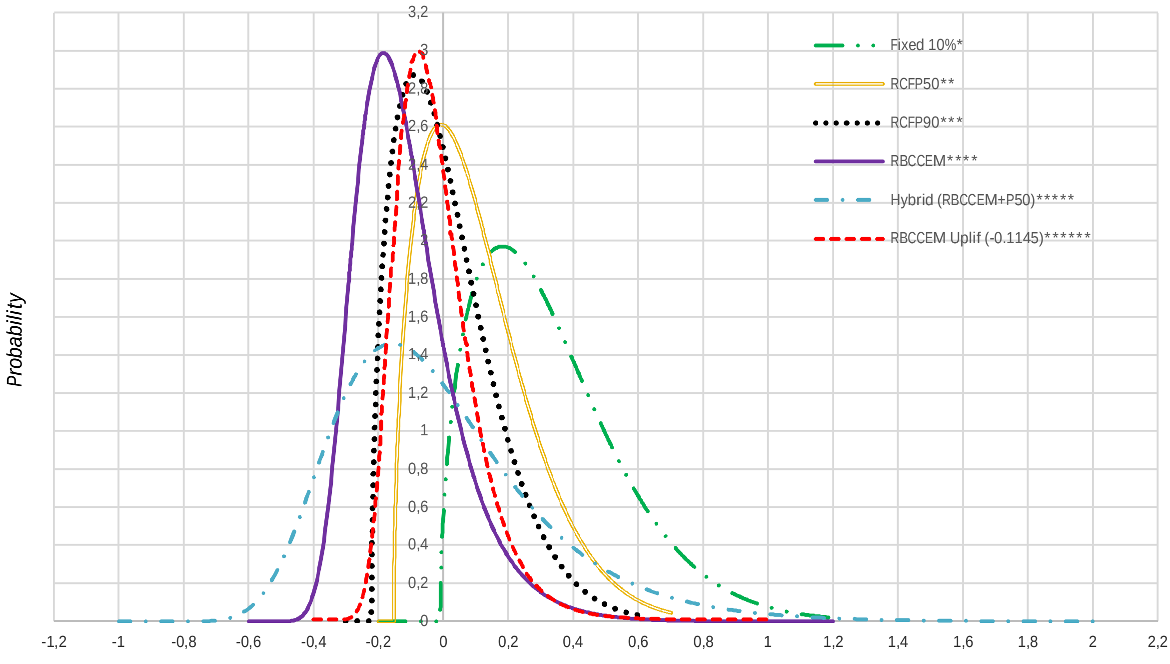
Figure 3 shows the mean distributions fitting to the data. As can be observed that all distributions are skewed to the left and the tails of the distributions are longer in the right. Therefore, the mode is the peak of each distribution, and the median and mean come after it in the right. Furthermore, the distribution of adjusted cost overrun percentage for RCF P50 and P90 are fitted to Weibull distribution as can be observed in the Figure 3 by the orange doubled line and black dotted line, respectively.

In addition, the fixed 10% cost overrun (green long dashed dot dot line) is fitted to Weibull distribution and hybrid (RBCCEM + RCF P50) (blue long dashed dot line) is fitted to exact value distribution. The adjusted cost overrun of RBCCEM distribution (purple solid line) is fitted to exact value distribution which is biased toward under-budget (mean adjusted cost overrun=-0.1145). Comparing the dispersions of the distribution curves presented in Figure 3, RBCCEM has the narrowest dispersion, supporting the above conclusion that RBCCEM produces the most consistent estimates for cost contingency of infrastructure projects.

Further, the small negative mean of adjusted cost overrun of using RBCCEM can be offset by adding an amount equal to 0.1145As a result, the distribution of RBCCEM +0.1145 (red dashed line) shifted around zero and has the narrowest dispersion compared to the other distributions.

6. Conclusions

Based on a cross-section survey of managers involved in infrastructure projects in Saudi Arabia, cluster analysis was used to reduce 41 causes of cost overruns to four clusters; scope changes, market and regulatory uncertainty, inadequate planning and control, and unforeseen circumstances. Using multiple - regression analysis, the risk-based cost contingency estimation model (RBCCEM) was developed by regressing project cost overrun on the four clusters. Then, validity of the RBCCEM was validated by multiple regression bootstrapping using the remaining split sample (sample size of 60) and by comparing the cost overrun outcomes of using cost contingency estimates from RBCCEM to those of using alternative estimating approaches such as RCF and fixed contingency. The validation analysis



*Note: * distribution fitting of fixed % cost contingency of cost overrun (Weibull distribution)*
*** distribution fitting of adjusted % cost overrun based RCF on 50% percentile (Weibull distribution)*
**** adjusted % cost overrun based RCF on 90% percentile (Weibull distribution)*
***** distribution fitting of adjusted % cost overrun based on RBCCEM (proposed model) (Exact value distribution)*
****** distribution fitting of Hybrid model (RBCCEM + RCF P50) (Exact value distribution)*
******* distribution fitting of adjusted % cost overrun based on RBCCEM (RBCCEM + uplift (-0.1145) (Exact value distribution)*

Figure 3: The fitting distribution curves of fixed cost contingency, RBCCEM, RCF (P50 & P90), hybrid and RBCCEM uplifted (RBCCEM-0.1145)

showed that the degree of dispersion of the cost overrun and the mean of the cost overrun after including the cost contigency is the lowest for RBCCEM, in which it is prefered method of estimation for cost contingency. However, the accuracy of cost contingency could be improved further by offsetting the negative mean of cost overrun using hybrid approach, i.e. by deducting the mean from the cost contingency produced by RBCCEM. Such an adjustment uplifts the means of cost overrun to zero while the degree of dispersion remains unchanged.

To apply RBCCEM, an organization needs to ascertain a comprehensive list of the risks to the cost overrun of similar projects through using questionnaire survey. The questionnaire should be based on the questionnaire used in this study and tailored to the project at hand. Assuming the survey responses of at least 30-40, then the organization can proceed to categorizing the risks by conducting clustering analysis. Subsequently, construct scores can be derived by aggregating the scores of individual risks within each category. Finally, regression analysis of cost performance on risk categories is conduced to drive the cost contingency model which will be used to predict cost contingency for the project. Bootstrapping using a holdout sample is a useful validation of the cost contingency estimation model.

The findings are based on a cross-sectional survey of managers involved in infrastructure projects in Saudi Arabia. Therefore, caution should be exercised when generalizing to other contexts. Future research needed to develop RBCCEMs in different contexts following the process for developing RBCCEM as in this study. This study is treating RBCCEM as static concepts that have a constant value, rather than dynamic concepts that evolve over time. Past research has suggested that project management practice changes over time due to a growing knowledge-based society which accelerates change in technological, social and economic knowledge (Jaafari, 2003). Therefore, the survey needs to be undertaken periodically and the subsequent processes need to be conducted to update the RBCCEN regularly. Finally, this study has not compared RBCCEM with the risk-based cost estimation approach future research should consider collect data on RBE estimates and compare the two approaches.

Proceedings of the CIB World Building Congress 2016

These proceedings (Volume I - V) bring together papers presented at the CIB World Building Congress 2016. The CIB World Building Congresses have for several decades been the leading global events on construction research and innovation.

The theme for CIB World Building Congress 2016 was "Intelligent built environment for life". It highlights the importance of build environment and its development to the society. This triennial congress focused on the intelligent processes, products and services of construction industry:

- How can research help to improve the contribution of constructed assets to digitalizing world and service needs?
- How will the research community meet emerging new needs of the users?

CIB is an association whose objectives are to stimulate and facilitate international cooperation and information exchange between governmental research institutes in the building and construction sector, with an emphasis on those institutes engaged in technical fields of research. CIB is a world wide network of over 5.000 experts from about 500 member organisations with a research, university, industry or government background, who collectively are active in all aspects of research and innvation for building and construction.

Preface

Volume four includes 58 paper contributions linked to the congress sub-theme “Understanding impacts and functioning of different solutions”. The proceedings provides insights to six sub themes. First of all the sustainable impacts are discussed from the perspectives of energy use and energy management. The diverse solution over the globe like sustainable housing in Colombia and a Net Zero Energy Building in Finland provide insights to culture specific issues.

The second theme is dedicated for the papers about building information modeling. Different phases of construction process are approached in diverse articles. Also this theme has an international flavors: research from Ethiopia and Singapore is presented among many other interesting papers. The third theme is about diverse working environments: in the office, at the schools and in connection with healthcare. Also housing and mobility are discussed.

The fourth theme includes economical case studies as well as issues connected to calculations with interesting insights to cost estimations to assessments and issues about infrastructure management. The fifth theme is focusing on construction projects especially in terms of productivity, networks and partnerships as well as regulations and norms. Also ever-green topic of lean production is touched in various papers. Finally the sixth theme is about diverse solutions: roofs, thermal conditions and ventilation have inspired the researchers. This book has hilarious amount of interesting papers from different countries and research organizations. In order to provide some key figures the amount of papers is among the themes following.

I Sustainability	8 papers
II Building information modelling	15 papers
III Work environments	6 papers
IV Economics and construction	9 papers
V Construction projects	12 papers
VI Solutions	8 papers

Abstract

Buildings are an essential part of the wider energy system. A significant share of electricity consumption occurs in buildings. Traditionally buildings have been places where electricity is consumed. Now they have a growing role also as a location where renewable energy production, such as solar power, occurs.

Demand response means the voluntary actions that are taken on the customer side as a response to something on the demand side. In practice, demand response can involve, for example, reducing the energy consumption during the peak times of the larger energy system or shifting the timing of the building's energy consumption by synchronizing it with local renewable energy production's profile inside the building. The building codes of Finland direct the designers' energy-related solutions both in new construction and licenced renovations.

In this conceptual paper the literature related to demand response and regulation is reviewed, and it is discussed what kind of a role the building codes could have in advancing the buildings' preconditions for demand response. Demand response is currently brought out in EU directives in the regulation with relation to network operators. However, preparedness for demand response could also be advanced by giving more attention to the timing of power use in the building codes.

Keywords: Building Codes, Demand Response, Energy Law, Energy Use, Power

1. Introduction

The balance between supply and demand in electricity networks has traditionally been achieved mainly by controlling the output power of generators. However, the role of the demand side may be growing. According to the newer paradigm, the system can be more efficient and environmentally friendly if also the fluctuations of demands are controlled (Albadi and El-Saadany, 2008).

Historically, night-rate electricity (and seasonal time of use) tariffs have been time-based incentives that encourage the timing of electricity consumption to those periods of the day or year when consumption without such pricing incentives would be lower. Hot water dispensers and both fully and partially storage heating systems in buildings have been tuned to work at night especially in many of the buildings built in Finland after the 1970s. A more recent step is electricity exchange (Nord Pool)-based consumer energy pricing, which has become increasingly popular. Electricity prices vary seasonally, daily, and hourly in the electricity markets; this variation is based on many factors, including the estimated balance situation (demand and supply). Building's energy consumption varies during different hours (Dirks et al., 2015; Vihola et al., 2015). Market price signal-based demand response can aid in the balance between supply and demand on the wider energy system.

In the future, a growing share of the electricity production will be based on intermittent generation with variable power output (Brouwer et al., 2014). The possibilities of managing the energy system by controlling the production side of electricity are more limited when the share of weather-dependent renewable energy resources (i.e., wind and solar) increases in the energy system. This is especially the case when the power is expected to be flexible upwards. Thus, there is a growing need for managing the demand-side resources of the built environment, including controllable loads, energy storages, and small-scale power generation. As a result, buildings that have been passive consumers in the energy system are expected to be more active and flexible parts of future smart energy systems (Bulut et al., 2015). At the same time, it is possible that profile of peak electricity demands in the building stock will change in the future (Dirks et al., 2015).

It is estimated that buildings account for approximately 20-40 % of energy consumption in different countries (Pérez-Lombard et al., 2008;), representing approximately 32 % of the worldwide energy demand and approximately 39 % of the total energy consumption in Europe (Allouhi et al., 2015). The need to increase the energy efficiency of buildings is nowadays recognized, and presently, energy regulations of buildings are under change. New houses should be "near zero energy buildings" (nZEB) in the European Union (EU) countries in the near future, following directive 2010/31/EU. Exceptions of this requirement include the smallest buildings and buildings that are intended to be used annually for a limited time; otherwise, most of the heated new buildings will be at least nZEB level in the future. "Near zero energy" regulations are a step towards meeting more energy-efficient requirements. The aim of the nZEB level building codes is to increase the energy efficiency of buildings and the share of energy that is produced from renewable sources. In practice, those requirements will likely increase the share of weather-dependent and small-scale energy production, e.g. solar energy and heating pumps and, in the built environment, which can influence the entire energy system.

2. Basics, advantages and problems of demand response

According to Darby et al. (2013), there are three approaches by which smart grids can reduce greenhouse emissions: (1) reduction of demand alias energy efficiency, (2) reduction of demand at peak times, and (3) increased penetration of renewable energy generation. In smart grids, it is possible to manage and reduce the demand peaks by changing the demand loads in such situations that previously were and currently are handled with energy generation from fossil energy sources. After the Paris Agreement in 2015 regarding global average temperature development, there will probably be growing pressure to develop energy systems towards such solutions that reduce greenhouse gas emissions.

Demand response (DR) denotes several types of voluntary actions that are taken on the customer side as a response to something in the energy system (Torriti et al., 2010). In practice, demand response can mean, for example, shifting energy consumption to a different time or reducing the energy consumption during the peak times in the larger energy system. The execution of demand response can be based on the energy price signal or, for example, on reliability (i.e., system security, capacity, or power balance based needs)-based actions (Aghaei and Alizadeh, 2013). Humans can have either an active role in controlling the loads in demand response or more passive roles, if DR is based, for example, on automated load shifting (Torriti, 2014). End users can have an active role, if households are, for example, scheduling their cooking times based on energy prices. Possible loads for automated load shifting, i.e., shifting that the end user does not necessarily even notice, when DR occurs can include the heating loads of buildings or boilers.

There are several papers on demand response from the perspectives of electricity retailers, distributors, producers, users, and DR technology (Kim and Shcherbakova 2011; Ruester et al., 2015; Shariatzadeh et al., 2015); however, the role of building codes has thus far nearly always been missing from studies related to DR and its opportunity to become more popular. In this paper, we consider how the demand response might be advanced by building codes and the instructions related to them. The regulation examples are written especially from the Finnish perspective, but many of them are also applicable in many other countries. The focus in this paper is on the forms of demand response actions where the end user can have a rather passive role: in this case, the holder of a building's electrical interface might need to commit to take DR in use but not personally or actively follow the demand situation.

By DR it is possible to affect environmental impacts of energy production. DR can aid in reducing CO_2 and other emissions if it is utilized to change the timing of energy use from the peaks, when fossil energy is utilized more frequently in the energy system, to those times when fossil energy sources are not needed as much (Cardell and Anderson, 2015; Gilbraith and Powers, 2013).

Smarter demand response actions were previously possible for only large energy users, e.g., industrial actors; however, with technological development, the situation may be changing (Ruester et al., 2014). One development is that there are currently some technological preconditions in the buildings, such as smart meters and other solutions, that can enable the use of real-time price information concerning individual consumers' consumption; the lack of such preconditions was earlier seen as a potential barrier to the realization of DR (Torriti et al., 2010). In addition, the amount and role of distributed energy generation is growing (Ruester et al., 2014), which can increase the need for DR. It can be most profitable for the building's owner if, for example, the solar energy produced in a nearby building is at least for the most part also used in that building. Such a situation requires synchronizing at least part of building's energy consumption with the local fluctuating energy production.

There are several technological possibilities for implementing load control in practice. In addition to smart meters, larger buildings normally have some type of building automation system. Technically, DR can be carried out by smart meters or separate appliances, e.g., a home energy management system (HEMS). Also for example electric alternations can be utilized in managing or controlling demand need variations inside the building.

DR can provide different advantages for different market players in the energy system. These advantages include system level power balance and frequency control for the transmission system operator; portfolio optimization and novel pricing structures for the electricity retailer; peak cutting for the distribution system operator; and new possibilities for minimizing the purchase costs of electricity for the end user (Aghaei and Alizadeh, 2013; Shariatzadeh et al., 2015). If DR cuts the peak demands and improves the reliability of the energy system, then it can also reduce the need for additional power plants and committing capital costs to those investments (Siano, 2014). Feuerriegel and Neuman (Feuerriegel and Neumann, 2014) argue that the financial benefit of DR could increase in the future due to rising energy prices, increasing price volatility at different times, and regulatory reasons (Feuerriegel and Neumann, 2014). The possible advantages of DR include the following:

- **End user:** Decreasing electricity purchase costs, optimizing the utilization of energy produced in users' local power plants, and optimizing the size of the main fuse.
- **Retailer:** Optimization of the procurement of the electricity (portfolio optimisation), management of the balance between procurement and sales, novel products and pricing structures, and new business opportunities (e.g., operating as aggregator).
- **Distribution System Operator (DSO):** Peak cutting in normal and disturbance situations, using demand response as a substitute for back-up lines, and optimizing the dimensioning of the network.
- **Transmission System Operator (TSO)**: System-level power balance and frequency control (balancing and reserve power) in normal and disturbance situations.

Both the amount and the reaction time of demand-side resources are important from the perspective of energy system management. The speed at which the load can be changed based on demand affects that capacity's market value (Valtonen, 2015). In addition, the length of the possible elasticity is meaningful for its value.

Significant potential DR resources in Finnish buildings include the electric heating loads of detached houses and ventilation, cooling, and lighting in larger buildings. When utilizing demand response, several types of restrictions must be considered, e.g., indoor air quality (Alimohammadisagvand et al., Forthcoming). In addition, pre-heating of cars, supplementary electric heaters, greenhouses, and freezing plants provide load control resources.

Currently, in Finland, almost every electric customer has a smart meter (~97%), which is remotely readable, registers hourly consumption, and has some load control enabling functionalities. Furthermore, the balance settlement is based on the measured hourly energy consumption of the end-users. It is estimated that Finland could currently have approximately 1800 MW of such controllable loads via smart meters, which are, in principle, technically ready for the utilization of DR, but in practice, there are obstacles for utilizing it (Honkapuro et al., 2015).

Several market places for DR and other flexible resources already exist in Finland. There are the day-ahead (Elspot) and intra-day (Elbas) energy markets offered by electricity exchange (Nord Pool) and the balancing and frequency-controlled reserve power markets offered by TSO (Fingrid Oyj). However, the holders of buildings or apartments are normally not wholesale electricity market parties. Thus, they cannot sell their own loads directly to these electricity markets; instead, they require a third party to join that market and connecting potential loads together. The business ecosystem for DR should be further developed, though some possibilities for smaller electricity users to participate in DR have recently emerged.

Though time-based pricing (night-rate tariff) was popular even before the electricity markets opened and although DR has been part of industrial and academic discussion for some time, a more developed, energy-market-based DR has not been rapidly adopted. Electricity market parties do not appear to have high incentive for developing DR markets. According to Kim and Shcherbakova, the main challenges that DR programs have met can be classified as consumer, producer, and structural barriers. Consumer barriers include the consumer's knowledge, the availability of required technology, fatigue related to continuously responding, technological costs, and the low level of real savings, whereas structural barriers include rate structures, technology, regulatory process, and policy support (Kim and Shcherbakova, 2011).

Greening argued that the reason for slow popularization of DR is not technical by nature and recommended that state regulators regulate DR by developing incentive mechanisms to promote the utilization rate of DR (Greening, 2010). Van Dievel et al. (2014) noted that the consumer privacy issue can also be one potential barrier to the use of demand response for both investors and consumers. The execution of demand response goes hand in hand with accurate consumption data, and these data can include private information. Further, the potential rebound effects after demand reductions must be managed (Fuller et al., 2011)

There can also be conflicting interests between the retailer and DSO that can make the realization of DR more difficult. These conflicting interests have been analysed, for example, in network simulations (Rautiainen, 2015) that examined how peak loads in real-life network would change if the electric heating of the households were controlled according to the market prices of different market places. According to the results, the peak loads of the distribution network would increase if the loads were controlled based only on the market prices.

Cottwald et al. (2011) reported that DR also has potential for producing new challenges, e.g., new types of peaks in energy system. Energy-price-based demand response can change both the load profile in the distribution network and the conflict of interest situations between stakeholders. If a distribution tariff is structured based on the power maximums instead of energy use, then customers are also provided incentives to decrease their peak powers (Rautiainen, 2015). Hence, this kind of tariff would prevent the market-based load control from negatively impacting the peak power of the network. If customers are incentivized to optimize their loads according to both the system price and the distribution network load in such a way that tariffs support the total energy efficiency of an energy system, then more environmentally positive outcomes can result.

3. Demand Response and EU Directives

Demand response is a new approach from the perspective of legal regulation. Present market rules for flexibility in the electricity markets were created in a context when demand response was not real alternative for generation-side resources (Koliou et al., 2014).

In the EU's most recent energy efficiency directives, some changes seems to be occurring compared to earlier energy policy. According to Butenko and Sceres, there is currently "*significant discrepancy between the dominant concept of the consumer as adopted in the hard and in the soft EU energy law*" (Butenko and Cseres, 2015). In particular, in some of the soft-law-type documents produced in the EU, the position of consumers appears to be more active than before: there, consumers are described as active providers of demand response services to the markers. In addition, in the Energy Efficiency Directive (2012), the consumer's role is presented as somehow active providers, whereas in many other directives, consumers are seen as more passive (Butenko and Cseres, 2015). In directive 2012/27/EU, the significance of demand response in developing energy efficiency is explained as follows:

> *"Demand response is an important instrument for improving energy efficiency, since it significantly increases the* ***opportunities for consumers or third parties nominated by them to take action on consumption and billing information*** *and thus provides a mechanism to reduce or shift consumption, resulting in energy savings in both final consumption and, through the more optimal use of networks and generation assets, in energy generation, transmission and distribution."*

In the same directive (2012/27/EU), in article 15, it is required that European Union's member states should ensure "*the removal those incentives in transmission and distribution tariffs… that might hamper participation of demand response, in balancing markets and ancillary services procurement*", "*that network operators are incentivised to improve efficiency in infrastructure design and operation, and, within the framework of Directive 2009/72/EC, that tariffs allow suppliers to improve consumer participation in system efficiency, including demand response, depending on national circumstances*", "*national energy regulatory authorities encourage demand side resources, such as demand response, to participate alongside supply in wholesale and retail markets*" and "*promote access to and participation of demand response in balancing, reserve and other system services markets, inter alia by requiring national energy regulatory authorities or, where their national regulatory systems so require, transmission system operators and distribution system operators in close cooperation with demand service providers and consumers, to define technical modalities for participation in these markets on the basis of the technical requirements of these markets and the capabilities of demand response*".

Thus, the Energy Efficiency directive sets requirements for network and retail operators to promote demand response by their pricing tariffs. In annex XI of the same directive, time-of-use tariffs, critical peak pricing, real time pricing, and peak time rebates are mentioned as examples of network or retail tariffs that could support dynamic pricing for demand response measures. However, this directive does not set requirements for building designers or for the consumer side related to demand response.

Network regulation (Agrell et al., 2013) and energy market regulation solutions are important tools when promoting demand response. However, in the literature, little attention has been paid to how demand response could be promoted in buildings by building codes and by buildings' original designers. In this paper, it is argued that preconditions of demand response could be promoted by building codes among other regulation instruments. Next, we examine this subject using Finland's building codes as a case example.

4. Building Codes and Energy Efficiency

Lee & Yik classified instruments encouraging energy efficiency in buildings into three categories: (1) building energy codes, (2) incentive-based schemes, and (3) eco-labelling schemes (Lee and Yik, 2004). Building codes affect buildings' design and construction processes and, thus, its features aside from land use planning regulations. Incentives include energy taxation and energy renovation aids; in addition, energy certificates can be seen as examples of eco-labelling.

Buildings codes have a meaningful role in reducing the energy consumption of buildings (Scott et al., 2015). The use of mandatory building codes in encouraging energy savings in the buildings became widespread in the 1970s after the energy crisis. (Allouhi et al., 2015; Lee and Yik, 2004). These building codes are currently widely used instruments, especially in many developed countries, and are used among other things to control the energy consumption levels of new or renovated buildings (Iwaro and Mwasha, 2010; Salvalai et al., 2015). The content of building codes varies in different countries and areas, where climate conditions and local needs can differ. Building codes are applied in the design and construction phases of new and renovated buildings; however, such codes are not necessarily able to give orders regarding the use of the buildings or buildings products, for which different legal instruments should be used. The legal status of building codes also varies in different places: their status is mandatory in some countries or areas, voluntary in others, and mixed in still others (Iwaro and Mwasha, 2010).

In Finland, building codes (see Building Codes of Finland) have traditionally included both mandatory rules and voluntary instructions in the same documents; however, the situation is changing, and there is ongoing a process for separating mandatory parts from instruction parts by 2017. All mandatory parts of the building codes will be in the future given by decrees of the Ministry of the Environment in Finland. In this paper, both the mandatory and instruction parts given by the responsible ministry or government are called building codes.

Finland's valid Land use and construction act (117 g §) mandates the Ministry of the Environment giving building decrees about the minimum requirements for energy efficiency in buildings; building products and technical systems and their calculation methods; heating systems in buildings; improving energy efficiency; measuring energy consumption; and the minimum energy efficiency requirements based on a building's intended utilization. Mandatory regulation regarding the electricity use of buildings is focused on safety issues and is given in documents that are not classified as building codes. HPAC issues are addressed in the building codes.

Building codes of Finland are applied when building licence is sought. Building codes guide the designers' solutions, and consequently the features of the buildings. When it comes to the many details of the energy systems, building professionals make several decisions for the end users. related to the details of buildings' energy systems. Thus the designers and electricians may play a key role in how DR-ready the new or renovated buildings will be or whether DR features are utilized. However, the building codes and the design solutions can impact the user behaviour only partly and indirectly in the utilization phase.

Even though building codes are currently instruments that can be used also in encouraging towards energy efficiency, their role in predefining the probable load profile of buildings' energy use has not often been dealt with. Plans of new buildings have to be in accordance with regulations. Current building codes in Finland set limits for computational annual energy use in new buildings, which is calculated based on plan documents. However, timing profile of energy use inside the year or energy load profile of building has no weight in current regulations.

5. Discussion

Through building codes it is possible to set requirements for technical solutions or technical readiness issues in buildings, to guide the selection of building products utilized in buildings, and also for example determine the targets, objects and methods of energy calculations. Table 1 provides some examples how demand response capabilities in new or renovated buildings could possibly be advanced by building codes. The cost efficiency and effectiveness of the means presented in the table are not analysed in this paper. It could be a theme for further research.

The ways how demand response capabilities in the buildings could possibly be advanced by building codes could include for example changes in minimal technical requirements; changes in the other details of energy efficiency incentives; and changes in things that influence designers', buyers' and public officers' awareness of the power behaviour of buildings and how it can be affected by design solutions. In principle, it is possible to respond by demand on many levels, including the energy market level, the distribution network, and the building's own electric network. Also the regulating means listed in Table 1 can have targets on different levels.

Table 1: Examples of how readiness for demand response could possibly be advanced by building codes (or voluntary actions related to them)

Means of regulation	Object of impact	Example
Defining the technical requirements so that readiness for DR grows in the buildings	Technical solutions and possibilities to exploit DR	Massive structures and boilers are often able to store heat energy in building, which can be utilized in DR. However, if HVAC systems are not easily ready for DR, those capacities are not so likely utilized.
Requiring that power use efficiency is noted when performing the energy calculations required for building licence	Power use behaviour of buildings	Target values for the electric power use could be set both for peak and empty use times of buildings for daily hours and different seasons. Those values could be calculated when the energy calculations of buildings are performed anyway.
Taking into account DR when determining the primary energy factors per energy carrier	Energy certification class & profitability of DR investments	Lower primary energy factors per energy carrier could be utilized for electricity in the primary energy calculations if DR are considered in the design
Instructions for synchronizing distributed local renewable energy production and energy use inside the building	Timing of energy use in comparison to timing of local energy production	The DR features of appliances could be encouraged to put into operation, when they have such
Instructions or recommendations for power management inside buildings	Power fluctuation management inside the building	It could be encouraged that especially larger loads, e.g., sauna stoves and heating pumps, are alternated to limit the probabilities of sharp power peaks in the energy demand of the building

Currently, the building codes of Finland concentrate on annual energy consumption, and the timing of the consumption or the power peaks do not play a significant role. However, as noted in the literature review, the timing of consumption can be an environmentally significant issue, and influence, for example, the greenhouse gas emissions of energy production and wider energy systems. Technical solutions affect some DR capabilities. For example thermally massive structures can slow temperature changes in a building and add the possibility of changing the timing of heating. To guide the designers' and building owners' attention towards the power use instead of annual energy use alone, some target power values could be set and calculated for both peak and empty use times that could be taken into account in the design phase.

One idea that we have proposed as an incentive for DR is that lower primary energy factors per energy carrier (see 2010/31/EU, Annex 1) could be utilized for electricity in the primary energy calculations if DR was utilized. The basic idea behind those primary energy factors is to encourage reduction of the total primary energy consumption and to promote the share of renewable energy sources. If DR could help to reduce the consumption of non-renewable energy sources, then this fact might be an argument for applicability of lower computational factors. The values for those factors are nationally appointed in the member states of EU. In Finland, those factors are given as a Government Decree and published also among the building codes.

The aim of the instructions for synchronizing distributed local renewable energy production and energy use inside a building is to direct the demand inside the building towards the production time and power profile of local energy production. The same technical structure for demand response system might be applicable in other levels and types of DR. In the present smart electricity meters, there are some readiness features for demand controlling that could, in principle, be utilized in some type of DR. However, those features are often not installed for use or are not utilized if they are installed.

In Finland, the electric sauna stove and heating systems of several residential houses have been alternated via the electric installations for decades without legal commands. Those alternations have reduced the power peaks inside the building and needs for larger fuse size. However, omission of such alternations has nowadays become more common in new buildings. Building codes have not traditionally regulated electric installations in Finland, but the power behaviour of buildings could be at least indirectly guided also by building codes.

When developing regulation related to DR, also the risk aspects must be considered so that the regulation wouldn't, for example, lead to such new losses that do not exceed the benefits obtained from the perspective of total energy efficiency. For example it is possible that if DR readiness is required by mandatory regulation, the features may not in all cases be utilized in practice, at least if DR features are not sufficiently economically profitable or easy enough to use. When developing regulation, also technological development and new types of future solutions for power management should be somehow taken into account. The focus in this paper has been in such types of demand management that do not require the end user to play an active in the using phase of the building's life cycle. However, the building's owner or user may need to make decisions whether the DR features are utilized in the building or not.

6. Conclusions

From the perspective of total energy efficiency of energy systems, it could be useful if the power aspects were considered more in the design phase of buildings in addition to annual energy use examination. Regulation by building codes is not the only possible approach for affecting preconditions of DR, but it can be one piece of the larger puzzle, which includes also for example information issues, taxation solutions, tariff structures in distribution network and energy market regulation.

Although the load profiles of different building types vary in different countries, the need for load management and demand response ability may grow worldwide as the structure of energy production is changing towards a more renewable nature. Further research is needed about the connections of DR and effectiveness of regulation in the built environment.

Abstract

Energy efficiency is a requirement included in building for the future constructions; modelling tools to manage the design, construction and maintenance of the building are available to assure quality in the process by controlling the interaction between disciplines connected with the built environment (i.e. architectural design, structural design, MEP design). The building construction management and the durability screening of the building can be improved and optimized by the BIM techniques that can also became an efficient tool to check the economic aspects during the building lifespan. The energy consumption during the running phase is the focus of possible future contract of building quality and the possibility of providing accurate and robust performance analysis, including prediction of uncertainties and variations related to change of use and occupants' profiles will become dramatically important. Define procedures and tools to provide a connection between models used in the design and management phases of the building with the objective of minimize the energy discrepancy between energy prediction in the project phase and actual energy consumption in the operating phase are accordingly the aim of the paper towards future energy assurance contracts. The paper describes the tested procedures to outline interoperability paths between BIM and BEM models with different software providing workflows that can be suitable in different design processes and work phases. The easiest process cannot be the more accurate and a results comparison with test reliability procedures can improve the reproducibility of the process and modelling strategies to facilitate the interaction between analysis tools at different levels.

Keywords: BIM to BEM workflow, energy efficiency, Building Information Modelling, Building Energy Modelling, Energy contract

1. Introduction

The housing crisis shifted the focus of the building sector from new construction to existing assets. International studies about energy retrofitting show the benefit of benchmarking in improving the energy efficiency during time. Benchmarking is the collection, comparison and sharing of building energy use data and ratings and can lead to an improvement of energy saving about 7% in few years (Vancouver Council, 2014; IEA-ECBCS, 2011). The use of digital methods to manage the design process allows the integration of multi-objective analyses (Asadi et al., 2012) (i.e. architectural, structural, MEP, energy modelling) into a main chain of information enhancing the effectiveness and the accuracy of the design, construction and management processes. Compared evaluation of multi-options scenarios and crosschecks between disciplines on a same BIM model (Building Information Model) can reduce time and cost due to variants and adjustments in the construction site.

The aim to prevent inconsistencies occurring in the standard design process led the BIM into the limelight in the public procurement as is explicit in the European Directive 2014/24/UE, art. 22/4 that states: *"4. For public works contracts and design contests, Member States may require the use of specific electronic tools, such as of building information electronic modelling tools or similar…"*. Consequently, the BIM model adopted to manage the whole building process in a wide-sense life cycle approach includes additionally the energy management of the building. The energy item should be included in the BIM model since it is could be a key factor in the building contracting. The building energy compliance to evolving regulation towards more and more restrictive thresholds of consumption during the lifespan of the building needs powerful tools that redraw the building status when maintenance changings occur. If there is an envelope improvement and/or a HVAC system replacement as well as the requirement to provide energy retrofit measures, the possibility to run a BEM model connected to BIM information is crucial both in existing and new constructions.

The residential and tertiary buildings have the considerably weight of 40% in the final energy consumption of the European Union (Directive 2010/31/EU). Energy reduction of about 30% of energy consumption of the building sector is mandatory in European directives to reach the 20-20-20 Climate-Energy Package (Directive 2009/87/EC) objectives. Furthermore, energy and environmental policies require greenhouse gas emissions reduction by at least 40%, a growing renewable energy production and energy efficiency by 27% (European Commission, 2030 Framework, 2013). The main field of implementation for energy efficiency is related to the new constructions as the renovation rate of the complete building stock is 1.1% and the existing buildings interested by retrofit represent about 1.8% (Ascione *et al.*, 2012) of the total amount. Additionally, renovation strategies should be based on cost-optimality criteria (BPIE, 2010).

Northern European countries commonly use the BIM model to manage public contracts and it is widely adopted at national level; nevertheless, a dissemination phase is still required. BIM tools enhance and optimize the interconnections between actors and stakeholders of a project allowing the rationalization of the different phases: design and programming, project management, construction, operation, maintenance and budget (East et al., 2013). In term of energy efficiency BIM is an influential tool to include the control and reduction of the energy consumption of the building during the design phase and running phase decreasing the related costs and environmental impacts. Therefore, the connection and interoperability of BIM (Building Energy Modelling) to BEM (Building Energy Modelling) is a key point to share information and results for development purposes between the experts in the involved fields. Furthermore, the reliability of the energy simulation and result is an additional issue when energy requirements are part of a sale or rent contract; currently the energy certificate of a building or an apartment is mandatory in these kind of trades.

2. BIM to BEM

The BIM federated model can be the information base or the main store of the data allowing designers to perform structural, MEP, energy analyses. According to BIM uses, the development of the input requirements permits to cover the more fields of knowledge. For an effective BIM to BEM workflow, reducing data loss, the correct information for energy modelling has to define the building information model according to the different stages of the project (COBIM 2012, Series 10). The possibility to use the same information included in the BIM model directly into the BEM model provides a guarantee in minimizing the discrepancy and loss of information between the two models. The need to implement the information, usually not included, in the architectural model, requires as first the cooperation in the team work of the energy analyst with the architectural team in a starting phase of the design (with positive consequences) and the enrichment of the model with energy information such as:

a) thermo-physical characteristics of the envelope materials;
b) specification of window energy performance;
c) space uses to identify homogeneous thermal zones;
d) thermal loads due to the specific use of the different thermal zones;
e) ventilation rates of the thermal zones (per occupant or space size criteria);
f) set point temperatures of the thermal zones;
g) HVAC systems for the building and for each thermal zone.

An additional information related to energy issues is the value of the embodied energy for each material, the data sheet for specific products (e.g. phase change materials, membranes, etc.) that can be useful to qualify the energy model; however, this information has to be post-processed in the BEM modelling phase. The relevance of a unique repository of structured information is the basis for the organized and shared set of data belonging to all the concerned parts. BIM allows the comparison of system configurations, to compute components (e.g. pipes, plants, etc.) by metric automatic calculation and to connect data sheets to the plant components or other elements of the project. The BEM simulation can provide a strong criterion in the decision process, when energy saving strategies to pursue economic targets are included.

The paper provides a list of BIM to BEM workflows with commercial available software to deliver enlightenment about this data interchange process. The research work aims in identify the most promising interoperability paths. The methodology adopted is explained in the following section 3 in which the interoperability workflows are discussed.

3. Methodology

3.1 BIM software

The BIM software used as starting point is Autodesk Revit, a BIM platform widely used in the professional and research field of construction and digitalization of the design, construction and operating phase of a building life cycle. Different BEM tools imported the output from Autodesk Revit to test the workflows. In section 6 the discussion of strengths and weakness for each software is reported considering the following indicators:

- Usability;
- Accessibility;
- Accuracy;
- Geometry import;
- Envelope thermal features;
- HVAC setup;
- Model export;
- Parametrization;
- Compatibility.

3.2 BEM software

The review of the BIM to BEM workflow does not claim to be exhaustive; however, the provided review covers much of the most significant options today available in the digital land for energy modelling in the professional field and advanced research. The tested energy simulation software are listed below:

- Autodesk Green Building Studio;
- SketchUp / Energy Plus;
- Design Builder;
- Grasshopper / Honeybee.

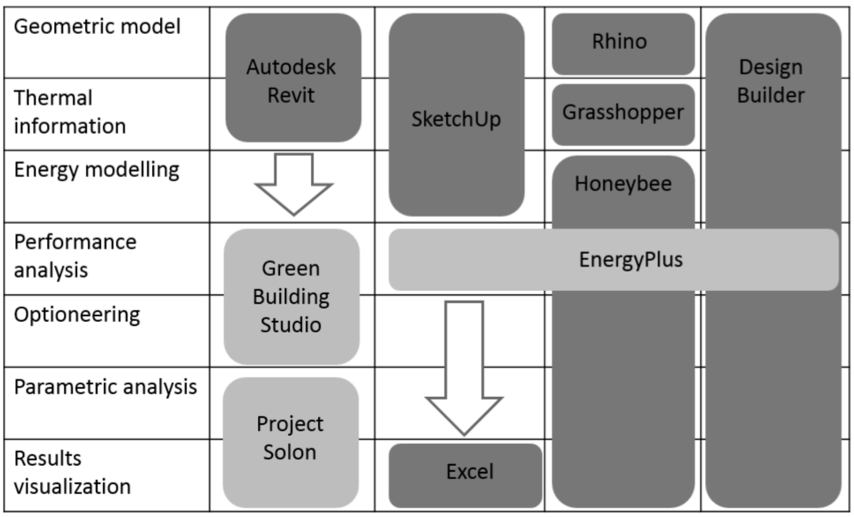

Figure 1: Digital tools used to manage different phases of the analysis process.

3.3 Research process

The work process has been structured by applying to three residential case studies, described in section 4, the different workflows following standard steps:

- Preliminary analysis of the project in order to evaluate the suitable thermal zoning (heated and unheated zones, shading surfaces, etc.) and thermal data collection (materials data);
- Realization of the BIM model of the buildings with thermal homogeneous spaces (spaces, rooms) to apply thermal zoning;
- Definition in the BIM model of the thermal characteristics of the envelope materials and components (both opaque and transparent);
- Setting of the heated and unheated zones in the BIM model (temperature set-point, internal loads due to people, appliances, ventilation rates, HVAC type applied to the thermal zone);
- Energy analysis within the software Autodesk Revit using the Energy Analysis form exporting to Autodesk Green Building Studio; then Green Building Studio can export Energy Plus software standard files (*.idf file);
- Import of the exported information to Energy Plus software, procedure of information transfer, tracking/checking/detection of critical issues;
- Realization of energy models into the listed software and reliability comparison of the results to assess the user friendliness, accessibility and robustness of the process.

4. Case studies

The three residential case studies are representative of the main problems extensively diffused in the existing building stock at national level considering the age of construction and technology. The buildings are located in northern Italy, in the city of Brescia (latitude 45.54°N, longitude 10.22°E). The sizes range from a detached house (Castenedolo) to apartment building (social housing in Casazza) to double family detached houses (social housing Case Marcolini), as shown in Table 1.

Table 1: Case studies located in Brescia province, Italy.

	Single family house, Castenedolo	*Social Housing, Casazza*	*Double family "Case Marcolini" settlement*

5. Workflows

The tested workflows are described in the following sub-sections. The simpler workflow is the basic one from Autodesk Revit to Autodesk Green Building Studio through the Energy Analysis toolbar. This workflow allows a first analysis and an output file to perform detailed simulations in EnergyPlus software. Moreover, other accredited energy software widespread adopted have been tested considering the criteria listed above in sub-section 3.1 and the goal was to achieve the detailed dynamic simulation with EnergyPlus software (LBNL, California).

5.1 Autodesk Revit to Green Building Studio

The energy simulation of the building takes place in the cloud using a special form in the main Autodesk Revit toolbar. As first, a detailed BIM parametric model of the buildings have been created. An accurate BIM library of materials, with defined thermal properties, has been used as basis to design the envelope. Internal loads, ventilation rates, detailed schedules of use and thermal plant features have been selected for each thermal zone. The “Spaces” tool permits to identify and describe the rooms as thermal zones. Autodesk Green Building Studio (GBS) has been used to analyze the buildings. The simulation in GBS runs 40 parallel parametric options of the project introducing variation in different parameters to evaluate the variability of the energy performance based on ASHRAE standard requirements. This tool is very powerful and the application of the Project Solon panel allows an effective results vitalization and communication. Project Solon is an experimental customizable interface to create dashboards and set up specific graphs and comparison chart used to manage and report the data about the energy performance. However, the user must carefully control the settings to export the model in Autodesk Revit to the GBS platform because the application is organized such as to give default settings to the model for the analysis and often the inexpert user cannot be so aware to avoid uncontrolled change/overwriting in the model features. The information are equipped of additional considerations that can be misleading for unprofessional user. The GBS tool allows a simple interoperability path giving access to the project team to the energy analysis in a smart way, it must be underlined the need of a supervision and verification process by energy experts.

5.2 Autodesk Revit to EnergyPlus (through GBS)

From the first workflow the EnergyPlus compatible file (file *.idf) has been exported. The file imported in EnergyPlus software has been verified to verify the data transfer. Three BIM to BEM models have been tested using different level of detail in the BIM model as listed below:

- Detailed architectural model;
- Simplified architectural model;
- Conceptual mass model.

The data transfer process from BIM model to EnergyPlus allowed successfully importing of the energy characteristics of the layers of the vertical walls, while errors occurred in the importation of floors and windows characteristics. Furthermore, the visualization of the model into the graphical interface SketchUp allowed pointing out serious problems in the intersections between the interior partitions and exterior walls and floors due to model specification in the "Spaces" configuration. The high level of detail of the BIM model is not always an advantage in the BEM model and sometimes a simplification, without significantly outcome on the energy results, is required to enhance compatibility. For this reason, a simplified parametric model has been realized and compared to the detailed one. In this way, it was possible to achieve an improvement in geometry transfer. Finally, a conceptual mass model has been analyzed. In this model, it is possible to simplify the assignment of energy characteristics even though with default constructions. These constrains leads to a time-expensive post process of the file in the EnergyPlus interface (EP-Lunch) due to the change in the naming transfer process that modify all the elements' name given in the BIM model, beyond the fact that the actual envelope characteristics have to be manually implemented.

5.3 SketchUp to Energy Plus

Upon the data transfer problems between Autodesk Revit and EnergyPlus, an alternative model in SketchUp has been developed and tested. SketchUp is a graphical interface used for the geometrical Modelling for Open Studio (NREL). On the same concept, the plug-in BESTenergy (Politecnico di Milano) allows to run EnergyPlus simulations through a simplified modelling in SketchUp. The geometrical model has been constructed as sum of adjacent thermal zones supplied by thermal characteristics of the envelope, internal gains and ventilation rates, schedule and temperature set points. The model allows to extract demands of sensible heating and cooling. The *.idf file exported from GBS has been tested in Open Studio and BESTenergy; however, problems in identification of materials, geometry, schedule for varying parameters and simulation setting have been reported and time-expensive procedure of adjusting have been compared to the "starting from zero" modelling process. The process is simplified (in comparison with direct use of EnergyPlus software) and transparent (compared to GBS process) easing the hourly dynamic energy simulation effort. When modelling errors or lacks are detected, the software generates a detailed list of errors that have to be corrected in order to successfully run the simulation. As opposite, in the GBS model the lacks are automatically corrected with default construction and settings allowing the energy simulation. This process enables the simulation on the other hand could contemporary lead to modelling errors out of user's control. Results can be organized in graphs and communicated through *.xls file data post-processing.

5.4 Rhinoceros to Honeybee (through Grasshopper)

An alternative workflow has been to model the geometry of the buildings into the software Rhinoceros, using the component Grasshopper and simulate the energy behavior through the plug-in Honeybee running EnergyPlus simulations. The file can be exported directly as *.idf file and as *.gbXML file through GrizzlyBear (Core Studio, 2015). This workflow was lunched with the aim of creating an energy model defined by algorithmic components of Grasshopper in order to subsequently develop retrofit solutions through the parametric solver Galapagos. The creation of the model is a time-expensive process requiring hardworking effort due to the software's complexity. In particular, the schedules' management has been reported as particularly complicated. It is possible to visualize and customize the output into Honeybee plug-in in order to underline the relationship between energy parameters (e.g. wall insulation/energy performance). The values of the results are comparable with results coming from other tools and actual energy bills (section 6), even so further verification on the accuracy of the data to calibrate the models and test of robustness of the interoperability process have to be applied.

5.5 Autodesk Revit to Design Builder

The parametric BIM model realized in Autodesk Revit can be directly exported by an add-in button to Design Builder software or through *.gbXML file. Design Builder is a complete commercial product including EnergyPlus thermal simulation, daylighting simulation, CFD and optimization tool (using JEPlus, a Java shell for EnergyPlus parametric analyses). The software can export *.idf file for direct use in EnergyPlus software. The Autodesk Revit to Design Builder add-in button allows transferring the correct geometry of the building; however, some problems in thermal characteristics of the envelope data transfer occur in multi-zone models. In single-zone models, a complete transfer of thermal properties of the stratigraphy of the wall through “Rooms” tool (instead of “Spaces” tool) could be verified however, other specifications cannot be included in this setting. The schedules’ settings (internal gains, ventilation rates and set point temperatures) and thermal plant have been setup in Design Builder software. Expertise in energy modelling specifically for thermal HVAC systems and operating is required to manage correctly the software and results analysis. A set of standard results visualization is available into the software. The exported *idf file is compatible in EnergyPlus (through an updating process in the EnergyPlus utility form).

6. Discussion

The tests carried out showed that information requirements in terms of energy analysis need a careful management, especially considering the quality of data implemented in BIM platforms used by designers (COBIM 2012, Series 10). Revit model has not to present a high LOD (level of detail), in order to reduce errors in the information workflow. At minimum, the architectural model has to define spaces and rooms. Some of the tested BIM-to-BEM workflows required the creation of a separate geometry model containing all the necessary energy requirements. The export file must essentially include features related to energy analysis by reducing them to essential data for the specific analysis in order to not burden the *.idf file transfer with information that may be distorted and compromise the successfully processing of the analysis within EnergyPlus software. The SketchUp plug-in can be extremely useful for displaying the geometry problem of data transfer that could not be pointed out directly in EnergyPlus interface (EP-Lunch). The interchange *.idf files created by GBS are not directly useable and a hard work of adjustment of the exported files turns into more convenient to restart to model into compatible graphical interfaces with EnergyPlus (SketchUp plug-in) or including it (Honeybee, Design Builder). In this way, the compatibility of the file is complete.

Design Builder is the most directly connected BIM to BEM model tool in the present review, however manually implementation of some data setting is required. A full interoperability occurs between Autodesk tools (Revit to GBS), although the reliability of energy calculations is not easily verified and comparison of results with actual data shows significant discrepancies (*Figure 2*).

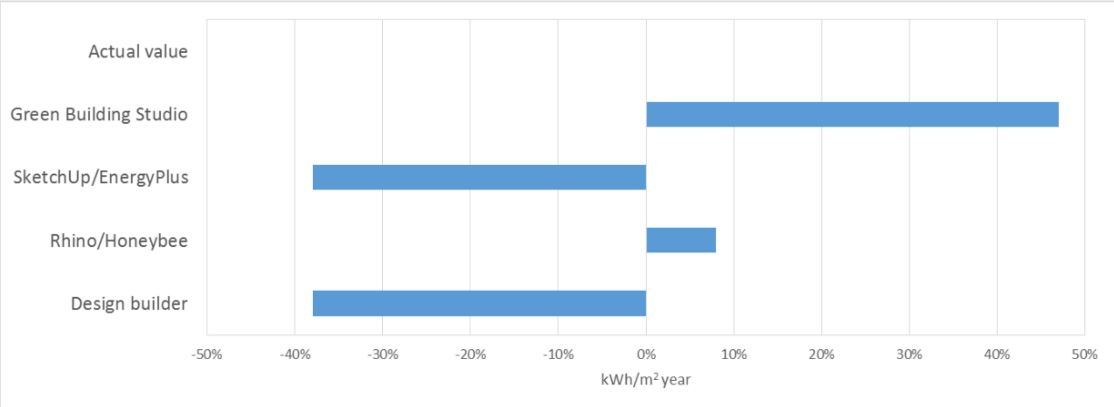

Figure 2: Energy results comparison between BEM software and actual results (energy bill).

Directly use of energy simulation software allows a parallel workflow starting from traditional data. The challenge is to find out an uninterrupted information flow even in both direction assuring reliable results. Interoperability workflow based on the *.gbXML format, such as the Autodesk Revit to Design Builder, can guarantee consistent results even though a detailed set up process of the thermal zone has to be performed. This workflow connects Autodesk Revit model to EnergyPlus (version 8.2) through a working *.idf file without additional adjustments, as is instead required for the *.idf file exported by GBS.

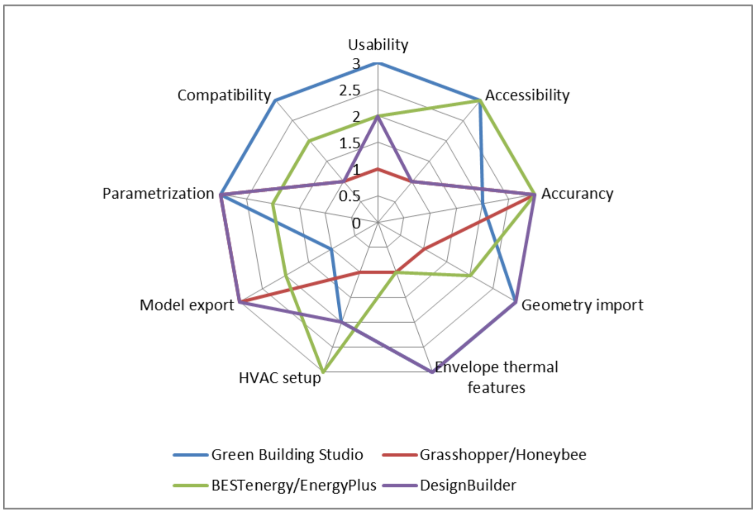

Figure 3: Spider diagram: evaluation of the BIM to BEM workflows.

Thermal zone properties defined in the BIM model can be also exported by using the interoperability workflows proposed in this research. For example, thermal properties can be added to spaces for energy analysis in Autodesk Revit. Geometrical attributes can be added in

Revit rooms. Both geometrical and thermal properties can be imported in Design Builder by the *.gbXML format, but more tests have to be completed on this data flow. The Industry Foundation Classes (ISO 16739:2013) IFC-based BIM to BEM workflow has been initially tested to be used with software Energy Plus (EnergyPlusTM, 2013) through SkecthUp interface, e.g. BESTEnergy (Aste et al., 2012) and Open Studio (Parker et al., 2014). However, it has not been resulted as a user-friendly option so far if compared to the results of other workflows. Further tests will be conducted as future works, especially for the IFC-based data flow Open Studio/SketchUp.

7. Conclusions

The research aims to evaluate the reliability and usability of workflows to ensure energy analyses for buildings in a market scenario in which the BIM model will be the reference database for the whole management of the asset. Issues as maintenance, LCC (Life Cycle Cost), LCA (Life Cycle Analysis), energy management and standard compliance can be controlled through the same exhaustive repository of a central federated model. In this scenario, the data sharing between all the actors of design and built management processes promotes the integration of skills and information without lack of knowledge. This can be achieved through interoperability processes and including platforms, especially if they are based on neutral data formats.

Nowadays, energy simulation are required to be dynamic in order to detail on hourly basis the energy behavior of the building. The Net Zero Energy Building task needs a tailored design, an accurate construction and a structured management to reduce the variability of the energy consumption due to factors introducing a fluctuation of the energy needs (i.e. user behavior, control of the running parameters vs. designed parameters, built quality, etc.). Finally, the possibility to carry out a monitoring phase of the energy consumptions through sensors installation connecting them to the BIM model could be the further step to manage the whole life of the building in a holistic vision and to calibrate the predictive models (Miller et al., 2014).

The performance gap commonly occurring in comparing energy simulation results and actual energy bills needs a crossing by providing a reliable model on which energy contracts could be based. Moreover, the information-based technologies allow visualizing, sharing and comparing data that become strong decision drivers for energy strategies and policies. Subsequently with the evolving energy regulations the energy performance of the building turned into a discriminating factor for the building sector market and the evaluation of the whole quality of the asset together with economical (that is strictly related) and location and space flexibility criteria. Standard test procedures ANSI/ASHRAE 140 and Regression test for Energy Results validation are decisive to evaluate and to define the consistency of prediction results; however, tests on real buildings to calibrate the model are not avoidable.

An informed use of energy simulation tools, based on the knowledge of physical and thermal exchange phenomena, is fundamental for the user to be able to crosscheck results using simplified models. Anyway the validation of input data is the first check to correctly predict, with a uncertainty rate, the energy result, in order to guarantee consistency between input and output (to avoid the “garbage in – garbage out” effect). For this reason, a solid knowledge of limits of the interoperability workflows can be seen as a core interest in the applied research. In this direction, the laser scanner technology integrated with BIM model is a step to survey existing building providing transparent and validated geometrical data.

Environmental Assessments in the Built Environment: How Reliable Are They?

Jukka Heinonen
Faculty of Civil and Environmental Engineering, University of Iceland
(email: heinonen@hi.is)

Abstract

Assessing the environmental consequences of using and developing the built environment is becoming more and more important. A huge problem is that in many cases the assessment methods are not well-enough developed to lead to credible results. Life cycle assessment (LCA) is one of the most widely used assessment approaches and it is believed to deliver reliable data. Still, two assessments can lead to very different outcomes even when following high academic rigor. In this study, a streamlined LCA to greenhouse gases (GHGs) was utilized to demonstrate certain problematic perspectives in the state-of-the-art of environmental assessments in the built environment. The focus of the study was on buildings and especially on the assessments of embodied GHGs in buildings, which provide an abundance of great examples of problematic issues. In the study, three examples are presented of situations where the reliability of the results of a certain study is questionable: (1) a wooden frame window, (2) a steel body passenger elevator, and (3) a multi-story concrete frame residential building. The particular uncertainty/error perspectives discussed are truncation error in conventional process LCAs in different assessment cases and the assessment scope differences between different studies. Through discussion the case results are positioned to depict the problems on a wider scale. The particular perspective with novelty value for the truncation error discussion is the so-called "first tier truncation error", which has received very little attention so far. The error arises if, for example, a certain building item, is assessed according to the different materials needed. The assessment de facto does not take into account the actual window manufacturing stage, resulting as an additional downwards bias.

Keywords: Built environment, environmental assessment, life cycle assessment, LCA, uncertainty

1. Introduction

Assessing the environmental consequences of using and developing the built environment is becoming more and more important. Developing our settlements sustainable is one of the grand challenges of our time (Rees and Wackernagel 1996; Seto et al. 2014). Climate change mitigation has already grown into an aspect to consider at virtually all levels of decision-making (Säynäjoki et al. 2014), and new global problem areas like biodiversity loss are gaining attention (Steffen et al. 2015). The environmental issues have penetrated into the processes of the users and developers of the built environment, and various assessments are run on regular basis to understand the environmental impacts of certain actions or activities and to compare different options (Säynäjoki et al. 2015). The huge problem is that these assessments are believed to produce reliable information, and the results are utilized to justify decisions and draw policy-guidelines, when actually both the quality of a high share of these assessments and often even our state-of-the-art in assessing certain impacts are not high enough to lead to credible results.

Life cycle assessment (LCA) has established a strong position among the environmental assessments and it is believed to deliver reliable data. Still two assessments can lead to very different outcomes even when following high academic rigor (Suh et al. 2004), and many assessments are lacking this quality. With other assessment approaches, similar and even more worrisome examples can easily be found. It is not even rare that a new study suggests entirely different impact factors to be utilized than the current tradition to assess the impacts of a certain action or activity.

In this study, a streamlined LCA to greenhouse gases (GHGs) is utilized to demonstrate certain problematic perspectives in the state-of-the-art of environmental assessments in the built environment. The focus of the study is on buildings and especially on the assessments of embodied GHGs in buildings, which provide an abundance of great examples. In the study, three examples are presented of situations where the reliability of LCA method in the built environment context is questionable: (1) a wooden frame window, (2) a steel body passenger elevator, and (3) a multi-story concrete frame residential building. The particular uncertainty/error perspectives discussed are truncation error in conventional process LCAs in different assessment cases and the assessment scope differences between different studies. Through discussion the case results are positioned to depict the problems on a wider scale. The particular perspective with novelty value for the truncation error discussion is the so-called "first tier truncation error", which is present in the majority of building and civil structure LCAs but has received very little attention so far. The first tier truncation error arises, if e.g. a certain building item, like window, is assessed according to the contributions of the different materials needed. The assessment does not take into account the actual window manufacturing stage, resulting as an additional downwards bias (in addition to the "traditional" truncation error inherent to all process LCAs).

The remainder of the paper is arranged as follows. In Section 2 the main LCA approaches are presented with the emphasis on the qualities potentially leading to biases and errors in the assessments. Section 3 presents the demonstration cases and the data. Section 4 shows the results and Section 5 provides discussion about the key issues. Section 6 presents some key conclusions.

2. Method

According to its name, LCA estimates the environmental burdens of goods, services or processes over their life cycle from cradle (e.g. raw materials extraction) to grave (e.g. disposal or recycling) (Klöpffer 1997). The method has been developed since the '60s (e.g. Hunt and Franklin 1996), but the use in the building sector has increased rapidly since the '90s at least in terms of number of academic publications (Fava 2006; Sartori and Hestnes 2007; Buyle et al. 2013; Sharma et al. 2011). There are two main approaches to LCA: process and input-output (IO) LCA. Both have their strengths and weaknesses, but are inherently different, potentially leading to very different assessment outcomes (e.g. Lenzen 2000). Here the methods are only briefly summarized, and the focus in the next sections is on the particular weaknesses which may add significant uncertainty to the results.

2.1 Process LCA

Process LCA is the traditional, most widely utilized, method for an LCA (e.g. Suh et al. 2004). Process LCA utilizes material quantities to estimate the impacts related to their production. The environmental data are typically taken from existing databases such as ecoinvent or GaBi. The method is held as accurate due to its quantity basis and the high-resolution material distinguishing ability. At the same time, however, the method suffers from an inherent truncation error from certain higher-order phases of the production and delivery chains being virtually always left outside the assessment boundary (e.g. Suh et al. 2004; Matthews et al. 2008). Lenzen (2000) has suggested these cut-offs to be quite significant overall, and in one of the very few building LCA comparisons Lenzen and Treloar (2002) suggest the error as potentially being 50% or even more in that context. Junnila (2006) has demonstrated the cut-offs to be significant in the service industries.

Another, much less discussed, issue is that there actually is a "first tier truncation error" quite typically present as well in process LCAs (Heinonen et al. 2016), particularly in the context of the built environment. When items are assessed through the material quantities, the final production and assembly phase might be omitted, especially in the case of pre-manufactured items utilized in the production of the assessment object, such as electricity and piping systems or elevators in a building. The material quantities omit potentially an important share of high-degree processing leading to a significant "first tier truncation error". This issue will be discussed through the selected assessment examples of this study.

2.2 Input-Output LCA

IO LCA assesses the environmental impacts based on monetary transactions and the spreading of the value-added through the economy. IO LCAs utilize environmentally-extended economic transaction matrixes (i.e. IO tables), which allow for summarizing the overall impact caused by a transaction on one sector based on how the value-added spreads through the economy. IO LCA is typically based on the IO tables of national accounts, although multi-region models exist nowadays. The method was first introduced by Leontief (1970) in the '70s. IO LCA achieves a theoretical full system completeness since an infinite number of upstream processes are inherently included (e.g. Suh et al. 2004). However, as Lenzen (2000) presents, IO LCAs don't inherently include the use and disposal phases (the life cycle ends at the factory gate) and thus they also suffer from a kind of a truncation error without amendatory actions.

The method suffers from several inherent problems. The most important are aggregation error and homogeneity and linearity assumptions. Aggregation error arises from the fact that each IO sector actually is just a weighted average of the emissions intensities of multiple sectors of an actual economy (e.g. Suh et al. 2004, Crawford 2009). Thus the intensity might randomly over- or underestimate the actual emissions from the assessment object. Homogeneity assumption means that all the products within an IO sector have the same emissions intensity. Linearity assumption refers to the inherent assumption of IO models that the exchange price would have linear correlation with the emissions, which in many cases doesn't hold true (Girod and de Haan 2009). IO LCA is thus a tool for assessments of average products and systems.

3. Research Design

In the study, three examples are presented of situations where the reliability of the LCA method in the built environment context is questionable: (1) a wooden frame window, (2) a steel body passenger elevator, and (3) a multi-story concrete frame residential building. Next each example is presented.

3.1 Wooden Frame Window

As depicted in the method section, one feature of process LCAs is the so-called "first tier truncation error". In this study the potential impact of this error is depicted with a case of a wooden frame window 1.2x1.9 m. The case window is a business-as-usual northern latitude triple-glazed window with insulation gas (argon) and wooden frames with the outer frame covered with aluminum. The insulation gas is omitted from the assessment as having a negligible climate change impact. The glass is assumed to be 4 mm uncoated flat glass and the frame 80x210 mm. In between the glass layers are aluminum board frames. The estimated material volumes are:

Glass	54.3 kg
Wood	29.3 kg
Aluminum	6.7 kg

The process LCA approach and SimaPro with ecoinvent 2.0 database (PRé Consultants 2010) are utilized in the assessment to compare two different assessment approaches. The first option is an assessment utilizing a traditional process LCA approach in calculating the quantities of wood, glass and aluminium and summarizing the contribution of each to the overall result. This approach is by far the most utilized when the window is assessed as one item of a building but leads to the so-called "first tier truncation error" presented in Section 2.1. As the second option, the same window is assessed utilizing the ecoinvent 2.2 sector "Window frame, wood U = 1.5 W/m2K, at plant". This sector includes the final production sector (first tier), and should suffer only from the traditional truncation error of process LCAs, thus enabling conclusions on the significance of the so-called "first tier truncation error". It is of course obvious that there might be other differences in the two approaches hindering this particular error from showing. For example, the binding materials in the window frame or the paint are not taken into account in the first type of approach, but this is a very typical cut-off in an LCA study in the building sector and just aggravates the problem of underestimation of the first approach.

3.2 Steel Body Passenger Elevator

The second case depicts the often significant difference between the two main LCA approaches, process LCA and IO LCA. An elevator is a great example of a case where the inventory of the main materials for a process LCA captures only a limited share of the actual overall GHGs related to the manufacture and assembly of the elevator. The production requires a significant amount of high quality processing in between the materials and the ready product, which is not fully captured with such typical building LCA approaches where the main material quantities are assessed in the LCI phase and given emissions intensities according to an LCA database. Overall it is thus a good representative for both types of truncation error that process LCAs can lead to. IO LCA for its part then again includes also the capital goods and overall does not suffer from the truncation error.

In this study a comparison was run between (1) a traditional process LCA with a bill of material quantities for a modern steel body elevator for a five-story residential building, and (2) the same elevator assessed with the IO LCA method utilizing the U.S. economy based EIO-LCA (Carnegie-Mellon University 2008) adjusted for inflation and the currency exchange rate. The estimated bill of quantities and the cost estimate for the elevator were:

Cables, doors, rails	1,000 kg
Motor	300 kg
Elevator body	700 kg
Cost	25,000 €

3.3 Concrete Frame Multi-Story Residential Building

The third case studied was a concrete frame multi-story residential building. The comparison builds on a literature review of the published case results from the academic literature. A total of 16 cases were found for comparison, presenting a huge variation in the results, not explained by the case characteristics but rather by the differences and uncertainties in the LCA methods. The cases are not presented one by one but rather the range of results together with a discussion of the utilized assessment approach.

For comparability, one m2 of gross space was utilized as the functional unit. If only net areas of the case buildings were reported, these were converted into gross areas using a conversion multiplier of 1.43 m2 based on Lylykangas et al. (2013). This was also in accordance with the respective ratio taken from Passer et al. (2012). In the cases when the original paper presents the results in embodied energy rather than in GHGs, a conversion factor of 0.266 kg CO2e per kWh was utilized taken from the EIO-LCA tool of Carnegie Mellon University (2008). For reliability, the factor was also compared to Junnila et al. (2006) and Fuller and Crawford (2011), who give estimates of 0.24 kg/kWh of and 0.25 kg/kWh.

4. Results

4.1 Wooden Frame Window

The two assessments returned significantly different results. For the three main materials the GHG LCA estimate is approximately 130 kg CO2e, whereas the wooden-frame window sector of ecoinvent 2.0 gives an estimate of 300 kg CO2e for the case window. It is obvious that the two assessments are not identical in their scopes since the material-approach excludes, for example, paint, glue, handles and hinges and is thus downwards biased in comparison to the window sector. The difference is still striking, however, and gives indications for two important issues: (1) the “first tier truncation error” (see Section 2.1) can potentially be of high importance in building LCAs, which tend to omit the final production phase of many items; (2) the main materials might in many cases not lead to a sufficient scope. The first issue is present with important systems and items of a building, e.g. with the electrical system in general, piping and fixed furniture. Heinonen et al. (2016) depict how these categories might have an important impact for the LCA results and should not be cut off as is often done, but it is alarming if the truncation errors are of this magnitude if only the main materials without the final production phase are included.

4.2 Steel Body Passenger Elevator

The steel body passenger elevator case demonstrates how different results the two LCA approaches, process LCA and IO LCA, can return. The process LCA result is approximately 5,500 kg CO2e, whereas the IO LCA result is almost 14,000 kg CO2e. Again a couple of important conclusions can be made. (1) While process LCA inherently leads to an underestimation of the actual emissions due to the truncation error, an elevator is a perfect example of an item in a building with which the main materials can only capture a considerably limited share of the actual overall emissions. In addition to the inherent traditional truncation error, the “first tier truncation” can be high. (2) A significant amount of materials is left out from such traditional assessments which only include the main materials, as in this study, and altogether these cut-offs can create a significant additional truncation error. (3) The IO LCA can randomly over- or underestimate the actual emissions due to the aggregation error, but this cannot easily be checked, and due to its quality of including a substantially wider scope than process LCA (e.g. the capital goods), an important share of the difference in these two results is likely to be due to the underestimation of the process LCA.

4.3 Concrete Frame Multi-Story Residential Building

The result range runs from less than 100 kg/m2 to over 1 ton, as shown in Figure 1. There are partial scope differences, for example just the frame taken into account vs. close to all materials, but also important assessment differences. Only one IO LCA was found for this comparison, but it has resulted in by far the highest estimate. With hybrid LCAs the varying amount of IO and process data make the comparisons difficult from this perspective. In the lowest end the low estimates are at least partially the product of adopted assumptions regarding recycling and carbon uptake, which often are not considered. The cut-off criteria varies significantly as well between the studies. According to the LCA tradition, it is typically claimed that only materials with minor impact are excluded, but as discussed by Suh et al. (2004) and depicted by Heinonen et al. (2016), these excluded shares can easily be heavily underestimated. Thus scope-wise a more complete assessment can lead to substantially higher estimates even when the assessments would otherwise be similar. Further differences, outside of those caused by the actual building

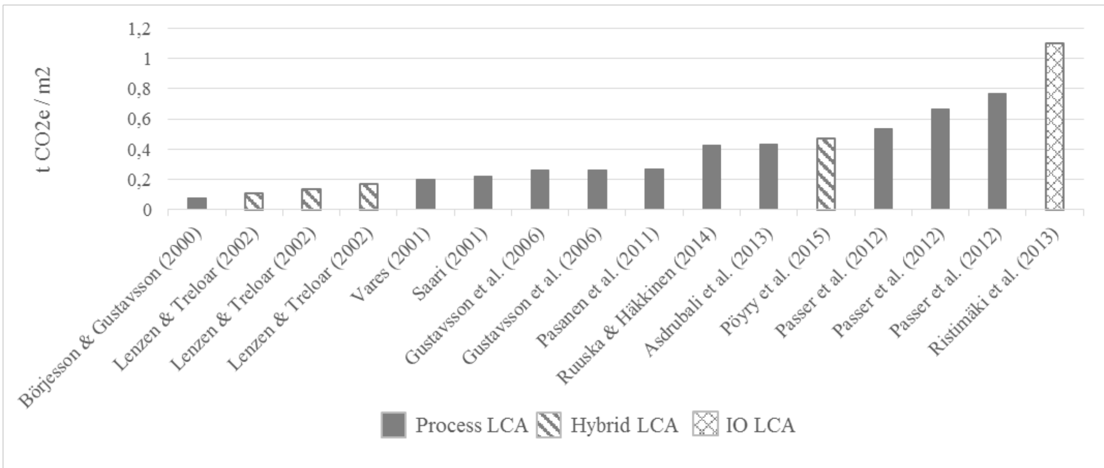

Figure 1. Results per m2 of the selected 16 cases.

qualities, can result simply from the assessment database choice, as depicted recently by Herrmann and Moltesen (2015).

5. Discussion

The aim of this paper was to study the reliability of environmental assessments in the built environment. The scope was further limited to GHGs and the LCA method, but it is very likely that a similar situation exists with regard to other impact categories and assessment techniques as well, as discussed previously by Heinonen et al. (2015). Three cases were presented to depict and discuss some problematic issues: (1) a 1.2x1.9 m wooden frame window, (2) a steel-body passenger elevator, and (3) a multi-story concrete frame residential building. Through each example different uncertainties were discussed.

The errors and uncertainties of LCAs have been studied for a long time (e.g. Lenzen 2000; Huijbregts 1998 a, b), but not many studies exist which have concentrated on the built environment. Lenzen and Treloar (2002) suggest that the truncation error can potentially be of the magnitude of 50% in building LCAs, but not many other such direct method comparisons or uncertainty analyses exist. Actually many studies report the results as if they were precise and not subject to uncertainty. While this study is very limited in scope and its ability to give evidence, it brings up issues which should be better taken into account and studied more in the future.

Overall it seems that there is room and need for development to make LCAs more robust in the context of the built environment. This is not to say that current assessments are worthless, but anybody reporting an LCA study or utilizing the results for decision-making should understand the method well enough not to draw wrong conclusions. For example, the cut-off impacts from the assessment boundary selection may well be underestimated, the different inherent errors make it difficult to compare the results of process LCAs and IO LCAs, and "first tier truncation" can be a severe problem, though currently not well recognized at all. It is striking how much an assessment with just the main materials included seems to underestimate the actual emissions, or how different is the outcome for an assessment of the same object but using a different LCA method. Furthermore, several other assessment assumptions can vary between two studies and cause the results to be very different, even for similar assessment objects, as was discussed with regard to the residential building cases in Section 4.3.

6. Conclusions

Based on this study, it seems obvious that there is plenty of room for development of LCA methods in the context of the built environment. Currently the assessments vary so much that the results are often not comparable between different studies without a deep understanding of the methods and the details of the studies. The study did not reveal particularly new issues, but surprisingly little attention has been devoted to the uncertainties presented, especially given the order of magnitude this study (and previous studies) indicates. The "first tier truncation error", meaning the last production phase being excluded when such objects are assessed which utilize prefabricated products, such as windows or pipes in building construction, has received very little attention in general. However, this error exists particularly in such sectors as the built environment, especially with buildings but to some extent with other civil structures as well. At least this study suggests that it can be a significant source of bias. Finally, this study only shows areas where more work should take place, though the message is still important and the development of needs is significant and urgent.

Acknowledgment

(email: yv.riveros1521@uniandes.edu.co)
Angélica María Ospina,
University of the Andes
(email: aospina@setri.com.co)

Abstract

Currently there are several rating systems or certifications systems for sustainable construction in the world such as LEED and BREEAM. These responds to a need for generating solutions to the big problems that construction involved: emission of greenhouse gases, energy consumption, waste generation, water and materials consumption.

In this order, these certifications systems are typically formed as checklists required to obtain a minimum number of points according to established evaluation guidelines and generally associated with certain categories of impact.

In the other hand, we have that Decision Theory provides a methodology called Analytic Hierarchy Process, which consist of a process of ranking criteria from the implementation of a matrix of pairwise comparison.

In this way, this study proposed to use the AHP methodology for the establishment of weights in an eventual rating system of sustainable housing in Colombia, according to its context and the kind of current information and tools at legal level that the country has. The above, considering that Colombia does not have a clear regulatory scheme for sustainable buildings yet. Therefore, this study seeks to provide a strategic tool for the regulatory framework for sustainable housing in Colombia from the integration of the Decision Theory with existing certification systems adapted to the country. All that, with a panel of experts with people from academia and industry.

As a result, the study shows how this proposed strategy can be helpful in countries which do not have sufficient technical tools to generate robust impact assessment schemes, as LEED in the United States. Thus, it can be obtained very good results from a consensus between academia and industry in Colombia, which are comparable with recognized certification systems in the world.

Keywords: Sustainable Housing, Analytic Hierarchy Process (AHP), Weights, Certification System, LEED.

1. Introduction

According to the definition of Sustainable Development from the Brundtland Report in 1987, it is important to consider the great contribution that construction industry can give to this concept because of its impact to the environment: consumption about 40% of the world's electricity, 17% water, 25% of felled timber, and production over 40% of overall waste and 33% of carbon emissions (Thakore, Jack, & Benuzh, 2013). Moreover, in the specific case of this research it will be important considering that cities in the world are composed around 70-80% by the residential sector.

In this way, nowadays it exists in the world classification and certification systems for sustainable buildings seeking to assess the presence of factors related to environmental quality in the different stages of the life cycle of a building. Although each of the certification systems is an approach or own philosophy, depending on where it has been conceived, all options provide design/construction that are environmentally responsible, and in turn deliver awards and public recognition to the additional effort required to conduct more sustainable projects (Secretarías Distritales de Ambiente, Habitát y Planeación de Bogotá, 2014).

In Colombia, recent governments have shown in one way or another some interest in the topic, however, it has not yet been given a broad and comprehensive policy for the country that offers some kind of official certification system that promotes sustainable construction.

Therefore, and in order to provide tools to facilitate and coordinate with the items that the country already have in terms of public policy aimed at promoting sustainable construction, the following study presents the research done for the generation of a first Referential of Sustainable Housing in Colombia (or certification system for the housing sector) and the establishment of the weights of their criteria, after the implementation of the Analytic Hierarchy Process methodology as a tool for decision making level.

2. Background

In this section we will understand briefly the determination of weights in the two main certification systems in the world (LEED and BREEAM) and the Analytic Hierarchy Process implemented in this study.

2.1 Leadership in Energy and Environmental Design (LEED)

Taking into account that LEED scheme is organized in categories and credits, it is important to understand that the process to be followed for this certification is basically to achieve a certain score from obtaining some criteria, known as credits within the system, which seek to meet the needs of sustainable development. These credits, according to the impacts they want to avoid, minimize or mitigate are classified into the following categories: Integrative process, Location & Transportation, Sustainable sites, Water efficiency, Energy & atmosphere, Material & resources, Indoor environmental quality, Innovation, and Regional priority.

In the previous version v3 credits' weights were determined by impact categories by TRACI software. For the current version v4 new impact categories were used.

For the current version v4 they coupled to the premise of making "greatest positive impact" and not "do less harm", for which the TRACI categories did not fit totally into their new goals. This was based on the fundament that categories did not capture totally sustainability goals anymore and they were not the best way to make a life cycle assessment for all components that a building has.

The above idea led to the United States Green Building Council (USGBC) to favor the creation of their own impact categories to broaden their approach to social, environmental and economic material. This made the certification stop focusing on how "environmental problems can be reduced", but in what LEED certified projects should contribute and achieve.

In this way the USGBC devised the form to work with impact categories and subcategories with which every credit was scoring. They basically did an exercise of association between credits and subcategories. This exercise had three aspects (duration, control and relative effectiveness) which were multiplied in a formula and in that way it was obtain the score of the credit. The score resulting from the association of each credit with all subcategories was computed and dictated the final score for each credit (Knaw, 2013).

2.2 Building Research Establishment Environmental Assessment Methodology (BREEAM)

Although this system does not name as "credits" the criteria they use within their categories, they have some similarity with LEED in their overall scheme. In that way, we can see they have the following categories for the assessment: Management, Energy, Health & wellbeing, Transport, Water, Materials, Waste, Land use and ecology, Innovation, and Pollution.

BREEAM uses a scoring system explicitly derived from a combination of weights and classifications product of a consensus by a panel of experts. The results of this exercise are used to determine the relative value of the environmental sections used in BREEAM and its contribution to the overall score of this Certification Scheme.

This scoring system is defined in detail in the BRE Global Core Process Standard (BES 5301) and in the documents that support its proceedings, which are part of the Standard BREEAM and Code for a Sustainable Built Environment. The classification of impacts used in BREEAM follows the same mechanisms score of BRE Green Guide to Specification and BRE Environmental Profiling Method for building materials. BREEAM FCO provides ways to adapt this system in specific credit score by region or country in which a project is certified (BREEAM, 2011).

2.3 Analytic Hierarchy Process (AHP)

It is a method that allows represents a problem using a hierarchical structure where the last link are alternative decisions. This method was developed in the 70s by Thomas L. Saaty and since there it has been studied extensively, currently it is being used in decision-making in complex scenarios, where people work together to make decisions when human perceptions, judgments and consequences have a long-term impact (Bhushan, 2004).

The application of AHP begins with a problem to be decomposed into a hierarchy of criteria in order to be easier to analyze and compare independently (See Figure 1). After this logical hierarchy is built, the decision makers can systematically evaluate alternatives when making comparisons between pairs for each of the criteria. This comparison can use the specifics of alternatives or human trials as a form of input information underlying (Saaty, 2008).

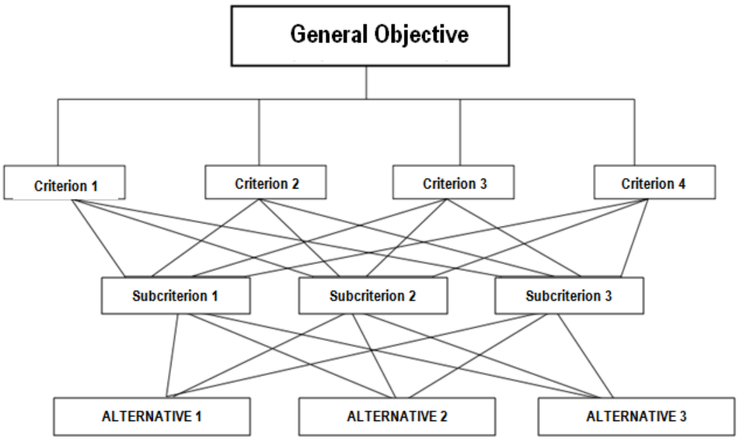

Figure 1: Example Hierarchical Structure

After the definition of the hierarchical structure, it is necessary to construct matrices. In this manner, using an appropriate scale, it should be performed pairwise comparison for each of the elements of each level in relation to the elements of the next higher level (Saaty T. L., 1994).

Then, using an estimation method, the relative weights for each element are calculated with respect to the other elements and at the next higher level. After obtaining the weights of each element, the weight of each of the alternatives is estimated and sorted. It is important in this point to understand the estimation method proposed by Saaty, which mainly part of the matrix principle of $A * W = \lambda_{máx} * W$ where A is a matrix with a dimension n, $\lambda_{máx}$ is the maximum eigenvalue of matrix A , and W is the final weight vector estimated appropriately normalized so that its components sum to 1 (Castillo, 2006). Theory behind the above can be revised in the literature.

Finally, a proper interpretation of the results projected by the model is done. Once interpreted the consistency of the results is analyzed and determines whether changes are needed to the model. Once it reaches a satisfactory answer, the right choice is determined.

3. Methodology

For the development to this study it is important to understand that first we had to limit the scope of this. In that way, although the present study was focused on generating a first Referential for

Sustainable Housing in cities of cold zone (see Table 1), this research despite assist in the establishment of categories and credits to be considered in this first version of the certification system, with the support of the Colombian Sustainable Building Council (CCCS), it was concentrated mainly in the establishment of the ID, Name, Objective and Weight of each of the credits to be considered in the Referential, but we did not work in their requirements, form of implementation, calculations, Regional Variation and References.

Table 1: Climatic zoning for the application of environmental criteria proposed by the Ministry of Environment, Housing and Territorial Development in Colombia

Warm zone – Wet	**Warm zone – Dry**
Altitude in the range of 0 to 800 meters above sea level, temperatures above 24 ° C and relative humidity above 75%	Altitude between 0 and 800 meters above sea level, with greater than 24 ° C temperatures and relative humidity below 75%
Temperate zone	**Cold zone**
Altitude in the range of 800 to 1,800 meters above sea level, mean annual temperature between 18 ° and 24 ° C and relative humidity between 70 and 85%	Altitude above 1,800 meters above sea level, temperature between 12 and 17 ° C and relative humidity between 60 and 80%

Additionally, it was considered appropriate to restrict climatically (cold zone) and typologically (new multifamily housing projects) the exercise given the geographical and urban conditions that are assumed can get to induce significant differences in generating a specific system of certification for housing, according to some discussions on the subject (Buendía López, 2013). Thus, this study, in addition to taking the initiative to generate a first version of a certification system that provides the theme of sustainability in the country, it leaves the door open for future research in different areas and different types of housing buildings to validate if the course assumed is correct or it could eventually generates a single Referential of Sustainable Housing for all Colombia.

Thus, after understanding the problem that we wanted to address - definition of credits that should be considered for a first version of a certification system for multifamily housing in cold areas of the country and the determination of its possible weights - It began with the selection of candidates, either for their expertise in environmental issues and/or their sustainability or outstanding professional preparation, for being considered as experts on these issues to participate in the development of this exercise. This group was mainly composed of professors from the University of the Andes and professionals from member companies of the CCCS.

From this, several meetings was agreed with experts who voluntarily wanted to participate in this study. The first meetings focused on establishing what the AHP methodology termed as criterions and subcriterions, which for purposes of this research are the same categories and credits respectively. For this phase, it was decided to begin the exercise taking into account the schemes of LEED Homes v4 from United States and the Reference House from Brazil, thus experts gave feedback on what they saw relevant or not to the Colombia case, as well as some criteria were not being taken into account and that experts considered they should be included. At this point, it is important to understand the modification done to the AHP methodology, because in this case we did not have alternatives, just criterion (or categories) and subcriterion (credits), this, using the same LEED terminology (see Figure 2).

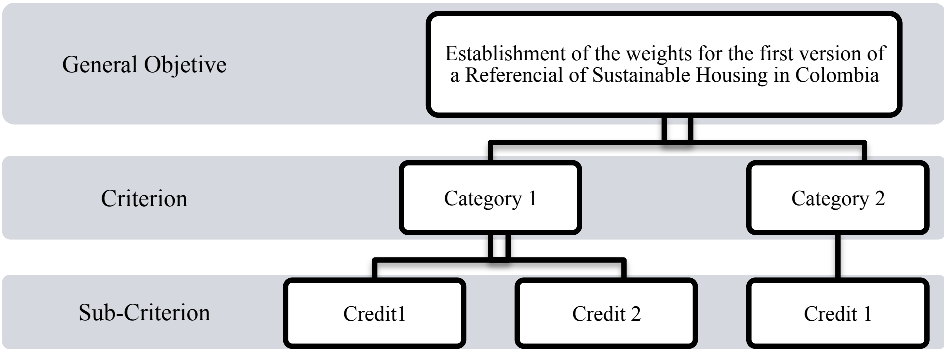

Figure 2: Structuring of the problem

Later, when all the information was gathered and some preliminary credits were established, we proceeded to the elaboration of the matrices according to the scale of Saaty[1], which was done using the software *ExpertChoice*, program that allowed evaluating immediately the index inconsistency of matrices, thereby reducing the error which would be evaluated later.

Although ideally suited for this type of methodology is the generation of a panel of experts, which all interact to finally define a single matrix, given the difficulty appeared to gather all participants in one place, due to the agenda that most of them handled, we decided to averaging matrices with a geometric mean, according to the suggestions of Professor Mario Castillo, an expert in AHP issues in the Industrial Engineering Department of the University of the Andes, to finally get results in terms of the score for each of the categories and credits considered.

4. Results

According to the methodology explained above, we finally had six matrices in agreement with the Table 2.

Table 2: Participants in each of the considered matrices

Assessed Level		Number of participants
Criterion	1.General Scheme – All the categories	6
Subcriterion	2.Implantation	5
	3.Efficient use of water	7
	4.Energy & Atmosphere	8
	5.Material & Resources	7
	6. Indoor Environmental Quality	7

[1] Saaty scale has a range between 1/9 and 9 where 1/9 means that the criterion compared with another one is extremely not important and 9 when the criterion is extremely important compared with the other one

The following Table shows the specific results in every final matrix obtained after the geometric mean applied to the several matrices for each level handled.

Table 3: Results of the weights obtained from the every considered case

Assessed Level	Matrix A	Vector W (Weights)
General Scheme – All the categories	see below	see below

Matrix A:

	CAT1	CAT2	CAT3	CAT4	CAT5
CAT1		2.61	1.59	2.96	1.41

Thus, starting from a base of 100 points for the entire Referential it can be understood that with the first matrix showed in the table above we made a distribution of these percentages to each category considered. So then, for example the category of "Efficient Use of Water", or CAT 3, with a weight of 0.16 will have 16 points, at the same way we make this exercise with the weights of the credits in every category. For example, on this category CAT3 we distribute 16 points for the credits (or CRs) considered in the category.

The following is the final Referential obtained, as previously it was explained:

Table 4: Final Referential of Sustainable Housing in Colombia

REFERENTIAL OF SUSTAINABLE HOUSING IN COLOMBIA

FIRST VERSION — **100 Possible Points**

IMPLANTATION	Possible Points	32
IMP CR1	Control of negative impacts by altering the field	4
IMP CR2	Project orientation based on the solar chart	6
IMP CR3	No use of invasive plants	2
IMP CR4	Site Selection	3
IMP CR5	Location near existing urban developments	3
IMP CR6	Access to open space	3
IMP CR7	Reducing the heat island effect	2
IMP CR8	Stormwater management	4
IMP CR9	Toxic products and plague control	1
IMP CR10	Compact developments	4

EFFICIENT USE OF WATER	Possible Points	16
UEA CR1	Efficient water use indoors	10
UEA CR2	Efficient water use outdoors	3
UEA CR3	Measurement and control of water consumption	3

ENERGY&ATMÓSPHER	Possible Points	22
EYA CR1	Quality of electrical installations of low voltage	3
EYA CR2	Energy efficiency of hot water system	2
EYA CR3	Artificial lighting	4
EYA CR4	Energy efficiency of the residence	5
EYA CR5	Efficient home appliances	2
EYA CR6	Generation of electricity through renewable energy	2
EYA CR7	Energy audit of installed systems	2
EYA CR8	Sectioned measurement and verification	2

MATERIAL&RESORUCES	Possible Points	9
MYR CR1	Management plan for construction waste	2
MYR CR2	Waste management plan for the operation of the project	2
MYR CR3	Environmentally sustainable products	3
MYR CR4	Products and materials with improved components	2

INDOOR ENVIRONMENTAL QUALITY	Possible Points	21
CAI CR1	Control of flue gas emissions	4
CAI CR2	Ventilation	4
CAI CR3	Outdoor air filtration	2
CAI CR4	Comfort of the indoor environment	2
CAI CR5	Control of particulate pollutants	2
CAI CR6	Protection from garajes pollutants	3
CAI CR7	Noise protection	1
CAI CR8	Cigarette smoke control	3

CERTIFIED	40-49
SILVER	50-59
GOLD	60-79
PLATINUM	80+ Points

5. Discussion

We did a whole analyses from the results in every matrix considered with the different experts' opinions, however, below only we will present the analysis made for the matrix of the general scheme case.

For the general case, which determines the weight or importance of each of the categories previously exposed, it looks like at the end of the procedure performed, on average the categories were organized from highest to lowest score as follows: Implementation, Energy & atmosphere, Indoor environmental quality, Efficient water use and Materials & Resources

Now, in Figure 3 we make a comparison of the results obtained for the Colombian case with the scheme in USA (LEED) and Brazil (Referential House) in terms of possible points within the certification systems. Thus, it is important to note, and although it was mentioned that while the whole exercise was done with relative weights with a base of 1, then the corresponding extrapolation was made to a system that considers 100 possible points.

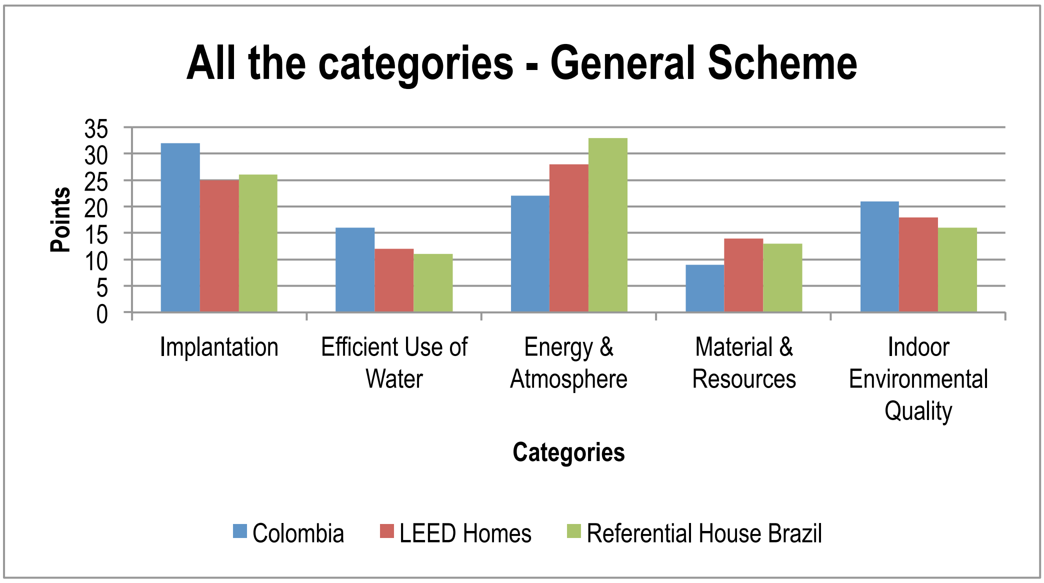

Figure 3: Comparison between categories of rating systems from Colombia, USA and Brazil

In that way, when we compare with the Referential House from Brazil and with LEED Homes from US, we can see in Colombia the most important category is Implantation, while for the others two countries is Energy & Atmosphere. For LEED, this can respond to the way of energy production in the country, linked directly with the emission of greenhouse gasses, one of the most important themes when we think about sustainability, while in Colombia this happens mainly through hydroelectric, related to water and biodiversity problems (Buendía López, 2013).

Likewise, this difference can be attributed in one or another way to the level of development in Colombia, because it exists a proportional direct relation of this with the energetic consumption, this for example in average the number of home appliances in Colombia is fewer than in USA and Brazil.

Taking into account that each of the systems certification represents an approach or own philosophy, depending on where it has been conceived, it can be seen how in Colombia the most relevant category is that which evaluates overall the place where the project is going to be develop, whose characteristics site promote pollution minimization and optimization of some work situations that facilitate the implementation of sustainable criteria. This is closely related to the planning and management of projects, one of the major problems in the country by the lack of practice of what is known today as *Systems Thinking* and *Integrative Processes.*

On the other hand, it is not surprising that the category with the fewest points have been the Materials & Resources, as well as being one of with less credits considered, because it has criteria that in the country are not very easy to achieve such as life-cycle assessment of materials, promotion of products whose ingredients are inventoried using an accepted methodology and the use of verified products that minimize the use and generation of hazardous substances. However, this does not diminish the importance of the category, because despite being the one with less points, it has few credits, which obtained a distribution of points similar to other categories. Similarly, this applies to the category of Efficient water use, which is the second to have less points globally, however, by having only 3 credits, they are those with most points when they are compared to other credits, even it is in this category where we have the credit with more weight (efficient water use indoors with 10 possible points). In this sense, it is important to note how in Colombia, despite being potency in water resources, there already is a concern to protect this resource since now.

Finally, we can say that the categories of Energy & Atmosphere and Indoor environmental quality, positioned as the second most important with similar weights, after Implantation, they are those that promote technical developments and some practical modeling of processes that are not widely used in Colombia, which are transcendental in driving the sustainable construction industry in the country. Similarly, these are credits that are undeniably connected with the promotion of high quality in the habitability of the spaces, a fact that undoubtedly affects different areas and dimensions of development and progress of the people.

6. Conclusions

According to the whole research here exposed, in this section we will describe some conclusions about the implemented methodology, the obtained results and some challenges that this study can deal:

- To have AHP as a strategy for the solution to the problem posed was an effective mechanism, because it allowed the structuration of this one under a multicriteria landscape, following a paradigm related to broad rationality, flexibility and realistic approaches compared to the traditional paradigm, in this way this allowed the incorporation of the human factor (integration of the tangible and intangible) in the search of the "best" solution to the problem (Moreno, 2002), we arrived to a Referential of Sustainable Housing according of Colombia's needs, despite the complexity of the situation. Above, taking into account also the lack of technical tools that the country still has to develop other mechanisms for the determination of the weights in this kind of certification system.

-We can say the geometric mean represents very well the most of the experts' opinions without the perturbation of the sample by extreme values. In the same way, although it was thought the panel of experts was ideal according the traditional AHP, we saw the methodology implemented by us, geometric mean, was adequate because of the possible partiality of experts in a table, while our methodology reached a balance between experts opinions. All the final obtained matrices were under 2% of inconsistency, which increase the reliability of results that in terms of Analytics or Theory of Decision allows to make decisions more easily.

- It is important to understand that this first exercise seeks to be an approximation to what a Colombian system certification of sustainable housing should be in the country. In this way, there should be more investigation about this topic that complement or change what we found, if these kind of things mean a real support for this research. In that sense, it will be necessary to work in the requisites, form of implementation, calculations, regional variations and references of the credits that we did not do in this first phase.

- Nowadays, although the entire advance the world has reached about sustainable techniques in construction industry, as the certification systems, there are things in which we have to work harder as a developing country like culture, education and awareness of the crowds, who are the final operators of the sustainable buildings. Thus, the really important thing is that certification system are responsible and search real sustainable projects more than senseless recognition, as it has been saw in some cases around the world.

COMPLEX INTEGRATED APPROACH OF SUSTAINABLE ARCHITECTURE
Based on Properly Modifiable Site Specific Database

Zsuzsanna Fülöp
Budapest University of Technology and Economics, Faculty of Architecture Engineering
(email. zsfulop@epsz.bme.hu)

Abstract

Preserving our environment has come to the forefront of our society's concerns and architects may not be indifferent. Widespread awareness of climate and other environmental change together with huge amount of the technical opportunities have triggered professional demands for architects with advanced skills. According to the new aspects and tools, the architectural design process must become more conscious. Our main task is not only to create new technical variations, but to re-define the design process taking into consideration the whole complexity of available information and data, while providing permanent control over the decisions. Design process plays a very important role in architecture, not just aesthetically, but technically as well.

Careful consideration of surrounding conditions from the earliest stage of the design process can have an enormous impact on reducing subsequent operating costs and protecting our nature. All over the world there are specific traditional solutions relating to climate in order to utilize the natural conditions for the benefit of human comfort. These traditions help us to develop really sustainable decisions in contemporary architecture.

Efficiency of design process depends on the adequacy of the data applied. Systematization and integration of all relevant information and aspects into creative design process is a crucial part of contemporary architecture. We should re-think architectural design process as a coordinated set of stages and sub-stages replacing traditional experience-related process by a more rational, and theory based approach of choices and solutions for specific design problems. There is a need for developing a systematic structural and material selection system that will enable architects to identify relevant criterias effectively and to evaluate the options accurately. Analysis of impacts, requirements, and structural performances at each design stages can be the common approach in the dialogue between architects and experts. Preventive and remedial measures should always be evaluated in the context of the whole by holistic method.

The Holistic Performance Based design method responds to surroundings by continuously fitted, properly modifiable Multilevel Project-oriented Site-specific Database. This system integrates skills, knowledge and tools of “passive” and “high-tech” design elements into a more conscious complex design process.

Keywords: Holistic, Performance-Based, Project-oriented, Site-specific, Database

1. Introduction – built environment: comfort and pollution

Shelter and comfort are the basic needs for all human beings no matter where they live. We want a comfortable place to protect us against heat/cold, humidity, environmental diseases, dangerous animals, burglary and other possible threats. We want a comfortable environment where we can live a protected and healthy life. The aim is to create a high level comfortable and stable climate for our everyday existence. Increasing functional requirements all together with growing human population and technical development resulted not only higher level of internal comfort but at the same time environmental pollution and health problems. (Fig. 1.)

Figure 1 [20, 21] Dream and reality of built environment

“Building design and construction use significant quantities of natural resources and materials. The building industry consumes 3 billion tons of raw materials annually -- 40 percent of the total material flow in the global economy. The manufacturing process of new materials is water and energy intensive and contributes to environmental degradation and pollution. Harvesting, extraction, mining, and processing new materials pollute the air and rivers and threat ecosystems and wildlife. North America, Europe and Japan consume more than 25 percent of the world's annual 4.5 billion cubic meters of wood production. According to the Natural Resource Defense Council (NRDC) [22] at present rates of destruction the rainforests will be gone by 2050. In addition, global wood production is expected to double over the next 30 years. Consumption of other raw materials and natural resources continue to accelerate. ” [23]

“The Building Sector is responsible for almost half of the energy consumption (49%) and greenhouse gas (GHG) emissions (47%) in the U.S. [24] The sector is expanding, which is bound to increase its energy consumption as it is declared in “Directive 2010/31/EU [25] of the European Parliament and of the Council of 19 May 2010 on the energy performance of buildings”. While the majority of the energy consumption, and their associated emissions, come from building operations (such as heating, cooling, and lighting), the embodied energy and emissions of building materials and products are also becoming increasingly significant. A very small amount of energy-efficiency improvement on this field could lead to significant economic savings. A building’s “energetic DNA” is hard-coded in the architectural concept. The possible deficiencies of architectural design decisions can be balanced only by costly engineering solutions.

Therefore, reduction of energy consumption and the use of energy from renewable sources in the buildings sector constitute important measures needed to reduce energy dependency and greenhouse gas emission. If we do not reduce GHG emissions, we risk triggering dangerous climate change, resource depletion, acidification, and eutrophication. The latest International Panel on Climate Change (IPCC) Fifth Assessment Report [26] confirms the necessity for immediate and sustained action on climate change, detailing how close we are to a turning point in the earth’s climate system. The underlying conclusion of the report is that the time has arrived for taking the necessary steps to preserve liveable conditions on earth. As quickly as possible, we must stop burning fossil fuels, aiming for a complete phase-out by around 2050.

And the products we select affect the quality of the spaces we inhabit. People spend appr. 90% of their time indoors in USA, and the quality of air in buildings has been proven to have significant negative health impacts on them. The indoor environment is not only a health and comfort issue. It also affects work performance and learning skills of the occupants. Many new buildings have proven to be physiologically uncomfortable and unhealthy as well. Several people, who live and work in modern houses, have complained of periodical symptoms of malaise (headache, fatigues, drowsiness, irritation in eyes and nose, dry throat, non-concentration, nausea and allergic symptoms). The choice of materials, constructions can improve or degrade our indoor air quality and we can affect that quality through the materials and products we select. (Fig. 2.)

Figure 2 [27] Polluted environment

Preserving our environment has come to the forefront of our society's concerns and architects may not be indifferent. Widespread awareness of climate and other environmental change (decreasing natural resources, pollution of environment) together with huge amount of the technical opportunities have triggered professional demands for architects with advanced skills. The successful integration of complex principles and new technologies into a creative design process in practice and education has proven elusive. [1]

In view of these environmental concerns, sustainable design embodies the following goals:

- Minimize consumption and depletion of material resources.
- Minimize the life-cycle impact of materials on the environment.
- Minimize the impact of materials on indoor environmental quality. "[28]

The basic question is how to create a really sustainable built environment to protect our natural surroundings and at the same time to provide comfortable, healthy life for people? Should we use more high-tech solutions or try to follow the passive adaptive design concept? How to find the balance and the best options?

2. Sustainability: adaptation vs. high-tech application

There is a close connection between the way we build our houses and the surrounding climate. Climate (sunshine, temperature and wind) has a crucial influence on all parameters of building such as orientation, glazing, thermal mass, insulation, ventilation and zoning. Fundamentally functional arrangement and construction of the house are to set the framework for indoor climate which is different from the outdoor climate. All over the world there were specific ways of relating to the climate. Whatever the general climate is - cold, hot, temperate, dry or humid - houses were built so that the local conditions are being utilized to a maximum. Most old cultures had a good knowledge of the local resources (climate, materials) and understood how to utilize it instead of working against it. People traditionally built their houses by hand out of local natural materials (stone, timber, grasses, burned clay etc.). Building types and constructions were developed for centuries, so they had time to have experiences how to create building shape, functional arrangement, to choose materials responding on their surroundings. Porch in front of the rooms provides shading in hot summer and sufficient lighting in winter, walls made of pise or solid clay brick had high thermal mass according to the temperate climate. (Fig. 3.)

Figure 3 [29] Traditional built example in the temperate zone (Hungary)

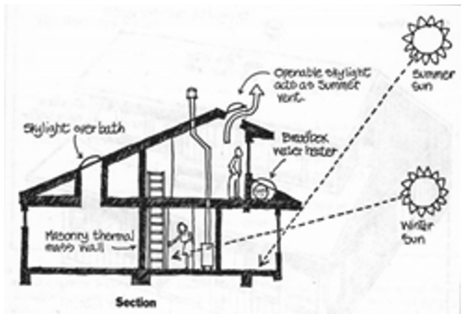

Figure 4 [31] Passive solar design

The environmental impact of ancient houses was slight. Living houses, until cc. the end of 20. Century, were mostly adaptive without crucial environmental impact. Experiences of traditions can be useful today as well. So called "passive architectural design system" [30] follows this way and relies on natural principles instead of mechanical systems to provide a non-polluting source for internal comfort. (Fig. 4.) Whether could we eliminate industrial products in our houses by this passive design method?

Figure 5 [32] Most of the modern houses consist of artificial materials and high-tech applications

Development of society and industrialization has resulted with us starting to move away from the individual houses and to begin building uniform and anonymous houses located close to factories. In the course of time, these houses have spread from the centre of the city to its enormous suburbs. Each individual, therefore, no longer has influence or understanding on the relation between their house and its external environment. In globalized market the building materials can be achieved almost from all over the world and we use a huge amount of artificial structures created by industry. (Fig. 5.) The required high level internal comfort is granted by mechanical equipment, e.g. HVAC systems and regulated mainly by high-tech solutions. Houses are centrally heated, air-conditioned and the location of the house in relation to the natural conditions is not that important any more. Buildings' functional arrangement, shape, materials are hardly determined by natural surroundings, but by industrial products, technical and economical possibilities.

Buildings today are complex concatenations of structures, systems and technology allowing modern-day building owners to select lighting, security, heating, ventilation, and air conditioning systems independently ("smart buildings"). "Smart building is about living in a machine that cares about you" [33]. (Fig. 6.) Recent advances in data gathering and analysis are opening up new possibilities for smart building management systems (BMS) -saving energy through targeted supply. Sensors are increasingly being installed in buildings to gather data about movement, heat, light and use of space. Such information may ultimately be incorporated into real-time Building Information Modelling (BIM), enabling live data to be held in the data structures used to describe building design. The lifespan of a building is currently around 50 to 100 years, while digital technology changes over a dramatically shorter two- or five year cycle. The "smart" buildings should be created as a core infrastructure into technical "applications" can be plugged. The vision of the future buildings *connect* the various pieces in an integrated, dynamic and functional way is that building seamlessly fulfils its mission while minimizing energy cost, supporting a robust electric grid and mitigating environmental impact." [34] Whether is it enough for sustainability?

Figure 6 [34] Mechanical control of internal comfort

Last period something surprising has been recognized about many so-called “sustainable” buildings. When actually measured in post-occupancy assessments, they’ve proven far less sustainable than their proponents have claimed. In some cases they’ve actually performed worse than much older buildings, with no such claims. A 2009 New York Times article, “Some buildings not living up to green label,” [2] documented the extensive problems with many sustainability icons. Systems may appear to be well engineered within their original defined parameters — but they will inevitably interact with many other systems, often in an unpredictable and non-linear way.

That means we should look towards a more complex design methodology, combining diverse approaches, working across many scales, and ensuring fine-grained adaptivity of design elements. We have to integrate skills and knowledge of “passive” and “smart” design elements into a more conscious comprehensive design process.

3. Consequences of technical integration

Design in contemporary architecture has become a lot more exploratory in recent years. Digital architecture and huge amount of construction products allows a diverse range of complex forms to be created. As technology evolves and software becomes more powerful, it enables architects to explore new possibilities. Introducing 3D software into the architectural design process has allowed contemporary architects to explore new depths and push design boundaries. The huge number of Information Technology Building Industry products (CAD etc.) gives architects the feeling that almost any geometrical shape may be physically realized. Consequentially, professionals envision increasingly unusual building types. (Fig. 7.) Houses are more often than not, too complicated and too expensive.

Figure 7 [20] Vision of a future city and built heritage of Budapest

Every building project involves the choice of building materials. Recently, we have thousands of new artificial materials and structures sold all over the world while the functions of our buildings have been changed and expanded. Selecting suitable building material options is a very complex process, being influenced and determined by numerous preconditions, decisions, and considerations. Likewise, multiple factors (cultural, economic, ecological etc.) should be often considered by the architect when evaluating the various categories of building materials. As a result, these sets of factors or variables often present trade-offs that make the decision process even more complex. Cautious consideration of contextual preconditions is crucial to defining appropriate building materials or products.

Database is the basic component of contemporary engineering calculation. The database information can be labelled according to data content, type of data affiliated in a computer program, the targeted group of stakeholders etc. Earlier database was an experience based system. Each stakeholders added their knowledge and information into the project. Elements of database were visible and accessible in documentations, maps, catalogues etc.

As part of globalization the building elements - materials and components - are arranged on internet through some product oriented building element basis. Clients may select structures and materials as they compile their specification. These extensive catalogues are continually being updated with specifications covering most common products. It seems to be used easily and quickly, but architects have some difficulties in choosing the best product from these databases because of the huge amount of elements (one database division – e.g. thermal and moisture protection - could contain more than 10 000 enterprises and their products!). (Fig. 8.) Comparison the data of several products sometimes is problematic because of the different background (standards, measurement methods, units etc.). In these databases there is no information on application of structures and materials according to the local conditions.

Figure 8 [35] Product oriented architectural database

The computer database programs through Database Management Systems (DBMSs) are a ubiquitous and critical component of modern computing. [3] A typical DBMSs needs to be compatible with many different connectivity protocols used by various client drivers. Computer Models can be created in 3D, and manufactured directly from the 3D data. Computer modelling programs rely on "sets of numbers stored in electromagnetic format. The computer database architecture is the set of specifications, rules, and processes that dictate how data is stored in a database and how data is accessed by components of a system. The digital database architecture includes data types, relationships, and naming conventions, describes the organization of all database objects and how they work together. This knowledge is implemented during the selection, designing and inspection of materials and construction components. The structure of computer databases is hidden, the architect can use it through the Dialogue Boxes, windows. (Fig. 9.) The storage and access of these data depend on the computer program so these are available only for those clients who have the appropriate software. These databases require the high level awareness of applied parameters and suitable computer program.

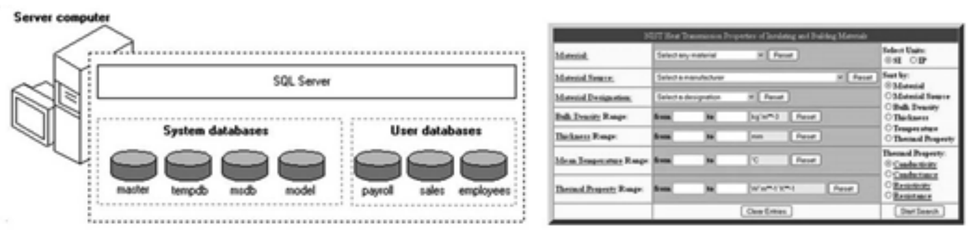

Figure 9 [36.] Computer Database Management Systems

Computer Analysis and simulation programs modelling environmental, technical and economic forces in order to quantify performance and enables us to analyse multiple design options.

Computer Aided Design systems (CAD) make the construction and drawing of building plans rapid and accurate. Projected physical dimensions and surfaces may be changed very easily. Architects – in theory - could have more control over the building design process, based on “freedom” of shaping, modification through computer modelling, simulation methods of reality. This technique does seem to be very accurate, but sometimes it can be difficult to recognize relation in between several calculation methods and parameters. Separated simulation computer algorithms sometimes result with reductionism (reductionism in science says that a complex system can be explained by *reduction* to its fundamental parts) replacing the holistic ("The whole is different from the sum of its parts" [37]) approach, because measures of building construction are separated in independent processes and complex, comparative analysis of requirements and product performances in the context of the whole is missing. (Fig. 10.) It can be sometimes problematic because of interaction in between of several parameters.

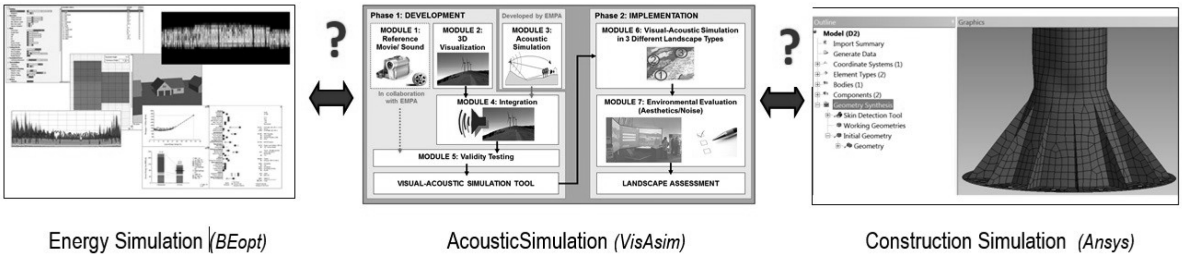

Figure 10. Computer simulation programs

4. Conclusions

According to the new aspects and tools, the architectural design process must become more conscious. Recently our main task is not only to create new technical variations, but to re-define a really conscious, continuously step by step controlled design process taking into consideration whole complexity of all available social, cultural, functional, economic, natural, structural, material and technological data, while providing permanent holistic control over the decisions. Design plays a very important role in architecture, not just aesthetically, but technically as well.

Careful consideration of surrounding impacts (climate: sunshine, temperature and wind, soil mechanics etc.) from the earliest stage of the design process can have an enormous impact on reducing subsequent operating costs and protecting our nature. The way we build should be in dialogue and reflect with local conditions instead of working against the surrounding nature. Traditional architecture relating to the climate utilizes natural conditions for the benefit of human comfort. These traditions could help us to develop really environmental friendly design decisions of contemporary architecture.

Buildings we design should be adapted to its real environment both in shape and structure providing maximum internal comfort and at the same time minimum harmful environmental impact. This seems to suggest that there is a need for developing a systematic structural and material selection system [4, 5] that will enable architects identify and prioritize the relevant criteria to effectively and accurately evaluate the trade-offs between social, technical, environmental, economic and performance issues during the construction evaluation and selection in design process.

Ibuchim Ogunkah and Junli Yang (2012) define material selection of vernacular buildings based on comparative analysis [6]. Their of the collected data pointed out that there are significant changes in building performance across countries, given their differences in building code restriction level in the use and mutual recognition of performance of materials, geographical and environmental conditions. (pp 19) (Fig. 11.) They holistically aim to develop a set of useful knowledge bases and structured ‘selection’ systems that will serve as the basis for evaluating such building materials in terms of their sustainability, during the design process of a building project. This research consists of a suggested toolkit of material selection.

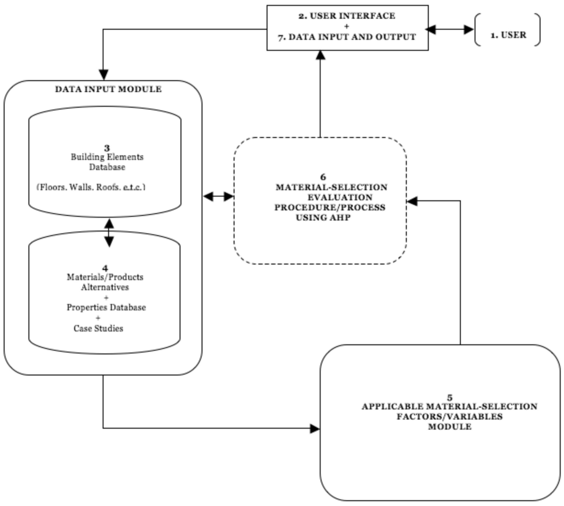

Figure 11 [6]Conceptual Model of material selection toolkit.

Therefore, to enable a structured and more comprehensive approach in the design-decision making process, it is important that the design-decision maker (architect, designer or expert) takes into account several material-selection factors or variables in order to facilitate the processes of comparing and identifying the best material option(s) across different categories. Actually the difference is how the designers interprets, synthesizes, and evaluates the collected data and techniques in their design process as result of all their perceptions, aims, convictions and skills.

Systematization and integration of all relevant information into creative design process is a crucial part of contemporary architecture. By re-thinking the architectural design process as a coordinated set of stages and sub-stages, replacing the traditional experience-related process by a more rational, and theory based approach choices and solutions for specific design problems, traditionally taken base on experience or individual thinking, can be now taken base in complex awareness and attentive to potential alternatives. [7] Preventive and remedial measures and decisions of architectural design process should always be evaluated in the context of the whole. (Fig. 12.) The house should be approached as a complete system, with specific features and performance requirements, not as a collection of independent industrial engineering disciplines (electrical, mechanical, structural, and so on), as an integrated part of a process in dialog with the surroundings and its inhabitants. Holism (from ὅλος *holos*, a Greek word meaning *all*, *whole*, *and entire*, *total*) is the idea that all the properties of a given system (physical, biological, chemical, social, economic, mental, linguistic, etc.) cannot be determined or explained by its component parts alone. Instead, the system as a whole determines in an important way how the parts behave. The idea has ancient roots. [37]

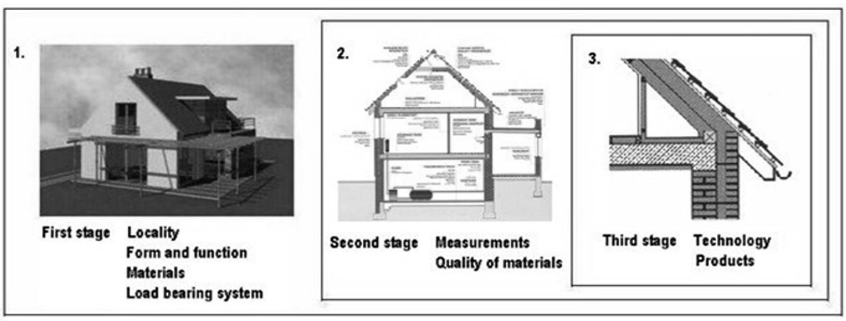

Figure 12 [8, 9, 10] Stages of holistically approached architectural design process

Analysis of impacts, requirements, and structural performances of each design stage can be the common ground of the dialogue between the architect and the experts according to the Performance Based Design method (PeBBu - CIB) [11]. (Fig. 13.) In Performance-Based Building Design evaluation of each design factors and aspects focuses on demands and on required performance in use.

Performance requirements translate user requirements in more precise quantitative measurable and technical terms, usually for a specific purpose. Steps of evaluation process are given below. Order of the performance based structural evaluation steps cannot be changed and need to be worked out for each condition (effect) due to the interaction of the parameters. We have to take into consideration the whole complexity of aspects and available data during the design process

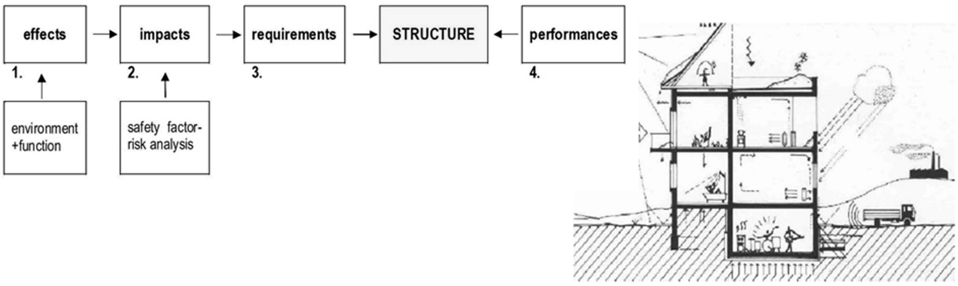

Figure 13 [12] Performance based evaluation method of architectural decisions

Efficiency of design process depends on the adequacy of the data applied. Architectural decisions can be correct if they are based on a comprehensive, real, and up to date and appropriate Database. [13] Database is always unique and local. The essential part of the decision process is a properly modifiable Project-oriented Site-specific Database, continuously fitted to the project, consisting of real, up to date and comparable data. (Fig. 14.) In this Database system, the compilation of information - according to the project and site - starts at the beginning of the design process, with the collection of the basic data of social, cultural, functional, natural, structural, material, economical, technological information. This multilevel database should be fitted to the project from the preliminary plan until construction phase. The applied systemized parameters should be controlled and consciously selected.

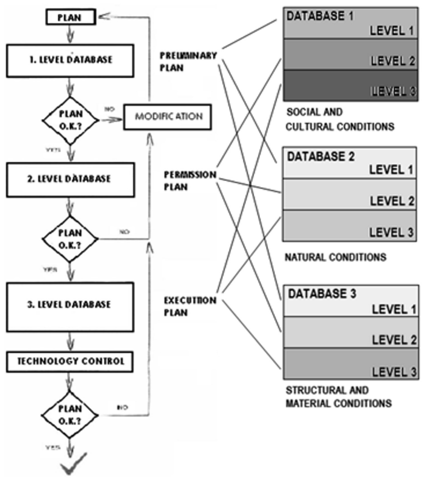

Figure 14 [14, 15] Project oriented complex database

The Holistic Performance Based design method responding on the surrounding conditions integrates skills, knowledge and tools of “passive” and “smart” design elements into a more conscious complex design process. In this design process the computer aided technologies are tools for architect, but not independent creative “intelligences” far from the human attitudes and real natural circumstances.

Holistic Performance Based (HPB) design process provides awareness whole complexity of technical knowledge for architects. By this way, the architectural and structural decisions made through the evaluation of real parameters and the complexity of the measurement will be more secure. As the attached figure shows the freedom of choice is the highest in the beginning, because later the decisions had been done earlier limit modifying of particular elements. As the project takes shape and becomes more detailed the degrees of freedom and the possibilities of choosing better alternatives are reduced. This complex attitude should be an integrated part of the designing process from the very first step. (Fig. 15.)

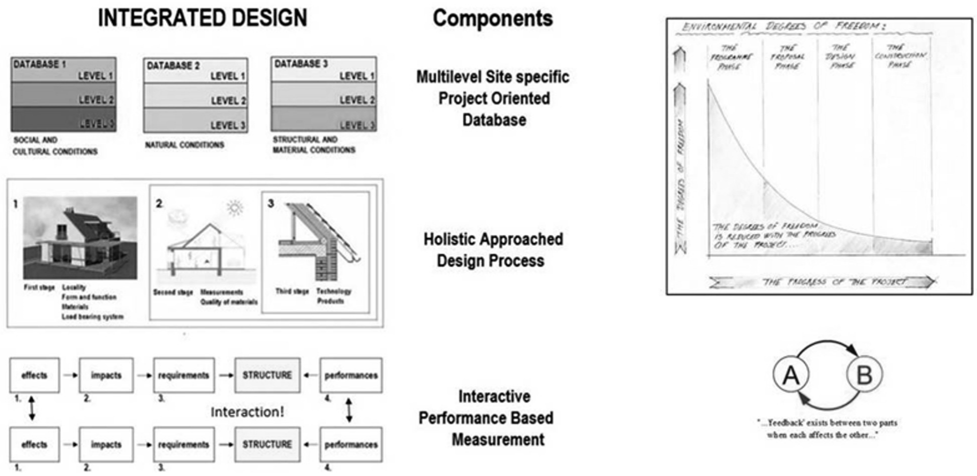

Figure 15 [16] Components of complex integrated holistic performance based architectural design

Matching of preliminary environmental parameters and required building parameters by holistic performance based evaluation method according to the multilevel project oriented site specific database is the basis of this complex design process. (Fig. 16.)

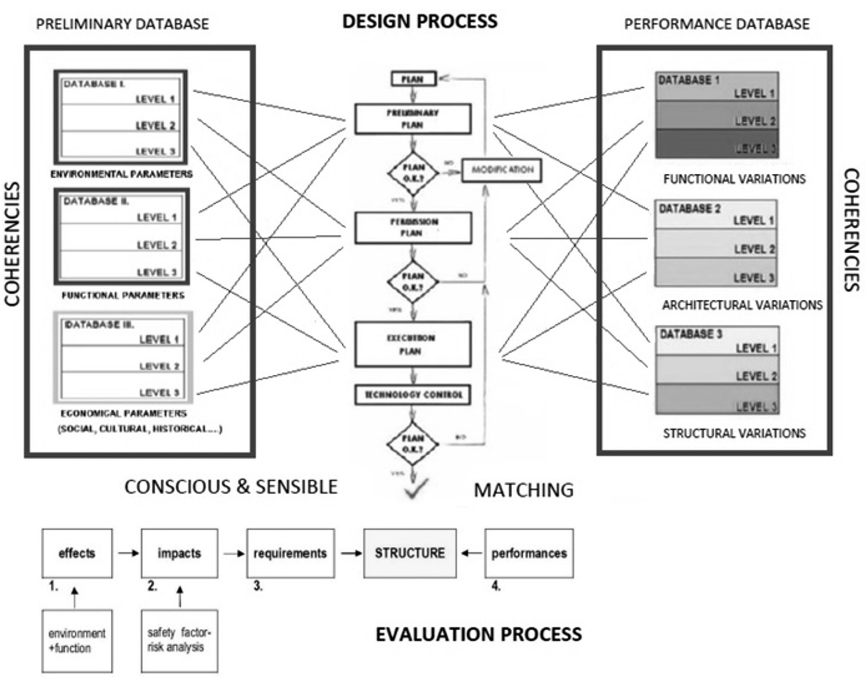

Figure 16. Summary of complex holistic performance based architectural design process based on the continuously fitted database system

This method could be used not only in design practice, but in university curriculum as well. [17, 18, 19] Tutorial practice should help students to discover how architects can capture locality, and how they can build databases to be used from the very first step of the design process. This teaching method should be always a multidisciplinary effort joining not only the various branches of architecture, but also involving IT specialists, meteorologists, civil engineers, economists, etc. We have to provide integration of several design aspects, requirements and tools into creative design process based on well systemized and determined site specific comparative database to achieve an optimum architectural and structural solution fitted to the given circumstances and demands.

ERASMUS program at Budapest University of Technology and Economics helps not only Hungarian but foreign students as well to use the complex holistic design method in their design tasks. In the comprehensive design studios the teachers of several professional fields help student to develop step by step their own optimum version for the given design program. Students match the environmental (natural, social, functional, economic) parameters to the possible architectural, functional, and structural solutions. (Fig. 17.) This conscious design process allows them to define and compare design choices in connection with performances of building and surroundings, to recognize, that each requirement criteria has different priority in several design situations.

To Follow Or Not To Follow Design Standards: A Question For Sustainable Coastal Engineering

Francine Baker
University of Central Lancashire
(email: FBaker1@uclan.ac.uk)

Abstract

This paper is concerned with what a contractor should do to fulfil his design obligations under a construction contract to assist the fulfilment of a sustainable design and/or end product. It considers this in relation to a recent Court of Appeal case law concerning coastal engineering, as this is an area where sustainability is at the forefront. This area concerns the use of relatively recent technology. It is not always clear from the provisions in construction contracts servicing recent technologies, how contractors can be protected from legal liability, even when the designer has apparently done all that is required under the contract. This is illustrated by the recent case law MT Højgaard A/S v E.ON Climate and Renewables UK Robin Rigg East Ltd and another [2015]. This paper will examine, the guidance in this Court of Appeal's judgement regarding a contractor's liability for design involving a fitness for purpose obligation, and the extent to which this may be tempered by other terms in the contract. This paper will combine such guidance with an explanation of the legal approach to the analysis and construal of contracts. In doing so, this paper will attempt to address questions which often arise concerning a contractor's design liabilities, such as, should a party to a contract follow the letter of the contract or should they follow standards set by professional organisations when carrying out their design task, and what should the parties do if there is a conflict between the terms of the contract and design standards?

Overall, it will evaluate how any conflicts may be removed with reference to current law and professional practice. The recommendations are applicable to all with design obligations. In summary they are that the proposed contract should be analysed by both parties to consider the various interpretations of provisions. To avoid disputes, a common interpretation needs to be agreed on in advance of entering into the contract. The conditions of a contract need to be clearly identifiable within the contract, unambiguously stated and a hierarchy and interpretation agreed upon by all parties to the contract in advance of the contract's application to the project.

Keywords: fitness for purpose, contract, design life, engineering

1. Introduction

Sustainability in construction is concerned with design, construction and operation, but also with contracts to enable such events and to avoid chaos. As Hibberd (2015) said, until ‘consideration of matters related to sustainability’ are ‘an intrinsic and an inherent component of one’s thinking – not a separate consideration’, contracts and especially the accompanying guidance on contracts’ will continue to play a very important role. He makes the seemingly obvious point that the contract should reflect the decisions which should have been made, however, in practice, this is not often straightforward. The process of agreeing an appropriate and effective contract is complicated by new technologies and innovations. The performance/sustainability of the structure and/or components may be uncertain. The performance, for example, of wind turbine foundations is subject to variables, which cannot always be predicted. As Scottish Development International (2010) reports:” Stable sea conditions are required for foundation installation and increased downtime is therefore to be expected with projects further offshore and in deeper waters.” (p.27). This paper considers a recent judgment of Court of Appeal which concerns the design life of the foundations of wind turbines and the design liability of its contractors. It is particularly important for designers involved in costal engineering construction projects understand their legal responsibilities and check that their contracts protect them from liability where possible. This may avoid delays, assist an efficient realisation of a smart sustainable construction, and avoid costly arbitration or litigation. It is also important to consider this because, as reported by O’Keeffe and Haggett (2012), offshore wind is likely to make the single biggest contribution towards UK government renewable energy targets across the UK because the UK has over 33% of Europe's potential offshore wind resource, with the majority of that resource lying off the coast of Scotland (p 3711).

Coastal engineering and construction contracts, including those used in the offshore oil and gas and wind farm sectors, often involve the use of design and build type contracts where the contractor is given responsibility for both the design and the construction itself. In such cases, it is increasingly common for employers to insist on absolute warranties. Many of the popular standard forms, such as the LOGIC standard contracts, include absolute fitness for purpose obligations. Contractors who accept these provisions should be aware that there is a high risk of potential liability. The contractual obligation that the work will be fit for purpose is quite different from the reasonable skill and care obligation that is more usually undertaken by designers of constructed facilities. It involves a strict liability regardless of fault. However, the all-important question in every case is "fit for what purpose?" Another question that arises with design contracts is what is meant by standard phrase design life, in the context of the contract? As Michael Curtis QC (2014) stated in his recent article, “There is no single definition that applies in all contexts.” (p1) With large projects and with coastal engineering projects the meaning of key phrases in the context of the purpose that the contractor has to achieve may be unclear. This is because it often has to be deduced from a collection of contractual documents of different authorship, containing ambiguous wording.

It is therefore not always clear from the contract, how contractors with design and build contracts can be protected from liability, even when the designer has apparently done what is required under the contract by strictly complying with the international recognised design standards referred to in the contract. This is illustrated by the recent case law MT Højgaard A/S v E.ON Climate and Renewables UK Robin Rigg East Ltd and another [2015]. The Court of Appeal judgment has helped to clarify how a designer can work out what he should do to avoid liability when things go wrong. But this is not enough. A contractor also needs to understand how contracts are construed and interpreted by lawyers, particularly by judges, as well as how key provisions are interpreted. This paper will therefore consider, with reference to case law, how designers may ascertain their legal obligations when there are conflicts between the terms of the contract concerning the designer's obligations and the design standards. It will assess current legal practice and provide guidance to contractors to assist them with working out the extent of their legal obligations under contracts regarding design.

This also requires consideration as to how contracts are interpreted by the Courts, whether there is a hierarchy of terms in a contract, and where there is a conflict, that is, inconsistency or ambiguity, between terms, how to assess which term has precedence in determining the designer's professional obligations.

2. Key Case Law

2.1 Facts: MT Højgaard A/S v E.On Climate And Renewables UK Robin Rigg East Ltd & Anor [2015]

Firstly, this paper will consider guidance given by the Court of Appeal in the currently leading case in this matter, MT Højgaard A/S v E.On Climate And Renewables UK Robin Rigg East Ltd & Anor [2015] EWCA Civ 407 (30 April 2015) (MTH). The Court of Appeal is the second highest court in the United Kingdom just above the High Court. In this case, the Court of Appeal was asked to reconsider the decision of the lower court, the Technology and Construction Court (TCC), which is part of the Queen's Bench Division of the High Court.

In 2006, E.On Climate and Renewables UK Robin Rigg East Ltd and E.On Climate and Renewables UK Robin Rigg West Ltd ("E.ON") entered a contract for €100 milllion with MT Højgaard A/S (MTH) to design, fabricate and install the foundations for 60 wind turbine generators at the Robin Rigg offshore wind farm in Solway Firth. This firth forms part of the border between England and Scotland, between Cumbria (including the Solway Plain) and Dumfries and Galloway. It stretches from St Bees Head, just south of Whitehaven in Cumbria, to the Mull of Galloway, on the western end of Dumfries and Galloway.

The Contract required MTH to carry out the Works with due care and diligence, and to ensure that they were fit for purpose. MTH's designer, Rambøll had relied on the international standard DNV-OS-J101 (J101) when carrying out the design of the foundations and the grouted connections. The reason he did this is because the fitness for purpose requirement in the contract was determined in accordance with the Specification, that is, the Technical Requirements, using

Good Industry Practice. The latter is generally defined to mean performance with the skill and prudence to be expected of an appropriately skilled and experienced contractor, in a manner consistent with recognised international standards. An objective test is applied. This is explained and elaborated upon in joint publication with Scottish Renewables (2015) at p. 4. The Technical Requirements specified that MTH must comply with the internationally recognised standard DNV-OS-J101 ("J101"). It also included a requirement that the foundations would have a service life of 20 years. So MTH complied with the contract by following J101. However, J101 contained a fundamental calculation error. MTH's designer, Rambøll was unaware of this when it carried out the design, (as were designers in general at this time). (But the fact that no-one knew the standard was faulty did not assist MTH at the TCC hearing.)

In 2009 it was discovered that movement was taking place in the grouted connections at a Dutch offshore wind farm which had a similar design to that at Robin Rigg. Shortly after completion of the works, the grouted connections in the foundations started to fail. The error in the J101 standard had resulted in a significant overestimation of the axial load capacity for wind turbines with grouted connections. In April 2010 it was found that the wind turbines at Robin Rigg were suffering from the same defects. A scheme of remedial works was developed and the remedial works were commenced in 2014. The parties agreed the cost of the remedial works which amounted to €26.25 million.

2.2. MTH: Technology & Construction Court (High Court)

E.ON then took MTH to the Technology & Construction Court for breach of contract, claiming damages for the cost of the remedial works. Mr Justice Edwards-Stuart found that MTH had indeed exercised reasonable skill and care and that it had complied with the DNV-OS-J101 standard. Neither party had been negligent. The problem, the judge said, was that the Contract and Technical Requirements stated that "The design of the foundations shall ensure a lifetime of 20 years in every respect…" The judge said that meant the contractor had warranted that the foundation structures which it designed and installed for an offshore wind farm would have a service life of 20 years. But they clearly did not fulfil this promise, as the foundations had failed shortly after completion.

The Court's reasoning relied on its examination of certain paragraph in the contract, viz., 3.2.2.2 (2) of the Technical Requirements, which stated that "The design of the foundations shall ensure a lifetime of 20 years in every aspect without planned replacement": and paragraph 3b.5.1 of the TRs which also stated that "The design of the structures…shall ensure a lifetime of 20 years in every aspect without planned replacement"; and clause 8.1 (x) of the Contract which required the contractor to complete the works such that the "Plant and the Works as a whole shall be free from defective workmanship and materials and fit for its purpose as determined in accordance with the Specification using Good Industry Practice." Note the mandatory language used, viz., 'shall' in each clause. This term is normally associated with absolute warranties. The TCC found that these clauses required MTH to provide foundations with a service life of 20 years; and that the failure of the foundations was therefore a breach of contract, including a breach of clause 8.1 (x)

Therefore, by accepting overall design responsibility for the Works, the contractor, MTH, although it did not do anything wrong, was held responsible for the risk of there being an error in the standard J101. The international standard did contain an error, which materialised, and therefore the High Court held MTH liable for the consequent damage.

2.3 Fair or Unfair?

You may consider this an unfair decision, as the contractor had been a good designer in following the approved design standard required by the contract. It does not seem right that it should be held responsible for the intrinsic error contained in the standard, which no-one knew about at the time of the damage. But in law, a warranty can be like a guarantee or entail strict liability. So it does not matter if you have done nothing wrong. You may still be liable because you agreed with your client that you would do things or provide certain things of a certain standard, which do not happen or turn out not to be of that standard, even though it is completely not your fault. If, for example, you tell your roofer that he should supply tiles which should have a ten year life and the roofer agrees to provide the tiles, but they do not last a year, because they were manufactured badly, then the poor roof tiler is responsible to replace the tiles at his own expense, even though, despite a reasonable inspection of the tiles he could not have known that they were faulty. Here the judge is saying that the contractor had warranted that the design itself, not the product that results from the design, would have a life of 20 years. Note the use of the mandatory words ‘shall’ in each of the paragraph referred to by the Court. This will usually indicate an absolute obligation, whether or not there is fault.

2.4 MTH: Appeal to the Court of Appeal

Luckily for MTH, the contractor, the Court of Appeal disagreed with the reasoning and decision of Mr Edward Stuart in the Technology and Construction Court. One would have thought the judiciary in the Technology and Construction Court were the experts in such matters, as this is a specialist court, however, when it came to the law and the interpretation of the contract the higher Court, the Court of Appeal knew better. It reversed its decision. Consequently, E.ON bears the agreed costs of the remedial works amounting to €26.25 million. They may yet seek leave to appeal to the Supreme Court. So how did this come about?

MTH had appealed to the Court of Appeal on the basis that the TCC’s interpretation of the Contract was wrong. E.ON then cross-appealed on the ground that MTH had committed other breaches in failing to carry our further testing prior to carrying out the Works, which would have discovered that there was an error in the J101 standard. Regarding the cross-appeal, the Court of Appeal did decide that MT Højgaard was in breach of the test data and experimental verification requirements, but it concluded that those tests would not have revealed the defects that had occurred, and therefore the breach did not cause any loss. Therefore, E.On was only entitled to recover nominal damages of £10 for its cross-appeal.

The Court of Appeal explained its view that the TCC’s interpretation of the Contract was wrong. It argued that the wording in Clause 8.1(x) that the works as a whole should be “fit for its purpose" was qualified by the phrase "as determined in accordance with the Specification using Good Industry Practice". It accepted that the Contract defined "Good Industry Practice" as requiring the exercise of reasonable skill and care as well as compliance with the DNV-OS-J101 standard. It concluded that MTH had exercised reasonable care and skill, and that they had followed the design standard.

The Court of Appeal particularly considered the wording in the Technical Requirements which said that "The design of the foundations shall ensure a lifetime of 20 years". The Court agreed that it was clear from the contract that MTH was required to assume full responsibility for the design as well as for the installation of the structures comprising the Works. However, crucially, the Court of Appeal made a very clear distinction between "design life" and "service life" saying that if a structure had a design life of 20 years, that did not mean that it would function for 20 years, that is, it didn't mean that it would have a service life of 20 years. What the Court said contradicted the TCC's decision that the contractor had warranted that the foundation structures which it designed and installed for an offshore wind farm would have a service life of 20 years. In other words, The Court of Appeal concluded that MTH did not guarantee or warrant that the foundations would have a 'service' life of 20 years.

This approach seems to be taking a literal interpretation of the words by limiting the guarantee to the design of the foundations. But surely this is not a common sense interpretation. Why would the client have agreed to that, when what is of vital importance to him is that the foundations will last for 20 years, e.g., "The design of the foundations shall ensure that the foundations have a service life a lifetime of 20 years [my inserts]". If the design is properly carried out, then the foundations' service life should be 20 years, just as in the case where you have agreed with your supplier that tiles he supplies must have a life of 13 years. This does not mean that there cannot be maintenance of the structure over time. There is no reason why this would detract from the obligation. The service life would end when it is not possible to replace one or more of the components essential for its operation.

The problem seems to be, as Curtis (2014) stated, that 'it is essential for a contract or specification to define precisely what the term design life is supposed to mean in the context in which it appears. Otherwise it is likely that the parties' expectations about its meaning will be very different . . .'(p 4). For example, does it mean that the foundations will function for 20 years without any maintenance or does it mean that the foundations will last for 20 years provided it is properly maintained? In reaching its decision the Court must also consider the other provisions of the contract as well as the construction of the contract as a whole, and so to shed light on the Court's reasoning for this decision, this paper will consider how the court goes about doing this.

3. Contract Interpretation

3.1 The intentions of the Parties

Firstly, it should be noted that the parties' negotiations prior to a contract being agreed are irrelevant, when determining the interpretation of contract provisions. In Chartbrook Ltd -v-Persimmon Homes Ltd [2009] UKHL 38, the House of Lords confirmed that that evidence of pre-contractual discussions should not be used as a tool of construction. However, relevant background fact or statement known to both parties may be relevant where a party claims that the written contract should be corrected to reflect the terms that were 'actually' agreed by both parties. The Court or Tribunal also does not take the subjective intentions of the parties into account when interpreting the contract. It is not interested in what they 'say' they intended to agree. Rather, the law uses an objective approach to interpretation. It will first give the words of the provision their natural meaning, so that the words that were actually used in the contract are be construed in the way that they would be understood by a (hypothetical) reasonable person, with the background knowledge available to both parties at the time the contract was made. The approach is not concerned with the way each party may argue they were used: Chartbrook Ltd -v-Persimmon Homes Ltd [2009] UKHL 38. It will then consider how the provision fits into the contract as a whole, i.e., what do the words really mean in the context that they were used?

So the trend in recent case law is that the actual language used in the contract is given priority, unless the language is ambiguous or unclear. This approach is apparent in the judgment of the Court of Appeal. It provides a useful summary of the principles of contract interpretation. In a key passage, at para 87, the Court's judgement delivered by Lord Justice Jackson states that, "a court seeking to construe the contract between E.ON and MTH must postulate a reasonable person (X) having all the knowledge available to those two parties. The court must consider what X would have understood clause 8.1 of the conditions and TR paragraph 3.2.2.2 (2) to mean. This is an iterative process, which involves checking each of the rival meanings against the other contractual provisions and investigating its commercial consequences".

The Court of Appeal did agree with arguments that the fitness for purpose requirement was determined in accordance with the Specification (the Technical Requirements) using Good Industry Practice, which, in summary, meant performance with the skill and prudence to be expected of an appropriately skilled and experienced contractor, in a manner consistent with recognised international standards. The problem, the Court argued, is that the Technical Requirements are inconsistent with the Contract conditions which required "due care, professional skill, adherence to good industry practice, and compliance with the Employer's Requirements. But the Court found this resolvable since the contract had provided a hierarchy of terms.

3.2 The Hierarchy of Terms in a Contract

It is usual with complex commercial contracts for a number of people to be involved in negotiating the different parts of the contract. This can make it challenging to know which terms, which are given in provisions of the contract, should be given priority over others, if there is any conflict in the language or interpretation. The contract will consist of a number of contractual documents, prepared by different people. These will include for example, the main terms and conditions, as well as/or technical requirements, specific schedules or appendices that deal with certain issues such as 'defined' terms, payment arrangements, service levels and the delivery timetable especially on larger projects. But it is not always clear which are the most important terms to be followed where there is conflict between them. So the parties often insert a 'hierarchy' or 'order of preference' clause (also referred to as a provision) into their contracts to safeguard against potential discrepancies between an agreement's various provisions and parts of the contract. Such clauses typically provide that, in the event of a conflict or inconsistency between the language and terminology used in contractual provisions (in this case "design life", "service life" and even "lifetime"), or parts, certain clauses or parts will prevail over others to resolve the conflict. However, the Courts do not jump straight to this hierarchy clause. They first attempt to reconcile any contradictory or overlapping clauses.

Recent Court cases demonstrate that the Courts are reluctant find that the contract documents are inconsistent with each other. They would rather attempt to give effect to an interpretation which avoids this, or reconciles any conflict: RWE Npower Renewables Ltd v J N Bentley Ltd [2014] EWCA Civ 150. The Court's judgment in MTH Højgaard A/S explains that in the contract in question, where there is inconsistency between terms of a contract, the terms which are the 'contract conditions' must be followed, because the hierarchy of terms clause says that the contract conditions are above the Technical Requirements in the contractual hierarchy of terms. The Court seemed to be implying that the TCC did not seem to have considered the order of hierarchy of the provisions of the contract when considering the contract as a whole.

The Court of Appeal found that clause 5.3 of the contract provided that the contract conditions which required "due care, professional skill, adherence to good industry practice, and compliance with the Employer's Requirements, take precedence over other contractual documents, and the Employer's Requirements came fourth in the order of precedence. The judgement noted at par 102 that the phrase "Good Industry Practice" is defined in the List of Definitions (a document which has parity with the conditions of contract in the order of precedence) and that although obligation requires the exercise of reasonable skill and care, as well as compliance with J101, it did not require or impose any form of warranty as to the length of operational life. Since the contractors had complied with these contract conditions they had fulfilled their obligations, despite the fact that the international standard was flawed.

The Court of Appeal argued that the overall drafting of the Technical Requirements was inconsistent with an intent to impose an absolute guarantee of a 20 year operational lifespan, since the 'detailed' 'input' requirements of the Technical Requirements (which required, among other things, compliance with J101) were inconsistent with an 'output guarantee' of a 20 year lifespan.

The Court concluded that one could not conclude that MTH gave a warranty requiring a 20 year service life (as opposed to design life) based on the individual provisions of the Technical

Requirements (para 106). The Court finally added that a reasonable person in the position of E.On and MTH would know that the normal standard required in the construction of offshore wind farms was compliance with the international standard, but that such compliance was not absolutely guaranteed, to produce a 'service' life of 20 years (para 104).

4. Discussion

So after deciding that the hierarchy of terms clause resolved this matter, the Court seems to cover its tracks by also justifying their decision by referring to the objective approach, the views of the reasonable man in the position of the parties. Firstly, regarding the hierarchy of terms clause, it has been recently held in RWE Npower Renewables Ltd v J N Bentley Ltd [2014] EWCA Civ 150, that it is only where there is a clear and irreconcilable discrepancy that the hierarchy clause should be resorted to. Effectively, it is a clause of last resort, not first resort. A clear and irreconcilable discrepancy does not seem to have been identified. It may be argued that the Court has not reverted to the hierarchy clause as a last resort, and its decision may be open to appeal on this point

Designers clearly must do what is required under the contract according to the standard required under the contract, to which they have supposedly agreed. Whether or not the designers will be successfully sued for damages for breach of contract for the consequences of errors in the design standard they could not have been aware of, will depend on the standard of care required by the contract. However, where a design standard is required to be followed, and the quality or duration of the standard of care required is uncertain due to conflicting wording in various provisions, or because of the effect of other provisions in the contract, it may be difficult to ascertain what were the intention of the parties at the time they made the contract.

It is unusual for a professional designer to agree to a guarantee his design will be fit for purpose or that the design life will be fit for purpose. However, a contractor, in a design and build contract is responsible for the design as well as building it, and is required to produce a structure fit for purpose- whether it is a bridge or wind turbine generators. This goes to the root of the contract. Unless the structure can do the job it is of no value. However the Court of Appeal seem to have got around this difficulty by arguing that there is a difference between the design life and the service life of the structure. But this seems to contradict current knowledge. It is standardly accepted that wind turbines are typically designed for a 20 year design and service life. For example, Windmeasurmentinternational states that 'Every machine has a set design lifetime based on how long the parts are expected to last. . . . The components of a wind turbine are typically designed to remain operational for twenty years.' So both the design life and the service life should be at least 20 years. This reality contradicts the view of the Court of Appeal which focuses much more on the construction of the provisions in the contract, rather than on a prior investigation of the commercial reality, The latter, as the above explains, indicates that it is likely that a reasonable man in the position of the parties would have intended to agree to guarantee a design and service life of 20 years. The Court of Appeal in MTH does not clearly seem to have considered this.

The Court did refer to some helpful guidance about the construction of contracts, even if it did not take it too seriously. Lord Jackson in the Court of Appeal cited the judgment of Lord Clarke in Rainy Sky SA v Kookmin Bank [2011] UKSC 50;[2011] 1 WLR 2900 who observed that "...if there are two possible interpretations of a provision, the court is entitled to prefer the construction which is consistent with business common sense". What makes more sense than for the contractor to be liable for a 20 design and service life of a turbine when this is standardly accepted by the industry as normal?

Lord Jackson also cited the judgment of Lord Collins SCJ in the case of Re Sigma Corp(in administrative receivership) [2009] UKSC 2; [2010] 1 All ER 571 in which it had been held that an "...over-literal interpretation of one provision without regard to the whole may distort or frustrate the commercial purpose". In this paper's view, both the views of Lord Clarke and Lord Collinscould have been considered more seriously, with more attention given to the commercial realities, when attempting to ascertain the intentions of the parties at the time they entered the contract. This step should have determined the outcome of the case.

4.1 Recommmendations

With complex projects or those involving new technology, it is worth paying for the extra time and fuss involved in having an experienced lawyer to ensure that contracts are clearly drafted to reflect the precise agreement between the parties, as accurately as possible. This will avoid incurring far more costs further down the line.

The proposed contract should also be analysed in the context of addressing the following questions. Are any of the provisions relating to design responsibilities open to misinterpretation or ambiguity? Could a provision be read in different ways? What do the clauses mean in the wider context of the contract as a whole? Could the provision be misunderstood? Consider how the provision could be applied to what may go wrong. Is this the application you intended?

Where there are conflicts between the provisions of the contract, and a hierarchy of terms clause/provision is not given in the contract, then the conditions of the contract will somehow need to be identified. They go to the heart of the contract, and so what they say impliedly takes priority over other provisions. But identifying which provisions are conditions should not be left up to the Courts. They may not get it right, with resulting further appeals, costs and delays to projects. To avoid such disasters, it should always be clearly stated in the contract what are the condition of the contract, i.e., 'It is a condition of the contract that …' and if some of the provisions have similar or conflicting wording, then it needs to be clearly, unambiguously stated in the contract which ones which ones have priority, should a conflict arise. All parties to a contract should be made be given clear notice of the conditions and priorities of provisions in the contract before agreeing to it or signing it. Such notice should be in writing through legal representatives to avoid disputes along the lines that these are unusual provisions which were not drawn to attention. If there is any likely conflict regarding the interpretation of the words or phrases in a contract, this must also be sorted out before the contract is agreed. One interpretation of them should be agreed by the parties.

It is therefore recommended overall, that where a clause is of vital importance to the employer or contractor, that party needs to obtain agreement with the other party to the effect that it does have such importance, and then, this must be highlighted in the contract. This means that the wording in the clause should be very clearly stated and the clause marked in a prominent position as the main condition of the contract having priority over all other conditions of the contract. For example, if E.ON had really wanted an absolute binding 20 year service life warranty, to avoid later argument, it should have insisted on that provision featuring prominently and unambiguously within the conditions of contract, rather than being closeted away in the Technical Requirements.

5. Conclusions

The MT Højgaard A/S case demonstrates the problems that can arise with complex contracts when various documents from different sources are incorporated at different levels into a contract. Contractors/designers need to assess their potential liability regarding inconsistencies between them, and attempt to remove any inconsistencies before agreeing to the contract.

The Court of Appeal supported the previous comments of the High Court that if the contract wording is sufficiently clear, an express obligation to construct a work capable of providing a 20 year service life can override the obligation to comply with the plans and specifications, which includes complying with the design standard. Then the contractor would be liable for the failure of the work, notwithstanding that it had been carried out in accordance with the plans and specifications.

It must be clear from this paper that fitness for purposes obligations for contractors who are designers or designer-builders should be avoided, excluded or limited, if possible. This is because if the product fails, a party may be liable for all the damage incurred, even if they exercised reasonable skill and care, and even if they followed the stipulated design standards to the letter.

Abstract

All new buildings in the EU are to be nearly zero-energy buildings (nZEB) by the end of 2020. Energy efficiency, reduced demand, and onsite renewable energy systems, are key characteristics of nZEBs; when this features are combined, the generation from the supply systems may exceed the energy demand of the building. Such has been the case in the zero energy building named Villa ISOVER®. It integrates photovoltaic panels, solar collectors, a ground-source heat pump and grid interactions, and adheres to strict regulations by the National Building Code of Finland. As well, a monitoring system records data from several channels such as energy generation and demand measurements, which allows to analyse the generation, demand, import and export of energy. In this paper, the data is first used to calculate the zero-energy balance of the building. Next, two indices: the onsite electrical energy fraction (OEFe) and the onsite electrical energy matching (OEMe) are calculated. The OEFe indicates the proportion of the total electrical demand which is covered by the onsite generation, and the OEMe indicates the proportion of the total electrical generation which is consumed in the building and system rather than being exported or dumped. The seasonal and time-resolution dependencies of these indices as well as different calculation methods have been studied. A series of outcomes have been deducted based on the measurement data. The annual net energy consumption of this building in 2014 is 15 kWh/m2a, which is thus, strictly speaking, a nearly zero-energy building. Furthermore, both the PV generation and electrical load are seasonal dependent, though in reversed behaviour: while generation is high during summer and low during winter, the load is low during summer and high during winter. This contrast leads to poor annual OEFe and OEMe, at 16% and 22%, respectively. Said indicators are indeed sensitive to time-resolution, depending on the available measurements and calculation method: coarser time resolutions may lead to overestimations of the matching capability. Finally, the recorded exchange with the electrical grid is seasonal-dependent: the normalized net-exported energy can be as high as 60% during summer, and as low as -40% during winter.

Keywords: Zero energy buildings, real measurement, matching analysis, grid interactions, onsite photovoltaic.

1. Introduction

All new buildings in the EU are to be nearly zero-energy buildings (nZEB) by the end of 2020. Energy efficiency, reduced demand, and onsite renewable energy systems, are key characteristics of nZEBs; when this features are combined, the generation from the supply systems may exceed the energy demand of the building. While this may at first appear to be a beneficial situation, it may represent an unfavourable condition for the distribution grid, and even for the user. For the grid, handling the surplus energy can be a challenge during peak hours. This is particularly risky when photovoltaic panels are present, as solar power is usually available around noon, when the grid utilization is high. For the user, exporting energy may not be the most attractive option. Self-consumption tends to be the preferred way to use of onsite generated energy, as the savings from avoiding electricity purchases are usually larger than the income from selling excess electricity to the grid. Thus, attention should be paid to the match between energy generation and demand, so as to identify the proportion of the generation which may be consumed onsite, and to predict how high the surplus fed to the grid could be. The purpose of this study is to analyse the generation, demand and interaction with the grid of a nZEB in southern Finland, and to study the behaviour of match indicators based on different methods and time-resolutions.

2. Zero-Energy Building Villa ISOVER®

Villa ISOVER® is a building conceived by ISOVER® and Fortum® to test the performance of a zero-energy building and its interaction with the electrical grid. It is a single-family house with a 175 m² net floor area built for the Housing Fair 2013, which was the winner of a design competition. The building is located in Hyvinkää, southern Finland. It integrates PV panels, Solar-thermal Collector (SC), a ground-source heat pump (GSHP) and an air handling unit (AHU); there is no connection to an external heating network, as the GSHP and SC fulfil the heat demand. A key feature allowing this configuration is the highly efficient thermal insulation. Thus, the building follows the design principle of first minimizing consumption and then using the locally available energy resources to fulfil the remaining needs as far as practical. A monitoring system keeps track of several heat and electricity onsite measurements, such as PV generation, electricity import and export to the grid, heat generation by SC and GSHP, and domestic hot water (DHW) demand, among others. As well, solar radiation and inside and outside temperatures are monitored. The data has a time-resolution of 1 hour. The building is presented in Figure 1.

Figure 1: Villa ISOVER® depicted from four directions [ISOVER®, 2013]

3. Energy Monitoring and Matching Analyses

3.1 Energy Monitoring Analysis

The original recorded data is based on a recording resolution of 1 hour over the year of 2014. The PV generation after the inverter is depicted in Figure 2, where a significant seasonal dependence can be seen. During the summer time, peaks of a magnitude of 6-7 kW can be noticed, whereas during the winter time, the magnitude of the PV generation after the inverter is mostly lower than 1 kW. The recording system also records the grid interactions between the building and the electrical grid. The electrical power imported from the electrical grid to the house and the electrical power exported from the house to the electrical grid are both recorded.

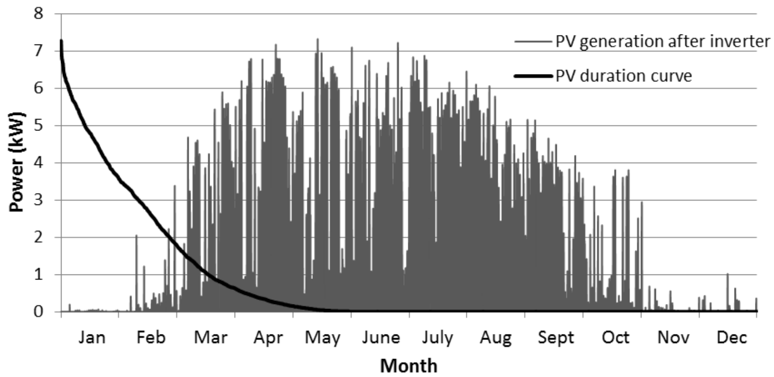

Figure 2: The recorded hourly PV generation after inverter

Figure 3 and Figure 4 depict the recorded hourly power imported from and exported to the electrical grid. As shown in Figure 3, the electrical power imported from the electrical grid also shows a seasonal-dependent characteristic. During the months of October to April, i.e. the winter time, the magnitude of the hourly electrical power imported from the electrical grid is between 0 kW and 5 kW. During the months of May to September, i.e. the summer time, the magnitude of the hourly electrical power imported from the electrical grid is within a range of 0-3.5 kW. The generally higher magnitude for the imported electrical energy in the winter time is mainly due to the higher heating load during the winter season, which can cause a more frequent operation of the GSHP and the AHU heating unit, as well as pumps and auxiliary equipment. On the other hand, during the summer season, the space heating load and the AHU heating load are quite low, and the DHW heating load can be mainly covered by the SC heating power, leading to a much less frequent operation of the GSHP and a lower total electrical consumption. Moreover, as shown in Figure 4, during the summer season the solar resource is sufficient, which means that the PV generation helps to cover the onsite energy load, which leads to less imported energy.

As can be seen in Figure 4, the hourly exported power to the electrical grid also shows a significant seasonal-dependent characteristic, with a much higher magnitude during summer than during winter. During the summer season, the exported power from the building to the electrical grid can reach a magnitude around 7 kW, whereas during the winter season, the exported power is mostly around zero. The main reason is that during summer, the electrical load is low due to the lower heating load, whereas the PV generation is sufficient due to the abundant solar resource. This leads to a significant export situation. During winter, the PV generation is quite low due to the poor solar resource in Finland, whereas the electrical load is very high due to the higher heating load. Therefore, during the winter season, most of the onsite PV generation will be consumed onsite, and almost nothing will be exported.

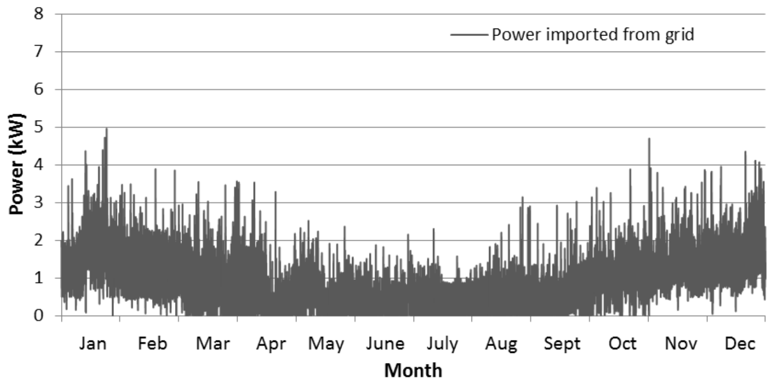

Figure 3: The recorded hourly imported electrical power from the grid

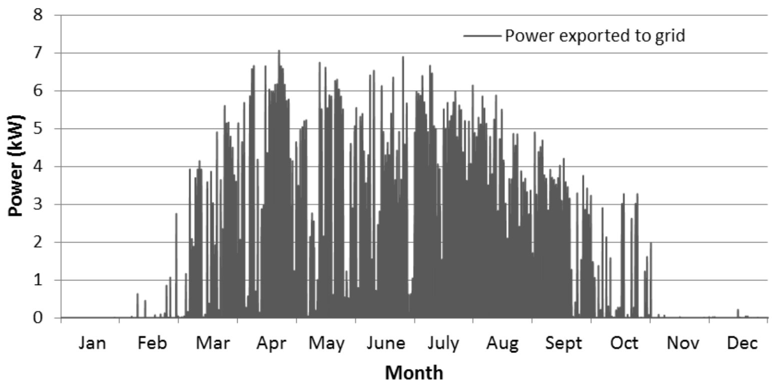

Figure 4: The recorded hourly exported electrical power to the grid

In addition, from the aforementioned hourly PV generation and the grid interactions, i.e. the hourly electrical energy imported from and exported to the electrical grid, the total electrical load can be correspondingly calculated via the following Equation (1):

$$L(t) = G(t) + I_p(t) - E_p(t) \quad (1)$$

Where the *G(t)* is the generation after the inverter, $I_p(t)$ is the electrical power imported from the electrical grid, $E_p(t)$ is the electrical power exported from the building to the electrical grid, and *L(t)* is the calculated total hourly electrical load. Figure 5 shows the hourly total electrical load calculated with Equation (1). The seasonal dependent characteristic can also be seen in Figure 5. During the winter season, the magnitude is mainly between 0.5 and 3 kW, while the peaks can reach 4.95 kW. During the summer season, the magnitude is mainly below 2 kW, while the peaks can reach 3 kW. The higher electrical total load during the winter season is mainly due to the higher heating load, which stimulates a more frequent operation of the electric heat pump.

Moreover, Figure 5 also shows a duration curve for the hourly total electrical load. It can be seen from the duration curve that peaks of 3-5 kW are actually quite rare in the electrical load. The maximum peak was 4.95 kW. There was only 0.09% (8 hours) of the year when the electrical load power was higher than 4 kW. There was only 1.2% (104 hours) of the year when the electrical load power was higher than 3 kW. Moreover, the percentage of time when the electrical load power is higher than 2 kW reached 10.4% (928 hours) ─ thus, still a quite small percentage for 2 kW. On the other hand, we can see that the percentage of time when the electrical load power is below 1 kW reached 57.5% (5033 hours), which indicates a base load level below 1 kW in the monitored building. By checking the ranges in the duration curve, it can be noticed that actually for more than 57% of the time (4974 hours) the electrical load is between 0.2 kW and 1 kW, which can result from the base load of ventilation fans, pumps, and the regular operation of household equipment such as refrigerator, freezer, and lights. Moreover, Table 1 shows the annual measurement data for the PV generation after the inverter, the annual imported electrical energy from the electrical grid, the annual exported electrical energy to the electrical grid, and the annual total electrical load.

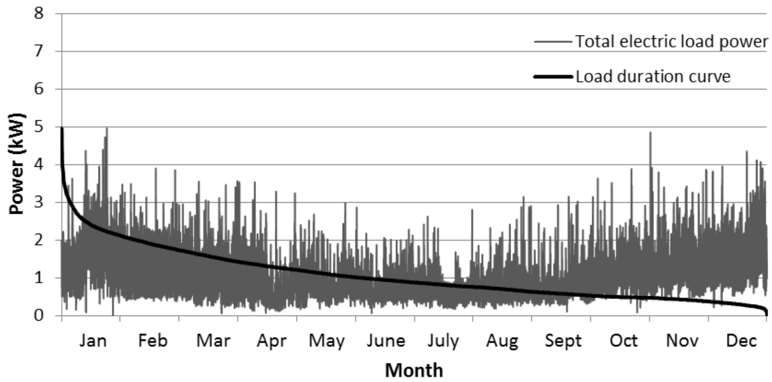

Figure 5: The hourly total electrical load and its duration curve

Table 1: The annual measured data concerning energy consumption

	Annual PV generation after inverter	*Annual electric energy imported from the electric grid*	*Annual electric energy exported to the electric grid*	*Annual total electric load*
Total (kWh/a)	*6612*	*7786*	*5149*	*9249*
Per unit area (kWh/m²a)	*38*	*44*	*29*	*53*

3.2 Energy Matching Analysis

From these recorded data, we can also calculate the matching indices and the grid interaction indices of the building. We use the onsite electrical energy fraction (OEFe) and the onsite electrical energy matching (OEMe) to analyse the matching [Cao et al. 2013]. The OEFe indicates the proportion of the total electrical load which is covered by the onsite PV generation, rather than imported from the electrical grid. The OEMe indicates the proportion of the total electrical generation which is consumed in the building and system rather than being exported to the electrical grid. There are two ways to calculate the OEFe and the OEMe:

Method 1:

$$OEFe = 1 - \frac{\int_{t1}^{t2} Ip(t)dt}{\int_{t1}^{t2} L(t)dt} \quad (2)$$

$$OEMe = 1 - \frac{\int_{t1}^{t2} Ep(t)dt}{\int_{t1}^{t2} G(t)dt} \quad (3)$$

Method 2:

$$OEFe = \frac{\int_{t1}^{t2} Min(L(t);G(t))dt}{\int_{t1}^{t2} L(t)dt} \quad (4)$$

$$OEMe = \frac{\int_{t1}^{t2} Min(L(t);G(t))dt}{\int_{t1}^{t2} G(t)dt} \quad (5)$$

Where the *L(t)* is the electrical load power, *G(t)* is the generation power, *Ip(t)* is the electrical power imported from the electrical grid to the building, *Ep(t)* is the electrical power exported from the building to the electrical grid. Method 1 is calculated by subtracting the proportion of the electrical energy which is imported from or exported to the electrical grid, whereas Method 2 is calculated by finding the minimum value between the generation and the load, which is the matched part between the generation and the load. From the illustration in Figure 6, Area I is the portion imported from the electrical grid; Area II is the portion exported to the electrical grid; Area III is the matched portion between the generation and the load. "dt" is the time-resolution used in the recording or the simulation system. If the recording system for certain building(s) includes the channels for the total PV generation (cumulative measuring system), the power imported from the electrical grid (cumulative measuring system), and the power exported to the electrical grid (cumulative measuring system), Method 1 can be used, and the results of OEFe and OEMe from Method 1 will not be influenced by the time-resolution. However, if the recording system for certain building(s) only includes the channels of the total PV generation (cumulative measuring system) and the total electrical load power (cumulative measuring system), Method 2 can be used; however, the results of OEFe and OEMe by Method 2 will be influenced by the time-resolutions, due to the averaging effect by comparing the generation and load. Moreover, it should be mentioned that when $\int_{t1}^{t2} L(t)dt$ is equal to zero, OEFe in Equations (2) and (4) should be equal to one, whereas when $\int_{t1}^{t2} G(t)dt$ is equal to zero, OEMe in Equations (3) and (5) should be equal to one.

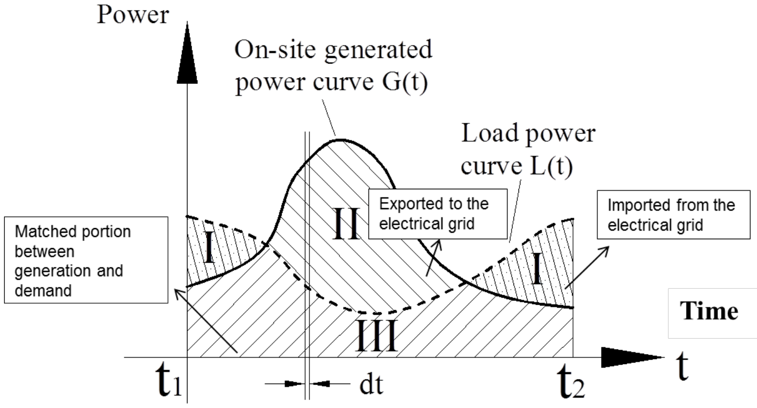

Figure 6: Illustration of the matching between the generation and the load

Figure 7 and Figure 8 show the hourly OEFe and hourly OEMe based on the calculation Method 1, and thus they are accurate values of the hourly OEFe and hourly OEMe referring to the real situation. As shown in Figure 7, the hourly OEFe shows a very clearly seasonal-dependent characteristic, with very frequent and high levels in the summer season due to the sufficient solar resource, whereas during the winter season, the hourly OEFe presents a generally low value with several peaks, mainly due to the higher electrical load during the winter season. This indicates that during the summer season, more onsite electrical load can be covered by the onsite PV generation, whereas during the winter season, most of the onsite electrical load cannot be covered by the onsite PV generation, i.e. it is covered by electricity imported from the electrical grid. On the other hand, as shown in Figure 8, the OEMe are in a reversed manner, with quite high magnitude during the winter season, indicating that the PV generation is sufficiently used in the building during the winter season. However, during the summer season, the OEMe is quite fluctuating, and reaches a minimum peak below 5%, which indicates a very poor summer self-utilization for the onsite PV generation, i.e. a large amount of PV generation is exported to the electrical grid.

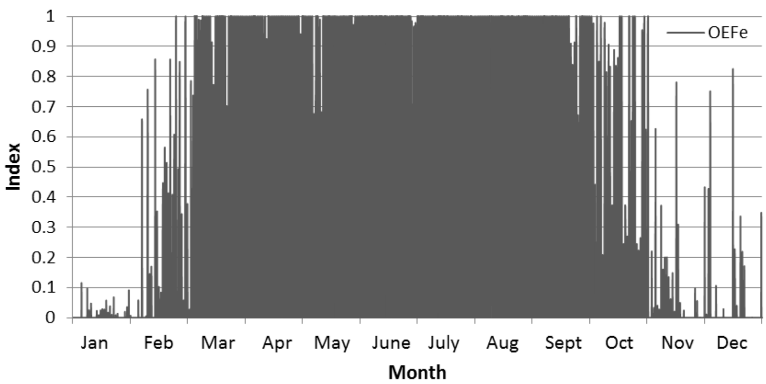

Figure 7: The hourly OEFe calculated with Equation (2) in Method 1

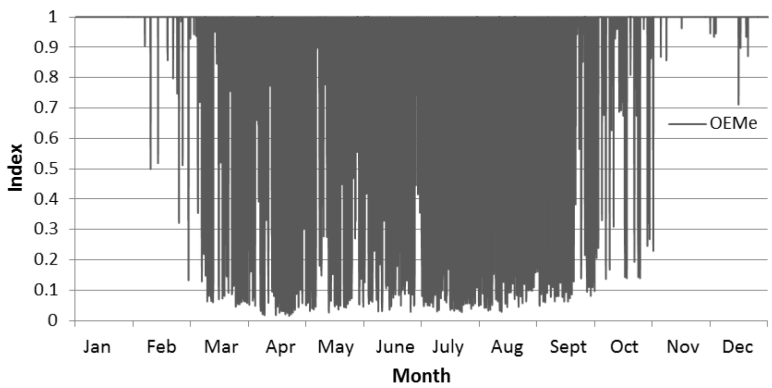

Figure 8: The hourly OEMe calculated with Equation (3) in Method 1

Table 2 presents the annual OEFe and annual OEMe with different calculation methods and time-resolutions. It can be found that with Method 1, the annual OEFe and OEMe are 15.8% and 22.1%, respectively, which indicates a quite poor matching capability. However, with the calculation Method 2, it is found that the results are overestimated by the coarser resolutions. Under the 1-hr resolution with Method 2, the annual OEFe and OEMe are 17.5% and 24.5%, respectively. Under the 1-day resolution with Method 2, the annual OEFe and OEMe are 38.6% and 54.0%, respectively. Under the 1-month resolution with Method 2, the annual OEFe and OEMe are 44.0% and 61.6%, respectively. Therefore, with a coarser resolution, due to the averaging effect by comparing the generation and load, the matching capability is overestimated. This kind of averaging error normally happens in the numerical simulations, when it is impossible to input a real high-resolution (such as 1-min or 1-s based resolution) weather, electrical device, generation, and load data [Cao and Sirén, 2014]. In simulations, normally a coarser resolution such as 1 hr is used. Another situation which will lead to the error in Method 2 is when the recording channels for certain buildings are limited to the total electrical generation (by cumulative measuring system) and total load data (by cumulative measuring system). Furthermore, it can be that Method 2 with 1-hr resolution is not quite deviated from the accurate results by Method 1. However, if the generation level is quite different from the existing system, the error can be quite different. We should conduct more research for different high-resolution generation and load patterns.

Table 2: The annual OEFe and annual OEMe based on different resolutions and calculation methods

Resolution / Indicator		*1 hour*	*1 day*	*1 month*
Annual OEFe	*Method 1*	*16%*	*16%*	*16%*
Annual OEMe	*Method 1*	*22%*	*22%*	*22%*
Annual OEFe	*Method 2*	*17%*	*39%*	*44%*
Annual OEMe	*Method 2*	*24%*	*54%*	*62%*

With Equation (6) [Salom et al. 2014], the normalized variable for the net exported energy $\overline{ne(t)}$ for the building can be calculated as

$$\overline{ne(t)} = \frac{Ep(t) - Ip(t)}{Edes} \qquad (6)$$

It represents the grid interactions of the zero-energy building. *Edes* is the designed capacity for the grid interactions, and *Ep(t)* and *Ip(t)* are the exported and imported power to/from the electrical grid, respectively. In this study, *Edes* is assumed to be 10 kW. Figure 9 presents the hourly normalized net export energy curve. It can be seen in the figure that during the summer season a significant amount of on-site generation is exported. The peak normalized net exported power can reach more than 60% of the designed capacity of grid interactions. However, during the winter season, the net exported energy shows a prevailing negative value due to the import of the electricity from the electrical grid. With Equations (7) and (8), we can define the peak power generation indicator and the peak power load indicator, which indicate the utilization ratio of the designed capacity for the grid connection by the peak generation and by the peak load, respectively:

$$\overline{G(t)} = \frac{Max(G(t))}{Edes} \qquad (7)$$

$$\overline{L(t)} = \frac{Max(L(t))}{Edes} \qquad (8)$$

According to the measured data, the peak power generation indicator is 73%, while the peak power load indicator is 50%. This means that the peak power generation can account for 73% of the designed capacity of the grid connection, whereas the peak load can account for 50% of the designed capacity of the grid connection.

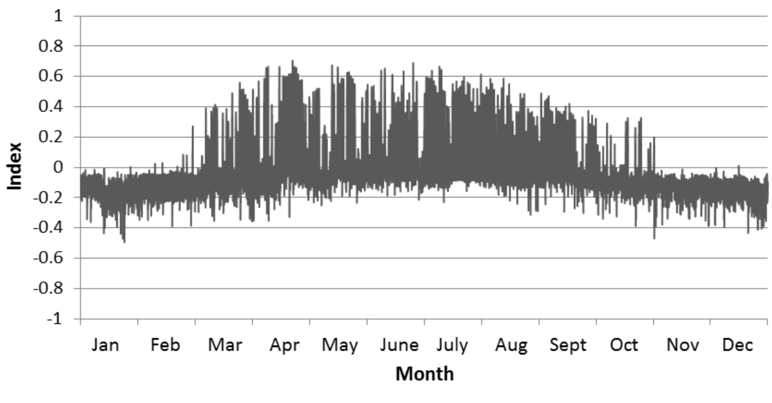

Figure 9: The normalized hourly net exported energy

4. Conclusions

Villa ISOVER® is a building conceived by ISOVER® and Fortum® to test the performance of a zero-energy building and its interaction with the electrical grid. It is a single-family zero-energy house built for the Housing Fair 2013. The building's energy systems have been metered, offering the opportunity to study the energy consumption and production in some detail. According to the measurement data, the annual net direct energy consumption of this building in

2014 is 15 kWh/m^{2}a, which is thus, strictly speaking, a nearly zero-energy building. Through the analysis of the measured data, a set of conclusions have been reached:

1. The PV generation shows quite significant seasonal dependent characteristics. The peak PV generation during the summer season is higher than 7 kW, whereas during the winter season the peak has a magnitude below 1 kW.
2. The electrical load is also dependent on the season, but shows a reversed behaviour: it peaks at around 5 kW during the winter season due to the frequent operation of the GSHP and AHU heating system, but it peaks at only around 3 kW during the summer season.
3. The contrasting behaviour between PV generation and electrical load leads to a quite poor annual OEFe at 16% and annual OEMe at 22%; these indicators are seasonal-dependant, as well.
4. Coarser time-resolutions may lead to overestimations of the matching capability depending on the measurement and calculation methods. In this case study, the matching results seem to be satisfactory with the hourly resolution but not with the daily and monthly resolutions.
5. The recorded imported and the exported power from/to the electrical grid show a seasonal-dependent characteristic, with higher export and lower import during the summer season compared to those during the winter season.
6. Under the assumption that the designed capacity of the grid is 10 kW, the normalized net-exported energy will peak at more than 60% in the summer season, whereas it has a negative peak below -40% in the winter season.

To summarize and conclude, it is not only meaningful to achieve the zero-energy balance during a pre-defined duration of time, but also to maximize the energy matching of the building's own generation with its demand and minimize its exerted impact on the grids.

Acknowledgements

This research is funded by the Academy of Finland Consortium Project "Advanced Energy Matching Analysis for Zero-Energy Buildings in Future Smart Hybrid Networks." Special thanks to ISOVER® and Fortum® for supplying the measured data and information about the building. The first author wishes to thank ISOVER® for sponsoring his participation in the CIB World Building Congress 2016.

Abstract

Sustainability has become a key issue in the construction industry. Currently most of decisions on awarding public building contracts are usually based on the lowest bid. The awarding authorities do not always consider quality indicators such as technical value, energy performance, environmental issues etc. Nonetheless, a holistic consideration of sustainability aspects in the tendering and awarding stage has not yet been implemented to a sufficient extent. This paper provides an overview of the current public procurement situation and emphasises the need for considering sustainability aspects within the range of selection and award criteria in the tendering procedure in order to improve the life cycle quality of building projects. Consequently requirements for the design of selection and awarding criteria are presented, with a particular focus on social, economic and environmental aspects. A part of their characteristics are based on comparability and applicability to existing building certification systems. With respect to legal boundaries, relevant frameworks will also be examined by outlining the options for the national implementation of the directive on public procurement (Directive 2014/24/EU), as proposed in the Austrian federal procurement law. However criteria are presented, regarding the technical requirements on the one hand and the relevant suitability of the bidders on the other hand. Based on a literature review on sustainable public procurement, this paper contributes to the question what kind of sustainable issues can be used and in what way to support the awarding of construction contracts, not only based on the lowest price. Therefore it is investigated, how awarding and selection criteria can influence the procurement decision. Furthermore in this context also the weighting of such criteria is important, that these aspects are contributing to a holistic approach in terms of an integrated project delivery. Overall, this paper should create a better understanding on how sustainability issues can be considered in the procurement process, whilst raising awareness for the need of an integrated project delivery. However this should help to improve the effective utilisation of production factors towards a life cycle orientated holistic approach.

Keywords: Sustainable Procurement, Selection & Awarding Criteria, Performance-based Approach, Integrated Project Delivery

1. Introduction

Fighting climate change is one of our main contemporary tasks. The United Nations stated 17 post 2015 sustainable development goals (United Nations, 2015) to adopt 'The 2030 Agenda for Sustainable Development'. Therefore goal number 7 affordable and clean energy, number 9 industry innovation and infrastructure along with goal number 11 sustainable cities and communities and the overall target of goal number 13 on climate action are further related to construction activities. Approximately 40 % of the global energy use is related to buildings as well as 50 % of the resource consumption is linked to construction activities (UNEP SBCI, 2003). Therefore the contribution of construction industry, to reach these sustainable development goals is very crucial. Considering these issues it becomes obvious, they can only be seen from a systems perspective, regarding all their interactions. Which means focusing on single aspects can help, but only to a limited extent. Consequently an overall integrated approach is needed to reach a sustainable development. Additionally this would benefit from synergies as well as cost savings and spillover effects. Based on integrated policies, the procurement process sets up legal boundaries for developing a construction project. Contributing towards a holistic life cycle orientated approach, key aspects of an integrated project delivery have to be focused and taken into account. In the following the procurement process and its influence towards a more performance-based approach, which is necessary to overcome current obstacles, is going to be considered.

2. Public Procurement

The procurement process influences the construction project in many different ways. Beyond its significance in terms of construction management and economics, the legal relevance of this key factors are equally important. Currently a strong focus is just on the economic aspects especially on the initial costs, neglecting follow up and utilisation expanses. Based on the market share of public procurement, this indicates a good starting point for implementing a paradigm change towards a more life cycle orientated approach. Moreover the procurement process influences both the quality of individual processes, the planning workflow and the overall quality of the project, as well as the number of construction process disruptions and thus the amount of additional costs claimed.

2.1 Policies and legal frameworks

Over the last few years several initiatives targeting the public responsibility have been published and comprehensive research was undertaken to improve procurement performance. Based on European and national initiatives, there are policies proposed to focus on additional aspects during the tendering procedure. One of the main commitments has been stated within in the white paper on public procurement in the EU and COM 96 (583) final and COM 98 (143) final. This was continued by the COM(2001) 274 with a focus on *"Commission interpretative communication on the Community law applicable to public procurement and the possibilities for integrating environmental considerations into public procurement"*. This resulted in the

European directive 2004/18/EC supporting the awarding of contracts based on the most economically advantageous tender.

Based on the goals of a sustainable development this shows the need to set up criteria to support the decision-making process focusing on a life cycle performance. Therefore in a first step the European directive 2014/24/EU enables tendering decisions based on a more life cycle orientated perspective.

2.2 Green and sustainable public procurement

In the past few years, strategies are designed supporting a sustainable development on international and national level. In this context, green public procurement (GPP) indicates the attempts of public authorities to procure goods services and works e.g. buildings with reduced environmental impacts over their life cycle. Therefore the work of the CEN/TC 350 on sustainability of construction works delivers a set of indicators, to assess environmental impacts of buildings cf. EN 15978. However GPP mainly focuses just on environmental aspects of products and services, whereas sustainable public procurement widens up the focus targeting all three pillars of sustainable development (ecological, economical and social issues).

Targeting a holistic approach, these aspects need to be considered in the tendering procedure, therefore criteria are needed to be defined taking into account these goals applied and linked to the particular building project. To enable a proper decision-making process, their objectives need to be defined at the beginning of the procurement process. Consequently they need to be stated clearly in the call for tenders especially how they are going to be assessed during the evaluation of tenders and also their weighting needs to be determined, to guarantee a transparent tendering procedure and therefore supporting an integrated project delivery.

3. Methodology

Based on the investigation of the current state on public procurement, requirements towards more sustainable procurement decisions are assessed. Therefore the basis of this contribution is an on-going research project dealing with the following selected research questions (RQ):

- RQ1: How can sustainability be considered in the procurement of construction works?
- RQ2: Which aspects can be used, to define such criteria?
- RQ3: What are the requirements for such criteria?

In order to consider the requirements for sustainability aspects, which can be used in the procurement of construction works, it is necessary to make a structural analysis of current approaches. Based on a comprehensive literature review (Wall and Hofstadler, 2016) the recent strategies and developments over the last few years in green and sustainable procurement have been assessed. Following a holistic approach, considering environmental, social and economic aspects of sustainability a set of indicators in terms of a multi criteria analysis is needed (Zavadska and Antucheviciene, 2006). Hence a key component of analysing the procurement system is examining the perspectives and approaches of multiple stakeholders of construction projects, to identify on which information and what criteria their decision-making process is based on. Following the hermeneutic circle, the findings of these investigations are reworked and therefore procurement stages as well as tender elements are analysed based on legal frameworks to identify possibilities towards a more performance-based approach. The requirements presented in the current contribution are the basis for an expert survey to gain empirical data for future needs and designs of such criteria.

4. Current situation of public procurement

Construction industry is characterized through highly competitive markets. Furthermore mainly the initial costs are taken into account for awarding the tenders. As a result service and quality is suffering as companies are forced to cut costs in order to survive these harsh conditions. To challenge these circumstances public procurement therefore has to make use of its crucial influence based on the market share and promoting a life-cycle-orientated and sustainable development. Using the 'most economically advantageous' tender could be helpful, for considering additional criteria, which are focusing more on a holistic approach. As illustrated in fig.1 there are several requirements on sustainable construction, which can be linked to the rise of building certification schemes (e.g. BREEAM, DGNB, LEED) on the left side and on the right side to normative requirements especially for the building products.

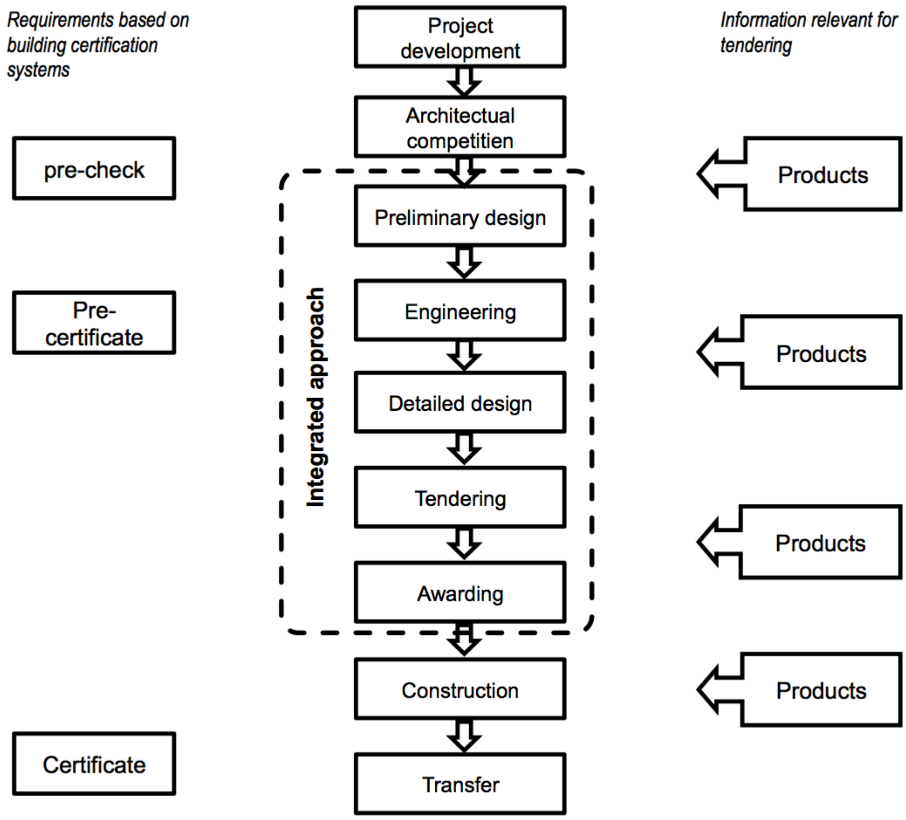

Figure 1: Construction project stages with requirements based on building certification systems and product-based information regarding the procurement and tendering decision cf. Wall 2016

Over the last few years, in terms of sustainable construction targets building certification systems are seen as a suited tool to consider these aspects in a measurable way. Otherwise more information on the environmental aspects and properties of building products are available. Various databases (e.g. baubook in Austria or WECOBIS and ökobaudat in Germany) are providing information on environmental impacts of different construction products and building components. Based on the methodology of life cycle assessment according to EN ISO 14040 et seq. their ecological performance can be determined. This information can be communicated with the help of environmental product declarations (EPDs), representing a suitable format to notify ecological aspects of products and building components in a standardized way. They can support decision-making in early planning stages. Nonetheless different building concepts can be compared in terms of their environmental aspects. Following their standardized information, they can also be used in the procurement process to indicate the consideration of sustainability aspects and can be seen as a good method for verification and quality management during the construction phase. Another important issue is the weighting of additional quality aspects to base the tendering decision on. A case study in Finland, Sweden and Denmark (Parikka-Alhola et al, 2006) investigated a range from 5-20 % for the quantification of additional aspects in the tendering procedure. Based on the chosen weighting it is not always obvious, if they can influence the final awarding decision.

One of the main problems of construction contracts is, that they are related to different spheres, legal boundaries and are influencing construction management and information flows. In fig.1 the sequential workflow is indicated by the single project stages. Targeting a life cycle orientated approach, all these conditions need to be evaluated and properly assessed to describe a construction contract.

Overall, decision support is demanded, in terms of organized efforts to produce, disseminate and facilitate the use of data and information to improve tendering decisions towards a life cycle consideration. This leads to the recognition, that decision processes are at least as important as decision themself on which the tender is going to be based on. To improve the decision-making process towards a holistic approach, a research focus is on how awarding decisions are made and what affects them. Therefore policy makers need insight on how current barriers (like quality of project development, organisational obstacles) can be removed through common-sense steps such as simplifying communications and making choices more clear. The challenge is to create awareness by stakeholders in different areas (environmental management and policy decision-making). In this context besides the ecological issues especially the processes in the design and engineering stage need to be considered more comprehensively. The interactions on product level and the overall performance of buildings are strongly influenced by planning processes. A life cycle optimized building can only be achieved through integrated planning processes providing the basis for a successful combination of the production factors. Focusing on such an approach, the question rises how can a sustainable performance be defined and considered during the procurement and tendering stage. How can such issues be measured and controlled? How and to what extend can they be implemented into the procurement stage? Especially if focusing on performance-based aspects, which are highly related to individual experiences and knowledge. How can such information be taken into account to base the tendering decision on?

Therefore requirements towards a more performance-based approach are presented in the following chapter, which can be seen as possible key performance indicators influencing the procurement process among the life cycle of a building.

5. Requirements towards a performance-based approach

Integrated project delivery is used, to identify the most suitable solution for a problem also considering its life cycle performance. Following this approach a more holistic thinking is triggered in construction industry. The overall aim is to enable and support competition based on sustainable innovations. In this context the procurement process is identified as a very crucial stage in the overall project delivery, because the influence at this stage is suited best, to implement a more life cycle based focus, which needs to be based on quality of related processes. Process quality is defined through the planning and construction processes as well as preparing the commissioning of buildings. Thus performance and quality of the building is significantly influenced at the early project stages. Consequently a more integrated and cooperative model is used to focus on the life cycle quality and responsibility aiming at the project development (AIA 2007).

Therefore a strong focus is not only on product level, especially the process level is addressed. Assessing the life cycle of products as well as completed buildings, their quality is acknowledged but the processes, which have been necessary to achieve such a performance, are often neglected and ignored. However they are contributing towards a more systematic decision-making process, which leads to a better overall project performance. Therefore especially the related planning and project management processes need to be targeted.

Supporting a quality-based (architectural) competition helps to promote innovative solutions and a more life-cycle-orientated project development already in early planning stages. The common project workflow is chronologically and sequentially structured, each task is processed, after the previous one is finished. This leads to a strict planning and working schedule. But in times of increasing complexity of building structures as well as the demand for advanced integrated building systems, each of the stages are linked together, based on contemporary requirements of planning and implementing such systems. For a comprehensive planning and processing of these tasks integrated information is needed. Consequently a more integral project workflow including all participants and involved stakeholders towards a holistic optimization of the project is targeted. Especially the process-related aspects need to be emphasized and should already be considered at the procurement stage of construction projects.

A performance-based procurement can only be achieved if the chosen issues for tendering can be planned, defined measured and justified to comparable for the evaluation of the different tenders. Therefore criteria are needed serving as indicators, index numbers and measureable values. Key figures can provide information based on facts. Indicators are describing qualitative and quantitative relationships, which cannot be measured directly. For measuring process quality indicators need to be identified in accordance to the particular project stages and tasks. In the following fig. 2 several aspects towards a performance-based procurement are listed.

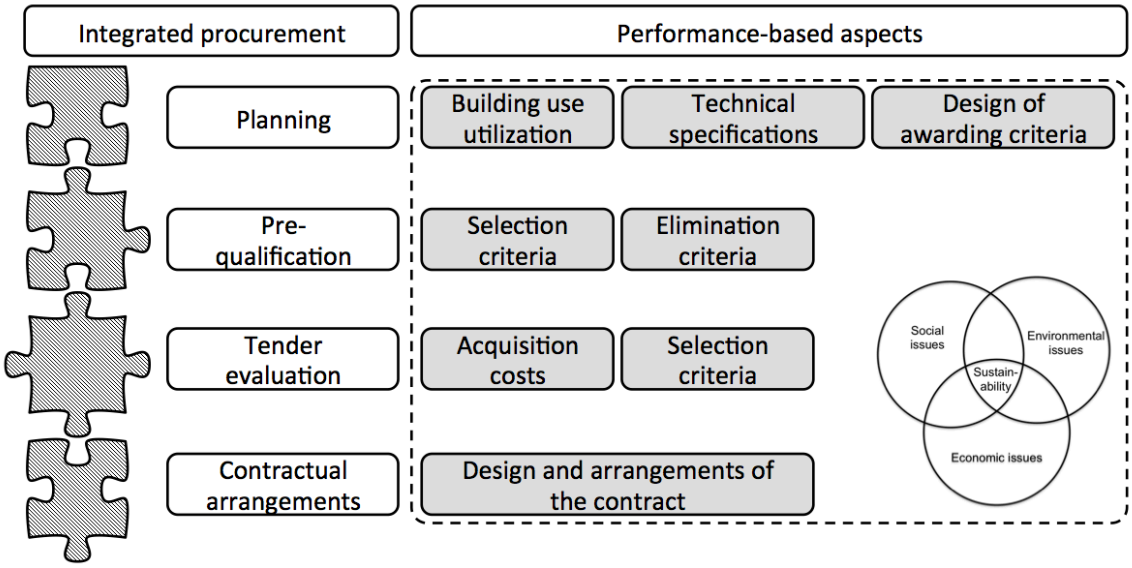

Figure 2: Aspects of an integrated procurement following KfW (2014)

Quality and qualification of the contractors is highly relevant for an integrated project delivery process and therefore needs to be examined. Their suitability and handling by project managers show a significant contribution towards a successful project realisation as mentioned by Hwang and Ng (2013). This correlation has also been stated by the Austrian court of audit in its statement on public financial control cf. ACA (2006). Additionally the ECJ confirmed in Case C-601/13 Ambisig 03/26/2015, using a criterion which takes into consideration the composition of the team, the experience, the academic and professional background of the employees, for enabling an evaluation of teams especially for the performance of the contract.

Another aspect seems to be the corporate philosophy of the contractor, related to the organizational issues of the project team, in terms of their company culture and how projects are realised. These aspects are very crucial for an integrated project development because it leads to the communication culture and information sharing among project participants for creating a cooperative climate between clients and contractors. This underlines quality standards and performance-based aspects of project management and project delivery. Internal project structures and organizational behaviour towards clients and subcontractors are highlighted based on the principles of the corporate philosophy of the enterprise (IG Lebenszyklus, 2015). This includes employment relationship, staffing schedule, and a proactive and solution-orientated working approach on the building project. In this context also the internal personal contribution can be seen as a crucial aspect towards a high quality performance on the construction site. This is discussed at the moment in Austria with the ‘fair procurement initiative’ focusing on the quality and qualification of employees influencing the later project performance. Performance-based tendering decision can therefore include expert interviews with key persons discussing their problem solving capacities and to assess their qualification and applicability for the project specific requirements.

Quality management and documentation during the construction period leads to an evidence-based knowledge management system, which considers all the information flows from the beginning of the planning stages to the construction stages, generating information to improve the commissioning phase of the building with its building technologies as a basis for monitoring activities and facility management tasks later on (influencing the total sustainable performance of a building). In this context lean thinking can be applied. This means information on what to do, when, in what quality and based on which conditions to guarantee optimal information flow as well as operational management. This can be used as part of selection criteria on prequalification see fig. 2.

Suitable criteria are used to specify the quality of the contractor to perform a specific task and how to handle a certain project. Therefore the technical competences can be targeted, which means professional entitlement but also financial and economic performance criteria that are linked to the specific project and/or construction works. For an easier verification of such issues, there are platforms (e.g. ANKÖ, PQ-VOB) providing information on performance records of contractors.

Finally the weighting is a very crucial point, because in the call for tenders the importance of such selection and awarding criteria has to be announced, that there are no spurious aspects, which are not that relevant for the final tendering decision. The awarding should be based on the technical and economically advantageous tender. Therefore usually a jury is necessary to support the awarding process. Especially if judging functional construction concepts on behalf of safety and environmental performance aspects. The awarding committee can assess intended workflow processes and problem-solving skills of the involved key persons with standardised interviews. Therefore the jury members should be involved right from the beginning on to define specific criteria in the call for tender and providing a consistent consideration of these issues and their weighting factors through tendering and awarding. This is stated e.g. by the Austrian National Committee of ITA (2014) on suggesting a procurement model for infrastructure projects. Following these suggestions the composition of the committee is crucial to gather experts from all the different backgrounds, related to the type and special requirements of the particular project. It is crucial for a successful project delivery to concentrate their competences and background knowledge considering all the clients and users requirements.

6. Discussion

Facing climate change public procurement is seen as a suitable tool to apply innovation policy. In this context current backward thinking in terms of focusing just on the initial costs combined with organisational obstacles need to be changed. A special focus is on the type of contract, showing a higher likeliness for design-built contracts considering green innovations cf. Monahan et al (2014). Currently there are still several barriers to sustainable public procurement. In their studies Uyarra et al (2014) reported a lack of interaction of procuring organisations and low competences of procurers resulting in difficulties in negotiating risk management issues due to the higher requirements of the building projects. Considering life cycle aspects, the procuring organisation has to be aware about their future needs and usage requirements. The determination of needs is often barley conducted, accompanied by insufficient understanding creating barriers to innovative sustainable solutions. If the procurer does not know what he is looking for it's not easy to set up functional specification and awarding criteria to evaluate the tenders for the most innovative (best suited) solutions. Despite numerous political statements and commitments towards sustainable construction, the state of the art in awarding public building contracts is mainly related to the lowest price. In the end only the building qualities are considered and visible, the processes, which have been necessary to undertake, are not seen anymore. Unfortunately they have a crucial impact on the success of the project. Therefore the goal is to identify the key-processes, which are needed to achieve a high performance building. Towards a more life cycle orientated consideration of buildings, a holistic approach is needed and has to be integrated and interdisciplinary designed. A crucial aspect in this context relays on the early project development stages that are of fundamental importance towards the final building performance. The current situation is more linked to single normative solutions, which are recognized more unsatisfying as also mentioned in the final report on major building projects (BMVI, 2015). Therefore a cultural chance is suggested, towards more cooperative project workflow characterised with comprehensive information exchange to focus on the project details and contents. This could help to overcome incomplete information and fragmented knowledge management. Towards a life cycle orientated building process, these information need to be considered during the procurement process. Overcoming the sequential process workflow, consequently a more performance-orientated approach is suggested like Uttam et al. (2014). Based on the literature review (Wall and Hofstadler 2016) a lack of interaction within the procuring organizations and the contractors has been identified, which causes different understanding and a reduced and disrupted information flow. To overcome these obstacles fundamental elements for enabling cooperative procurement have to be promoted. In fig. 3 the requirements towards a more performance-orientated approach are illustrated following Owen et al. (2010).

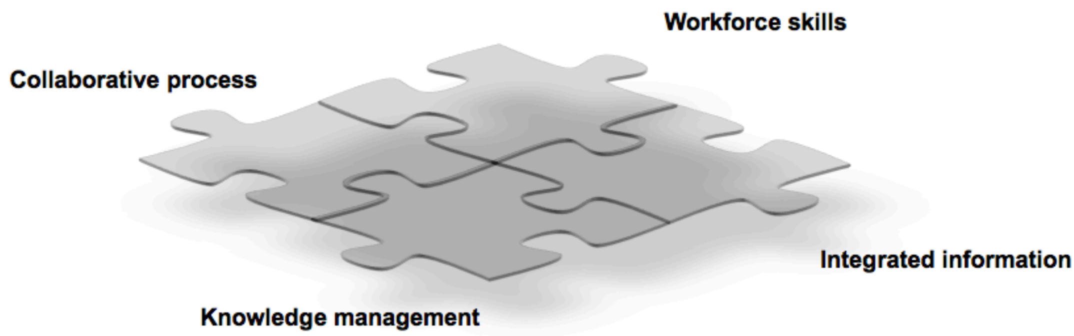

Figure 3: Requirements towards a more performance-orientated approach

Collaborative processes, workforce skills integrated information and knowledge management are the requirements to overcome silo mentalities combined with cultural prevail and document-based information exchange. Bresnen and Marshall (2000) stated the importance of partnering for improving construction performance directly, by promoting stronger client and contractor interaction. To reach these conditions, organisational and cultural change is necessary, especially in context of implementing sustainability aspects and focusing on the life cycle of a building. Incorporating environmental, economical and socio-functional issues into project delivery, this will help to consider a more comprehensive life cycle perspective, and enabling newer greener technologies and fostering innovative developments, this approach is supported by Hwang and Ng (2013). In their work they investigated the contribution of project managers to green construction projects, they stated the need for knowledge and skills to deal with the increased requirements of sustainable building projects. Eriksson and Westerberg (2011) proposed a holistic procurement framework, dealing with a broad range of factors related to procurement and showed, that relationships among clients and contractors are influencing project performance (e.g. trust and commitment among project partners). Similar approaches are introduced e.g. by IG Lebenszyklus (2015), setting up requirements towards a cooperative project culture pushing a performance-based approach providing optimal project conditions for an integrated project delivery. Evidence is provided by taking care of the clients' definition of requirements, stetting a focus on project management and project workflow. Additionally keeping in mind legal and financial boundaries to deal with these issues in terms of risk management.

Currently there are several initiatives focusing more on changing the procurement model towards the most economically advantageous tender. They are targeting the project itself and with the help of a performance-orientated procurement a holistic life cycle optimization can be achieved, because the interdisciplinary organizational structures are more and more important. This demands a more cooperative project delivery, which cannot be reached with common sequential waterfall approaches.

Focusing on the implementation of such a performance-based approach, it can be linked to future developments of procurement models like cooperative procurement and competitive dialog procedure. Therefore legal requirements are important focusing on the type of procurement and the chosen framework (e.g. project is awarded on a lump-sum basis or as a total). However the legal procurement framework conditions need to be considered. This highlights equal and uniform treatment of all bidders and a transparent awarding decision, which is based on expert knowledge. Therefore the used criteria have to be defined, measureable and assessable regarding to various sustainable aspects of building performances.

7. Conclusions

This contribution underlines the need for a cooperative procurement approach to achieve the goals of a sustainable development in the construction sector. Answering the research questions stated at the beginning, RQ1 a consideration of the whole life cycle of a building or construction project can only be realised with the help of integrated design and delivery solutions. Therefore life cycle orientated issues have to be used for formulating criteria, which can be used for a performance-based cooperative tendering procedure. They can be divided into selection and prequalification criteria to support these processes (RQ2). The requirements for such criteria (RQ3) are based on the building utilisation, technical specifications, also economical performance issues and the overall organisational structures, which are linked to the contract. This procedure is all about information management, contents and knowledge need to be processed, transferred and communicated among the involved stakeholders. Consequently tools like building information modeling can support these ambitions and providing a platform for exchange and a basic ideal surrounding for improved workflows to reach the goals of an integrated design and project delivery.

8. Acknowledgements

The current contribution is part of an on-going research project aimed at implementation of sustainability aspects in construction project management and is funded by the "ZUKUNFTSFONDS" of the provincial government of Styria.

Built environment and its parts: towards an integrated study of the construction as a system using an evolving technological knowledge

Abstract

To consider the built environment as a single system is in contrast with the tendency towards specialization and analysis. Multiple changes are now taking place simultaneously in the planning process, the construction techniques, the organization of a building site, the production of materials and the technical information. All this is driven by a progressive specialization of knowledge and an increasingly important role of data and tools coming from different scientific apparatus. The richness of building methods is always evolving to meet very different requirements in extremely varied conditions and environments. This, however, makes the understanding of the construction and the environment as a 'system' difficult and, consequently, all of the various elements that must contribute to forming the system. All this is in a scenario dominated by "Big Data" and computerized processing of information that seem to make natural language completely inappropriate to the task. In this situation and in our role as professors involved in the training of future professionals, we are committed to defining a method for dealing with the processing of information relating to construction within a system that permits operating at the level of analytical details without losing the connection to the system in general.

The study presented here is based on the use of cognitive maps to represent the parts as a general whole of the construction as a system, through a coded breakdown of sentences that convey information. Considering the need to maintain all the usual forms that architects use in their design work, as well as relying on known and familiar examples of constructions, we link basic elementary concepts to the most widespread architectural journalism. Essentially, examples of solutions which refer to parts of the construction system empower designers to grasp the essential function of the parts to reach a complete and organic understanding of them in relation to the system itself. Starting from the five main themes that compose the construction system (ground anchoring, structure, enclosure, roofing and systems), we synthesized in a few booklets the basic information necessary for an architect to understand the construction and its parts as a 'system'.

Keywords: construction system, innovation, knowledge, concept map, information

1. Introduction: transforming information while maintaining the usual forms as much as possible

To study the construction as a system, it is not enough to know the various elements that compose it; obviously, it is equally important to know their connections, otherwise the operation of the system is not comprehensible. Today, however, technological knowledge usually relies on publications illustrating long list of different types of building elements, distinguished, for example, by materials, forms or dimensions (i.e.: Di Chiara, 1990,Zaffagnini, 1992). Even, the most recent overviews of the architectural elements, such as the one presented at the Venice Biennal exhibition in 2014, ignored their organization as a system (Koolhaas, 2014).

Construction as a system is considered mainly when management and engineering problems, such as automation, are faced. It happens only when new building systems are introduced, but it almost never happens when we are dealing with traditional techniques (Van de Sompel, 2004). Objectively, we cannot deny that a great difficulty exists to entail general aspects when it’s necessary to deepen the analysis and study of details.

For this reason, reminding that technological knowledge transmission has always been basically visual (i.e., Encyclopédie by Diderot and d’Alembert), in this study, we tried to find out graphic forms of its presentation according to its systemic nature. Therefore, we found out a corresponding form to those purposes in the methods proposed by Novak and Gowin (1984). Conceptual maps allow a visualization of knowledge in which it’s possible to go deep without loosing sight of the system essence as a whole (Figure 1).

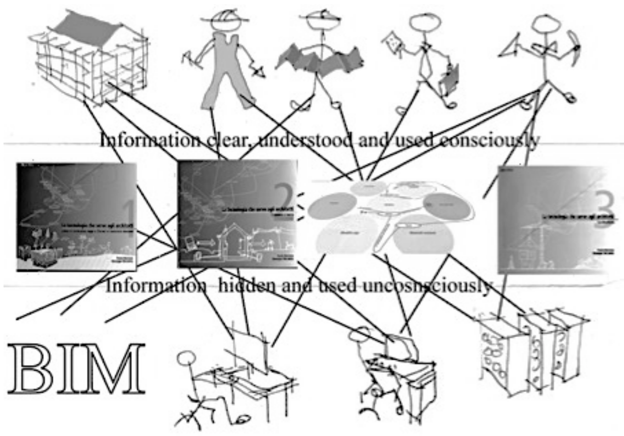

Figure 1: Fundamental strategy: connecting all elements

We applied that method taking care that the graphic forms were similar to those commonly used by the professionals of the sector.

The research presented here deals with a new way of communicating technological knowledge; through a series of steps, the study demonstrates how we succeeded in maintaining traditional forms.

In order for this communication to be made easy to understand, we have tried to maintain a form very similar to that which characterizes traditional communications, i.e. the forms of representation and content commonly used in the industry.

To understand both the theoretical principles that have guided the research and the underlying structure of the presentation of technological knowledge in a new form, it is useful to follow the studied transformation process.

2. Transformation process

2.1 Completing the transmitted information

The traditional form of communication used by industry professionals when attempting to transmit information on the building system prefers to present the study of details to present the parts which make up the represented element.

This description is generally incomplete because it only describes the part or parts, while ignoring the reasons underlying that choice, or at least not defining the way in which the represented element was or is planned to be made (Figure 2).

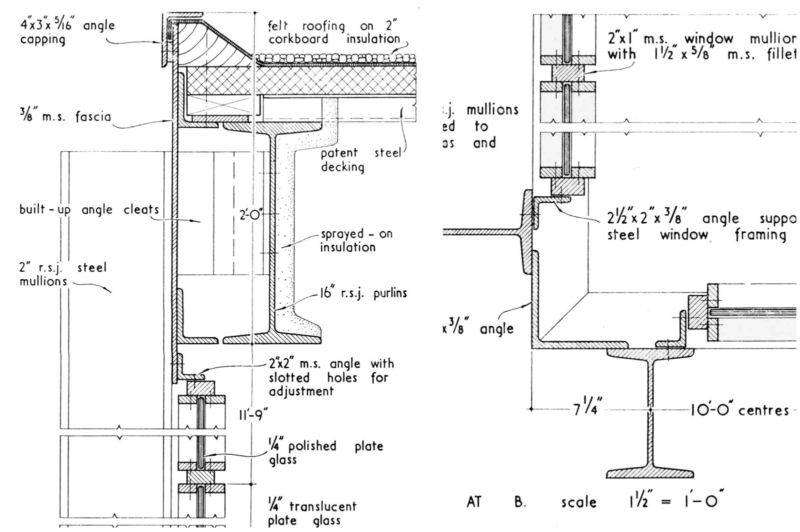

Figure 2: Details and traditional captions

For this reason, a first improvement on the 'traditional' type of communication may be achieved by introducing information concerning not only 'what' is being talked about, but also 'why' it is there and 'how' one intends to make it or has made it.

We studied this transformation of information in a way intended to maintain as much as possible the characteristics of understandability of the traditional forms of communicating technological information to make them more comprehensive and organized.

2.2 Linking the information contained in the traditional forms of communication with the unified classifications

The study of technologies entrusted to the presentation of particular examples of buildings or specific projects is inevitably very partial. Only in specialized books, albeit theoretical, can one trace the different technological solutions for the building elements of the architecture.

To obtain the same result, no longer with a theoretical presentation but through the study of a series of examples, the descriptions must be given such as to make it possible to compare alternative solutions presented in other examples, framing particular problems within more general ones.

This is possible if, in the analysis of the example, a direct reference is made to some order of classification of the different solutions (Figure 3).

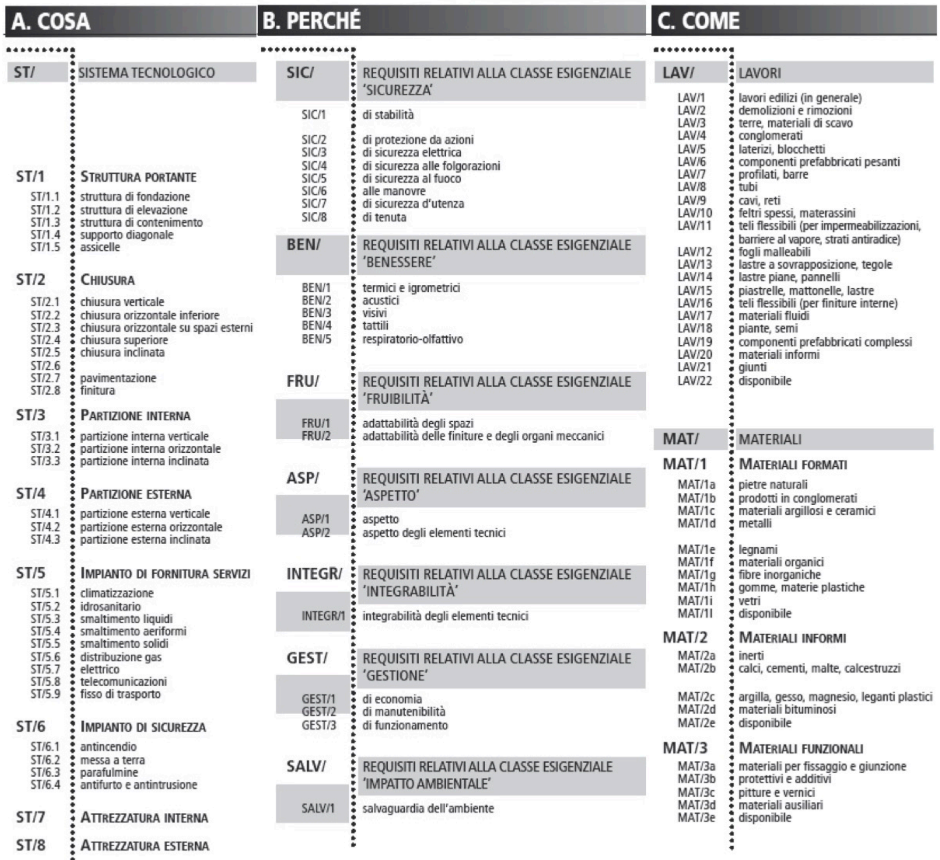

Figure 3: The classification system, 'what', 'why' and 'how'

There are institutions and bodies for standardizing which produce coded classifications, grouping the possible construction choices that exist for each element. They also encode the requirements the elements must satisfy, and every possible processing type that may be used for executing the various building forms that the elements themselves can assume.

These classifications have been used in the descriptions/captions that we have produced to define the items that refer to 'what', 'why' and 'how'. The technological information contained in the description was thus coded and formally linked to unified systems of classification well known to designers.

2.3 Identifying the constructive alternatives by ordering examples according to unified classifications

By assigning each element of the example to the classifications and then scrolling through these, one can find similar solutions in the same class and constructive alternatives in other classes. The finding of an example in a given class means it is possible to use it in the various examples given.

Figure 4 shows the table highlighting the location of the examples in the classification of 'how'. There is a similar organization in the other two fundamental classifications.

It is thus possible to use these tables as indexes when searching for examples with particular characteristics (Van de Sompel, 2004).

Figure 4: The alternatives in 'how'

2.4 Identifying the construction problem faced by the detail analyzed.

In the ‘construction’ system, the study of a construction detail is useful for understanding the reasons for the solution in light of the problem addressed. The problem, which in general can be summarized in an intuitive form, is useful for starting the return from the particular to the general, which is necessary in order not to lose sight of the unity of the ‘construction’ system (Figure 5).

If the examples are chosen with the aim of addressing, in a certain order, the constructional problems to be studied, it is possible to present a topic using the form of rhetorical question and answer.

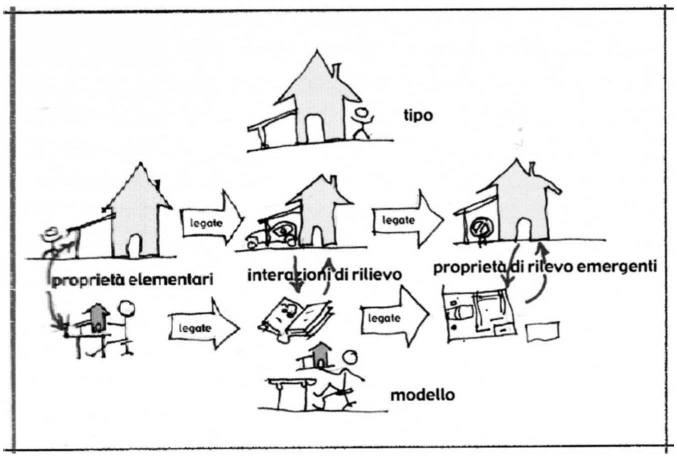

Figure 5: A synthesis process of a constructive problem

The rhetorical question and the related answer is ‘constructed’ and positioned on a concept map.

2.5 Constructing a discourse on the topic

Without disturbing the ‘systems theory’ by Ludwig von Bertalannfy, and sharing that technology as a subject is presented, for the main part, graphically, our contribution concerned the visualization of the construction system using maps.

All the problems detected in the various examples can thus build a discourse on the theme that frames the element studied in the construction system. The form given to this work comes from the application of J.D. Novak and D.B. Gowin (1984) applied pedagogical studies described in their famous work “Learning how to Learn”.

This approach led to the organization of a general and articulated explanation regarding a construction element starting with a crucial question containing some concepts, followed by a series of rhetorical questions that contained other concepts explained by the subsequent relative answer (Figure 6).

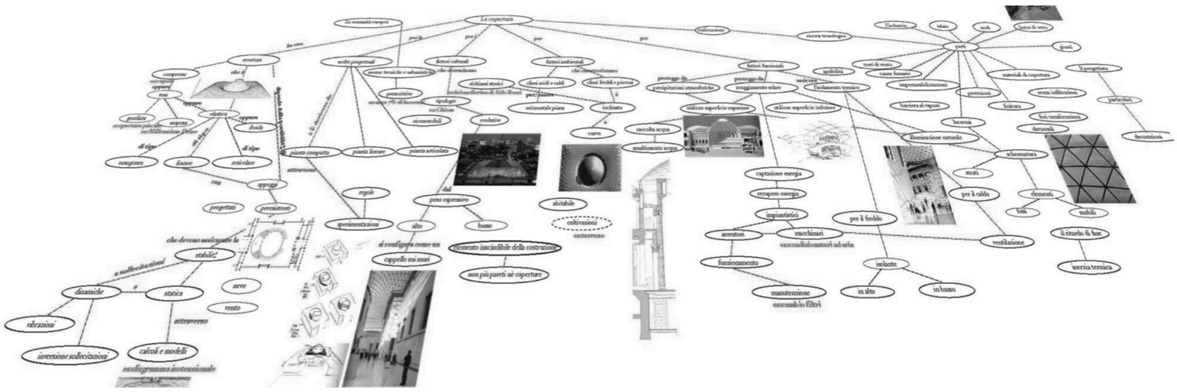

Figure 6: Map with concepts grouped into sets

Such a form of communication, or form of explanation, concentrates the key objects of the discourse in the concepts covered. However, by reporting the various concepts in a concept map, one runs the risk of having a confused form. To avoid this, the concepts have been grouped into sets.

2.6 Linking the description of the detail with the construction from which it was taken

Every good professional knows that, in addition to the reasons for the particularities of a detail presented, there are also reasons that allow one to arrive at a full analysis of the project. For this reason, it is interesting to describe the project in its entirety.

If the construction system is useful for understanding construction problems, the architecture system can be especially useful for helping people to understand the design choices made. Therefore, we determined it was equally essential to recall a brief description of the architectural design (Figure 7).

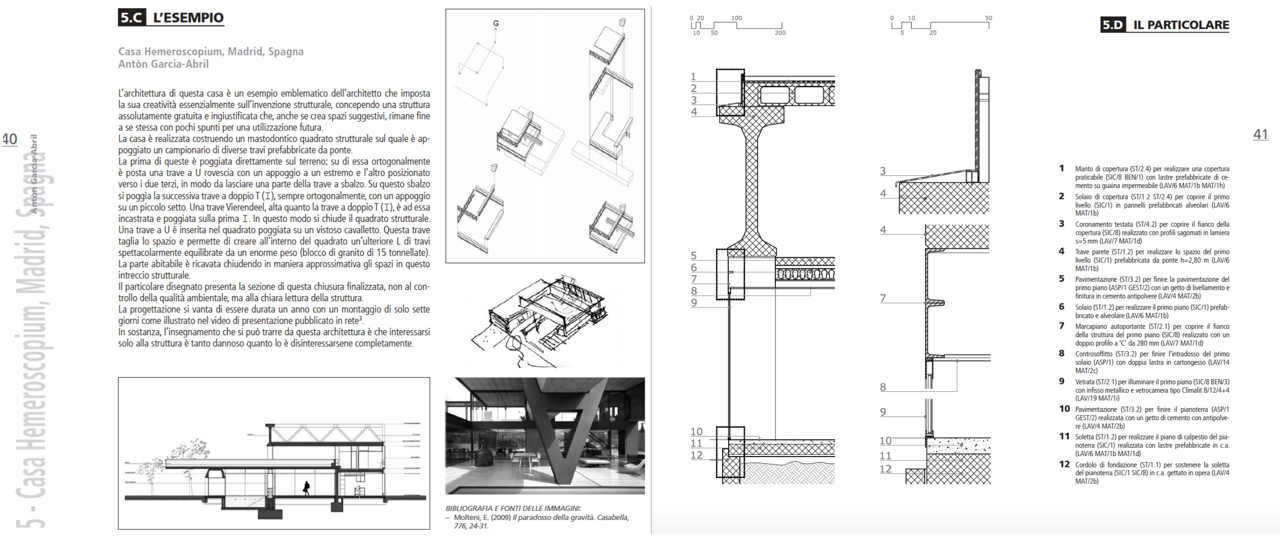

Figure 7: Description example

We believe this is the moment when one can address the essential reasons that led to the design of that particular element. In essence, through the design one can explain the detail.

2.7 Linking the detail in the construction with other similar details

As the detail is born of a designer's choice from among the many that he/she could have made, reference to such alternatives delves into the issue of the element in the study of the detail. To do this, the caption of the individual items of the elements studied is organized according to the system of unified classifications adopted. The link to the classifications allow one to conceptualize the problems and construct a clarifying rationale about them. At the same time, given that this conceptualization is closely linked to a well-defined example, one does not run the risk of making a crippling theoretical discourse.

2.8 Achieving a close connection between the elements of the construction system

In constructing discourses on different themes, sets appear that are part of several theme domains. For example, the concepts defined in the discourse on the 'structure' may also be present in the study of other elements (e.g. envelope or roofing). The concepts that recur in several elements thus constitute such links. Indeed, it is then possible to construct a multi-dimensional concept map defined by identical sets belonging to multiple themes, because a set that is a circle in a two-dimensional representation, it is a sphere in a three-dimensional one (Figure 8).

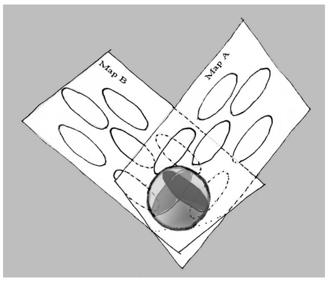

Figure 8: The set is a circle in a 2-dimensional representation, a sphere in a 3-dimensional one

This graphical representation, which is possible with new computer equipment, is impossible on paper. Also, the representation of the concept map, very clear with the new computer equipment, looks very complicated in paper form.

2.9 Connecting with traditional architectural journalism

The writings that are produced following this systematization of information are, for obvious reasons, greatly reduced. The information on choices of technologies is rather concise and one feels, therefore, the need to return to traditional forms of communication.

It was decided, therefore, to give each identified concept a reference bibliography where the reader can find a description of the same concept in a more extensive form.

This communicative aspect is in no way secondary to the discourse made; rather it is a key element in any in-depth analysis because, as Diderot remarked, the bibliography allows a panoramic vision of the concept discussed.

3. Application of the method

It seemed possible to concentrate the whole discourse on the building as a system in five papers published in as many booklets. It is evident that it would have been easier to make a more detailed breakdown of the themes discussed; however, wanting to show that it was possible to concentrate technological knowledge to the maximum, we employed a reduced breakdown.

The five themes identified are: ground anchoring, structure, envelope, roofing and floor plans, systems and secondary internal elements.

3.1 How content in publications are presented

The discourse on construction elements thus identified occurs through examples chosen to represent the various forms with which the elements themselves are materialized in architecture.

All the booklets contain a number of examples, i.e. constructions presented according to the form described. The concepts identified in the discussion of the example constitute the core of the general discourse presented in the concept map. Each example is shown in four pages in which one finds all the contents and information as described above (Figure 9).

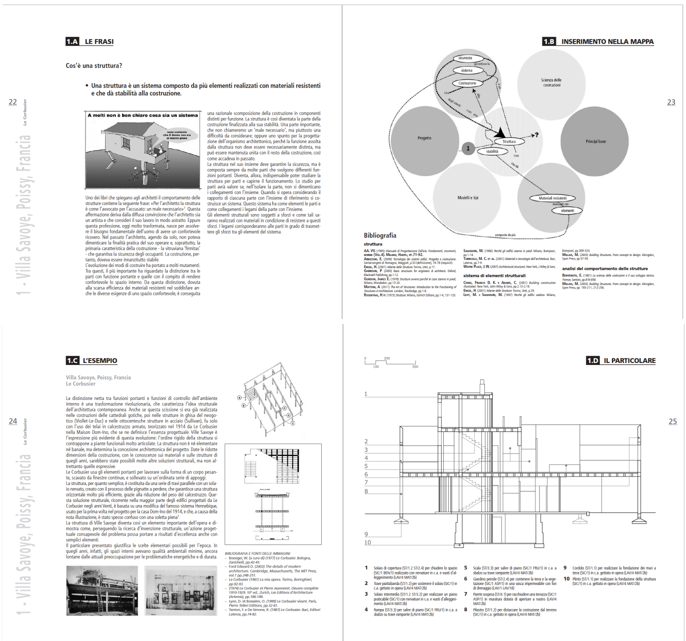

Figure 9: Contents of the four pages and reports

In this representation, the essence of our work is concentrated in an innovative form. With this graph we wanted to highlight the series of connections that exist between the information which, being presented in the traditional form, do not generally highlight the references that are indispensable for communicating the technological knowledge in a comprehensive way so that the system-construction engages with the system-architecture.

4. The construction as a set of forms materializing in the architecture

Underlying this discourse are examples that exemplify the choices used to represent the various forms in which the construction elements in the architecture materialize. Even if one adopts the concept maps, one should not lose sight of the fact that the information is not aimed only at knowledge, but rather is also a handy tool for an applied use. Basically, what we have proposed is essentially a refinement of the design procedures based on reasoning on the cases (CBR- Case Based Reasoning).

5. Discussion

Having wanted to maintain a very tight link between the proposed method and information commonly used by designers leads to our main intention which is a complete revolution of the communicative form. One can note that despite the current massive introduction of computer graphics, the journalistic style used by designers has not changed: what is usually presented is simply an adaptation or a reduction of the computer processing according to the traditional forms of the drawings, perspectives and false photographs, leaving everything unchanged.

What we are proposing, even if we consider only the organization of the captions of the drawings, is definitely a step towards more accurate communication. In publications today, one can see, in the captions of drawings, of the same element one is presented as "*flashing*", another as "*completion of waterproofing*" and yet another as "*aluminum profiles*". It would have been clearer, however, to write a caption organized thusly: "*Flashing (what) for completing the waterproofing (why) using an aluminum profile (how)*".

Bringing order and communication, keeping the building as a system in mind, also involves communication such as we propose.

6. Conclusion

The publications are small-format (15x21 cm) of about 150 pages printed in black and white. The small size depends on the choice of matching the number of sentences contained in the map to the number of examples presented. Increasing the number of examples would surely enrich the volume, but processing them would lead to the need to increase the phrases needed for describing the element well. Therefore, this would make the conceptual map unwieldy, which, already with the limited number of concepts, would make it difficult to deal with the graphics problem. Only a complete computerization of the text could improve this rigid schema.

Abstract

This paper deals with the evaluation of sustainability as a theoretical, methodological and operational tool to support and improve learning on regenerative transformations of the built environment. In contrast with the scale-centred approach underlying the existing sustainability evaluation systems of buildings and urban areas, we propose i-UrBE (**i**ntegrated-**Ur**ban **B**uilding **E**valuation) an evaluation approach which draws on a socio-ecological interpretation of the built environment and is finalised to support a regenerative urban and building design. In our approach, the evaluation of the sustainability of a building or an urban plan is focused on *reciprocity* of interactions between human and non-human world, is carried out in a socio-ecological space that we define *urban matrix* and is based on few holistic indicators. These last are conceived as crucial tools reporting about what we define the *reliability* of an action, i.e. the ability of an action addressed to sustainability of buildings or an urban context to stimulate and transform into capacity the regenerative socio-ecological potential of a specific place.

Moving our work from the theoretical to the operational level, in this paper, we describe the evolution of i-UrBE approach for evaluating/assessing the regenerative sustainability of built environment focusing on *reciprocity* and *reliability* as crucial keys for an integrated urban-building evaluation. The paper underlines the relevance of *reliability* assessment based on few holistic indicators. In our evaluation approach, *reliability* reports on *reciprocity* by highlighting the 'co-creative' qualities of a design action addressed to a building to stimulate regenerative socio-ecological relationships shaping the built environment. At the operational level, *reciprocity* and *reliability* help to: (i) deal with sustainability in a pragmatic way on qualities inherent in an integrated process of urban-building design; (ii) improve knowledge generation on sustainability by enabling actors to identify trends, navigate sustainable transformations and highlight uncertainties associated with their actions.

Keywords: Regenerative Sustainability, Integrated Evaluation, Built Environment, Holistic Indicators.

1. Introduction

Evaluation systems in building and urban development have increasingly become a common language on sustainability among actors involved in making cities and urban areas smart, a fundamental tool to orient design and planning choices and influence the market. However, the large investments in this field have not produced the expected results, leaving significant margin for such systems development (Heinonen et al., 2015). One of the reasons determining scarce results is considered the lack of integration among different scales of evaluation of sustainability and in particular between the urban and building level. For example, considering urban sustainability as achievable through the evaluation of building sustainability has now become a new cliché, a sort of a 'necessary' activity to deal with climate change, energy savings or gas emission reduction in a smart way. Although necessary, this kind of building sustainability is not sufficient to speak about urban sustainability and improve it.

According to such a diagnosis, several solutions have been proposed in order to relate the urban and building sustainability better. These include the search for an intermediate scale of evaluation or multi-scalar evaluation frameworks. If, on the one hand, these solutions have not yet produced meaningful results, on the other they have generated an obsessive search for and proliferation of indicators and assessment systems that currently depicts a jeopardizing scenario (Reith and Orova, 2015) which risks to threaten the quality of results. From our point of view, in order to imagine and implement sustainable urban development a new approach is necessary.

2. i-UrBE: a socio-ecological interpretation of urban complexity

i-UrBE is a research project aimed at constructing a possible approach to tackle the urgent need for a cross-scale methodological framework for designing sustainability in the city by overcoming the limits shown by existing evaluation approaches linked to a scale-centred perspective, a linear conception of time and an archaic vision of integration among the socio-economic and environmental dimensions of sustainability. In contrast to dominant managerial approach to design and implement sustainability in the city, which sees evaluation procedures as an important tool to account for the results (Cole et al. 2013) and improve investment quality, in our research evaluation is conceived as an active learning process helping the design process. i-UrBE does not respond to a need for more complex and sophisticated evaluation technologies and tools. It offers a method and a tool enabling learning on what means and implies designing and planning sustainability in a spatially sensitive perspective. Despite the learning perspective could reduce the operability, efficacy and efficiency of i-UrBE, its use is a way to admit that when we deal with the evaluation of sustainability from an integrated, spatially sensitive perspective there is the constant need for doubt and dialogue (van der Knapp 2004).

In order to transcend the scale-centred perspective, our approach to the sustainability evaluation hinges on socio-ecological system (SES) interpretations of the built environment (Moffat and Kohler, 2008; Gandy, 2006). These are seen as indispensable to dismantle the anthropocentric vision on interactions between natural and urbanised worlds and a conception of urban complexity as resulting from interactions among clearly bounded and isolated physical systems that, from our point of view, is at the base of the scale-centred approach.

According to SES, urban complexity can neither be reduced to the opposition between urban and natural worlds (Moffat and Kholer, 2008) nor disaggregated in a set of isolated social and ecological systems reciprocally interacting in some obscure way. Built environment is something more than the sum of the built (physical, economic, cultural and social) parts of cities and ecosystems from which it depends on (Hassler and Kholer, 2014). It reflects the socio-ecological relationships created by political decisions and the culture of design through which we interconnect in a specific way technical, environmental, economic, socio-cultural and political dimensions shaping urban life. If reconsidered from this point of view, nature is anything but a product of urbanisation and its metabolism (Kaika and Swyngedouw, 2014).

Anchoring this SES perspective to interpretations of urban complexity as assemblage (Latour, 2005; Gandy, 2008), the built environment can no longer be taken as a dead background for human and non-human life (Kaika and Swyngedouw, 2014). It evolves from complex and networked relationships among human and non-human agents (Monno and Conte, 2014). Any agent composing the built environment is a socio-ecological system in itself: it is a bridge between natural and human worlds which is shaped by and shapes the built environment. Each building, neighbourhood or infrastructure is individually a socio-ecological agent/node in the built environment. Therefore, the idea of the built environment as a socio-ecological networked assemblage includes a vision of urban space as emerging from the bottom-up, through the dynamics producing it.

Consequently, i-UrBE abandons a widespread idea of the built environment as an indefinite whole to be disaggregated into a collection of man-made objects (human-non human systems) interacting individually in a more or less complex way with local ecological dynamics or wider ecosystem through impacts or flows of matter and energy. It considers the built environment as a spatial context of interactions (assemblage) among different socio-ecological agents (buildings, infrastructures, public spaces, ecological dynamics, decisions, people, etc.) connecting urbanised and natural worlds in a specific spatial configuration. Although determined by a specific vision of urban space (i.e. the anthropocentric one), any agent can change the spatial context.

However, none of the agents can be considered in isolation from the spatial context in which it interacts. The set of networked socio-ecological relationships configures the spatial complexity and the sustainability of both the built environment and any individual agent/node composing it. This set of socio-ecological relationships determines the built environment metabolism, its influence on agents, as well as its spatial extension, and the level of quality of life (human and non-human) of the assemblage of agents.

Coherently to SES perspective on the built environment, i-UrBE evaluation approach also abandons the generic definition of sustainability intended as a process of integration of the economic, environmental and social dimensions of implementation to focus on the transformations of the built environment in terms of regenerative behaviour (Monno and Conte, 2014). Rather than merely reducing, and then assessing, environmental social and economic impacts, and/or evaluating sustainable design choices comparing their performances to agreed sustainable targets, i-UrBE aims at supporting design choices triggering the transformation of the regenerative potential of the built environment into capacities (Mang and Reed 2012). As underlined by du Plessis (2012), "the regenerative paradigm provides an alternative that is explicitly designed to engage with a living world through its emphasis on a co-creative partnership with nature based on strategies of adaptation, resilience and regeneration" (p9).

In i-UrBE carrying out an integrated evaluation does not mean to discover a new scale for evaluating sustainability (as for example a neighbourhood), but understanding how to change the specific set of socio-ecological networked relationships shaping unsustainable metabolism and therefore working on those crucial relationships of *reciprocity* and interdependence linking agents composing the built environment so to make it regenerative.

2.1 From theory to practice

i-UrBE is thought of as the result of an evolutionary exploration method. This last facilitates new discoveries and the growth of knowledge since it proceeds by trial and error-elimination and is based on the idea that "as much as the experimenting agents, humans no less than other organisms, base their tentative problem-solutions on already acquired knowledge, wherever their trials go beyond what is already known they 'cannot go but blindly'" (Vanberg, 2014, p101). The trial and error-elimination method generates a continuous move from theories to practice. Therefore, the construction of i-UrBE proceeds cyclically: the evaluation approach is translated into an integrated urban-building assessment framework for the evaluation of sustainability of the built environment and, then, critically analysed also involving experts in the field of sustainability evaluation.

i-UrBE evaluation approach is still under construction. At the current stage, it is the result of just one trial and error elimination cycle assuming as a test-bed of our socio-ecological approach an assessment framework for the sustainability of buildings.

The first provisional structure of the integrated assessment was determined by the need to make explicit the multiple urban-building socio-ecological (sustainable and unsustainable) reciprocal interdependences. In order to achieve this goal, and following the SES perspective, the built environment in which a building is localised was redefined as *urban matrix*. Within this definition, the *urban* alludes both to the urbanised space and to the urbanisation of nature. Hence, the *urban matrix* is more than the neighbourhood in which a building is situated: it is a multi-scalar space defined by the metabolic interactions among agents/nodes composing the neighbourhood and the sustaining ecological dynamics. The borders of *urban matrix* are defined by its metabolism, meaning by that the assemblage of socio-ecological networked material and immaterial flows and relationships connecting the agents composing the built environment to ecological dynamics. Within the *urban matrix*, a building is an agent/node contributing to and shaping the *urban matrix* metabolism. Therefore, it is through metabolism that the built environment and a building interact.

The integrated assessment framework was also determined by the need to make explicit the *urban matrix* metabolism by identifying the multiple *urban matrix*-building sustainable and unsustainable reciprocal interdependences. At this purpose, we identified as categories of analysis of the *urban matrix* metabolism its physical structure, flows of matter and energy, environmental quality, and lifestyles. The sustainable building was instead described through its performances, as used in the most popular assessment systems, but reorganised in the following macro-categories: site, indoor and outdoor environment, operation and technical design. The vulnerability of *urban matrix* was chosen as a parameter able to represent at what extent a design action addressed to a building can change the *urban matrix* metabolism and if such a change can be able to activate an *urban matrix* resilient behaviour (Conte and Monno, 2012).

2.1.1 A focus on the evaluation of sustainable buildings: the need for *reliability*

To allow the assessment of a sustainable building in a SES perspective on the built environment we introduced the *reliability* concept. *Reliability* is a concept largely used in several fields of study to connect the effectiveness of an action to an expected behaviour of a system. Usually, this concept represents the ability of an agent –human or not human– to behave in an expected way during time, and the likelihood of an action to be effective. For example, in engineering fields it is adopted in relation to maintenance operations (EN 13306:2010); in the construction field it refers to a maintenance action capable of triggering an integrated and cooperative functioning among different components interacting in a building system. We retained the engineering definition of *reliability* of a system as being able to perform cooperatively. However, working in a socio-ecological system and a regenerative perspective, we dismissed its deterministic features. We then defined the *reliability* of a building as the ability of a sustainable building, basing on its design choices, to activate a cooperative integrated system of interactions between the building itself and the built environment (Conte and Monno, 2012). Thus defined *reliability* is a connector among scales of evaluation and a crucial conceptual tool to carry out both theoretically and operatively an integrated approach to sustainable design. *Reliability* could be assessed through few holistic indicators thought of as a combination of indicators representing a specific macro-category of analysis obtained through a comparison between macro-categories describing the sustainability of both buildings and the *urban matrix*. Such indicators measured those performances of a building inducing a vulnerability change in its context, i.e. impacts of a sustainable building on the built environment.

2.2 A critical analysis of the assessment framework

Once built the i-UrBE assessment framework (Fig.1), we verified if it was able to relate the sustainability of a building to the multiple dimensions shaping *urban matrix* metabolism. Our analysis showed that it was able to focus on socio-ecological relationships rather than on social, economic and environmental characters of urban and building sustainability. By relating the sustainable building to the variations of vulnerability of the *urban matrix*, it also helped to correlate better local and ecological scales of evaluation as well as natural and cultural worlds. Comparing i-UrBE integrated assessment framework to the existing assessment systems, it showed what is missing in them and how it could complement them helping to make the design more powerful and the evaluation more transparent.

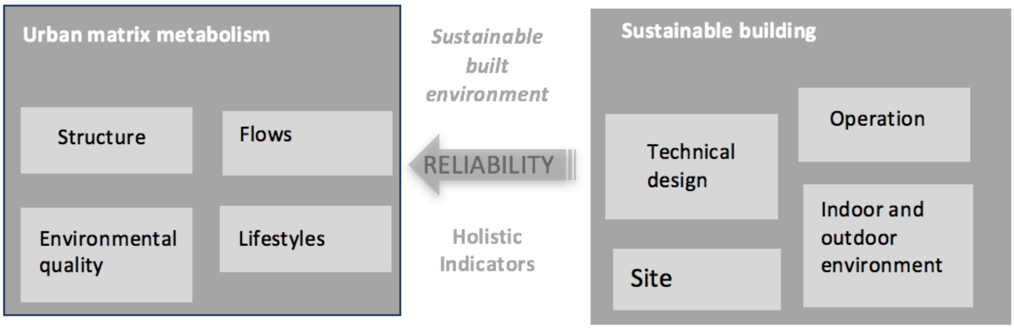

Figure 1: i-UrBE provisional assessment framework

Nevertheless, an inter-scalar perspective on the assessment was still recognisable, so weakening the integrative potentialities of i-UrBE evaluation approach. Furthermore, the regenerative perspective had not properly been incorporated in the assessment framework. Although expressing the *urban matrix*-building relationships, the variations of vulnerability showed a strong focus on resilience. The assessment of *reliability* was focused on the building and its impacts on the *urban matrix*, rather than on the interactions between the building and the *urban matrix*.

Parallel to this critical analysis, we discussed our approach to the integrated evaluation with some experts who actively work in the field of building and urban sustainability at the regional and national level. Experts were involved through semi-structured interviews and personal communications (face-to-face conversations). In depth, semi-structured interviews and face-to-face conversations were intended to grasp both technical and tacit knowledge as well as potential improvements and inadequacies of the existing evaluation systems of sustainable buildings and neighbourhoods when contextualised in an urban context. They also concerned issues related to inter-scalar urban-building relationships and the idea of urban complexity.

In both interviews and personal communications, we asked experts to give us their opinion about the efficacy of current evaluation systems in orientating design for sustainability and describe what causes the shortcoming of their action. They ascribed the modest efficacy of their action to contextual institutional, cultural and political constraints, rather than to the evaluation systems they had used for assessing urban or building sustainability. In particular, the experts emphasised the extremely usefulness of these systems in promoting sustainability of buildings. Yet, when obliged to reflect on the efficacy of these systems, experts could not avoid arguing that they should be considered as an initial step towards urban sustainability mainly aimed at changing the current unsustainable culture underlying the process of production of the city.

From experts' point of view, existing evaluation systems can help to measure the sustainability of a building intended as a producer of environmental pressures. However, they can only slightly challenge dominant economic driven conceptualisation of what is a sustainable building and what constitutes its contribution to the sustainability of the urban context in which it is situated. These systems are mainly used to favour the improvement of the (energy) efficiency of urban environments and buildings. Although buildings could reduce pollution, natural resources depletion and gas emissions in the atmosphere, the environmental urban quality still remains underestimated, social aspects undervalued and no meaningful regenerative clues of built environment could be detected. For the experts, one of the most important problems with the current evaluation systems is the absence of a multi-scalar perspective, which prevents them from linking sustainability of a building to urban sustainability and vice versa.

As far as the experts' opinion on our assessment framework is concerned, they found interesting both i-UrBE approach and the concept of *reliability*. They perceived the socio-ecological approach as a perspective capable of filling the absence of an integrated and inter-scalar evaluation and assessment. For them, i-UrBE approach pushes current mainstream ways of evaluating sustainable buildings towards a new way of conceiving the relationships between the building and the built environment. After we explained the meaning of *reliability*, experts started to think about the interactions among a sustainable building and the urban context.

For example, one of them argued that in order to consider a building sustainable, a new set of actions should be imagined beyond the existing approaches. These actions would imply reconstructing parts of a city to restore the relationships connecting buildings to the ecosystems, or transforming existing buildings so to regenerate the urban environments according to the ecological dynamics shaping the nature in the city. However, from their point of view, our approach and assessment framework could complement but not substituting the existing systems.

Interviews and face-to-face conversations confirmed the result of our critical analysis of the assessment framework. The *reliability* concept was too related to the performances of a building. Although being a useful conceptual tool to assess a potentially integrative building-urban reasoning, *reliability* only partially responded to the need for considering reciprocal interactions between buildings and the *urban matrix*. There was not a clear relationship between vulnerability and *reliability*. Hence, we were unfit to define and identify meaningful holistic indicators. Consequently, in the assessment process the use of *reliability* did not allow us to really understand if the interactions between a sustainable building and the *urban matrix* triggered an interdependent and regenerative process of the built environment.

By paraphrasing Costanza (2014), we had to admit that making the transition to the world we want is not easy since "in many ways we are locked-in, trapped, and in a very real sense "addicted" to the current regime" (p43). Both the concept of *reliability* and the holistic indicators had to be reframed.

3. *Reciprocity* as a regenerative quality of sustainable built environment

In order to make i-UrBE more adherent to the socio-ecological perspective as described above, we focused on *reciprocity* as crucial spatial quality of any sustainable built environment. *Reciprocity* implies the existence of co-constituting and mutually supportive spatial interactions among the agents composing a sustainable built environment seen as socio-ecological networked assemblage. Accordingly, we adopted a new definition of *reliability* that draws on the regenerative approach (Mang and Reed 2012), as it emphasises co-creativity among human and non-human worlds (du Plessis 2012). Co-creativity emphasised by the regenerative approach assures the interdependence which should characterise a socio-ecological sustainable built environment. Within this last, the co-creative performances do neither belong to a building nor to its ecological dynamics: they represent the potential and existing regenerative socio-ecological relationships which mobilisation requires the involvement of local communities seen as an active (and not impersonal) agent of sustainability.

Having in mind the idea of *reciprocity* as regenerative, co-creative quality of the built environment, in i-UrBE evaluation approach *reliability* is reconceptualised as the ability of a design action to trigger a system of interactions among different agents composing the built environment (for example buildings, ecological dynamics, local communities) so to exploit its regenerative potential and transform it into regenerative capacities. *Reliability* has to express the ability of a design action (a plan, a project, a technical solution) to activate a co-creative system of interactions between the building and the *urban matrix*. Furthermore, *reliability* can no longer be a feature of an agent defined by generic actors: it has to be reconceived as a result of a democratic, collective judgment involving ethical issues and concerning responsibility, accountability and transparency of decisions and decision-makers.

This new focus on *reciprocity* and the co-creative performances signals a crucial shift in i-UrBE assessment framework. The new assessment framework describes the features of *reciprocity*, i.e. the kind and direction of transition towards sustainability triggered by the design process in the built environment (Fig. 2). Besides considering *reliability* in terms of the impacts produced by a sustainable building on the different kinds of metabolism of an *urban matrix*, the assessment of *reliability* also focuses on the transformations of *urban matrix* metabolism into a regenerative one. In particular, in the new assessment framework, *reciprocity* helps to define the kind and the ‘degree’ of *reliability*, and, hence, it helps to understand and navigate the transformation activated by sustainable building design actions in the *urban matrix* showing its changes towards co-creative performances.

At the present stage of the research, we have identified four evaluation criteria expressing *reciprocity* and that can help to assess *reliability* through holistic indicators. The evaluation criteria are: cooperation, regeneration, adaptation and alignment. These criteria are crucial to signal the regenerative, co-creative character of transformations enacted in the built environment. If the regeneration of existing situations of crisis and cooperation between natural and human systems are a basic characteristic of a regenerative metabolism, adaptive capacity between natural and technical systems has to be activated in order to deal with the uncertainty underlying any design activity and guarantee the resilience of built environment to stresses and disturbances (Mang and Reed, 2012; du Plessis, 2012). Last but not least, a process of alignment between economic development requirements and socio-ecological worlds of life has to be detectable. The evaluation criteria stress the relevance to adopt design choices beyond the dominant economic culture, technological constraints and contextual limiting imperatives.

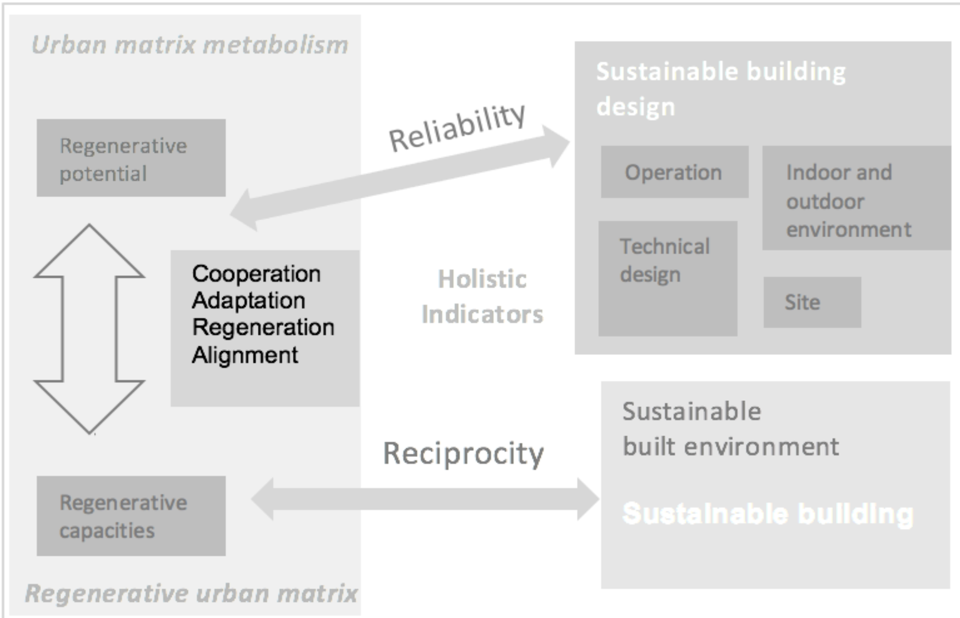

Figure 2: i-UrBE revised assessment framework

Operatively, the assessment framework enables to analyse how the regenerative potential of *urban matrix* shapes the sustainable building design and how, reciprocally, a sustainable building transforms that regenerative potential into capacities. However, due to the new definition of *reliability* in our assessment framework, the sustainability of a building can no longer be related to usual macro-categories describing its performances. They have to refer to the meta-design choices (a system of design actions) and their ability to trigger a regenerative process of a place. The vulnerability of the *urban matrix* remains an important parameter in the assessment. It still describes the variations of *urban matrix* resilience and metabolism and their regenerative direction. *Reliability* specifies the characteristic of that direction highlighting the kind of sustainability that is pursued through sustainable meta-design choices. The improvement of the assessment framework is showed by its ability to be applied to both urban and building design. In fact, for example, a sustainable urban plan has to produce reliable buildings.

Indirectly, *reciprocity* and the new definition of *reliability* highlight the transformative capacity, transversality, openness, and flexibility of the design process. The transformative capacity signals what and how much has been changed by the design process in the *urban matrix* metabolism. The transversality refers about the ability of a design action to interconnect socio-ecological relationships and shows the kind of interconnectedness (weak/strong). The openness highlights what has been ignored or lost in each of the four metabolic relationships and if there is any possibility to change the project of a sustainable building or neighbourhood. The flexibility coincides with the possibility to adapt the project to changing situations.

4. Conclusions

This paper argues that the problem of spatial integration in the design and evaluation of sustainability of the built environment cannot be solved by working within the current existing approaches supporting and supported by evaluative and assessment frameworks. In fact, they have been flourishing within a vision of the world in which social and ecological systems are separated and observed through detached, scalar and hierarchical dimensions and structure of analysis. The paper then proposes i-UrBE, an integrated urban-building approach based on a SES reconceptualization of the built environment and the regenerative perspective on sustainability; it is an approach suitable for designing, evaluating and assessing sustainable built environments. In a socio-ecological perspective on the built environment, spatial integration is a challenge and an opportunity to radically restructure sustainability in the city and support its design through evaluation. Furthermore, considering that evaluation is more than an accounting activity, why not use it as a learning tool to promote the cultural shifts required by the regenerative sustainability perspective, proceeding in practice in parallel to the theoretical issues?

Following these premises, the paper discusses opportunities and challenges which have emerged throughout i-UrBE development. In particular, the paper stresses the theoretical and operative relevance of both a socio-ecological perspective on the built environment and the concepts of *reciprocity* and *reliability* of the action in structuring the spatially integrated evaluation process.

Reciprocity and *reliability* of an action in i-UrBE open up new development prospects for the integrated evaluation and assessment of sustainability of the built environment since they help to:

- report on the socio-ecological and regenerative performance of the process;
- consider actions in a co-evolutionary and integrated spatial perspective;
- contextualise the action without disconnecting it from proximate and distant spatial relations;
- focus on meta-design actions;
- measure the ability of an action to stimulate the co-creative and adaptive capacities of the context and the level of activation of its regenerative potential;
- actively involve a wide range of actors, many of those are only rarely considered in the design and evaluation process;
- show potentialities of actions directed towards a regenerative development process.

In particular *reliability* stimulates innovation of available knowledge and current technologies – particularly those fielded and used in recent decades as an attempt to move towards a sustainable development– and encourages experimentation (de Vries and Peterson, 2009). At this stage of the research, we refrain from identifying the holistic indicators to assess *reliability* and the methods to measure them. As we have shown, *reciprocity* and r*eliability* assessment cannot be the result of an expert activity which randomly involves communities with the aim to complement or complete certain phases of the assessment and in relation to certain requirements of the evaluation procedure. Design choices, evaluation criteria and holistic indicators for measuring *reliability* can only be defined through a collective effort involving expert and local knowledge. Their dialogic and democratic construction will not exclude conflicts so to highlight what has still to be done towards the construction of a socio-ecological co-creative built environment.

Although in an ongoing process of development, i-UrBE already proposes a different way of thinking, speaking about, designing and evaluating sustainability in the city that we suggest can efficiently contribute to sustainability implementations. By focusing on *reciprocity,* the co-creative performances in the *urban matrix*, and *reliability* of buildings, i-UrBE offers a possible operative way to overcome the limits of existing scale-based frameworks for designing and evaluating sustainability in the city, thus making our judgment on sustainability more consistent.

Acknowledgments

We like to thank for their useful collaboration all the experts with whom we discussed our approach. In particular for the willingness to be interviewed, we like to thank: Luisella Guerrieri, engineer, responsible of Urban Planning and Environment Office in the Municipality of Alliste, Lecce; Salvatore Paterno, architect, EnergyConsulting, PassivHaus expert, TBZ Gravina in Puglia, Bari; Daniela Petrone, architect, energy manager, environmental sustainability assessment expert, vice-president ANIT, Corato, Bari. Abstract

Building Information Modelling (BIM) is the current expression of construction industry innovation generating a wide range of augmented market deliverables, new requirements and emergent roles. For organizations to cross the innovation chasm, they need to progressively implement complementary tools, workflows and protocols. Such multifaceted implementation is not instantaneous but passes through recursive periods of implementation readiness, capability acquisition, and performance maturity. Similarly, BIM diffusion within organizations is not a frictionless derivative of BIM implementation, but a function of competition dynamics and institutional isomorphic pressures. While there are a number of academic studies and industry surveys covering organisational readiness, software implementation or innovation diffusion, there is no single conceptual construct to describe, explain and test BIM adoption as a single construct connecting all these concepts. Based on published research and experiential knowledge, this paper introduces the Point of Adoption (PoA) model which integrates these concepts into a single visual model. The PoA model – not only clarifies the connection between these concepts but – facilitates the assessment of current organisational abilities, and clarifies a step-wise approach to BIM adoption and continuous performance improvement.

Keywords: BIM Implementation, Performance Assessment, Innovation Diffusion

1. Introduction

Building Information Modelling (BIM) is an expansive knowledge domain. Over the past few years, much research has been conducted into the connotations and impact of BIM tools and workflows on the construction industry. BIM has been repeatedly described as a 'disruptive technology' (Smith & Tardif, 2009, p. 32) instigating a 'process change' (Eastman, Teicholz, Sacks, & Liston, 2011, p. vii), or as an 'unbounded' and 'systemic' innovation (Harty, 2005, p. 51) (Taylor & Levitt, 2004, p. 84). These and other descriptions invariably position BIM as the *current* expression of innovation within the industry, and that BIM technologies, processes and policies are significantly impacting industry's deliverables, relationships and roles. While there are numerous studies relaying the many benefits of BIM, there are far fewer studies identifying the steps taken by organisations to realise these benefits. To remedy this shortfall, this article presents a performance model which overlays the concepts of BIM readiness, BIM implementation, and BIM diffusion.

2. Research Methodology

This section introduces the methodology used in developing the Point of Adoption model. The exercise builds upon and further extends the BIM Framework (Succar, 2009) by employing its existing conceptual constructs – terms, classifications, taxonomies, models and frameworks – to identify, explain and test new constructs. Through the 'BIM Framework's Conceptual Reactor' (Figure 1), a theory-building exercise is conducted using three iterative stages (J. R. Meredith, Raturi, Amoako-Gyampah, & Kaplan, 1989) (J. Meredith, 1993). The first stage develops a *description* of reality; identifies phenomena; explores events; and documents findings and behaviours. The second *explanation* stage builds upon descriptions to infer a concept, a conceptual relationship or a construct; and then, develops a framework or a theory to explain and/or predict behaviours or events. Finally, the third *testing* stage inspects explanations and propositions for validity; tests concepts or their relationships for accuracy; and tests predictions against new observables. The proposed Point of Adoption model follows a cyclical path as the one described by J. Meredith (1993) from describing; to explaining; to testing; and then back to describing. First, the model is generated through process of inductive inference (Michalski, 1987), conceptual clustering (Michalski & Stepp, 1987) and reflective learning (Van der Heijden & Eden, 1998) (Walker, Bourne, & Shelley, 2008). Second, conceptual models are developed to visually *explain* the knowledge structures. Third, each model is *tested* through either a focus group, peer-review questionnaire, or focus groups (Succar & Kassem, 2015).

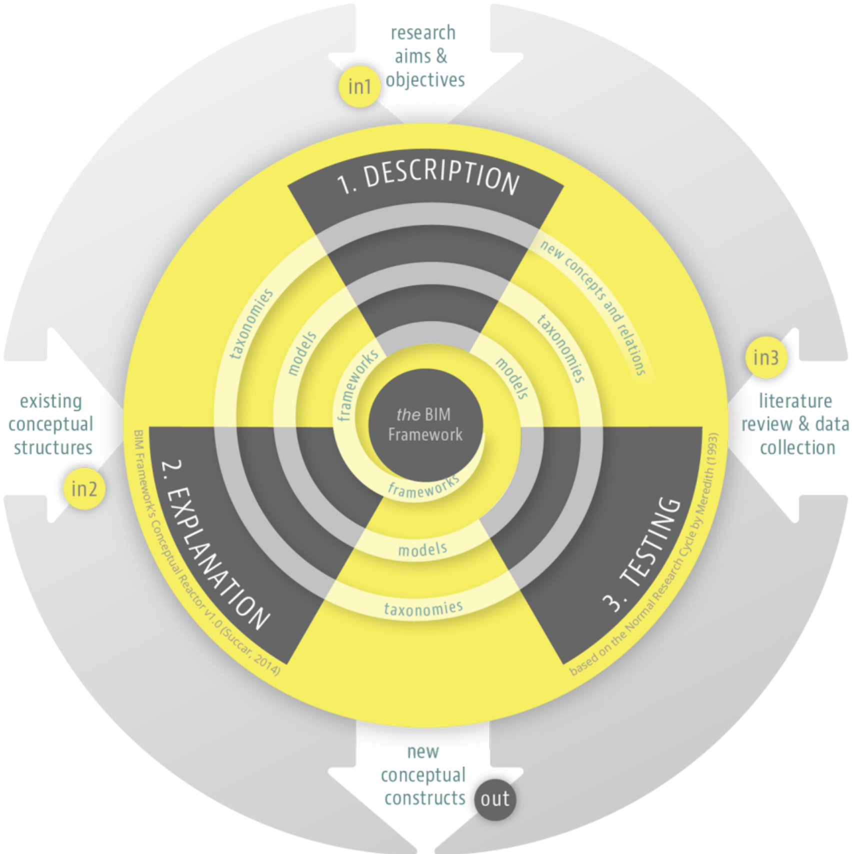

Figure 1. The BIM framework conceptual reactor

3. Terms, Concepts and their interaction

Before introducing the Point of Adoption (PoA) model, it is prudent to delimit a number of terms. The terms used to describe the act of implementing an innovative system/process are often confused with the terms used to describe the spread of this system/process within a *population* of adopters – be it within an organization or across a market. This delimitation is both artificial and necessary: it is *artificial* as other researchers can recalibrate the connotations of the same terms to fit their own unique purposes. It is *necessary* due to the availability of a large number of relevant diffusion models (Pierce & Delbecq, 1977) (Saga & Zmud, 1993) (Fadel, 2012) which do not differentiate between the stages of implementation - e.g. between acceptance and routinization as in Cooper and Zmud (1990) - the mechanics of diffusion, and the pressures causing the shift from one stage to another.

In introducing and delimiting these terms, we also limit ourselves to BIM as an innovative set of tools, processes and policies within the construction industry. This limitation is also both artificial and necessary: it is *artificial* as implementation/diffusion models introduced later are arguably applicable to other innovations within and outside the construction industry (e.g. to GIS and PLM). It is *necessary* due to the dearth of investigations covering innovation diffusion within the construction industry (Taylor & Levitt, 2004) thus warranting – as exemplified below - a focused attention on industry-specific and, by extension, BIM-specific terms.

3.1 BIM Implementation

Implementation refers to the wilful activities of an identifiable player[1] as it adopts a novel system/process to improve its current performance. More specifically, *BIM implementation* refers to the set of activities undertaken by an *organizational unit* to prepare for, deploy or improve its BIM deliverables (products) and their related workflows (processes). BIM implementation is introduced here as a three-phased approach separating an organization's *readiness* to adopt; *capability* to perform; and its performance *maturity*:

- BIM readiness is the *pre-implementation status* representing the propensity of an organization or organisational unit to adopt BIM tools, workflows and protocols. Readiness is expressed[2] as the *level of preparation*, the *potential to participate*, or the c*apacity to innovate*. Readiness can be measured using a variety of approaches – product-based, process-based, and overall maturity (Saleh & Alshawi, 2005) – and signifies the planning and preparation activities preceding implementation;
- BIM capability is the wilful *implementation* of BIM tools, workflows and protocols. BIM capability is achieved through well-defined *revolutionary stages* (object-based modelling, model-based collaboration, and network-based integration) separated by numerous *evolutionary steps* (Succar, 2009). BIM capability covers many technology, process and policy topics and is expressed as the *minimum ability* of an organization or team to deliver a measureable outcome; and
- BIM maturity (or *post-implementation*) is the *gradual and continual improvement* in quality, repeatability and predictability within available capabilities. BIM maturity is expressed as *maturity levels* (or performance improvement milestones) that organizations, teams and whole markets aspire to. There are five maturity levels: [a] Ad-hoc or *low maturity*; [b] Defined or *medium-low maturity*; [c] Managed or *medium maturity*; [d] Integrated or *medium-high maturity*; and [e] Optimised or *high maturity* (Succar, 2010).

3.2 BIM Diffusion

In contrast to *implementation* which represents the successful adoption of a system/process by an organization, diffusion represents the spread of the system/process across the organization. That is, the diffusion of a solution occurs after the solution has been adopted (Peansupap & Walker, 2005) or what we term as the *Point of Adoption* (PoA). However, the mere acquisition of an innovative solution (e.g. a software) "need not be followed by widespread deployment and use by acquiring organizations" (Fichman & Kemerer, 1999, p. 256).

---

[1] Depending on the 'scoping lens' applied, BIM players are either individuals, groups, organizational units, or whole organizations. BIM players, deliverables and their requirements have been extensively covered in earlier works (Succar, 2009).
[2] Definitions adopted from the e-commerce context as used by the Asia-Pacific Economic Cooperation (APEC), Center for International Development (CID) at Harvard University (CID, 2014).

E. M. Rogers (1995, p. 5) defines diffusion as the "process by which an innovation is communicated through certain channels over time among the members of a social system", a definition that covers the increase in "number of firms using or owning a technology (inter-firm diffusion) [and the] more intensive use of the technology by the firm (intra firm diffusion)[3]" (Stoneman & Diederen, 1994, p. 919) (Mansfield, 1963). Diffusion is also identified as the third and final phase of the well-noted Schumpeterian Trilogy: "invention (the generation of new ideas), innovation (the development of those ideas through to the first marketing or use of a technology) and diffusion (the spread of new technology across its potential market)" (Stoneman & Diederen, 1994, p. 918).

There are numerous studies dedicated to innovation diffusion across a population of adopters (Bass, 2004; Kale & Arditi, 2010; Mansfield, Rapoport, Romeo, Wagner, & Beardsley, 1977; E. M. Rogers, 1995). These studies either explain and expand-upon the S-curve diffusion pattern (Cumulative Normal Distribution) (Everett M Rogers, Medina, Rivera, & Wiley, 2005) consistently encountered when analysing the spread of innovation; or introduce *diffusion models* that "depict the successive increases in the number of adopters and predict the continued development of a diffusion process already in progress" (Mahajan, Muller, & Bass, 1990, p. 2).

According to Geroski (2000), there are two main types of diffusion models providing insights into the manner and speed of technology adoption – the epidemic model and the probit model. The 'epidemic' diffusion model attributes the diffusion of technology (software in particular) to a given population's knowledge of its existence; its comparative benefits; and the spread of its use through word of mouth. As a result, in the epidemic model the spread of innovation is largely affected by the transfer of knowledge and information among the involved population. As it focuses on a whole population of adopters, the epidemic model is interested in the gradual, unfolding impact of a new system/process on a market through its aggregate use. This contrasts with the 'probit' and 'salience' diffusion models which focus on the effect of *individual decision-making* on the spread of innovation and account for the differences in adoption time between individuals due to their distinct goals, needs and abilities (Geroski, 2000, p. 614; Strang, 1991).

This individual decision-making affecting diffusion follows three identifiable patterns – contagion, social threshold and social learning (Young, 2006, p. 4):

- Contagion represents how an industry player (e.g. an engineer or an engineering company) adopts an innovative system/process upon *contact with another player* who has already adopted it;
- Social Threshold represents how an industry player adopts an innovative system/process when *enough similar players* have adopted it; and
- Social Learning represents how an industry player adopts an innovative system/process when *enough proof is available* of prior adopters finding it worth adopting.

---

[3] To avoid conceptual overlap, the spread of a solution within an organizational unit will not be referred to as intra-diffusion but as improved implementation (or higher level of maturity) across the whole organization.

These diffusion models and patterns have been shown to collectively describe and help predict the incremental diffusion of technological solutions across a population. However BIM is not solely an innovative technological solution proliferating incrementally across the construction industry (Fox & Hietanen, 2007) (Mutai, 2009) (Gu & London, 2010) but a an organizational and *systemic* innovation (Taylor & Levitt, 2004) of complementary technologies, processes and policies. While BIM may be initially classified as a *technical innovation* (Murphy & Wardleworth, 2014), it will need to be urgently reclassified - upon its transformative adoption by organizations - as an *organizational innovation* characterised by the "generation, acceptance, and implementation of new ideas, processes, products or services" (OECD, 2005; Thompson, 1965, p. 2).

As covered in depth in earlier research (Succar, Sher, & Williams, 2012) and briefly explored in Figure 1, BIM adoption by an organization passes through three adoption points pertaining to three capability stages. Even if multiple organizations pass through the first Point of Adoption (PoA) separating pre-BIM status from minimum BIM capability (Stage 1), the spread of *modelling* practices among this population does not necessarily or automatically translate into a diffusion of multidisciplinary *collaboration* or interdisciplinary *integration* practices (Stages 2 and 3 respectively). Similarly, BIM is not a mere technological solution but reflects a combinatory and mutational diffusion of technologies, workflows and protocols (Merschbrock & Munkvold, 2014) (Yoo, Richard J. Boland, Lyytinen, & Majchrzak, 2012). This multi-stage, multi-faceted, and multi-component nature of BIM – resembling a *complex adaptive system* (Johnson, 2002) - prevents the effortless application of technology-centric diffusion modelling and invites the development of more representative BIM adoption models.

4. Point of Adoption Model

The Point of Adoption (PoA) model combines many of the concepts introduced earlier (Figure 2). In addition to distinguishing between invention, innovation and diffusion (Stoneman & Diederen, 1994), the three implementation phases – readiness, capability, and maturity - are also depicted). As explained further below, PoA is a term that identifies the juncture(s) where organizational readiness transforms into organizational capability:

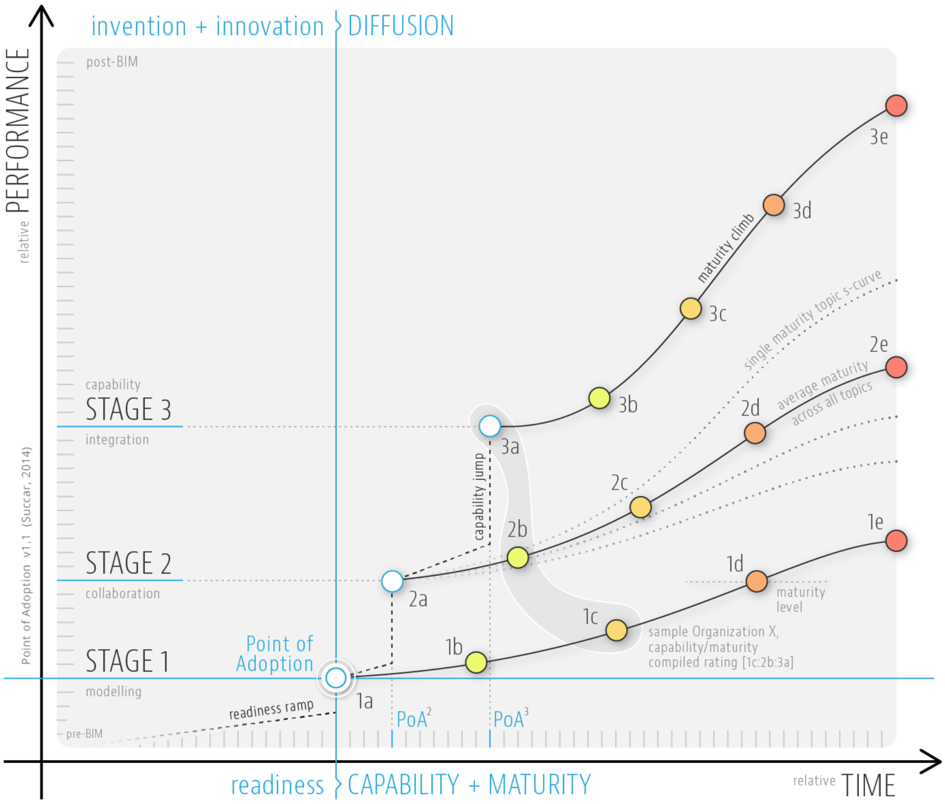

Figure 2. Point of Adoption model v1.1 (full size, current version)

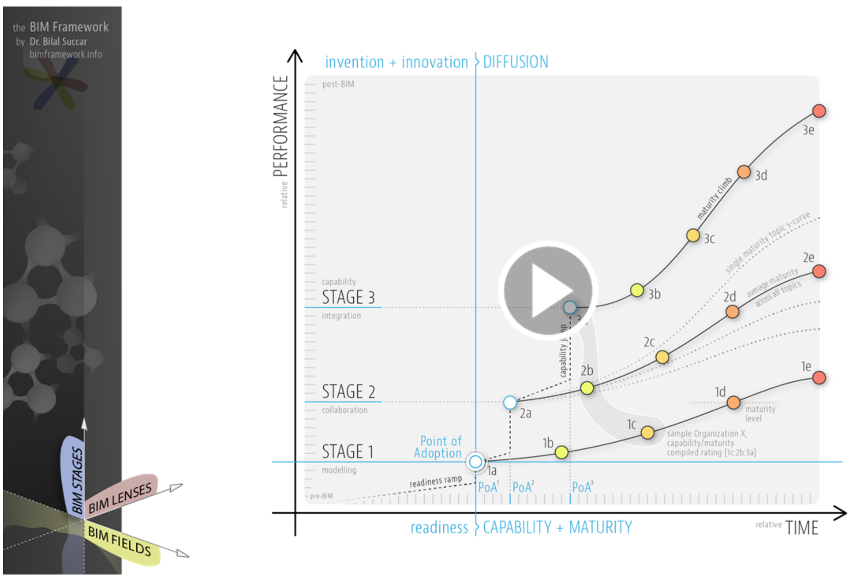

Video 1 . Point of Adoption Video (YouTube Link[4])

[4] Point of Adoption (PoA) video on YouTube: https://www.youtube.com/watch?v=weMqv31Np_4 (16:33)

As explored in Figure 2 and clarified in Video 1, transformative BIM adoption starts at the Point of Adoption (PoA) when an organization, after a period of planning and preparation (readiness), successfully adopts *object-based modelling* tools and workflows. The PoA[5] thus marks the initial *capability jump* from no BIM abilities (pre-BIM status) to minimum BIM capability (Stage 1). As the adopter interacts with other adopters, a second capability jump (Stage 2) marks the organization's ability to successfully engage in model-based collaboration. Also, as the organisation starts to engage with multiple stakeholders across the supply chain, a third capability jump (Stage 3) is necessary to benefit from integrated, network-based tools, processes and protocols. Each of these capability jumps is preceded with considerable investment in human and physical resources, and each stage signals new organizational abilities and deliverables not available before the jump. However, the deliverables of different organizations at the same stage may vary in quality, repeatability and predictability. This variance in performance excellence occurs as organizations climb their respective BIM *maturity curve*, experience their internal BIM diffusion, and gradually improve their performance over time[6].

The multiple maturity curves depicted in Figure 2 reflect the heterogeneous nature of BIM adoption even within the same organization (e.g. sample Organization X in Figure 2 has a compiled rating of 1c, 2b and 3a). This is due to the phased nature of BIM with each revolutionary stage requiring its own readiness ramp, capability jump, maturity climb, and point of adoption. This is also due to varied abilities across organizational sub-units and project teams: while organizational unit A1 (within organization A) may have elevated *model-based collaboration* capabilities, unit A2 may have basic modelling capabilities, and unit A3 may still be at the readiness stage preparing to implement BIM software tools. This variance in ability necessitates a compiled rating for organization A as it simultaneously prepares for an innovative solution, implements a system/process, and continually improves its performance.

5. Conclusions

The Point of Adoption (PoA) model represents the sequence and relationship between multiple performance assessment concepts. By overlaying the readiness, implementation, invention, innovation and diffusion concepts into a single term, and into a single visual representation, the PoA model clarifies the progression of BIM adoption within and across organisations. Also, through well-defined BIM Capability Stages and BIM Maturity Levels, the PoA model offers a simplified template for measuring BIM performance as well as for planning structured BIM adoption activities.

---

[5] The Point of Adoption (PoA) is not to be confused with the critical mass 'inflection point' on the S-curve (E. M. Rogers, 1995) (Everett M Rogers et al., 2005); or with the 'tipping pint', the critical threshold introduced by Gladwell (2001).

[6] The X-axis in Figure 2 represents time relative to each PoA, not as an absolute scale. That is, this version of the chart does not represent a snapshot view of compiled capability/maturity at a specific point in (absolute) time.

The PoA model has several theoretical and practical implications. At the theoretical level, it demonstrates how (a) BIM is a multifaceted innovation; (b) current theories of innovation diffusion may be inadequate for studying BIM diffusion; (c) it is possible to overlay the concepts of readiness, implementation and diffusion into a single adoption model; and (d) the need for a more in-depth theoretical study to underpin BIM adoption and multifaceted innovation diffusion.

At the practical level, the PoA model highlights (e) the simultaneous coexistence of varying BIM abilities within the same organisation; (f) the need to account for these variances when certifying organisations or pre-qualifying tender participants; and (g) the need to revise or discard the prevailing market maturity assessment methods which do not account for such variances.

Abstract

The Singapore government has been actively promoting the use of Building Information Modelling (BIM) in the construction industry. Since 1 July 2015, all plans of new building projects with gross floor area (GFA) of 5,000 sq. m. and above have to be submitted in BIM format. Moreover, raising productivity in all sectors has been the top priority. On the safety part, the government has introduced a number of initiatives, with the main aim of reducing fatalities to 1.8 per 100,000 workers by 2018. Taking advantage of these initiatives, there are opportunities to maximise the potential of BIM to help improve productivity and safety in the industry. Semi-structured interviews were carried out from January to December 2014 to find out the industry's views on the current state of BIM, productivity and safety in the construction industry in Singapore. It was revealed that despite the support from the government and the opportunities offered by BIM, the industry faced a number of challenges in the implementation of BIM. They include collaboration, technical, legal issues, time and cost consideration. Many of the respondents acknowledged that BIM has a lot of potential, yet this had not been maximised. Much more needs to be done to further utilise BIM for improving productivity and safety in the industry. Hence, the paper highlights an intelligent system which has been designed to provide solutions for the challenges and create opportunities for the industry to derive greater benefits from BIM. The system incorporates both productivity and safety performance, using BIM as the platform.

Keywords: BIM, challenges, opportunities, productivity, safety

1. Introduction

1.1 Overview

The Singapore government has been actively promoting the use of Building Information Modelling (BIM) in the construction industry. It has identified BIM as a critical tool in the national productivity drive, which has the aim of raising the level of productivity in all sectors of the economy, including construction. Since 1 July 2015, all plans of new building projects with gross floor area (GFA) of 5,000 sq. m. and above have to be submitted for development approval in BIM format. On the safety part, the government has introduced a number of initiatives, with the main aim of reducing national fatalities to 1.8 per 100,000 workers by 2018. Singapore's Workplace Safety and Health Council (WSHC) outlined the national WSH 2018 vision, which is "A safe and healthy workplace for everyone and a country renowned for best practices in WSH" (WSHC, 2010). Taking advantage of these initiatives, there are opportunities to maximise the potential of BIM to help improve productivity and safety in the industry. However, the implementation of BIM by the firms is not without challenges. The paper outlines the opportunities offered by BIM and some of the challenges encountered by some of the firms in the construction industry of Singapore on their BIM journey. The paper also highlights an intelligent system which has been developed to address the challenges. The system was designed to provide solutions for the challenges and create opportunities for the industry to derive greater benefits from BIM.

1.2 Singapore's BIM Roadmap

Governments worldwide, including Denmark, Finland, Norway, South Korea, UK, and USA play an important role in leading the construction industry in BIM adoption. Singapore is one of a few countries in Asia which have implemented BIM (Wong *et al.*, 2009). Others are Hong Kong, PRC and South Korea. In Singapore, the Building and Construction Authority (BCA) implemented the BIM Roadmap in 2010 with the aim that 80 percent of the construction industry would use BIM by 2015. This is part of the government's plan to improve the construction industry's productivity by up to 25 percent over the next decade (BCA, 2011). The latest survey on BIM adoption (Lam, 2014) shows that almost all the firms in Panel One of the public-sector panel of consultants have adopted BIM (Figure 1). However, the adoption rate was not that high for contractors (Figure 2).

BCA introduced a number of initiatives to prepare the industry, following the BIM Roadmap (Figure 3). After the first BIM Roadmap was launched, a National BIM Steering Committee, comprising representatives of professional institutions, trade associations, major government procurement entities and regulatory agencies, was set up in 2011 to provide a governing framework to steer the implementation of the BIM Roadmap (BCA, 2013b). The committee led the development of the "Singapore BIM Guide" and "BIM Particular Conditions". Platforms such as BIM Manager Forums have been organised to discuss and address technical issues faced by the industry.

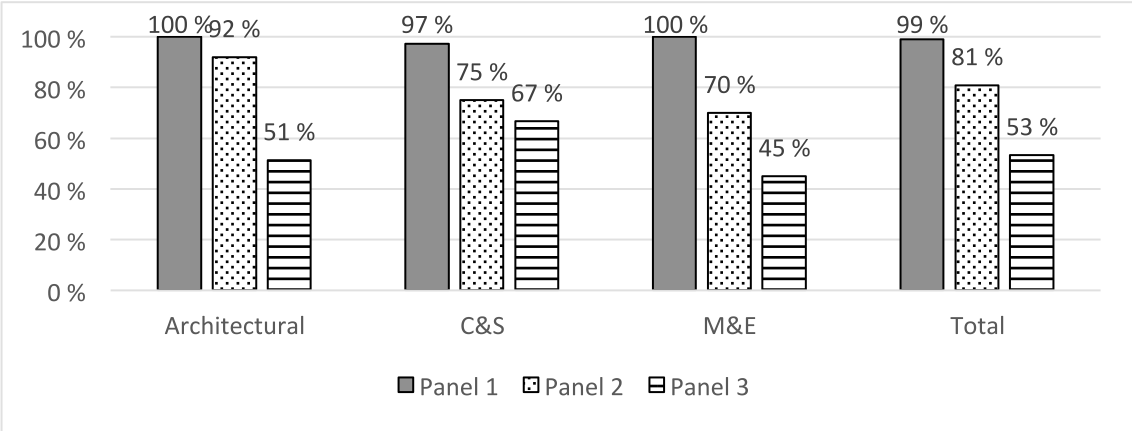

Figure 1. BIM adoption landscape of the public sector panel of consultants in the Singapore construction industry. Source: Lam (2014).
** Tendering limits:*
Panel 1: S$90 million
Panel 2: S$42 million
Panel 3: S$14 million

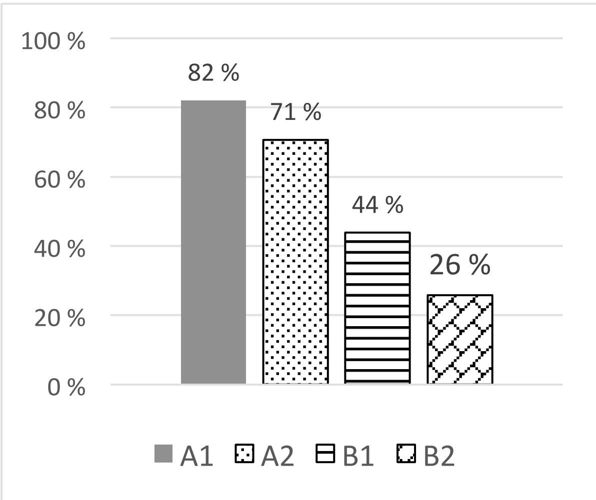

Figure 2. BIM adoption landscape of the Grade A1-B2 contractors. Source: Lam (2014).

** Tendering limits:*
Grade A1: unlimited
Grade A2: S$90 million
Grade B1: S$42 million
Grade B2: S$14 million

One of the initial challenges recognised in the BIM Roadmap is the need to obtain the manpower and financial resources needed to build up BIM expertise. To meet the high demand for skilled BIM manpower, BCA had been working closely with relevant Institutes of Higher Learning (IHLs), BCA Academy and BIM vendors to organise training and incorporate BIM in academic programmes. To overcome the challenge of obtaining the financial resources, the BCA BIM Fund provides incentives to construction firms to adopt BIM.

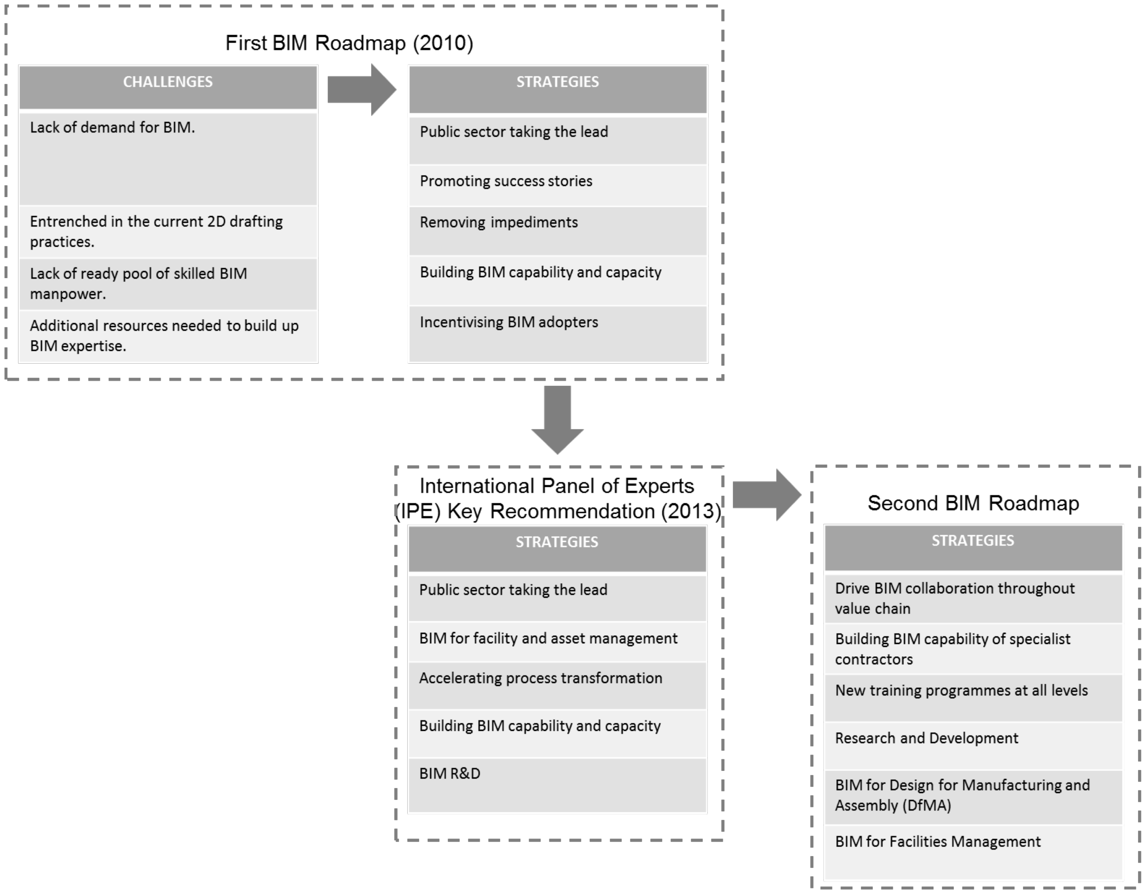

Figure 3: Singapore's BIM Roadmap. Source: Adapted from Lam (2014).

In 2014, the second BIM Roadmap was launched after the International Panel of Experts in BIM proposed a number of key recommendations, which included the public-sector taking the lead, BIM for facility and asset management, accelerating process transformation, building BIM capability and capacity and BIM R&D (Lam, 2014). The report presented a review of the current state of BIM adoption. The developers are detached from the BIM process and lack the know-how to drive the process. The consultants focus too much on e-submission and lack the time to undertake design co-ordination. Main contractors commented on the lack of quality models from consultants. The main contractors are currently not taking advantage of the full potential of BIM to resolve issues with consultants and subcontractors. The specialist subcontractors lack BIM skills. There is a lack of BIM usage for facilities management. It was also highlighted that there is a lack of BIM collaboration among project participants.

Hence, the main focus of the second BIM Roadmap is to drive BIM collaboration throughout the value chain. The funding level from the BCA BIM Fund had been increased from 50 percent to 70 percent for Project Collaboration Scheme. The "Singapore BIM Guide" and "Public Sector BIM Requirement" would be reviewed to include BIM coordination and model handover. Procurement methods and contract conditions would be developed based on BIM.

2. Literature Review: Opportunities and Challenges

The emphasis on national productivity and safety improvement, together with the drive for industry-wide BIM implementation, provides an opportunity for investigating how BIM could be used for improving productivity and safety in the construction industry.

BIM, as a process, allows the exchange of information among the project stakeholders, such as architects, engineers, contractors, consultants and clients. BIM is able to generate and analyse different views, data and information appropriate to various users' needs, which can be used to facilitate decision making and to improve the process of delivering the facility (AGC, 2010). The important feature of BIM is its capability to enable the item to be constructed to be built virtually, prior to building it physically, in order to identify and resolve problems, and simulate and analyze potential impacts (Smith, 2007). BIM can be used for many other purposes in the design and construction process such as visualization, scope clarification, trade coordination, collision detection and avoidance, design validation, construction sequencing planning, plans and logistics, marketing presentations, options analysis, walk-throughs and fly-throughs, virtual mock-ups and sight-line studies (AGC, 2010).

Teo (2014) discussed how BIM could be utilised help to improve productivity and safety in a number of ways. BIM could result in productivity improvement due to reduction in the disruption of the flow of information in the design and construction stages; effective response to changes during the construction stage; improved communication and collaboration among stakeholders in the construction project; informed decision-making; information sharing and interoperability; and fewer changes, less workload and more savings. The application of BIM in construction may improve the performance of onsite operations due to the reduction of manual efforts, time and costs involved (Gong and Caldas, 2011). During the construction phase, BIM contributes to the success of a project by enabling practitioners to effectively control schedule, budget and quality, and to reduce risks (Ku and Mills, 2008). Sacks and Barak (2006) report the reduction of total number of hours spent on three construction projects owing to the use of 3D modelling instead of 2D. Nath *et al*. (2015) found productivity improvements in the precast shop drawing generation due to the use of BIM.

Teo (2014) further argued that BIM could lead to safety improvement because BIM helps practitioners visualise the compatibility of architectural, structural and mechanical and electrical (M&E) design aspects, as well as feasibility of construction of design features or elements. BIM is able to simulate each step of work activities so that construction sequencing and the required safety measures may be identified. BIM also facilitates the communication of any identified safety risks to relevant stakeholders. Zhang *et al*. (2013) developed an automated safety checking platform which is able to inform construction engineers and managers of the various safety measures needed to prevent fall-related accidents before construction starts. The system automatically analyses a building model to detect safety hazards and suggest preventive measures to users. Benjaoran and Bhokha (2010) developed a rule-based system that is able to detect any work-at-height related hazards and propose necessary safety measures. Factors related to building components and activities such as component type, dimensions, placement, working space, activity type, sequence, and materials and equipment are used as input data. These factors are examined to find any work-at-height hazards. Thereafter, the system is able to suggest necessary safety measures including activities or requirements. Choi *et al*. (2014) developed a BIM-based evacuation regulation checking system for high-rise and complex buildings. Their system allows architects, designers and owners to evaluate the design at the design stage to ensure that the design meets the design requirements. Continuous checks are possible due to an automated system and detailed guidelines.

Although BIM has the potential to improve overall construction project performance, it is also widely acknowledged that BIM brings about various challenges in its implementation. Among others, BIM requires collaboration among the project stakeholders. To implement BIM, owners and general contractors must select subcontractors with BIM experience. This changes the contractor selection process, which traditionally focuses on the lowest bidder. Meanwhile, BIM implementation requires a significant up-front investment. Furthermore, construction safety professionals often are involved late in the project development process, which does not allow them to contribute to BIM effectively. Technical challenges are also commonly encountered (Rajendran and Clarke, 2011). For example, adding construction safety elements and temporary systems such as scaffolding, boom lifts, cranes and scissor lifts into BIM can be a challenge.

3. Field Study

3.1 Interviews

The information for the part of the field study reported on this paper was obtained from a series of semi-structured interviews with representatives of twelve firms and institutions in the construction industry in Singapore. Semi-structured, face-to-face interviews were carried out from January to December 2014. The main objective of the interviews was to find out the views of the practitioners in Singapore's construction industry on the current state of BIM, productivity and safety in the industry.

There was a total of 30 interviewees from six contractors, two architectural firms, one cost consultancy firm; and representatives of a professional institution, a trade association, as well as representatives from the government. Selection of the interviewees involved a snowballing sampling technique. The first group of interviewees was identified from reports and articles indicating that they had played a key role in implementing BIM in their projects; or their companies had exceptional productivity and safety performance records.

3.2 Findings: Opportunities and Challenges

The interviews revealed that the firms were utilizing BIM at different levels. Some firms had been using BIM at relatively advanced levels. Some other firms still used BIM at the beginning stage, mainly for meeting the statutory requirements of building plan submissions in BIM format. One firm was still testing the use of BIM internally, to prepare itself for full BIM implementation.

The interviewees acknowledged that BIM brings about many benefits. It helps to visualise, highlight the problems and propose solutions before construction starts. Project stakeholders could view, discuss and analyse different scenarios. BIM is also able to minimise communication and coordination problems among the different disciplines involved in a construction project.

The form of support from the government which had been most popular with the firms was the financial support provided. The majority of the firms of the interviewees had utilised the BIM Fund to the maximum limit. They acknowledged that the funding had been useful and expected that there will continue to be assistance from the BIM Fund in the future.

The interviews gathered that the firms faced a number of challenges in the implementation of BIM, three of the main ones of which are now highlighted. Firstly, BIM implementation requires a multi-disciplinary approach. Specifications in great details from consultants and contractors are required to develop a useful BIM model. For example, to integrate scaffolding specifications with design specifications, information from formwork or scaffolding suppliers is needed. However, many of the parties were concerned with the confidentiality of the information on their projects; hence, it sometimes took a longer time than necessary to share the required information.

Most of the time, an initiative from one of the project stakeholders is able to push the implementation of BIM. For example, one contractor took the initiative to develop an in-house BIM division and train its own personnel in BIM. The contractor developed the BIM models obtained from the consultants further. It also made sure the subcontractors (for the M&E works in this case) to update the BIM models so that the models could be coordinated with the architectural and structural models. It required a great deal of commitment as a significant amount of investment in terms of time, training and equipment is required. Some of the challenges include additional time commitment required for updating the models throughout the duration of the project. For example, subcontractors prefer 2D drawings to 3D and BIM models as they had more experience with the former than the latter. A significant amount of time was spent on modelling and checking as models submitted for submission often are not up to the standard required in the subsequent stages of the project. Hence, they still need to be further developed. In terms of human resources, it was always a challenge getting the people competent in BIM, since there was an acute shortage of these persons. The BIM team in the office needed more support from the site, hence the site team needed to be trained as well. The reluctance of the site personnel to provide this support was mostly due to lack of knowledge, skills and time. As contractors and subcontractors are often under pressure to meet project deadlines, there was no sufficient time for developing the BIM competence required. For similar reasons, there was also no time for continuous and complete updating of the models.

Secondly, in terms of legal framework, there are still uncertainties of the legal responsibilities. For example, a BIM server is expensive. There is also an issue of maintenance costs. Thus, the server will have to be put into the contract for the project. There are also issues of intellectual property from, and ownership of, the BIM developed in earlier stages of the project, as well as responsibility for errors in the BIM. Furthermore, when the project ends, there is a question of who should take ownership of the BIM on the project. Most of the firms interviewed suggested that it would be most appropriate for the client to take ownership of the BIM models.

Some consultants and contractors acknowledged that there is a need to align what the developers want with what the project team can deliver. Many consultants were still not ready to meet the developers' expectations; such as the need to launch the sale of units in the project as soon as possible. Some contractors and consultants also provided the feedback that they were not ready for a full-scale BIM implementation. Hence, some contractors and consultants proposed that BIM should be implemented in stages. There was a need for all project participants to collaborate effectively. All in all, the interviewees suggested that developers should take the lead in the process of developing and using the BIM, but have realistic expectations from the project teams.

Thirdly, there were technical issues. Those which were most commonly encountered by interviewees were: interface issues, the loss of information when transferring the models from one software to another, licenses, bandwidth and security. One technical issue that was commonly encountered by the industry was because BIM models were created using different versions of the popular software. If the models had been prepared using earlier versions of the software, which are no longer available in the market, there will be some productivity loss due to the time spent contacting the manufacturer directly to obtain the particular version of the software before they were able to gain access to the models.

Another example was when one contractor was trying to transfer the BIM models to another party. They were discussing with the BIM vendor on how to transfer the models without losing much information. However, the BIM vendor was unable to resolve the issues. As a result, the other party had to use BIM models which were not the most comprehensive; a considerable amount of time was needed to put in additional information before the BIM models could be used by the other party.

Some other difficulties encountered were because the BIM models were of low level of detail. Hence, a great deal of time and effort was needed to improve the quality of the models so that rule-checking and quantity calculation could be performed.

4. Proposed Intelligent System for Productivity and Safety Improvement

Realising the challenges that the Singapore construction industry faced, an intelligent system has been developed which incorporates both productivity and safety performance, using BIM as the platform. The proposed system is the key deliverable of a research project funded by the

Ministry of Manpower, Singapore. The system, named Intelligent Productivity and Safety System (IPASS), was designed to provide a solution to improve productivity and safety performance by addressing the challenges and creating opportunities for the industry to maximise the benefits of BIM (Figure 4). IPASS enables collaboration among the project stakeholders as they analyse the productivity and safety performance before the start of a project. The system comes with a BIM modelling guide which specifies the method of inputting information in some detail. Thus, it will help to minimise disputes and improve the level of details of the BIM models developed by the consultants and contractors.

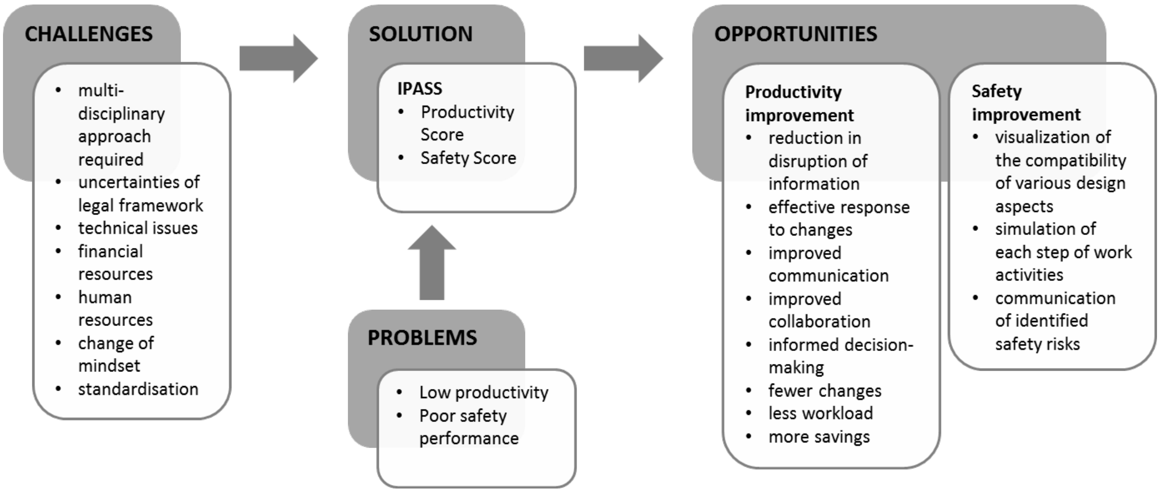

Figure 4. The development of IPASS as one of the solutions which can overcome the problems and challenges faced by the industry and create opportunities.

The system is also able to act as a monitoring tool for productivity and safety performance as the project progresses. IPASS automatically identifies safety hazards and provides solutions to mitigate the identified hazards. IPASS also allows the users to apply different structural and wall systems and see how they affect the buildability score individually or in combination, and to work to achieve the targeted score. Hence, during different stages of a construction project (pre-construction, design and construction stages), IPASS is able to help designers look at and improve the productivity and safety aspect of the design of a building. BIM models generated will help to visualize the different scenarios, enabling continuous productivity and safety monitoring.

The productivity score is computed based on the Buildable Design Score (BD Score) of the BCA's Buildable Score Assessment System (BDAS). The BD Score of a project is made up of three parts: Structural System (maximum 45 points), Wall System (maximum 45 points) and Other Buildable Design Features (maximum 10 points). The maximum productivity score achievable is 100 points. The BDAS was developed by the BCA as a means to measure the potential impact of a building design on the usage of site labour (BCA, 2014). Over the years, BCA has increased progressively the minimum BD score for building plan approval; this is aimed at boosting productivity. Hence, it is necessary for designers to include more productive technologies and standard components in the building design.

The safety score is computed based on the prevention and control of hazards detected in the structural systems and wall systems, and the Construction Safety Audit Scoring System (ConSASS) assessment. ConSASS is a tool to measure the maturity of the WSH system which includes its documentation and implementation, aiming at providing a standardized scoring system for the construction industry (MOM, 2013). ConSASS is aimed to provide an easy comparison between construction sites in term of their effectiveness in managing safety and health risks. ConSASS consists of an audit checklist and a score card. The audit checklist is derived from the Singapore Standards for Occupational Safety and Health Management System (SS506), Code of practice for safety management systems for construction worksites (CP 79) and the Universal Assessment Instrument (UAI) published by the American Industrial Hygiene Association (AIHA). The questions in the checklist are grouped into bands, from Band I to IV, in order to reflect the increasing level of maturity of the elements being audited. The results are tabulated in the score card, which shows the maturity of the different elements in the Occupational Safety and Health Management System (OSHMS).

The maximum safety score that can be achieved based on the prevention and control of hazards is 90 (maximum 45 points for the structural system and maximum 45 points for the wall system). ConSASS assessment is taken into consideration by giving the building a score for each band attained (from Band I to IV). The maximum score that can be achieved through ConSASS assessment is 10, which is when the building under assessment could achieve the highest band (Band IV). The maximum safety score achievable from the prevention and control of hazards as well as ConSASS assessment is 100 points. The full details on the development of the system can be found in other paper/s.

5. Conclusion

The Singapore government is playing an important role in leading the industry construction industry in adopting BIM through the first and second BIM roadmap, launched in 2010 and 2014 respectively. The roadmap put in place a number of strategies necessary for BIM implementation in the industry. However, it would appear that many firms in the construction industry in Singapore have yet to utilise BIM to its maximum potential. There are a lot of opportunities to utilise BIM for more strategic and important tasks than the current application for visualisation and meeting the requirements of building plan submissions.

The paper highlighted three challenges commonly encountered by the local firms. Firstly, successful BIM implementation requires a multi-disciplinary approach, but many players are still not ready for full collaboration since developing a useful BIM model requires sharing of information and specifications in great details. Secondly, there are still uncertainties of the legal responsibilities. The firms were still unclear about maintenance costs and the ownership of the BIM. Thirdly, there are still some important technical issues that have to be solved.

To bring BIM and its application to a higher level, it is essential to address those challenges. BCA had been trying to address some of the challenges. The second BIM Roadmap focuses on this. BIM can be utilised at a more advanced level when the construction industry has addressed the more fundamental issues. Some suggestions include involvement of all project stakeholders (rather than leaving it to the authority); initiatives and drive towards process transformation; and closer collaboration between consultants and contractors so that BIM can be utilised to achieve higher productivity and safer projects in the construction industry.

To address the challenges, an intelligent system has been developed which incorporates both productivity and safety performance, using BIM as the platform. The system, IPASS, was designed to provide solutions for the challenges and create opportunities for the industry to derive greater benefits from BIM. It was developed in line with the second BIM roadmap which emphasises collaboration to achieve higher productivity. IPASS enables collaboration among the project stakeholders as they analyse the productivity and safety performance before the start of a project. The system is also able to act as a monitoring tool for productivity and safety performance as the project progresses.

6. Acknowledgements

The authors gratefully acknowledge the funding received from the Workplace Safety and Health Institute (WSH Institute) of the Ministry of Manpower (MOM), Singapore. The authors are also grateful to the collaborating organisations, the Building and Construction Authority (BCA) and Samwoh Corporation Pte Ltd. They would also like to thank the practitioners who agreed to be interviewed and those who shared the BIM models of their projects.

Abstract

Building information modelling (BIM) has been seen as one of the most promising recent developments in the architecture, engineering, and construction (AEC) industry as well as a revolutionary change for managing a project from beginning to end. The Singaporean government has promoted the use of BIM in the AEC industry to help firms improve their productivity. The objectives of this study are to investigate the BIM adoption status and to identify the hindrances to BIM adoption in Singapore. To achieve the objectives, a preliminary questionnaire survey was performed with 34 professionals. A BIM adoption index (BIMAI) was proposed to measure the extent of BIM adoption. The low average BIMAI implied that the BIM adoption in the Singaporean AEC industry was still immature. Consultants were found to have a higher level of BIM adoption than contractors. Additionally, three-dimensional presentation, clash detection, design coordination, and construction system design were found to be the functions that were significantly applied in practice. Furthermore, the statistical analysis results showed that the mean scores of hindrances ranged from 3.79 to 2.65. Nine of the 20 hindrances were statistically significant, and thus were considered as critical hindrances to BIM adoption in the Singaporean AEC industry. "Lack of subcontractors who can use BIM technology", "cost of investment", and "lack of demand for BIM use" were the top three hindrances. This study provides an understanding of the BIM adoption status in Singapore and allows the practitioners to take measures to reduce the critical hindrances.

Keywords: Building information modelling (BIM), hindrances, construction projects, Singapore.

1. Introduction

Building information modelling (BIM) has been seen as one of the most promising recent developments in the architecture, engineering, and construction (AEC) industry (Azhar, 2011). BIM is defined as "a set of interacting policies, processes and technologies generating a methodology to manage the essential building design and project data in digital format throughout the building's lifecycle" (Succar, 2009, pp. 357). This definition highlights BIM's holistic nature, which covers not only software that allows the geometrical modelling and the input of information but also project management-related tools and processes (Bryde et al., 2013). In reality, BIM has been seen as a revolutionary change for managing a project from beginning to end (Chen et al., 2013). It requires the use of information and communication technology (ICT) to simulate the planning, design, construction and operational phases of a building project (Azhar, 2011), in order to provide a safer and more productive environment for users, to assert the minimum impact on environment from its existence, and to be more operationally efficient for the owner throughout the project lifecycle (Arayici and Aouad, 2010).

Application areas of BIM include, but are not limited to site analysis, design option analysis, 3D presentation, design coordination, cost estimating, energy simulation, clash detection, construction system design, schedule simulation, quantity takeoff, site resource management, and offsite fabrication (Azhar, 2011, Bynum et al., 2013, Cao et al., 2014, Eastman et al., 2011, Li et al., 2012, Monteiro et al., 2014). Previous studies have identified a number of benefits that may be brought by BIM adoption. According to a recent study by McGraw Hill Construction (2014) in Australia and New Zealand, the most significant short-term benefits were reduced errors and omissions, enhancement of organization's image as an industry leader, reduced rework, and the most significant long-term benefits were maintained repeat business, reduced project duration and reduced construction cost. In terms of time saving, Autodesk (2008) argued that Revit® Architecture software saved 91% of the time on checking and coordination and 50% on design development, compared with traditional Computer Aided Design (CAD) tools.

In Singapore, the Building and Construction Authority (BCA) and buildingSMART Singapore have been promoting the use of BIM in the construction industry because BIM is identified as a key technology that will enhance productivity and integration across diverse disciplines in the construction value chain. In 2010, BCA initiative the BIM Roadmap with the ambitious target that at least 80% of the construction industry uses BIM by 2015. To achieve this target, one strategy is to introduce the legal provision to mandate BIM-based plan submission (Teo et al., 2015). Since 2013, mandatory BIM electronic submission has been introduced in phases. Thus, it is compulsory for practitioners to submit architectural or engineering plans in the BIM format for regulatory approval.

Despite the efforts from the government and industry, the BIM adoption in Singapore still faces some hindrances and challenges. The objectives of this study are to investigate the BIM adoption status and to identify the hindrances to BIM adoption in the Singaporean construction projects. This study provides an understanding of the status quo of the BIM adoption in Singapore and critical hindrances, which allows the government and practitioners to develop strategies to reduce these hindrances and further promote the use of BIM in the construction industry.

2. Background

2.1 BIM in Singapore

In recent years, the government of Singapore, through the BCA, has highlighted productivity in the construction industry, and initiated a Construction Productivity Roadmap to transform the construction industry and raise its productivity (BCA, 2011b). Because of the potential to enhance construction productivity, driving BIM adoption has been seen as one strategic thrust (Teo et al., 2015). In 2011, a National BIM Steering Committee was set up to provide a governing framework to steer the implementation of the BIM Roadmap (BCA, 2011a), and led the development of the "Singapore BIM Guide" and "BIM Particular Conditions" (BCA, 2013).

To encourage the BIM adoption in Singaporean AEC industry, BCA (2011b) has provide a series of initiatives. For example, BCA and buildingSMART Singapore developed BIM submission templates, a library of design objects and project collaboration guidelines. In 2011, pilot projects with BIM were performed with the public sector clients. Subsequently, BCA issued regulations to make it compulsory for practitioners to submit architectural, structural as well as mechanical and electrical plans for building works for approval in the BIM format (BCA, 2015). Specifically, after 1 July 2013, all architectural plans of new building projects with gross floor area of more than 20,000 m^2 must be submitted in the BIM format; after 1 July 2014, all the engineering plans of new building projects with gross floor area above 20,000 m^2 must be submitted in the BIM format; and after 1 July 2015, all plans of new building projects with gross floor area above 5,000 m^2 must be submitted in BIM format. In addition to the regulations, BCA also set up the BIM Fund, which is aimed to help firms establish BIM collaboration capability by covering the costs for training, consultancy services and purchase of hardware and BIM software (BCA, 2014).

2.2 Hindrances to BIM adoption

Although the benefits of BIM have been recognized within the AEC industry and the technology supporting BIM has grown matured, BIM adoption has been slower than anticipated (Bernstein and Pittman, 2004). Thus, a number of studies have been performed to identify the factors influencing BIM adoption (Cao et al., 2014). Most of these studies have focused on the industry professionals' perceived hindrances to the diffusion of BIM in the industry (Eadie et al., 2013, Howard and Björk, 2008). In Australia, Gu and London (2010) indicated that the lack of experience in BIM due to a limited understanding of the industry needs and technical requirements was a major hindrance to the advancement and adoption of BIM related technologies within the Australian AEC industry. Additionally, Gerrard et al. (2010) found that lack of BIM expertise, lack of awareness and resistance to change were the main barriers to BIM adoption. A more recent study by Alabdulqader et al. (2013) reported that BIM were not well adopted mainly because practitioners perceived the existing CAD system can fulfil the need and BIM was expensive to operate and maintain. Through a literature review, a total of 20 hindrances to BIM adoption were identified, as shown in Table 1.

Table 1: Identification of hindrances to BIM adoption

Code	*Hindrances*	*References*
H01	*Cost of investment*	*(Bernstein et al., 2012, D'Agostino et al., 2007, Eadie et al., 2013, Eastman et al., 2011, Gilligan and Kunz, 2007, Khosrowshahi and Arayici, 2012, Ku and Taiebat, 2011, Tse et al., 2005, Won et al., 2013, Yan and Damian, 2008, Young et al., 2009)*

H14	*Lack of relevant expertise and knowledge*	*(Becerik-Gerber and Kensek, 2010, Eadie et al., 2013, Gilligan and Kunz, 2007, Khosrowshahi and Arayici, 2012, Tse et al., 2005, Won et al., 2013, Young et al., 2009)*
H15	*Limitation of current BIM applications*	*(Gilligan and Kunz, 2007, Won et al., 2013, Young et al., 2009)*

H16	*Lack of industry standards*	*(D'Agostino et al., 2007, Eastman et al., 2011, Young et al., 2009)*
H17	*Lack of BIM implementation data in construction phase*	*(Eastman et al., 2011, Won et al., 2013, Young et al., 2009)*
H18	*Perception that current technology is enough*	*(Yan and Damian, 2008)*
H19	*Lack of tangible benefits*	*(Becerik-Gerber and Kensek, 2010, D'Agostino et al., 2007, Gu and London, 2010, Khosrowshahi and Arayici, 2012, Won et al., 2013)*
H20	*Lack of demand for BIM use*	*(Eadie et al., 2013, Khosrowshahi and Arayici, 2012)*

3. Method and Data Presentation

A large research project that attempts to investigate BIM adoption in the AEC industry in Australia, Singapore and China has been implemented. In this study, a preliminary questionnaire survey was performed to investigate the status quo and critical hindrances to BIM adoption in Singapore. The comprehensive literature review supported the development of the questionnaire. In the survey, the respondents were asked to rate the extent of adopting the areas of BIM in their organizations, and the influence of the 20 hindrances on ERM implementation using a five-point scale (1=very low, 2=low, 3=neutral, 4=high, and 5=very high). In addition, they were requested to provide general information, such as their firm type, years of industry experience, designation, and years of BIM experience of their firms. Furthermore, they were asked to provide the number of the projects that their firms had undertaken in the past five years as well as the number of the projects where BIM were adopted.

The population consisted of all the industry practitioners in the Singaporean AEC industry. As there was no sampling frame in this survey, the sample was a non-probability sample. The non-probability sampling can be used to obtain a representative sample (Patton, 2001), and has been recognized as appropriate when the respondents were not randomly drawn from the entire population, but were rather selected based on whether they were willing to participate in the study (Liu et al., 2016, Wilkins, 2011, Zhao et al., 2013).

A total of 130 questionnaires were sent out and 34 completed questionnaires were received, yielding a response rate of 26%, which was acceptable compared with the norm of 20–30% with most questionnaire surveys in the construction industry (Akintoye, 2000, Hwang et al., 2015). In spite of a relatively small sample size, statistical analysis can still be carried out because the central limit theorem holds true when the sample size is greater than 30 (Ott and Longnecker, 2001). The profile of the respondents is shown in Table 2. Out of the 34 respondents, 79% were from contractors while 21% were from consultants, including design firms. In terms of experience, 50% had more than 10 years of industry experience, demonstrating the reliability of the data collected from the survey. In addition, 47% of the respondents had more than two years of experience in BIM. Because the electronic submission of architectural plans began to become mandatory after 1 July 2013, it has been around two years since most firms started to adopt BIM. Thus, it was not surprising that 35% had adopted BIM less than two years. Six firms did not have BIM experience. There may be two reasons for this. First, these firms perform only small projects, for which electronic submission in the BIM format for approval was not mandatory. Second, they outsourced BIM-related tasks to BIM moulders or specialists to satisfy the mandatory requirements from BCA.

Table 2: Profile of respondents and their firms

Organization type	N	%	Industry experience	N	%	BIM experience	N	%
Contractor	27	79%	5-10 years	17	50%	None	6	18%
Consultant	7	21%	11-15 years	11	32%	1- 2 years	12	35%
			16-20 years	4	12%	3-4 years	12	35%
			Over 20 years	2	6%	5 years and more	4	12%

4. Results

4.1 Status quo of BIM adoption

To measure the extent of BIM adoption in firms, a BIM adoption index (BIMAI) is proposed in this study as follows:

BIMAI = No. of projects with BIM adoption / Total no. of projects of a firm × 100%

In this study, the denominator of this equation was the total number of the projects that a firm had undertaken in during the past five years. Thus, the BIMAI of each company surveyed was calculated (see Table 3).

Table 3 shows that the BIMAI of contractors was 26% while that of consultants was 42%. The overall average BIMAI was 30%. These results implied that the BIM adoption in the Singaporean AEC industry was still immature. Consultants, including those BIM specialists and design firms, had a higher level of BIM adoption than contractors. Only three out of the 27 contractors (11%) received BIMAI over 50%

Table 3: Status quo of the BIM adoption in Singapore

BIMAI	Contractor	Consultant	Overall	
			No.	Percentage
0%	5	1	6	18%
10-19%	7	1	8	24%
20-29%	4	0	4	12%
30-39%	4	0	4	12%
40-49%	4	2	6	18%
50-59%	1	1	2	6%
60-69%	2	1	3	9%
90-100%	0	1	1	3%
Total	27	7	34	100%
Mean	26%	42%	30%	

In terms of application areas of BIM, 14 areas were identified from literature review (Azhar, 2011, Bynum et al., 2013, Cao et al., 2014, Eastman et al., 2011, Li et al., 2012, Monteiro et al.,

2014) and presented in the survey. The one-sample t test was used to check whether these areas were significantly applied (see Table 4). Only four areas (three-dimensional presentation, clash detection, design coordination, and construction system design) received mean values above 3 and p-values below 0.05, suggesting that these four areas had been significantly applied in the Singaporean AEC industry. This result was consistent with the low overall BIMAI in Singapore.

Table 4: Application areas of BIM

Application areas	*Description*	*Mean*	*Rank*	*P-value*
Site analysis	*Analyzing project site location*	*2.38*	*9*	*.001**
Analyzing design options	*Exploring and comparing design options based on three-dimensional models*	*3.18*	*5*	*.362*
Three-dimensional presentation	*Three-dimensional presentation of complex structures to nonprofessionals*	*4.26*	*1*	*.000**
Design coordination	*Coordinating design of architectural, structural, as well as mechanical, electrical, and plumbing systems*	*3.65*	*3*	*.002**
Cost estimating	*Project cost estimating during design stage*	*2.76*	*7*	*.274*
Energy simulation	*Analyzing building's energy distribution and consumption*	*1.94*	*13*	*.000**
Other performance simulations	*Analyzing building's other performances such as lighting, acoustics, air flows, and pedestrian circulation*	*2.06*	*12*	*.000**
Clash detection	*Checking conflicts among building systems prior to construction*	*3.85*	*2*	*.000**
Construction system design	*Designing and analyzing the construction of complex building systems in order to increase planning*	*3.41*	*4*	*.021**
Schedule simulation	*Simulating master schedules and construction sequences*	*3.09*	*6*	*.675*
Quantity takeoff	*Quantity takeoff and cost estimation during construction stage*	*2.74*	*8*	*.255*
Site resource management	*Integration with schedules and onsite information to manage the storage and procurement processes of project materials and equipment*	*2.29*	*10*	*.001**
Offsite fabrication	*Generating digitized information to facilitate greater use of prefabricated components*	*2.24*	*11*	*.001**

** The one-sample t test results are significant at the 0.05 level (test value=3).*

4.2 Critical hindrances to BIM adoption

To enhance the level of BIM adoption, critical hindrances should be identified and addressed. The one-sample t test was used to check whether the 20 hindrances had significantly negative influence on BIM adoption in the Singaporean AEC industry (see Table 5). The mean scores of hindrances ranged from 3.79 to 2.65. A total of nine hindrances received mean values above 3 and p-values below 0.05, implying that they were deemed as critical hindrances to BIM adoption.

"Lack of subcontractors who can use BIM technology" received the top rank (mean=3.79), indicating that it was not sufficient to promote BIM adoption in only main contractors. Subcontractors, which were also important participants in construction projects, also have to be involved in the trend of BIM adoption. However, the subcontractors were likely to undertake small projects that did not face mandatory requirements for BIM submission, and thus do not have incentives to adopt BIM.

“Cost of investment” was ranked second (mean=3.74), suggesting the costs associated with BIM were still a great concern of the AEC industry practitioners in Singapore. Although BCA has set up the BIM Fund that may be used to cover the costs for training, consultancy services and purchase of hardware and BIM software (BCA, 2014), there were also specific requirements for the applicants. Thus, some firms may not be eligible for the BIM Fund and have to bear the costs on their own.

Table 5: Critical hindrances to BIM adoption in Singapore

Code	*Mean*	*Rank*	*P-value*	*Code*	*Mean*	*Rank*	*P-value*
H01	*3.74*	*2*	*.000**	*H11*	*3.44*	*9*	*.023**
H02	*3.47*	*8*	*.001**	*H12*	*3.79*	*1*	*.001**
H03	*3.62*	*4*	*.004**	*H13*	*2.65*	*20*	*.032**
H04	*2.79*	*18*	*.269*	*H14*	*3.62*	*4*	*.001**
H05	*3.26*	*11*	*.173*	*H15*	*3.18*	*14*	*.362*
H06	*3.26*	*11*	*.221*	*H16*	*2.79*	*18*	*.228*
H07	*2.79*	*18*	*.228*	*H17*	*3.18*	*14*	*.280*
H08	*2.97*	*16*	*.845*	*H18*	*3.59*	*6*	*.009**
H09	*3.29*	*10*	*.143*	*H19*	*3.59*	*6*	*.006**
H10	*3.21*	*13*	*.214*	*H20*	*3.65*	*3*	*.001**

** The one-sample t test results are significant at the 0.05 level (test value=3).*

“Lack of demand for BIM use” occupied the third position (mean=3.65), implying that the actual demand for BIM in the industry was not as great as the government thought. Indeed, the government recognizes BIM adoption as one of the strategic thrusts that can significantly raise the productivity in the construction industry. Thus, the government should use the potential benefits from BIM to convince industry practitioners that it is really necessary to use BIM to replace two-dimensional CAD.

5. Conclusions and recommendations

Building information modelling (BIM) has been seen as one of the most promising recent developments in the architecture, engineering, and construction (AEC) industry as well as a revolutionary change for managing a project from beginning to end. The Singaporean government has promoted the use of BIM in the AEC industry to help firms improve their productivity. The objectives of this study are to investigate the BIM adoption status and to identify the hindrances to BIM adoption in Singapore. To achieve the objectives, a questionnaire survey was performed with 34 professionals. The low average BIMAI implied that the BIM adoption in the Singaporean AEC industry was still immature. Consultants had a higher level of BIM adoption than contractors. Additionally, three-dimensional presentation, clash detection, design coordination, and construction system design were found to be the functions of BIM that were significantly applied in practice. Furthermore, nine hindrances were recognized as critical hindrances and should attract more attention from the government. “Lack of subcontractors who can use BIM technology”, “cost of investment”, and “lack of demand for BIM use” were the top three hindrances.

There are limitations to the conclusions. First the identification of the hindrances may not be exhaustive with the passage of time. Additionally, the sample size was relatively small in this preliminary survey, so cautions should be warranted when the analysis results are interpreted and generalized. Moreover, the single-source data are very likely to cause common method biases (Jiang and Jiang, 2015, Jiang and Wang, 2014), which is a common limitation of the studies using questionnaire survey (Zhao et al., 2016). Furthermore, the findings of this study are interpreted in the context of Singapore, which may be different from the context of other countries.

Future studies would investigate the interaction mechanisms among the hindrances to BIM adoption, and identify the influence paths comprised by some of these factors. Also, as BIM adoption may involve changes in firms, organizational change theories would be used to interpret the critical hindrances and provide the theoretical rationale behind these interaction mechanisms.

Abstract

Building Information Model (BIM) based designs, plans, drawings and other information needed on construction sites can be used more and more by mobile devices as hardware, software and cloud-based data sharing are developing rapidly. As a result, the safety information can also be "mobilized". If compared to the traditional safety documents, the mobile versions provide more efficient workflow and possibility to completely new kind of information contents. However, the most important benefits will likely be, that safety information can be brought closer to the production event, where it can genuinely affect occupational site safety. Additionally, up-to-date safety level information including safety violation statistics can be provided for site management purposes, and this safety data is automatically stored for later analysis and development purposes.

Mobile opportunities have been implemented to safety purposes in limited extent this far. This research aims to clarify the possibilities of useful mobile tools and promising new ways of delivering BIM-based information needed at field. Results are based on an analysis focused on 1) the different types of mobile applications currently available for safety purposes, 2) the most promising new ways of sharing and recording safety related information at site using mobile devices, and 3) the apparent potential of mobility in construction safety management. Data was collected by literature study, experience got by hands-on software testing, and interviewing and discussing with industry representatives in various meetings related to an on-going collaborative research and development project. The goal of the research project is to develop publishing, management and usability of digital building information by web-based solutions and procedures in the construction supply chain.

The identified most promising mobile opportunities for improving the occupational site safety will be tested in a real on-going building construction project. Selection of use cases will be carried out by the involved development project partners, including software vendors, research institutes and industry representatives such as a general contractor, precast fabricator and structural engineering company. Experience will be used to take advantage of BIM and mobile tools more efficiently on construction sites in the future, and to encourage software houses to develop the needed final more suitable applications for the industry.

Keywords: occupational safety, building construction site, mobile information, BIM, mobile safety management

1. Introduction

Building Information Modelling (BIM) is very current topic worldwide. Reasons for increasing BIM implementation are demands from governments/building authorities, demand from big conscious client organizations, competitors' good experience in BIM as a tool to support and intensify the design and construction processes, the emergence of common national BIM guidelines to standardize the main principles and procedures in projects, the general global digitalization in construction industry, and simply the identified business opportunities related to BIM. The current fast construction digitalization is highlighted e.g. in a summary of BIM adoption around the world published by Construction Management magazine (CIOB 2015). Examples of reported safety related uses of BIM in building construction sector are BIM-based 3D site layout and fall prevention planning, and BIM-based workflow visualization and analyses including hazard identification (Sulankivi 2014). In a survey conducted by McGraw Hill Construction in US (2013), a large percentage (43%) of the firms that use BIM reported that BIM use has a positive impact on safety.

In the construction industry, ICT systems were designed for stationary office use, but have been pushed out to the production environment, which have resulted in that construction management teams are tied up inside the site offices at their desktop computers a large part of their working hours (Löfgren 2007). According to previous research, construction management personnel have a clear need to use digital information while at field, not in the site office only (Lemmetty 2013). Now, after mobile technology has become an essential part of our everyday life, it's rolling into professional use as well, improving e.g. the access to construction documentation and other production information for site staff. Löfgren (2007) describes how Skanska, one of the largest building companies in the world, become among the first ones interested in mobile ICT as a result of identifying problems related to the overwhelming quantity and poor quality of information in the field in a US construction project 2005. The collaborative effort between a software developer and the production management team in the project resulted in improved understanding of the limitations of existing technology and the generation of new tools that were more useful to the construction site environment. Good experience in mobile ICT got in Skanska US led rapidly to a global development initiative involving e.g. Sweden, UK, Norway and Finland. Focus was first on the management of drawings and specifications used on construction sites, but soon mobile tools and procedures started to be developed to replace existing administrative on-site work processes as well. Also according to Fender & Wolfley (2014) portable electronic devices such as tablets and smartphones can be useful for safety professionals, and the right apps can improve efficiency and tablets can pay for themselves quickly.

As a result of rapid development of hardware, software and cloud-based data sharing, also BIM-based designs and other new kind of information needed on construction sites can be used more and more by mobile devices. However, mobile opportunities have been implemented to safety purposes in a limited extent this far. This research aims to clarify the possibilities of further digitalization by identifying useful mobile tools and promising new ways of delivering BIM-based plans and other information needed at field. Several current mobile hardware and software can serve construction project management as a whole, including safety, but this paper introduces new mobile opportunities from the specific viewpoint of occupational site safety, the final target being to bring relevant safety information closer and more easily available in the production events and site management procedures, where it is needed to conduct the construction work safely.

2. Research method

Results are based on an on-going collaborative research and development project, which main goal is to develop publishing, management and usability of digital building information by web-based solutions and procedures. Results presented in this paper aim to promote safety management from the same information sharing aspects as construction production management as a whole is being developed in the research project.

Potential new technology and exploitation possibilities have been analysed based on information got by literature study, surveying available mobile applications intended or suitable for building construction industry, studying and testing the features of these applications, discussing about the needs and expectations of e.g. site staff with the research project partners in various meetings, and by individual interviews. Beside research organizations, industry representatives such as a general contractor and a precast concrete manufacturer, engineering companies, as well as software developers providing and developing both BIM-based and mobile applications for construction industry are involved in the research and development project. Based on the collected information, this analysis considers practical safety information needs at field, possibilities of the newest mobile or BIM-based software, as well as the found leading edge mobile work flow and procedures.

Selected most promising new mobile opportunities for improving the occupational site safety will be studied in more detailed level and tested in a real on-going construction project. If a suitable tool or a prototype for a specific need is not available for testing, research organizations will demonstrate the needs to software house representatives to encourage them to develop the needed final applications for market.

3. Results

3.1 Mobile technology for site safety

After surveying available web-based/cloud-based mobile applications intended or suitable for building construction industry, those including some kind of safety related features were analysed in more detailed level and 4 different kind of categories of applications identified. These different types of mobile safety related applications are presented in Table 1 together with few examples of real tools of each type.

Table 1: Examples of different types of mobile safety related applications.

Types	*Examples of existing mobile tools*
1: Construction project management applications including safety related tools	*Trimble ProjectSight, Autodesk 360 Field, bim+ Connect, Aconex, Procore construction management software, PlanGrid*
2: Safety auditing or safety level inspection/measurement/rating apps	*iAudit, iOSHA Process Safety Management Auditing, Trimble Inspector, Kotopro TR-mittaus, T3, InstaAudit*
3: Applications for a single specific purpose	*Dakota's EHS Pocket Guide, ChemAlert, iTriange, Clinometer HD, SoundMeter, DMD Panorama, Tekla Field3D, Safety Coach*
4: Applications meant for a specific construction phase or work	*Daily Reports (e.g. for concrete work), Concrete calculator, Fall PtD, Raksamittari PRO*

The first type, *construction project management applications including safety related features*, are comprehensive project management or collaboration solutions typically aiming to connect the office to the field, as described by Trimble (Lavine 2015), as well as distributing/sharing up-to-date project documentation and information regardless of time and physical location of the user. At site office or headquarters these solutions can be used by PC using a web browser as the user interface. At field, mobile device such as iPad or a mobile phone is usually used together with the corresponding mobile application installed to the device. That's why they are usually tied to a specific operating system such as Windows, Android or iOS, but some applications are available for several operating systems. However, when a browser is the interface in the mobile device also, the application is available to all devices with internet connectivity regardless of the operating system.

The second type of applications are developed for systematic and effective *mobile site safety auditing or safety level inspection/measurement/rating*. As a result of cultural differences in safety regulations and inspection procedures, these are typically country-specific applications. For example, "Kotopro TR-mittaus", "T3" and "Insta Audit" are based on a Finnish method to calculate the weekly safety level, serving the Finnish building construction sector only. In turn there is e.g. an US application called "iOSHA Process Safety Management Auditing" based on US regulations. On the other hand, there could be some good ideas related to the mobile application or the original auditing process, which might be useful to be transferred from one country (and application) to another.

The third type of applications are developed for *a single specific purpose* such as issue management, browsing H&S regulations, checking employee qualifications, searching chemical data or medical information, measuring site conditions, as well as viewing 3D building information models. Issue management applications included in this group can typically be used for many different purposes and even in different industries and could thus be called "general issue management solutions". The fourth type, applications meant for a *specific construction phase or work*, include mobile tools for flooring or concrete pouring, for example, and include some safety related features just for these specific work tasks.

If considering all different available mobile applications, one typical common feature is the possibility to use them off-line. This is important at building construction site, where internet connection can't be guaranteed all the time. The main principle is that e.g. recording issues and other work at field can be conducted off-line, and uploaded to the cloud-based project database when possible. Another common feature is, that the applications typically indicate if there is updates available to the project data stored into tablet, but the user decides if updates are downloaded instantly or later using better internet connection or to avoid disturbance for the work task going on at the moment, for instance.

3.2 Exploitation of Mobile devices and Safety data on site

Exploitation of mobile devices is relatively new phenomenon in construction sites. According to interviews performed in a Finnish construction company, at the moment the biggest issue concerning mobilization is the implementation of the new procedures into production. However, more and more applications are being released and software houses are constantly developing more user friendly applications, in order to help the implementation into construction sites. This on-going research project is encouraging software houses into development by evaluating mobile applications together with construction companies.

Similar to organizations in other industries construction and engineering organizations are leveraging mobile and wireless solutions to address the need for greater collaboration among a highly mobile and distributed workforce (Krebs 2009). Many mobile tools have also been tested for different kind of safety related purposes already, including sharing project designs and plans, recording and documenting safety observations, browsing safety data and guidelines, and various safety related measurements and calculations. Summary of found different kind of uses for mobile tools in context of safety management is presented in table 2, and the use cases are visualized by practical examples of possible utilization.

By the interviews carried out in the Finnish construction company, this research aimed to determine the utilization rate and user experience of mobile devices. One of the main findings was, that a safety level inspection application is considered the most valuable applications concerning occupational safety in the company at the moment. Production management personnel stated that it genuinely provides effective tool to audit safety level, and the additional features such as action assignment and automatic follow-ups were appreciated highly/evaluated useful. The possibility to assign task or notification to the responsible person by email straight from the application is not only saving time but making production management more efficient. Previously this whole procedure been conducted using pen and paper, and it must have been transferred to digital format after the inspection. As a result of using a mobile device, the inspection and reporting is completed once during the inspection tour, which saves time significantly. Mobile devices can be used also to take photos and attach them to the inspection report, making the documentation and positioning more accurate. At the moment, general contractors use mobile tools more than their sub-contractors/special contractors. As a result, there is still need to deliver information by e-mail to most of the subs, but in the future they will be provided an access to a web-based system to e.g. record safety notices and to get notifications of issues assigned to them. On the whole, the goal is to make safety observations available to all workers at the site, not only to the production management personnel.

Table 2: Safety related use cases of mobile applications.

Use case	***Short description or practical example of possible use***
1. Project and Safety document sharing	*Documents needed at field are carried along digitally in a mobile device or accessed on-line by web.*
2. Viewing BIM-based construction and safety plans	*Reviewing e.g. 3D fall protection plan with help of BIM viewer application.*
3. Safety Notices Management	*Recording notices at field digitally by mobile tools and putting an issue to someone's responsible and following corrective actions. Collecting, filtering and analysing up-to-date safety data is also possible, helping to decrease specific safety violations and develop safety management procedures.*
4. TR Safety level measurement (weekly observed safety level at the site, a Finnish method)	*Conducting mobile TR-safety level inspection and filing safety observations digitally, as well as calculating the weekly safety level rating automatically by the tool.*
5. Other safety inspections	*Ready-made digital checklists and forms, and filling out those digitally once while the inspection. Inspection forms may be for safety inspection process or checking cranes, for instance. Electronic time stamping registering visit entry and departure may also be included.*
6. Browsing Safety and security regulations and guidelines, and accessing safety and health sites	*Browsing OSHA-regulations, best practices, or fire protection standards at site. Browsing information on personal safety equipment requirements for a specific work*
7. Getting information and help without delay in case of illness, accident, or other H&S related situation	*E.g. iTriange: By entering the symptoms, one gets information about likely causes and a proposal for the treatment/action. By entering name of a drug/medicine, provides basic information and warnings related to the substance, and the location of the nearest first aid centre. (Professional Safety 2014)*
8. Accessing chemical safety data	*Information for chemical safety management by accessing chemicals database by mobile application. E.g. ChemAlert provides access to over 100 000 chemicals, and includes e.g. hazards classifications, recommended personal protective equipment and first aid information.*
9. Photos and Panoramic photos (360 degrees)	*Cameras can be used for documenting worksite conditions and helping safety personnel to identify safety hazards. Panoramic photos can be used for e.g. incident investigations and safety inspections, and created by help of specific applications such as DMD Panorama (Professional Safety 2014).*
10. Measuring safety of the working conditions	*Measuring angles of slopes to evaluate safety (e.g. Clinometer HD), or measuring sound level dB (e.g. SoundMeter) to determine whether a more precise measurement using more accurate device is necessary. Or measuring thermal conditions (e.g. OSHA Heat Safety Tool). (Professional Safety 2014).*
11. H & S related calculations	*E.g. iPad apps available for conventional safety management calculations (ready-made calculation formulas included in apps such as HSE Buddy).*

One of the first purposes of mobile tablet computers was to support more efficient access and viewing of 2D building designs and other construction documents at field, and at the same way, the traditional safety documents can be viewed digitally using tablets. However, designs and construction plans are used more and more by viewing BIM-based 3D models with tablets at field. As a natural step forward, BIM-based safety plans such as 3D fall protection plans can be viewed as part of construction documentation in the future. Figure 1 demonstrates how BIM-based safety plans could be viewed using e.g. iPad. Model viewing tools are already available for tablet computers, but BIM-based safety plans such as fall protection plans are not common in real construction projects yet. According to Krebs (2009), while BIM solutions were not designed with mobile applications in mind per se, mobilizing BIM applications significantly enhances not only their value but also the strategic value of mobile solutions to construction and engineering operations.

Figure 1: Structural 3D model including safety railing viewed in iPad using mobile application Tekla Field 3D.

3.3 Impact and benefits of the new technology

Summary of found and potential benefits of the new mobile technology are presented in table 3. Many of these listed safety related benefits may likewise be achieved in the quality assurance and management, for example, but information collected, recorded or analysed would just differ from the ones presented as examples in the context of safety management.

Table 3: Benefits of mobile technology in safety management.

Benefit	*Examples*
1. Time savings, and at the individual level easier to deal with issues/work assignments on one's own schedule	*Safety observations and notices are recorded and documented at once while inspection. Mobile application may also automate calculations related to safety auditing. Meeting minutes are made once during the meeting.*
2. Improved productivity	*Beside time savings, faster access to up-to-date project and safety related information improves productivity, as documents needed at field are carried along digitally in a mobile device or accessed on-line by web.*
3. More systematic, transparent and traceable process	*All concerned parties can see who and when created a safety notice or other record, who is responsible for correcting actions, how urgent it is to correct the issue, and a notification of fulfilling the task.*
4. Better information quality	*Easier to manage the project information timeliness with help of a cloud-based system. Easier access to e.g. safety regulations to consider safety more carefully in a specific construction phase or work task. More accurate documentation of safety issues, since information structure/content is standardized by digital forms in app and e.g. photos can be attached to any issue.*
5. Faster resolution of problems and faster access to first aid information	*Faster access to safety information and guidelines e.g. in a case of injury. After an accident, the history data of issue management may help find the reasons at the background of it. Additionally, faster resolution of any occurring issue in a project decreases also safety hazards.*
6. Automated reporting, filtering and summary concerning site status	*A list can be produced e.g. of all safety notices recorded at one building site, or of all which one specific firm is responsible for. Summary of the most common safety violence types at the specific construction site can also be automatically filtered from a cloud-based database, to tell which issues should be addressed and corrected.*

The most obvious benefits are 1) *time saving in resource use* and 2) *improved productivity*. According to a survey conducted by VDC Research, investments in mobile and wireless solutions provide real and measurable benefits, improvements in worker productivity being 30.1% (Krebs 2009). For example, in case of safety inspection, there isn't need to make written notes first and then make documenting as an additional task after getting to the office. Experience shows, that this speeds up the safety inspection process significantly (Lemmetty 2013).

In a tablet computer pilot construction project described by Löfgren (2007), the users experienced improvements in their own personal productivity when equipped with updated project information on tablet computers. Also to solve arisen on-site problems and critical construction issues there is a need for quick access to necessary information. Previously production management personnel used to run back and forth between the construction site and their computers inside the site office, leading to inefficient use of managerial resources. With issues resolved quickly and returned to the field accurately, field staff was able to continue to work unhindered. Additionally, meeting notes can be taken directly with the electronic pen on the tablet computer. Using the built-in tablet computer text recognition tool, the notes can be translated into an ordinary data text document when the meeting is over, which directly can be distributed via e-mail to project participants. (Löfgren 2007)

At site level, mobile cloud-based tools enable *more systematic, transparent and traceable safety issue management process*. Various players of the building project get better opportunity to inform others about their safety concerns, and all parties concerned get notification about the issue, as well as how and when it was solved. E.g. various subcontractors get better opportunity to plan their own tasks, since they will be notified if problems affecting their work occur at site, as well as when the issue is solved. At the end of the project there are less unclear issues.

Better information quality: Distribution speed, information quality and understanding of production issues communicated to involved actors can be enhanced (Löfgren 2007). Mobile tools provides faster creation of records once it is identified at field, and understanding of occurred issues is easier if text descriptions are supplemented with attached photos, for instance. Also information quality is better in manner of timeliness: If compared to the traditional way of carrying along blueprints, there is faster access to safety related up-to-date information, since drawings, 3D models and other documents can be updated to the mobile device for viewing whenever, provided that there is just Internet connection. Site staff does not need to go to view their computers inside the site office to get the information needed. In the other words, relevant safety information can be brought closer to the production event, where it can genuinely affect occupational site safety.

Faster resolution of problems and faster access to first aid information: In case of injury or accident, various mobile applications provide faster access to first aid information and help making documentation for later analyses. In the future, mobile information delivery provides possibility to completely new kind of information contents as well, since information is available in the web and can be combined automatically with the information, which origin is in totally different place or different parties of a building project.

Automated reporting, filtering and summary concerning site status: Beside direct benefits, the indirect benefits of mobile tools may actually be even more significant. If information on e.g. safety issues is systematically recorded, resulting project-specific database makes it possibility to automatically summarize, filter and analyse current safety hazards at site, as well as identify development needs in the longer term. Additionally, based on occurred safety issues on site, automated alarms become possible, such as issues to take care of today, issues to take care of in a coming week, and actions that are overdue. Such features are included e.g. in Trimble's "ProjectSight" application, when PC and web-browser is used as interface to project data recorded at site. The "Project dashboard" shows the summary of realized safety on the specific site, and by help of this automated safety issue analyses, the site manager can monitor what kind of safety violations have occurred most. Other automated features include possibility to filter safety notices in various ways such as "All" or "Pending me", for instance.

As a result of cultural differences in the traditional construction procedures, there are differences in the most appropriate or useful use cases of mobile tools in various countries. Löfgren (2007) describes that while supervising teams in the U.S. appreciated the tablet computer in their first pilots as a tool for handling and updating digital drawings, in Sweden that had a very limited application area due to a completely different way of administrating the blueprint update process. The tablet computer project in Sweden was leaning more towards enabling more effective on-site administration of construction activities through mobile on-demand access to existing business information systems and construction project administration tools to e.g. fill out field work report forms online. Cultural differences make also localization of the mobile applications necessary, since the interface of the tools should be as easy to use as possible and guide the user to common systematic workflows including e.g. using a relevant record type for a specific issue and filling the related information in a same way each time. These requirements can't be fulfilled, if terms are in foreign language and thus not clear to the users.

4. Discussion

Exploitation and effective use of mobile applications require features which are appropriate for construction and safety management procedures at field. As a result of national differences in traditional processes, this will most likely lead to localizations of the most promising tools. On the other hand, it's possible, that as a result of implementation of new genius mobile tools, the more effective working procedures are adopted and spread around the world deceasing cultural differences in construction processes. However, the traditional processes should not be digitalized as such, but at the same time with the mobilization it should be considered, if the process itself could be simplified as is the target in the Lean construction. Current web-based application stores provide very efficient selling and delivery network of mobile applications already now, but the internationalization of workflows would further increase their markets, and speed up development of the digitalization in construction industry on the whole.

In case of construction site´s mobilization, it´s important to take into consideration also risks related to mobile devices in general. Mobile devices and digitalization rise up concern about data security and reliability of mobile information. Further research concerning risk management of mobile applications at construction sites is definitely needed. It is also clear that mobile device itself can cause near miss situations or accidents by occupying personnel's focus in a dangerous working environment.

The Internet of Things (IoT) development of computer technology will bring whole new kind of possibilities to combine information for improving occupational site safety management. For example, Jiang et al (2013), identifies possibility to add new monitoring devices such as smoke sensor to the web-based safety management system. IoT development enables variety of data to be analysed and reported. By utilizing IoT and computer technology for example individual wellbeing of site staff can be monitored and analysed in order to support occupational safety and health.

5. Conclusions

Utilization of mobile tools is increasing rapidly on construction sites, and so do availability of mobile applications and cloud-based solutions meant for construction industry. Found mobile tools including some kind of safety related features were categorized in this research into 4 types: *Construction project management applications including safety related tools, Safety auditing or safety level inspection / measurement/rating applications, Applications for a single specific safety related purpose*, and *Applications meant for a specific construction phase or work*. These has been tested for various purposes in different countries, and especially mobilization of BIM and e.g. issue management seems significantly increase the value of mobile devices in the future.

The most obvious benefits resulting from mobile tools are time savings in resource use, and other productivity improvements at personal, site or company level. Achievable benefits include also more systematic, transparent and traceable issue management process, for instance, and better information quality e.g. in terms of timeliness. Faster resolution of problems and access to e.g. first aid information may become a lifesaver for an individual. However, the indirect benefits of automated reporting, filtering and summary concerning site status may be even more significant from the view point of improving site safety. If e.g. safety issues are systematically recorded, resulting project-specific database makes it possible to automatically analyse current safety hazards at site, as well as identify development needs in the long term. Additionally, based on occurred safety issues on site, automated alarms become possible, such as issues to take care of today, leading to more effective hazard prevention proactively. When sub-contractors also begin to use more tablet computers and the mobile applications, the general contractors and the building projects as a whole start to gain more benefits from these tools in terms of efficiency. That's because the same information doesn't need to be provided in many different ways for the various project parties anymore. Mobilizing BIM own remarkable potential to enhance their value, but also the value of mobile solutions to construction and engineering operations.

Abstract

Modern facilities management in digital systems requires user-friendly tools for visualization and decision making, and improved data. To help achieve this, 3D models can operate as a platform for integrating sensor data and other documentation for a building. If 3D models are not readily available for a specific building, measuring methods can be applied. In this article, a prototype of a building model with a sensor data visualization system is presented using an open source 3D platform. The prototype is utilized to visualize 3D models produced by terrestrial laser scanning, thermal camera images, and sensor data. Several development directions are identified for such systems.

Keywords: indoor air quality, building model, laser scanning, maintenance, visualization

1. Introduction

In building information modeling (BIM), the information representing different disciplines in the field of construction (architecture, engineering, etc.) are integrated into a three dimensional (3D) digital model. With the help of BIM, it is possible to detect collisions and conflicts in an early stage of design (Azhar, 2011) and, for example, improve scheduling in the construction phase (Tulke et al., 2008).

However, the construction and planning only represent a small fragment of the total life cycle of a building. Contemporary buildings contain a multitude of different technical systems that need to be managed during the operational life of the building. The increasing complexity of the buildings is putting pressure on the traditional methods of facilities management, as stated by Ahn and Cha (2014). Several authors have suggested that a BIM-based solution has to be applied for facilities management (Becerik-Gerber et al., 2012; Ahn and Cha, 2014). By aggregating facilities management data into a BIM model, the data management issues caused by missing or non-synchronous documentation can be solved (Ahn and Cha, 2014).

Sick building syndrome exists in Finnish public buildings (Audit Committee of the Parliament of Finland, 2013), as in so many other countries globally. Complicated building structures and growing needs for better indoor air quality increase the need to monitor, adjust, and supervise building parameters properly and illustrate data visually in a compact form (Hietsalo et al., 2014). More sensors and wireless networks are needed to fulfill those requirements. In particular, there is a demand for better control of relative humidity (RH), dew point calculations, CO_2 sensors and total volatile organic compound (TVOC) sensors to assure healthy indoor air. The absolute amount of water vapor in indoor air can be determined by combining data on RH and temperature. The difference between the amount of water vapor in indoor and outdoor air is a good indicator of the efficiency of building ventilation. In a similar manner, the pressure difference between the building interior and exterior is a good indicator of a properly operating ventilation system: If the ventilation system is correctly adjusted, the pressure difference should be low to prevent any unintentional air flows, and so forth. For monitoring the building envelope, continuous measuring is important, as the amount of moisture can, for example, vary significantly during a single day. As a result, one time measurements become unreliable. Sensors can also be integrated into building structures. By measuring the moisture of building structures, it is possible to monitor, for instance, the drying of a concrete structure after repair work. By combining the data from indoor condition measurements and structural measurements, there is the potential to estimate the risk of mold growth.

If BIM-based facilities management methods are to be applied in these cases, measuring and modeling becomes essential. On this point, Tang et al. (2010) provide an overview of the automated as-built BIM reconstruction problem and some of the partial solutions. This reconstruction can be performed manually, by viewing a point cloud in a computer-aided design (CAD) suite and building the model (Mill et al., 2013). A similar approach can be found in building modeling using terrestrial laser scanning (TLS), as presented by Arayici et al. (2007)

for example. In most cases, however, the modeling is too laborious. While the project may be carried out without the comprehensive model, many of the benefits of BIM are not attained.

For both manual and semi-automatic BIM reconstruction, laser scanning can be used as a measuring method. In measuring the built environment, it is usually applied as TLS, with the instrument being mounted on a tripod. In laser scanning, the laser pulse travel time or phase difference is used to calculate distances relative to the scanner position. By combining data from the scanning angle and impact of atmospheric reflection caused to the speed of light on the time data, 3-dimensional locations of the scanned points can be identified. If the scanner positions are known, several scans can be combined to create a larger point cloud of the built and natural environment (Virtanen et al., 2014c; Lehtola et al., 2014; Kankare et al., 2013). The high point density and fast acquisition speed make laser scanning an efficient method for documenting complex building surfaces (Virtanen et al., 2015), rapid prototyping (Virtanen et al., 2014a), and detecting structural deformations in buildings with great accuracy (Virtanen et al., 2014b). On this point, Chee Wei et al. (2010) present the workflow for utilizing terrestrial laser scanning from a cultural heritage documentation project. The documentation of the chosen artifact is conducted with a laser scanner. Scanning targets are used for both registering the scans and geo-referencing the project. In addition, digital images are taken with the integrated camera system of the scanner to obtain RGB values for the scanned points (Chee Wei et al., 2010).

Mobile laser scanning (MLS) has generated a large amount of interest for measuring and modeling urban environments. In particular, it is suited for measuring in outdoor environments, producing models of e.g. building facades. Typically, MLS systems are mounted on regular cars, but there have been implementations of MLS on a cart or an all-terrain vehicle (ATV). One such example of a MLS system is the ROAMER system, developed at the Finnish Geodetic Institute (Kukko et al., 2007). The essential components of a MLS system are a laser scanner, GPS receiver, inertial measuring unit (IMU), and data recording system. The GPS and IMU are jointly used for the accurate localization of the MLS systems (Kukko et al., 2007).

In addition to laser scanning, image-based measuring methods (digital photogrammetry) can be applied for precise 3D documentation (Virtanen et al., 2012; Kurkela et al., 2012). Different types of images (panoramic image mosaics, image databases, sensor images, and multispectral photographs) are employed to produce information from the environment.

Another significant source of data concerning buildings are sensors. Several types of sensors can be installed in a building to measure a variety of parameters (such as CO_2, temperature, and amount of light). In this field, one of the research directions is wireless sensor networks (WNS) that can be applied in construction and building maintenance. As the “health” of a building is dependent on a large group of factors, different sensors are required to follow a group of parameters. To produce comprehensive data, these sensors have to be scattered across all parts of the building and also installed inside the structures. WNS can help reduce the amount of cabling needed for such installations and thus help reduce costs. When using sensor data for decision making in construction, data visualization becomes a central task. A large amount of data must be presented, preferably dynamically, so that it can be seen in near real time

(Hammoudeh et al., 2015). If this data is to be utilized in decision making with the 3D building models, they have to be visualized together. This both simplifies the interpretation of data and enables the detection of correlations (Motamedi et al., 2014). It is possible to identify temporal correlations from the sensor data, e.g. the impact of microbiological activity on the CO_2 concentration. It is also possible to search for long term trends and thus try to identify potential problems before they emerge and become acute. In current planning and maintenance systems, buildings are mostly studied as individual entities. This reduces the overall efficiency that could be reached by looking at interactions not only within a single building but between buildings. Networking the buildings and analyzing their data, energy, and resource flows is the key to unlocking the full potential of these networked, smart buildings. The resulting Internet of Buildings can share resources and thus optimize the use of energy and services, to maximize the efficiency when using renewable natural resources. For buildings in this networked ecosystem, new business models can be created, thus improving the conditions of the building owner as both a consumer and provider of services (Lukin, 2015).

The four mentioned aspects are combined in the future digital models used for building upkeep and maintenance (Figure 1). Firstly, a digital 3D model operates as a platform for information and forms the starting point for all building maintenance activities. Secondly, all data concerning the building is aggregated on top of this model, the individual data sets being bound to respective model components. Thirdly, the sensor data from the building is integrated into the same model and visualized. And finally, the model has to operate in a networked system, enabling the integration of several buildings or other online resources. In addition, if the proposed solution is to be applied to the current building stock, for which no BIMs exist, the starting data for the model has to be generated using the existing 3D measuring techniques.

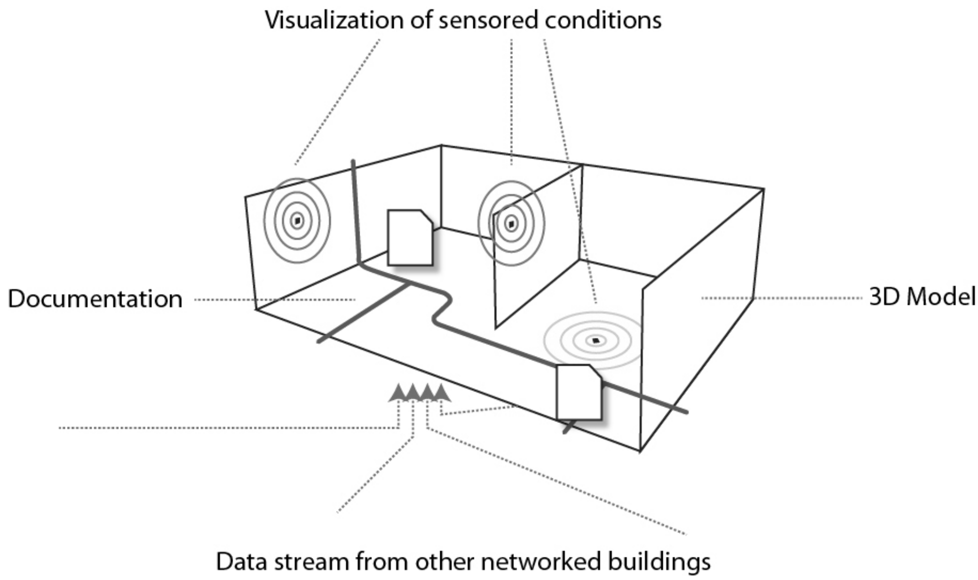

Figure 1: The aspects of future digital models used for building upkeep and maintenance

Thus, this paper presents a 3D visualization method as a tool for analyzing and viewing 3D building models with additional sensor data. 3D measuring techniques are utilized to produce models that depict the building as it is in use. The visualization results focus on indoor air quality measurements. This solution will provide information for monitoring the status of the indoor environment of the building. The goal of the system is to improve indoor air quality and reduce the cost of unnecessary renovations.

To proof the system, various sensor data will be combined with a 3D model. Data from imaging sensors, such as a thermal camera, and individual sensors, such as temperature, moisture, and carbon dioxide, is used as the test data set. Moreover, an open 3D application development platform is utilized to visualize the building models. A user interface is then developed to facilitate the study of time series. The resulting model can then be used to study the state of the building and its indoor air quality. Based on this prototype, the aim is to outline future development directions. To take the whole operational life of the building into account, models have to include, as much as possible, all information concerning the use and upkeep of a building.

2. Materials and methods

2.1 Measuring methods for indoor environments

The open source 3D Internet application platform was used to host the building models created and operate the developed applications. The resulting virtual scene is defined in a TXML file, following the XML syntax. Each object in the scene is defined, with the object geometry being stored in an external file, accessible over an http connection (realXtend, 2015; Alatalo, 2011).

To obtain indoor measurement data from one of the test sites, the test utilized the Faro Focus 3D terrestrial laser scanner and Matterport Pro 3D Camera. Faro Focus 3D is a conventional TLS instrument with an integrated camera designed to obtain texture images that can be used to colorize the point cloud in later processing (Faro, 2015). The distance measurement accuracy of the instrument is ±2 mm at a distance of 25 m (Chow et al., 2012). Faro Scene software was utilized to process and co-register the TLS scans. Matterport is a commercial solution for measuring indoor environments based on depth camera technology (Matterport, 2015). The device is used to acquire a set of panoramic depth images from the environment, with each image covering a full 360° field of view. The 3D reconstruction process is performed automatically with cloud computing. After the user has uploaded the measured data, an optimized alignment of the 3D captures is solved, and a textured mesh model created (Bell et al., 2013).

Four different model reconstruction methods were employed: three dimensional models were created from the TLS point cloud using AutoCAD 2016 and Geomagic Design X. In addition, the automated generation of a mesh model was performed from the TLS point cloud by using Geomagic Studio 11. For the Matterport data, the automatic online service of Matterport was used to obtain the mesh models. After the modeling, game engine compatible models were created in Blender for use as game engine equivalents for the visualization.

2.2 Sensor networks

Data from the 720 indoor air quality measuring system (720, 2015) was employed in the experiment. The sensors were installed in two rooms of the test building. The data consisted of the hourly averages of the CO_2 concentration, relative humidity, temperature, and TVOC concentration. In total, the time series contained some 1030 readings, spanning a time period of 43 days. A small application was also written on the platform to visualize the data.

2.3 Online 3D building maintenance model

To assemble an online 3D representation of all data available from the building, a data model was utilized that divided the data into both individual spaces and data types. In the resulting model, each single entity of data (e.g. a Flir image or a 3D indoor model) was given two identifiers, a room code and a data type. The data types are provided in Table 1. The full set of metadata defined for objects is given in Table 2.

Table 1: Data types

Name	*Description*
2D CAD	*Two dimensional CAD drawing*
3D CAD	*Three dimensional CAD model*
Mesh	*Triangulated 3D mesh*
FLIR	*Thermal image*
Picture	*Image*
Point cloud	*Three dimensional point cloud*
Document	*Text document*
Other	*Other than above types*

Table 2: Object metadata

Attribute	*Description*
Data type	*Data type (listed in Table 1.)*
Data source	*Description of source (e.g. measuring instrument used)*
Room identifier	*Unique identifier of room in building (e.g. room number)*
Building identifier	*Identifier of building (e.g. address or name)*
URL	*Path of the full data (e.g. on intranet server)*
Additional information	*Any additional descriptions of data set*

As the chosen game engine-based system was unable to represent all object types, game engine equivalents were created for all objects. These equivalents were created by producing mesh models of the reduced polygon counts for all 3D objects and textured planes for the 2D objects. After this, the location of the actual data was input to the metadata of the object in TXML. Thereafter, an application was developed that allows the user to select individual spaces of the building, to choose the displayed objects according to data types, and to study the values of the sensor time series.

3. Results

By using the methods described, a virtual scene depicting two rooms of the test building was created. The orientation of these data sets was resolved manually, and the metadata was input for the objects. The resulting scene was hosted using a realXtend server. In the tests, a local machine was used to run the server and access the scene. In the scene, different measuring data sets are displayed in the same virtual 3D space.

In the scene, a user can filter the displayed object according to the data structure described, fetching data sets of a certain class from each room individually. The counts of objects available on the server for each type are displayed. In addition, there are tools to hide all data sets or isolate an individual data set for study. The values obtained by the 720 sensors are displayed next to each room. To enable functionality, a user interface is provided for jumping backwards and forwards in the time series. Accordingly, Figure 2 illustrates the system displaying Matterport mesh models for both rooms, the sensor data for both rooms, and a set of thermal images for the other room. As shown, the user can move freely in the virtual 3D space. Figure 3 also demonstrates a preview of a thermal image being shown inside a mesh model.

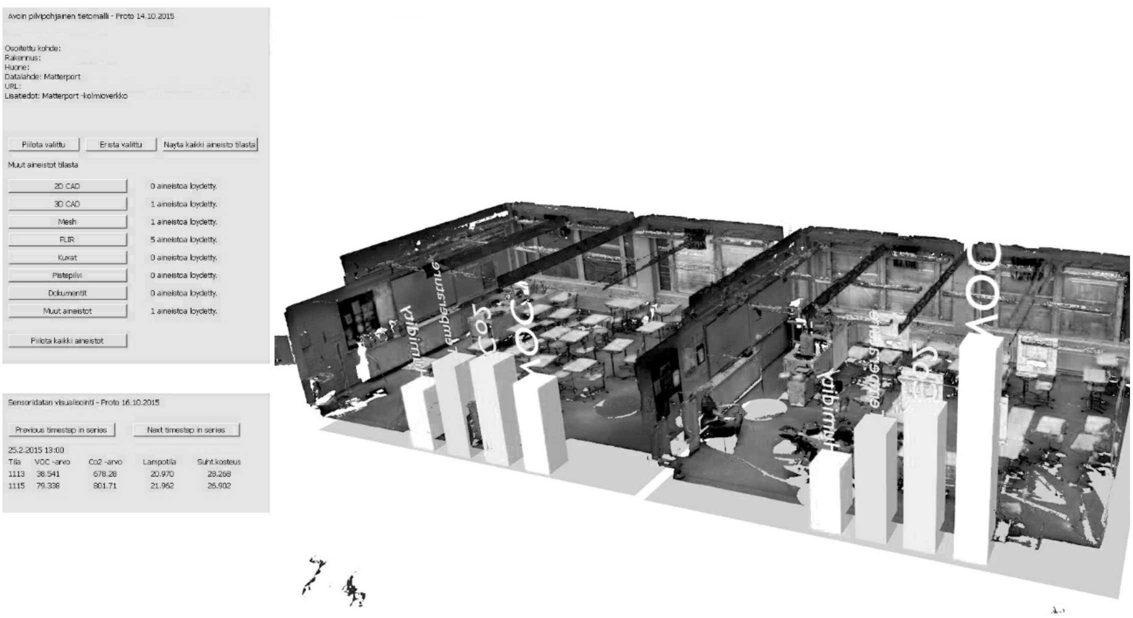

Figure 2: System in use, displaying some data for both rooms

Figure 3: Studying an individual thermal image in the data set

4. Discussion

The presented setup is able to display objects of different types in a virtual 3D space and also sort them according to the metadata. There are a number of advantages that can be found in the proposed system. Firstly, the concept of using game engine equivalents is essential for the development of computationally light applications that operate over the Internet. As there are already browser-based systems that utilize the same architecture (Meshmoon, 2015), the possibility of developing fully browser-based tools remains. A simplified, game engine-optimized model can, in these systems, be used to depict a larger, more complex model. In this way, the user can preview the model relatively quickly and then download the full model later, using the existing tools of the industry (e.g. point cloud processing software or full-featured CAD) to study and process the actual model. Secondly, the usage of game engine equivalents enables the utilization of existing game engines for application development. This is already being conducted in several cases where, for example, Unity (Unity, 2015) is used to display building models. Thirdly, by leveraging the typical features of game engines, the system is able to represent both 2D and 3D data along with dynamic and static data in the same environment.

However, as the system is still a very early prototype, it has a number of apparent shortcomings. Firstly, the amount of automation in the content production is very low. Content building methods more familiar to the game development industry than construction have to be applied for making game engine equivalents of the 3D models. As such, the system is unable to directly support model formats commonly used in construction (e.g. DWG or IFC). Secondly, the orientation of the data sets with respect to each other has to be solved manually, if the data sets are in a different coordinate system. For example, Matterport mesh models had to be manually moved to match the coordinate system of the TLS campaign. Finally, there are no automated tools for adding new objects to the scene; the user must use the tools offered by the platform. These shortcomings render the current system unfeasible for immediate wider adaption.

Comparing the presented prototype to the aspects of future digital models employed for building upkeep and maintenance as presented in the introduction, it is possible to identify several development directions for the system. The future development roadmap is summarized in Table 3. The main development directions are the increase in the applicability of the system to large models, the inclusion of the entire building life cycle, and finally the support for sensor networks. With these development directions, the integration of geometric, sensor, and maintenance data becomes an important research focus.

Table 3: Future development directions

	Large, detailed models	*Building Life Cycle*	*Network of smart buildings*
Application	*Renovation* *Existing building stock* *Modeling of large complexes*	*Life cycle simulation* *Building maintenance* *Comparison with as-built data, identification of deviations*	*Multi-building systems* *Prediction models, alerts*

Data sources	*Big Data* *Open Data* *Measuring methods*	*Facilities management* *Building planning*	*Internet of Buildings* *Dense sensor networks*

5. Conclusions

Smart management of existing buildings requires new tools that integrate data from several sources and enable the study of networks of buildings. Based on the literature, the four features of future models used for building upkeep and maintenance were identified: the use of a virtual model as a starting point for operations, the aggregation of data on top of the model, the integration of sensor data to the model, and the building of an Internet technology-based networked system for maintaining and accessing the model.

In the presented experiment, data from 3D measuring techniques and imaging was used to build a prototype of such a model, consisting of two rooms in a larger facility. To achieve this, virtual world technology was used as a platform for the prototype. A simple application was then developed to facilitate the study of the models and other data. As such, the system was able to visualize the data. However, the low degree of automation in constructing the model prevents the immediate adoption of the proposed system.

Future development directions include the increase of automation in the content building of the presented system, the utilization of browser-based technologies, and the pilot use of the system to better identify development needs. With measuring techniques such as MLS, a 3D time series can be created for identifying geometric changes in the environment. 3D application platforms based on client-server architecture are well-suited for prototyping these models and visualizing data from the various sensors together with the 3D models.

Abstract

Building Information Modelling (BIM) as emerging technology, bears promise to enhance the process-integration in the AEC industry and thereby enable life-cycle optimization of built environment. BIM model should serve as a joint knowledge database for the interdisciplinary planning team, offering thereby significant potentials for analysis and optimization of the over-all energy- and resources efficiency already in the early design stages; however these potentials remain largely still unexplored.

This paper explores the potentials of BIM as support tool for life-cycle assessment (LCA) and structural analysis in the early design stages on a case study of a timber-structure housing block. The timber-based structure and wooden façade promise higher eco-efficiency in terms of CO2 saving, however in order to support the decision making process towards such more sustainable construction, a decision making process towards optimisation of the structure based on life cycle and structural analysis is needed in the design stage.

Upon initial creation of BIM architectural model in Archicad, we carried out a comparative life cycle analysis study for assessment of the environmental impacts of the construction materials. The automated process using BuildingOne Tools with direct access to BIM model linking the eco-indicators to the specific materials and building elements and assessing overall eco-efficiency was compared to the "manual" data handling and LCA-calculation using Exel Software.

The varying needs concerning the Level of Development (Level of Development is the degree to which the element's geometry and attached information has been thought through) and semantical differences in the modelling procedures of the part-taking disciplines (architecture and engineering) were identified as main reasons for the defects of the building models.

Further on, lack of standards for parameterization of intelligent, digital building products in terms of LCA, that would unify property definitions used by eco-inventories or environmental product footprints and BIM libraries represents difficulty for the automation of life-cycle assessment. zIn order to improve BIM based life-cycle analysis, not only interoperability of the software has to be improved, as well as re-design of the design process and enhancement of individual capabilities.

Keywords: BIM, LCA, Optimization, Structural Analysis

1. Introduction

The achievement of sustainable built environment is based on energy and resources efficient construction. Thereby the design stage is of crucial importance (Azhar et al, 2011), since the impact of decisions made in this stage has the largest impact on the life cycle performance, at a very low cost. Simultaneously, the early design stage is critical in terms of decision-making and knowledge management, since the level of design-information is low, the design-knowledge is mostly implicit and difficult to grasp or communicate, which makes decision-making process extremely difficult. Simple, easy to handle tools for the prediction of future building performance that would enhance the decision support in the early design-stages are lacking. Thereby, design-oriented methods for prediction, simulation and optimization enabling decision making support in the choice of most balanced solution in terms of environmental performance and resources efficiency are needed.

Buildings run through various life cycle stages – design, construction and operation, where in each phase data is exchanged among team members, in order to document the current state of the building. The information exchange occurs on several levels – face to face communication, analogue, drawings or planning documents, digital or CAD planning documents - along proprietary or open data standards (interfaces) in various software platforms. There by knowledge transfer and loss represents the greatest challenge, partly due to the fragmented nature of AEC industry and silo-thinking, and partly to the lack of efficient means and methods for data exchange and transfer.

Building Information Modelling (BIM) as emerging technology, bears promise to enhance the process-integration in the AEC industry and thereby enable life-cycle optimization of the built environment (Fellows and Liu 2010). BIM, as defined by National Building Information Model Standard Project Committee (buildingSmart, 2015) is a digital representation of physical and functional characteristics of a facility. Various 3D, intelligent, data-rich building information models can be exchanged within the project team and ideally throughout the life cycle of a facility (Smith and Tardif, 2009). BIM acts thereby as an integrated platform for team members to share and exchange project information in the phases of design, construction and operation (Eastmann et al, 2011) thus serving as planning documentation as well as for data management; supporting decision-making process. In order to enable smooth data exchange and transfer without data-losses, open standards and interfaces are needed, such as IFC - Industry Foundation Classes (buildingSmart, 2015).

Further on, BIM as a parametric, data-rich model enables follow up analysis such as structural analysis, thermal or lightning simulation, assessment of environmental and economic impacts through life cycle assessment, life cycle costing etc. (Diao et al, 2011). However, in order to employ such follow up analysis in the early design stages, and make it a standardised procedure within design process as decision support instrument, ease of use, user-friendliness and high level of automation in data exchange between various tools is needed.

Using a case study of timber-structure housing block, we will explore the potentials of BIM as knowledge platform for life cycle optimization in the early design stages. Thereby we will apply the BIM modelling methods for the creation of architectural model, and carry out follow up analysis involving life cycle assessment and structural analysis, thus enabling design-optimization in the early design-stages. Thereby we will evaluate the employed software tools as well as the work-flows, and outline the potentials and deficits.

2. Related Work

Potentials of BIM-use for life cycle analysis in the design stage has been of increasing interest in the research community. Especially interesting is so called BIM to BEM approach – transfer of building information models to building energy modelling for follow up thermal simulation. Model exchange in this area has been especially troublesome, since commercial BEM software such as Energy Plus or similar do not support IFC interface, but a proprietary gbxML interface, which makes the transfer particularly troublesome. Researchers such as O'Donell at al (2014) propose a workflow for BIM to BEM based on IFC interface, proposing so called BIM Model View Interface, allowing semi-automated model exchange. Schlueter and Theselling (2009) develop a proprietary tool for energy performance analysis in design stage for Autodesk Revit software platform. Azhar et al. (2013) undertake a thorough analysis of BIM fitness for sustainability assessment using LEED rating analysis, establishing a procedural framework between the environmental analysis that can be carried out using BIM model, and LEED credit requirements, however they conclude that the automation of the workflow is not possible, due to the lack of LEED features integrated in the software.

3. Research Design

Upon initial creation of BIM architectural model in Archicad 19 BIM-Software platform, we carried out a comparative study of life cycle assessment of the environmental impacts of the construction materials. The semi-automated process using BuildingOne Database with direct access to BIM model linking the parameters of eco-indicators to the specific materials and building elements and assessing of overall eco-efficiency was compared to the "manual" data- and parameter handling and LCA-calculation using MS Excel. The obstacles in the semi-automated process will be identified as well as the difficulties in the manual process.

In the further step the primary loadbearing structure from the architectural model was transferred to the structural analysis software package via .ifc interface, in order to optimise the load bearing structure. Thereby data-transfer was tested in terms of data-losses and model coherence from architectural to structural model.

The Case Study consists of following steps:

1. Step: Creation of BIM model for a specific case – exploration of densification potentials of supermarket sites

2. Step: BIM for LCA – comparative study of a) semi-automated LCA using BuildingOne Database and b) manual LCA using Excel sheet (not automated)
3. Step: Work flow analysis of Transfer of BIM model to Structural Analysis via IFC interface

3.1 Methods and Tools

For the creation of Architectural Model, Archicad 19 was used, as certified software for both .ifc import and export. The model was created in the Level of Development 300 (BIMforum, 2013). Thereby the building elements are defined as load bearing and not-loadbearing (walls, columns and slabs). The building elements are defined as multilayer-building elements, in order to be allow latter parameterization of material and elements through parameters such as area, eco-indicators, etc. of the building elements, needed for the LCA.

Life Cycle Analysis was carried out applying the IBO (Austrian Building and Ecology Institute) OI3 Index (2013) methodology. The OI3 Index is generally based on assessment three of indicators – Global Warming Potential - GWP, Primary Energy Indicator- PEI and Acidification Potential (AP) for the construction-materials of a building. The single materials are bundled into the multi-layer building elements (e.g. exterior wall). The methodology finally proposes an assessment of a single, synthetic indicator as weighted sum of the three sub-indicators, which is benchmarked with the proposed grading system, finally obtaining a level of certification within the IBO-Index system. The methodology proposes several scenarios regarding (spatial) system limits, ranging from inclusion of building envelop only, to inclusion of complete building systems. We have opted for so called BG1 scenario, where complete thermal building envelope and interior slabs only are included in the assessment (interior walls excluded). The data-base used for the attribution of eco-indicators is also IBO Catalogue of Elements.

BuildingOne (2015) is a database originally created for the management of room-data sheets, enabling quantity survey, cost calculation and estimation. It offers bi-directional data exchange between the database and BIM software, such as Achicad 19 or Revit, and the data synchronisation. Through compilation of own queries customised calculation can be carried out, and exported into MS Office Platform (Excel). Since quantities (parameters) can be user-defined, the follow up calculation it terms of LCA can be carried out using customised queries and scripts.

Structural Analysis of primary loadbearing structure (timber) is carried out using Dlubal REFM software, for the Finite Elements Analysis. RFEM provides deformations, internal and support forces as well as soil contact stresses. Add-on modules facilitate the data input by creating structures as well as connections automatically and perform further analyses and designs. Since there is no direct, proprietary interface between Archicad and Dlubal REFM; the data is transferred using IFC interface. The model in Archicad is crated in such way, that building elements are differentiated in load bearing and not-loadbearing elements, only loadbearing elements are transferred in the Structural Analysis Software, for the simplification of the analysis-process.

4. Case Study

4.1 Architectural Model

In the year 2025 a population of almost two million people is being expected in the city of Vienna, which means that about 11.000 new apartments will be needed each year. As building land reserves are rapidly decreasing, new concepts for supporting densification are required. Numerous supermarkets within highly urbanized neighborhoods and their related vast parking spaces represent huge building land consumers, promoting urban sprawl as a result.

In this case study, a densification-concept is developed through proposing a timber housing block on the parcel and above one of such supermarkets in Vienna, in order to improve the overall ecological efficiency of the site (expressed in kg of CO_2/Occupant). Thereby the design is carried out using BIM planning method, exploring the potentials of BIM for follow up analysis such as life cycle assessment for compilation of eco-efficiency and structural analysis for feasibility and optimization of the load-bearing system.

The model is as mentioned in the chapter 3.1 modelled in Archicad 19 BIM software (Figure 1), as open-platform BIM software, enabling data-transfer using .ifc interface (open standard). Projects are temporary constructs, characterized through high level of uncertainty, e.g. unknown planners and software-constellations. In such setting, open interfaces are needed for smooth data transfer and project progress.

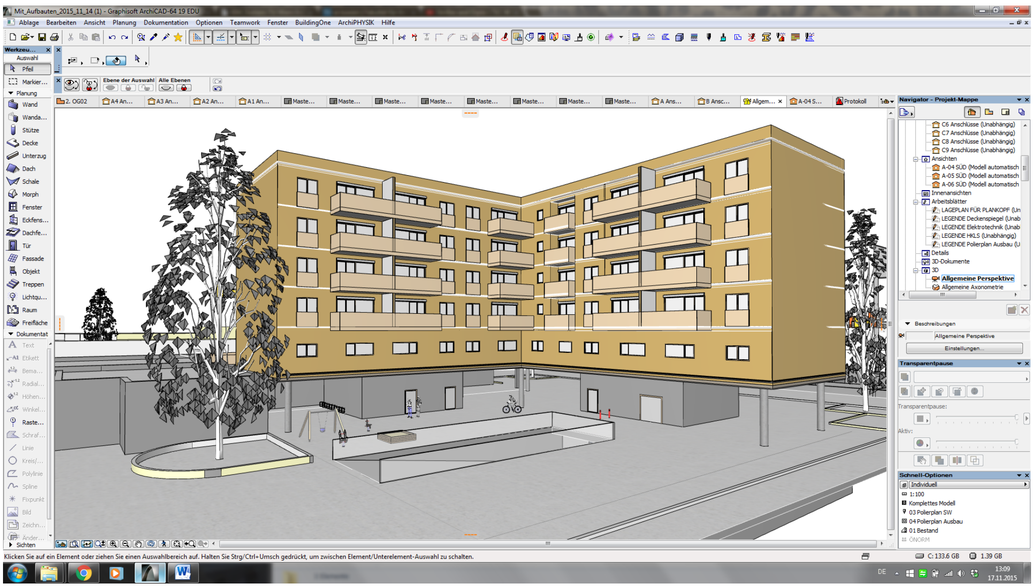

Figure 1: Architectural Model

All of the building elements regarding the building envelope (outer façade walls, roof, bottom slab) as well as the interior slabs were modelled as multi-layer elements (Figure 2), in order to be able to carry out the latter LCA according to OI3 Index, with system limit BG1.

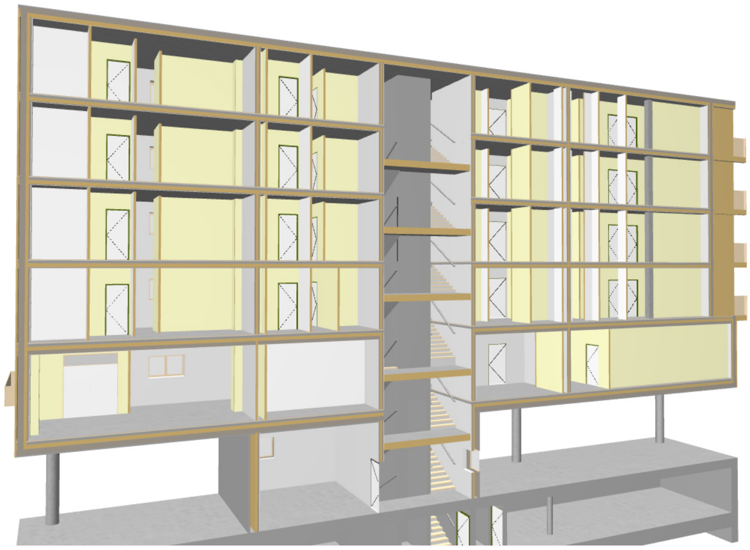

Figure 2: LOD – Multi-Layer Elements

Since eco-indicator data is difficult to obtain for specific materials, as first step the layers were defined in descriptively in .xls using the eco-indicators. Only after this the multi-layer elements were modelled and parameterised in Archicad – Model (Figure 3).

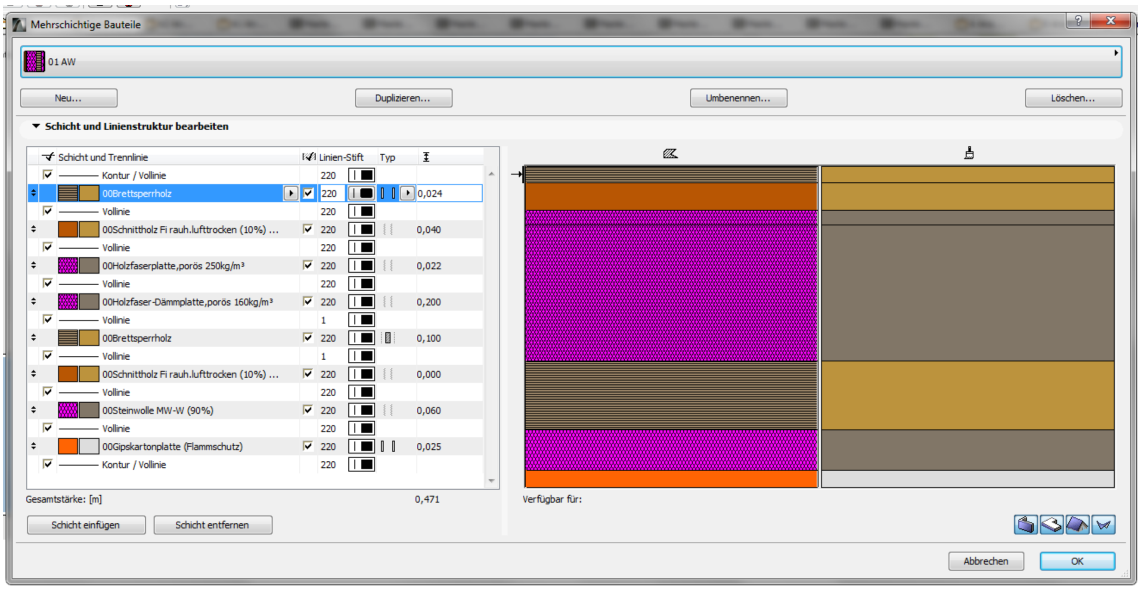

Figure 3: Multi-Layer elements – Parameterisation in Archicad

4.2 Life Cycle Assessment – A Comparative Study

After defining the multi-layer elements, two ways of carrying out the LCA were tested. In the first step the BuildingOne Database was tested, using BuildingOne plug-in in the Archicad. Initially a configuration was carried out, which we defined which building elements and properties should be exported to the database. To make this process easier, we created a layer combination called "OI3" in Archicad, which includes the building components relevant for the OI3-Index. Through this configuration, later mistakes, which can appear through synchronisation of wrong building components were avoided. Afterwards the multi-layer elements together with relevant parameters such as area, volume, layer (material) etc. were exported in the BuildingOne (Figure 4). In BuildingOne the elements were further parameterised through eco-indicators, which was carried out manually. However, due to the direct connection with the BIM model, all of the model-changes are synchronised with the database. For the calculation of the each OI3 Index indicator (GWP, PEI or AP) customised queries have to be compiled, as well as for the final calculation, which requires know-how and experience in the work with databases, which normally the designers and architects do not have. Finally the eco-efficiency report from the database can be exported in .xls for further processing.

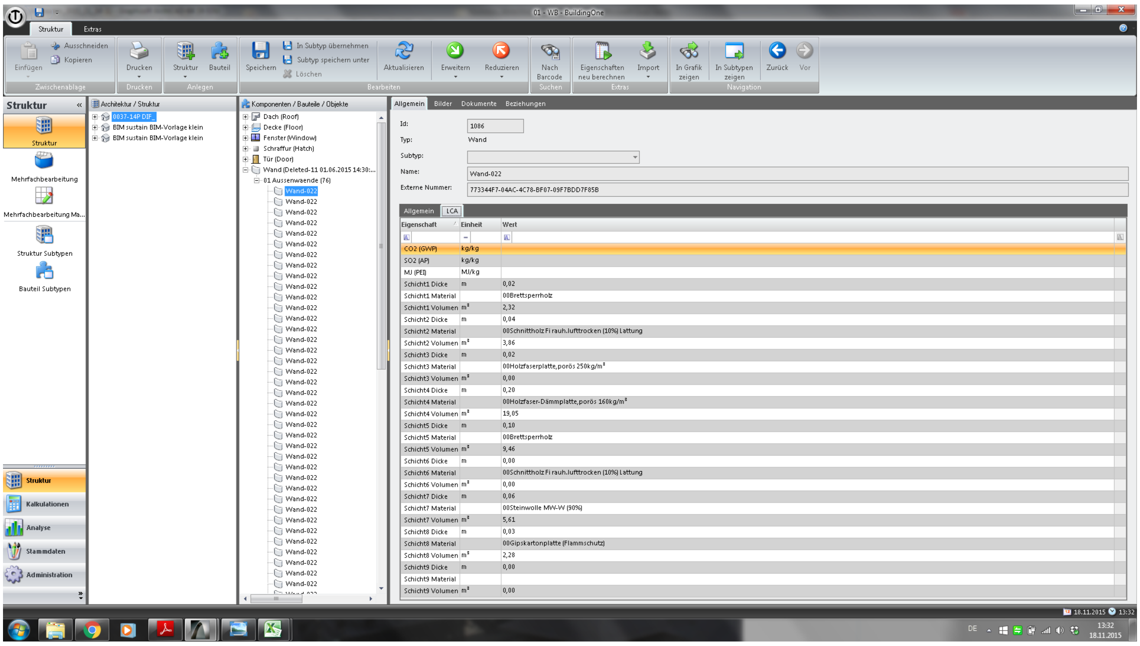

Figure 4: Data Management in BuildingOne

For comparison, the manual handling of data was carried out directly in .xls, where the originally compiled list of building elements and related eco-indicators was manually processed by adding the parameters such as areas and weight for final calculation of OI3 Index (sum of the parameters). The manual processing was easy and fast for handling, however due to the lack of automated synchronisation, prone to errors due to model-changes, such as areas, which had to be adapted manually. Figure 5 shows the comparative study, and advantages and disadvantages of both processes.

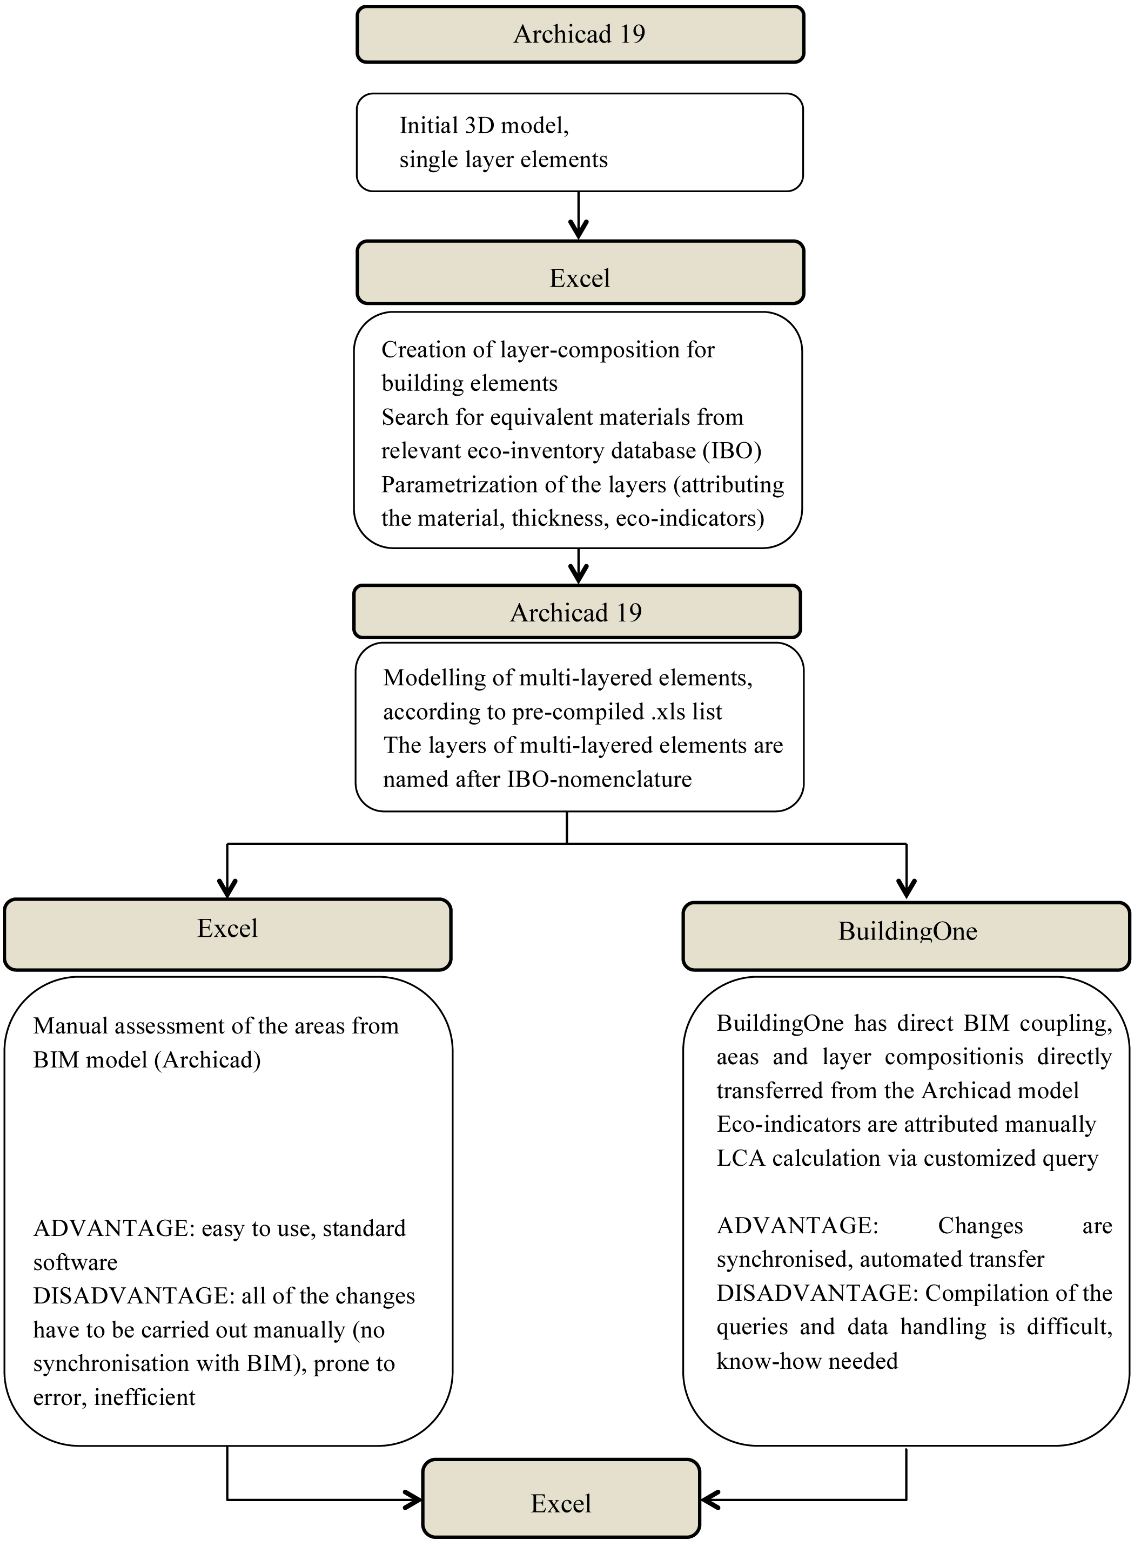

Figure 5: Comparative Study: LCA using BuildingOne and MS Excel

4.3 Structural Analysis

The primary focus of this study was to prove the data exchange efficiency between architecture (Archicad 19) and structural design and analysis (Dlubal REFM) modelling. The data and model exchange process still required model-repairs after the import in the structural analysis, despite the fact that the architect was instructed by the engineer about the required model-quality for the transfer. The work-flow analysis is presented in Figure 6.

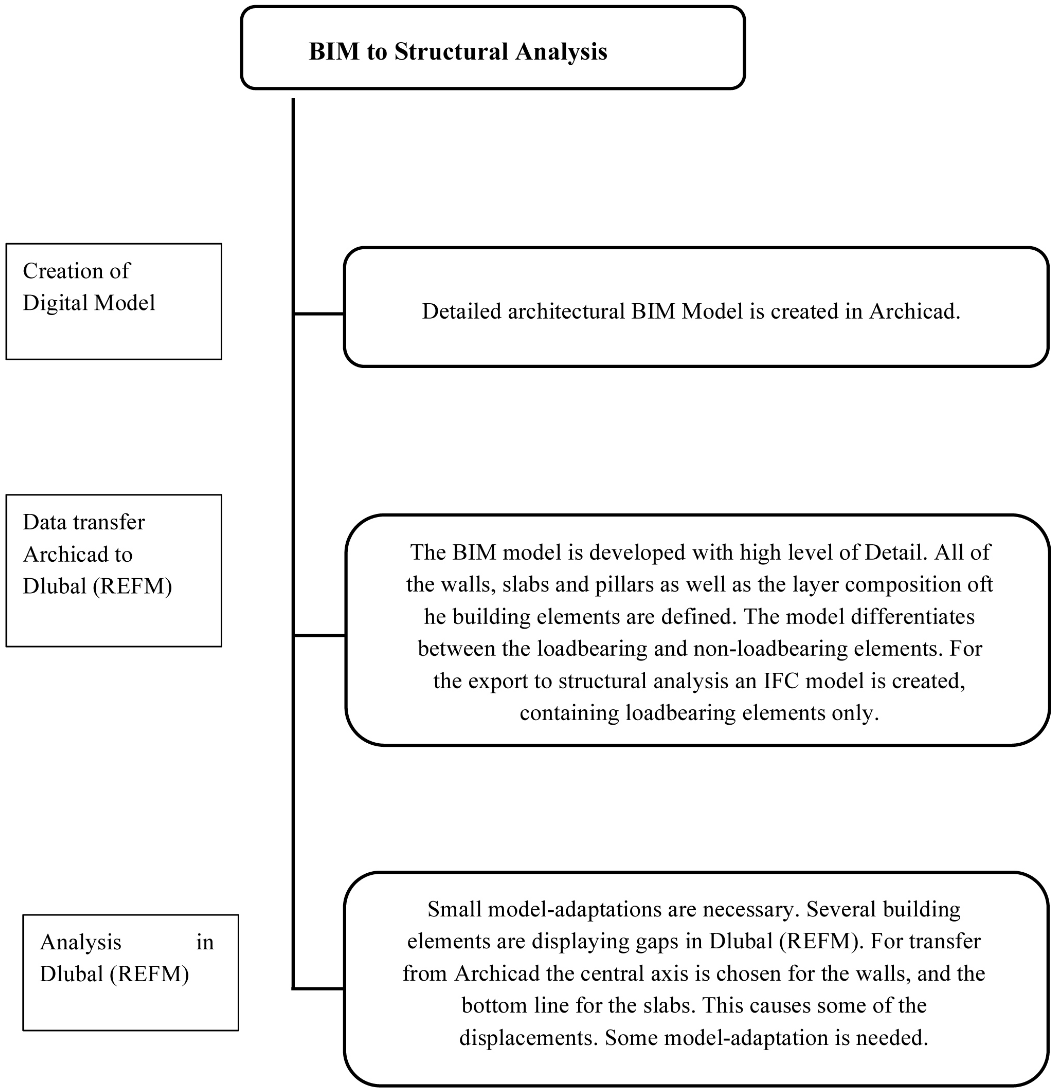

Figure 6: Structural Model before repair (slabs and walls intersecting)

In order to solve the lacking of geometrical intersection of various elements or of the wrong interpretations of geometry after export, model-repair had to be undertaken as shown in Figure 7.

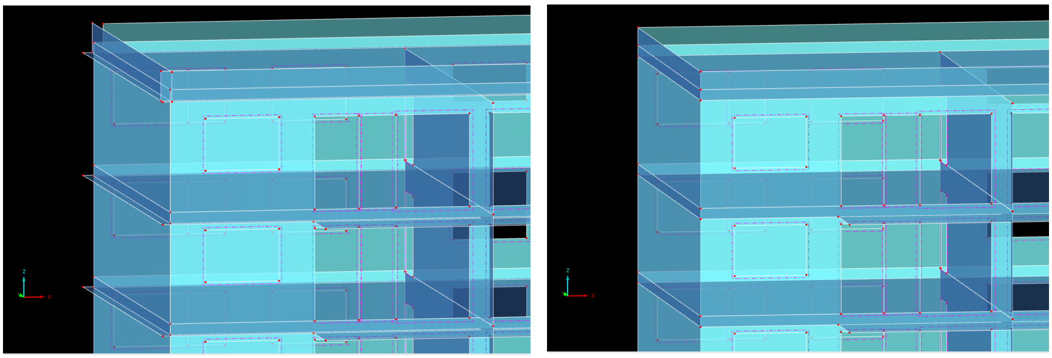

Figure 7: Structural Model before (Left) and after (right) repair (slabs and walls intersecting)

A development of a method for the discretization of geometry is here required, to bridge the semantical differences and varying needs in the modelling of architecture and structural engineering (e.g. slab-to-slab column in architecture; continuous column in structural engineering). The automation-procedures for model repairing and bi-directional exchange should be developed, in order to enable more effective interdisciplinary BIM supported design process.

5. Discussion

Despite of the intensive efforts of bodies such as buildingSmart (2015) or Austrian Standardisation Institute (ÖNORM A6241-2, 2015) to support interoperability through unification of building objects and their attributes (buildingSmart Data Dictionary – bSDD, 2015) there are large differences between the BIM data and the eco-inventories. Databases contain diverging descriptions (nomenclature) of building elements or materials, which again disables process-automation. Further on, manual parameterisation (attributing of eco-indicators) of materials of either multi-layer or single-layer elements in BIM model itself is not possible at the current moment (in Archicad 19). The elements contain some eco-indicator data already, however this data does not correspond to the Austrian LCA-Standard, nor are the system limits known (black-box problem), thereby the provided data is not valid for a sound LCA assessement.

BuildingOne has proved as potentially very useful tool. Due to the fact that its original purpose was cost accounting and area management and not LCA, some difficulties were encountered along the line of discussion above - some of the identical walls have a different identification number (attributed according to the position). A query for grouping of the elements must be compiled. A lot of effort is needed to customise the database, so if using such a tool, designers need skills and enhancement of capabilities.

As further general problem the Level of Development can be identified. The question remains in which Level of Development the model should be modelled for each life-cycle stage and for which specific purpose. The LOD 300 is defined by BIMforum (2013) as:

” The Model Element is graphically represented within the Model as a specific system, object or assembly in terms of quantity, size, shape, location, and orientation. Non-graphic information may also be attached to the Model Element. “

The problem encountered in the conducted case study, was that the various disciplines needed various detailing and data-richness of the model (e.g. LCA very detailed model, structural analysis very basic model), but in the same design-stage. This poses challenges on the designer. Thereby, an integrated process is needed where partaking disciplines can discuss model-needs for their specific purposes from the beginning, thus establishing project-related conventions, instead of relying on standards, which do not reflect the specific needs of the project. For example, if architect had not been working with structural engineer from the beginning of the process in the case study, it would not have been possible to provide a proper model. There by experience as well as interdisciplinary collaboration are two crucial factors for BIM supported analysis.

Further difficulty for LCA in general, however using BIM software in particular, is that the required Level of Development is often too high for such early design stage - all of the layers of the building elements have to be defined in order to attribute the eco-indicators, and carry out the follow up analysis. Often this cannot be done, because of the many unknown design-parameters in such an early design stage.

6. Conclusions

In this paper we have explored the potentials of BIM as joint knowledge base for the follow up life cycle assessment and structural analysis in the early design stage. Thereby various software tools were employed and workflows were analysed in terms of efficiency of data transfer and management, data-losses and ease of use. The comparative LCA-study has demonstrated that data-handling with standard software is easy, however prone to errors due to the numerous changes in the design which have to be adapted manually – the semi-automated process using BuildingOne database is more reliable in terms of change management, however requires skills and competencies of designers, which they normally do not have. Model-transfer to structural analysis required small model adaptations due to semantical differences in geometry, despite the interdisciplinary collaboration and coordination between the architect and engineer in terms of modelling.

We can conclude that integrated planning approach is necessary, where all of the members of design team work together from the beginning of the process, in order to discuss the specific Level of Detail as well as of Development needed for the follow up analysis. Standardisation process for creation of international reference libraries for digital products and materials has to be more intensified on transdisciplinary level, in order to enable the life cycle analysis of built environment.

Abstract

The construction projects in developing countries have been negatively influenced by communication gaps and lack of interoperability in design and construction processes. BIMs appeared as an enablers of interoperability, but today the implementation of Building Information Modelling as an information management paradigm that spans over the projects' entire life-cycle provide unique opportunities for facilitation of the processes in all phases of the construction lifecycle. In order to explore the full potential of the implementation of the Building Information Modelling as an information management strategy, opportunity analyses covering different phases of the life-cycle is required. This paper focuses on providing an opportunity analysis to explore the opportunities provided by the BIM to facilitate collaboration and coordination in the design phase of construction projects.

Keywords: BIM, Opportunity, Design, Donor, Projects

1. Introduction

The construction projects in developing countries have been negatively influenced by communication gaps and lack of interoperability in design and construction processes. Some countries who are under economic and political pressures frequently face difficulties in completing the large projects. In a few of them such as Palestine (i.e. West Bank & Gaza Strip) government projects are funded by donor organizations due to county's difficult economic situation. Donor-funded construction is a rarely observed economical model for the construction industry and neither its processes nor the difficulties and opportunities contained in the model has been in the focus of built environment research. On the other hand, Palestine appears as a nice case which contains many cases of donor-funded projects. Key projects in Palestine depend on aid from donor countries and organizations. The bodies and organizations that offer grants to the construction industry in Palestine are the World Bank (WB), the Islamic Development Bank (IDB), the United Nations Relief and Work Agency (UNRWA), the U.S. Agency for International Development (USAID), United Nations Development Program (UNDP), the European Union (EU), German and Japanese institutions, Welfare Association and World Vision (Abdulhadi, 1994). The construction industry in Palestine is one of the key industries and is the main force motivating the Palestinian National Economy. The industry can be viewed as an advancement enabler for achieving nationwide goals in modern society In the country, the problems in construction projects are not only caused by the lack of technical skills and financial resources but also as a result of inadequate coordination, integration, communication and control of project activities.

The paper focuses on providing a review of opportunities provided by the use of Building Information Modelling in the design phase of donor-funded projects. The review provided in this paper is based on outputs of authors' previous research on i.) opportunities provided by the implementation of Building Information Modelling in several phases of the construction life cycle and ii.) exploring and mapping the processes of donor-funded construction projects. The latter effort was unique in terms of depicting and formalizing the processes of donor funded projects and also in terms of discussing how the processes in donor-funded projects can be facilitated by better communication and coordination between all stakeholders. The paper will summarize the results of this latter effort together with providing information on the opportunities provided by the utilization of Building Information Models. The paper starts by summarizing the construction industry in Palestine, including different contract types and actors. The 3rd section introduces the concept of process-based construction management. The 4th section discusses coordination problems in donor funded projects. The 5th section focuses on the details of the processes in the design phase of the donor-funded projects. The 6th section discusses the opportunities provided with BIMs in donor funded projects. The paper finalizes with a summary and conclusion section.

2. Overview of the Industry

The projects in the construction industry have a significantly high rate of business failure, and collapse and bankruptcy. The projects in the industry has been significantly affected by economic, environmental and political cycles due to many uncertainties resulting from many players of multiple disciplines who are brought together at various stages throughout a single project (Enshassi et al., 2006). Palestine construction industry is not an exception to this. The industry is complex and influenced by factors which may cause weakness including changing economy, closures, mismanagement of projects and the lack of skills and technology (Enshassi & Abu Rass, 2008). Elbeltagi (2006) indicates that the construction projects in Palestine can be classified into four major categories as:

- *Residential Housing Construction* which includes single-family houses, multi-family dwellings, high-rise apartments.
- *Institutional and Commercial Building Construction* which encompasses a great variety of project types and sizes, such as schools, hospitals, sports stadiums, retail chain stores and large shopping centres.
- *Specialized Industrial Construction* such as oil refineries, steel mills, chemical processing plants and coal-fired or nuclear power plants.
- *Infrastructure and Heavy Construction* which includes projects such as highways, mass transit systems, tunnels, bridges, pipelines.

Different types of enterprises take part in the construction industry of Palestine, according to PCU (2003) these can be classified as,

- *Donor (International Financing) Enterprise* which appeared as a result of general economic situation and financial failures that prevented the completion of the projects.
- *Public Enterprise which* covers governmental institutions that owns or manages public projects.
- *Private Enterprise*

In construction projects, three main actors are present as (Elbeltagi, 2006):

- *Owner (Client)* can be a public or a private entity and is the body who funds the project as result of the donation received.
- *Designer* is the design professional, this group includes architects, engineers, and design consultants.
- *Contractor (The Construction Professional)* is the party who undertakes the responsibility of construction from the owner (Bockrath, 2000).

A Contract can be defined as an agreement between two or more parties that creates for each party a duty to do something (e.g., to provide goods/ a service at a certain price and according to a specified schedule for one party and to pay for the service provided for the other) (Owen, 2003). Construction contracts in the country can be classified into the following types as; General (Traditional) Method "Unit Price" Contracts, Cost Plus Contracts, Design-Build Contracts, Turnkey Contracts, Management-Oriented Contracts, Construction by Daily Labor Contracts, Target Estimate Contracts, Guaranteed Maximum Price Contracts, Construction Management Contracts, Lump Sum Contracts, (BOT) Build–Operate–Transfer Contracts, and Special Contracts. The selection of the contract type in Palestine depends on several factors such as government agency type, project type, and sponsor identity. Sometimes the local agencies are even enforced to use the contract template of the sponsor organization’s country.

Based on the result of interviews that were conducted during this research, 4 different types of contracting methods were found to be actively in use as

- General (traditional) contract Method “Unit Price” Contracts
- “Special Contract Method” Contracts
- “Construction by Daily Labor” Contracts
- “Turnkey” Contracts

In addition, there are 2 more types that are in use which are the Lump Sum and (BOT) Build–Operate–Transfer Contracts but they are used less frequently.

3. Process Based Construction Management

Process Based Construction Management can be defined as the management of the activities in construction projects based on well-established processes which are formalized by process protocols, frameworks and models. A Process Protocol is a tool and methodology for formalizing the process in the construction industry. The formalization of the processes serves for better understanding of the flow of events and interactions between the parties, finally resulting in better coordination during the design and construction stages. The approach has its roots in systems engineering and total quality management, where each molecular level component of a business (i.e. a process) is identified in detail. This identification includes the identification of the activities (i.e. the atomic level business components), actors that take part in this process, the input and outputs of the process, and identification of the relations between different processes, between super and sub processes. U.K. and U.S institutions are the leading research bodies in this field. The U.K. Construction Industry Process Protocol is a well-known protocol and is based on a recognized process model. Process Protocol Website (2013) defines this protocol as *“a common set of definitions, documentations and procedures that provides the basis to allow a wide range of organizations involved in a construction project to work together seamlessly”*. In the model, construction processes are grouped in 4 main stages as pre-project, pre-construction, construction and post-construction. Then this stages are divided into ten phases. Also, the participants within the Process Protocol are organized into activity zones. As stated in Wu (2004), the major benefits of Process Protocol are:

- The archiving and retrieval of project information
- Rapid communications
- Effective co-ordination
- The visualization of client’s requirements
- The visualization of structural and spatial requirements

There are also process frameworks based on technology re-engineered processes, a key example of these is the framework presented in BIM Execution Planning Guide. This study outlines the re-engineered processes based on the use of specific information management approach known as Building Information Modeling (BIMPEPG, 2013). Identifying the process models helps in identification of deficiencies in process along with risks associated with these deficiencies. On the other hand process maps provides a clear understanding of processes, their sequence, and their relations with other process. This in turn provides a foundational framework for identifying the opportunities related to each process. Following a review of the coordination related problems in the industry remainder of the paper will present a process map of design-phase activities in donor funded projects and discuss the opportunities provided by the BIMs in these type of projects.

4. Coordination Problems in Processes

Mohd Noor (2011) mentioned that 90% of all problems on site are due to late or inadequate information. Late information can cause thousands of dollar of losses in design and construction phases. In this research the identification of coordination related problems in donor-funded projects is accomplished by semi-structured interviews that were conducted with twenty experts including i.) engineers who work in government or NGO (non-governmental organizations) or at private engineering offices, ii.) contractors , and iii.) project managers. The interviewees were selected based on their experience in construction projects, In addition, they were working in different institutions and each have key positions in the government, in the contracting companies or at engineering offices. The interview process took over a period of two months. Open-ended questions most of which were prepared prior to the interview were used mainly as the interview instrument, and some emerging questions were asked spontaneously during the interview. Once the interview is concluded, the researchers analyzed the responses. The problems that were identified through literature review and problems appeared as the result of the interviews were grouped together, in six main groups, which are problems related to construction information, management, legal, financial dimensions, and included design phase problems and technical problems.

The construction information related problems were appeared in the form of problems related to the coordination due to; i.) lack of operational information such as change orders, ii.) unclear or contradictory information which is not comprehensive enough, iii.) incomplete drawings and documents, and iv.) problems in scheduling. The interviewees indicated that there exists gaps between the implementation of the drawings on site and the requirements in the specifications due to misinterpretation of drawings. Management problems are related with planning, controlling and so on. Unclear task specifications, problems in planning stage, and unpredictable changes in the project scope and requirements were identified as the key problems. The legal problems identified were i.)weakness in the harmonization of laws, and ii.)ambiguities such as legal disputes that emerge during the construction phase, iii.) changes that occur in government regulations and laws during the construction of the building. The financial problems were related to poor cost management and quantity surveying practices, and to the lack of cash flow management systems. The design phase problems include conflicts between consultants and design engineers, and uncoordinated (structural, mechanical, electrical) design. Finally, the technical problems were related to lack of technical support for the project, team and lack of human resources with required technical skills. Problems appeared as a result of rushed bidding process, and the use of obsolete technology in planning and construction stage were also reported during the interviews.

5. An Overview on the Design Phase Processes of Donor-Funded Projects

The Building Construction process in Palestine is initiated by the owner organization. The owner organization first indicates a requirement for a building to the responsible body of government, such as Ministry of Education, Ministry of Public Works and Housing. Then the government agency elaborates on this project idea, conducts a feasibility study and start to look for the financial authority that would support the project. As a result of the economic situation in Palestine, most of the projects depend on grants from donor countries or organizations. Once a donor is found and the support request for proposed project is approved by the donor the pre-design phase concludes. The donor organization then starts the transfer of the funds for the project through the Ministry of Finance. Most of coordination problems observed start in this phase, due to misinterpretation of clients' needs and due to problems in feasibility studies.

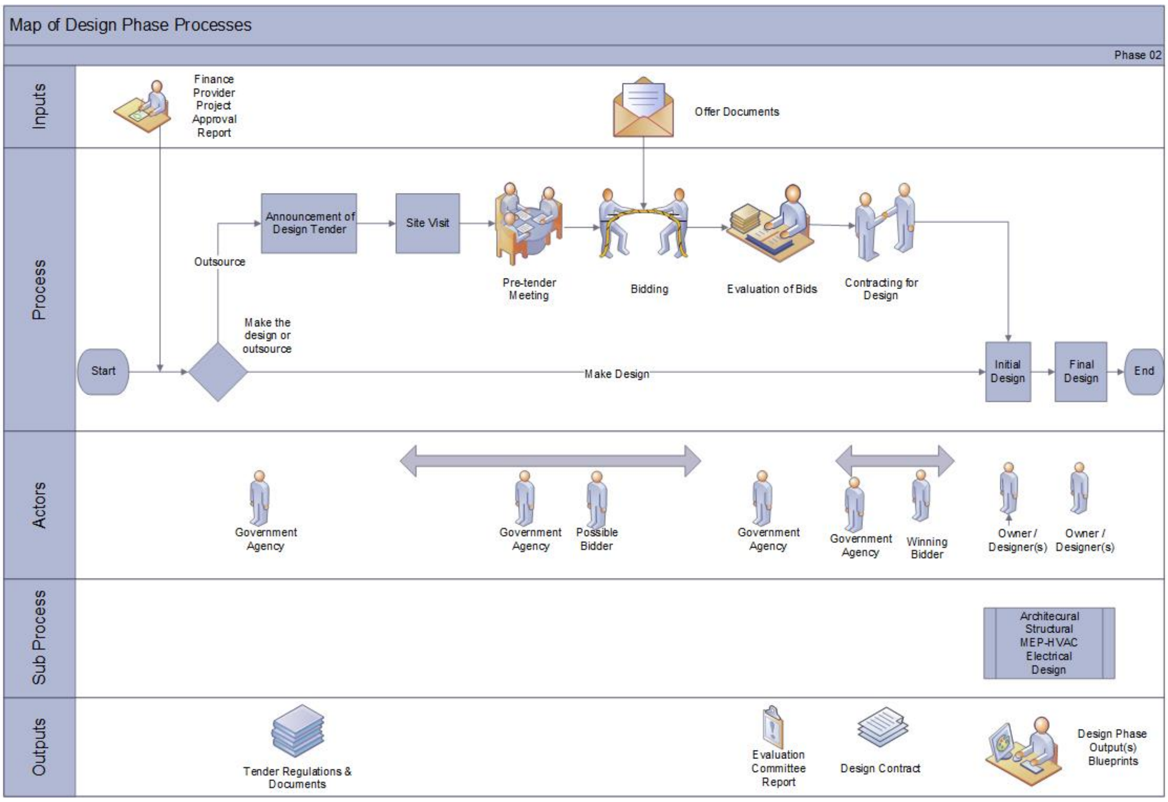

Figure 1. Design Phase Processes of Donor-Funded Projects

The following phase of the projects is the design phase. The process map for the design phase is shown in Figure 1. Once the government arranges the financing of the project at the pre-design phase there are two routes to follow. In the first one the Design and Supervision Department prepares the design, and the construction tender documents based on the client specifications, the conditions of the client and the budget allocated for the project. On the other route the design is delegated to a design consultant as a result of a bidding process. In this option the tender-for-design is announced in local newspapers in order to reach sufficient number of bidders. This is followed by a visit to the site, and an initial meeting to respond to the information requests of the possible bidders before the tender is opened. Once the tender is opened and finalized, the evaluation of the bids is conducted by the Evaluation Committee of the Government Agency. A design development contract is signed with the winning bidder. The winner prepares design documents, and the documents required for the construction tender (including detailed design, BOQs and so on).

6. Opportunities provided by BIM for Design Phase Processes

The implementation of Building Information Modelling as an information management strategy covering the projects' whole lifecycle and as a design management approach would facilitate design processes by enhancing communication, collaboration and coordination between the stakeholders. The opportunity analysis presented here is prepared by narrowing down the coordination related problems identified in the earlier phase of the research based on the design phase processes presented in previous section. The opportunities provided can be grouped into 4 categories as provision of consistent information, provision of comprehensive information, nD capabilities of BIM and process facilitation through the implementation of BIM methodology, which are presented in Table 1. BIMs contain detailed and comprehensive information about the building elements, their materials and material properties, elements' current state, their relations with other elements. The information residing in the BIM is always consistent in terms of 3D geometry of building elements and their semantic attributes. Views (i.e. subsets) can be generated from the model on demand or periodically and blueprints can be automatically derived from the model. Thus there will not be any inconsistencies between the digital model and the shop drawings. Finally, BIM methodology (BIM as an information management methodology) will help the facilitation of different processes in the lifecycle of the building. Below presents an overview on how the coordination problems mention in Table 1. can be eliminated by using the BIMs.

Table 1. Opportunities provided by BIM in Design Phase Processes of Donor-Funded Projects

Causes of Coordination Related Problems	**Opportunities Provided by BIM**
Unclear or contradictory information which is not comprehensive enough	-Provision of Comprehensive Information
Incomplete drawings and documents	-Provision of Consistent Information
Problems in scheduling.	-nD Capabilities of BIM
Unclear task specifications	-nD Capabilities of BIM
Poor cost management and quantity surveying practices	-nD Capabilities of BIM
Conflicts between consultants and design engineers	-Provision of Consistent Information
Uncoordinated (structural, mechanical, electrical) design	- Process facilitation through implementation of BIM Methodology
Lack of technical support for the project	-Process facilitation through implementation of BIM Methodology
Lack of human resources with required technical skills.	-Process facilitation through implementation of BIM Methodology
Legal disputes that emerge during the construction phase	-Dispute resolution through implementation of BIM Methodology

Provision of comprehensive information: BIMs provide comprehensive information about all building elements including, geometric and semantic properties, their materials, to-be-built dates, and relationships between them. The information provided by BIM will help in removing the unclarified information representation and flows which occur during the construction processes.

nD Capabilities of BIM: The use of BIMs will help in increasing efficiency in scheduling with the help of 4D scheduling simulations, will facilitate processes by eliminating problems occur due to lack of clarity in design communication. The information contained in BIMs will help in building up better design workflows and better specification of design and construction related tasks. The semantic information contained in BIMs will facilitate the process of quantity take-offs The implementation of automatic calculation of quantities will produce efficient inputs for the bidding phase in a timely manner. This in turn will be the first step for the better cost management practices.

Provision of consistent information: The BIMs contain 3D information with associated semantics where 2D drawings can be derived from it. During the construction of the BIM tools such as clash detection are used to prevent inconsistencies in the model. Thus the derived 2D models, and blueprints would eventually be components of complete and consistent design documentation. Thus the incompleteness in design documentation would be provided by the use of the BIMs. The BIM-derived shop drawings and design documents would contain detailed information about each building element together with details regarding the construction and assembly of the element, which in turn would be very helpful in preventing the conflicts between the consultants and designer which emerge in not well documented construction processes.

Process facilitation and dispute resolution through implementation of BIM Methodology: BIM methodology can be defined as an information management methodology that spans over the projects entire life cycle and focuses on management of the construction project based on the information derived from the BIMs. Building Information Modelling methodology proposes the use of design collaboration tools and software which would facilitate the coordination in the design process between architects, structural, electrical and mechanical engineers. The implementation of Building Information Modeling methodology will help in getting technical support in collaborative workspaces. The implementation of Building Information Modelling methodology requires highly skilled workforce on BIM related technologies and this generates the need for BIM training. An important impact of the training is development of a highly skilled workforce which in turn can be utilized in future projects. As indicated in Koc and Skaik (2014) the information derived from the BIM will be helpful in supporting the claims of the parties. In addition, BIM can also be helpful in dispute resolution through efficient representation of building elements that are related with the dispute. Furthermore, the 4D representation of the dispute event will contribute to the resolution efforts, as it will help the parties in evaluating the problem in focus in more detail.

7. Conclusions

The paper presented a structured review of opportunities provided by the use of Building Information Modelling in the design phase of donor-funded projects. The opportunities provided by the use of BIMs facilitate i.) design phase processes and ii.) processes which are dependent on design phase processes. The opportunities arise by the use of BIMs as shared information models and the implementation of Building Information Modeling as an information management methodology in the design phase. The BIMs provides comprehensive and consistent information which in turn enables better collaboration, communication and coordination of the design phase activities. The information contained in the BIMs are more reliable than conventional CAD models as BIMs contain agreed 3D geometries and semantic information, where sub models and other graphical representations (such as 2D) can be generated automatically. On the other had the implementation of Building Information Modelling as an information management method will also contribute to increase the skill levels of the employees, while providing a them a more efficient working environment.

Abstract

The use of Building Information Modelling (BIM) in the Architectural, Engineering, and Construction (AEC) industry has increased lately due to the awareness of this methodology's potential to improve the performance and efficiency of projects and reduce errors. Similarly, there is a growing concern with energy consumption and environmental impact of buildings. If BIM is integrated with other methodologies that assess the environmental impact of buildings and its energy consumption, such as Life Cycle Assessment (LCA) and Life Cycle Energy Analysis (LCEA), it is possible to achieve higher levels of sustainability of the urban environment.

This paper (i) identifies which information LCA tools require and how to incorporate it in BIM objects, (ii) determine how that information can be incorporated in the BIM model, and (iii) perform an energy and environmental analysis of two different buildings and compare the results obtained in order to understand the impacts of designer's choices on the building's performance. The authors not only identify which information is required for an automatic LCA analysis of BIM-based projects, but also assess which phases and materials contribute the most for the environmental impact of buildings.

Keywords BIM; LCA; LCEA; multi-family house; single-family house

1. Introduction

The building sector accounts for 40% of energy consumption and 36% of carbon dioxide (CO2) emissions in Europe, with a similar scenario in the United States (Commission 2015). As the building sector is the main contributor of greenhouse gas (GHS) emissions and a huge consumer of raw materials, it is extremely important to develop adequate legislation for construction, in order to achieve the Kyoto emission targets. In the case of EU, the goal is to achieve a 20% energy efficiency target, 20% share of energy from renewable sources until 2020, and reduce greenhouse gas emissions by 80-95% by 2050, compared to the levels of 1990 (Commission 2012).

If methodologies such as Life Cycle Assessment (LCA) and Life Cycle Energy Analysis (LCEA) are employed in the Architectural, Engineering, and Construction industry (AEC) the EU will more likely achieve these targets. The LCA methodology predicts how a building will perform during its lifespan, considering its entire life-cycle (environmentally focused) (ISO 2010). LCEA assesses the energy consumption of the whole project (energy efficiency focused), considering: (i) embodied energy, which is the amount of energy due to the process of production, construction, transportation, and possible renovations; (ii) operating energy, which is the amount of energy used to maintain the indoor air quality (IAQ) and thermal conditions of the inside environment through heating and cooling, as well as lighting and operating appliance; and (iii) demolition energy of the building, which is the energy required to demolish the building and dispose of the material (Cabeza et al. 2014). As the operating energy is responsible for about 80-90% of total energy consumption and environmental impact (EI) of a standard building during its lifecycle, it becomes crucial to choose the solutions that will enhance the energy performance of the building from the very first phase of the project (Asdrubali et al. 2013). This must be taken into account when we are performing an LCA or LCEA of a project, in order to achieve a sustainable construction.

Nonetheless, in order to fully use the potential of methodologies such as the ones described above in the AEC industry, an integrated approach capable of supporting all life cycle phases and gathering and processing a high volume of information is needed. Building Information Modelling (BIM) might be the solution for that problem. BIM is a methodology that enhances the collaborative aspect amongst all different fields of expertise throughout the project design and enables a more efficient management of a building's operation cost (Costa and Grilo 2015). The potential of BIM in the field of energy simulation and building performance has also been recognized lately, with applications ranging from photovoltaic (PV) simulation, waste management, energy rehabilitation of existing buildings, etc. (Ahn et al. 2014; Cheng and Ma 2013; Gupta et al. 2014).

Despite the growing amount of published papers in the last years regarding BIM synergies with energy and building performance (Hiyama et al. 2014; Marzouk and Abdelaty 2014; Woo and Menassa 2014), so far, the literature in BIM-LCA only analyses the theoretical advantages of this integration (Antón and Díaz 2014; Díaz and Antön 2014), with only three papers having a more empirical approach (Basbagill et al. 2013; Jalaei and Jrade 2014; Jrade and Abdulla 2012). Identifying this need for additional BIM-LCA discussion, the current paper focuses the integration between BIM and LCA/LCEA tools, and reports an energy and environmental analysis of two different buildings and compares the results. The rest of the paper is structured as follows: section 2 describes the methodology used; section 3 identifies the required information for BIM-based LCA/LCEA; section 4 presents a pilot case study conducted to test existing tools for energy analysis and environmental performance of buildings, and in section 5 conclusions are presented.

2. Methodology

As mentioned above, the aim of this paper is to briefly discuss the integration of LCA/LCEA with BIM methodology and conduct an LCA study resorting to a pilot case study. As a result of this BIM and LCA/LCEA integration, this paper contributes to: (i) the efficient use of LCA and simulation methods in design processes, (ii) promotion of performance-based methods within designers, contractors, and providers of facility maintenance and energy services, and (iii) the improvement of product information management throughout the construction life cycle.

The first part of this paper describes the LCA and LCEA methodology and what type of generic information should be included in the BIM model. In this sense, the authors initially search for existing standards in the field of LCA and then identify the key information required to conduct an LCA study, and that should be included in the LCA databases.

In the last part of this paper, an LCA/LCEA is conducted using BIM-based software, using the pilot case study method. Two different solutions representing the residential buildings are analysed and compared: a single-family building and a multi-family building. Revit software is used to create the BIM models, while Revit Energy Analysis tool is used to conduct the energy analysis and Tally tool to perform the LCA study of the above mentioned solutions.

The results of the Revit Energy Analysis are based on the geometry and materials of the BIM model and automatically consider some predefined options based on ASHRAE standards (e.g. Occupancy Schedules and number of people living in the dwellings). The authors only specify the Analysis mode ("building elements"), the HVAC system ("Residential 14 SEER/8.3 HSPF Split Packaged Heat Pump"), the location ("Lisbon, Portugal"), and the building type ("single" or "multi-family"). The obtained results are then imported to Tally in order to consider the environmental impact of operation phase, and the impact assessment method used is TRACI 2.1.

3. BIM and LCA/LCEA tools Integration

3.1. Definition of LCA/LCEA

According to AIA (Bayer et al. 2010), the LCA methodology have almost 50 years, when researchers demonstrated their concerns over the resources depletion and energy waste, searching for new ways of sustainable lifestyle (Adalberth 1997; Bekker 1982; Sharma et al. 2011). LCA's potential started to be noticed only in 1997 with the International Organisation for Standardisation (ISO) publishing a set of standards promoting the adoption of LCA method and presenting a framework for conducting an LCA analysis, with four phases (ISO 2010):

- The scope of an LCA: depends on the subject and the intended use of the study,
- The life cycle inventory analysis phase (LCI phase): consisting of the inventory of input/output, involving collection of the data necessary to meet the goals of the defined study,
- The life cycle impact assessment phase (LCIA): provides additional information to help assess a product system's LCI results,
- Life cycle interpretation: the results of an LCI and/or an LCIA are discussed as a basis for conclusions, recommendations, and decision-making in accordance with the goal and scope definition.

Although LCA method has been used in a variety of sectors for a long time, it was studied only in the last decade in the AEC sector (Antón and Díaz 2014; Buyle et al. 2013; Díaz and Antön 2014; Jrade and Abdulla 2012). As LCA is a very consistent tool to evaluate environmental impacts, the AEC industry is increasingly incorporating this method and suitable product selection into decision making processes in order to optimise the whole construction process (Asdrubali et al. 2013).

In addition to the LCA method, there are other methods that assess the environmental impacts of constructions, such as Life Cycle Energy Analysis (LCEA) and Life Cycle Cost Analysis (LCCA). Unlike the LCA methodology, LCEA is more focused on the energy inputs of a building during its life cycle, including the embodied energy, operating energy, and demolition energy (Cabeza et al. 2014), and the sum of all the energy consumed in the building is the life cycle energy (Ramesh et al. 2010). Designers that resort to LCEA are able to identify the phases that have the highest energy demands, having the possibility to make more appropriate material choices. LCEA can also quantify GHG emissions through the primary energy of the building by multiplying it by a factor. However, LCA tools provide more precise results (Ramesh et al. 2010), as in this methodology, the product's environmental impact is assessed from the beginning of the analysis.

In order to successfully design a sustainable building with better performance, the designer not only should use BIM, as it is a methodology that has the ability to analyse different scenarios faster than the traditional methodologies, but also take into account a great diversity of different simulations, such as (Krygiel and Nies 2008): (i) Building orientation, (ii) Building massing, (iii) Daylighting, (iv) Water harvesting, (v) Energy modelling, (vi) Renewable energy, and (vii) Materials. As such, the designer must be aware which type of information fed into the BIM model will have a greater impact on the results of the LCA analysis.

3.2. Information required for LCA/LCEA tools

One source for LCA/LCEA tools databases is the Environmental Product Declaration (EPD), legislated and harmonised with the EN 15942:2011. EPDs have the purpose of facilitating the communication of a product's environmental performance for business-to-business (B2B) (Standards 2011). LCA can use generic, average, or specific data (Silvestre et al. 2015), with EPDs fitting in the last category. Specific data is the data collected at the manufacturer's plant. However, the product's impacts can differ from other similar products (Silvestre et al. 2015). This is easily explained, as for the same products different manufacture processes can be used. If a manufacturer intends to develop an EPD of a product, the following information must be provided (Standards 2011): (i) General information of the product; (ii) Parameters describing the environmental impacts of the product; (iii) Parameters describing the resource use and primary energy use of the product; (iv) Parameters describing the resource use, secondary materials and fuels, and use of water of the product; (v) Information regarding waste categories of the product; (vi) Output flows of the product; (vii) Additional technical information; (viii) Additional information on release of dangerous substances to indoor air, soil, and water during the use phase.

In order for BIM-based tools to perform an automatic or semi-automatic LCA of a project, BIM objects must therefore contain the information described above. If manufacturers include that information in BIM objects, there will be no need to connect to specific LCA databases, promoting the open access to environmental information, as most LCA databases are paid. Also, it will be much faster and simpler to execute an LCA study in this situation, as designers will not need to learn how to work with additional tools. However, there are some data that designers should add in the BIM objects that are site-specific (e.g. energy and water used, site location, transportation from factory to site, etc.). In order to include the required data in BIM-based objects, manufacturers and designers can resort to parametric modelling, which allows to incorporate the information regarding different specialities in a single object, as well as defining parametric relations and constraints (Lee et al. 2006). International guides for a BIM object library should be used in this process, such as NATSPEC BIM Object/Element Matrix and NBS BIM Object Standard.

4. Pilot Case Study: multi-family house vs single-family house

The purpose of this pilot case study was to understand the effect of designer's choices in the environmental impact of the building and to compare the energy consumption and environmental impact of a multi-family house with a single-family house, according to Figure 1. As such, the authors used Autodesk Revit to develop the BIM model, Revit Energy Analysis for energy simulation, and Tally for environmental assessment of the projects, as explained in Section 2.

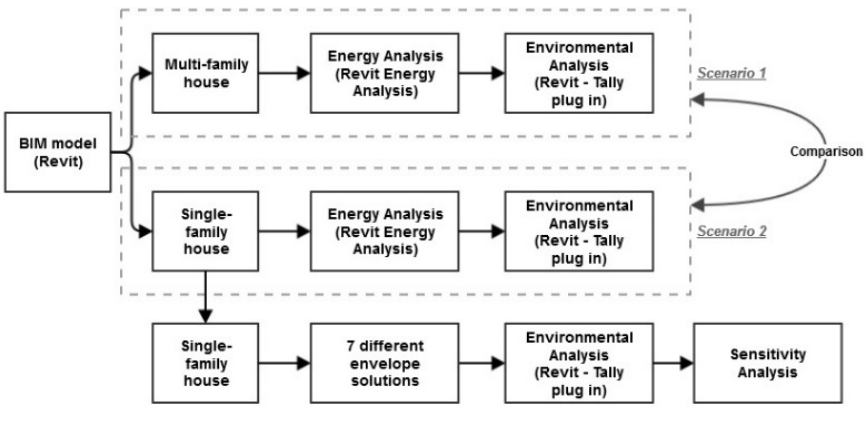

Figure 1 – Pilot Case Study methodology

The initial step was to model two simple buildings in Revit (Figure 2 and Figure 3), both with same envelope solutions, in order to guarantee that the results obtained are independent of material choices. After the development of both BIM models, the authors used the Revit Energy Analysis option to simulate the energy consumption (Table 1) and Tally plug-in to perform the LCA of these projects (Table 2), assuming a 60-year lifetime. Unfortunately, Tally plug-in did not recognise the chosen materials in Revit, only the construction solution, as this tool only works with GaBi's database. Extra work was therefore required in order to select the corresponding materials in Tally's database. This could compromise the accuracy of the expected results, as the tool users can select only the available materials. Nonetheless, as the purpose of this paper is to compare two scenarios with the same materials solutions, this software limitation will not jeopardise the expected results (both in Revit and Tally).

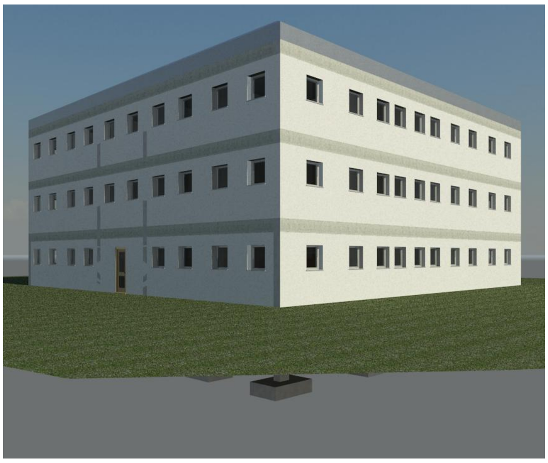

Figure 2 - 3 floor multi-family house (3D view)

Figure 3 - single-family house (3D view)

The second step of this Pilot Case Study was to analyse the environmental impacts due to materials selection, by examining the results of seven different envelope solutions (Figure 1). Unlike the first step, in which the authors' objective was to compare the energy and environmental analysis of different types of buildings, in this step the authors seek to understand the impact of designer's choices of materials, using a single scenario (single-family house).

Table 1 - Revit Energy Analysis results (multi-family house vs single-family house)

	Multi-family house	**Single-family house**	**Units**
Area	1,120.00	100.00	m2
Electricity Use	88.00	90.00	kWh/m2/year
LC Electricity Use	2,956,800.00	270,000.00	kWh
	270.0	24.7	kWh/day
PV low efficiency	46,514.00	11,243.00	kWh/year
PV medium efficiency	93,029.00	22,487.00	kWh/year
PV high efficiency	139,543.00	33,730.00	kWh/year

Table 2 – Tally results (multi-family house vs single-family house)

	Total	**1948**	**143**	**480442**	**0.03**	**20715**	**6617635**	**4333636**	**2283992**

As it is possible to observe from Table 2, Tally provided six different Environmental Impact categories: Acidification Potential, which causes fish mortality, forest decline, and the deterioration of building materials; Eutrophication Potential, which can cause an undesirable shift in species composition; Global Warming Potential, which causes an increase of the greenhouse effect; Ozone Depletion Potential, which leads to higher levels of UVB ultraviolet rays; Smog Formation Potential, which leads to respiratory issues and damage to ecosystems; and Primary Energy Demand, which measures the total amount of primary energy extracted (non-renewable plus renewable resources). In general, the environmental impacts from the multi-family house are about 10 times higher than the single-family house, being almost proportional to the area of the building.

The Global Warming Potential (GWP) is one of the most relevant impacts, and in both cases it is mostly due to operational energy consumption. However, for the single-family house the weight of the operational phase is lower than for the case of the multi-family house. On the other hand, the manufacturing processes contribute more to the GWP of the single-family house than the GWP of the multi-family house. So, we might argue that there is an economy of scale in terms of manufacturing (as an example we can refer that there are several construction elements, such as foundations, roof, etc., that are not proportional to the number of floors) but in terms of operational energy consumption the same logic does not apply, as the multi-family house has higher relative energy consumption (what might be related to the relevant energy consumption of the common/social spaces).

It is also important to understand which kind of materials have higher environmental impact, and if these materials represent a considerable portion of the building's mass. Table 3 and Figure 4 display the environmental impact of all materials used in the single-family house, throughout the different project phases. For this purpose, it is meaningless to display both scenarios (multi-family house and single-family house), as our real concern is only to analyse the environmental impacts due to materials selection, not to compare the two scenarios.

Table 3 - Tally (single-family house material's EI)

	Building Phases	Sum of Acidification Potential Total (kgSO2eq)	Sum of Eutrophication Potential Total (kgNeq)	Sum of Global Warming Potential Total (kgCO2eq)	Sum of Ozone Depletion Potential Total (CFC-11eq)	Sum of Smog Formation Potential Total (kgO3eq)	Sum of Primary Energy Demand Total (MJ)	Sum of Non-renewable Energy Demand Total (MJ)	Sum of Renewable Energy Demand Total (MJ)

	Grand Total	**1948**	**143**	**480442**	**0.02**	**20715**	**6617635**	**4333636**	**2283992**

As expected, concrete was the material with the highest mass percentage of the building, having a relatively low environmental impact/mass ratio (except in the manufacturing process). On the other hand, metal-based materials and insulation materials have a very high environmental impact/mass ratio, particularly on GWP, Acidification Potential, and Eutrophication Potential, despite their low representativeness in the total mass of the building. If designers are aiming for sustainable solutions, the selection of insulation material and its thickness is an extremely important aspect for the environmental impact of a building. It is relevant to mention that the higher the insulation thickness, the less thermal loss, leading to a decrease of operational energy consumption. So, for a sustainable solution to be reached, it would be advisable to perform a multi-objective optimisation of both (environmental vs energy consumption).

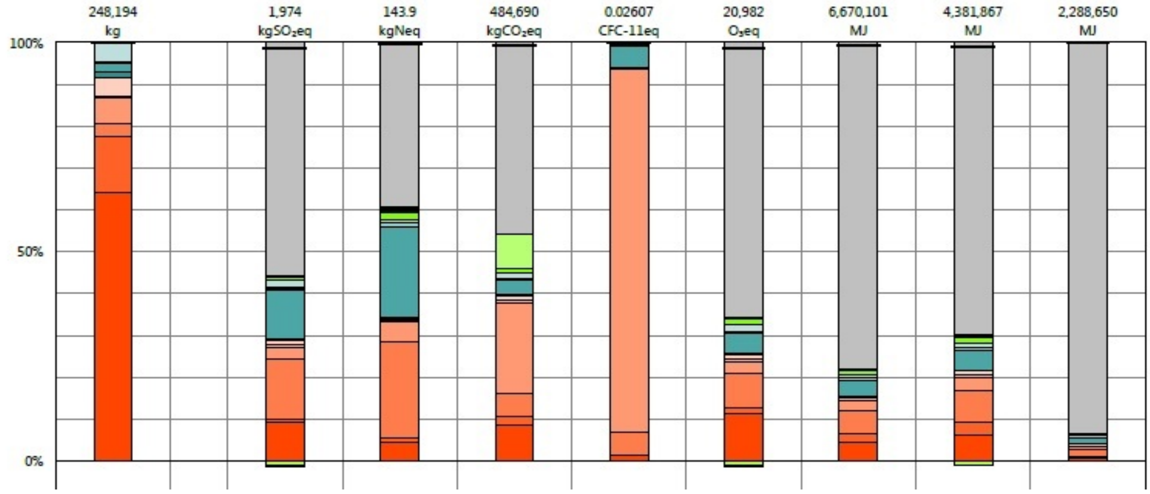

Figure 4 - Tally (single-family house material's EI)

However, in order to demonstrate how the designer's choices can profoundly affect a building's environmental impact, the authors decided to use the scenario of a single-family house and select different Revit and Tally solutions for the envelope. As observed in Figure 5, the original option (studied earlier) is one of the best sustainable solutions for most environmental impact categories. Also, wood-based solutions (option 3 and option 5) are the ones in which renewable resources can suppress most of the required Primary Energy Demand. Interestingly though, these two solutions also seem to be amongst the least environmentally friendly solutions (option 3 – wood roof: 1st in Acidification Potential, 1st in Eutrophication Potential, and 1st in Primary Energy Demand; and option 5 – timber floor: 2nd in Eutrophication Potential and 2nd in Global Warming Potential). However, if we examine Figure 6, we can conclude that most of those environmental impacts result from the End of Life potential use (recycling/reuse/recovery) of wood-based solutions, assuming that these materials are still in good condition. They are also the only ones with a positive energy return at the end of life (through burning processes). Regarding Smog Formation Potential, Acidification Potential, and demand from non-renewable resources, option 6 (full concrete envelope) comes as the least environmentally friendly solution.

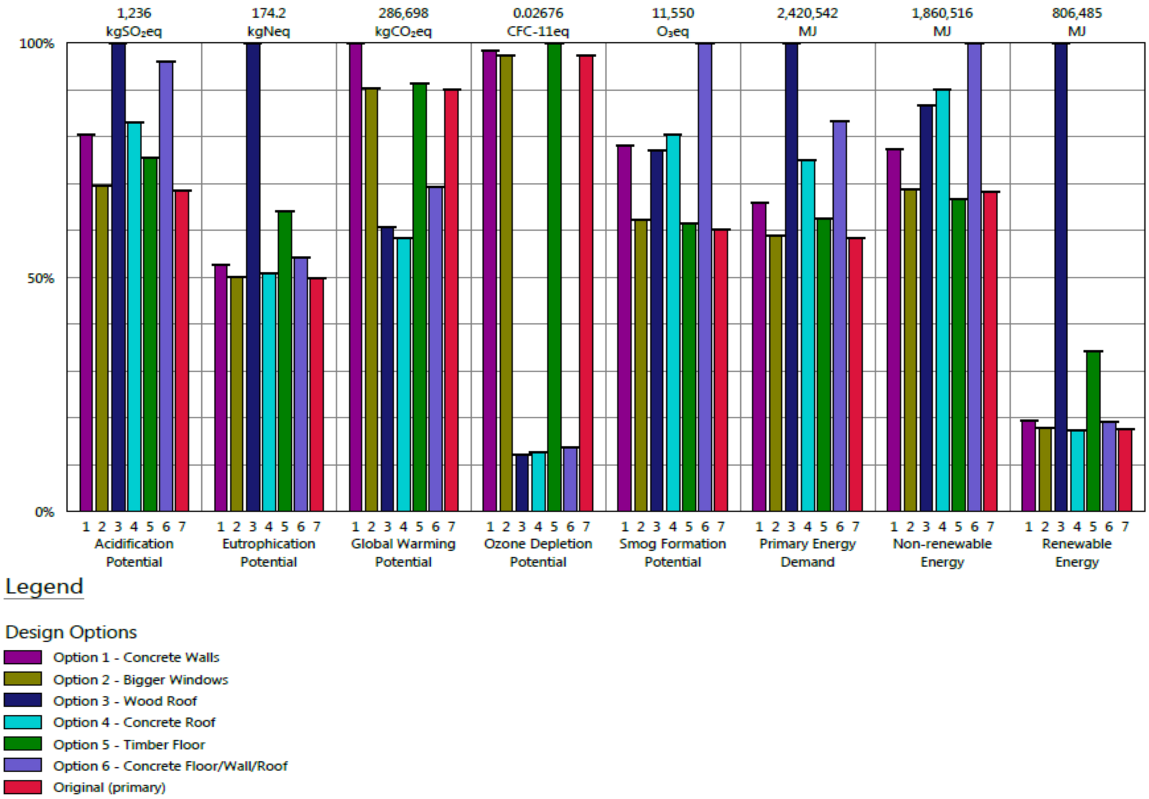

Figure 5 - Tally LCA analysis of single-family house (7 different options)

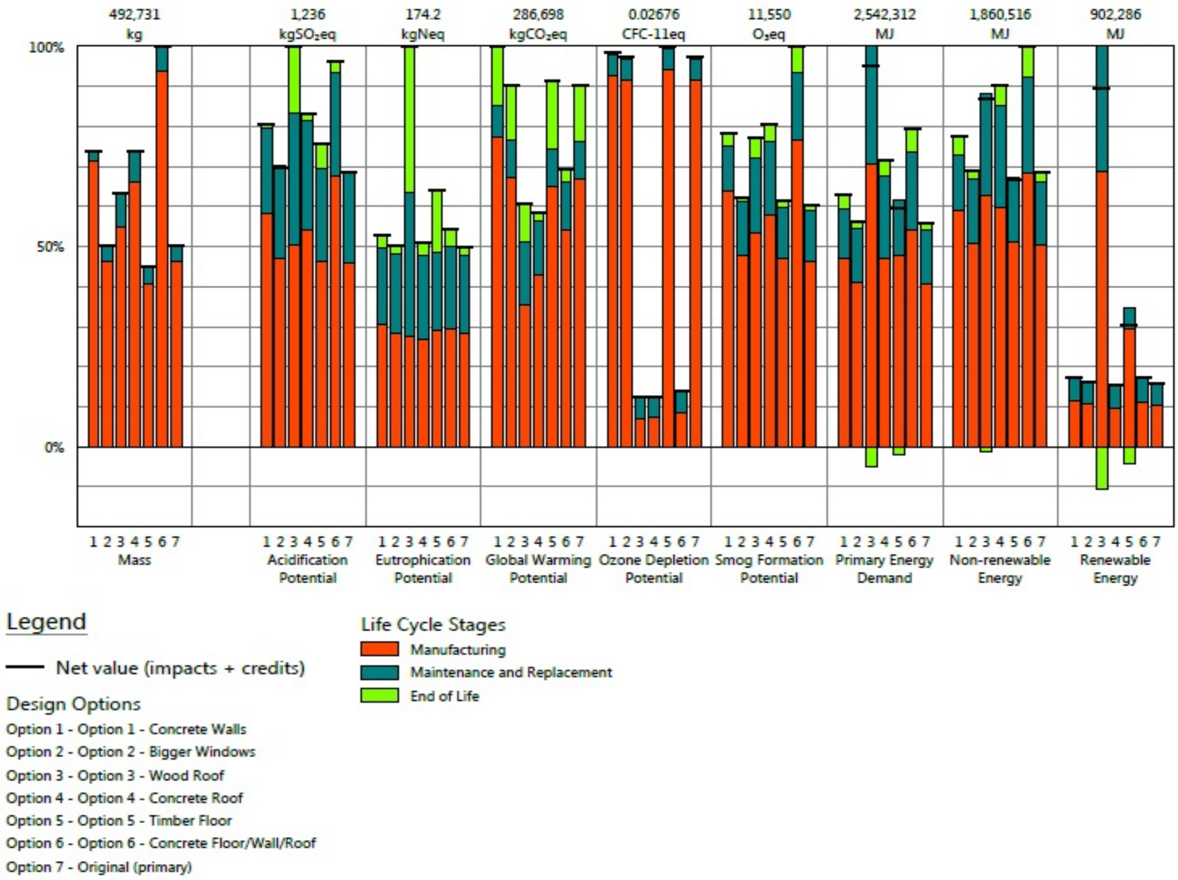

5. Conclusions

The first purpose of this paper was achieved through the analysis of existing ISOs and ENs, in which EPDs were identified as one of the main sources for LCA's databases. As such, in order to develop a BIM-based LCA automatic simulation tool, BIM-based objects must contain some crucial information that is requested by EPDs (see Section 2). The LCA plug-in used in this article, in spite of identifying Revit elements present in the project, did not recognise the object's information, as it works with GaBi's databases. This means that all information used by this tool must be manually added by the user after designing the architecture and type of solutions in the Revit. The second goal was achieved by performing Revit Energy Analysis, in order to obtain the expected energy consumption of both multi-family house and single-family house, and then by performing an LCA by using Tally. As mentioned above, the authors had to manually add the energy consumption of the selected scenario (provided by Revit Energy Analysis) with the purpose of obtaining results due to Operational phase, and also manually add the materials chosen to be used in the construction of the building, from a pre-defined list.

Despite the innovative environmental approach of Tally plug-in, designers will be greatly limited by existing options. However, the designers must also bear in mind that Tally plug-in represents only a quick and approximate analysis of a building's environmental impact. The authors initially assessed that both multi-family house and single-family house had a similar energy consumption (kWh/m^2), with multi-family house having about 10 times greater area, higher energy consumption, and greater environmental impact in most categories. The authors concluded that there was a positive correlation (in most cases) between energy consumption and environmental impact of buildings. Lastly, after the analysis of several envelope solutions for the single-family house scenario, the authors identified some effects due to the designer's material choices. Wood-based solutions are those in which renewable resources can potentially suppress most of the required Primary Energy Demand. Wood-based solutions are also those with higher End of Life potential use, leading to greater environmental impacts due to recycling/reuse/recovery processes. Option 6 (full concrete envelope) is one of the worst solutions, being on top of Smog Formation Potential, Acidification Potential, and demand from non-renewable resources. This is explained by the concrete's manufacturing environmental impact, which is very high compared with other materials.

Abstract

The Sultanate of Oman is facing rapid population growth, fast urbanization and a steeply increasing energy demand. A major load is the cooling energy necessary for the ever-growing number of single-family houses in the hot and humid climate. In order to develop solutions to this pressing issue, the German University of Technology in Oman (GUtech) has designed and built a net-zero-energy residential building, the EcoHaus. The objective of this study is, to benchmark the thermal behaviour – and in conclusion the cooling energy demand – of the EcoHaus against the cases of buildings built according to the building regulations as well as according to the standard building practice.

The calculations are based on a dynamic model, which reflects the geometry of the EcoHaus and uses approved methods of heat transfer. The model is implemented in a MATLAB® simulation code, which is used to calculate summer- and winter scenarios. The most interesting results are summarised and discussed. These are the stand alone behaviour of the house, the energy balance of the inner air volume and the temporal cooling load as well as the cooling energy demand in the summer scenario.

The study shows that the EcoHaus achieves major energy savings in comparison with the chosen cases, which is founded in the (passive) design strategies. Furthermore, it was found that the house can keep the air temperature stable over a long period of time. The benefits in comfort conditions are significant and surmount the conditions in a standard house, although the energy demand is lowered.

Keywords: Benchmarking, Net-zero-energy building, Building simulation, Hot climate, Oman

1. Introduction

The Sultanate of Oman is facing a rapid urbanization with half the housing stock built within the last decade (Al-Awadhi 2007; Asif, Sharma et al. 2015). With view of the demographic situation and the current land distribution policies, this trend is likely to continue. About half the population is under the age of 30 years (Department of Economic and Social Affairs of the United Nations 2015) and every citizen is eligible for a plot of 600 m. at the age of 21 years; a trend that accelerates the urban growth and energy demand. The predominant house design is based on the building typology of the free-standing single-family house, and the predominant construction method is a reinforced concrete frame with a single-layered infill of concrete hollow blocks without further insulation on walls, roof, or windows. This standard low-cost design solutions and construction methods neither address the climatic conditions, such as the very high temperatures (up to 45 °C) and high humidity (up to 90 %) in summer (Dorvlo and Ampratwum 1998), nor do they link to the cultural traditions, in which a high degree of privacy in the house is required. The result of the first is high energy consumption for cooling buildings to reach comfortable interior conditions. With depleting availability of fossil fuel resources within the country and decreasing income generated from exporting these resources, the high subsidies for electricity consumption are questioned. The need for better solutions is obvious, and there are first initiatives to address this problem.

In 2011, The Research Council of the Sultanate of Oman (TRC 2015) gave grants to five universities in the country to design, build, operate, and monitor a net-zero-energy residential building on their campus. The project of the German University of Technology in Oman (GUtech), the EcoHaus, was completed in 2014. It is recognized as a successful contribution through national and regional awards for its concept, design, construction, and also the involvement of students.

While data of the actual performance of the house still being logged, this paper presents a dynamic model, which is used to simulate the assumed performance. With this, a benchmarking of the EcoHaus as an as-built case is undertaken against two other cases, the case of a building according to the building regulation requirements as well as the case of the actually used standard construction system. Not many such studies are undertaken in hot climates, especially not in the region. One example is the 'Baytna'-project in Qatar, in which two identical villas are built adjacent to each other - one built to usual standards and the other to "Passivhaus” standards - to allow for a comparison of their performances. The results of this benchmarking, however, are not published yet (Quatar Foundation 2015). Ochoa and Capeluto investigated the effect of an implementation of active- (e.g. blinds, lighting control and forced night ventilation), passive- (e.g. fixed shading, low-emissivity glass, or natural night ventilation) and a combination of both strategies in an office building in Haifa, Israel (Ochoa and Capeluto 2008). They found an energy saving potential of around 50-55 % in comparison with the actual building and stated a necessity to include energy saving strategies in early stages of the design process.

2. Model

The benchmarking is based on a dynamic model of the EcoHaus reflecting the geometry and the heat transfer properties of the basic building components. In this modelling approach, the house is divided in two parts, the envelope and the inner volume. The inner volume is divided in the solid volume that stands for all inner walls and other thermal masses within the building, and the air volume. The air volume temperature is the command variable of the model. Figure 2.1 shows the floor plans of the EcoHaus, where the parts of the envelope and of the solid volume can be distinguished: the inner surface of the envelope that is in heat exchange with both, the solid volume and the air volume, and the outer surface that is in heat exchange with the environment. For both surfaces, heat transfer by convection as well as by radiation is considered, while the heat conduction in the wall is solved according to the Binder-Schmidt-method. The envelope is discretized in circumference to picture the irradiation in dependence of the sun position. The same pattern is implemented for the roof as well as for the windows, where in addition the sun light transmission is considered.

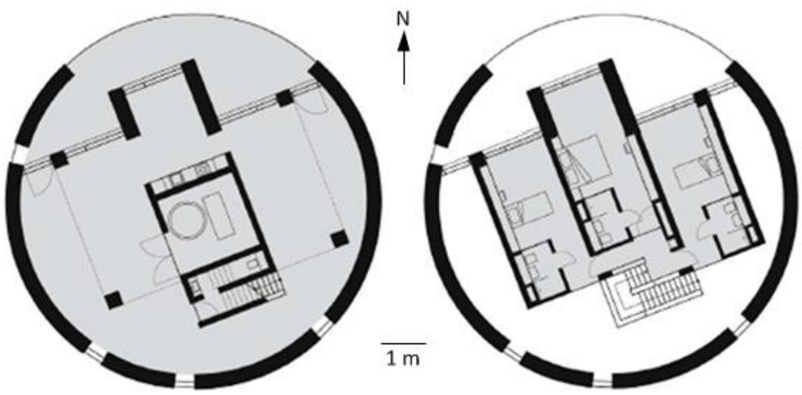

Figure 2.1: Floor plans of the EcoHaus

The model is implemented in a MATLAB® simulation, which is discretized in sufficiently small time steps. Due to this dynamic approach, the model can perform beyond estimations, which includes static temperature conditions and a steady state temperature profile in the wall. In the approach presented in this work, the thermal capacity of the wall and the dullness of heat transfer effects get considered in a sufficient way.

The most important input parameters for the simulation are the weather data and the material data for all reflected house parts. As weather data, including the hourly sun position, direct and diffuse sun radiation and environmental temperature, periodic input signals are used. The necessary values for the materials are the heat conduction coefficients, the density, the heat capacity and the minor geometrical information like the wall thickness.

The equations for different kinds of parts are simulated in modules. A superordinate code compounds the modules in a specific way for the EcoHaus geometry. The details of the model set-up will be presented in another publication. The focus of this study is on benchmarking the EcoHaus.

3. Case study

3.1 Material properties

The objective of this study is to benchmark the EcoHaus's performance in terms of energy consumption and indoor comfort conditions against common building types in Oman. In the comparison, the building material and material quality is changed for the outer walls, the roof and the windows – hence the envelope – according to these building types. The major geometry stays the same due to the code architecture of the superordinate simulation code.

To define the cases, information about the material properties has to be collected from different sources and a quantity for the differences between the envelopes in each case is needed. In architecture and civil engineering, the use of the U-value to quantify the heat transfer properties of a wall is usual. This value is quite useful to have a direct comparison of different structures. The static heat flow can be calculated in dependents on the air temperature on both sides and with an assumed steady state temperature profile in the wall. It therefore not only pictures the material properties, but the convection coefficient on the surface as well. As the simulation is transient, however, the convection coefficient changes with each time step and the thermal properties of the wall are pictured by the conduction coefficients (and heat capacities) of the wall only, which are fixed material properties. To gain a quantity capable of comparison of the heat transfer properties in the transient approach, the U*-value is introduced in equation (1). With this, the heat flow can be calculated in dependents on the surface temperatures of the wall. For a multi-layer wall it is given by

$$U^* = \frac{1}{\frac{\delta_1}{\lambda_1} + \frac{\delta_2}{\lambda_2} + \cdots + \frac{\delta_n}{\lambda_n}} \quad (1)$$

with δ as the layer thickness and λ as the certain heat conduction coefficient. The U-value is

$$U = \frac{1}{\frac{1}{\alpha_I} + \frac{1}{U^*} + \frac{1}{\alpha_O}} \quad (2)$$

with α_I as the heat transmission coefficient on the inside boundary and α_O on the outside. With this distinction, the cases are defined as following.

Case 1 "as built" is the EcoHaus in the actually build condition. The wall is made of an outer layer of light-weight concrete blocks with pumice as aggregate. The core layer is perlite as loose insulation infill and the inside layer is made by compressed earth blocks produced by the university's team on campus. The windows are constructed as curtain walls with air-tight joints to the walls and gaskets, frames of UPVC with thermal breakers, and an argon-filled double glazing. The outer surface is equipped with a sun protective coating, which influences the radiation properties. The roof is a multi-layered construction with a loadbearing structure of reinforced concrete slab, an EPS insulation layer and a cover of sand and white cement tiles (Figure 3.1). The thermal material properties are taken from tables.

Case 2 “regulations” is a building according to the thermal performance requirements set in the Muscat Building Regulations from 1992 (Muscat Municipality 1992), which are still valid today. This document sets U-values to be U = 0.741 W/m.K for external walls and U = 0.57 W/m.K for the roof. However, no material specifications are made. To gain representative material data, an U-Value calculator conforming to the German norm DIN 4108 (DIN Deutsches Institut für Normung 2014) is used in an exemplary temperature setting. A suitable material configuration in accordance with the regulations is set concluding a support structure and an insulation layer. The properties from these materials are used for the simulation. The windows are not clearly specified in the regulations and therefore the same window properties as in the EcoHaus are used.

Figure 3.1: as built case - energy-efficient construction method of the GUtech EcoHaus

Figure 3.2: practice case – standard construction method for villas in Muscat

Case 3 “practice” is a building according to the standard building practice in Muscat, which for reasons of low-costs and non-enforcement of the above mentioned regulations, can be considered the standard. Here, the material specifications are assumed based on observation at the many construction sites in Muscat (see Figure 3.2). Houses are structurally based on a reinforced concrete frame of columns, beams and solid concrete slabs. The infills are made with a single layer of concrete hollow blocks, joined with cement mortar and rendered with a cement plaster on both sides. The blocks are partly built in semi-industrial plants and partly in “backyard factories”. Therefore, an even standard regarding their material properties cannot be assumed. However, it is reasonable to use data from industrial product catalogues and material property tables (Bobran and Bobran-Wittfoht 2008; Thomas Armstrong Ltd 2015). The commonly installed windows are single panes in aluminium frames. The heat conduction resistance of the pane is negligible against the convection on the surface. For the windows, a sun protective coating is assumed. Even though the standard construction system disregards the issue of thermal bridges and air leakages, this disadvantage is not further reflected in the model.

An overview of the resulting U*-Values for all cases is given in Table 1.

Table 1: U-values in W/m²K for house parts*

Case \ House part	*Wall*	*Windows*	*Roof*
Case 1 "as built"	*0.14*	*2.07*	*0.15*
Case 2 "regulations"	*0.85*	*2.07*	*0.62*
Case 3 "practice"	*1.83*	*25.00*	*5.48*

3.2 Defining weather input data

For the analysis of the case study, periodic weather data in dependence on typical daily data in summer and winter season is created. Figure 3.3 shows the data exemplarily for 10 days in the summer. T_environment is the environment temperature, E_direct the direct sun radiance and E_diffuse the diffuse sun radiance. The temperature development is full periodic over 24 hours, while the radiance is half periodic during day time. The respective sun course is taken from (Hoffmann 2015), while the weather data is created in dependence on data from the company "Weather Analytics" (Weather Analytics LCC 2013).

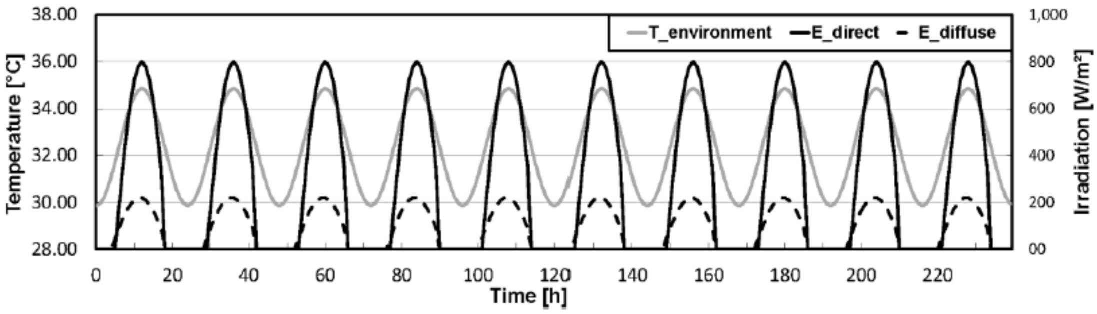

Figure 3.3: Weather data for the summer scenario

The environmental temperature for the summer scenario is between 30 °C and 35 °C. For the winter scenario, the same input signal is used with temperatures between 19 °C and 25 °C.

3.3 Examination

In a first step, the behaviour of the house is investigated without any cooling. This setting is called "stand-alone". To allow all examined temperatures to settle at a constant average value, 40 day periods are simulated. For the summer scenario an inner volume start temperature of 30°C is chosen, for the winter scenario it is 24 °C. The stand-alone setting is suitable to show the dullness (phase shift) and the relation of amplitudes between the air volume- and environment temperature. The air volume energy balance for this setting is analysed in detail afterwards to get a closer view on the temperature development and rate the envelope part's contribution. The balance is

$$c_{P,A} \cdot V_A \cdot \rho_A \cdot \frac{dT_A}{dt} = \dot{Q}_{Wall} + \dot{Q}_{Window,North} + \dot{Q}_{Window,South} + \dot{Q}_{Roof} + \dot{Q}_{Solid} \quad (3)$$

With $c_{P,A}$ as the heat capacity of the air, V_A as the volume of the air, ρ_A as the density of the air, T_A as the air temperature and with the heat fluxes on the right side. The respective index shows, which part of the house the air volume interacts with. In the analysis, the development during the 40 days of each flux will be examined.

Afterwards, the most interesting and significant value to compare the cases – the cooling load in the summer case – is examined. To implement this setting, the indoor temperature is limited at a certain comfort condition, but it can fall below this limit. This behaviour pictures the control of a simple air conditioning. Here, 24 °C and 20 °C are chosen as comfort conditions.

4. Discussion

4.1 Stand-alone temperature development

Figure 4.1 shows the temperature development for all three cases in the summer scenario with the air volume temperature of the as built case, the regulations case and the practice case. The environmental temperature is shown for comparison.

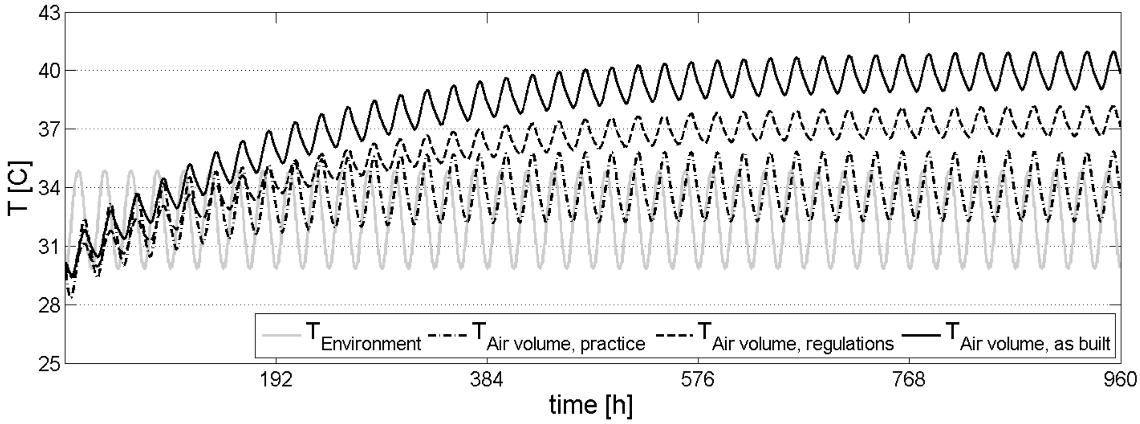

Figure 4.1: Air volume temperatures for summer scenario, stand-alone setting

The average air volume temperature settles above the environmental temperature in all cases, while the average temperature is maximal for the as built case. The relation of the amplitudes differs from the relations of the average temperatures. The regulations case shows the smallest amplitude, although the average temperature is in the middle of the three cases. The amplitudes of all simulated temperatures are significantly lower than the amplitude of the environmental temperature. The phase of the air volume temperature post-pulses approximately 5 hours behind the environmental temperature with nearly no differences in all cases. This phase shift is due to the high thermal mass with low thermal conductivities. The house's behaviour is the same for the winter scenario (Figure 4.2), but at a different temperature scale. The phase shift varies a bit and now post-pulses 2.5 to 4 hours behind the environmental temperature with a minor spreading. The air volume temperature is influenced by heat exchange with the inner surface of the envelope parts and with the solid volume. To see the relations between these flows, they are examined in Figure 4.3 to Figure 4.6 according to equation (3).

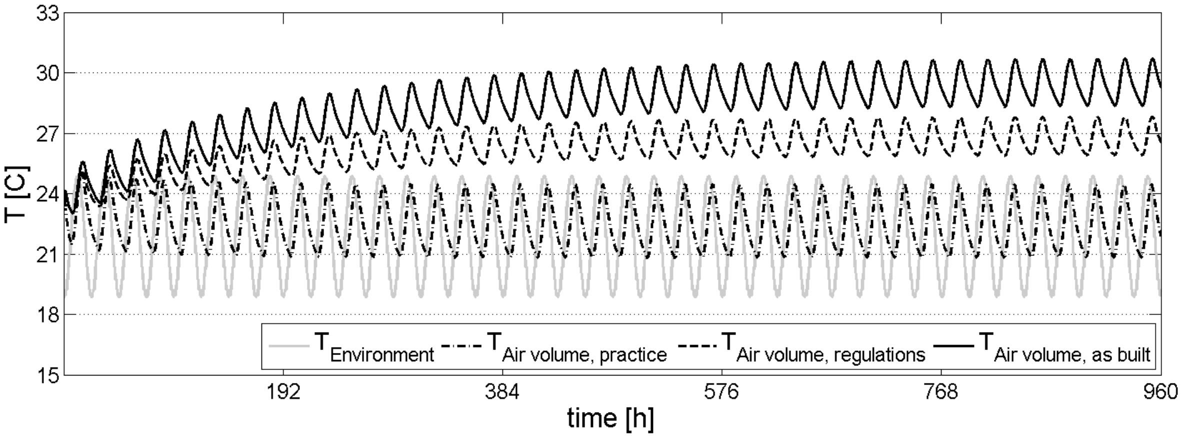

Figure 4.2: Air volume temperatures for winter scenario, stand-alone setting

4.2 Air volume energy balance

The contribution of the respective inner surface in the air volume energy balance is a result of the air volume temperature and the surface temperature. This one is influenced by heat that conducts through the wall and radiation that is transmitted through the windows. The radiation heats the inner walls and the solid volume, but not the ceiling. Heat conduction occurs for the wall, the roof and the windows.

The convective flow from the north side window to the air volume is drawn in Figure 4.3 for the practice case. The large area with the high heat conduction coefficient is not exposed to direct sun light due to the orientation and the air volume temperature is above the environment temperature. Therefore, this window mostly acts as a heat sink with amplitude up to -1400 W. The south side windows show a similar behaviour with minor amplitude of up to -300 W (Figure 4.4). These windows are exposed to direct sunlight only for a few hours a day.

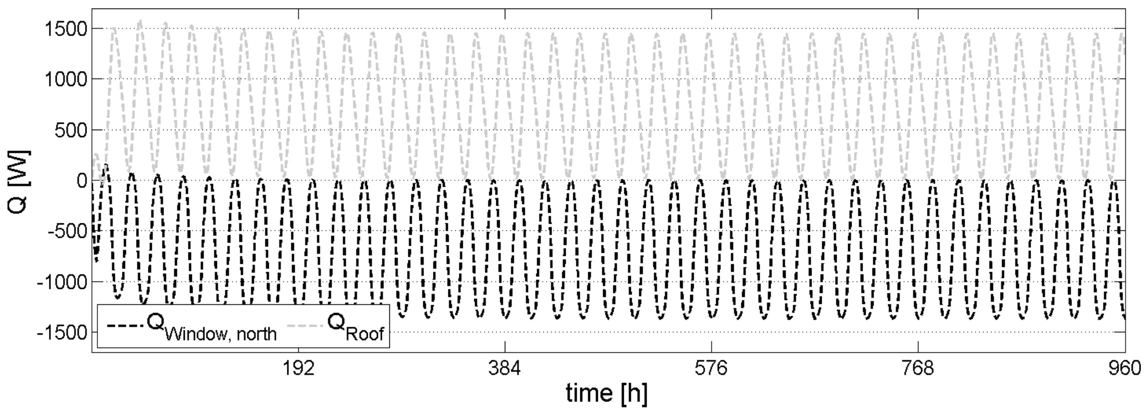

Figure 4.3: Heat fluxes in air volume energy balance for summer scenario, practice case, part 1

The heat flux through the roof is drawn in Figure 4.3. It is phase shifted by approximately 10 hours in relation to the window flux and the amplitude reaches the same order of magnitude – around 1500 W. Due to the constant sun exposition of the outer surface during the day and the resulting heat conduction, the heat flux is positive.

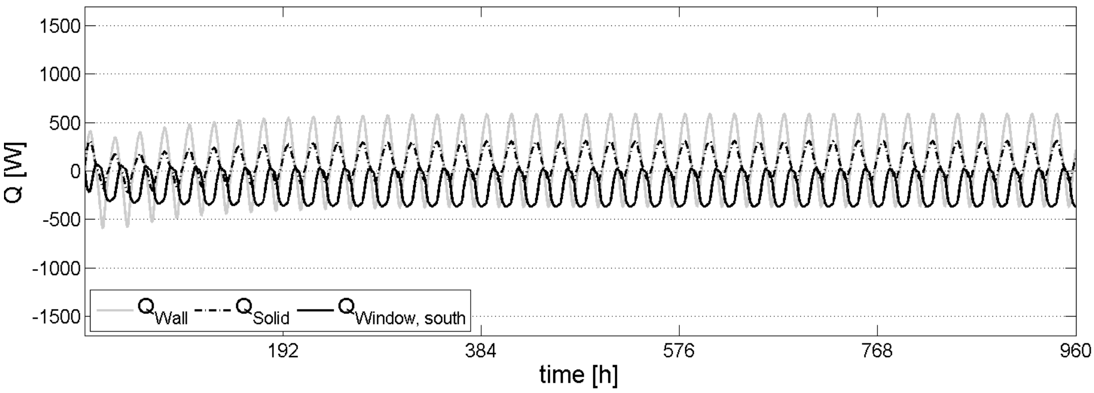

Figure 4.4: Heat fluxes in air volume energy balance for summer scenario, practice case, part 2

The heat exchange with the solid volume (Figure 4.4) is mostly positive at around 1/3 of the north side window- and roof flux amplitude. The solid volume is heated only by the transmitted radiation. As the phase is the same for the solid volume and the wall (between the roof and the windows flux), the transmitted radiation influence on the wall flux must be dominant against the conduction in the wall, although the outer surface of the wall is exposed to the sun several hours a day. This is due to the very high insulation.

For the regulations and as built case (Figure 4.5 and Figure 4.6, please notice different scale than in Figure 4.4), the phase correlations are generally the same. The roof and north side window fluxes are significantly lower and in the order of the other fluxes. This is in accord with Table 1, since the U*-values are in another order of magnitude. In general, the air volume temperature above the environment temperature in all cases is an indicator for the dominance of the transmitted irradiation against the convection.

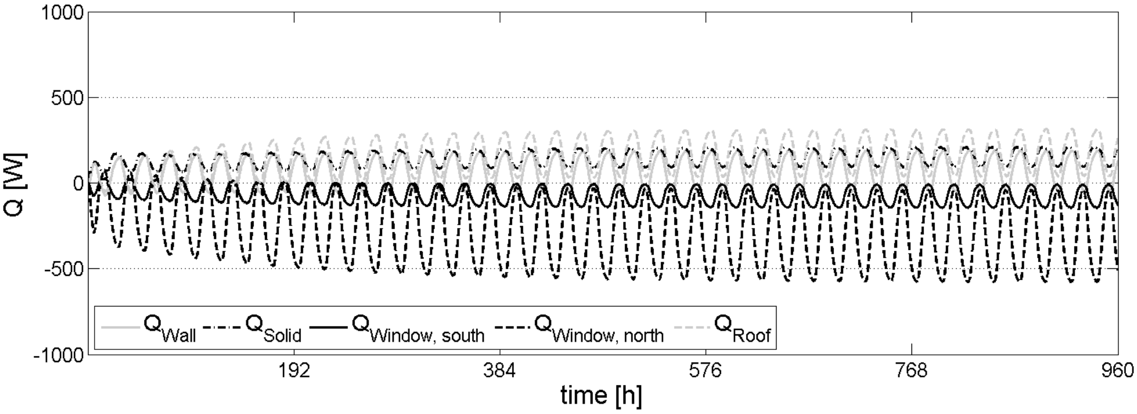

Figure 4.5: Heat fluxes in air volume energy balance for summer scenario, regulations case

The reason for the amplitude correlation in the temperature development (Figure 4.1) is in the phase shift of 10 hours between window and roof flux, which is nearly half a period. Due to this, effacement occurs and the amplitude of the temperature gets lowered. The higher conduction ability of the roof allows the heat during the day to escape better.

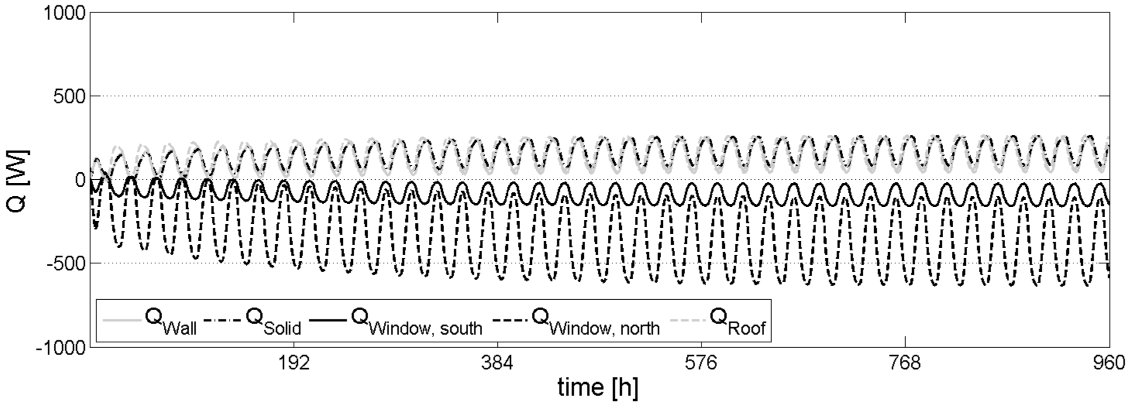

Figure 4.6: Heat fluxes in air volume energy balance for summer scenario, as built case

Overall, the house isolation holds the energy that is yielded by the radiation, from conducting to the cooler environment. The air volume is “decoupled” from the environment. This leads to a high dullness of the average settle temperature. Due to the different sun exposition of the parts, the contribution in the energy balance is not always in the relation indicated by the U*-values. Just these results get visible by the time dynamic modeling approach exclusively.

4.3 Cooling load

By the analysis of the cooling load and accordingly the summarised cooling energy demand for the 40 day period, the advantages of the EcoHaus can be quantified. Figure 4.7 pictures the load over the time for the summer scenario for all three cases normalised to the living area of 210 m.. Both, the amplitudes and the settle averages, are in accord with the stand-alone setting. The results for the summarized cooling energy demand are shown in Table 2 for two set temperatures. The advantage of the EcoHaus is obvious with a saving of up to 30 % in comparison with the regulations case and up to 60 % in comparison with the practice case. In reality, the practice case is supposed to show a significantly higher cooling load, since air leakages are not considered in the model and in this benchmark, some passive strategies (round shape and north-orientation) are implemented in all cases due to the same geometry.

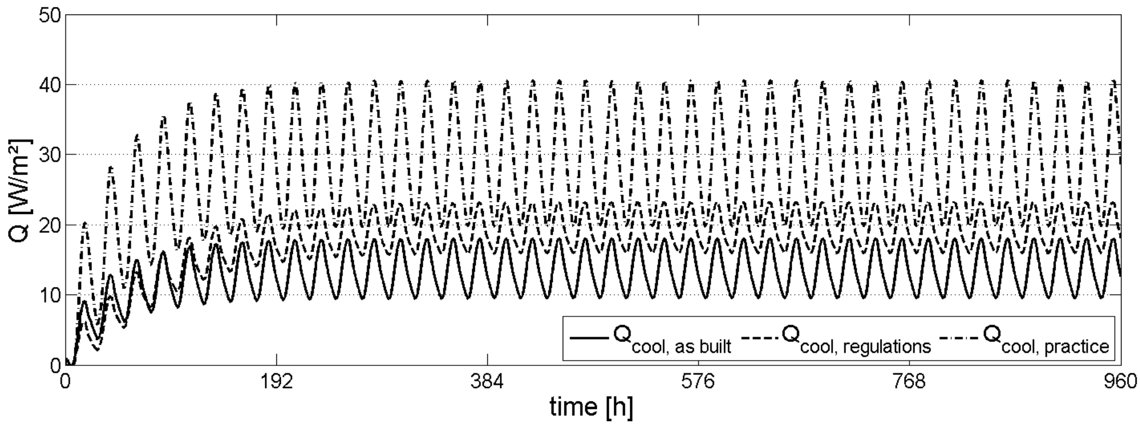

Figure 4.7: Cooling loads for summer scenario with set temperature 297 K

During the winter period a cooling by natural ventilation is possible. Therefore, the winter scenario has no relevance for the cooling load considerations.

Table 2: Accumulated cooling energy demand for 40 days in kWh for the summer scenario

Set temperature \ Cooling energy	as build	regulations	practice
24 °C	2600	3550	5340
20 °C	3240	4660	8120

5. Conclusions and Outlook

The benchmarking for the summer period shows that – based on model calculations with a fixed geometry – the EcoHaus saves 30 % of the cooling energy demand in comparison with a building built according to the Muscat Municipality regulations. Further, it saves 60 % of the cooling energy demand in comparison with a building built according to the standard construction methods.

In preliminary considerations, the EcoHaus is examined in a stand-alone setting, where the thermal properties of the house are investigated. The high insulation decouples the inside of the house from the environment and promotes the radiation influence on the temperature but also damps the amplitude in comparison with the environment temperature. The resulting high dullness can be advantageous. For example, the temperature stays stable enough during the night without uncomfortable cooling.

All parts of the envelope participate differently in the air volume energy balance. The period of time in each day, in which they are exposed to the sun and the insulation differ strongly. The main window front is oriented to the north side, which means that it is never exposed to direct sun radiation. Therefore, heat entrance or transmission of direct radiation at the thermal weak point of the house is avoided. This design enables the house to be equipped with a window of huge size without increasing the cooling load too much. As a result, the rooms are sufficiently lit by daylight without compromising on energy efficiency. For a residential purpose in the Omani cultural context, more privacy would be required and shades would need to be installed.

The comparisons show the high impact of the passive design strategy to construct a highly insulated, protective envelope. Other passive strategies like the compact volume are included in the model with the geometry for all examined cases. In result, the cooling load is at a low to average level in all cases, showing the advantage of these strategies. The geometry differs significantly from common residential houses. A comparison with the actually built design of single-family villas in Muscat – that do not consider any passive strategies – would show the advantages of the EcoHaus design even more. Due to the modularity of the simulation, this is possible, also for new house designs, but it requires a new superordinate code.

The benchmarking extracts the cooling energy demand quantitatively, but does not address the question of how efficiently it can be provided. Here, the EcoHaus's cooling system - a combination of a hydronic, radiant cooling device and energy recovery ventilation is much more efficient than the generally employed AC-split-unit. Furthermore, the installed cooling system is seen as a major contribution to increasing the living comfort since the air-velocity is low and with minimal audible sounds.

The study shows that significant savings in the energy consumption of buildings in Muscat and comparable hot and humid climates can be achieved through better designs and better construction systems. However, the problem of achieving better performing buildings not only lies in the knowledge generation about the best solutions, but also in the knowledge transfer to get these solutions implemented. The EcoHaus project of the GUtech in Oman is an example that through the involvement of students into research and practice, both elements, knowledge generation and transfer to the next generation in the country, can be combined successfully.

BIM for Infrastructure Sustainability in Developing Countries: the case of Ethiopia

Denamo Addissie Nuramo,
University of KwaZulu-Natal,
EiABC, Addis Ababa University
(email: denamo.addissie@eiabc.edu.et)
Prof. Theo C. Haupt,
University of KwaZulu-Natal
(email: haupt@ukzn.ac.za)

Abstract

Investment in infrastructure in developing countries is essential for poverty reduction and it positively and significantly correlates to their economic growth. As infrastructure development involves consumption of considerable natural and capital resource and as it has long term impact on socio-culture of societies, it should be sustainable both in terms of delivery and service. Achieving sustainable infrastructure entails concerted considerations all the way from inception to demolition stages. In contrary to the fact that the issue of sustainability is in vogue, its implementation in infrastructure development in developing countries like Ethiopia is still at its infancy. In the traditional design and delivery approach where sustainability issues are not adequately addressed, resulting infrastructure becomes fragmented that is highly unsustainable and vulnerable. Due to presence of huge input and complex process in sustainable infrastructure design and delivery, the need for innovative information based interventions like Building Information Modelling (BIM) is inevitable. While implementation of BIM in the developed world is very encouraging, its application in the developing countries, especially in the area of infrastructure is very much limited. In this regard, the role higher educational institutes play in the diffusion of this technology into the industry is vital. The objective of this study is to explore the preparedness of Architecture, Engineering and Construction Management (AEC) undergraduate students to use BIM in the construction industry upon their graduation. Literature review and a semi-structured questionnaire were used to establish the conceptual background and acquire empirical data respectively. 95 Architecture, Civil Engineering and Construction Technology and Management graduating class students studying at the prominent state owned university in Ethiopia were included in the study. The response rate was 95% and the results of the study indicated that awareness and preparedness of the graduating students to use BIM in the Ethiopian AEC industry is very low. This is especially true to Civil Engineering students who are responsible to design and manage construction of majority of infrastructure projects in the country. Respondents indicated unpreparedness of the AEC industry and absence of appropriate software and work stations as the two major challenges to offer BIM at their university

Keywords: BIM, infrastructure, Sustainability, higher education, Developing Countries

1. Introduction

Investment in infrastructure in developing countries is essential for poverty reduction (Fay, et al., 2011) and it positively and significantly correlates to economic growth. According to the World Bank report there is a huge gap in infrastructure provision which is estimated at $1 trillion in low- and middle income countries, and the demand continues to grow as countries develop (The World Bank Group, 2008). The fact that infrastructure facilities last long signifies the need to make them sustainable by designing and constructing them to accommodate the several requirements that would emerge in due course of their lifetime. These requirements include social, economic, financial, and environmental considerations.

Achieving sustainable infrastructure entails concerted considerations all the way from inception to demolition stages. In contrary to the fact that the issue of sustainability is in vogue, its implementation in infrastructure development in developing countries like Ethiopia is still at its infancy. In the traditional design and delivery approach where sustainability is not adequately considered, resulting infrastructure becomes fragmented that is highly unsustainable and vulnerable (Sarte, 2010).

Due to presence of huge input and complex process in sustainable infrastructure design and delivery, the need for innovative information based interventions like BIM (Building Information Modelling) is inevitable. While implementation of BIM in the developed world is very encouraging, its application in the developing countries, especially in the area of infrastructure is very much limited. It is argued that lack of skilled and knowledgeable professionals is one of the bottlenecks for successful implementation of the technology. The role higher educational institutes play in regards to breeding the new BIM literate generation is vital. This signifies the need to assess the current trend in higher educational institutions in regards to training and capacitating Architectural, Engineering and Construction Management students in the developing countries like Ethiopia.

This study attempts to explain the role of BIM in sustainable infrastructure design and delivery and it investigates the preparedness of Architecture, Civil Engineering and Construction Technology and Management undergraduate students to implement BIM in the construction industry to attain sustainable infrastructure in Ethiopia. The research tried to identify the possible challenges faced by higher education institute in Ethiopia to offer BIM in these programs.

The study is limited to adoption of BIM in Ethiopia with a particular emphasis on Architecture, Civil engineering and Construction Technology and Management final year students. The findings are expected to be of assistance to Ethiopia and other developing countries in the design and delivery of sustainable infrastructure through implementation of BIM. It contributes to the body of knowledge in the area of sustainable infrastructure design and delivery in developing countries.

This article has six sections. Sections two and three discuss about sustainable infrastructure and BIM correspondingly. Sections four and five present the research methodology and survey results. Concluding remarks and recommendations are stipulated under section six.

2. Sustainable Infrastructure

2.1 Background

In the broader context the term infrastructure may refer to either "soft" or "hard" infrastructure. Hard infrastructure entails provision of physical structures for basic services including energy, water supply, sewerage, transportation, waste removal, sanitation, communication, health and education. While hard infrastructure is about provision of physical assets, soft infrastructure is about development of skill and knowledge and access to appropriate services (Casey, 2005).

Infrastructure can also be categorized as economic and social infrastructure where economic infrastructure is part of an economy's capital stock used to facilitate economic production. Structures including power utilities, piped gas, telecommunication, roads, drainage, railways, runways and seaport are typical examples of economic infrastructure. Social infrastructure on the other hand facilitates investment in human capital with a result of improving workforce productivity. Health, education, safety and recreation service facilities are typical examples of social infrastructure (UN-HABITAT, 2011). This study is limited to hard and economic infrastructure.

According to the World Bank report (Fay, et al., 2011) despite the fact that 10 percent increase in infrastructure investment contributes to one percent growth in GDP, there is a gap in infrastructure provision which is estimated at USD 1 trillion in low- and middle-income countries, and the demand continues to grow as countries develop. While developing countries are engaged in massive construction undertakings to curb their infrastructure deficiencies, only limited progress has been made so far (Calderon & Serven, 2004).

African countries, especially, sub Saharan Africa countries trail behind other regions in terms of infrastructure delivery and quality. This has becoming an impediment to their economic development and a major constraint on poverty reduction. To fill the infrastructure gap, an estimated USD 93 billion, which is about 15% of GDP a year investment in infrastructure is needed in Africa (UN-HABITAT, 2011). Infrastructure access gap looms large in the developing world where an estimated 748 million people live without access to safe water, 1.2 billion without electricity, 2.8 billion still cook their food with solid fuel such as wood, 1 billion people live more than two kilometres away from an all-weather road, 2.5 billion without sanitation, and more than 1 billion without access to telephone services (Lin, 2005; Todaro & Smith, 2012; Fay, et al., 2011).

Ethiopia is a country in East Africa with one of the fastest growing economies in the world and having an average growth rate of above 10% for the last decade where this momentum is expected to continue at a rapid pace over the next five years (AfDB; OECD; UNDP, 2014). With a population of more than 90 million it is the second most populous country in Africa following Nigeria.

The Global Competitiveness Report 2014-2015 (World Economic Forum, 2014), positioned Ethiopia 125th out of the total 144 countries considered in the survey in terms of overall quality of infrastructure where the report highlighted the need for significant improvement to enhance competitiveness of the country's competitiveness in the global market.

According to the United Nations report (United Nations Human Settlements Programme, 2011), only less than 20 percent of the Ethiopian population has access to any modern infrastructure. Surveys indicated that infrastructure constraints are responsible for an estimated 50 percent of the productivity handicap faced by Ethiopian firms (Foster & Morella, 2011).

In the course of time, infrastructure and utilities age and will require substantial maintenance and retrofitting if not demolished. Martland (2012) argues that social and environmental impacts of infrastructure systems likely become more apparent over their life time suggesting the need to consideration of sustainability aspect starting from the very early stage of the project design. According to Kibert (2013), the built environment has direct, complex, and long-lasting impact on the planet than any other human venture.

According to a report by CIB (1999) sustainable construction entails sectorial contribution made by the AEC industry in the areas of environmental, social, ecological and cultural aspects in the effort to achieve sustainable development. Sustainable construction is defined by Agenda 21 for Sustainable Construction in Developing Countries discussion document as follows (CIB & UNEP-IETC, 2002): "Sustainable construction means that the principles of sustainable development are applied to the comprehensive construction cycle from the extraction and beneficiation of raw materials, through the planning, design and construction of buildings and infrastructure, until their final deconstruction and management of the resultant waste." (pp 6)

Williams (2007) described the sustainability design process as integration of design into the ecology of the place which is the flow of materials and energy residing in the community. Compared to conventional design, sustainable design needs additional criteria and items (Azapagic & Collett, 2006). To implement sustainability on real projects, it needs to understand sustainable practices and then choose appropriate measures to facilitate sustainability realization (Chang & Tsai, 2015). As a sustainable approach new options to substitute the services that were provided by the old infrastructure need to be looked into (Williams, 2007). The emergence of BIM which is an important milestone in the AEC(Architecture, Engineering and Construction) industry affects the traditional approaches to project design and collaboration (Kibert, 2013). The next section describes the concept and benefits of BIM.

3. Building Information Modelling (BIM)

3.1 Background

Yan and Damian (2008) described BIM as powerful software tools used in the construction industry offering a considerable benefits throughout life cycle of a building including design, construction and facility management. BIM is a fairly new innovation in the construction industry changing the conventional way of designing, constructing, and operating buildings and infrastructure. The aim of BIM approach is to be able to digitally view and access information about the construction project from a single-source model (Krygiel & Nies, 2008). Unlike 2D drawings where drawings merely show a representation of the final object, BIM models have simulation capabilities. High level of accuracy and design efficiency can also be achieved by using BIM (Krygiel & Nies, 2008).

Building Information Modelling (BIM) is a relatively new technology and has been in use in many countries where several researches and surveys were made to assess level of adoption of the technology (Jung & Lee, 2015; Hussain & Choudhry, 2013; Abubakar, et al., 2014; Langar & Pearce, 2014; Wong, et al., 2010; Mohannadi, et al., 2013; Rogers, et al., 2015). The AEC industry will be able to utilise the full potentials of BIM only if it is widely endorsed by the stakeholders and adopted throughout the industry.

3.2 BIM Implementation and Barriers

In contrary to the fact that BIM offers immense benefit to the construction industry, its adoption is impeded by several barriers. Liu, et al (2010) conducted a study to identify factors influencing adoption of building information modelling in the AEC industry and indicated that maintaining staff with sufficient knowledge to perform facility management using BIM is one of the limitations faced by companies to adopt BIM. Hartmann and Fischer (Hartmann & Fischer, 2008) indicated the scarcity of BIM conversant practitioners as one of the major hindrances for its widespread adoption.

Adoption of new technologies requires identification of potential barriers and key effective implementation strategies in order to ensure successful diffusion and implementation of the technologies. Research in UK indicated that lack of BIM knowledge and skills raised concern and delay in the uses of BIM in the UK (Young, et al., 2008). According to Fox and Hietanen (2007) lack of highly skilled cross trained staff with both construction and IT skill is one of the barriers hindering realization of BIM benefits.

3.3 BIM in Higher Education Institutes

The introduction of AutoCAD about thirty years ago paved a way to computer assisted design in the construction industry. Currently, computer-based design courses are streamlined and given in several undergraduate courses specially in developed countries. According to Dean (2007) BIM should be taught in educational institutions as graduates with BIM literate graduates have more advantage over BIM illiterate graduates. Fox and Hietanen (2007) highlighted that students and graduates with BIM knowledge and proficiency play an important role in the use of BIM within their organizations. A research in the UK recommends rearrangement of construction courses at universities to better equip students to meet the growing demand of the construction industry (Bataw, et al., 2015).

Construction education should keep itself updated with new innovations and industry. According to Deutsch (2011) BIM should be integrated into Architecture, Construction and Engineering programs. Ahbab, et al. (2013) stated that educational institutions should produce BIM enabled professionals for adoption of BIM in the construction industry. Cooksey and Schiff (2012) recommended that students should be able to acquire knowledge about the capabilities of BIM and effective use of the tool before they join the profession.

4. BIM for Sustainable Infrastructure

The AEC industry is becoming more and more complex and requiring more specialization. Specialization in turn opens a door for fragmentation in the industry and contributes to the decline in efficiency of the industry compared to other industries (Krygiel & Nies, 2008). In line with complexity of building and infrastructure systems, the presence of plentiful design requirements and the complex interrelationship between these requirements suggest the need for an integrated approach to design, construction and operation of buildings and infrastructure.

The construction industry is currently under immense pressure globally in terms of timely delivery, consideration of sustainable practice, value for money, etc. Several attempts were made to improve the situation through devising alternative procurement methods, introducing better innovative construction technologies and innovative processes including Computer Aided Design (Abubakar, et al., 2014) .

Vallero and Braiser (2008) indicated that BIM offers a great potential for sustainable design through increased teamwork and integration across different disciplines. BIM helps to test "what if" scenarios at the early design stage of projects and enable designers analyse several options which is an essential element of sustainable infrastructure design (Vallero & Braiser, 2008). Crotty (2012) stresses that safety, soundness and sustainability concerns of the public will be accommodated in software programs in a BIM-based industry. Malina (2013) suggests that BIM can be considered as a more sustainable and cost effective tool to deliver sustainable buildings.

A holistic design which is an approach for sustainability of the AEC industry calls for collaboration of different professional including architects, engineers and urban planners where these professional share information and tools supporting this approach need to emerge (Shen, et al., 2009). BIM enables designers to iterate and analyse sustainable design options faster than in a more traditional process (Krygiel & Vandezande, 2014).

One of the emerging project delivery methods called Integrated Project Delivery (IPD) is claimed to have many of the attributes of construction delivery systems very much compatible with Energy and Environment certification systems. According to Kibert (2013) BIM is instrumental in the successful implementation of IPD by providing the possibility for good collaboration on construction projects.

A study has indicated that BIM is a very effective tool to teach students concepts of building sustainability. It is argued that while sustainable building design and construction is being gradually integrated into construction curricula in higher educational institutes due to the complex nature of the subject, its instruction and learning is a challenge (Shen, et al., 2012).

5. Methodology

The research methodology employed includes literature review in relation to the role of higher educational institutes in facilitating BIM adoption rate of the construction industry. The review also used to identify the role of construction education institution in adoption of the technology in the AEC industry. Following the literature review, a semi-structured questionnaire was developed and a survey was conducted among final year Architecture, Civil Engineering, and Construction Technology and Management undergraduate students to assess their acquaintance with BIM and their perception about its benefits and practicability. The survey is designed to explore Architecture, Civil Engineering and Construction Technology and Management students level of preparedness to use BIM upon their graduation. It further aims to assess students willingness to learn BIM if they are given the opportunity.

The survey was conducted at the Addis Ababa University, the largest and oldest university in Ethiopia. The University is located in Addis Ababa, the capital city of Ethiopia and it is a flagship state owned educational institute. It was the first institute to start all the three undergraduate programs namely Architecture, Civil Engineering and Construction Technology and Management in the country. In 1955 a four year Civil Engineering program was introduced followed by Building engineering program in 1958. Lately a bachelors program in Construction Management and Technology program was opened in 2002. The university is considered as a trend setter in the country and it is fair to assume that it is a very good indicator of the situation in educational institutes in Ethiopia especially in terms of AEC studies. As graduates of the three field of studies involve in the design, construction and facilities management of infrastructure project the study focused only on these programs.

The research questionnaire has three sections: it begins with background questions followed by structured questions asking students to give their opinion about their competence and orientation towards BIM. The second section also includes a question asking students to prioritize the possible challenges of offering BIM courses in their respective programs. The last section has semi-structured questions dealing with students awareness and the types of BIM software programs they are acquainted with.

6. Results and Discussion

This next sections presents results of the survey and discusses on the findings.

The questionnaire survey was conducted at the end of 2015. The data analysis included descriptive analysis and comparative statistics.

A total of 100 questionnaires were distributed to a randomly selected students and 95 completed questionnaires were returned which is a 95% response rate. Out of the total respondents 33.7% (32) of them are female and the remaining 66.3% (63) of them are male. According to their field of studies students studying Architecture and Civil Engineering constitute 31.6% each and the remaining 36.8 % of the respondents are students from Construction Technology and Management. In the researchers opinion, the field of study composition of the respondents is a fair representation of the professionals involved in infrastructure planning, design, construction and facilities management. All respondents are final year students and are expected to join the AEC industry within one to five months time depending on their program structure.

Table 1 depicts that all architecture students are aware of BIM but only 33.7 % of them are aware of its benefits. 31.8% of architecture students said they have used BIM during their studies and only 27.9% of them indicated they have taken a course on BIM on campus. 23.2% of Civil Engineering and 18.3% of Construction Technology and Management students said they have never heard about BIM. As to awareness of BIM and its benefits, 66.3% of the respondents responded positively out of which half of them were Architecture students. In all cases Architecture students have shown better awareness and level of competence about BIM. However, involvement of Architects in Infrastructure design and construction in Ethiopia is limited when compared to the other two field of studies.

Table 1: Respondents awareness about BIM

Questions / *Field of Study*	*Never heard about BIM*	*Aware of BIM and its benefits*	*Used BIM on campus*	*Taken a course on BIM on campus*
Architecture	-	*33.7%*	*31.8%*	*27.9%*
Civil Engineering	*23.2%*	*13.5%*	*10.2%*	*10.1%*
Construction Technology and Management	*18.3%*	*19.1%*	*14.8%*	*3.8%*
Total	*41.5%*	*66.3%*	*56.8%*	*41.8%*

As shown in Table 2 the respondents indicated unpreparedness of the construction industry and absence of adequate and appropriate software and work stations as the two major challenges to offer BIM at the institute under consideration.

Table 2: Challenges of offering BIM at higher education institute as rated by respondents

Field of study / *Challenges*	*Architecture*	*Civil Engineering*	*Construction Technology & Management*	***Cumulative***
Unpreparedness of the Ethiopian construction industry to widely implement BIM	*4.03*	*3.84*	*4.03*	***3.97***
Absence of adequate and appropriate software and workstations	*3.67*	*3.35*	*3.86*	***3.61***
Lack of awareness of the institute management and academic staff	*3.10*	*3.41*	*3.79*	***3.42***
Lack of well trained staff	*3.43*	*3.32*	*3.24*	***3.33***

Note : *1 = Strongly disagree; 2=disagree; 3=neutral; 4=agree and 5=strongly agree*

86% of the respondents showed a very high interest to learn about BIM and 93% of them indicated that BIM would be very instrumental to improve the AEC industry in Ethiopia. Of the total students who responded that they are aware about the benefits of BIM, 52% of them failed to provide correct answers to the questions asking about benefits of BIM. This implies that the awareness of the students about BIM could be even below than the figures indicated in Table 1.

7. Conclusions

Investment in infrastructure is key for economic development especially for developing countries like Ethiopia. As infrastructure development involves consumption of a considerable natural and capital resource and as it has long term impact on socio-culture of societies, infrastructures should be sustainable both in terms of delivery and service. One of the innovative tools to help the AEC industry deliver sustainable infrastructure is BIM. While developed countries are in a better level in making use of BIM, developing countries are still struggling to benefit the great advantages of the technology. The role higher educational institutes play in the diffusion of this technology into the industry is vital.

Results of this study indicated that awareness and preparedness of AEC graduating students to use BIM in the Ethiopian AEC industry is very low. This is especially true with Civil Engineering graduating students who are responsible to design and manage construction of majority of infrastructure projects in the country. According to the study Architecture students have better acquaintance and competence in using the program showing the prospects that Civil Engineering and Construction Technology and Management program can also enable their students gain the knowledge and skill their students need.

To pave a way to make use of the vast potentials of BIM, educational institutes in Ethiopia should go extra mile to equip their students with this technology. Teaching students BIM at a university level before they join the industry should be reasonably less costly and it plays a vital role to help the industry move towards wide implementation of BIM for delivery of sustainable infrastructure.

(email: dyenerim@pagethink.com)
Mark J. Clayton,
Texas A&M University
(email: mclayton@arch.tamu.edu)

Abstract

Colonias are substandard and low-income self-help housing developments along north of Mexico - US border. There has been an increasing concern over sustainable development and energy efficient design techniques which addresses both new and existing housing. However, there is a need for housing policy focuses on informal self-built low-income housing context (Sullivan and Ward 2012). In this paper, we discussed the potential way of integrating BIM technology to address sustainable improvements in informal settlements housing policy.

This paper builds on our previous research that proposed a new tool, Colonias BIM Toolkit (CBT) to model and assesses the incremental changes over time and the building performance (Yenerim 2014). To explore this goal, we have investigated the possible use of CBT based home models and energy estimates for policy stand point. Our provision was to guide residents towards better individual decisions on design of their homes by utilizing this tool. The proposed technique can be applied to any informal settlements around the world. However, as a matter of convenience, the proposed technique was tested on Colonias in Laredo, Texas. We proposed a technique to devise a Building Information Modeling toolkit to model informal settlements and a multiple analyses to produce a probabilistic estimate of energy consumption. We argue its benefits through one colonias home in Laredo, Texas which has been built in three stages over three years.

Our hypothesis was that BIMs of homes and communities can be stored as a database to be used by policy makers and researchers on investigating their growth pattern and to set up regulations on rehabilitation of these structures. If policy makers have data on existing construction techniques and materials of homes and a 3-dimensional visual data on the form of homes, policy makers can monitor and control the form of houses and the growth of the settlements. Moreover, having estimate of existing energy consumption of homes and communities can enable policy makers to set up regulations and rules for more sustainable home design and rehabilitation of existing ones.

Keywords: Informal housing, colonias, Colonias BIM Toolkit, Sustainable Cost Efficient Housing, policymaking

1. Introduction

The aim of our research is to determine basic aspects of the practicality of a model-based approach to guide policy decisions about informal settlements in terms of energy conservation. We speculate that modelling an entire community of homes in an informal settlement and simulation of homes could provide insights about energy consumption, visual qualities, and other considerations, enabling analysts to examine multiple scenarios of how the community might change. Policy-makers could use the growth patterns and consumption patterns to plan regulation and interventions to achieve improved outcomes and to help residents to build more formal homes. Our study has shown the feasibility of using Building Information Modelling (BIM) and energy simulation to support analysis and prediction of the performance of homes that can be aggregated to show the performance of communities. To predict the performance of homes, we have determined the probable performance of homes by utilized parametric variation and simulation. Our models have not yet been calibrated; future work could examine the predicted energy consumption against the actual consumption. We believe that our process can be used for informal settlements around the world to estimate current and future energy use and guide development of policy.

In a previous study, we devised a toolkit (the Colonias BIM Toolkit, or CBT) from BIM technology to enable rapid modelling and simulation of the homes that make up a community (Yenerim 2014). Our process was to collect physical data pertaining to house footprint, materials and construction techniques by using a face-to-face interview with residents and in-depth on-site home inspection. The CBT includes a library of building components and systems observed in a test sample of homes in colonias. Our study used colonias along the border between Texas and Mexico as an example of informal settlements.

In this paper we present the use of the toolkit to model a single house and then perform a parametric study of energy simulations to determine a range of possible energy performance.

2. Informal settlements and Building Information Modelling

One of the major challenges is the unpredicted sprawl of informal settlements and their potentially deleterious impacts upon environments and explosive growth in consumption (UN-Habitat 2003). Informal settlements are substandard low-income housing development for people who cannot afford formal housing structures. They occur in most developing and developed countries (UN-Habitat 2003; Amis 2002; Burdett and Sudjic 2007; Davis 2006; Turner 1977). According to literature, there are several methods for upgrading informal settlements : relocation, resettlement, or self-help in-situ construction (Huchzermeyer and Karam 2006). Self-help improvement through participation of residents is frequently cited as the most successful way of rehabilitation of these settlements.

Informal settlements can consume high levels of energy in comparison to formal settlements with building codes and construction standards (UN-Habitat 2008). However, an estimated energy use of existing structures or communities may be difficult to determine due to lack of knowledge of existing construction methods and insulation values. There is a lack of knowledge about the construction techniques and materials about these structures. Moreover, estimating the energy consumption of communities could enable policy makers to set up regulations and legislations on energy efficient home improvements and improve building code regulations for these structures. It could also be possible to use technology to assist field agents in advising residents how best to upgrade their homes in self-help projects.

For a test case, we selected the colonias in Texas as having many characteristics in common with informal settlements in other parts of the world. As a substandard housing development, most of these structures do not meet building codes (Bradshaw et al. 2005; Donelson and Esparza 2010; HUD 2008; Parcher and Humberson 2009; Ward et al. 2010). As a result, colonias residents pays more for their energy bills per square footage than an average U.S. resident pays (Gharaibeh et al. 2009; Giusti and Estevez 2011; Gharaibeh et al. 2009; Ward et al. 2010).

Three main housing types within the colonias have been identified: self-help homes, single or double wide manufactured homes and modular homes, and recreational vehicles (Sullivan and Ward 2012). Many homes combine all three of these. The self-help housing process results in a variation in construction materials: wood, concrete blocks, cardboard, and even dilapidated trailers (McKenzie 2002; SOS 2012). A common scenario is that a resident chooses a lot in colonias and lives in a temporary structure such as a trailer or camper. The residents build their homes by themselves or with the help of other residents and family members. Availability of money and materials is one of the major determinants for the how long the construction process would take place. Moreover, according to their changing needs such as expansion of their families, residents continue to add more rooms and expand their homes.

Because of being built over an extended period of time using materials that are ready at hand at the moment and being constructed outside of regulatory oversight by unskilled or semi-skilled labour, colonias homes show a great variety in terms of the quality of the structure. On one hand, some homes are built by reputable developers and homebuilders, while other residents live in make-shift structures, repurposed farm buildings and dilapidated trailers (Sullivan and Ward 2012; Ward et al. 2011). To that extent, although there are several studies focused on colonias homes and their materials, there are still unknown parameters about these houses.

Contemporary advanced computer software could provide those working to improve homes in the colonias with new and more effective methods to effect change and establish policy. Building Information Modelling (BIM) is an object-oriented modelling technology that is becoming widely accepted in building industry, replacing Computer-Aided Design (CAD) technology (Eastman et al. 2008). BIM integrates graphical and non-graphical information and enables users to control them through established parameters (Eastman et al. 2008). Furthermore, BIM facilitates the conduct of simulations that can predict the performance of building designs. In our study, we selected BIM technology to take advantage of its several capabilities such as 3-dimensional visualization of a structure, ability to document data, library of components and system families, parametric modelling capability, and simulation tools.

Our research is focused on exploring the benefits of the use of software, expressed as the CBT, to estimate the existing energy consumption of homes in the colonias and monitor the growth of the communities to aid in development of policy. Our approach is intended to model existing homes and communities rapidly, and to estimate current and future energy consumption of informal communities. By collecting models, it will be possible to build an extensive database which can be helpful to monitor the increase in energy use due to the growth of these settlements. We discuss the potential benefits this toolkit for policy makers to establish guidelines on low-cost energy efficient design and construction strategies for residents and to improve the building codes. We argue that policy makers can provide assistance in more sustainable energy efficient improvements in design and construction methods according to the adopted architectural patterns by residents.

3. CBT Methodology: A Process to Guide Policy Decisions

Modelling and simulating homes in informal settlements is difficult due to the lack of data about construction and other factors that affect energy performance. We have used parametric modelling and simulation, and statistical methods to determine potential likely range of energy performance of a home. We have tested 20 scenarios on unknown parameters of the homes.

We used Autodesk Revit 2014 for modelling homes and Autodesk Green Building Studio (GBS) to perform energy simulation. Several factors have an impact on energy use of buildings: building components, such as floors, walls, ceilings, roof, and window and doors, air movement through the envelope of the building, heating, cooling and lighting systems ,residents, and outside factors such as; wind, sun, temperature, and humidity. When it comes to informal settlements, it is even more difficult to predict these variables because these structures are self-built substandard construction which, most of the time, do not meet building codes. We used Autodesk GBS web-based tool which runs DOE-2 at the background. Autodesk Revit and GBS are interoperable with each other, we exported BIM of homes as a gbXML file. GBXL is editable spread sheet with DOE-2 inputs. It embeds all the parameters assigned in Revit environment. After adjusting the parameters for multiple energy analyses run, we uploaded them to GBS and performed energy simulation.

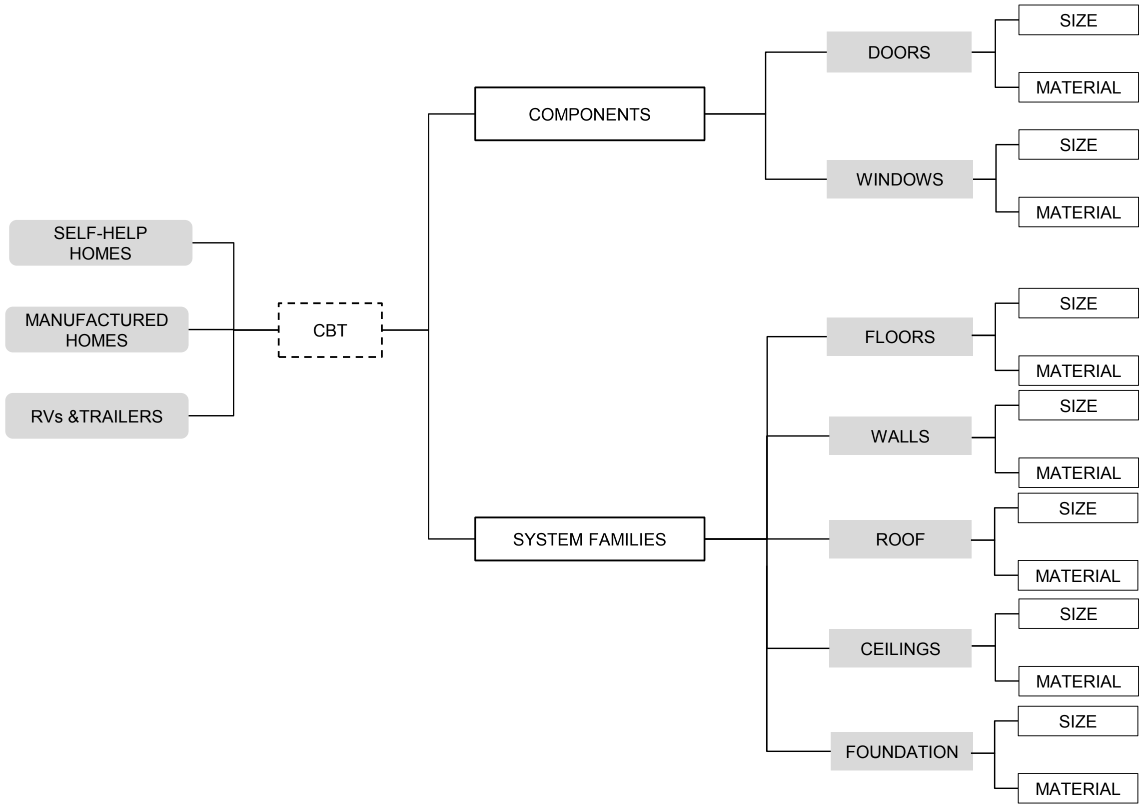

Figure 1: Conceptual Diagram of CBT Development

Although Autodesk Revit has its own library of materials and building component and system families, they are inadequate to model the non-standard constructions in colonias homes. We developed CBT as an Autodesk Revit template file which includes unique library of building components and materials used in colonias homes. The Colonias Autodesk Revit Library encompasses existing architecture and construction patterns of colonias self-help housing in and near Laredo, Texas. Three types of homes observed in Colonias were considered for each component and system family (Figure 1). The variation between each type was determined by considering size and material parameters. Age is also another important parameter in terms of the likely construction methods within a home (Ward et al. 2010). We have referred to age parameter to identify scenarios for unknown parameters.

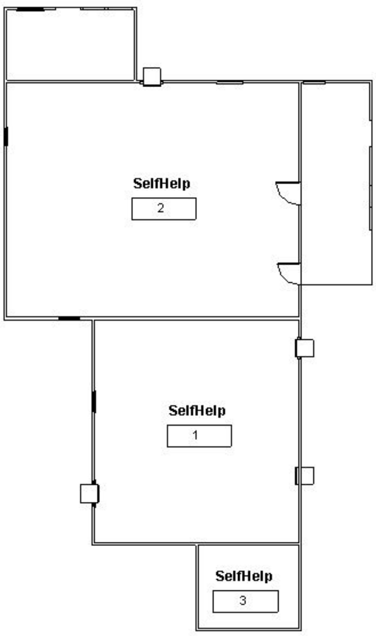
3.1 Development of CBT

Three colonias in Laredo, Texas were selected as a test case. Data was collected from 30 self-help houses as a representative sample from these colonias using face-to-face interviews with residents and on-site home inspection. We used two data collection instruments: (1) interview questionaire for residents on construction techniques of their houses and (2) home inspection checklist for site observation (Yenerim, 2014). The data collection instruments were built on existing studies (Keall et al. 2010; Meng and Hall 2006; Reimers-Arias 2009; Ward et al. 2010).

We were able to compile a list of materials used and measure the home. Three types of houses, self-help homes, manufactured homes and recreational vehicles or trailers, were considered, and represented within under categories. To that extent, CBT design kit includes a wide range of materials and construction techniques. However, there are several unknown data elements that are required for energy simulation: (1) R-values of the building components, (2) heating and cooling systems, and (3) air infiltration value. To overcome this challenge, we performed multiple analyses to produce a probabilistic estimate for energy consumption.

3.2 CBT Test Case

The use of the CBT is demonstrated through one self-help colonias home. The home was built in three stages in 1999, 2001 and 2002 (Figure 2). It comprises wood frame structures on concrete slabs with shingles on the roof. Residents reported to have used tile as a floor finish. According to the interview with the residents, first, they have built a structure with 1 kitchen, 1 dining room, 4 bedrooms, and 2 bathrooms. The second stage structure consists of 2 bedrooms and 1 bathroom. In the final stage, the residents added 1 bath and a porch.



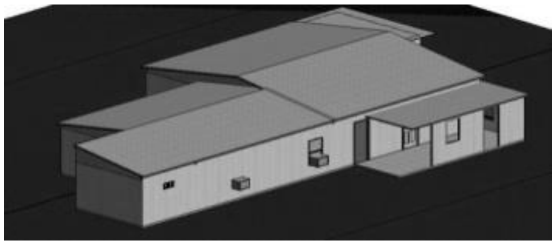


Figure 2: Plan of the home (left) and BIM of the home created by utilizing CBT (Yenerim 2014)

To model the house without R-values, HVAC type, and air infiltration value, we developed 20 scenarios and ran 20 simulations to generate a probabilistic range. We have tested a combination of two educated guess on air infiltration values by utilizing Lawrence Berkeley National Laboratory database (Bazjanac 2008), two different insulation thicknesses on building components, and natural ventilation, and 3 HVAC systems (Yenerim 2014). The results suggest that total annual electricity use ranges from 15,806 kWh to 25,141 kWh and total energy use intensity falls between 37 and 60 (kBtu/ft^2/year).

Table 1: 20 energy simulation runs

Scenario	Infiltration	RUNS	Annual Elec Use	Annual Fuel Use	EUI

	MOST LIKELY INFILTRATION	**MOSTLIKELY.xml**	**15,990**	**7**	**37**
		HVAC_RES 17 SEER/0.85 AFUE Split/Pkgd	16,224	10	39
		HVAC_RES 14 SEER/0.9 AFUE Split/Packaged Gas	24,038	10	56
		HVAC_RES 14 SEER/8.3 HSPF Split Packaged Heat Pump	23,661	7	53
SCENARIO-B	WORST INFILTRATION	**WORST.xml**	**17,790**	**7**	**41**
		WORST.xml_Infiltration_0.17_ACH	16,174	7	37
		WORST.xml_Infiltration_3.5_ACH	21,302	7	48
		HVAC_RES 17 SEER/0.85 AFUE Split/Pkgd	17,443	15	45
		HVAC_RES 14 SEER/0.9 AFUE Split/Packaged Gas	25,090	15	60
		HVAC_RES 14 SEER/8.3 HSPF Split Packaged Heat Pump	25,141	8	56
	MOST LIKELY INFILTRATION	**MOSTLIKELY.xml**	**16,361**	**7**	**38**
		HVAC_RES 17 SEER/0.85 AFUE Split/Pkgd	16,467	12	41
		HVAC_RES 14 SEER/0.9 AFUE Split/Packaged Gas	24,293	12	57
		HVAC_RES 14 SEER/8.3 HSPF Split Packaged Heat Pump	24,054	8	54
		MAX VALUE	**25,141**	**15**	**60**
		MIN VALUE	**15,806**	**7**	**37**
		MEDIAN	**19,310**	**8**	**46**

Modeling and analysis required less than a day. Therefore, it is very practical.

4. Discussion

Our investigation shows that, using CBT, a researcher can model homes and communities in a very quick way and can perform energy simulation to predict their current energy use. Having an estimated current energy use of individual homes can lead to an estimated energy use of the community. These numbers can be useful for policy implications and to monitor the growth and its reflection in energy consumption. These data can be assembled as a database for colonias and be updated as new data collected and as homes are updated. Scenarios of future homes and communities can be modelled with relative ease, allowing policy-makers to consider different outcomes and ranges of outcomes. This process of developing and utilizing BIM toolkit for modeling informal settlements and perform energy analyses can be applicable to other informal settlements as well.

Having visual models of homes would be beneficial for policy makers as well. They can have knowledge about existing architectural practices. By architectural practices, we refer to both design patterns, and construction standards and materials. It is crucial because they reflect the traditional and cultural mind-set of residents. It is very important for policy makers to understand the existing construction activities adopted by residents in order to propose improvement techniques and methods acceptable by residents.

By utilizing aerial photography from different years, an analyst may examine the changes on individual homes and on a community as a whole. It may be possible to calibrate a model of a community based on change of building form and energy use over time, enabling increased accuracy of predictions for the future.

In order to make the results more accurate and reliable, more accurate and detailed data collection for each home is required. By increasing the number of sample homes, and also number of runs, energy simulations results become more accurate. We have tested only 20 scenarios on a single home for this study and have a range of energy use of the residents. However, with more and more energy simulation runs of a significant number of homes in a community, it would be easy to extrapolate these results to the whole community and have a lower standard error of the whole community.

5. Conclusions

Although BIM has been widely used as a design and modelling tool for formal structures, applications in informal settlements context is new. Nevertheless, BIM is a powerful tool for modelling informal settlements. Using a toolkit, such as the CBT, it is possible to model rapidly a home or many homes in an informal settlement. Missing data, such as insulation and infiltration levels, may be estimated by systematically varying parameter values and conducting energy simulations to reach a probable energy performance. Given the BIM of the home, it is possible to project future modifications to the home and estimate future energy costs, aiding policy-makers to project future energy needs and guide development of policy. As the sample of homes in a community is increased, the range of probable community-wide energy consumption should narrow, leading to greater confidence in predictions.

We demonstrated how BIM of informal homes and simulation can be used to inform, and determine policy decisions related to design and construction of homes. In this paper, we argued that multiple analyses can produce a probabilistic estimate of energy consumption. As the sample of homes increases, the accuracy of the energy consumption of the community increases, aiding support of policy decisions. For example, the uncertainty around the energy analysis of a single home can be demonstrated by the standard deviation of possible outcomes of its simulation. This uncertainty can be quite large for a single home since the unknowns associated with the home can create a big range of energy analysis outcomes. As we repeat the analysis with different houses and increase our sample size, the standard error (variation of sample mean) would decrease and the precision of the analysis around the average single home would increase. The larger the sample, the more precise our analysis would be for the total community.

Having the CBT and BIM of homes allows testing and evaluating alternative materials, insulation, heating and cooling systems and even alternative layout design options (Yenerim

2014). Besides estimating energy use based on heating and cooling loads, BIM of homes has other benefits; it allows users to perform wind, daylighting, and cost of the home.

To sum up, by having 3-dimensional BIM of homes and parametric simulation results, policy makers could determine not only required insulation improvements, glazing options, or HVAC system alternatives for the existing structures to upgrading existing informal settlements, but also the form and location of the additions. Moreover, policy makers could provide low-cost passive design techniques such as extending roof overhangs, use of porch or planting trees for shading purposes. Our focus is Texas colonias in this study but the 3-dimensional BIM of homes and energy simulations of colonias homes in other states such as New Mexico, California and Arizona could also enable policy makers to identify scenarios considering energy use in different climates. To that extent, developing a toolkit for different colonias and creating BIM of homes located in different states would be beneficial for policymakers. As these are self-built and self-managed homes, residents can improve their homes to meet the required building codes for this area by themselves.

Abstract

Over the past five years from 2010 to 2015, Building Information Modeling (BIM) has gained significant popularity in Singapore's building and construction industry with the implementation of the first BIM roadmap by BCA (Building Construction Authority). It is observed that, the project stakeholders adopt BIM in their work flow mainly in the design and construction processes. It is unclear the extent to which successful BIM adoption be extended to post-construction Facility Management (FM) stage. Considering that most of the buildings in Singapore are existing buildings constructed and operated without any BIM experience, it is important to know how the building owners react to BIM adoption in FM. In this research, we selected a large institutional organization in Singapore to investigate the BIM readiness of the building owner and facility managers. Our aim is to evaluate the awareness and willingness of BIM adoption, identify the motivators and challenges of BIM implementation, and explore the strategies and potential issues of BIM adoption in FM. The research provides value to the implementation of the upcoming BCA's second BIM Roadmap with the focus on process transformation, BIM for specialty contractors, BIM for design-for-manufacturing-and-assembly, BIM for facilities management, and BIM research and development. We adopted a qualitative method of unstructured interview with open-ended questions to collect rich information and data from the interviewees with greater details and depth of content. The transcripts were coded for qualitative analysis. Interview data revealed that the owner and facility managers have a fairly high degree of awareness of and willingness to BIM adoption in FM, with many external and internal motivators and challenges identified. Some potential issues which may hinder the BIM adoption are discussed in five key components, i.e. people, process, technology, policy, and BIM manager.

Keywords: Building Information Modeling, BIM, Facilities Management, FM, Institutional Buildings, Singapore.

1. Introduction

Building Information Modeling (BIM) is an emerging virtual design and construction technology which has been revolutionizing the architecture, engineering and construction (AEC) industry over the past decade. BIM redefines the process of asset delivery and provides multi-disciplinary virtual models generated from a wide range of data and exchange files in many levels of detail or development (i.e. LOD, a measure of project development and information certainty in the associated BIM models; see also BIM forum, 2013) throughout the life cycle of building and infrastructure development and operation. The three-dimensional (3D) models and the rich underlying data allow for various trades to collaborate and coordinate the information with each other to improve productivity and increase return on investment (ROI) attributed to the virtual modeling and proactive problem solving approaches.

Researches on BIM have increased significantly in the recent years. Yalcinkaya and Singh (2015) reviewed 975 academic papers related to BIM between 2004 and 2014 and reported that out of 220 papers in the factor of "BIM implementation and adoption", 4% were published between 2006 and 2008, 38% were published between 2009 and 2011, and 58% were published between 2012 and 2014. Other BIM research factors include energy management, academy and industry training, information exchange and interoperability, safety management, urban/building space design and analysis, construction and project management, design codes and code compliance, as-is, as-built data, promotion and technology development, maintaining and managing facilities, and architectural design process. The following trends can be observed: a) BIM researches become more and more popular since 2004, especially after 2009; b) BIM researches cover a broad range of topics in the building life cycle; c) the majority of BIM researches focus on the project development phase, while researches in the post-construction phase are limited; and d) BIM researches on owners and facility managers are much less than those on architects, engineers, and contractors among all the project stakeholders.

At present, the benefits of implementing BIM in the design and construction phases have been increasingly recognized and realized (Barlish and Sullivan, 2012; Bryde et al., 2013; Eadie et al., 2013). However, the benefits of implementing BIM in the whole of building life cycle, especially in the operation and maintenance phase, have not been equally demonstrated and explored. For most asset owners, the true benefits of BIM in the post-construction stage are difficult to be measured using quantitative means. Therefore, evaluation should not only focus on the operational improvements enabled by BIM, but those of a managerial, organizational, infrastructure and strategic nature (Love, et al., 2013). Adopting BIM in the traditional facility management (FM) workflow requires a fundamental change of business practices, rather than merely a technical enhancement. The barriers need to be identified and evaluated at various levels of business organization, within which the majority of workforce currently have little or no prior experience in BIM applications.

This research project aims at identifying the barriers and drivers of large clients towards BIM adoption and implementation in the post-construction phase. It focuses on the perspectives of building owners and facility managers, who are the decision makers in adopting BIM and the executing BIM implementation, respectively. This project is part of a comparative research of BIM adoption between Australia and Singapore for whole of life BIM model delivery (from project inception stage to facility management stage). We conducted five formal interviews with five employees of a large institutional organization in Singapore, who represent the owner, the FM team, and the project management (PM) team. The audio recordings were transcribed and coded for qualitative analysis. The results generated from this study help understanding the challenges and motivators of BIM adoption in FM, assess BIM readiness of owners and facility managers in the context of Singapore institutional built environment, and provide strategic recommendations in several political, technological, economic and social themes.

2. Background

Singapore has substantially accelerated BIM adoption with the implementation of the first BIM roadmap by BCA (Building Construction Authority). Over the past five years from 2010 to 2015, BIM has gained significant popularity in Singapore's built environment. Figure 1 shows a summary of the challenges and strategies in BIM adoption identified by BCA (Cheng 2011). BIM implementation in the public sector was initiated with selected projects between 2010 and 2012 (see Table 1). Subsequently, mandatory BIM e-submissions were enforced progressively between 2013 and 2015 with specific milestones given to the architecture and engineering disciplines. By July 2015, it was stipulated that architecture and engineering BIM e-Submission be implemented to all new building projects with gross floor area (GFA) of 5,000 m^2 and above.

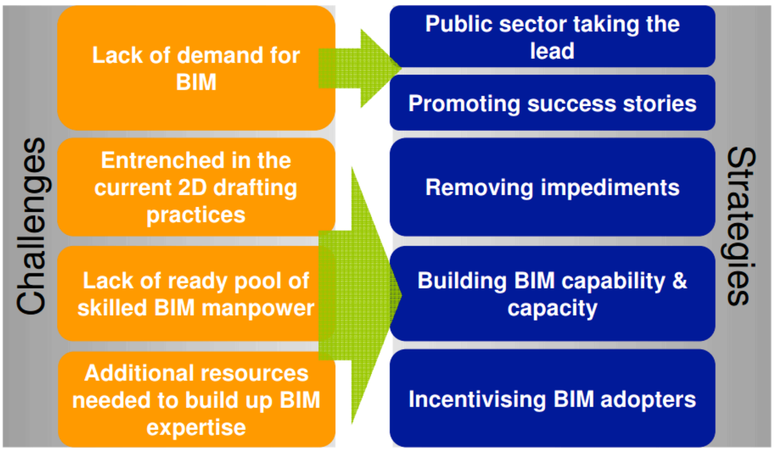

Figure 1: Singapore BCA's first BIM roadmap: Challenges and Strategies

Table 1: Singapore BCA's first BIM roadmap: Implementations

Year	Implementation
BIM Implementation in the public sector projects (2010-2012)	
2010	*Establish Centre for Construction IT help key agencies and construction firms to kick start BIM*
2011	*Work with key agencies on pilot projects*
2012	*Work with key agencies to prepare consultants and contractors who undertake the public sector projects to be BIM ready*
Mandatory BIM e-Submission (2013 – 2015)	
2013	*Mandatory Architecture BIM e-Submission for all new building projects > 20,000 m^2*
2014	*Mandatory Engineering BIM e-Submission for all new building projects > 20,000 m^2*
2015	*Mandatory Architecture & Engineering BIM e-Submission for all new building projects > 5,000 m^2*

BCA's first BIM roadmap primarily targeted on architects, (structural, mechanical, electrical, and plumbing) engineers, and contractors. From a discussion with several BCA staff in the late 2015, it shows that the majority of submitted BIM models are created at LOD 150 to 200 levels (i.e. the schematic design stage) just to meet the compliance requirements. Nevertheless, it is no doubt that the mandatory BIM submissions have greatly accelerated BIM adoption in Singapore in the design and construction workflow, though there is still a long way to go for BIM adoption and implementation to be extended to the entire building life cycle.

In October 2015, BCA announced the second BIM roadmap (2015-2020) which promotes BIM adoption to all asset stakeholders in the whole building life cycle. Six key measures were introduced, including: a) driving BIM collaboration throughout value chain; b) building BIM capability of specialist contractors; c) providing new training programs at all levels; d) promoting BIM for Design for Manufacturing and Assembly (DfMA); e) promoting BIM for FM and smart building; and f) promoting BIM-based research and development (R&D).

To extend BIM adoption into the post-construction phase, a paradigm shift of the present best practices in building life cycle management is required. Admittedly BIM for FM applications are still rare in Singapore according to the discussion with the above mentioned BCA staff. This is not only because of the fact that the vast majority of buildings do not have any BIM models or do not have BIM models with sufficient details, e.g. LOD 500 as-built models or LOD 600 as-is models, but it imposes great challenges to five key components in the built environment, i.e. People, Process, Technology, Policy, and BIM manager (Bew and Underwood, 2010; BIM Journal, 2011). While 'People' and 'Process' are instrumental to improvement and change, without 'Technology' these elements cannot be sustained. BIM adoption will inevitably result in major transition of skills, practices, and knowledge associated with people and processes by taking advantage of technology advancement and subsequently enabling more technological innovations. 'Policy' plays an important role in terms of providing standards and guidelines to mitigate the risk of mistakes and failures. 'BIM manager' is a critical success factor to ensure the other four components work in unison.

Considering that most building owners and facility managers in Singapore have little or no real experience in BIM, which is evident from the lack of BIM adoption and implementation in FM, it is valuable to investigate the BIM readiness of building owners and facility managers in terms of awareness, willingness, motivators, challenges, strategies, and roadmap. Some benefits of the research are as follows. First, it helps understanding the current status of BIM adoption in the FM stage before the second BCA BIM roadmap is implemented. Second, it helps identifying the key drivers and barriers of BIM adoption and implementation in FM. Third, it helps establishing an enhancement framework to expedite BIM for FM. Last but not least, it allows to benchmarking the performance of BIM for FM in Singapore with those of other countries for further improvement.

3. Research Settings

The main objective of this study is to identify the barriers and drivers for BIM adoption in FM and evaluate the BIM readiness of owners and facility managers in Singapore. We decide that a qualitative method of unstructured interview with open-ended questions is more suitable for collecting rich information and data from the interviewees with greater detail and depth in content. A large institutional organization in Singapore is selected as the case study, which owns more than 200 buildings and has hundreds of internal staff and external workers. The organization still adopts a 'traditional' facility management framework, where the workflows are based on 2D drawings. Most of the existing buildings do not have BIM models. Several new buildings are being tendered or constructed with BIM models at LOD 200 to 300 levels (i.e. the detailed design stage). This is a typical large organization in Singapore, in terms of FM practice. It has not formally started BIM implementation in the FM, but some BIM applications have been initiated in the PM phase.

The interview team comprises three co-authors of this paper, who have fairly good understanding of BIM in terms of theory, technology, best practice, and the BCA's BIM roadmaps. Two interviewers are based in Singapore and familiar with the local industry context. The other interviewer is based in Australia, who provides an additional perspective to this research.

The interviewee team comprises five employees from the same organization. Three interviewees are from the department of facility management: one director (F1), one senior associate director (F2), and one contract manager (F3). None of them have real BIM hands-on experience. The other two interviewees are from the department of project management under strategic planning division: one senior associate director (P1) and one assistant manager (P2). P1 has no prior BIM hands-on experience. P2 previously worked as a BIM coordinator in a design firm for two years. The interviewee team consists of senior management, middle management, and executives of both FM and PM processes. Collectively, they represent the building owner and facility managers to provide a reasonable sample for the research study.

Questions cover the interviewee's background and awareness of BIM related to his/her work, the interviewee's willingness of BIM adoption in his/her workflow, the challenges or barriers of BIM adoption in FM, the motivators or drivers of BIM adoption in FM, and the strategies to be taken.

Figure 2 shows the research framework where the key value of this research is to provide strategic recommendations to: a) remove the barriers of BIM adoption in FM at organizational level; b) increase the motivators of BIM adoption; and c) facilitate the implementation of BCA's second BIM roadmap.

One of the limitations admitted by the authors is that this research is based on a single case study. The validity of the research findings are subject to further validations with other organizations in Singapore, though many of them may share similar sentiments due to the rather standardized industry environment and the strong policy and regulatory guidance. Meanwhile, the open-ended questions allow the interviewees to share insightful experiences and opinions based on their job backgrounds. However, it is difficult for the authors to provide a list of individual questions here as most questions (except for the opening ones) are based on the conversation context. Nevertheless, the questions are primarily focused on the awareness, willingness, challenges, motivators, and strategies of the BIM adoption in FM. Lastly, the authors adopt a simplified framework in this paper based on Figure 2, without extensively exploring the interrelationships of various interviewee inputs, which will be covered in another paper.

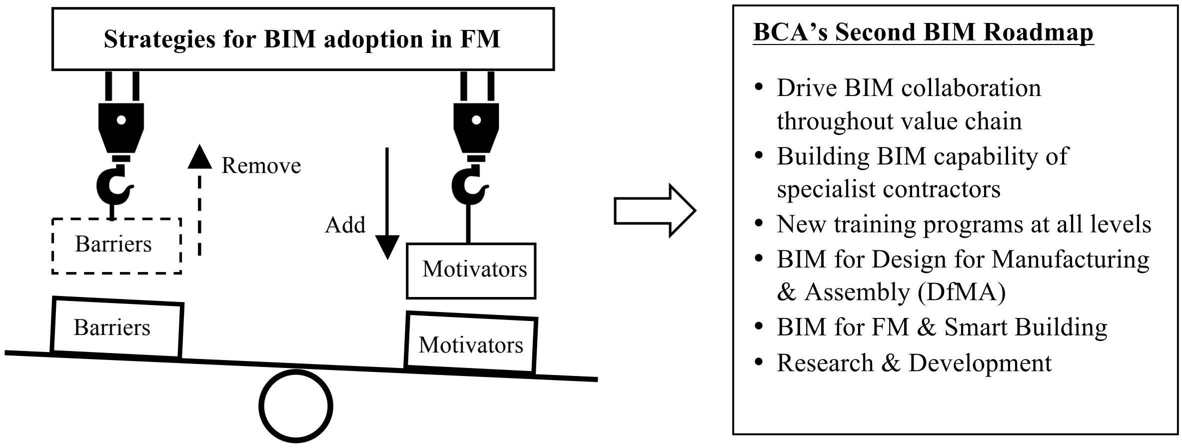

Figure 2: Research framework for promoting BIM adoption in FM

4. Data Collection and Analysis

All interviews were audio recorded and transcribed. The transcripts were then coded in NVivo for qualitative analysis. The top level coding structure includes the following elements: status, motivators (or drivers), challenges (or barriers), and strategies.

4.1 Status of BIM adoption in FM

The interviews with F1, F2 and F3 indicate that BIM for FM has not been adopted in the organization. All five interviewees are aware of BIM, though only interviewee P2 has prior BIM hands-on experience in another design firm. Regarding the willingness to adopt BIM for FM, interviewee F1 (FM director) expressed that "*We are keen to start it*", "*We don't let the authority or the agencies push us to do that. We feel if it is the right way, let's do it*", "*In fact, we are quite tempted to do that, just by lock, stock and barrel*", and "*So now the question is how to create that kind of journey ourselves*". It is therefore clear that the organization is at the early stage of BIM adoption, and the senior management of FM has a strong interest in initiating BIM adoption and implementation.

4.2 Motivators of BIM adoption

Motivators are a combination of factors that encourage or force BIM adoption in the organization. Interviewee F1 admitted that "there is this external push and this internal push". We classified these factors as externa motivators and internal motivators.

External Motivators

The first external motivator is **authority encouragement and enforcement**. In Singapore's context, currently there is no policy requiring or insisting that FM group takes up BIM, but BCA encourages early BIM adoption for FM. F1 disclosed that funding could be available if they start looking into it. Similar case can be found in the implementation of BCA's first BIM roadmap, where BIM adoption was first tested out in the public sector between 2010 and 2012, and subsequently mandatory adoption was required for the industry once the experience was built up. Likewise, it is possible in the future that using BIM for FM becomes a compulsory requirement, which will increase the risk of non-performance.

The second external motivator is **peer effect**. F1 disclosed that he was invited to participate an overseas study trip to Europe, and witnessed some best practices of BIM applications for FM. F1 commented that the BIM-FM system demonstrated is at "*mature stage. They are using at the facilities management stage. ... Here they call it various D: 3D, 4D, 5D and 6D. They are at the 6D level right now*", and "*We didn't see the difficulty, how they reached it. We saw the outcome, the final outcome that it really benefits the facility management group, yeah, and their operators. In fact, their contractors are all into that system as well; it's all interrelated*". Peer effect or peer pressure is a well-known influence that encourages people in a peer group to change their attitudes, values and behaviors to conform to those of the influencing group or individual. In this case the showcase of mature BIM applications for FM certainly provided a high level inspiration, especially when the influenced peer already had a strong desire to adopt BIM.

The third external motivator is **organizational image**. F1 disclosed that "*being a leader in many areas, at the senior management level when I attended the meeting they also say - why don't we just take a step forward?*".

Internal Motivators

The first internal motivator is **benefits to organization**. F1 disclosed that "*We can see the benefits at the facility management level rather than at construction level*", and "*looking at from other requirements like Green Mark or even like Barrier-Free Accessibility, we believe in it; actually it works*".

The second internal motivator is **desire to be ahead**. F1 disclosed that the senior management of the organization suggest "*So instead of being pushed, why don't we just take the first step and get it done ourselves?*".

The third internal motivator is **catching up with the PM office**. F1 disclosed that the FM department in the organization is linked to the PM department. Based on the BCA's first BIM roadmap, most new buildings of the organization will have BIM models submitted in the future. "*So I am doing the catching up with the other group*".

The fourth internal motivator is **benefits to FM**. F1 suggested two benefits as data and data analytics, which could enable preventive and predictive FM. "*I would say data; I think more importantly, I think it is the analytical part of it. I think, okay, if I don't look at that difficulty, I look at the benefit straight away, I think they link all the data together and generate a lot of what we call analytics to guide the facility management in terms of preventive maintainers. So we don't have to do what we call... 'guessing game'.*" "*So we should move more to preventive, even better predictive, and I think we have this kind of expectations from various laboratory and institute that we should actually be, keep improving on maintenance stuff, before it breaks down.*

So I think it ties with a core mission, yeah, and these tools really, from what they demonstrated is definitely really useful.". F2 (zone manager) suggested an example of asset lifecycle planning. "*Asset lifecycle replacement for example. So right now we are not able to fine tune the real details and currently we don't have the nitty gritty details of specs ... if everything could be easily integrated into one source where everything is overlapped, so it's not only just BIM only but that's why we are moving towards into our first phase which is going into the modular software where we can actually track repair cycles.*"

The fifth internal motivator is **benefits of efficiency and cost**. F2 believes BIM could help speed up information retrieving and handling. "*I think it's more about being able to manage information a lot faster. Instead of having to work on just CAD drawings and then having to put information together for different sources you have everything as one integrated source. That will cut time pretty much.*" F3 (contract manager) commented several times about the potential reduction of time (and cost) in retrieving drawings and other related data. "*Yes they will need probably I would say at least 20-30% of their time (to retrieving information).*"

Other mentioned benefits include visualization, clash detection, scheduling, and construction management, which are related to the native benefits of BIM technology.

4.3 Challenges of BIM adoption

The interviewees disclosed many challenges concerning BIM adoption and implementation, which are summarized as follows.

- **Cost**. F1 disclosed that "*normally cost and resources are the barriers*", and there is a lot of initial investment as well as maintenance cost to create and operate the infrastructure for BIM-FM. Estimated cost for the organization over a period of 10 years could exceed 10 million Singapore dollars.
- **Time**. F1 disclosed that it took 12 year for the European organization he visited to reach mature stage of BIM-FM application. Although he is confident in shortening the duration to less than 10 years, it would still be a long period of time and therefore there could be many uncertainties. "*Normally, once I start showing ten year, or data that shows what goes beyond 10 years I know I will lose their interest.*"
- **Return of investment (ROI)**. F1 disclosed that the initial calculation of ROI (for the planning purpose) is rather low, around 6% to 8%, which makes it difficult to get support from the senior management. "*Unlike my other projects where I show returns of 12 to 15%, and let's say solar PV, renewable energy; it scored a higher return, 12%. And even then they're still hesitant, because 12%, because there will be a lot of unseen things.*"
- **Technical competency**. The organization has over 100 internal employees and 2000 external contracted workers for various types of asset operation and maintenance tasks. Most of them do not have much information technology (IT) background. "*So there's a big gap there.*" Internally, it is estimated that the training cost for BIM is high, and many employees will retire in 10 years. "*So the question is, is it worth it? And second, this group of staff that we have actually at a certain level at age, yeah, they have about maybe 10 more years to retirement.*" Externally, "*getting educate the contractor is another issue because so far even through a normal submission where we got a simple submission for procurement you already have problem. So to get them to use BIM I think it's a challenge*".

- **Training and contractor buy-in**. On top of technical competency, one practical challenge is to provide training to the entire ecosystem to ensure sufficient qualification. This is not a trivia task considering the large number of internal staff and external contractors.
- **BIM model availability**. The organization has more than 200 buildings. "*The drawings are not being related to BIM format. For us to convert to that level is a massive exercise, so I think that that's one hesitation*." In fact, this is a major barrier for any organization to begin with BIM adoption.
- **Software**. At present, a mixture of vendor supplied and in-house developed proprietary software are seen in the BIM-FM applications. Interoperability is a common issue. The interviewees expressed their concerns about software selection and maintenance.
- **Organizational structure change.** The organization is currently undertaking several structural changes in the area of asset management. Drawing and documentation management is one of the examples, which resulted in temporary impact to the business operation. If BIM adoption is determined, additional complexity would be created.
- **Investment priority**. FM investment has lower priority, compared with other core business functions, in the organizational budget planning.
- **Tangible results**. Intangible benefits need to be translated into dollars or tangible value for quantitative evaluation and comparison, otherwise it is hard to convince the senior management. Meanwhile, clear objectives, path, and schedule need to be provided in the proposal.

4.4 Strategies for BIM adoption

Although the organization has not formally started BIM implementation for FM, the experience shared by the interviewees is still useful to the non-BIM users as a reference. The strategies summarized from the interviews include the following.

- **BIM study trip**. It seems that peer effect has a very strong influence in encouraging BIM adoption. It is not a simple duplication. The interviewee who joined the study trip did make a lot of contemplation and attempted to adapt the practice into the local context. The biggest value is that the visitor could see the final outcome and the tangible benefits of BIM-FM applications. Another value is to allow the visitor to make more realistic estimation of time, cost, schedule, and resources.
- **Case study**. BIM implementation is no-double a long and tough journey. It is less risky to start with simple case study, for example one or two new buildings. The downside is that it will require a long time to generate sufficient feedback.
- **Jump start**. Time is critical. Another strategy is to take the action immediately, on certain areas first. "*… they're asking us to jump start, certain areas don't bother, don't go and do, don't try, no more experiment. Just jump start*."
- **BIM department**. F1 disclosed that "*I definitely need a BIM department to push item because every initiative, whether it's on safety or on BIM, definitely you always need a champion there, and this is why I've got my colleague*." Before the BIM department is established, he suggested appointing a few people to be the champion. "*I was following the other safety model where a few people are singled out to be the champion for the BIM, and then for example, it leads to changes into the organizational group. So I am envisioning the same thing for my colleagues, those from contract and procurement.*"

- **Progressive cascading effect.** The interviewee suggested a progressive cascading effect to build the system and let the contractors to follow up, by the influence of both owner and authority. **"***I do not see immediate, a big jump immediately. I see a gradual transformation. I definitely need to build up the BIM champion. I need to put that into every part, procurement part, it's what the contractor part, to ask them to be slowly moving to the BIM, enable part of it. And it cascaded down to all my partners and the suppliers, and of course I hope that the agency can support me on this item because it takes two roles. Mine will be the encouragement part because I cannot force it very hard because it will result in a high construction or management cost. But hopefully they just see a push from their levels, and to make sure every time the contractor try to get certification, this definitely will be requirement.*"
- **BIM model and data acquisition**. BIM model and accurate data are two major constraints and should be handled with high priority. "*Now, we were hoping at new buildings level the consultant, contractors, even at the building owner level, we've got all the inputs correctly, so when the drawing reach us we don't have to do so much work, and then we can straight, start extracting the info or make the use of all this data that's residing in the BIM."*
- **BIM Specifications in the contract.** Previously BIM requirements were not explicitly indicated in the contract. P1 (strategic planning manager) disclosed that "*now we are starting to put in specifications for our BIM projects, ... we are in the midst of appointing a consultancy for first project where we will have a full suite of BIM implementation, so that's where we are as today*".
- **Standard information template.** The interviewee F2 talked about standard information template for contractors. This practice has been seen in the pilot COBie applications, i.e. Construction Operations Building Information Exchange (Smith E et al. 2012).

5. Discussions

The interviews show that the organization under investigation has fairly high BIM readiness by owner and facility managers in terms of awareness and willingness. However, many related issues cannot be ignored, which are discussed with the previously mentioned five key components: people, process, technology, policy, and BIM manager.

- **People**. Firstly, the interviewees P1 and P2, both from the project management office, expressed their concerns on the shortage of skilled manpower. "*whether it is basic draftsmen, or BIM coordinators and BIM managers, especially for local employees, it is hard to find, and if they are to look for foreign employees, they are also constrained, make sure manpower are on station, all this, so it's a challenge, so everybody is hungry for the manpower, everybody is finding, so, this is the main constraint here*", and "*So I guess our main challenge is basically resources, like people with the right knowledge and to drive it in that direction*". The same issue of skilled manpower will be seen in the FM-BIM process. Secondly, for the hundreds of existing manpower internally and externally, most of them are non-IT trained. It takes many measures to upgrade their skills and readjust their scope of work to adapt to the new workflow. Thirdly, future FM-BIM applications will require new talents in many new areas (such as high performance building science, sensors, data processing and analytics, and smart applications), who may be in a shortage as well.

- **Process**. The success of BIM for FM is strongly impacted by the upstream PM processes. FM-BIM requires high level of detail, ideally at LOD 500. However, most present building projects in Singapore rarely deliver BIM models beyond LOD 350 or 400 (i.e. the construction stage). Many facility managers may not have chance to obtain complete BIM models. On the other hand, advanced FM-BIM applications (such as preventive and predictive analyses) require deep knowledge in the domain. With the complexity of FM BIM models, a lot of research and development as well as process integration are needed.
- **Technology**. The BIM technologies can be broadly divided into two categories, geometric and non-geometric. After over a decade of development, software solutions have become more and more mature in geometric modeling, object library creation, and interoperable integration. Nevertheless, modeling and model updating are still largely based on the manual processes, which are time consuming and costly (Volk et al. 2014). This is one of the major challenges of BIM adoption in the FM. The non-geometric technologies include a wide spectrum of information and communication technologies (ICT) and data technologies. FM-BIM is still one of the areas that need significantly more innovations, for example, smart and sustainable applications.
- **Policy**. The present BCA's second BIM roadmap provides indicative guidelines. For the FM industry to massively convert to the BIM platform, a lot more supports and incentives are needed. Examples are pioneering local FM-BIM showcases, providing FM-BIM guides, providing FM-BIM benchmarks and appraisals, providing FM-BIM training and certification, etc.
- **BIM manager**. An experienced and qualified BIM manager is critical to the success of BIM adoption and implementation in FM. The BIM manager must not treat FM-BIM as little "bim" (lowercase), in terms of software. He or she must treat FM-BIM as BIG "BIM" (uppercase), in terms of integrated design and exchange of project data (Jernigan 2008). BIM is a combination of tools, platforms, processes, databases, communications, and organizational cultures. The BIM manager is the person to maximize the benefits of this new infrastructure to the FM teams.

6. Conclusions

With the release of Singapore BCA's second BIM roadmap, applications of BIM for facility management are recommended in the Singapore built environment sector, which potentially become a compulsory requirement in the future. This research project aims at investigating the awareness, willingness, motivators, challenges, and strategies of building owners and facility managers. A qualitative method of unstructured interview with open-ended questions were adopted to collect rich information and data from the interviewees of a large institutional organization in Singapore. Interview data revealed that the owner and facility managers have a fairly high degree of awareness and willingness to adopt BIM in FM. Three external motivators are authority encouragement and enforcement, peer effect, and organizational image; and five internal motivators are benefits to organization, desire to be ahead, catching up with the PM office, benefits to FM, and benefits of efficiency and cost. The challenges can be found in many aspects, which include but are not limited to, cost, time, return of investment (ROI), technical competency, training and contractor buy-in, BIM model availability, software, organizational structure change, investment priority, and tangible results. Finally, the potential issues related to BIM adoption in FM were discussed based on five components, i.e. people, process, technology, policy, and BIM manager.

Assistant Professor, Department of Civil Engineering, Aalto University
(email: vishal.singh@aalto.fi)

Abstract

Constructions Operations Building information exchange (COBie) is a rapidly evolving standard to capture the digital information of facilities. As the building information modeling (BIM) for facilities management (FM) research is gaining greater emphasis, COBie standard is becoming increasingly central to the discussion. COBie can be delivered in different formats. For the ease of use by the end users, spreadsheet format of COBie deliverable is the most applied one since spreadsheets provide some end-user implementation techniques and have been in use for decades. Although the end-users are familiar with spreadsheet actions, dumping all the facility data to a repository with number of workbooks and associated fields has some unintended effects and poses new challenges in handling and using the COBie data. Therefore, this research evaluates the functional and usability aspects of the COBie spreadsheet deliverable from the cognitive perspectives for end-users, and identifies the key points that can increase the functionality of COBie data structure. The research applies the initial phases of design thinking principles to identify the issues with COBie spreadsheet in general by reviewing the literature about spreadsheet design, human-spreadsheet interaction, spreadsheet errors, and information visualization. The identified usability issues and functionalities provide basic steps towards improving the current spreadsheet representation of COBie. The findings will contribute to future development of COBie, driven from the perspective of user interaction and usability.

Keywords: COBie, Facilities Management, BIM, Usability

1. Introduction

In the Architecture-Engineering-Construction (AEC) and Facilities Management (FM) industry, one of the central issues has been to determine how to structure digital information of a facility such that it enables data sharing among different disciplines throughout the project lifecycle. From that viewpoint, there is an increasing call to use Building Information Modeling (BIM) data in FM (Yalcinkaya & Singh 2015), because a lot of BIM data for an upcoming facility is generated in earlier phases of the project, especially in the design phase. Overall, the dependent facility information is created by numerous BIM, FM and construction management (CM) software applications throughout the project lifecycle. However, all these applications structure and present the FM data in their own proprietary formats which causes inefficiencies in interpreting and processing the data. Construction Operations and Building Information Exchange (COBie) is one of the most dominant, open and vendor-neutral industry standard that describes product and process of collecting and validating building lifecycle data generated during various phases of project lifecycle (buildingSMART 2010; East 2007). Although COBie is relatively new when compared with other AEC/FM standards, it is being widely promoted for BIM and FM. The end-result of the COBie specification can be considered as a common template in which the information structure and the delivery format of COBie specification is planned to reduce inefficiencies in facility information handover.

Currently, COBie-based information can be delivered in any of the three formats, IFC STEP (standard for exchange of product model) Physical File Format, ifcXML (extensible mark-up language format of IFC) and/or SpreadsheetML (open XML schema used by spreadsheet application such as MS Excel). IFC STEP and ifcXML can be interpreted and visualized in various parsers and/or web browsers. However, interpreting these formats requires some information technologies (IT) knowledge which not all end-users have. Given the end-users' inexperience and limited familiarity with the first two file formats, spreadsheet has become the most common way to represent COBie. Spreadsheet format of COBie deliverable provides some useful end-user implementation techniques such as sorting, querying, and/or simple mathematical functions if needed. It is human readable, checkable and editable as well. A COBie spreadsheet deliverable includes several workbooks and columns in which the users export the information from BIM and/or computer-aided facilities management (CAFM) software applications' data mapping or export tools; and/or fill in manually. The data is distributed in workbooks and associated columns such that each row includes specific entities of facility data. Depending on the delivery phase and the project size, a COBie spreadsheet can include thousands of rows of facility data.

Despite the easiness of spreadsheets and familiarity of end-users with spreadsheet logic and actions, storing and representing large amount of facility data in a tabular repository with number of dependent sub-sections may have unintended effects and challenges in handling and interpreting COBie data, for example, challenges in visualizing the overall content, duplication of data entries, understanding data dependencies, memory overload due to high amount of number and text-based data, etc. Similar issues are also discussed in the literature about the usability and cognitive aspects of spreadsheet (Chen & Chan 2008; Kohlhase 2013; Hendry &

Green 1994; Thorne & Ball 2008). Accordingly, the main difficulty that end-users have in understanding the data in COBie spreadsheet can be summarized as the high amount of data and lack of explicit dependencies between the cells and workbooks. Users need to recognize the data and their dependencies in COBie spreadsheet, which imposes a heavy memory load. The schema of the COBie spreadsheet is available in COBie Responsibility Matrix (East 2013) to check and interpret. However, handling two separate files or adding one more workbook to the existing COBie spreadsheet may increase the memory load even further. Responsibility Matrix (East 2013) to check and interpret. However, handling two separate files or adding one more workbook to the existing COBie spreadsheet may increase the memory load even further.

In this paper, we highlight and address the complexities and challenges involved while handling and interpreting the COBie spreadsheet. The contribution of this research is twofold. First, we present our findings by reviewing the literature about spreadsheet design, human-spreadsheet interaction, spreadsheet errors, and visualization. We have identified the issues that are common with the COBie spreadsheet representations. Second, we propose a framework to enhance the usability and functionality of COBie spreadsheet representation. Findings of this study and the proposed framework are expected to identify and outline the potential areas of future development for COBie, especially from the point of view usability and interaction with the data.

2. Background

2.1 Development of COBie Standard

In 1983, the National Research Council Building Research Board (BRB) proposed an integrated database solution for facility information (Scarponcini 1996). Other computerized systems such as CAFM, CMMS, etc. were already available to organize, manage and deliver FM information. The variety of software products and their versioning caused inefficiencies in automatic transfer of data. Consequently, the manual information delivery is still commonly used, even though it is inefficient, error-prone and tedious (William East et al. 2012). COBie specification was developed to overcome such challenges and establish a non-proprietary version of exchange data (East 2007). The development process began in 2006 under National Institute of Building Sciences (NIBS) FM and Operations Committee with an extensive review of literature and private industrial/association efforts. The development of COBie standard is mainly focused on two aspects. First, to determine the useful minimum in terms of specific information requirements, responsible actors and associated life cycle phases. Second, to define data exchange standards to eliminate existing inefficiencies in information exchange. The life cycle information exchange were evaluated based on business cases, specific business requirements, information handover plan and implementation with software applications (East 2007). Association efforts played a vital role in the development of COBie. Machinery Information Management Open Systems Alliance (MIMOSA), an industry sponsored non-profit organization, published important specifications such as the Open Systems Architecture for Enterprise Application Integration (OSA-EAI) (MIMOSA 1998) and for Condition-Based Maintenance (OSA-CBM) (MIMOSA 2006). These standards describe how to integrate asset information and how to transfer information in a condition-based maintenance system. Similarly, IAI and its open-source framework for exchange of facility information IFC, describes the majority of components, systems, ownership and the process history. Twelve published data exchange standards for the process industry were reviewed to identify equipment, process, systems, procurement, operations and management datasets for the development of COBie (East 2007).

The practices of the public sector were also considered in the development of COBie. US Naval Facilities Engineering Command (NAVFAC), Unified Facilities Guide Specifications (UFGS) provides Operations and Maintenance Support Information (OMSI). OMSI as an information package includes the key information produced during design, construction and commissioning of a facility. The information is organized in three groups: facility information, primary systems information, and product data (NAVFAC 2014). The OMSI package is generally submitted in three formats including hard copies, electronic (PDF) format and compatible with CMMS applications. The main information types and delivery phases were evaluated in the development of COBie. The Electronic OMSI (eOMSI) provides the required facility information in a structured spreadsheet file with a specified template, during the information handover. Besides OMSI, the Department of Public Works (DPW) of US offers a specification called Operations and Maintenance Manuals which covers a variety of facility information such as system descriptions, installed equipment lists, etc. This specification was also considered in the development of COBie. Besides these, such specifications and/or submittal processes provided by US Department of Defence and National Aeronautics and Space Administration (NASA) were also considered in the development of COBie (East 2007).

2.2 Human-Spreadsheet Interaction

Spreadsheet platforms are popular tools for storing, analysing and visualizing data across all domains, ranging from business to science. In Human-Computer Interaction (HCI) community, spreadsheet is often referred as a task-oriented platform with high computational power. By providing a combination of an expressive high-level formula language with an easy tabular format to organize and display data, spreadsheets are easy to learn and use. In addition, spreadsheet actions can effectively guide the decision-making process without the need for complex computing actions and professional support. Therefore, the flexible and direct approach to data manipulation and management in spreadsheets has led to a widespread usage (Panko 2000). Besides, almost in every business or professional domain, spreadsheets are not only used as a single-user application, but also in multi-actor environments as a collaboration tool, and as means of communication, exchange and integration of domain knowledge (Nardi & Miller 1990).

Although spreadsheets are powerful, simple, easy-to-use, and facilitate the tasks of single/multiuser organizations, yet crucial errors can easily occur. Several studies mentioned the common mistakes and challenges of spreadsheets usage in different scenarios (Panko 2000; Powell et al. 2008; Chen & Chan 2000). There are two levels of a spreadsheet: (1) concrete and visible surface level, and (2) abstract and hidden level beneath the surface (Saariluoma &

Sajaniemi 1989). The tabular layout appears at the surface level, while the connection of cells is established in a network defined by the dependencies in the deep/hidden level. One of the basic difficulties during the handling of spreadsheets is establishing the connections among the data distributed in cells and workbooks (Hendry & Green 1994). For large spreadsheets like COBie, tabular layouts for textual and numerical data do not show any direct mapping with the deep level; and in most cases, users deduce the semantic connection among the cells, columns and workbooks by visually checking them, which imposes a heavy memory load. Consequently, the process of investigating dependent data can be tedious and error-prone because many spreadsheets, including COBie, contain widely separated data.

Therefore, it is desirable that the data shown at the surface level, and its dependencies with the deep structure, are represented and integrated in a visual and interactive way, such that users can find the relevant information with lesser cognitive load. This remains a challenge in most spreadsheet-based solutions, and this limitation is carried onto COBie by default.

3. Research Method

The primary objective of this paper is to outline the issues which make COBie data less accessible and usable by users, including inexperienced and non-FM and/or operations and management (O&M), who would likely have difficulties in understanding and using the large COBie spreadsheet effectively. To reach this objective, it is essential to understand the characteristics of the existing representation, and the current challenges and expectations of the users, such that these can be addressed through ideations and enhanced features. This research adopts the initial steps of design thinking process which relies on the co-evolution of the problems and solutions through an iterative process (Dorst & Cross 2001; Poon & Maher 1997) to understand the issues with COBie representation, formulate the problem, and ideate the solutions with respect to the findings of the literature review.

The implementation steps of design thinking are generally organized in five basic steps which are: (1) Understand: understanding the experience and expectations of the users, whom we are designing for, through surveys, observation, interaction and/or self-experiencing the problem; (2) Define: processing and synthesizing the findings in order to form a user point of view for the proposed solution; (3) Ideate: exploring the variety of solutions by generating diverse possible solutions from a range of ideas; (4) Prototype: transforming the ideas into a tangible form to experience and interact with the proposed solution(s); (5) Test: testing the prototype, observe desired users' experience and get feedback to refine it. Following subsections present the understand and define sections of the design thinking as applied in this research to evaluate the current spreadsheet representation of COBie standard and understand the issues with it. Since this paper reports a work in progress, the next steps are currently underway and will be reported in future publications.

4. Problem Identification and Definition: Requirement for COBie Improvement

4.1 Step.1 Understand Spreadsheets and COBie Spreadsheet

The first step is to understand the problem context and assess the key challenges in effective usage of COBie spreadsheet in its current form. As described in previous sections, the underlying usability and navigational challenges with large spreadsheet is one of the key challenges and problems that is carried onto COBie by default, and this needs to be addressed. Therefore, it is important to understand how users interact with the large spreadsheets, navigate through the data, and establish the semantic connections; and what are the causes and effects which increase the cognitive load while handling spreadsheets.

Based on literature (Woods 1995; Woods & Watts 1997), it was found that navigation through large spreadsheets affects the decisions and actions that contribute to a user's ability to find and understand the relevant information. When the virtual representation of any type of data is distributed and much bigger than the actual computer screen, users cannot process the data parallel, in-mind, with what they see on screen. Instead, they split up the large structure and navigate the preceding/succeeding sections via zoom and/or move-to actions. In literature, this issue is referred as the key-hole effect (Woods & Watts 1997). Another issue in dealing with large spreadsheets like COBie is getting lost in which the user becomes lost in the virtual environment and fails to achieve the original task while he/she navigates and searches within the data. According to Woods (Woods 1984), the users "... do not know their present location in the system relative to the display structure and find it difficult to decide where to look next within the system" Another problem is referred as trashing (Henderson Jr & Card 1986). As in the COBie spreadsheet, when the user tries to find dependent information -sets- from different workbooks, he/she must serially shift among different workbooks which causes extra time and memory load. The increase in the memory load can also trigger the mental workload by focusing on the interface instead of the original tasks. While the user is experiencing the spreadsheet structure, he/she may need to memorize certain amount of semantic links and paths between different sections to achieve their task. In many cases, the professionals of AEC/FM industry are expected to deliver their tasks in a limited time and under limited sources; and experiencing the COBie spreadsheet within these conditions can be challenging. In this case, users generally tend to adapt their existing work style to the limitations of the environment/systems. To find a specific COBie data, user can simply use the search functionality of spreadsheet applications. However, in case of the need for checking the dependent information of the specific entity, user has to perform this action repetitively.

COBie data can be generated automatically with BIM, construction management (CM), FM software application and/or their add-on modules. This method provides efficiency by enabling faster production and preventing duplications. However, not every software application has the functionality to export all the data required in each workbook of COBie spreadsheet. Besides, COBie is not designed to handle every specific information requirements that can vary in each project. Therefore, users may need to enter the data manually which can cause duplication.

Since data entities in COBie have one or more dependencies, this mistake can cause duplication and/or omission of data for specific entities. As specified by (East 2007), the handover of COBie file should occur in different phases of the project. Therefore, the data in a COBie spreadsheet increases in each delivery with new data entries and/or addition of new attributes of the existing data. Users may want to see the changes in each phase of delivery or the information sets.

Visualization of any data improves human perception by increasing the cognitive capability and reducing the complex cognitive work. The easy recognition of sensory symbols based on shapes, colours, photographic images and their meaning in the human brain, facilitates recognition of patterns without the need for pre-attention (Duncan & Humphreys 1989). It is also because the rich content of visual triggers such as colour, size, shape, position, etc. reduce the need for explicit serial process of the data. Instead, the large network of neurons in the eyes can rapidly capture the features of visual representations and implicitly pick the visual patterns with the image-based meaning of symbols. In contrast, all geometric and non-geometric data of a facility is represented in numerical and textual form in COBie spreadsheet, which increases the cognitive load of users. Processing and deriving the semantics from COBie dataset is slower than any appropriate visualized form, because the textual or numerical data is processed in a consecutive series of activities while the visual representation is processed in parallel with the perception (Ware 2012). Therefore, one of the key issues of current COBie implementation is the lack of information visualization that could enhance comprehension and reduce cognitive load.

4.2 Step.2 Define Requirements with COBie Spreadsheet

The previous section gives an overall picture of COBie and spreadsheets, and the common challenges that a user is likely to face when they are interacting with them. As a next step, to outline the problem definitions and the potential enhancements, it is essential to state the target user's role and expertise assumed in this research. The proposed development is intended for all potential users of FM data, including inexperienced and/or non-FM/O&M people who have limited to no experience with the COBie spreadsheet. These users may need to interact with and use the COBie data in different ways, including potential responsibility to interpret and generate COBie data for the later phases of the project lifecycle. The reason why we also focus on the inexperienced users is to keep the proposed development as inclusive as possible. From our ongoing and previous interactions with industry partners and collaborators, we know that in both FM and O&M domains, many professionals have expressed difficulties in understanding and using COBie spreadsheet. Therefore, we aim to define the requirements for a solution that can not only increase the efficiency of experienced users while they interact with the COBie data, but also enable lay users to access relevant COBie data. To keep the problem definition as discrete and simple to understand, we structure the requirements as a set of statements, each following the same template: "**As a user, I ... I need to/have to ...**" Based on this template, the list of requirements for targeted improvements in COBie can be defined as: **As a user, I**

- lose my focus while navigating among workbooks. **I need** a platform in which navigation is easier (interactive).
- am having difficulty to process COBie data within different workbooks. **I need to** see all the relevant COBie data and dependencies at an easy and abstract level.
- have difficulty to see the dependent information within workbooks. **I need to** explicitly see the dependencies of a specific COBie data.
- cannot search a specific data based on its dependencies. **I need to** be able to find the specific COBie databased on its dependencies.
- have difficulty in understanding the semantic links among different COBie entities. **I need to** see my search results in a simplified format.
- want to access a specific data entity and its dependencies. **I need** the functionality that does not force me to navigate repetitively.
- want to select the COBie data entity with the 3D BIM model and see selected entity's dependencies. **I need** a platform in which BIM model and COBie data is mapped with each other
- may have duplications when I enter COBie data manually. **I need** a platform that warns me for duplications and prevents multiple data entries automatically.
- have difficulty tracking the new COBie data in each delivery phase of project. **I need to** track previous and new information sets effectively.

These requirement statements were defined and validated through an iterative process in a collaborative setting. The iterative process led by the researchers, included other researchers, software developers and industry partners. More importantly, consistent with design science, the requirement definitions also evolved as the researchers conceptualized and ideated on potential solutions with respect to the current solutions. Consequently, some of the requirement statements such as "... *have difficulty in understanding the semantic links among different COBie entities.* ***I need to*** *see my search results in a simplified format*." have been more concretely defined.

5. Limitation and Future Work

The reported findings are part of an on-going research, which means the requirements and our understanding of the limitations of the current COBie implementations may improve further as we refine our prototypes and solutions for a visual and interactive COBie (VisualCOBie) representation that is currently being developed and tested. The VisualCOBie platform has already undergone a few iterations and it will shortly be introduced in another publication, once additional validation and usability tests are conducted empirically.

One of the other limitations of this research was the limited understanding and usage of COBie in Finland, where the research is being conducted. This limitation is further compounded by lack of academic articles reviewing COBie. This limitation can be seen in two ways. First, the authors had to rely on feedback with only those industry partners who had familiarity and reasonable understanding of COBie from international markets. Second, considerable amount of COBie related issues were identified from discussions within the research community, as well as from online discussion forums on COBie. Third, the lack of adequate understanding about COBie in the Finnish industry, and the lack of academic articles on COBie also prove the key point that even though COBie is being promoted as the key data format to enable the use of BIM for FM, it is yet to capture the attention of the end-user. In addition, it also means that this paper raises a timely issue, bringing attention in the academic community towards COBie and its strengths and weaknesses in its current form.

6. Conclusion and Discussions

The main contribution of this paper is the evaluation of COBie from the perspective of end-user interaction, usability and functionality; and defining the requirements for improvement of COBie from usability perspective. The findings presented in this paper are part of an on-going research aimed at developing an interactive and visual solution for COBie data. Based on a critical review in a research that adopts design research methodology, the main limitations of the COBie standards are traced back to its dominant representation as a set of spreadsheets, with large amount of textual data. Consequently, the usability issues associated with large spreadsheets such as getting lost and keyhole effect automatically emerge with COBie as well. In addition, similar to many other situations where spreadsheets are used as collaboration tools, COBie spreadsheets are also expected to be filled and contributed to by various actors, and at various stages of the project lifecycle. This collaborative aspect creates further usability challenges, because users need to track the changes and additions to the data, leading to issues such as version management and duplication.

Based on the review, it is evident that the widespread use of spreadsheets, their low usage barrier, and their ease of information gathering and editing capabilities, were the dominant reasons for spreadsheets being the primary representation for COBie data. At the same time, it appears that one of the key reasons for the usability challenges associated with spreadsheets, and hence with COBie, is the lack of mechanisms to explicitly map and visualize the dependencies between the different data entities spread across different parts of the spreadsheets as well as across different workbooks. Thus, it can be argued that the information management issues and process view of data integration were the key factors considered so far in COBie development, while the usage and usability factors have so far remained overlooked. This problem of ignoring the usability and end-user perspective is not limited to COBie, but it is a typical trend in construction technology related developments. Not surprisingly, many of these technological developments fail to reach the desired rate and desired level of adoption, because users find them difficult to use, despite their technical capabilities. Singh et al (2011) make similar arguments, emphasizing that the support technical requirements that improve usability and focus on the end-users should be considered in parallel with the operational technical requirements, and not as separate add-on activities. Therefore, this research puts usability and the end-user perspective at the core of the chosen design science methodology, and such an approach is directed towards addressing the industry feedback and commonly reported grievances about the complexity and lack of understanding about COBie.

Walk the Talk: Creating a Collaborative Culture in an Activity-Based Workplace

Mari Ekstrand

Abstract

Creating organisational change by moving in to new premises has recently gained increased interest and attention. Business driven and process oriented relocation strategies – continuing after the relocation – enable organisations to re-design both space, current business practices and corporate cultures. The question, however, is whether such projects succeed in the end of the day. This paper explores how the process of moving in to a new workplace concept strategically may be used to change an organisation's collaboration culture. This is studied from the perspective of cultural artefacts, change management as well as physical and structural change. The discussion builds on semi-structured interviews with 65 employees from a Norwegian organisation. The findings indicate that the physical change, supported by process activities and change management actions, paved way for a cultural change towards more collaboration amongst employees as well as increased collaboration across hierarchical levels. However, misalignment in some areas between the new concept and existing cultural assumptions, values and norms, also restricted the organisation in fully achieving the intended ends. Therefore, the study highlights challenges and issues to overcome in order to use facilities as a tool for strategic change. The findings further underline the importance of creating a continuous change process, extending beyond the moving process itself.

Keywords: Artefacts, Change management, Workplace concepts, Activity-based working, Socio-materiality.

1. Introduction

Succeeding with organisational and cultural change is a challenging task (Schein, 2004; Balogun, 2006). Often advocated spatial efforts to enhance organisational collaboration, especially through open workspaces, common pathways and increased sightlines have also been found to have their limitations and sometimes fail in achieving the intended ends (Pepper, 2008; Becker et al., 2003; Rylander, 2009). Becker et al. (1994) however argue that business driven and process oriented relocation strategies – continuing after the relocation – may better enable organisations to re-design both space, current business practices and corporate cultures. It is furthermore becoming more and more recognised that in order to succeed with strategic change, different organisational factors need to be aligned with the new strategy. This approach recognises that the physical workplace is an integral part of the organisational structure and culture. Interweaving organisational structures and culture in organisational change processes, may thus provide organisations with greater opportunities to achieve transformational change (Becker et al., 1994; Schriefer, 2005; Miles, 1997). In this perspective, the organisational structures or space may function as a catalyst for change (O'Neill, 2007; Inalhan and Finch, 2012; Allen et al., 2004) or the other way around, be used in order to reinforce and stabilise the change (Bate et al., 2000). However, in execution of organisational change strategies, Miles (1997) argues that organisations often start up by changing structures and infrastructures. Changing people, culture and core competencies generally require a longer process. This article aims to explore the culture-structure relationship in an organisational change process.

1.1 Cultural Artefacts and Organisational Change

When executing a strategy, managers must handle a number of different factors, organisational culture being one of the most important (Balogun and Johnson, 2004; Schein, 2004). According to Schein (2004), an organisational culture consists simultaneously of three reciprocally connected levels: *(1) artefacts*, *(2) espoused believes and values,* and *(3) taken for granted assumptions*. The three levels are based on the degree to which the phenomenon is visible to the outsider. Taken for granted assumptions being on the lowest level and artefacts on the highest – most visible level. Artefacts, physical and/or non-physical, are all organisational phenomena that one may see, hear and feel. Espoused values and believes, as well as assumptions have been found to have a significant role in determining employee perspective, adaptation to and use of space (Hirst, 2011). Although not always visible to the observer, they are expressed and shared through social processes (Schein, 2004). Artefacts are furthermore environmental signs conveying information about social orders – thereby influencing and constraining social actions (Baldry, 1999; Bechky, 2003). Therefore artefacts are often considered as a form for organisational message (Cooper et al., 2001; Allen et al., 2004). Klingmann (2007: 259) argues that architecture is "a visual symbol for the expression of a corporation's culture and personality". Thus, space may be used as a cultural creator – forming and reinforcing the culture (Schein, 2004; Steele, 1973).

Space and artefacts are also socially produced and culturally constructed – leading people through embodied experiences in the form of feelings, emotions, and memories (Kornberger and Clegg, 2004; Taylor and Spicer, 2007; Dale and Burrell, 2008). Language and the way we talk about space further construct spatial experiences, not only steering our interpretation of space but also forming actions, behaviour, interpretations and judgements (Airo et al., 2012). As people make subjective judgements of physical environments, the experience and judgement of a particular place may not simply be reduced to strategies, intentions, managerial and architectural plans (Ropo et al., 2013). For example, Rylander (2009) found that project managers, designers and users, through their different understandings, perspectives and experiences apply substantially different meanings to a new workplace concept. In line with the concept of affordances developed by Gibson (1979) actions are formed not only by the space and its artefacts, but also by social processes informing people about space and its meaning. In this perspective, artefacts do not determine behaviour but rather provide cues of socially accepted behaviour in a particular context (Värlander, 2012; Gibson, 1979).

Artefacts are furthermore commonly used to lead, manage and divide people and support hierarchies (Vaasgaasar, 2015; Taylor and Spicer, 2007; Grenness, 2015; Baldry, 1999). Building on such argumentation, leadership may be formed without the presence of the leader, this through artefacts providing the observer with information forming actions and the meaning-making process (Ropo et al., 2015; Greenlees, 2015). Size, location and furnishing of individual offices are especially often used for this purpose (Muetzelfeldt, 2006; Baldry, 1999). Edenius and Yakhlef (2007) also argue that spatial markers and symbols are useful in order to formalise rules. However, when spatial change is made without addressing the other cultural dimensions, unintended changes within the political culture of the organisation may occur (Markus, 2006). Ultimately, if new artefacts are in contrast to other artefacts and/or existing assumptions, values and norms an equivocal message may be created, leading to misinterpretations and possibly unintended outcomes (Schein, 2004; Gibson, 1979; Pepper, 2008).

1.2 Leadership and Cultural Artefacts

Space in it self does not hold meaning. Meanings attached to space is rather created, changed and defined by time and former experience. The same process goes for culture and leadership, this as leaders create culture, and culture defines and creates leadership (Schein, 2004). Leadership is, however, not only a social phenomenon, this as "leadership is being shaped, modified and constructed by material workplace arrangements" (Ropo et al., 2015: 2). The ways in which leaders and organisational members act, behave and use space – such as the CEO's position at the head of the table – are in fact cultural artefacts, affording people and their actions (Schein, 2004; Gibson, 1979). Thus, space is connected to the way organisations are used to seeing and regarding leaders. The general trend to move from a 'hierarchical' control system to 'horizontal' network structures, is however changing the role and view of leadership (Dale, 2005). In this perspective, transition to open, transparent and activity based workplaces, where leaders and employees work side-by-side, may influence new cultural assumptions (Blakstad, 2015), decrease boundaries and hierarchies (Värlander, 2012), and support values of equality amongst organisational members (Grenness, 2015; Bakke, 2007). Nevertheless, ownership of space is still deeply connected to assumptions such as status, importance and value. Transition to a non-territorial workplace without owned space may for some imply lower status, lack of interest in employee comfort (Hirst, 2011) and even signal that everyone is replaceable (Bakke, 2007). Leaders that are forced to give up their office may thus feel that their personal status is threatened (Elsbach, 2003).

As change in cultural artefacts challenge existing norms and assumptions, this may result in strong emotional reactions and even resistance. To cope with the new workplace, organisational members need to 'unlearn' old values and norms an 'relearn' new ones (Grenness, 2015). Building on the argumentation by Schein (2004), placement of oneself in relation to others and to different functions symbolise factors such as membership, status and social distance. Here, leader's actions, functioning as cultural artefacts, are pivotal in forming values, behaviours and norms (Balogun, 2006). Especially top-level management actions and belief in the value of the change have been found to be pivotal in succeeding with organisational relocation strategies (Bakke, 2007; Schriefer, 2005). Miles (1997) further argues that successful change managers are those who take any opportunity, no matter how trivial, to demonstrate and act the change. This may constitute a new corporate storytelling, which may act as an effective support mechanism for the change processes. Behavioural stories may function as a means of guiding employees in their everyday decision making processes, help employees to understand the rationale for change and be a tool for communicating a message (Stegmeier, 2008). This is a continuous process where the 'change agent' assists others in the transition from the present state to the desired state (Becker et al., 1994).

Schein (2004: 170) argues that, "shared assumptions arise only over the course of time and common experience". To this end, actions and use of space may function as meaning-making triggers contributing to organisational learning (Balogun, 2006) and through 'learning by doing', activities gradually form new sets of rules and norms (Steele, 1973). The open office environment daily offers opportunities to support the change effort and "lead through own appearance and action" (Vaasgaasar, 2015: 80). In the transition to new workplaces, managers need to 'walk the talk' – explaining the new strategy through their own actions. This is an iterative process were managers often are challenged, this as the transition itself may lower their status and force them to start to earn status in other ways than through physical artefacts and cues (Grenness, 2015). Higgins and Mcallaster (2004), however, observed that top managers generally do not perceive the links between changing strategy, changing culture, and changing cultural artefacts. As assumptions are often taken for granted, managers are also seldom aware of their own assumptions and what effect this has on the change process (Schein, 2004). If manager behaviour is not in line with the new strategy this may become a hindrance, allowing employees to act on old values and norms (Balogun, 2006; Balogun and Johnson, 2004).

2. Methods and Case

The empirical material draws on semi-structured individual and group interviews with 65 employees from a Norwegian professional service network provider. The organisation provides services within fields such as auditing, consulting, financial advisory, risk management as well as tax and legal. Participants were purposely selected from the different business areas and levels within the organisation, this to include organisational members with different roles, work tasks and responsibilities. In between interviews, use of the workspaces was studied through unstructured observations. Brief informal discussions with approximately 40 employees were also conducted during the study. The study was conducted in three main phases approximately 1,5 years after the transition to the new headquarters. Data from each phase was analysed before moving onto the next phase. To identify differences and similarities between the business areas, data from the units was furthermore coded and analysed separately. The focus was, however, on cross-unit analysis, thus the reported findings cut across all units, unless otherwise stated.

The change started early in the process with a new organisational strategy. The intention of the relocation was to set *"a new standard for collaboration"*. The strategy focused on better collaboration and utilisation of knowledge within and across the different business areas. The organisation wished to build on the newly implemented strategy, and by transition to the new building, reframe the culture-structure relationship. The new concept was activity-based, supported by free-seating and clean-desk principles. Due to high resistance towards free-seating, confidentiality requirements and other practical needs, some departments were allowed to have individually owned workstations. The different zones range from silent- and semi-silent zones, project areas, meeting- and collaboration rooms to open centrally located areas for social interaction. Signs hanging from the ceiling mark each zone. The signs have a colour, a symbol and a short description – explaining and giving cues to what activities are appropriate within each zone. The main focus was on facilitation of interaction processes, as explained by one manager: *"It is important that the new building facilitates employee interaction. The building cannot create interaction by itself, but it may facilitate interaction*".

3. Findings

3.1 Collaboration within Departments and across Hierarchies

Where free-seating and space-sharing structures were implemented, employees reported that internal communication and collaboration had increased. Work in the new office was described as "more social" and collaborative than in the old office. Several employees commented that, as they often worked close to others they had gained a larger internal network and also befriended new colleagues. As told by one of the employees: *"You come in contact with people that you normally don't come in contact with". "I've got new friends here",* comments another. Several experienced that this eased seeking help from others. Many also remarked that they had gained a closer connection and more knowledge about different areas within their own department. Working in open workspaces was furthermore reported to help streamline work processes.

Perceptions, however, varied between departments. In departments where individual workstations had been implemented some managers and partners seemed to perceive an increase in collaboration, however, most employees did not perceive any noticeable increase – rather in some instances a decrease. At these locations several employees stated that, as one were afraid to disturb others, one did not 'dare' to talk in the open landscape. Thus a 'whispering' culture was created at several areas. As employees became more used to the open landscape, this code of conduct gradually changed towards more interaction at most areas. Nevertheless, some groups still struggled with social interaction at the time of the study. At these areas the norm and assumption was that work processes were mainly conducted as individual tasks, thus the workspace ought to be quiet allowing for individual concentration. This sub-cultural norm and the high value placed on individual work also effected interaction within adjacently located groups. In the words of one employee: *"I find it useful to throw out a question to colleagues in an open workspace, however, I don't feel comfortable with doing that here".* Some, especially lawyers, further stated that, due to confidentiality requirements it was challenging to discuss work related issues in the open landscape. A perception, however, not shared by all – especially not by partners and managers. Contrarily, these groups argued that confidentiality was no problem as long as one followed the organisational confidentiality ethics and guidelines and also used the available collaboration rooms. Nevertheless, some used individual work processes and the confidentiality requirement as legitimate claims for having own offices.

To facilitate random encounters and collaborative work processes, each floor had a centrally located coffee area, furnished with lounge furniture and high-stand tables. Despite this and the signs, explaining the purpose of the zone, these areas were mainly seen to be unused after the transition. In the beginning, many believed that spending time in these areas was perceived as "being lazy" or "non-efficient". As one employee stated: *"As a consultant, you charge the customer by the hour. You need to be efficient. Hanging out in a sofa may give the wrong impression".* To change such assumptions, some managers hung additional signs, emphasising the value of collaboration and informal interaction. To 'walk the talk' some further started to spend more time working and collaborating from these areas. At the time of the study, use of these spaces had remarkably increased. To facilitate team collaboration, open landscape 'project areas' were also located adjacent to the informal areas. Also, these areas were mainly unused after the transition. The general openness and caution of sharing sensitive information to others seemed to restrict employees from using these areas. Furthermore, as these areas also were new functions with which employees did not have any experience, some reported that they were insecure with regards to what kinds of work processes and activities that were appropriate or allowed. However, at the time of the study, these areas were highly appreciated and believed by many to be crucial for collaborative working and creating 'workflow'. Being able to share documents on screens on the walls and spread out work material were seen as especially important. Several employees also commented that the project places were efficient in sharing knowledge and informing others – *"the people just passing by"* – about on-going projects.

The former workplace concept had a hierarchical workplace structure with individual offices mainly assigned to seniors, managers and partners. Going from this to a workplace structure where members from the different levels of authority shared workspaces created challenges as well as benefits. The new workplace facilitated a flatter structure allowing organisational members at different levels to sit 'side-by-side', thus collaboration across hierarchical levels was seen to have been improved. Many also described the organisational hierarchy as being flat, especially with comparison to similar organisations outside the Scandinavian countries – an observation in line with research on Scandinavian workplace cultures (e.g. Grenness, 2015). Arguably, the new workplace was perceived to better reflect the low-hierarchical structure. Transitioning to a new workplace also changed the hierarchical map of the workplace. In the former workplace, free-seating had been implemented in one department. However, informal rules and behavioural norms, grounded in the hierarchical structure and culture, defined where different organisational members were *expected* to find a desk. As such, areas for managers, partners, seniors and newly employed had been created. With few exceptions, these sub-groups had disappeared during the transition in to the new office. The exceptions were mainly related to areas were members from the top-level management situated themselves. As a result others seemed to avoid situating themselves at these particular places. Nevertheless, as most top-level managers situated themselves adjacent to the informal areas, they also – through their choice of place – invited employees to engage in interactions by the 'manager's' table. Employees' perception was that when top-level managers and also other managers worked from these areas they simultaneously signalled that they appreciated a low-hierarchical culture and were open for inquiries and interactions. Several employees also reported that knowing partners and managers spatial patterns both eased finding them and also eased knowing when they were available for inquiries. Moving managers and partners from assigned offices were, however, by some seen to create higher boundaries and challenges in terms of communication. Previously, the sign of an open door functioned as a cultural artefact informing organisational members of the person's availability. Uncertainty of whether the persons were actually available for questions or having to ask them to join in for a conversation at another location seemed for some to make the threshold for making contact somewhat higher. Few managers and partners on the other hand perceived this to be a challenge, rather stating that inquiries had increased – however, becoming shorter and more efficient. Managers and partners also perceived that working next to others facilitated 'workflow', tacit knowledge sharing and sharing of sensory experiences.

3.2 Collaboration Across Departments

In the old building, a centrally located staircase connected the different departments and was described as a place where people 'bumped into each other'. The new office – higher and narrower in structure – seemed to decrease spontaneous encounters and therefore also collaboration between organisational members from different departments. However, areas such as an in-house coffee bar, the previously mentioned social and project areas, and a project area accessible for the whole organisation on a separate floor, created substitute areas for spontaneous encounters and collaboration activities. Employees who spent more time at these locations did not, to the same extent, share the view that spontaneous encounters or collaboration across departments had decreased. Contrary, these employees believed that the new facilities provided better locations for more relaxed and 'deeper' conversations and interactions. Especially the in-house coffee bar functioned as an area where organisational members from different departments were seen to interact with each other. Stated by one employee: *"I went to work at the coffee bar one time, and a person that I just had sent a mail to came in. So we sat down and had a brief conversation"*. Additionally, internal staircases connecting some of the floors were found to benefit spontaneous interactions.

Nevertheless, the view shared across the organisation was that knowledge of and connection to other departments had diminished. Many assumed that, as they did not see members from other departments as much, they did not collaborate as much. The ultimate effect is, however, questionable, as most employees perceived that their own work had little or nothing to do with other organisational departments. However, in instances where specific projects were held across different departments, employees were seen to move around more, also working from multiple floors. The sharing structure and freedom of movement within the building did in this perspective offer opportunities for work in and between the different departmental floors. The perception of less cross-departmental collaboration may further be related to the fact that the organisation since the transition had experienced a significant growth. Some employees expressed that this had resulted in less communication and fever instances of informal group meetings – also within their own departments. In this perspective, some artefacts from the old workplace had also been lost. For example, the staircase in the old building facilitated weekly status meetings, also called 'stair-meetings'. Although these meetings still occurred, they were not as frequently held and no longer perceived as an important cultural artefact. Ultimately, some expressed a loss of a former 'homey' culture and feared that as the organisation continues to grow this would continue to affect the organisational belonging.

3.3 Time and Management

Prior to the transition, workshops and process activities were conducted with the aim to discuss issues such as, what 'a new standard for collaboration' meant for each department. The general answer to this question was that: *"The new standard for collaboration is something we develop together over time"*. As previously described the patterns for socialising, collaborating and communicating had since the transition gradually changed. When moving to the new workplace many seemed to categorise the workplace into primary, secondary and tertiary workstations. The 'own' work desk was perceived as the primary workstation, meeting- and project rooms functioned as secondary workstations and informal meeting places were perceived as tertiary workstations. As the different cultural dimensions gradually changed, many started to regard the former secondary and tertiary workstations more as primary workstations – ultimately considering a multitude of workstations as being suitable for conducting different work processes. A 'mentality change' was also seen to have happened amongst some groups of managers and partners. Prior to the transition, several of these groups requested a separate area assigned to them, a request, however, turned down by the management as they believed it to be against the strategy and the desired collaborative culture. After the transition none of the interviewed managers and partners requested such an area. However, at one department the free-seating structure was gradually redefined into one area for managers and partners and another area for 'others'. This was not a formalised structure, rather as one employee put it: *"When managers and partners always choose a place in the same area, no one else dare to sit there"*. Thus, there were still instances were managers' and partners' behaviour maintained a hierarchical structure, thus the social relationships across hierarchical levels were not yet fully developed. As a result, behavioural artefacts restricted development of a collaborative culture.

Statements and actions given by specific organisational members were further seen to influence organisational members' assumptions and norms. Early in the process, the CEO and the top-level management informed the organisation of the intention and vision for the new workplace concept. Doing so they also stated that they would work in the same workplace, with the same sharing principles as everyone else – adding that anyone that wanted something else could come and talk to them. Few came. Since the transition the CEO and the top-level management have kept their words, working according to the free-seating structure. Also other managers and partners commented that they felt obligated to be early adopters and give good examples for co-workers. This question was also raised in the process where managers and partners were told that if they didn't feel that they could lead the change, they should at least try not to be openly negative. Nevertheless, few partners and managers perceived that there had been any focus on them as regards to being 'change agents'. Although managers' behaviour was found to be important for 'leading the change', few regarded their actions in the office to be of any importance. Several organisational members, however, commented on specific managers, their actions and how this had been important for creating a 'new standard'. Placing oneself in a highly visible area, working from different locations and actively participating in the everyday work environment were by many seen as important cultural artefacts. Contrary, when managers and partners seemed to do the opposite – creating own areas, choosing the same place every day or removing them selves from the work environment – employees often reacted negatively, arguing that they should at least try to lead by example and try the concept. As a result, some groups of employees also had a tendency of breaking the concept rules, creating sub-groups and their own rules. Noticing the importance of the process and management actions, some managers emphasised the value of putting enough resources into the process: *"If you really want to create a transformational change then you need to put resources on changing minds"*.

4. Discussion

Implementing a new workplace concept with an open shared space structure did in many ways facilitate "a new standard for collaboration". However, creating a new standard for collaboration did not only require a physical change but also a change within the other cultural dimensions. In line with the argumentation by Schein (2004), the findings illustrate that where a change in assumptions, values and norms had not happened, no remarkable change occurred or unintended outcomes emerged. As for the departments where individual work was valued higher than collective work, the new spatial artefacts worked in direct contrast to the existing cultural norms and values. As such, employees also resisted the new workplace, arguing that it did not support them in meeting the intended ends – findings also in line with Grenness (2015), Rylander (2009) and Pepper (2008). In this perspective, the new artefacts in themselves did not have the power to 'break through' and change the other cultural dimensions. However, at departments where team and project work processes were valued higher, change was more seen as an alignment and modification of the physical workspace to better fit the culture and the already implemented strategy. To this end, the workplace and its artefacts both paved way for the change as suggested by O'Neill (2007), Inalhan and Finch (2012) and also Allen et al. (2004), but also, as suggested by Edenius and Yakhlef (2007) and Bate et al. (2000) functioned to formalise rules which further stabilised and reinforced the change.

As suggested by Schein (2004) and Hirst (2011), employee assumptions, values and behavioural norms guided and formed adaptation to, use of, and satisfaction with the new workplace. Old assumptions such as: the standard desk is the primary workstation, and that fun and informal conversations are not an important part of core work processes did thus create barriers for change. The fear of 'sharing information' and the pending confidentiality discussion at some departments represented a 'confidentiality culture' where information should be 'guarded' and properly handled by the employee. During the transition, the value of knowledge sharing, however, became more and more prominent at most departments than the value of confidentiality. As managers also took a more present part in the landscape, breaking down the hierarchical boundaries, this further supported the non-verbal message and ultimately the change initiative. The change in values influenced both use and the ways employees related to and talked about space, findings also supported by Airo et al. (2012). By time, the new concept started to work more in harmony with a newly formed organisational collaborative culture – stressing the fact that structure and culture must co-evolve (Bate et al., 2000). The process here was one of continuous learning, changing and learning from changing. The process of 'unlearning' and 're-learning', as emphasised by Grenness (2015), may in this perspective be seen as an iterative process where old and new values and assumptions are tested against each other. This in turn, stress the need for a change management process extending beyond the transition itself, as also emphasised by Becker et al. (1994).

As a new set of assumptions, values and norms gradually was created at some departments, and especially as some hierarchical structures were broken down, employees also got more freedom to start to explore the new concept. However, the fact that the project was seen to be finished soon after transition and that no formal structures were developed to follow and further steer development of the original vision, may also have hampered goal achievement. The focus on spatial change as a tool for affecting cultural change, also contributed to the creation of a rather rational deterministic thinking. Supporting the argumentation by Värlander (2012) and Rylander (2009), the deterministic perspective was found to be challenging and partly unfruitful in achieving the intended ends. The additional cues and behavioural artefacts implemented by some managers and partners may in this perspective have been crucial for achieving the intended ends. However, as some managers' and partners' actions and use of space also reinforced hierarchical levels, the boundaries within the organisation were not eliminated – rather redrawn in the new office. In line with Becker et al. (1994), Balogun (2006) and Miles (1997) corporate managers' and partners' actions strongly defined the value of the new cultural artefacts as well as the meanings employees assigned to the different spatial solutions. As such, sub-cultures and norms became visible in the open workplace structure. The lack of physical boundaries between groups and members, also allowed for cultural norms to transmit and travel between groups. Due to the complicated interaction between the spatial workplace and the organisational identity, as well as the different identities within different sub-group, achieving the intended ends were seen to require as extended process. Thus, the study stresses the need not only for a continuous iterative change management process but also the need for applying a set of different tools, measures and strategies within the overall strategy.

5. Conclusions

The article illustrates that use of a new workplace concept to effect cultural change is dependant on an alignment between spatial artefacts and other structural and cultural dimensions. If an organisation attempts to utilise a relocation process for strategic change organisational aspects, cultural values, norms and assumptions needs to be addressed and handled as an integrated part of the strategy. This will ultimately lead to a situation where space and culture may co-evolve into alignment. In a physical transition it is further important not only to renew critical cultural artefacts, but also to maintain those that already support the new strategy and the desired culture. In accordance with the perspective of space as socially constructed, management and sub-groups' use and relation to the concept were also found to be important in shaping new cultural assumptions and norms. Arguably, implementation of new workplace concepts with the intention to affect and change cultural dimensions need to be handled as an on-going process, continuing after the relocation and also supported by management action and behaviour as well as supported by a multiple set of integrated tools and strategies. Organisational members' appropriation of space and buildings are furthermore significant in achieving high levels of building usability. Addressing the socio-material relationship in research as well as in the development and implementation of new workplace concepts may provide the building sector with more knowledge with regards to buildings' usability and strategic use of the built environment.

How employees value the support of activity based and traditional work environments

Abstract

New Ways of Working (NewWoW) are popular, both for increasing employee and organisational effectiveness and attracting new talent. As Corporate Real Estate management (CREM) is responsible for delivering a supportive office environment for employees and the organisation as a whole, they must align by providing a work environment that aims for employee satisfaction, increased support of productivity and other added values. This is often done through introducing the shared workspaces and facilities of activity based working (ABW). However, lack of proof of advantages of such work environments is feeding a more reserved attitude towards NewWoW. This paper aims to provide evidence for differences between traditional and ABW environments in workplace support of organisational goals as perceived by employees.

Online questionnaires (2010-2014) from the Leesman Database amongst 47,913 office employees (mainly Western European organizations) were analysed for employee opinions on workplace support. Respondents were split in two groups based on their workspace: ABW or a traditional, dedicated seat. Statistical tests of differences between both groups provided insight in five types of added value.

The ABW employees were more positive on all added values included in the questionnaire and the support of their workspace for important activities. Also, they were more satisfied in general and with most of the individual features and facilities of their work environment. Only satisfaction with their desk, chair, personal storage, phone equipment, desk/room booking systems, in-office network connectivity and the ability to personalise was lower than the employees working at dedicated seats. The design of the ABW workspace had a more positive (perceived) impact on culture, corporate image and environmental sustainability. Further, they agreed more with statements that the design of their organisation's workspace contributes to a sense of community, creates an enjoyable environment to work in and enables them to work productively.

The results from this analysis provide CRE managers with proof for implementing ABW environments in their office portfolio. Not only did employees that work flexibly feel more supported in their work by their workplace, they also felt that it better supports general strategic organisational goals like productivity, corporate image and sustainability.

Keywords: added value, work environment, employee preferences, chi square tests, independent samples t-tests

1. Introduction

The workplace is said to be a strategic tool for organisations, but there is still little evidence to show how and in what contexts (Kampschroer and Heerwagen, 2005; Blakstad et al., 2009; Steen and Markhede, 2010). Therefore, for many organisations it is still mostly a costly resource for which cost reduction is the main aim (Gibler et al., 2010). However, corporate real estate (CRE) managers at contemporary organisations increasingly try to work with a workplace strategy aiming at a more optimal cost/benefit ratio (Jensen, 2009; Pullen et al., 2009). For benefit they look at the added value of the physical work environment for employees and the organisation as a whole. Jensen et al. (2012) detected six different types of added value of CREM in their review of the literature:

- Use value: quality in relation to the needs and preferences of the end users;
- Customer value: trade-off between benefits and costs for the customers or consumers;
- Exchange value: economic trade-off between costs and benefits;
- Social value: connecting people;
- Environmental value: environmental impact;
- Relationship value: experiencing high-quality services.

While exchange value lies fully within reach of the CRE manager, the effect of the other added values is (partly) indirect and thus cannot be isolated from other variables, which makes it harder to prove the relevance (De Vries et al., 2008). These added values do not only have an effect through the real estate itself but also through the employees (use, social and relationship value) or clients and society (customer and environmental value). As employees and clients are important for knowledge organisations, a positive influence on this should be highly valued by their corporate management. Unfortunately, measuring these indirect added values is often troubled by a lack of outcome indicators, making it hard for CREM to show proof. As Feijts (2006) suggested that the indirect effects explain the majority of performance changes, this deserves more research.

With the rise of strategic CREM, many companies have redesigned their buildings and workspaces to influence employees' attitudes and behaviours (Robbins, 2003). Large companies are increasingly moving towards new ways of working practices (from here on called NewWoW) (Inalhan, 2009) and the so-called activity-based office concept. But evaluating whether these designs have succeeded in their goals of adding value is difficult and not done much yet (Pullen, 2011; Maarleveld et al., 2009; Laihonen, et al., 2012). Particularly little is known about the consequences for employee attitudes and well-being (Ten Brummelhuis et al, 2012; Peters et al, 2014). Therefore, this paper focuses on the question how contemporary office design relates to organizational performance, from the viewpoint of the office employees working in it.

The next section provides a short overview of the literature on the contemporary work environment and different added values it might have. Then the research approach is explained, which is based on statistical analyses of questionnaires among 47,913 employees from 115 different organizations. In the results section the findings are described, followed by a discussion and recommendations for further research.

2. Contemporary work environments

Despite of the hype and well-known terminology, a survey taken by Van der Meulen (2012) showed that 67% of the organizations that are orientating themselves on NewWoW implications do not know exactly what NewWoW encloses nor what benefits it could provide. Half of the respondents even had negative associations with it. The coverage on NewWoW in magazines and journals is often either very positive or very negative (Pullen, 2011). This has led to a more reserved attitude of some organizations towards introducing NewWoW (Baalen et al., 2011) and the effort to convince management to do so, has increased over the years (Van der Meulen, 2012).

The term Activity Based Working (ABW) has become a widely used expression for different office concepts that support NewWoW and is regarded as one of the most advanced concepts (Ross, n.d.). These concepts have in common that all users, from employee till general management, can choose to work at all available workspaces and collective facilities and where nobody is allowed to claim their own workspace. ABW offices offer a variety of different types of workspaces aimed at supporting different activities. So there are no dedicated seats and people are supposed to choose different workspaces throughout the day, based on their activities at that moment. Besides exchange value through cost reduction (a decrease of m^2's), added use value through increased employee satisfaction and productivity are important goals of organizations implementing ABW (Van der Voordt, 2004; Baalen et al., 2011). A positive image and as a consequence attraction and retention of scarce personnel and clients, more flexibility and environmental impacts (CO2) have also been mentioned as additional aims of the ABW environment (Ruostela et al, 2014; Blok et al, 2011; Van der Voordt, 2004).

But expectations and realizations of NewWoW do not always coincide (see Figure 1). In a study of Baalen et al (2011) among more than 250 organisations, all aims of implementing ABW, except more flexibility, showed a lower achieved effect than the original expectation. While the effects on the organisational process (flexibility, costs) largely matched expectations, effects on employee output (productivity) and organisational image towards their employees (employee wellbeing, satisfaction, image) lagged behind. In a before/after study questioning employees that moved towards an ABW environment, Blok et al (2012) also showed no higher appreciation of use value (satisfaction and the suitability for work tasks) nor social value (collaboration with other employees). Top-down implementing new working conditions is said to be insufficient to achieve positive work outcomes, as it might not change the actual behaviour at the office and could even be a source of stress (Peters et al, 2014). So it seems important to know in more detail what employees with dedicated seating think of their work environment versus the ones working in an ABW environment to discover which added values are perceived by them.

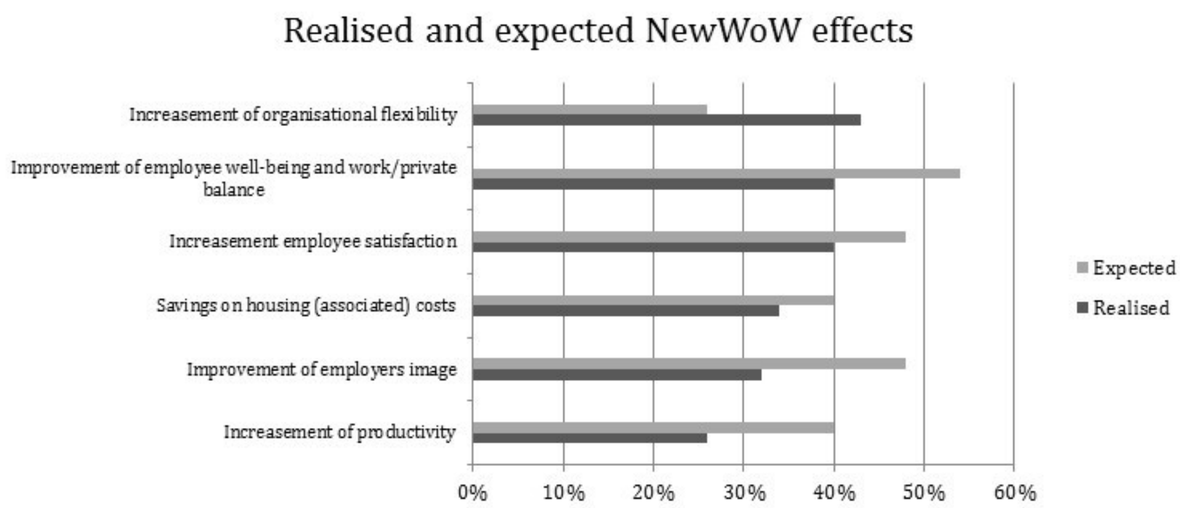

Figure 1: Realised and expected NewWoW effects (Baalen et al., 2011)

3. Research approach

As this paper focuses on employee opinions about the work environment, an existing large, multinational dataset of employee questionnaires was used. The questionnaires have been developed and collected by Leesman ltd (from 2010 up to February 24, 2014). Their online surveys of employees question various workspace aspects and some general data on the respondent (e.g. age, gender, position etc.). Average response rate to the Leesman survey is 64%. The so-called convenient sample taken for this paper included 47,913 employees from 115 different organizations divided over more than 370 locations (average 369 employees/location).

Respondents mostly worked at organizations in Western Europe that approached Leesman to survey their employees. Although the database contained respondents from 22 countries spread over all continents except Asia, 59% of the respondents work in the UK and 22% in Sweden. The other 19% had a very diverse origin. The organisations belonged to many different sectors, both profit and non-profit. Because of the non random sampling method the results were interpreted with care. However, the large number of organizations and employees included supported generalizability to Western European Offices.

From the complete set of 47,193 respondents, those who pointed out to spend <50% of their time at the primary office were not taken up in the sample (= 4,122 respondents or 8.6%). This guaranteed that respondents who only visit the office for short periods of time did not influence results. The rest was split in two groups (ABW flexible environments versus traditional environments with dedicated seating (TradWoW)) based on the work setting they indicated to work in most of the time. TradWoW employees worked at a private office, cubicle, technical area (e.g. drafting table), shared office with own desk, own workstation in open plan area or other. ABW employees mostly worked at a pre-booked hoteling or hot-desk, shared team table, informal work-setting, flexi/shared workstation or touchdown area. The NewWoW group obtained 6,243 (14.2%) respondents and the TradWoW 37,557 (85.8%) respondents.

To look at the employees' opinion on use value, the following survey questions were used:

- Opinion on importance of workspace design (on a 7 point scale of -3 to 3);
- Perceived support of activities that were important to them (For 21 different office activities the respondent was asked to state whether it is an important activity for them (yes/no). If yes, the respondent was asked to rate support of this activity by the workspace design on a 6 point scale of -3 to 3, without 0. Support of all activities was added up and averaged);
- Satisfaction with 31 features and fifteen facilities of the physical work environment (For each feature and facility the respondent was asked to state whether it is important (yes/no). If yes, the respondent was asked to rate satisfaction for his or her current workspace (on a 5 point scale of -2 to 2). A respondent indicating to find a certain feature/facility not important was not asked about satisfaction with this aspect. This is considered to be neutral satisfaction (=0) in the further analyses. Satisfaction with all features and with all facilities was also added up and averaged to get total scores);
- Opinion on workspace design enabling them to work productively (on a 7 point scale of -3 to 3)

For customer value, the questionnaire contained one question on the impact of workspace design on corporate image. Exchange value was disregarded as employees do not have insight in workplace costs and how efficiently these are managed. Social value was studied with questions on workspace contribution to workplace culture and a sense of community at work. Environmental value was measured by the perceived impact on environmental sustainability. Relationship value was measured with questions about whether the environment is enjoyable to work in and whether they are proud to bring visitors. All these questions were asked to be rated on a 7 point scale (of -3 to 3).

To test differences between both groups, either $\chi 2$- or t-tests could be used. As the 7-point scales are quite large, one could argue that t-tests on the group means are allowed, although it is not a fully continuous scale. But as several of the variables did not show a fully normal spread (most lean towards the positive side of the scale), $\chi 2$-tests were used to test significance of differences observed for most of the added values. For the use value, new variables were calculated in SPSS, namely the mean satisfaction with all features and with all facilities of the work environment and the mean support of important activities. These were tested with t-tests to look for differences between both groups, as these were continuous variables with a normal spread. All statistics are visible in Table 1.

The flexible and the dedicated seating group did not show significant differences with regard to gender (58% male, 42% female), age (normal distribution), part time employees (6%) or time working at this organisation. Only on the country of residence, the groups showed significant differences ($\chi2(23, N=43791) = 2817.6, p = .000$). The NewWoW group consisted of 75% UK employees (vs. 47% in TradWoW) and employees from the Netherlands, Germany, France and Sweden, so only European countries. In the TradWoW group the Swedish account for 24% of the group (vs. 8% in NewWoW) and several other non-European nationalities were also present.

Table 1: Statistics on all the added values

	statistics			
	n	*χ2-value*	*t-value (equal variances assumed)*	*p-value (* = sign.)*

environmental value				
impact environmental sustainability	*43524*	*1139.4*		*.000**

4. Results

The design of the workspace mattered to most employees (85.2% agreed with this statement), both in ABW and in dedicated seating environments (see Figure 2). But in ABW environments significantly more employees agreed on this (see Table 1). Looking at the use value that was experienced by both groups of employees, on all matters the ABW employees were more positive than the ones with dedicated seating. The perceived support of important activities by ABW employees was higher (M=.79, SD=1.2) than among the dedicated seating employees (M=.59, SD=1.2). Workplace satisfaction in general with the features and with the facilities also showed significant higher scores for the ABW group than the TradWoW employees. ABW employees scored (on a scale from -2 to +2) the features on average with .19 (SD=.45) and facilities with .39 (SD=.49) and dedicated seating employees with .13 (SD=.46) and .24 (SD=.47). Looking at the individual features and facilities, satisfaction of ABW employees was higher for all facilities (except desk/room booking systems) and for most of the features (e.g. indoor climate, parking, meeting rooms, accessibility, noise and décor), except for their desk, chair, personal storage, phone equipment, in-office network connectivity and the ability to personalise. The last question on use value regarded the support of productivity and again ABW employees felt better supported by their workspace (see Figure 3 and Table 1).

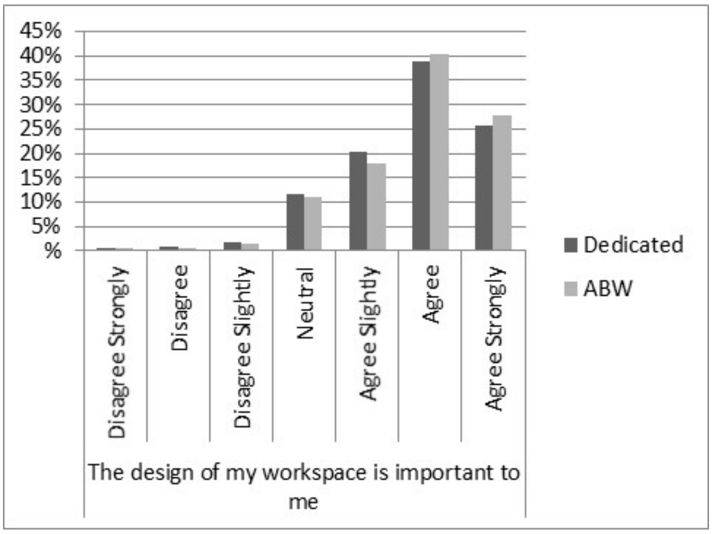

Figure 2: Importance of workspace design

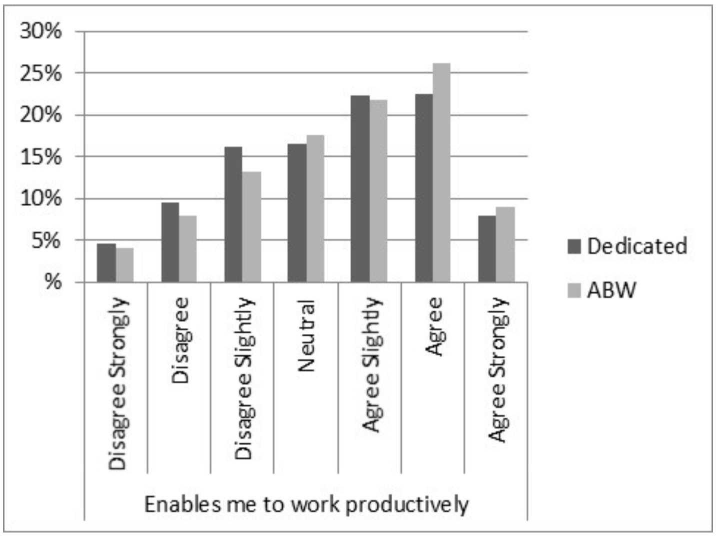

Figure 3: Added use value through support of productivity

Besides use value, the ABW employees also valued the added social value of their workspace. The impact on workplace culture was more positive and also the contribution of the workspace to a sense of community at work (see Figure 4 and Table 1). Both these items are known to help connect people. The last indirect added value through the employees is relationship value, which also scored very highly in the ABW environment. The employees felt more strongly about the fact that it creates an enjoyable environment to work in and they felt more proud to bring visitors to their workplace. Figure 5 shows that especially pride was much higher among the ABW employees.

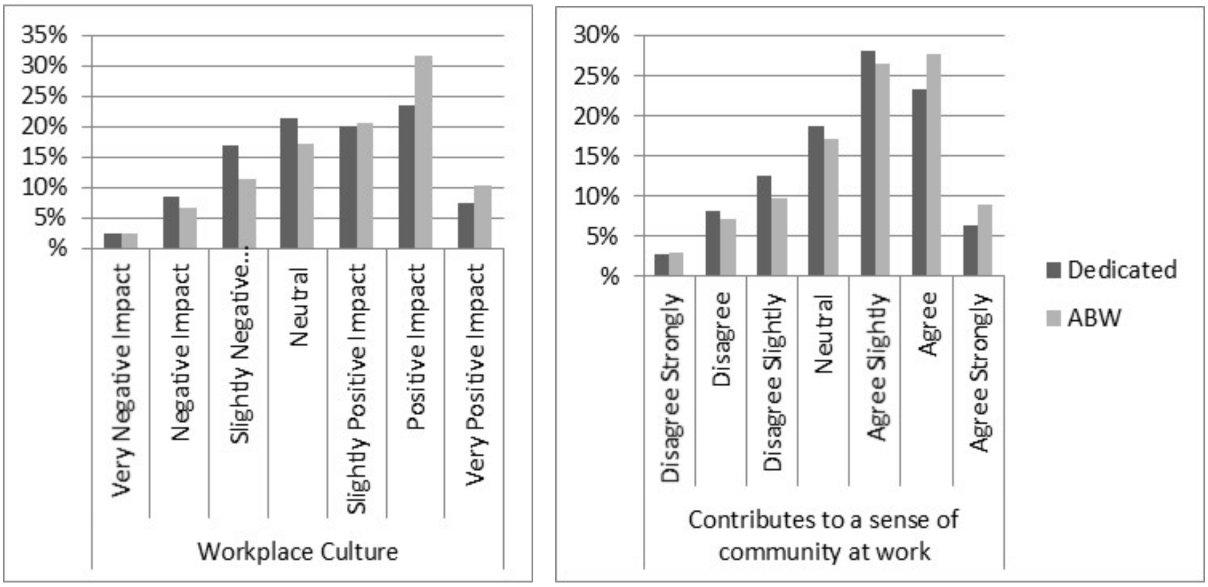

Figure 4: Added social value

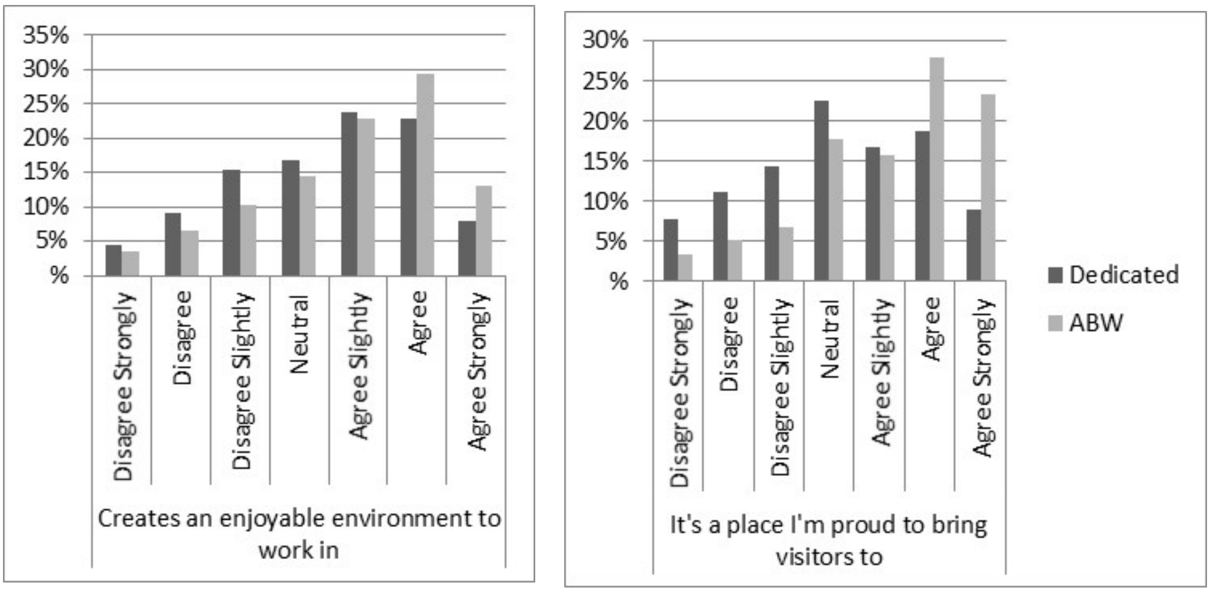

Figure 5: Added relationship value

Although customer value and environmental value are indirect added values which are best measured by opinions outside the organisation, it is also interesting to know what employees have to say about it. With regard to customer value, employees felt more strongly that their ABW environment had a more positive impact on corporate image and environmental sustainability (see Figure 6). Opposed to use, social and relationship value, these 'outside' values might be the hardest for CREM to quantify the actual effect for, as it is not common to question customers and society about this. For the question on environmental sustainability 42.2% of the respondents remained neutral, which might also imply that they did not know how to value this aspect.

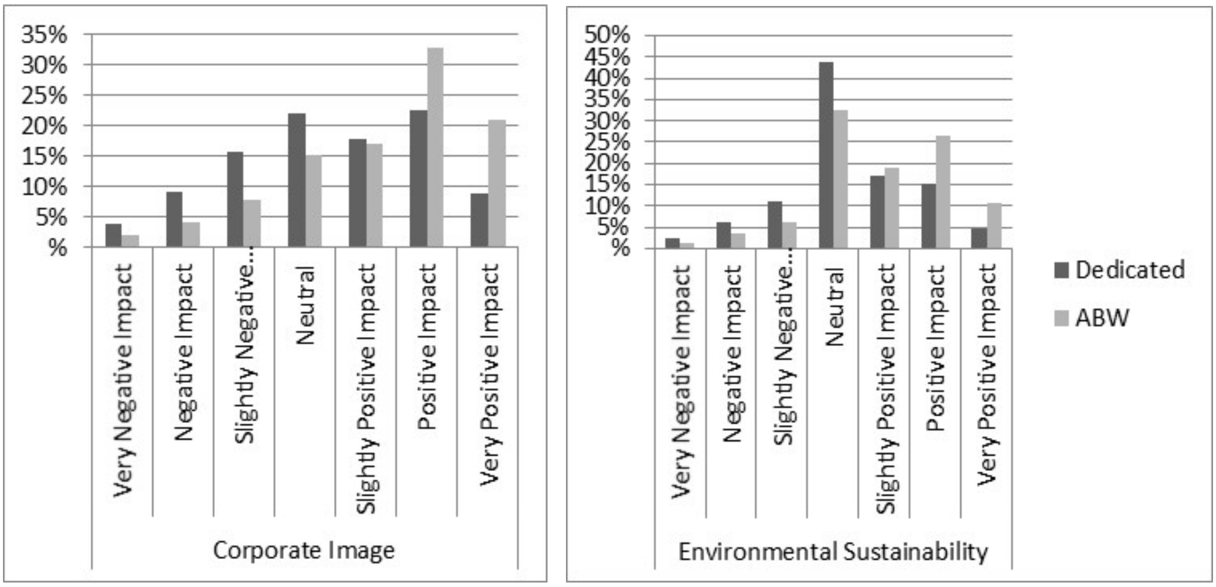

Figure 6: Added customer value and environmental value

5. Discussion

In today's knowledge economies, the employees are the most important asset. To measure their perception with regard to use value, social value and relationship value probably has provided valid results, as these are perceived values. However, for customer and environmental value it would be better for future research to also include research among clients, passers-by and local residents. In future comparisons of NewWoW and TradWow environments, it is also important to take the building itself into account. It is likely that the ABW environments in general were newer (or more recently renovated), which has probably led to more modern climate installations and decor.

The results of these analysis showed that ABW environments scored better on almost all aspects and added values. That would imply that all organisations can improve their performance by moving from dedicated seating towards these types of work environments and NewWoW. However, ABW might not be suitable for all job types and also not for all types of people. Also, research has shown, that these environments are not always used as intended, because people still claim the same seat everyday anyway and do not change during the day (Appel-

Meulenbroek et al, 2011). If employees are not guided well during the implementation, they might even oppose the intended changes on purpose (Inalhan, 2009).

It is unknown which added value is the most important for organisations and their performance. For knowledge organisations it would seem that social value is particularly valuable as knowledge sharing increases the innovativeness of the organisation. Asking about the contribution of the work environment to workplace culture and a sense of community probably did not cover this entire concept of social value yet. Innovation requires stimulation of both interaction and creativity (Oseland et al, 2011) and CREM can take specific steps to do so with the physical work environment design (Kastelein, 2014; Dul and Ceylan, 2014). These studies have not yet identified whether ABW are better at it than traditional work environments, so this is subject to further research.

Looking at satisfaction with some of the individual features and facilities that scored negative for both groups, it becomes clear that people walking past your desk and noise levels are not solved satisfactory in any of the work environments (as there was no significant difference). And although satisfaction with temperature control and art/photography were significantly less negative among ABW employees, they were still dissatisfied a lot. After desk, chair and different types of office equipment, temperature control was important for the highest percentage of respondents. So research how CREM can add value with these important aspects is necessary, as it does not seem that the modern ABW environments have succeeded (much) in doing so.

6. Conclusions

The physical work environment is very important to office employees, both in contemporary as in more traditional work environments. Therefore CRE management can add value to the organisation by offering important features of the physical work environment and facilities to the satisfaction of their client's employees. The results of this study suggest that on average (European) employees were happier and supported better with ABW environments than with dedicated seating, so introducing these office concepts seems promising for CRE managers to add more value. Besides the exchange value that it will bring (through reduction of m^2's), the respondents felt that also all the other added organisational values benefit from it. The challenge for CREM remains to express all the added values in terms of money, as interventions in the physical environment do require an investment and thus approval of corporate management.

(email: j.veuger@pl.hanze.nl)

Abstract

The purpose of this paper is to investigate which theoretical elements of adding value by real estate are applied in practice in accommodating primary education and in what way these are elements relevant to the stakeholders. A literature study of usual CREM strategies has been used to build a theoretical framework with regard to the value a building can create for different stakeholders. Then interviews were held with various professionally involved people in order to understand to what extent the general theory is taken into account with regard to "added value" for the stakeholders of primary school buildings. The factors marketing, increased satisfaction of employees, increased productivity, flexibility, and reduction of costs were mentioned explicitly as possibilities to add value for stakeholders by real estate. It seems reasonable to assume that the sector of primary education strategically focuses little on increasing the value of real estate. The article summarizes the theory of the added value of real estate for organisations. The empirical findings show that professionals are aware of the possible added value of real estate for the primary process. The added value is expressed in many ways and is also perceived differently by the stakeholders. However, the possibility to add value by real estate hardly ever plays a role in a real estate strategy, nor is it used as an argument to increase available budgets. Due to the limited number of interviews, further research is needed regarding the assumed relationship between real estate strategies and the perception and behaviour of the different stakeholders. In The Netherlands, various studies have been conducted into the importance of CREM theory for decisions on real estate for Higher Education. Similar research on housing for primary education is almost lacking. The data show that not all potential possibilities to add value with real estate for primary education seem to be applied in practice.

Keywords: Corporate real estate, Added Value, Primary education, Stakeholders

1. Introduction

The main purpose of this research is to give insight in the way primary school buildings can add value, from the perspective of different stakeholders. Most of the recent literature (Jensen et. al, 2012 and 2014), (Beckers et. al., 2015) is about the added value of the process of CREM or FM to an organisation. Research with a focus on the meaning of added value for the different stakeholders of a specific school building itself, is lacking for primary education.

In order to get the best out of the real estate of an organisation, it is vital to see real estate not only as a shell within which the organisation's everyday activities and processes take place, but to see it as a capital asset that can be used for goals that may be achieved in the longer term (Appel-Meulenbroek, 2007). Lindholm (2006) concluded that the possibilities of adding value through real estate often were not recognized or even considered. Therefore, it is an obvious assumption that a strategic planning with regard to the real estate of organisations also can influence the results. A lot has been written about what this means for the "for profit sector". More and more, the CREM principles are applied to real estate with a public function.

De Vries (2007),Den Heijer (2011) and Kok (2014) did research on the importance of CREM and FM for decisions on real estate for higher education and universities. Their research showed that housing had a direct influence on the primary process of universities. For instance, the change in the funding of universities has led to a change in the process of prioritising. Previously, cost efficiency, architectural quality and centralization were prioritised, whereas factors like customer appreciation and social cultural aspects are considered more important now (Geselschap, 2013).

For higher education institutions there also is research available about the relationship between Corporate strategies and real estate management. Beckers (2015), for instance, found that the CREM strategies in use, nowadays are more clearly aligned with the corporate goals of an institution. Based on a comprehensive literature review De Kok (2014) found that the assessment of added value of a facility depends on the perceived functional or emotional advantages offered by that facility in relation to the costs, efforts and the risks involved in using that facility. According to Appel-Meulenbroek (2014), it is obvious that more fundings will be made available for investments in real estate if there is proof that real estate adds value to the organisation. Most likely, the CREM principles can also be applied to other sectors in education in The Netherlands, like for instance primary education. Similar research on the effects of real estate management on certain decisions with regard to housing for primary schools has not been done yet.

In the current situation, school boards receive the financial means for exploitation of the school directly from the Ministry of Education. Financial means for building and renovating school buildings are not included, because, in principle, a municipality is legally obliged to place a school building at disposal. For this, the municipalities receive funds from the so called "Municipal Fund". These funds, however, are not "earmarked" for school buildings. Based on the current regulations, one could opt for further decentralisation. This implies that the financial means for the realisation of the school buildings are made available to the school boards and that further agreements with the municipality have to be made about the conditions in which way the means can be spent by the school board. In primary education, this possibility is hardly made used of. Although there are other possibilities to divide the financial means for school buildings, the question remains whether these possibilities provide sufficient freedom of policy to the school boards in the present situation. It could very well be that, if the means could be spent directly by the school boards, it would be possible to create school buildings that add more value to the organisation.

Real estate is generally recognized as the fifth business resource (Joroff, 1993). Several authors have written about the "added value of Real Estate". Nourse and Roulac (1993) and Krumm et. al. (1998), among others, wrote about the added value of real estate for an organisation. Later, Lindholm et. al. (2006) and Jensen (2010) wrote about a "framework that describes how real estate and facility management can create added value, either in a corporate real estate context or in a facility service provider context".

In the current situation the complicating factor is that the municipality, as a result of current regulations, often is the beneficial owner of the building, and the school board just the legal owner. In this situation, the question arises whether the real estate should be seen as the fifth business resource to the school board or the municipality. The role of the real estate as a business resource for the municipality is very different from the role it has for the school board. Because municipalities are the beneficial owners of the school buildings, they will probably steer towards financial performance indicators (cost minimization), whereas a school board is likely to be more interested in the added value that the building can give because of the role it plays in the educational process.

This article aims to answer the following questions:

1. What is, in general, perceived as "the added value of real estate";

2. Who can be regarded as the stakeholders of housing of primary education in The Netherlands;

3. To what extent are the theoretical possibilities of adding value with real estate recognisable in relation to the stakeholders of the school buildings for primary education.

Below the methodology that has been applied when answering these questions will be described. Subsequently, the results will be summed up, followed by the conclusions.

2. Method

The first two questions are necessary in order to describe a solid theoretical framework. The answers to these are based on a literature study. This research has provided a theoretical insight with regard to the possibilities for creating "added value" and the stakeholders that can be distinguished when it comes to housing of primary education. This resulted in a hypothesis regarding the relationship between the stakeholders and the possibilities to add value with real estate. Subsequently, this hypothesis was tested through interviews.

These interviews were held with representatives from several groups of stakeholders, in order to find out to which extent the principles from theory actually "live" in practice. These interviews were held with four school board members, four actors with an advisory role, and a representative from a municipality. A representative of one of the largest school boards in The Netherlands, a board member and an advisor of one of the most progressive school boards in The Netherlands, a member of a board of public education that has been involved in a lot of new housing projects during the past years, and finally a representative of a municipality, a representative of a school board and an advisor that are currently working on a number of innovative school buildings have been interviewed. The question has also been answered by a legal expert in the field of housing of education and to a housing advisor who has been involved in several school construction projects.

The interviews were held according to the narrative method. The only question asked was: "from your perspective, which added value could housing of primary education have for the various stakeholders (municipality, school board, employees, parents and children, and the environment)?". The purpose of this approach was to find out to what extent the theoretical possibilities of adding value to an organisation by means of real estate, for the benefit of the stakeholders, was recognised by the interviewed professionals. The interviewer has asked as little extra questions as possible. The interviews were recorded with the consent of all interviewees and were transcribed completely afterwards.

3. Current Theory

Here the result of the literature study will be described. Firstly, the functions that real estate can fulfil will be taken up and the existing theory with regard to the value of real estate for an organisation will be described. Subsequently, the different stakeholders of real estate and which types of added value theoretically are applicable to each of them will be taken up.

3.1 Functions of Real Estate

Each individual real estate object has multiple functions. In his thesis "Focus on customer value", Smeets (2010) mentions five functions of real estate at object level. These five functions are listed below.

- the protecting function: Real estate fulfils the human need of conditioned space by providing both the necessary biological/physiological and physical shelter and mental shelter in the social and psychological sense. In short: we need a roof over our heads that protects us against weather conditions and that gives us privacy.

- the utilitarian function: Accommodation and organisation of necessary human activities and utterances, both personally, socially, culturally, educationally, sportily, economically, etc. Concretely, real estate offers a place to work, to learn, to train, etc.

- the domain and spatial function: The relationship of real estate with the environment in all its different levels makes it the starting and ending point of a social and economical network, in other words a meeting point in terms of accessibility, as well as a starting point for economical and social relations and activities. At the same time, it offers the option to withdraw from these.

- the communication and symbol/status function: Real estate is a medium to disseminate the (intended) own identity and the distinguishing status of the acquired social and economical position. It gives the possibility to realise a certain desired look by, for instance architecture.

- the financial/economical function: The capital intensive character, both in terms of investment needed and maintenance , implies a relation between the financial and fiscal equity position and its development. Thus, an owner who lets a property has a source of income. A user considers the costs of property as necessary within the production process.

The same functions are described in a slightly different wording by De Vries (2008). She gives a broader interpretation to the communication and symbol/status function, and includes the domain and spatial function in this category. According to De Vries, this results in only four functions. Since for real estate for education in particular the domain/spatial function is very clear, Smeets' principle will be followed.

Because it fulfils the above mentioned functions, real estate is often regarded as the fifth business resource of an organisation (Joroff et. al. 1993). Just like capital, know-how, technology, and human resources, real estate can add value by contributing to the realisation of an organisation's goals (Den Heijer, 2011). Previous literature, as summarised by De Vries et. al. (2008) shows that there are in fact two ways to improve an organisation's achievements. On the one hand by increasing the turnover, on the other hand by reducing the costs. Liow and Choulet (2008) call this the "Business perspective of CRE", with the following indicators: "costs", "profitability", and "productivity". In addition they mention "the financial perspective of CRE", which means that owning real estate influences a "firm's credit facility, its financial statements, and its operating economics.

According to Appel-Meulenbroek (2007), real estate has a direct influence on the achievements of an organisation, for instance through lower maintenance costs and reduced energy consumption, but mainly through the indirect effects that the real estate has on employees, visitors, and processes. Therefore, real estate has an important role in the process of creating value by an organisation.

In the past, several authors have defined the various interventions with regard to real estate that can influence an organisation's achievements. Veuger (2014) states that "by Corporate Real Estate Management (CREM) the real estate portfolio can be brought into line with the requirements of the core business of the corporation". His research, based on a comprehensive literature study, resulted in a number of lessons learnt from Corporate Real Estate Management. These lessons are listed in the figure below.

	13 Lessons
1	Real estate can contribute to improving an organisation's social objectives.
2	A company-specific approach to creating value from real estate management makes a greater contribution to the company's objective.
3	Making the added value measurable is essential for the role as a real estate discussion partner in a company in which strategic decisions are made.
4	Becoming more flexible in the static nature of real estate and the speed at which society develops can be addressed by consciously thinking about the longer term. Decisions need to be taken in this regard that create opportunities for future optimisation.
5	Real estate interventions and effects reinforce the organisation's objective.
6	One of CREM's jobs is to formulate and implement an optimum solution.
7	CREM is playing an important role in reducing the burden of debt and building a dominant market position.
8	Sustainable competitive advantage compared to other companies is determined by three generic strategies that do not always go together: focus, differentiation and low cost.
9	Effects follow different eventualities and depend on the organisation's starting position and culture.
10	Cause-effect chains are unclear due to influences by several factors and performances are formed by complex end-means chains.
11	Real estate interventions depend on starting position and policy choices, in which context is subject to change.
12	A target-focussed company provides more consistent reasons for real estate interventions.
13	Collaboration is necessary in order to achieve social results, in which one monopolistic arrangement cannot deliver the benefit of values. Politics also has its own dynamics and interests that can cause rational considerations to disappear into thin air.

Figure 1: Lessons learnt from Corporate Real Estate Management (Veuger 2014: 132).

This has been elaborated concretely by Lindholm et. al. (2006). It appears from the above that different interventions can influence all kinds of achievements of real estate. Real estate can be of added value for an organisation through (1) increased value of property, (2) marketing, (3) increased innovations, (4) increased satisfaction of employees, (5) increased productivity, (6) increased flexibility, and (7) reduction of costs.

After this the question who can be regarded as stakeholders of housing of primary education will be answered. Subsequently, these stakeholders will be linked to the different ways in which real estate can add value to an organisation. It is important to understand this in order to be able to weigh the interests of the stakeholders when making a decision with regard to the real estate.

3.2 Stakeholders

When deploying a building, various stakeholders can be distinguished (among others Den Heijer, 2011, De Vries, 2007, and Mobach, 2009). Generally, this mainly concerns the owners, the users, and the environment of the real estate.

From the perspective of the Corporate Real Estate Management (CREM), Den Heijer (2011) distinguishes the stakeholders according to different functional domains: Strategic (Policy makers), Financial (Controllers), Functional (Users), and Physical (Technical managers).

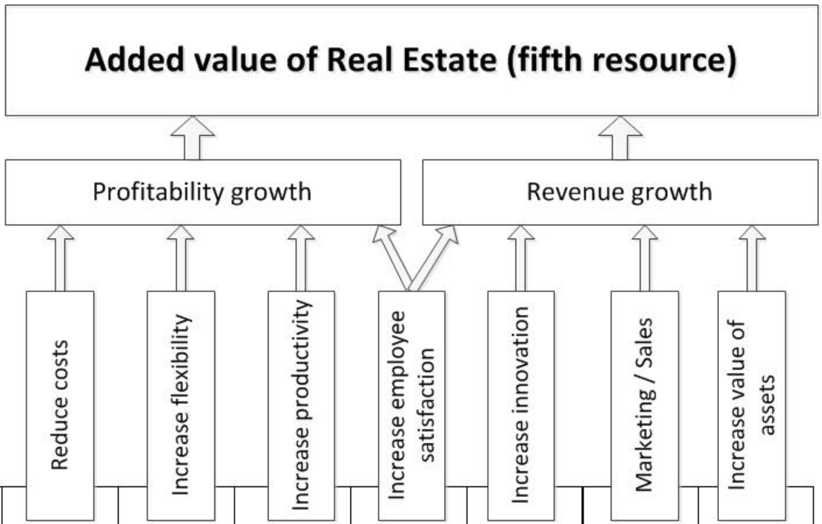
Kemperman et. al. (2013) describe creation of value as "the sustainable result for all parties" and they distinguish value for customers, value for employees, and financial value. Stakeholders of companies are individuals, groups of individuals, or organisations that are influenced by how the companies function (Van den Bosch, 1996).

Lindholm (2006) notes that an important part of the effects of CREM in practice is measured with instruments that are based on the Balanced Score Card (BSC) system, which was developed by Robert Kaplan and David Norton in 1992. Within the BSC system, four focus areas are distinguished: the financial, the managerial, the innovating, and the customer perspective. When these four perspectives are linked to the stakeholders that have been defined with respect to housing of education, it appears that the stakeholders sometimes have to do with several perspectives.

Converting this to school buildings, it seems that municipalities and school boards have interests in their role as owners, and that employees and parents and children have interest from their role as users. It is not unlikely that these stakeholder interests could overlap partly. For instance, a school board does not only have interests as an owner, but as a user as well.

It is more difficult to interpret the environment as a stakeholder of a school building. When thinking of a specific building, one could think of the immediate neighbours. On a more abstract level, one can even consider society in general, because of the significance of primary education. However, confining ourselves to the aspects that are manageable for decision makers with regard to a specific building, it concerns the immediate neighbours and the nearby area.

The above mentioned has provided a theoretical framework according to which the interests of the stakeholders of housing of primary education can be related to all possible real estate strategies. The table below shows the relation between the stakeholders and the previously mentioned strategies to add value to an organisation through real estate. The figure shows that, for most stakeholders, real estate can add value in many different ways. The figure shows the assumed relevance of the way in which real estate can add value for the different stakeholders. This assumption has been tested by means of a number of interviews with school boards, municipalities, and advisors.



Stakeholders perspective:	Reduce costs	Increase flexibility	Increase productivity	Increase employee satisfaction	Increase innovation	Marketing / Sales	Increase value of assets
Municipality	Y	Y	N	N	N	N	Y
School Board	Y	Y	Y	Y	Y	Y	N
Employees	N	Y	Y	Y	Y	Y	N
Parents/Children	N	Y	Y	Y	Y	Y	N
Environment	N	Y	N	N	Y	Y	N

Possibility to add value (Assumed):
Y: relevant for stakeholder
N: not relevant for stakeholder

Figure 2: own adaptation D. Kootstra 2015, based on Lindholm et. al., 2006

4. Empirical findings

Finally, the results based on the interviews will be given. As mentioned before, the interviews were held according to the narrative method. The only question asked was: "which type of added value should housing of primary education, seen from your perspective, have for these stakeholders: municipality, school board, employees, parents and children together, and the environment?" The different stakeholders were mentioned in the question, but not the different ways in which the building could add value for them.

This way was chosen in order to get an idea of the awareness of the different parties with regard to the possibilities of adding value to the organisation through the property. For that reason the results will be listed per strategy and not per stakeholder.

(1) Increased value of the property: Contrary to what was expected, this possibility to add value to an organisation was not mentioned in any of the interviews. Assumed was that added value could at least be found in limiting the depreciation of buildings. Considering the situation with regard to funding of housing of primary education in The Netherlands, where the municipality is the beneficial owner of the school buildings, it was expected that this possibility of adding value would be relevant for the municipalities at least.

(2) Marketing: This function of real estate is clearly recognisable in the sector of primary education. The interviews confirm clearly that a new, or at least a good-looking building "sells" to parents who are looking for a school for their child. Marketing is used in different ways though. Some school boards choose to use the building as an instrument to increase their market share. Other school boards have, from this very understanding, made agreements to divide the children over the different school buildings as well as possible, in order to get to an efficient capacity utilisation of the buildings.

The Marketing function is related to the environment as well. As said, in this research "environment" is explained as the immediate neighbours and the nearby area. In particular the municipality seems to be designated to look after the interests of the environment as a stakeholder. This is because of the steering tools a municipality has available for spatial planning. Seen from this role, the municipality can influence the location and the appearance of a school building.

Sometimes schools are placed in an accommodation where cooperation with for instance a community centre or an organisation organising activities for children is brought about. Also, a few examples were mentioned where the municipality stimulated sustainability investments. However, this was not done for financial reasons, but proceeding from a sustainability ambition.

(3) Increased innovations: Of course, the school as a "not for profit" organisation is not aiming for market innovations. The primary process is focused on childrens' learning and not on innovations. It turned out from the interviews that the stakeholders do apply innovative concepts in order to achieve education that suits modern times. With this in mind, the building teams are made up multidisciplinary. They are also advised professionally, to make sure that a new building does not just become a modernised version of an old building. Innovation as a way to increase revenues is obviously not an issue for primary schools. The benefits of an innovative building concept will mainly be reflected in the increased user satisfaction, increased productivity, increased flexibility and cost reduction, as mentioned below.

(4) Increased satisfaction of employees: The role that a building plays in the work perception of employees was recognised in most cases. As the employer, the school board is responsible for this aspect. None of the interviews have given reason to believe that savings in the form of less sick leave were associated with a higher budget for a school building though.

(5) Increased productivity: The interviews left no doubt about the role that is seen for a good building in primary education. Good housing is a condition for education. A building has to support an educational concept and through a good climate make it possible for children to keep learning and for teachers to keep teaching.

(6) Increased flexibility: This aspect is of importance at different levels. On the one hand, flexibility with regard to the needed capacity is a factor. One has to consider which capacity is needed in which phase of the "life" of the building. On the other hand, flexibility with regard to the possibility of using the building differently within education is important, so that one can move along with the changing methods of education.

(7) Reduction of costs: The interviewed professionals linked the financial aspects of housing for education to the school boards. As mentioned before, this does not concern the possibilities for

increased value of the properties, but the exploitation costs. Now that school boards since 1 January 2015 can dispose of the financial means for external maintenance of the building themselves, this aspect on the border of renovation and construction leads to discussions between municipalities and school boards more often. After all, municipalities are responsible for the expenses of construction, whereas school boards pay for renovation.

The interviews have given a clear indication that real estate, in accordance with the theoretical possibilities, is used as a means to reduce costs in the form of exploitation expenses, such as costs for energy, maintenance, and cleaning.

5. Discussion

Though the number of interviews was limited, the results still give reason to further investigate the assumed relation between real estate strategy and stakeholders. This research has made clear that the seven usual real estate strategies (in other words, ways to add value to an organisation) can very well be linked to the interests of the stakeholders of a school building. Only the strategy of adding value by increasing innovations does not seem to fit for the housing of primary education.

The interviews also made clear that "Environment" as a stakeholder could very well mean more than just the immediate neighbours, as was assumed. For instance, also the institutions that benefit from the use of school buildings after school time and children using the playground after school, could very well be seen as a different category of users.

6. Conclusions

On the basis of this research, the conclusion seems to be justified that a school building should be seen as the fifth business resource for school boards, but not for municipalities. The interviews confirm that the people involved seem to be aware of the meaning (or the added value) of real estate for the primary process. The different parties express this in very different ways.

The research has not provided any evidence that these aspects are used to apply the available funds for housing for education differently. Most remarkable is that none of those interviewed sees possibilities in the value development of the property, for instance by restricting depreciations.

The interviews also show that this possibility to create value hardly ever plays a role in a real estate strategy, or is used as an argument to increase available budgets. No indications have been found that school boards make use of a clearly defined strategy in which the investigated possibilities for adding value are used. Possibly, the parties concerned are insufficiently aware of these possibilities.

Abstract

Integrating public transportation and land use policies is one of the key strategies in an attempt to achieve more sustainable communities. While economic consequences are an essential dimension in decision making, there is yet very limited evidence for the impact of accessibility to bus transportation on surrounding residential property values. This study is the first of its kind investigating the price impact in Tampere – the largest city outside the capital region of Finland. An empirical strategy utilizing fixed-effect hedonic pricing models has been applied to specify valuation effects of accessibility to bus transportation.

A premium of 1.1 percent was estimated for housing units located no farther than 50 meters from a bus stop. Housing units located in zones with more diverse amenities and better bus connections were also estimated to be higher appreciated, with the exception that housing units in Private car zone sell at higher prices than units in Intensive public transportation zone. As Tampere is a relatively monocentric city with great coverage and service frequency of public bus transportation, the distance to CBD seems to be a more important determinant in terms of accessibility than proximity to the closest bus stop; one kilometer increase in distance to CBD was estimated to command 4 percent depreciation in housing values.

As there are significant differences between cities, some limiting factors should be taken into account when interpreting the results. Price impact on residential property values was studied only in Tampere, Finland, and it is important to notice that the city structure, extensive coverage of the bus network, local market conditions, and other potential differences between cities may have a notable impact on the outcomes. Thus, more studies are needed before the results may be generalized across other geographical locations.

The evidence gained in this study can be utilized when striving for more viable and sustainable cities. Understanding the influence of accessibility to bus transportation on housing values should be of interest to a wide range of city planners, policymakers, and community stakeholders.

Keywords: bus stops, bus traffic, housing prices, public transportation, residential property values, traffic related zones, urban form

1. Introduction

Integrating public transportation and land use policies has been identified as one of the key strategies in an attempt to achieve more sustainable communities (Newman and Kenworthy, 1996; Todes, 2012). It has also been recognized that public transportation investments and land use policies may induce changes in housing prices. (Du and Mulley, 2006; H.M. So et al., 1997; Henneberry, 1998).

Accessibility of public transportation is one of the factors taken into account when city planners are searching for to identify potential locations for new housing. In addition to their influence on land use decisions, public transportation stops may also impose externalities capitalizing into housing prices (Cervero and Kang, 2011). Previous studies have found that investments in public transportation may – particularly within walking distance – command a premium in housing prices (Dubé et al., 2013). However, Mohammad et al. (2013) suggest that due to researchers' tendency to publish only statistically significant results, published literature may introduce a biased general view of housing price effects from bus transportation.

Property value effects may depend on income level of residents in the area (Munoz-Raskin, 2010). Osland and Thorsen (2008) argue that there are two important components of accessibility that should be taken into consideration when estimating housing price effects. The first component is accessibility to central business district (CBD) where urban attractions are located, and most of activities occur. The second major component is recognized to be labor-market accessibility as commuting to work places is a central part of people's daily lives.

Public transportation connections are usually relatively stable, which may promote their propensity for capitalizing into housing values. However, the propensity may be dependent on transportation technology. A subway or suburban train is usually associated with higher appreciation in housing prices than bus connections (Bocarejo et al., 2013). The reasoning behind this may be that rail traffic always requires heavy infrastructure and substantial investments, resulting in relatively permanent structures. While, it is much harder to predict future development of bus connections as substantial investments on infrastructure are not needed, and thus, the system is more flexible for changes. Consequently, the impact of bus connections on housing prices may be less than what alternative forms of public transportation would induce.

Given that both positive and negative estimates of land and property values have been reported in different studies investigating rail project impacts (Mohammad et al., 2013), it is not self-evident that the impact from public transportation would only be positive. Although improvements in accessibility are likely to induce positive impacts, also a number of negative externalities, such as increase in noise and crime, can be linked to a better access to public transportation (Pope and Pope, 2012; Szczepańska et al., 2015). Attempts to control traffic volume by road tolls has been reported to have minor positive impact at least on residential leases which may result from decrease in negative externalities (D'Arcangelo and Percoco, 2015).

To date, there are relatively few studies investigating the impact of public transportation on housing values in developed countries. Mulley (2014) argues that, presently, there is a lack of evidence for the residential land value impact of bus networks in the developed countries. Particularly, the housing price impact from bus transportation in the Nordic Countries is underexplored. This study contributes to the existing body of literature, addressing the void in knowledge by investigating the impact of accessibility to bus transportation on housing prices in Tampere, Finland.

2. Data and Public Transportation System in Tampere

The data utilized in this study is from the city of Tampere in Finland – the largest urbanized area outside the capital region and home to more than 220,000 residents by the end of December 2015. Tampere is also the provincial center of Pirkanmaa region with slightly more than 500,000 residents. Tampere is an example of a quite monocentric city as for its bus network. Interestingly, the city center can be accessed through almost every bus line with only a couple of exceptions that do not pass through the city center. The public transportation system is mainly based on busses as there are no subways or streetcars. Tampere railway station is one of the central hubs in the Finnish railway network. However, the only stop for passenger trains is the Tampere central railway station located in the city center. Thus, in Tampere, the railway network only serves transportation to other cities and municipalities, but not the local traffic within the city limits. As the public transportation is relying on busses, Tampere is a potential geographical location to be studied to reveal the relevance of bus network to housing prices.

The impact of accessibility to bus transportation on residential property values was investigated by utilizing five unique datasets, including i) housing sales transactions from 2008 to 2012, ii) complete property registry for the city of Tampere, iii) spatial boundaries for traffic related zones of urban form (©SYKE), iv) locations of bus stops in the city of Tampere, and v) grid data containing information on residents' median income (©SYKE and TK). The spatial nature of the data allowed all five data sets to be combined using locational attributes.

The Finnish housing market is diverse in nature with property types ranging from single-family detached to multifamily apartment blocks. The average housing unit was constructed 39.8 years ago and sold for €137,047 (or €2,179 per square meter for a 62.9 square meter unit). The average number of rooms was 2.4 including bedrooms, living rooms, and studies, but not kitchens, bathrooms, private saunas, and walk-in closets. Private saunas are an important amenity, associated with 45 percent of the apartments sold. Housing transactions occurred on average in areas where the annual median income is 32,997 € and distance to Tampere Central Square is 4.42 kilometers. 63 percent of sold apartments were considered to be in good condition, whereas brokers reported 22 percent to be in acceptable condition and 1 percent in poor condition. Condition for 14 percent of the observations was not reported. 2 percent of the sold apartments were located in properties that have an elevator. The average distance to a bus stop was 137 meters. 22 percent of the transactions were located in Pedestrian friendly zone, 1 percent in Fringe zone, 19 percent in Public transportation zone, 9 percent in Private car zone, and 5 percent in Suburban center zone. The remainder of 44 percent was located in Intensive public transportation zone, which was the comparison level for the analysis. Table 1 presents summary statistics for the residential transactions.

Table 1: Summary statistics

Variable	*Mean*	*Std dev*	*Min*	*Max*
Sale price (€)	137,047	63,451	40,000	750,000
Property age (years)	39.8	20.1	5	160
Unit size (sq. meters)	62.9	23.9	15	275
Weeks on market	38.1	25.7	1.0	104.0
Number of rooms	2.4	1.0	1.0	8.0
Maintenance dues (€)	163	67	0.0	867.0
Floor number	2.6	1.8	1.00	12.00
I{Multi-story apartment block}	0.79	0.41	0	1
I{Townhouse}	0.17	0.38	0	1
I{Single-family house}	0.02	0.14	0	1
I{Duplex}	0.02	0.14	0	1
I{Sauna}	0.45	0.50	0	1
I{Elevator}	0.02	0.16	0	1
Income	32,997	13,234	9305	105796
Distance to CBD (km)	4.42	2.77	0.06	10.81
I{Condition: Acceptable}	0.22	0.41	0	1
I{Condition: Poor}	0.01	0.12	0	1
I{Condition: Unavailable}	0.14	0.35	0	1
I{Pedestrian zone}	0.22	0.41	0	1
I{Fringe zone}	0.01	0.12	0	1
I{Public transport zone}	0.19	0.39	0	1
I{Private car zone}	0.09	0.29	0	1
I{Suburban center zone}	0.05	0.22	0	1
I{Not within a zone}	0.12	0.32	0	1
Distance to bus stop (m)	137.49	86.56	7	756
I{Bus stop within 50 meters}	0.11	0.31	0	1
I{Bus stop within 100 meters}	0.38	0.49	0	1
I{Bus stop within 150 meters}	0.65	0.48	0	1
I{Bus stop within 300 meters}	0.95	0.21	0	1

Notes: This table presents the means, standard deviations, minimum and maximum values for the full sample of residential transactions. Price is the transaction price for residential units, in Euros (€). Time on market is measured in weeks. Building size and Unit size are measured in square meters. Property age is in years. Floor number is for the unit. The I{·} operator designates an indicator variable, taking on a value of one for the characteristic in brackets and zero otherwise. Property types included in the analysis are Duplex, Single-family (detached), Townhouse, and Multifamily (suppressed). Property condition categories include Acceptable, Poor, Unavailable and Good (suppressed). Maintenance dues are reported as monthly fees in Euros, and take on a value of zero for units in buildings that have no maintenance dues.

3. Estimating housing price impact

The empirical strategy in this study was to estimate a hedonic regression model for residential transaction prices. The objective was to evaluate price differences between different traffic related zones of urban form, and isolate the impact that proximate bus stop has on surrounding housing values while controlling for differences in property characteristics. The first estimated hedonic equation takes the following form:

$$\begin{aligned}\ln(\textit{Price}) = {} & \beta_0 + \beta_1 \cdot \ln(\textit{Property age}) + \beta_2 \cdot \ln(\textit{Unit size}) + \beta_3 \cdot \ln(\textit{Time on market}) \\ & + \beta_4 \cdot \ln(\textit{Number of rooms}) + \beta_5 \cdot \ln(\textit{Maintenance dues}) + \beta_6 \cdot \textit{Floor number} \\ & + \beta_7 \cdot \mathrm{I}\{\textit{Type: Single family}\} + \beta_8 \cdot \mathrm{I}\{\textit{Type: Townhouse}\} + \beta_9 \cdot \{\textit{Type: Duplex}\} \\ & + \beta_{10} \cdot \mathrm{I}\{\textit{Sauna}\} + \beta_{11} \cdot \mathrm{I}\{\textit{Elevator}\} + \beta_{12} \cdot \ln(\textit{Income}) + \beta_{13} \cdot \mathrm{I}\{\textit{Condition: Acceptable}\} \\ & + \beta_{14} \cdot \mathrm{I}\{\textit{Condition: Poor}\} + \beta_{15} \cdot \mathrm{I}\{\textit{Condition: Unavailable}\} + \beta_{16} \cdot \text{Distance to CBD} \\ & + \beta_{17} \cdot \mathrm{I}\{\textit{Pedestrian zone}\} + \beta_{18} \cdot \mathrm{I}\{\textit{Fringe zone}\} + \beta_{19} \cdot \mathrm{I}\{\textit{Public transportation zone}\} \\ & + \beta_{20} \cdot \mathrm{I}\{\textit{Private car zone}\} + \beta_{21} \cdot \mathrm{I}\{\textit{Suburban center zone}\} + \beta_{22} \cdot \mathrm{I}\{\textit{Not in the zone}\} \\ & + \beta_{23} \cdot \mathrm{I}\{\textit{Distance to bus stop}\} + \textstyle\sum_{i=1}^{4} \beta_{i+23} \cdot \mathrm{I}\{\textit{Year}_i\} + \textstyle\sum_{j=1}^{31} \beta_{j+27} \cdot \mathrm{I}\{\textit{Submarket}_j\} + \varepsilon. \qquad (1)\end{aligned}$$

The dependent variable is *Price*, logged. *Property age* is included to reflect the impacts of depreciation and technical obsolescence on housing values. Variables measuring the physical property dimensions include *Unit size*, *Number of rooms*, and *Floor number*. *Time on market* reflects one dimension of real estate marketing outcomes, and *Maintenance dues* reports monthly financial obligations connected to the property sale. *Distance to CBD* captures locational impacts, measuring distance to the Tampere Central Square. Indicator variables are used to classify property pricing according to property type, sauna, elevator and property condition. The sample of property sales spans from 2008 to 2012, and 4 year indicator variables are included to control for calendar year fixed effects. In addition, 31 submarket indicator variables are included to control for geographic differences in pricing at the zip code level. β are parameters to be estimated and ε is the normally distributed error term.

To capture the impact of different traffic related zones of urban form[1] on residential property values, five indicator variables are included for housing units that are located in *Pedestrian zone*, *Fringe zone*, *Public transportation zone*, *Private car zone*, or *Suburban center zone*. Indicator for *Intensive public transportation zone* is suppressed from the equation to refrain from linear combination. Variable *I{Not within a zone}* is included to capture pricing difference for housing transactions that are not located within any of the above mentioned zones. The log-linear model structure allows the coefficients for included traffic related zone indicators to be interpreted as the percentage difference in housing values to residential transactions occurred in

[1] The classification of traffic related zones of urban form is based on a spatial dataset by the Finnish Environment Institute (SYKE). For a detailed description, please see the Meta Data Portal: http://metatieto.ymparisto.fi:8080/geoportal/catalog/search/resource/details.page?uuid={96F338EA-75AF-432C-A780-31A3CDECBDF2} (in Finnish).

the *Intensive public transportation zone*. Furthermore, *Distance to bus stop* variable is included to isolate the impact of proximity to a bus stop. Results from the estimation of Equation (1) are presented in Table 2.

Adjusted R^2:	90.97%	
Observations:	12,449	

Notes: This table presents results from the least squares estimation of Equation (1). The dependent variable is Price, logged. The coefficients for I{*Pedestrian zone*}, I{*Fringe zone*}, I{*Public transportation zone*}, I{*Private car zone*}, and I{*Suburban center zone*} indicate the estimated price impact of traffic related zones of urban form. The coefficient for *Distance to bus stop* variable indicates the estimated price impact of distance to the closest bus stop. T-statistics corresponding to the coefficients are reported in parentheses. ***, ** and * designate statistical significance for the estimated coefficients at the 1%, 5% and 10% levels, respectively.

The estimated coefficients reveal that housing values are decreasing as properties age, likely resulting from depreciation and technical obsolescence. Housing values are increasing in unit size, but units that require longer marketing periods are revealed to sell at a significantly lower price. Units with higher maintenance dues are discounted. Units on higher numbered floors sell at a premium, estimated at 1 percent per floor. Single-family, duplexes, and townhouses all sell at positive and significant premiums relative to multifamily apartments (which is suppressed to avoid perfect multicollinearity). In Finland, the sauna is considered a precious amenity, associated with premiums in the magnitude of 13 percent. Elevator does not command a positive premium, which might not be the case if only transactions in multi-story apartment buildings were investigated. Higher median income is associated with higher housing values as wealthier people tend to live in higher appreciated neighborhoods. Housing units located farther from CBD (Tampere Central Square) sell at lower prices, so that 1 kilometer increase in distance commands 4 percent depreciation. Property condition identified as less than good (which is omitted to avoid linear combination) are discounted accordingly.

Estimates of indicator variables for traffic related zones of urban form reveal that housing prices are relatively highest in the Pedestrian zone, which usually indicates location in downtown area, and is associated with 12.5 percent premium relative to Intensive public transportation zone. In Fringe zone premium is estimated to be 9.3 percent, in Suburban center zone 2.7 percent, and in Private car zone 2.1 percent relative to Intensive public transportation zone. While, housing units located in Public transportation zone with weaker public transportation connections than in Intensive public transportation zone sell at 2.3 percent lower prices.

The coefficient for *Distance to bus stop* does not differ from zero, indicating that proximity to bus stop does not have an impact on housing values. However, the price impact is not likely to be linear resulting in that the continuous variable may not tell the whole truth. To further investigate the price impact of proximity to a bus stop another specification of the model was estimated. The second specification of the model takes the following form:

$$\begin{aligned}\ln(\textit{Price}) = {} & \beta_0 + \beta_1 \cdot \ln(\textit{Property age}) + \beta_2 \cdot \ln(\textit{Unit size}) + \beta_3 \cdot \ln(\textit{Time on market}) \\ & + \beta_4 \cdot \ln(\textit{Number of rooms}) + \beta_5 \cdot \ln(\textit{Maintenance dues}) + \beta_6 \cdot \textit{Floor number} \\ & + \beta_7 \cdot I\{\textit{Type: Single family}\} + \beta_8 \cdot I\{\textit{Type: Townhouse}\} + \beta_9 \cdot \{\textit{Type: Duplex}\} \\ & + \beta_{10} \cdot I\{\textit{Sauna}\} + \beta_{11} \cdot I\{\textit{Elevator}\} + \beta_{12} \cdot \ln(\textit{Income}) + \beta_{13} \cdot I\{\textit{Condition: Acceptable}\} \\ & + \beta_{14} \cdot I\{\textit{Condition: Poor}\} + \beta_{15} \cdot I\{\textit{Condition: Unavailable}\} + \beta_{16} \cdot \text{Distance to CBD} \\ & + \beta_{17} \cdot I\{\textit{Pedestrian zone}\} + \beta_{18} \cdot I\{\textit{Fringe zone}\} + \beta_{19} \cdot I\{\textit{Public transportation zone}\} \\ & + \beta_{20} \cdot I\{\textit{Private car zone}\} + \beta_{21} \cdot I\{\textit{Suburban center zone}\} + \beta_{22} \cdot I\{\textit{Not in the zone}\} \\ & + \beta_{23} \cdot I\{\textit{Bus stop close}\} + \textstyle\sum_{i=1}^{4} \beta_{i+23} \cdot I\{\textit{Year}_i\} + \sum_{j=1}^{31} \beta_{j+27} \cdot I\{\textit{Submarket}_j\} + \varepsilon. \qquad (2)\end{aligned}$$

The second specification is consistent with Equation (1) with the difference that the continuous variable *Distance to bus stop* is replaced with an indicator variable *I{Bus stop close}*. To understand the price impact of proximity to a bus stop, four separate variations of the model were estimated. All four estimated models are consistent with Equation (2), and the difference is that each one has unique definition for a proximate bus stop. The following radii for proximity are estimated: 50 m, 100 m, 150 m, and 300 m.

Results from the estimation of Equation (2) for the 50 m, 100 m, 150 m, and 300 m radii are presented in Table 3. In the interest of brevity, only estimates for I{*Bus stop close*} are reported in Table 3 as the remainder of coefficient estimates is consistent with the results in Table 2. Testing various radii for proximity reveals that better accessibility to public transportation commands a premium which diminishes relatively fast with distance. Housing units located within 50 meters from a bus stop sell at 1.1 percent higher prices, but statistical significance seems to disappear already beyond 50 meters. Interestingly, the coefficient for 300 m radius indicates that transactions within 300 m radius from a bus stop are discounted 1.4 percent relative to observations that are located farther away. At this point it is important to notice that only 5 percent of the housing transactions are not located within 300 meters from a bus stop, potentially resulting in a bias. Thus, it is likely that the estimated negative price impact cannot directly be associated with proximity to a bus stop, but rather captures price impact from other factors.

Table 3: Estimated price impact, Equation (2)

Radius for close proximity:	**50 m**			**100 m**		**150 m**		**300 m**		
Variable	*Coefficient*		*(t-stat)*	*Coefficient*	*(t-stat)*	*Coefficient*	*(t-stat)*	*Coefficient*		*(t-stat)*
I{Bus stop close}	0.011	***	(3.0)	0.000	(0.2)	0.004	(1.3)	-0.014	**	(-2.1)
Year indicators:	Included (4 variables)									
Sub-market indicators:	Included (31 variables)									
Adjusted R^2:	90.98%			90.97%		90.97%		90.97%		
Observations:	12,449			12,449		12,449		12,449		

Notes: This table presents results from the least squares estimation of Equation (1) for the 50 m, 100 m, 150 m and 300 m radii. The dependent variable is Price, logged. The coefficient for I{*Bus stop close*} indicator variable indicates the estimated price impact of proximity to a bus stop. T-statistics corresponding to the coefficients are reported in parentheses. *** and ** designate statistical significance for the estimated coefficients at the 1% and 5% levels, respectively.

It is reasonable to assume that price impact from proximity to a bus stop may vary between different locations. Thus, to investigate interactions between distance to a bus stop and location in different traffic related zones of urban form, the third and fourth specifications of the hedonic model were estimated. The third specification is consistent with Equation (1) with the difference that six interaction terms are included to capture the joint impact of each traffic related zone and distance to bus stop. Also interaction term *Dist to bus stop**Dist to CBD* is included to capture if the price impact from the distance to a bus stop differs with the distance to Tampere Central Square. The fourth estimated specification of the hedonic model is consistent with Equation (2), but with the difference that six interactions terms are included to capture the joint impact of each included zone indicator and the indicator variable for a proximate bus stop. Results from the estimations of the third and fourth model specifications suggest that price impact may vary between traffic related zones, but due to inconsistencies drawing reliable conclusions based on the results is difficult. The issue behind the inconsistent results is likely to derive from that the third and fourth model specifications divide the full data sample into several subgroups. This results in too small and unevenly distributed subsamples, potentially introducing a bias in the results.

4. Conclusions and Discussion

Although economic consequences are an essential dimension in decision making, yet little is known about the impact of accessibility to bus transportation on housing values. In this study, the void in knowledge was addressed investigating the bus transportation related housing price impact in Tampere, Finland. An empirical strategy utilizing fixed-effect hedonic pricing models was applied.

Results from the estimations indicated that there are statistically significant valuation differences between traffic related zones. The analysis was performed relative to *Intensive public transportation zone*, and estimates revealed that housing prices are relatively highest in the Pedestrian zone, usually indicating location in downtown areas. In Pedestrian zone, housing prices were estimated to be 12.5 percent higher than in Intensive public transportation zone. In Fringe zone, usually located in close proximity to downtown areas, the premium was estimated to be 9.3 percent, in Suburban center zone 2.7 percent, and in Private car zone 2.1 percent relative to Intensive public transportation zone. While, housing units located in Public transportation zone with weaker public transportation connections than in Intensive public transportation zone sell at 2.3 percent lower prices. In an attempt to capture the price impact of distance to the closest bus stop with a continuous *Distance to bus stop* variable, no statistically significant price difference was found. However, testing another model specification utilizing indicator variables, a premium of 1.1 percent was found for housing units located no farther than 50 meters from a bus stop. *Distance to CBD* (Tampere Central Square) was estimated to be an important determinant for housing prices as one kilometer increase in distance results commands 4 percent depreciation in housing values.

The estimation results are in line with assumptions, given that Tampere is a relatively monocentric city with notably extensive bus transportation network; almost every bus line passing through the city center, and 95 percent of the housing transactions being located no farther than 300 meters from the closest bus stop. Due to the great coverage and service frequency of public bus transportation, the CBD is relatively easy to access from anywhere within the city limits. Thus, in Tampere, the distance to CBD seems to be a more important determinant in terms of accessibility than location of the closest bus stop. Valuation of traffic related zones is also mainly consistent with the assumptions as housing units located in zones with more diverse amenities and better bus connections are higher appreciated, with the exception that housing units in Private car zone sell at higher prices than units in Intensive public transportation zone. However, this observation is logical as Private car zone can be associated with comfortable and secure suburban neighborhoods where owner-occupied single-family houses are the predominant form of housing. In this kind of neighborhoods, bus transportation is of less importance as wealthier suburban residents often choose to use their own cars.

This study is the first of its kind investigating the impact of accessibility to bus transportation on housing values in the largest city outside the capital region of Finland. The results do not provide any big surprises but rather confirm authors' presumptions. However, as there are significant differences between cities, some limiting factors should be taken into account when interpreting the results. Price impact on residential property values was studied only in Tampere, Finland, and it is important to notice that the city structure, extensive coverage of the bus network, local market conditions, and other potential differences between cities may have a notable impact on the outcomes. Thus, more studies are needed before the results may be generalized across other geographical locations. In this study, the price impact was studied using Euclidean distance between the housing unit and bus stop. However, in reality, the accessibility to a bus stop is a much more complicated phenomenon than distance measured as the crow flies (Kang, 2015).

To improve the analysis, it might be useful to use a more advanced approach to define accessibility in further research. For example, accessibility could be defined more precisely taking into consideration the actual characteristics of the surrounding neighborhood. The analysis could also be extended to cover more detailed information on which bus lines serve the proximate bus stop, how often the busses arrive, which areas can directly be accessed via the bus stop, and what is the average driving time to the destination. Adding these above mentioned dimensions in the analysis would allow better understanding of the actual accessibility and its impact on housing values. Also alternative empirical strategies, such as geographically weighted regression (GWR) or combining matched sample methodologies with the hedonic regression, could be applied in an attempt to improve the analysis.

The evidence gained in this study can be utilized when striving for more viable and sustainable cities. Understanding the influence of accessibility to bus transportation on housing values should be of interest to a wide range of city planners, policymakers, and community stakeholders.

(email: D.J.M.vanderVoordt@tudelft.nl)

Abstract

Purpose: To present an integrated process model of adding value by Facilities Management (FM) and Corporate Real Estate Management (CREM) that is a generalisation of existing conceptual frameworks and aims to be a basis for management of added value in practice.
Background: The growing research on the added value of FM and CREM over the last decade has resulted in the development of several conceptual frameworks and the collection of much empirical data in practice. However, the practical application of current knowledge has shown to be limited and difficult. The reasons seem to be that the different frameworks are too complex and lack of common terminology and clear operationalisations of intervention-impact relationships.
Approach (Theory/Methodology): A generalised Value Adding Management process model is developed based on a common cause-effect model identified in existing conceptual frameworks combined with the basic process model of input → throughput → output. The proposed model consists of interventions as input, management of implementation as throughput and added value as output/outcome.
Results and practical implications: The Value Adding Management model provides a simple framework which aims at supporting the practical management and measurement of added value. A typology with six types of FM/CREM interventions is developed from earlier research. The concept of Value Adding Management is investigated and the 12 most important added value parameters are identified.
Research limitations: The process model still has to be tested on its empirical validity and practical applicability. This is being done and will be presented in a forthcoming book on how to manage and measure value adding by FM and CREM.
Originality/value: The Value Adding Management process model condensates research in an original and simple model with the potential to make value adding management more applicable in practice.

Keywords: Facilities Management, Corporate Real Estate Management, Interventions, Value Adding Management, Added Value.

1. Introduction

Facilities Management (FM) and Corporate Real Estate Management (CREM) are two closely related and relatively new management disciplines with developing professions worldwide and which attract increasing academic attention. Both disciplines have from the outset had a strong focus on controlling and reducing cost for property, work space and related services. In recent years there has been a change towards putting more focus on how FM/CREM can add value to the organisation. The growing research on the added value of FM and CREM has resulted in the development of several conceptual frameworks and collection of much empirical information. However, the practical application of this knowledge has shown to be limited and difficult. The reasons seem to be that the different frameworks are too complex and lack of common terminology and clear operationalisations of input-output/outcome relationships.

The purpose of this paper is to present an integrated process model of adding value by FM and CREM which builds onexisting conceptual frameworks and aims to be a basis for value adding management in practice. The paper is related to a forthcoming book, where the model is further explained and validated. It is the result of work in a EuroFM research group established in 2009. The paper is mostly conceptual, but it is based on a huge amount of research and empirical evidence.

2. Conceptual Model

2.1 Existing Conceptual Frameworks

When the research group began there were 3 conceptual frameworks that formed the starting point. One framework was the FM Value Map developed in Denmark by Jensen (2008 and 2010). The other frameworks were more related to CREM. One CREM framework was developed in Finland by Sarasoja – then Lindholm (Lindholm and Leväinen, 2006). The other was developed in the Netherlands by De Vries (De Vries et al., 2008). A fourth framework was later developed in the Netherlands by Den Heijer (2012) - partly based on the framework of De Vries, but redesigned in a different form and extended with various other value parameters.

The FM Value Map and the framework by De Vries both include a basic process model based on input → throughput → output, but in a different way. In the FM Value Map the process model refers to processes in FM and not in the core business, with input being FM resources, the throughput being FM processes and output being FM provisions. The logic of the FM Value Map is that the FM provisions as outputs can lead to different types of outcomes i.e. impacts on added value parameters related to core business and the surroundings and various stakeholders. The distinction between FM as a support function to a core business is a fundamental part of much theory on FM – although not undisputed. This distinction is even included in the definition of FM in the first European FM standard (CEN, 2006) using the term primary activities as representing the core business.

In the framework of De Vries the process model is related to the overall business organisation and business processes and various stakeholders as well; there is no distinction of a separate CREM process as such. The inputs are divided in 5 general business resources: Human Resources, Technology, Information, Capital, and Real Estate, referring to real estate as the fifth resource (Joroff et al., 1993). Embedded in the process model is a brief overview of real estate interventions that may lead to different types of influences (added values) on the business process and business outputs. The model can be seen as a cause-effect model similar to the outputs leading to impacts in the FM Value Map. The framework of Anna-Liisa Sarasoja does not in a similar way include a process model, but it is basically structured as a cause-effect model with real estate decisions and operation leading to different types of added values that cumulate into increased shareholder value.

2.2 The Value Adding Management Model

In the conceptual frameworks mentioned above a general process model can be recognized:

Input → Throughput → Output → Outcome → Impact = Added Value

We can also identify an underlying cause-effect model that is included in all the four conceptual models with different wordings as shown in Table 1.

Table 1: Cause-effect model in the 4 conceptual frameworks

Framework	***Cause***	***Effect***
FM Value Map	*Provisions / Output*	*Impact / Outcome*
Sarasoja	*Real estate decisions and operation*	*Added Value*
De Vries	*Real estate intervention*	*Influence / Added Value*
Den Heijer	*Real estate projects / Input*	*Added Value / Performance*

By combining the general process model with the cause-effect model and including value adding management as the intermediary between cause and effect we can define the generalised Value Adding Management process model: Intervention → Management → Added Value.

Intervention is used as the general term for cause and Added Value is used as the general term for effect. This model is very simple and combines essential aspects of the different conceptual frameworks supplemented with the management of implementing the intervention to ensure that the FM/CREM interventions lead to added value for the organisation. In relation to the general process model the focus in the generalised Value Adding Management process model is on how output by appropriate management can lead to outcome and added value.

This is equivalent to: Decision on type of change → Implementation → Outcome/Impact.

And also to: What → How → Why.

What is the kind of change and the improvement FM/CREM intends to make to add value; *how* is the way FM/CREM manages the change and implements the improvement and *why* is the benefit the core business organisation is expected to achieve i.e. the positive outcome of benefits versus sacrifices in terms of costs, time and risks.

The three elements in the Value Adding Management model as presented above can be seen as "black boxes". In the following section we will open each of these black boxes and reveal what they contain in a FM and CREM context.

3. Opening the Black Boxes

3.1 FM and CREM Interventions

This sub-section explains the first part of the generalised Value Adding Management model called "Intervention" or "Decision on type of change". It presents a typology of FM and CREM interventions based on earlier research consisting of the following six types of FM and CREM interventions:

1. Changing the physical environment (on different scale levels: portfolio, building, space)
2. Changing facilities services
3. Changing the interface with core business
4. Changing the supply chain
5. Changing the internal processes
6. Strategic advice and planning

Changing the Physical Environment

The physical environment is essential to both FM and CREM. It includes buildings, internal and external spaces, technical services (installations), indoor climate, fitting out, furniture, workplaces, technology, artwork and ambience. Typical examples of changing the physical environment include:

- Moving to another location (new or existing building)
- New building
- Rebuilding, refurbishment or adaptive re-use i.e. conversion to new functions
- Changing workplace layout, e.g. conversion of a cellular office with personal desks to an activity-based work setting with shared use of a variety of task-related workspaces
- Changing appearance, e.g. to support corporate branding

Changing Facilities Services

The facilities services are the operational FM activities. In the European standard on taxonomy for FM (CEN, 2011) the facilities services are divided in demand related to Space & Infrastructure and demand related to People & Organisation with both categories sub-divided in standardised facility products as shown in Table 2. The standardised facility products Space and Workplace in the table are partly overlapping with Changing the physical environment, but the physical environment basically concerns tangible artefacts, while the facilities services mostly concerns intangible service activities.

Table 2: FM taxonomy with standardised facility products (CEN, 2011)

Demand related to	***Standardised facility product***
Space & Infrastructure	*Space (Accommodation)*
	Outdoors
	Cleaning
	Workplace
	Primary activities specific
People & Organisation	*HSSE (Health, Safety, Security and Environment)*
	Hospitality
	ICT (Information and Communication Technology)
	Logistics
	Business Support (Management Support)
	Organisation specific

Changing the Interface with Core Business

When organisations reach a certain size and complexity, FM and CREM are typically established as separate functions or departments. The interface between the core business and FM/CREM is defined specifically in each organisation and is not static. If the FM/CREM function is successful, it will in many cases get the opportunity to increase its area of responsibility. This is often part of a centralisation of the responsibility from several parts of the core business organisation to the FM/CREM function, thereby creating opportunities for economies of scale.

Changing the Supply Chain

FM is in most cases organised as a mixture of an in-house FM-function and a number of external providers of facilities services, which constitutes a FM supply chain. The situation is to some degree similar for CREM, but the CREM supply chain is more project-related and mostly consists of consultants, designers and contractors. Changes in the supply chain are primarily changes in the delivery process, but they often also have consequences for the incentives for the different parties and the management of the mutual relationships between the parties. The number of external providers varies a lot depending on the type of company and the sourcing strategies. Outsourcing in FM has over the last decades been constantly increasing in most countries and is a common way to achieve cost reductions. Even though the general trend is towards more outsourcing in most countries, there are also many examples of insourcing of former outsourced services.

Changing the Internal Processes

What we deal with here is increasing the efficiency of operational processes within a specific organisation without necessarily changing, neither the product, nor the supply chain. The organisation can be in-house or an external provider. Within management theory and practice there are a number of concepts aimed at increasing productivity and process efficiency, for instance Total Quality Management, Business Process Re-engineering, Benchmarking and Lean Management. Typical elements in such concepts are eliminating waste, implementing new technological solutions and optimising the work flow. Many companies conduct projects by using such concepts and the FM function is often included in the project. Many provider companies also work systematically with developing process innovations. This is also the case for some of the larger in-house organisation.

Strategic Advice and Planning

Strategic advice and planning are essential elements in the strategic and tactical activities of FM and CREM. The areas for strategic advice and planning can cover many different aspects and they will typically change over time according to what is of strategic importance for the company. A typical area of strategic advice to top management concerns the development of a long-term strategy for the corporate property portfolio. This requires a profound and up to date understanding of the overall corporate strategy to identify the future demand for property and close dialogue with evaluation of options, scenarios and proposals concerning the future supply of property. Another typical area is investment planning and feasibility studies, which concerns decision support on choosing between alternative options for fulfilling a need for changes in the capacity of space or similar. This can for instance be whether the company should extend existing facilities, relocate, build new building, sell or buy property, rent or rent out space.

3.2 Value Adding Management

This sub-section explains the second part of the generalised Value Adding Management model called “Management” or “Implementation”.

The term “Value Adding Management” and related terms are widely used in business and management literature. In manufacturing related literature “Value Adding Management” or VAM is often used in a way close to Lean Management with a focus on eliminating non-value adding or “waste” activities. However, VAM is also seen as part of an overriding strategy, where the corporate mission is *what* and VAM is *how* (Anonymous, 2014). This resembles our generalised Value Adding Management model, but there is no mentioning of *why***,** except indirectly with including “value adding” in the term. The industrial consultant Carlo Scodanibbio even calls VAM the philosophy of the second industrial revolution and the guiding light for the year 2000 industries (Scodanibbio, 2014).

It relation to FM and CREM essential aspects of VAM are strategic alignment between FM/CREM and core business and stakeholder management and relationship management as part of the implementation of changes. Here we will solely focus on strategic alignment. Aligning, in an active sense, implies moving in the same direction, supporting a common purpose, being synchronized in timing and direction, being appropriate for the purpose and in a passive sense, the absence of conflict (Then et al., 2014).

Figure 1 connects the terms alignment and added value to show that corporate real estate only adds value when its supports the organisational objectives. It shows that alignment of the accommodation and building related facilities and services requires a thorough understanding of the organisational strategy and its structure, culture, primary processes and so on. When the FM/CREM department develops its mission, vision and strategy, this should be done in connection to the mission, vision and strategy of the organisation. FM/CREM interventions should not only be checked on its impact on FM/CREM performance and organisational performance, but also on its impact on attaining organisational goals. A better performance does not per definition deliver added value. For instance, if an FM intervention results in a higher ranking on "green buildings" but the organisation was fully satisfied with the original ranking, this higher ranking does not add any value to the organisation.

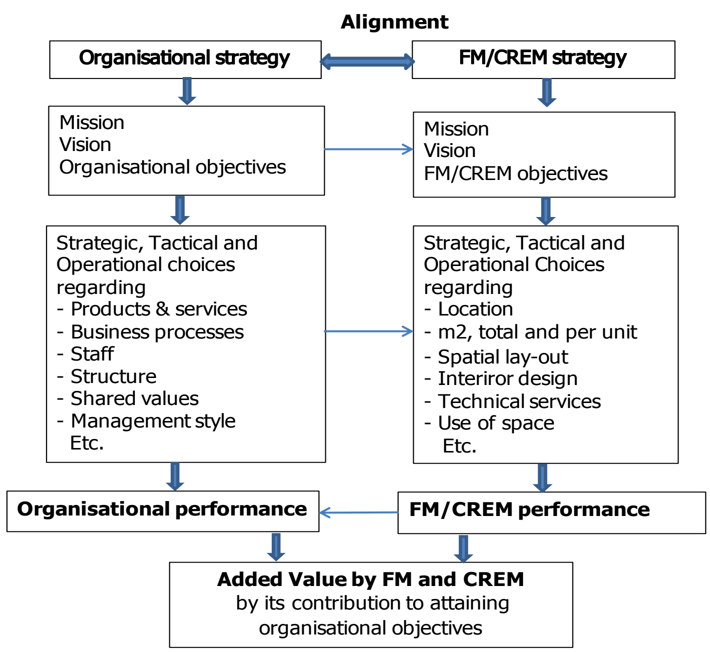

Figure 1: Connections between alignment and adding value (Van der Voordt, 2014)

3.3 Added Value Parameters

This sub-section explains the third part of the generalised Value Adding Management model called "Added Value". Table 3 presents an overview of the value parameters that were discussed in various studies and which have been classified in the six categories of performance measurement mentioned by Bradley (2002). With the division of the category Organisational development in 5 sub-groups table 3 provides 10 different value parameters with slightly different names. Remarkably the list of parameters by De Vries et al. (2008) is lacking in this list.

Table 4 presents a comparison of the 4 models mentioned in section 2. One difference is that it uses a more recent version of the model by Sarasoja, which includes Supporting environmental sustainability (Lindholm and Aaltonen, 2012). The different value parameters have been categorised under the four headings People, Process, Economy, and Surroundings.

Table 3: Different value parameters classified into the six categories (Riratanaphong and Van der Voordt, 2015)

Bradley (2002)	*Nourse and Roulac (1993)*	*De Jonge (1996)*	*Lindholm & Gibler (2005); Lindholm (2008)*	*Van Meel et al. (2010)*	*Den Heijer (2011)*	*Van der Zwart and Van der Voordt (2013)*	*Jensen et al. (2012)*
1.Stakeholder perception (employee satisfaction)	*Promoting HRM objectives*	-	*Increasing employee satisfaction*	*Attracting and retaining talented staff*	*Supporting user activities* *Increasing user satisfaction* *Improving quality of place*	*Increasing user satisfaction*	*Satisfaction*
2.Financial health	*Capturing real estate value creation of business*	*Increasing of value*	*Increasing the value of assets*	-	*Increasing real restate value*	*Improving finance position*	-
	Flexibility	*Increasing of flexibility*	*Increasing flexibility*	*Increasing flexibility*	*Increasing flexibility*	*Improving flexibility*	*Adaptation*
	Facilitating managerial process and knowledge work	*Changing culture*	-	*Encouraging interaction* *Supporting cultural change*	*Supporting culture* *Stimulating collaboration*	*Improving culture*	*Culture*
3.Organisational development	*Promoting marketing message Promoting sales & selling process*	*PR and marketing*	*Promoting marketing and sales*	*Expressing the brand*	*Supporting image*	*Supporting image*	-
	Facilitating and controlling production, operation and, service delivery	*Risk control*	-	-	*Controlling risk*	*Controlling risk*	*Reliability*
	-	-	*Increasing innovation*	*Stimulating creativity*	*Stimulating innovation*	*Increasing innovation*	-

Bradley (2002)	*Nourse and Roulac (1993)*	*De Jonge (1996)*	*Lindholm & Gibler (2005); Lindholm (2008)*	*Van Meel et al. (2010)*	*Den Heijer (2011)*	*Van der Zwart and Van der Voordt (2013)*	*Jensen et al. (2012)*
4.Productivity	-	*Increasing productivity*	*Increasing productivity*	*Enhancing productivity*	*Supporting user activities*	*Improving productivity*	*Productivity*
5.Environmental responsibility	-	-	-	*Reducing environmental impact*	*Reducing the footprint*	-	*Environmental*
6.Cost efficiency	*Occupancy cost minimization*	*Cost reduction*	*Reducing costs*	*Reducing costs*	*Decreasing costs*	*Reducing costs*	*Cost.*

Table 4: Comparison of added value parameters in four models

	A. Jensen et al., 2008	***B. Lindholm and Aaltonen, 2012***	***C. De Vries et al., 2008***	***D. Den Heijer, 2011***
Core business				
People	*Satisfaction* *Culture*	*Increase employee satisfaction*	*Image* *Culture* *Satisfaction*	*Increasing user satisfaction* *Supporting image* *Supporting culture*
Process	*Productivity* *Reliability* *Adaptability*	*Increase innovation* *Increase productivity* *Increase flexibility*	*Production* *Flexibility* *Innovation*	*Increasing flexibility* *Supporting user activities* *Improving quality of place* *Stimulating innovation* *Stimulating collaboration*
Economy	*Cost*	*Increase value of assets* *Promote marketing and sale* *Reduce cost*	*Cost* *Possibility to finance* *Risk control*	*Controlling risk* *Increasing real estate value* *Decreasing cost*
Surroundings	*Economic* *Social* *Spatial* *Environmental*	*Supporting environmental sustainability*		*Reducing the footprint*

The parameters related to People include (employee) satisfaction in all models. Model A also include “Culture”, while both model C and D include “Culture” as well as “Image”. Model B only includes “Increase employee satisfaction” under People. This model does as the only model include “Promote marketing and sale” placed under Economy. This parameter can be seen as an economical expression of “Image”, understood as brand. All four models include at least three parameters for Process with many overlaps. The differences can partly be seen as different degrees of sub-dividing. In relation to Economy, model A (the FM Value Map) only includes the parameter “Cost”, while the three other more CREM based models include parameters for “Value of real estate”, “Value of assets” or “Possibility to finance”. The parameter “Controlling risk” in model D is defined as related to financial goals, but it is also strongly related to the Process parameter "Reliability" in model A. In model C "Risk control" is included as well, partly related to reducing financial risks, but also to improving health and safety. Model A was the first model to include parameters related to Surroundings, including the "Environmental" parameter. The more recent CREM based models B and D also include a parameter for "Environmental sustainability" or "Reducing the footprint".

Based on the parameters in Table 3 and 4 we have decided to use the 12 value parameters listed in Table 5. All the parameters in Table 3 and 4 are more or less included, but the names of the parameters have been harmonised and Corporate Social Responsibility has been added. The parameters are like in Table 4 organised with four headings, but the heading Process has been changed to Process and Product.

Table 5: Added value parameters

Group	***Parameter***
People	*Satisfaction*
	Image
	Culture
	Health and Safety
Process and Product	*Productivity*
	Adaptability
	Innovation and Creativity
	Risk
Economy	*Cost*
	Value of Assets
Societal	*Sustainability*
	Corporate Social Responsibility

4. Discussion and Conclusion

Figure 2 shows the Value Adding Management model from section 2 with the 6 types of interventions from sub-section 3.1, the different aspects of VAM from sub-section 3.2 and the 12 added value parameters from sub-section 3.3. The model is seen as an integrated model for FM and CREM, which is generic for all kinds of businesses and for all types of property and facilities.

In order to be able to define the added value of an intervention by FM/CREM, it is important to measure the outcomes and impact of any intervention, ex-post and preferably also ex ante, as input to a business case (Van der Zwart and Van der Voordt, 2015). Clear performance indicators make it possible to assess how well people or facilities perform. The outcomes can provide the inspiration to achieve higher levels of effectiveness, efficiency, quality, and competitiveness. As such, performance measurement is an important aid for making judgments and decisions, which can help managers to answer five important questions: 1) where have we been; 2) where are we now; 3) where do we want to go; 4) how are we going to get there; and 5) how will we know that we got there (Lebas, 1995). Besides the need to operationalise the various value parameters in SMART performance indicators (Specific, Measurable, Assignable, Realistic and Time-related), performance measurement should be precise about the performance of *what*, e.g. people, facilities, or services.

Apart from clear performance indicators, it is also important to be able to define the causes of high or low performance, and to understand which changes are needed to improve what kind of performance. De Vries et al. (2008) concluded that cause-effect relationships are difficult to prove, due to the impact of many interrelated input factors, and the way interventions are implemented. It is our ambition in our further research to assess the 12 selected value parameters on what we know, what we still need to know, and what Key Performance Indicators could be applied to measure the different added values (Jensen and Van der Voordt, 2016).

Managing Network Risks in Health Facilities

Martin Loosemore
Faculty of the Built Environment, University of New South Wales
(email: m.loosemore@unsw.edu.au)
Vivien W Y Chow
Department of Real Estate and Construction, University of Hong Kong
(email: vivien.chow@gmail.com)

Abstract

Health facilities play a crucial role in maintaining healthcare services to the community during an extreme weather event. Health facilities managers operate within a wider network of organisations which include emergency services, health resource suppliers, local authorities, external health agencies and governmental organisations. Their response to an extreme weather event depends significantly on their ability to manage the network risks which may arise between actors in this complex system. Yet existing research has tended to look at facilities managers in isolation. Through an in-depth case study of how health services in the State of New South Wales, Australia would respond to an extreme weather event, the interface risks between these various agencies are explored from a facilities management perspective. An analysis of 139 documentary sources which would dictate the inter-agency response shows that health facilities managers face numerous hidden risks arising from overlapping, complex and unresolved governance conflicts between the agencies on which they depend. It is concluded that these interface risks can be reduced if facilities managers employ a number of strategies. These include: mapping hospital dependency on other agencies; resolve overlapping operational boundaries with other agencies; undertaking proactive risk reduction for critical external support infrastructure; and better understanding potential conflicts with external agencies in responding to an extreme weather event.

Keywords: Facilities management, hospitals, risk, inter-agency, governance

1. Introduction

Using systems theory, Loosemore et al. (2012) provided empirical evidence to show that if healthcare facilities are to become more resilient to extreme weather events (EWEs), they cannot be treated in isolation from the wider systems in which they exist. EWEs are defined as weather patterns such as heatwaves, storms and floods that exceed a particular threshold and deviate significantly from mean climate conditions (Linnenluecke and Griffiths 2010). These interdependent systems include other organisations such as: the police, the army, the fire services; water, electricity and gas authorities; off-campus hospital suppliers; polyclinics; aged care facilities; and other critical service providers. Although the health facilities management literature acknowledges that the health system is complex, it provides little insight into the interface risks associated with the coordination and integration of all these organisations when the system is under stress. The ability of these various organisations to effectively coordinate with each other before, during and after an EWE can have a direct impact on a hospital's ability to cope. For example, records from the 1997 heat wave in Adelaide, South Australia, show that hospital computers overheated and failed and that outages occurred in water supply, air-conditioning and energy supply (Emergency Management Australia 1998). The 2005 Sydney heat waves had similar impacts and particularly affected the elderly and other vulnerable populations such as the obese and chronically ill, causing increased hospital admissions relating to heatstroke and cardio vascular diseases. This is not a problem unique to Australia. For example, in 2007 a tornado hit Greymouth in the South Island of New Zealand cutting electricity lines, damaging buildings and flooding access roads to many critical facilities (New Zealand Ministry of Civil Defence and Emergency 2007). Many other EWEs such as Hurricane Sandy in the USA in 2012 and the UK floods in 2007, have highlighted the vulnerability and inherent interconnectedness of critical infrastructure such as hospitals, power generation, water and transport networks, leading to calls for greater investment to make these systems more resilient to these emerging risks (Gardiner 2013, Committee on Climate Change 2014).

This intricate interdependency on other infrastructure systems indicates that health facilities managers have to operate within a complex system containing 'systemic risks' which propagate through numerous pathways, spreading quickly and rapidly, in non-linear and unpredictable ways (Koubatis and Schönberger 2005). Helbing (2013: 51) defines 'systemic risk' as "the risks of not just having statistically independent failures but interdependent so-called 'cascading' failures in a network of N interconnected system components". In other words, systemic risks result from looped connections between different system components (sub systems), leading to localised initial failures spreading and potentially inflicting unbounded damage. As White (1995), Jaafari (2001), Stahl, et al (2003) and Koubatis and Schönberger (2005) argue, complex systems are inherently unstable and characterised by multiple elements which are so interlinked that it is rarely possible to trace a risk event back to one singular event. This inherent instability arises from the important property of 'self-organization' (the ability of a system's connections and interdependencies to change, adapt and develop on their own without the influence of external managers). Systems researchers have shown that the property of self-organisation ensures that complex systems tend to settle at a 'critical edge' where a small change in the system can lead to catastrophic changes in the overall system through 'cascading interdependencies' which exist between different parts of a system. This property of systems is called 'self-organised criticality' and Kampmann (1999) argues that the world is made up of complex systems which may appear under control on the surface, but exist in a state self-organised criticality which makes sudden catastrophic collapses in response to external disturbances almost inevitable.

It is within this context that the paper aims to explore the systemic network risks which facilities managers face in the health sector. Responses to EWEs are studied as these events represent a real and growing threat to the health sector and address an important yet missing inter-organisational dimension in the facilities management and disaster management debate, which hitherto has been largely confined to intra-organisational issues.

2. Interface risks and extreme weather events

Numerous researchers such as Ansell and Gash (2008), have recognised the challenges of how multiple interdependent organisations mobilise, co-ordinate and control their actions and resources to respond to, cope with and recover from external threats such as an EWE. The earliest work in this field is attributed to Prince (1920), who derived a 'social theory' to explain human response to disaster. Later, Mileti et al. (1975) introduced the concept of the "disaster life cycle" and established the fundamental concepts of mitigation, preparedness, response and recovery used in most contemporary disaster management plans and facilities management literature. Drabek (1986) refined this work and introduced the concepts of emergent behaviour and human systems in disaster response, igniting the current debate over the validity of the centralised or bureaucratic model promoted in disaster management. Contemporary research into multi-agency responses to natural disasters (eg. Houghton et al. 2006; McMaster and Baber 2009) is concerned with the challenges faced by multi agencies in adapting their governance boundaries from standard operating procedures to accommodate the broader dynamic inter-agency interdependencies required in a disaster or crisis. During a threat such as an EWE, multiple agencies are required to change their modes of operation, to perform different functions and to work on multiple tasks simultaneously and under considerable time pressures. This requires path dependencies to be challenged and a certain degree of adaptive capacity to break with the 'normal' routines that are known to work when the system is not under threat.

From an interface risk management perspective, contemporary disaster management theory can be divided into two schools of thought. The first emphasises the importance of a centralised authority for a successful disaster response and the value of agreed, well-practiced operating procedures (Drabek and McEntire 2002). The second acknowledges emergent behaviours and is orientated towards decentralised or self-organising models operating on the basis of cooperation and collective problem solving (Mendonca et al. 2007). Recent research has also raised doubts about the effectiveness of the traditional command and control model (Mendonca et al. 2007, Kapucu and Arslan 2010). It is argued that while a central coordinating authority and pre-determined disaster management plans can be of value, it can also reduce the opportunity for improvisation and adaption to novel conditions which might typically arise during an EWE. Recent research is showing that the effectiveness of disaster response is highly dependent on pre-existing relationships between responding agencies established prior to the event (McMaster and Baber 2008; 2009, Department of Homeland Security 2012). The body of research outlined above indicates the importance of facilities managers establishing and maintaining relationships well in advance of an EWE event, yet Heng and Loosemore's (2011) research shows that this can be problematic because facilities managers are often seen as trivial and marginalised from central social networks in and around healthcare operations.

3. Methods

To investigate the interface challenges that hospital facilities management might face in managing this network of interactions, we conducted an in-depth analysis of the complex inter-agency governance structure responsible for managing healthcare delivery in the state of New South Wales, Australia. Australia comprises six states and two internal territories. All states and internal territories have their own parliaments and administer themselves, working in partnership with the Federal Commonwealth Government. Each state also retains the power to make their own laws over matters not controlled by the Commonwealth and have their own constitutions, as well as a structure of legislature, executive and judiciary. In terms of health services, the Federal Commonwealth Government provides leadership, financing, research and national information management around health policy while the states and territories are largely responsible for the delivery of public health care services and the management of healthcare workers in the public and private sectors. The states and territories deliver public acute and psychiatric hospital services including school and child health programs. Residential aged care is financed and regulated by the Federal Commonwealth Government and is outsourced mainly to the non-government sector (religious, charitable and for-profit providers). The Commonwealth, states and territories jointly fund and administer community care (such as delivered meals, home help and transport).

The state of New South Wales (NSW) provided an ideal context in which to study interface risks in this system. It is Australia's most populous state, with a population of about 7.5 million people served by about 230 public hospitals over an area of 809,444 km² which provide a wide range of other connecting services including emergency care, elective and emergency surgery, medical treatment, maternity services and rehabilitation programs. In addition to the Ministry of Health, the NSW Health service structure includes Local Health Districts, statutory health corporations and affiliated health organisations. New South Wales public health services include public hospitals, community, family and children's health centres, ambulance services and an extensive range of specialty services including mental health, dental, allied health, public health, Aboriginal health and multicultural health services. There are 15 Local Health Districts that are responsible for providing health services in a wide range of settings, from primary care posts in the remote outback to metropolitan tertiary health centres. The Ambulance Service of NSW is responsible for providing responsive, high quality clinical care in emergency situations, including pre-hospital care, rescue, retrieval and patient transport services.

Data about the interagency response boundaries and interactions revolving around healthcare facilities issues were collected using 139 documentary sources which would dictate the inter-agency response to an EWE. These documents included:

- Published governance structures for operating and maintaining public hospitals in New South Wales;
- Hospital, agency and community disaster management plans; government policy and legislation;
- Building control and standards guidance; published agency and government analysis of past EWE disaster responses;
- Annual reports of responding agencies; government inquiries into EWE responses; internal discussion papers;
- Disaster and emergency agency websites.

This data was analysed by cross-tabulating the responsibilities of the various agencies' names in these documents. The focus was to look for gaps and overlaps in their response mechanisms which could compromise the business continuity of a hospital in delivering health care services to communities during and after an EWE. A single case study approach of NSW (albeit with multiple internal dimensions), like any approach, has well-recognised limitations, particularly around representativeness and generalizability (Yin 2009). However, as discussed in the literature reviewed above, the number of potential agencies potentially involved in the response to an EWE and the complexity of interactions requires an in-depth approach to properly understand. Furthermore, in response to potential criticisms around generalizability, Flyvbjerg (2011: 301) argues that "while it is correct that the case study is a detailed examination of a single example, it is not true that a case study cannot provide reliable information about the broader class". Therefore, while the advantage of large samples might be breadth and representativeness, the advantage of case studies is depth and validity.

4. Analysis of interface risks

Our analysis indicated seven critical governance risks that can potentially impact a hospital facilities manager's ability to respond effectively to an EWE. These are:

- Inter-agency cooperation;
- Surge capacity;
- Preparation time;
- Gaining access to and from the disaster field;
- Resolving overlapping operational boundaries;
- Coordinating with agencies external to the health system;
- Resolving potential conflicts between external agencies.

Each of these risks is discussed in more detail below:

4.1 Inter-agency cooperation

In NSW, responsibility for the formulation and maintenance of disaster plans is delegated to 152 local governments which develop individual whole-of-community plans coordinated across the 11 Emergency Management Districts. Responsibility for disaster management of individual hospitals (both public and private) is allocated to 17 Local Health Districts (LHDs) with a different set of operational boundaries. Not only does this complex and overlapping governance landscape create potential coordination problems for facilities managers in preparing and responding to an EWE, it also creates the risk for disaster planning for hospitals to be undertaken in isolation from the whole-of-community disaster plans that are coordinated by Local Government officials.

4.2 Surge capacity

Our analysis indicated that surge capacity is a recurrent problem in hospitals and while financial constraints are often blamed for this, other issues identified in post disaster reports include fragmented governance of surge resources, offsite storage of resources, over-loaded supply chains and poor communication about overflow management.

4.3 Preparation time

Post disaster reports show that hospitals need preparation time to deploy a response team, be sufficiently resourced to receive mass casualties, as well as to assist with the health response during the community's recovery period. It also depends on careful planning to provide sufficient temporary additional treatment space through a range of measures including cancelling elective surgery, diverting emergencies not related to the disaster to other hospitals, and potentially transferring patients.

4.4 Access to and from the disaster field

There is an assumption that access to and from the disaster field will be possible during the course of a disaster response and recovery period. Not only does this assumption rely on surrounding infrastructure remaining operational (for example, roads, helipads or airports), it also relies on transport vehicles and equipment being capable of handing the conditions within the disaster field. However, our analysis indicated that dependency on other overloaded agencies to supply transport and the inability of the available responders to negotiate flooded roadways or rough terrain can significantly affect the effectiveness of hospital responses.

4.5 Overlapping operational boundaries

Our analysis shows that EWEs typically affect a wide catchment area and are likely to be covered by more than one local disaster plan, and in severe cases potentially even some regional or district-based disaster plans. This requires hospitals to be familiar with the procedures and arrangements contained within multiple disaster plans, and also to build operational relationships with a wide range of stakeholders and responding agencies.

4.6 Funding of asset development

In Australia, the state government will typically own a hospital's physical assets including the site, and through its various agencies, oversee and fund its upgrade or renewal. Individual hospital facilities managers and regional health boards tend to have funding and delegated responsibility to manage the operation including routine maintenance of individual sites and supporting built infrastructure. There are two obvious problems with this arrangement: firstly, the people on the ground with the responsibility for preparing for and responding to an EWE have limited influence over decisions to upgrade or renew their hospital which could affect their ability to respond. Secondly, at a state level, decisions regarding capital expenditure on the upgrade or renewal of assets within an individual site are typically prioritised, with reference to the entire hospital portfolio. What may be of high priority to an individual hospital in its disaster planning may not necessarily be considered so by government at the state level.

4.7 Coordination with agencies external to the health system

Although most health systems attempt to ensure independence through backup systems such as the installation of generators, our analysis showed that hospitals inevitably have to rely on interactions with agencies outside the health sector when an EWE strikes. LHDs have limited influence over the centralised procurement from warehousing facilities supplying support services such as linen, catering, IT or consumable medical supplies within their districts. In the same way, during an EWE, LHDs will have little influence in mobilizing other agency resources. Given that hospitals are not geared to provide their own disaster transport, they are highly dependent on other emergency service agencies to assist with the deployment of medical teams and supplies into the disaster field and also to transfer casualties from the field for treatment in hospital. Therefore, the quality and timeliness of the ‘health’ response is dependent on the cooperation of other agencies.

4.8 Potential conflict between external agencies and hospital objectives

One major problem for a facilities manager in dealing with an EWE is that external agencies may have conflicting objectives to those of the hospital. For example, records show that local aged care facilities often lack a disaster plan and tend to evacuate their patients and residents to tertiary hospitals during an event such as a flood, to prevent them being cut-off. Not only could patients become stranded en-route, but the arrival of additional vulnerable elderly persons into a hospital at a time when it is already under stress puts undue strain on the response effort.

5. Discussion

Past research on facilities risk management governance issues has taken an intra-organisational focus and the aim of this study was to balance this with inter-organisational insights. The findings add further qualitative evidence to Loosemore et al's (2012) research which argued that hospital facilities management is best conceptualised using a systems perspective that recognises the wider system in which hospitals are placed. The findings also support McMaster and Baber's (2008) and Uhr's (2009) contention that effective inter-agency coordinating is highly dependent on pre-existing relationships between responding agencies established prior to the event. In doing so it has also exposed the potential problems of 'sequential single agency response' highlighted by McMaster and Baber (2009). From a contemporary disaster management theory perspective, our results question the efficacy of the centralised governance school of thought which argues that a successful disaster response depends on the development of agreed, well-practiced operating procedures (Drabek and McEntire 2002). However, our findings also showed that the boundaries defining what each agency will tackle are often confused and are unlikely to adequately consider the dynamic inter-agency interdependencies required to ensure an effective response to an EWE. Furthermore, our research shows that while hospital facilities managers are responsible for managing critical assets during an EWE, they are unlikely to be an integral part of a common operational picture or a shared situational awareness which disaster management researchers like Wickens (2008) advocate. Our research suggests that during an EWE people will need to move outside these procedures and that it is therefore important to acknowledge emergent informal systems and behaviours, and the need for decentralised or self-organising models operating on the basis of cooperation and collective problem solving (Mendonca et al. 2007). In terms of future research, our findings therefore suggest that there is a need to more deeply explore the interaction between formal and informal systems and procedures in disaster response and in particular, how informal processes and procedures can act to support the formal systems that central policy-makers have put in place.

6. Conclusions

The aim of this paper was to explore the systemic network risks which facilities managers face in the health sector. Theoretically, these findings add to the facilities management literature by highlighting the importance of power for facilities managers as determined by their position in the social networks that are defined by disaster management plans. They also highlight the need to develop brokerage and relationship-building skills which are largely ignored in the facilities management literature. While interviews with key stakeholders would provide further valuable insights and while further research is clearly needed into the inter-agency challenges of the facilities management function, the value of this research is that it reveals a set of issues and skills which are not typically covered in facilities management research literature. In particular, it highlights the importance of: adopting a systems perspective in understanding the health system as a whole; understanding the power, politics and economics of governance; stakeholder management; inter-agency relationship building; and understanding the objectives, plans and constraints of other organisational functions (external and internal) which the facilities manager depends on. As evident from our findings, it is important that any future analysis of these issues should take care not to neglect the social networks in which facilities managers are imbedded and of their power relationships with other disaster management stakeholders.

Operating Cost Estimation: A Comparison of Methods

Benjamin Lasshof
Institute for Construction Economics, University of Stuttgart
(email: benjamin.lasshof@bauoekonomie.uni-stuttgart.de)
Christian Stoy
Institute for Construction Economics, University of Stuttgart
(email: christian.stoy@bauoekonomie.uni-stuttgart.de)

Abstract

Operating costs represent a significant amount of the overall expenditures over the life-cycle of buildings. Therefore, it is a crucial task for all participants involved in the planning process to determine operating costs as early as possible. Accordingly, cost-benefit analyses can be developed and planning alternatives can be evaluated economically. Likewise, costs incurring during the operation of buildings can be monitored and controlled in an iterative process. Consequently, methods for an accurate estimation of operating costs are essential and can serve as a foundation for decision-making and budgeting.

The current approach focuses on the comparison of statistical methods for the estimation of operating costs using empirical data as a basis. Therefore, a sample consisting of 206 occupied facilities located in Germany is employed. The data was gathered in the years 2008 to 2014 from 25 project partners and contains 11 different facility types. Linear and nonlinear regression models and artificial neural network models are developed, specified, and validated. Additionally, categorised cost indicators for the estimation of operating costs are introduced, using the results of the developed statistical models as a basis. All statistical methods are evaluated for their accuracy employing an independent, randomly selected, and representative test sample.

The results show the best estimation accuracy for the nonlinear regression model and the artificial neural network model with mean absolute percentage errors of 15.4% and 16.6% respectively. The minor differences of the measures of performance and quality for both models utilising the same 7 predictor variables indicate correctly specified models. The procedure of model development and the evaluation of the results are presented in detail and may serve as a basis for further research on the estimation of operating costs and the identification of significant predictor variables. The extension of the data sample, the consideration of further facility types, and the implementation of additional statistical methods may be considered by future approaches to improve the accuracy of operating cost estimation.

Keywords: Operating costs, estimation, statistical methods, regression analysis, artificial neural networks

1. Introduction

A significant amount of the financial expenditures over a building's life-cycle are represented by operating costs. Various studies illustrate the financial relevance of these costs and point out the substantial potential of cost savings for property owners and leaseholders. For instance, operating costs for school facilities of between 27.93 and 35.44 Euro/m²*a (per m² usable floor area) are published by Beusker (2003). Accordingly, it is an increasingly important task to determine operating costs as early as possible in the process of planning. This is the only way to develop cost-benefit analyses and evaluate planning alternatives holistically. Likewise, costs incurring during the operation of buildings can be monitored and controlled in an iterative process.

Consequently, methods for the estimation of operating costs under consideration of significant influential variables are essential and can serve as foundation for decision-making and budgeting. Though various statistical methods for the estimation of construction costs and corresponding influential variables are extensively examined and evaluated, there are currently only the studies of Stoy and Kytzia (2006) (office facilities) and Beusker (2013) (school facilities) introducing statistical methods for the estimation of operating costs and evaluating the quality and performance of the developed models.

The current approach develops and evaluates several statistical methods (regression, artificial neural networks, and cost indicators) for the estimation of operating costs. Based on a wide range of possible predictor variables and a data sample of 206 occupied facilities, the procedure of model development is presented in detail including specifications and parameters of the best-fitting model. Significant variables influencing operating costs are identified and validated. Categorised cost indicators for the estimation of operating costs are introduced using the results of model development as a basis. All statistical methods are assessed according to their estimation accuracy employing an independent, randomly selected, and representative test sample. The main objectives of the current study are:

- Development and specification of linear and nonlinear regression models and artificial neural network models.
- Identification of significant variables influencing operating costs.
- Introduction of categorised cost indicators.
- Evaluation of the estimation accuracy of the presented statistical methods.

Chapter 2 gives an overview of the statistical methods that are employed to conduct the current approach and defines operating costs as the response variable of the study. Chapter 3 contains a description of the data sample and includes descriptive statistics of variables serving as basis for the statistical analysis. The development of the statistical models and indicators for cost estimation is presented in Chapter 4. The best-fitting statistical model is specified in detail including relevant parameters. The estimation accuracy of the statistical methods is evaluated by an independent test sample. Before concluding the study in Chapter 6, a summary of the results including a discussion is given in Chapter 5.

2. Methodology

Statistical models are designed to capture and represent the reality as close and accurate as possible in practice and may be used for investigation or prediction (Fellows and Liu, 2008). Regression analysis is a method to determine functional relationships among variables and can be employed for description, model building, estimation, prediction, and for control aims (Chatterjee and Hadi, 2006). In multiple regression the attributes of one response variable depending on several predictor variables are explained by the following generalised relationship (Backhaus, Erichson, and Weiber, 2013):

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_i X_i + \varepsilon$$

where Y is the response variable, β_0 is the constant and β_i are the coefficients, X_i are the predictor variables, and ε is the error term of the regression. The unknown model parameters β_0 and β_i are to be determined from the data as accurate as possible by the so called ordinary least squares (OLS) method. Therefore, the mean squared error term ε (difference between observed and estimated value) for all observations is kept as small as possible.

Regression models for the estimation of costs in the field of construction are utilised since the 1970s. The current study introduces linear and nonlinear regression models to estimate operating costs. The nonlinear model includes transformation of predictor and response variables for correcting non-normality in the distribution of the data by application of the Box-Cox-Plot (Box and Cox, 1964). Therefore, an improvement of the model in terms of quality and performance is expected (Schmidt, 2009). Consequently, the term nonlinear does not indicate a nonlinear relationship between predictor and response variables.

In contrast to regression models, artificial neural network (ANN) models are able to represent nonlinear relationships between response and predictor variables. Inspired by the operation of the nervous system of humans and animals, ANNs are capable of learning and generalising from experience. They are considered as tools for construction since the 1990s (Moselhi, Hegazy, and Fazio, 1991) and are utilised for the estimation of construction costs in various studies.

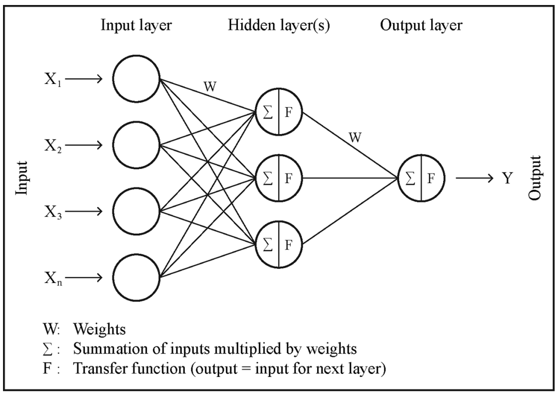

Figure 1: Typical architecture of a MLP neural network

For the estimation and identification of cause-effect relationships, the neural network architecture of multi-layer perceptrons (MLP) is most suitable (Backhaus et al., 2013) and therefore employed as a statistical method in the current study. MLPs typically consist of multiple layers of neurons as illustrated in Figure 1. Values of the predictor variables X_i are fed to neurons in the input layer, weighted and transferred to neurons of the first hidden layer. The inputs are summed up and then processed to the neurons of the next layer (or output layer) if the requirements of a transfer function are fulfilled. The output error is kept as small as possible by continuous comparison of the estimated and observed values and adjustment of the connection weights.

Based on the results of the regression and ANN models, cost indicators as a further method for the estimation of operating costs are developed and evaluated in the current study. Therefore, a suitable reference quantity is determined and cost indicators categorised according to identified predictor variables are presented.

The estimation quality and performance of the regression and ANN models can be determined by the accuracy of estimation compared to the underlying empirical data by the coefficient of determination R^2 as goodness-of-fit-index. The adjusted R^2 additionally takes the degree of freedom into account and consequently serves as a more reliable measure not depending on the number of predictor variables included in the model. Furthermore, the normalised root-mean-square error (CV)RMSE is used as an indicator to measure the standard deviation of the distance between observed and estimated values for evaluation of the statistical models.

The mean absolute percentage error (MAPE) is not only utilised as a measure of quality and performance to determine the goodness-of-fit of the statistical models, but also to measure the estimation performance under independent and unbiased conditions employing a test sample. The MAPE is defined as follows:

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{O_i - E_i}{O_i}\right| * 100\%$$

where O_i is the observed value, E_i is the estimated value, and n is the size of the sample.

To conduct statistical analysis based on empirical data, potential variables predicting the response variable have to be selected by the review of literature, by interviews, or by surveys (Fellow and Liu, 2008). Based on a selection by review of literature, a wide range of variables potentially influencing the operating costs (cf. Chapter 3) are considered for model development in the current study.

The response variable of the statistical models is defined as operating costs per year (Euro/a) according to German standard DIN 18960 (2008). Operating costs basically include supply of water, heating energy, electricity, disposal of water and waste, and costs for cleaning and care of indoor and outdoor facilities. Furthermore, costs for operation, inspection, and maintenance of building structures and technical installations as well as costs for security, surveillance, and statutory charges are included.

3. Data sample

The empirical approach of the current study employs a data sample consisting of 206 occupied facilities. The data collection was conducted in the years 2008 until 2014 in Germany and includes data provided by 25 project partners. The data were complemented on-site the facilities, using a standardised questionnaire. Among operating cost data, the sample contains possible predictor variables, e.g. quantities, information about utilisation and location, and evaluations of the condition of building structures and technical installations.

Table 1: Available qualitative variables

Variable	Characteristic	No. obs.	Percentage[a]
Thermal mass	Heavy thermal mass	176	85.4%
	Light thermal mass	30	14.6%
Standard of building automation	High standard	82	39.8%
	Low standard	124	60.2%
Standard of technical installations	High standard	153	74.3%
	Low standard	53	25.7%
Cleaning services	External contractor	189	91.7%
	Internal cleaning services	17	8.3%
Type of heating energy source	District heating	70	34.0%
	Electricity	11	5.3%
	Gas	110	53.4%
	Oil	15	7.3%
Type of facility	Care retirement home	13	6.3%
	Church building	11	5.3%
	Community hall	5	2.4%
	Fire department	5	2.4%
	Kindergarten	102	49.5%
	Library	4	1.9%
	Municipal building	8	3.9%
	Research/teaching	10	4.9%
	School facility	22	10.7%
	Sport facility	19	9.2%
	Town hall	7	3.4%
Kitchen	Kitchen/canteen	115	55.8%
	Tea kitchen	35	17.0%
	None	56	27.2%

[a] Total sample size is 206.

Potentially relevant qualitative variables are presented in Table 1 including their characteristics, their particular number of observations, and their percentage of the total sample. All available quantitative variables employed in the statistical investigation are described in Table 2. Operating costs as analysed response variable are adjusted to 2nd quarter 2015 prices including German VAT. Cost data were monitored over at least 1 up to 5 years, depending on the availability of data from the particular project partner. Cost indicators are created employing the gross external floor area (GEFA) defined by CEEC (2008) as reference quantity (cf. Chapter 4.1).

For an unbiased validation of the examined statistical methods, the total sample of 206 observations is divided into two subsamples. The training sample consists of 186 observations

(90% of the total sample) and serves as a basis for the development of the statistical models and cost indicators. The test sample includes 20 observations (10% of the total sample) and is used to measure the estimation performance of the developed models and cost indicators. The test sample is selected randomly and shall be representative of the training sample.

Table 2: Available quantitative variables

Variable	Type[a]	Mean	Standard deviation	Min.	Lower quartile	Median	Upper quartile	Max.
Absolute operating costs (Euro/a)[b]	RE	97,481	124,719	7,000	20,288	44,419	126,546	702,644
Operating cost indicators (Euro/m² GEFA*a)[b]	RE	39.13	15.21	10.21	28.37	37.81	47.78	79.76
Gross external floor area GEFA (m²)	CN	2,873	3,774	160	578	1,276	3,438	22,272
Share of usable floor area UFA on GEFA (%)	CN	0.54	0.12	0.25	0.46	0.54	0.62	0.81
Share of heatable GEFA (%)	CN	0.88	0.12	0.39	0.82	0.91	0.96	1.00
Share of ventilated and air-conditioned GEFA (%)	CN	0.09	0.15	0.00	0.00	0.02	0.12	0.76
Share of regularly cleaned usable floor area UFA (%)	CN	0.78	0.13	0.21	0.72	0.83	0.88	0.94
Share of sanitary area on GEFA (%)	CN	0.05	0.03	0.00	0.03	0.05	0.06	0.17
Average floor size (m²)	CN	695	628	87	292	496	878	3,954
Average storey height (m)	CN	3.95	1.50	2.50	3.10	3.50	4.26	14.08
Number of floors	DN	3.52	2.22	1	2	3	5	14
Number of elevator stops	DN	1.23	2.16	0	0	0	2	12
Number of sanitary facilities	DN	8.66	14.98	0	2	4	8	122

Share of double or triple glazing on ext. glass surfaces (%)	CN	0.91	0.27	0.00	1.00	1.00	1.00	1.00
Share of defective building construction (%)	CN	0.14	0.14	0.00	0.03	0.11	0.19	0.81
Share of defective technical installations (%)	CN	0.12	0.15	0.00	0.00	0.06	0.17	0.77

Number of observations for all quantitative predictor variables: 206.
[a] RE stands for response variables, CN stands for continuous numeric variables and DN stands for discrete numeric variables.
[b] Costs and cost indicators are adjusted to 2nd quarter 2015 prices including VAT.

4. Statistical investigation

4.1 Model development

Based on the pre-analysis presented in Chapter 3, statistical models are stepwise developed employing a training sample of 186 observations. Describing the causal interrelations between the response and the predictor variables, the main objective of the models is set to be the estimation of operating costs. Besides a linear regression model, a nonlinear regression model with transformed variables for the correction of non-normality of the underlying data is presented. Furthermore, an artificial neural network (ANN) model is developed. The models are summarised in Table 3 including measures of quality and performance.

Table 3: Comparison of relevant statistical models for estimation of operating costs

Model		No. variables	R²	R² (adj.)	MAPE	CV(RMSE)	Outliers	No. obs
Response variable: Operating cost indicators (Euro/m² GEFA*a)								
OP_1	Linear regression model	5	63.2%	59.7%	20.4%	23.8%	9 (4.8%)	186
OP_2	Nonlinear regression model	7	77.3%	74.9%	16.5%	21.4%	6 (3.2%)	186
OP_3	Artificial neural network (MLP)	7	*	70.3%	16.8%	21.6%	12 (6.5%)	186

It can be assumed that the estimation of cost indicators has more practical relevance for a variety of reasons, e.g. the comparability of indicators for benchmarking or long-term monitoring of performance. Based on the evaluation of models estimating absolute costs and cost indicators, the gross external floor area (GEFA) is identified as most suitable reference quantity. Therefore, only models estimating operating cost indicators (Euro/m² GEFA*a) are presented in the current study. Comparing the developed models, the nonlinear regression model OP_2 offers the best quality and performance in terms of accuracy with a R^2 of 77.3% and an adjusted R^2 of 74.9%. Furthermore, the MAPE of model OP_2 indicates the best accuracy with the lowest value of 16.5% compared with nonlinear regression model OP_1 and ANN model OP_3.

4.2 Specifications and parameters of the best-fitting model

As presented in Chapter 4.1, various statistical models for the estimation of operating cost indicators are developed. In the current chapter, the best-fitting nonlinear regression model OP_2 is specified and relevant parameters are presented in detail. Table 4 gives a description of the included predictor variables and their coefficients.

Table 4: Description of coefficients for nonlinear regression model OP_2

Response variable (Y)		Transf. (λ)	R²	R² (adj.)	MAPE	CV(RMSE)	p-value	No. obs.

	Sport facility	*	-0.438	0.093	*	-4.69	0.000	2.96
	Town hall	*	-0.477	0.115	*	-4.14	0.000	1.70

Following equation describes the nonlinear regression model OP_2:

$$Y = e^{\beta_0} * e^{\beta_1 X_1{}^2} * e^{\beta_2 X_2{}^2} * x_3{}^{\beta_3} * e^{\beta_4 \sqrt{X_4}} * e^{\beta_5 X_5} * e^{\beta_6 X_6} * e^{\beta_7 X_7}$$

Transformations of both response and predictor variables are presented with their respective lambda (λ) as determined by Box-Cox transformation. The coefficients (β) for the regressions constant and variables are complemented by the standard error displaying the standard deviation of the coefficient's estimate for the sample. The standardised coefficients indicate the effect of the predictors even if they are measured on different scales. The standardised coefficients for categorical predictor variables are determined by re-calculating the regression including composite variables as established by Eisinga, Scheepers, and van Snippenburg (1991).

According to the t-values exceeding a value of 1.972 (significance level alpha set to 0.05), a generalised significance is indicated for all predictor variables included in model OP_2. The 4 quantitative and 3 qualitative variables are tested on their empirical significance complying with the threshold of the p-value on an α-level of 0.05. Since the present study is not conducted on an experimental level where variables can be observed isolated, multi-collinearity of the predictor variables exists to an extent (Chatterjee and Hadi, 2006). Nonetheless, values of the variance inflation factor VIF fall below the determined threshold of 5 for all predictor variables.

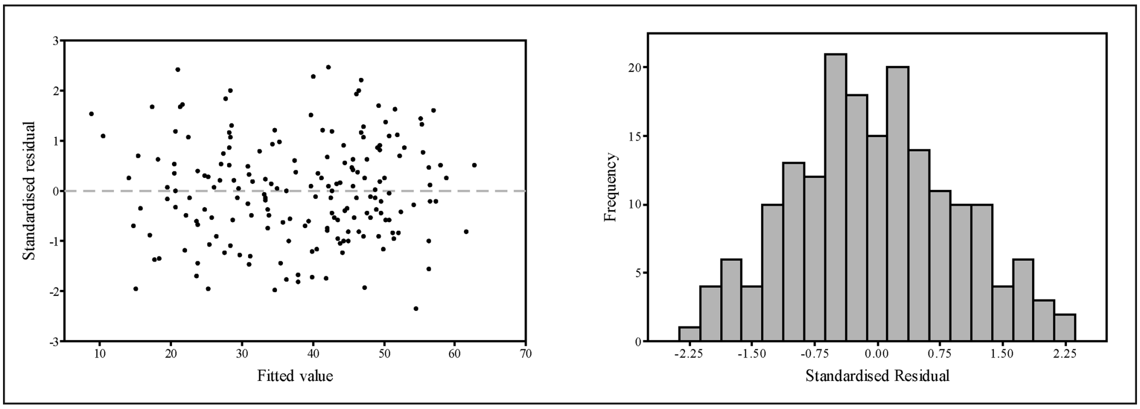

Figure 2: Residuals versus fitted values and histogram of residuals for model OP_2

As illustrated in the scatterplot and histogram in Figure 2, the variance of the residuals (difference between observed and estimated values) appears to be independent, randomly scattered, and heteroscedastic. Therefore, a correctly specified regression model OP_2 with no missing terms, extreme outliers, or influential points is indicated.

4.3 Cost indicators

The statistical methods compared in the current study include the estimation of operating costs employing cost indicators. As specified in Chapter 4.1, the best results in terms of quality and performance can be achieved for models including the gross external floor area GEFA. Therefore, the GEFA is determined as reference quantity for the generated cost indicators (Euro/m² GEFA*a). According to the standardised coefficient, the type of facility is identified as predictor variable with the greatest effect on operating costs in nonlinear regression model OP_2 (cf. Table 4). Based on the training sample including 186 observations, cost indicators with a categorical distinction according to the type of facility are presented in Table 5. In addition, corresponding boxplots are illustrated in the Appendix of the current study.

Table 5: Utility supply cost indicators

Type of facility	Lower quartile[a]	Median[a]	Upper quartile[a]	No. obs.
Care retirement home	30.11	45.64	67.48	12

[a] Operating cost indicators (Euro/m² GEFA*a), costs are adjusted to 2nd quarter 2015 prices including VAT.

4.4 Evaluation of performance and quality

The validation of the statistical methods is performed employing a test sample of 20 observations not included in the development of the statistical models and cost indicators. Therefore, unbiased and independent inferences about the estimation accuracy are expected. Observed and estimated values for the statistical models and the estimation by cost indicators are presented in Table 6. The estimated values are calculated by applying the observed predictor variables into the models (OP_1, OP_2, and OP_3) or selected according to the respective type of facility (indicators).

Total (MAPE)				17.5%		15.4%		16.6%		28.6%	

[a] Observed and estimated values: Operating cost indicators (Euro/m² GEFA*a), costs are adjusted to 2nd quarter 2015 prices including VAT.
[b] Absolute percentage error.

The absolute percentage error (APE) quantifies the accuracy of the estimated values for all 20 observations of the test sample. Furthermore, the preference for a statistical method according to the estimation accuracy is presented. With a preference of 9 out of 20 observations, values of the APE ranging between 0.7% and 42.1%, and a mean absolute percentage error (MAPE) of 15.4%, the most accurate estimation is indicated for nonlinear regression model OP_2.

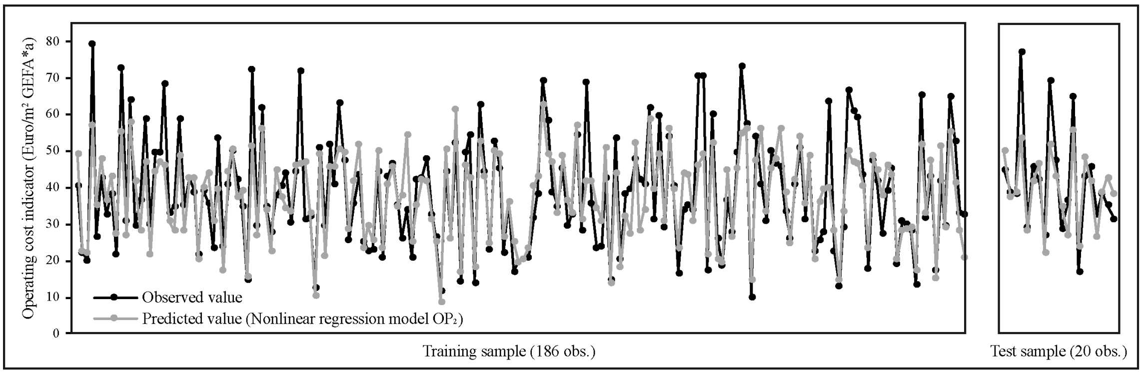

Figure 3: Comparison of observed values and values estimated by model OP_2

A comparison of the observed values and the values estimated by nonlinear regression model OP_2 is illustrated for both training sample and test sample in Figure 3. The graph reveals relatively consistent and small residuals for both training and test samples and indicates a good estimation accuracy for the statistical model.

5. Results and discussion

Comparing statistical methods for the estimation of operating costs employing an independent and representative test sample of 20 observations, a mean absolute percentage error (MAPE) of between 15.4% and 28.6% can be achieved as summarised in Table 7. The adjusted R^2 of the developed linear and nonlinear regression and artificial neural network models ranges between 74.9% and 59.7% with a CV(RMSE) of between 21.4% and 23.8%. The most accurate estimation of operating costs is provided by the nonlinear regression model OP_2 employing the gross external floor area GEFA as reference quantity. The model offers an adjusted R^2 of 74.9%, a CV(RMSE) of 21.4% and a MAPE of 16.5% (training sample) and 15.4% (test sample).

Table 7: Summary of statistical methods estimating operating costs

Sample	Linear regression (OP_1)		Nonlin. regression (OP_2)		ANN (OP_3)		Indicators (Median)		
	R^2 (adj.)	CV(RMSE)	R^2 (adj.)	CV(RMSE)	R^2 (adj.)	CV(RMSE)	R^2 (adj.)	CV(RMSE)	No. obs.
Training sample	59.7%	23.8%	74.9%	21.4%	70.3%	21.6%	*	*	186
	MAPE	No. pref.	MAPE	No. pref.	MAPE	No. pref.	MAPE	No. pref.	No. obs.
Training sample	20.4%	27 (14.5%)	16.5%	81 (43.5%)	16.8%	42 (22.6%)	25.3%	33 (17.7%)	186
Test sample	17.5%	4 (20.0%)	15.4%	9 (45.0%)	16.6%	4 (20.0%)	28.6%	3 (15.0%)	20
Total	20.1%	31 (15.0%)	16.4%	90 (43.7%)	16.8%	46 (22.3%)	25.6%	36 (17.5%)	206

With a significance level of alpha (α) determined as 0.05 for the current study, 7 significant predictor variables influencing operating cost indicators are identified for model OP_2 (ordered descending by the size of effect determined by the standardised coefficient of the regression):

- Type of facility
- Cleaning services

- Share of heatable gross external floor area
- Average floor size
- Share of regularly cleaned usable floor area
- Type of heating energy source
- Share of defective technical installations

The developed statistical models show better results in terms of accuracy comparing them to cost indicators employed for the estimation of operating costs. Due to a relatively small data sample, cost indicators with a categorical distinction according to only one predictor variable can be presented and evaluated. Therefore, the accuracy of the estimation by the regression and ANN models including between 5 and 7 significant predictor variables is expected to be more accurate. The correction of existent non-normality in the distribution of the data results in a better performance of the nonlinear regression model compared with the linear model. Though the nonlinear regression model performs slightly better, nonlinear relationships between the response variable and the predictor variables are indicated by the results achieved by the ANN model.

6. Conclusion

The current study examines multiple statistical methods for the estimation of operating costs on the basis of a data sample of 206 occupied facilities. Therefore, linear and nonlinear regression models and artificial neural network models are developed, specified, and evaluated in terms of their estimation accuracy. Significant variables influencing the operating costs are identified and presented. Based on the results of the developed statistical models, categorised cost indicators for the estimation of operating costs are introduced. All statistical methods are evaluated for their performance and quality employing an independent and randomly selected test sample.

The results show the best estimation accuracy for the nonlinear regression model and the artificial neural network model. The minor differences of the measures of performance and quality for both models utilising the same predictor variables indicate correctly specified models. The procedures of model development and the evaluation of the results are presented in detail and may serve as a basis for further research on the estimation of operating costs and the identification of significant predictor variables.

Future research may improve its results considering the limitations of the current study. Due to a limited number of observations of some types of facilities, the accuracy of the presented statistical methods could be improved by extension of the data sample. Moreover, future approaches may consider further types of facilities for the development of cost estimation methods (e.g. health service facilities, industrial facilities, laboratories). The data sample employed in the current study includes solely properties owned and operated by public-sector institutions. For the identification of the influence of strategies on operating costs (e.g. energy contracting, outsourcing, public-private partnership, maintenance strategies), further research may include data from properties owned and operated by private institutions.

Though operating costs represent a substantial amount of the life-cycle costs of facilities, further approaches may extend their focus on cost types such as the maintenance and the repair of facilities. Likewise, the implementation of additional statistical methods for the estimation of costs may be considered and evaluated (e.g. decision tree analysis). Ultimate objective should be the development of standardised cost models and applicable tools for the holistic estimation of life-cycle costs of facilities including planning, construction, operation, maintenance, repair, and reuse or demolition.

Abstract

This paper presents two case studies about developing budget reference systems. One of them was created to support contractors decisions related to construction costs in a private company. The other one is an ongoing job where "Caixa Econômica Federal", the main public institution dealing with financial support to construction in Brazil, intends to improve its skills to estimate construction costs. In order to improve managers demands, this paper shows how to develop a reference system, based on data site collection and analysis. This empirical procedure gives more confidence to the proposed figures.

Keywords: Budget, productivity, construction costs

1. Introduction

Construction cost estimation is always an important theme to be discussed. Contractors and public and private developers often debate about the correct value to be adressed to a specific project (BAKHSHI; TOURAN, 2014; LAI et al, 2008; OZTAS; OKMEN, 2003; SHEHU et al, 2014; WILMOT; CHENG, 2003). Cost understanding allows several managers decisions: from the project´s viability to the cost control during the building production (JIBOURI, 2003). But it is very accepted that construction costs may vary in a large range accordingly to several features of the project being produced (CHENG, 2014; MAHAMID, 2013; POLAT et al, 2014; WILLIAMS; GONG, 2014).

In order to help decisions based on cost understanding, estimates reference systems are available to support cost estimation. Private and public companies dealing with construction base their cost estimation on a process that uses Cost Data Books. In this context it is important these books contain widespread and reliable information.

In Brazil exists a public database of cost construction which is a reference to finance several kinds of building construction by the Brazilian Government. It's called National System of Costs Survey and Indexes of Construction (SINAPI), which is indicated in the Brazilian Law. The system is maintained by the Brazilian government's financing agent Caixa Econômica Federal. The SINAPI is being updating by a pool of universities in order to represent the different used construction all over the country, as well to comprehend new technologies not contemplated in the previous versions.

Based on author´s previous research experiences, this paper presents both guidelines for the development and some parts of two cost estimation systems developed by them recently for a private and a public companies.

2. Cost construction reference system

Cost estimation can be discussed under several points of view including: monetary versus physical resources approach; global versus partial costs; type of project; contents and context of a project; developer versus contractor; etc.

Based on the literature, the authors see the process of estimating the building construction cost, in terms of direct costs [1],as composed by the following steps (Figure 1): 1) the breakdown of the final product into smaller parts; 2) the quantity estimation of each part (surveying); 3) the

---

[1] DIRECT COSTS – *"Costs of completing work that are directly attributable to its performance and are necessary for its completion. 1) In construction, the cost of installed equipment, material, labor and supervision directly or immediately involved in the physical construction of the permanent facility. 2) In manufacturing, service, and other non-construction industries: the portion of operating costs that is readily assignable to a specific product or process area"*. (AACE; 2015)

forecast of the effort (in terms of the items labor, material and equipment) associated to one unit for each part of the product; 4) the evaluation of unit costs for each item; 5) defining global cost.

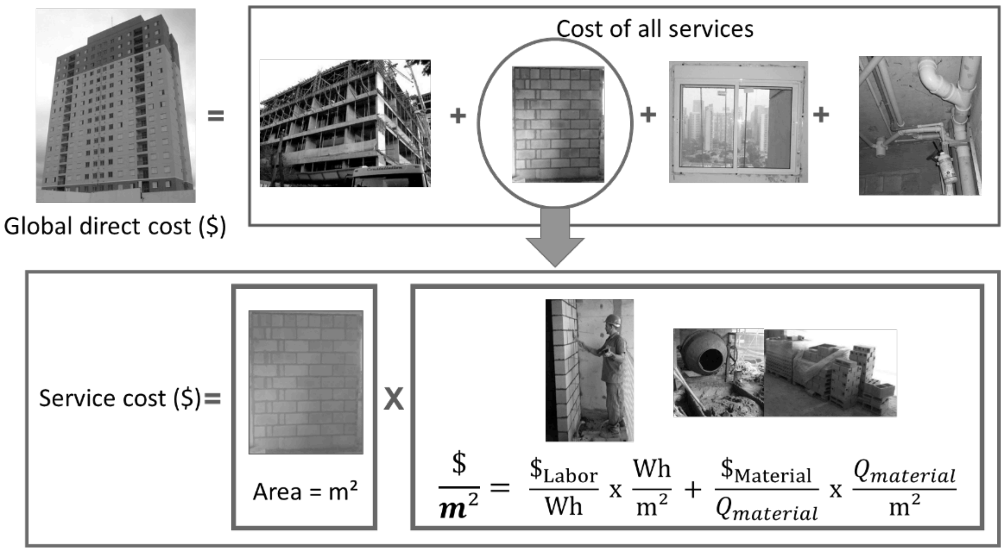

Figure 1: – Estimating building construction cost (Wh = workhours, Q material = quantify of materials)

2.1 Product breaking down

Several approaches are presented in the literature to help divide the whole product into smaller parts (ISO TR 14177:1994; ISO/ DIS 12006-2, 1998; RS Means, 2008; Cho et all , 2013). This paper considers the approach suggested by Marchiori (2009) as the direction to be followed. Breakdown (Figures 2 and 3) is based both on the division for the product but also in terms of the process to be adopted.

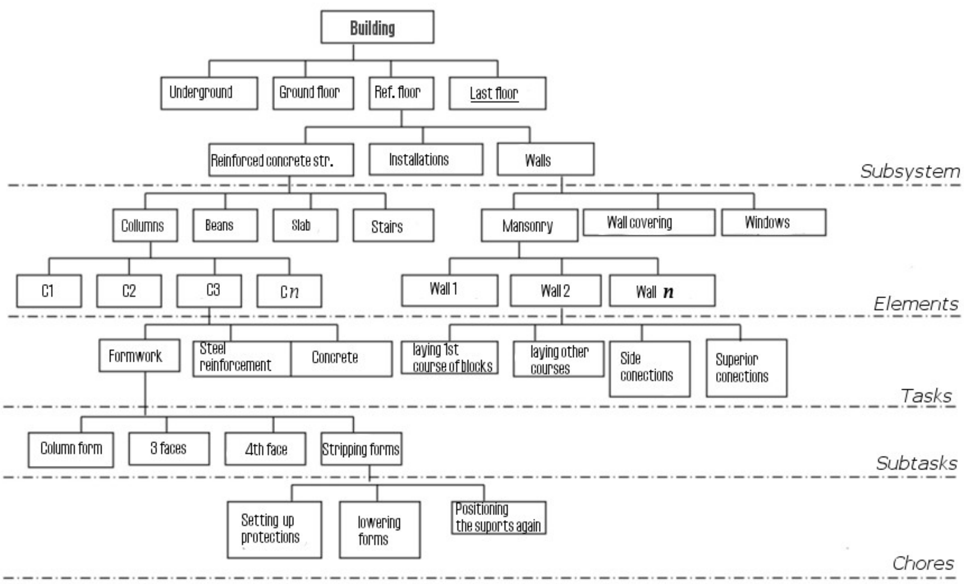

Figure 2: Division of the product (Marchiori, 2009)

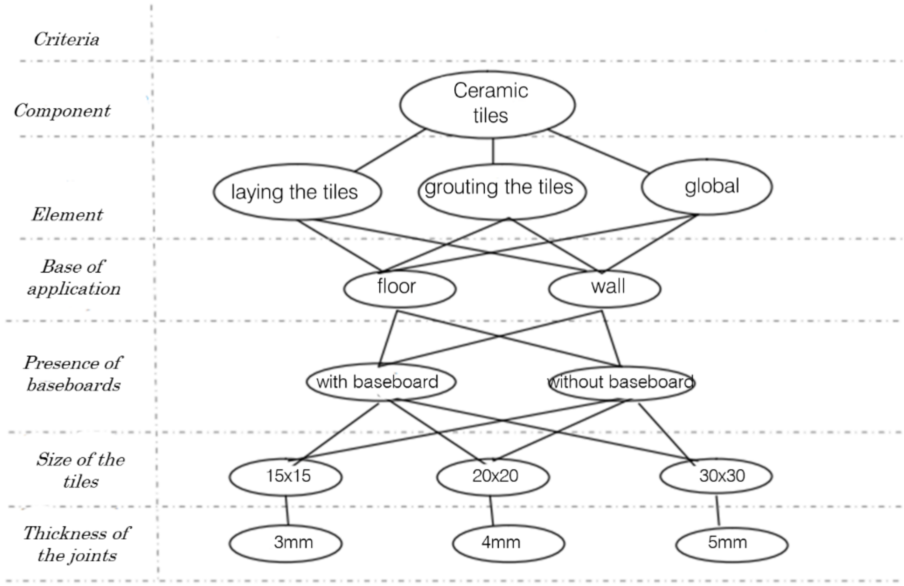

Figure 3: Division in terms of the process (Marchiori, 2009)

The structure proposed by Marchiori (2009) represents better the found conditions in the building sites than the previous structure of information in the Brazilian construction cost databases, once it contemplates what is being done, by who and where, allowing to use of this structure for the integration of information systems, for example to control costs and time in the level of detail that anyyou wants to analyze. This structure was used in both case studies.

2.2 Surveying

Once the "parts" are defined, one have to measure each part extension. Two different approaches are normally found in the literature: measuring the effective extension (BANSAL; PAL, 2007; JADID; IDREES, 2007; SHEN, ISSA 2010) versus take into consideration specificities of the product to define "equivalent" amounts to be produced. See Figure 4 as an example of the two alternatives.

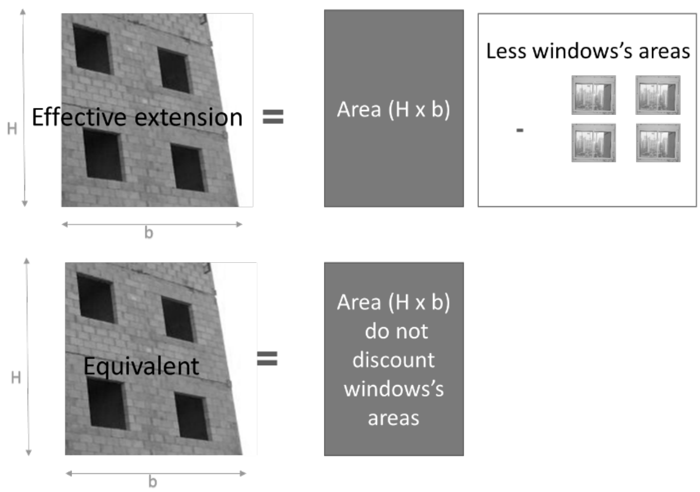

Figure 4: Measuring blockwork.

The authors consider the effective amount of a job has to be considered in order to avoid mistakes in defining what is quantity and relative difficulty.

2.3 Unit Efforts

Different approaches can be used to express the needed "efforts" to produce an amount of certain product. For example, RSMeans define a team with equipments and indicates the job quantity this team makes in one hour (see Figure 5 as an example of RSMeans approach).

22 11 Facility Water Distribution
22 11 13.74 - Facility Water Distribution Piping

22 11 13.75 Pipe, Plastic

		Crew	Daily Outputs	Labor-Hours	Unit
1930	3" diameter	Q1	53	0,302	L.F.

Crew Q-1
1 Plumber
1 Plumber Apprentice

Figure 5: Unit demands accordingly to RSMeans (2008)

The authors consider the most appropriate way to define effort associated to a product production is expressing the amount of each resource demanded to produce 1 unit of the addressed product. Figure 6 show an example accordingly to TCPO.

Plumbing installations
Plumbing - PVC pipe

13.007.000096.SER PVC pipe for adhesive jointing ø 75 mm - unit

Code	Components	Unit	Average Consumption
01.001.000005.MOD	Plumber Apprentice	h	0,406
01.001.000001.MOD	Plumber	h	0,406
14.001.000471.MAT	Cleaning solution for PVC	l	0,001
14.001.000511.MAT	Brown PVC pipe for adhesive jointing (75 mm diameter)	m	1,05
14.001.000564.MAT	jointing adhesive for PVC	kg	0,002

Figure 6: Unit demands accordingly to TCPO (2014)

Unit efforts can be seen as the efficiency in processing the resources. As far as the demanded resources are labor, materials and equipment, the estimator has to deal respectively with labor productivity, material consumption and equipment efficiency.

This paper considers efficiency rates should be defined based on the Factor Model approach (see Thomas et al (1990) for additional information). Figure 7 shows the indicator to be used in a budget is calculated adding a potential unit rate (pUR) to a value considering the usual lack of efficiency (dUR). Both pUR and dUR can be defined based on the statistical analysis of a real database collected in projects of the company defining its budget reference system.

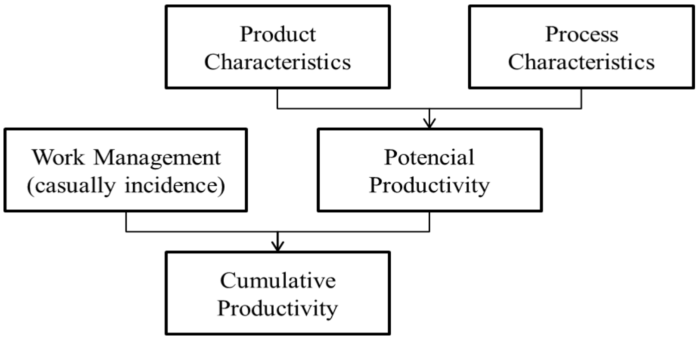

Figure 7: Factor Model as basis to define efficiency unit rates (SOUZA et al, 2014)

2.4 Unit Costs Definition

Each resource has to be evaluated in terms of its cost. The process of evaluating unit costs can also follow several directions. It can be based on price lists, available in specialized magazines, or it can result from a unit cost search.

Both in contractors and in developers many times one can find a department responsible by collecting local prices to support local projects cost estimation. It is also usual to consider the minimum value coming from the search to be adopted to compose the budget.

Once the reference system has to be used in a larger area (for example a country), unit prices can vary accordingly to regional features. In this case, search have to take into account this variability; the subareas to be represented can be larger or smaller as a function of the reliability to be given to the reference system.

2.5 Global Cost

Once the product is divided into parts, each part is measured, unit resources demand is adopted and unit prices are considered, global direct cost is easily determined (accordingly to Figure 1 previously described).

3. Proposed Budget Reference Systems

This item describes some parts of two budget reference systems the authors have the opportunity to help improve. One of it belongs to a private multi story building developer; and the other is still being improved for the largest public funding company in Brazil.

3.1 Case Studies

3.1.1 Private multi story building developer (company A)

Company A is a large Brazilian construction company that works both with developing and producing its projects. Built area in 2015 was more than 16 million m². The goal was to improve building structures cost estimation for multi story buildings in the São Paulo city area.

3.1.2 Public funding (company B)

Financial institution that is the largest public bank in Latin America. This institution operates the application of funds from the Brazilian Federal Budget and operates in the financing of public and private works, mainly focused on basic sanitation, infrastructure and housing (OLIVEIRA et al, 2015).

This bank is also the sponsor of SINAPI – National System of Costs Survey and Indexes of Construction. According to the decree 7.983/2013, directs costs of a public construction must be based on the service compositions of an official system, as the SINAPI (OLIVEIRA et al, 2015).

This System, created in 1969, is the main source of free public construction costs in the country. Every month, the SINAPI web publishes costs references for housing, infrastructure and sanitation works carried out in an urban environment for the Brazil's 27 state capitals (OLIVEIRA et al, 2015).

The goal is to improve the existing budget reference system, dealing with more than 5.000 resources unit rates table providing support to better define unit costs.

3.2 Adopted Aproach

In both cases the goal was to define unit rates for each resource demanded for a certain construction part. In order to get to these indicators, real values were collect in the field.

For company A, the number of case studies for each part was the case studies available at that moment. Due to the high number of ongoing contracts, the sample was ever bigger than B. For company B it was defined a minimum sample sample of 10 contruction sites for any study.

Based on the collected data, the authors processed and analysed than in order to define the unit rate values. For company A, the results were expressed as a range of values associated to the reasons for better or worse performances. For company B, an unique value is associated to specific job description due to the public use of the figures. Figure 8 shows the main steps in developing the reference systems.

Figure 8: Main steps in developing the reference systems

One usual question is about how to take into account the job quality. It is important to state that data collection is related just to the production in accordance to the public and private standards.

3.3 Results

Here some relevant points are present, and not the complete performed job.

3.3.1 Company A

Concrete reinforced structure is one of the most important systems composing the multistory buildings of company A. Then, it was important to improve cost estimation for it. Once the structure conception vary significantly from one building to another, one of the most strong innovation in this reference system was to use the concept of variable productivity.

Figure 9 shows the process to define labor unit rate for column formwork. One can see the labor productivity can vary 90% from the easiest to the hardest conditions to produce one square meter of formwork.

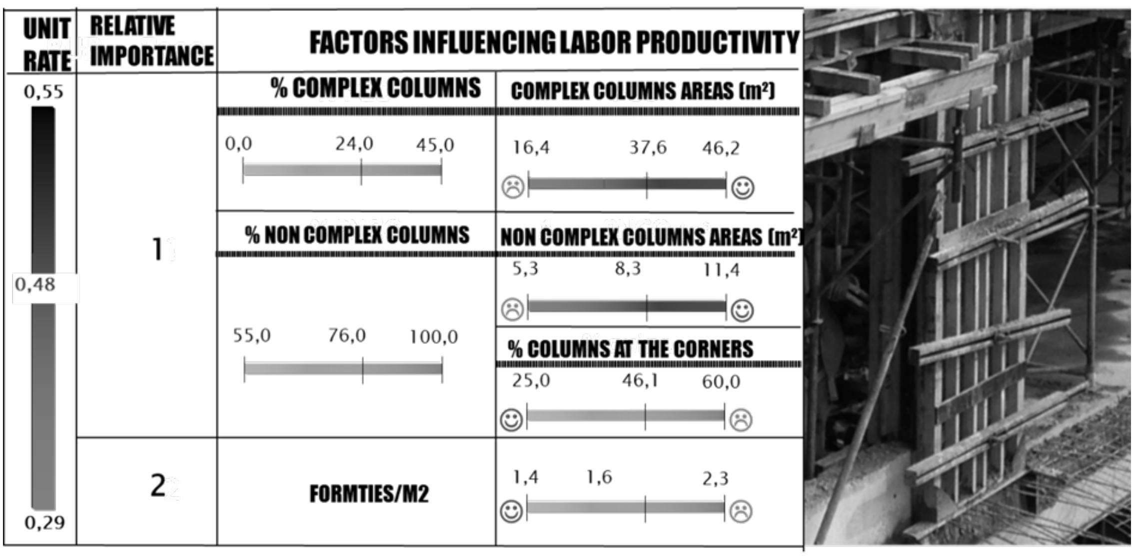

Figure 9: Results of Company A: Labor unit rate for column formwork

3.3.2 Company B

This still ongoing research job is being produced by a team with about 60 people and includes site data collection in 11 cities representing 3 areas of Brazil (see Figure 10)

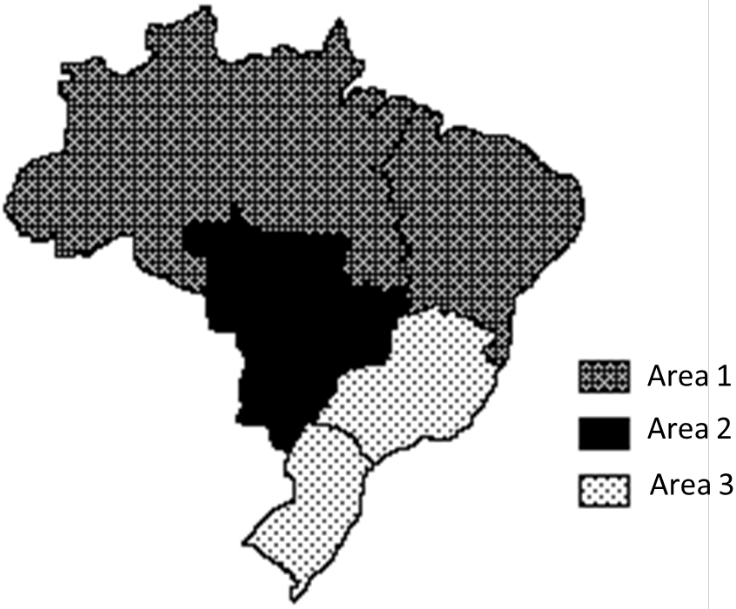

Figure 10: Represented areas in Brazil

Figure 11 shows an example of adopted “product breakdown” for one part of the building (screed). Notice that instead of having just one resources unit rates table for the job, figure 11 shows an extense bunch of alternatives to represent it.

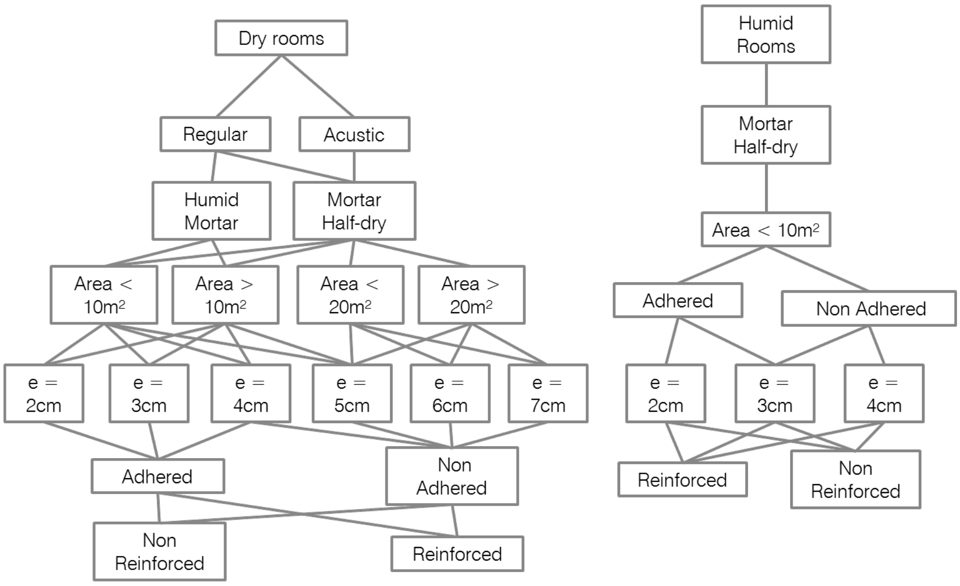

Figure 11: Breakdown of screed

Table 1 summarizes resources unit rates table defined to represent the same job. Here, instead of defining ranges of variation for each resource, a group of resources unit rates table tries to represent all the different features one can face to perform the job. Notice the labor unit rates described varies 200%; and the materials unit consumption includes losses that vary from 0,031m³/m² to 0,076 m³/m².

Table 1: Breakdown of screed

nº	Local	Area	Type	Adhered	thickness (cm)	Reinforced	laborers (h/m²)	Helpers (h/m²)	Mortar (m³/m²)

4. Conclusions

The authors have a large experience in dealing with efficiency in construction and also are often questioned about misunderstandings about construction costs. They believe construction efficiency can widely vary but the variation can be in a large part understood. Cost reference systems can be a very strong tool to discuss costs once they are carefully composed and represent nowadays technology and efficiency. In both presented cases, the users of the improved reference systems describe they can not only improve the figures resulting from its use but they can more easily discuss cost with other agents dealing with construction projects.

In both cases the produced reference system became an important tool to take decisions. Company A use it to discuss new buildings from the conception stage to the site decisions. And Company B is using its reference system to base all decision regarding to funding Brazilian construction.

An Energy Expedition

Experiences of a Dutch collective of house owners aiming for energy neutrality

Mieke Oostra,
Hanze University of Applied Sciences & Saxion University of Applied Sciences

Abstract

The municipality of Apeldoorn had polled the interest among its private home-owners to turn their homes energy neutral. Based on the enthusiastic response, Apeldoorn saw the launch of the Energy Apeldoorn (#ENEXAP) in 2011. Its goal was to convert to it technically and financially possible for privately owned homes to be refurbished and to energy neutral, taking the residential needs and wishes from occupants as the starting point. The project was called an Expedition, because although the goal was clear, the road to get there wasn't. The Expedition team comprised businesses, civil-society organisations, the local university of applied sciences, the municipality of Apeldoorn, and of course, residents in a central role. The project was supported by Platform31, as part of the Dutch government's Energy Leap programme. The #ENEXAP involved 38 homes, spread out through Apeldoorn and surrounding villages. Even though the houses were very diverse, the group of residents was quite similar: mostly middle-aged, affluent people who highly value the environment and sustainability. An important aspect of the project was the independent and active role residents played. In collaboration with businesses and professionals, through meetings, excursions, workshops and by filling in a step-by-step plan on the website, the residents gathered information about their personal situation, the energy performance of their home and the possibilities available for them to save and generate energy themselves. Businesses were encouraged to develop an integrated approach for home-owners, and consortia were set up by businesses to develop the strategy, products and services needed to meet this demand. On top of making minimal twenty from the thirty-eight houses in the project energy neutral, the ultimate goal was to boost the local demand for energy-neutral refurbishment and encourage an appropriate supply of services, opening up the (local) market for energy neutral refurbishment. This paper will reflect on the outcomes of this collective in the period 2011-2015.

Keywords: Energiesprong, #ENEXAP, LALOG, energy efficiency, local energy initiative, co-design

1. Introduction

As a result of the ongoing trend of individualisation, people are eager to actively influence and shape their own environment (Oostra, 2013). This paper will describe a case study in which owner-occupants did just that, no longer waiting until professionals were ready to deliver the kind of services and offers they wanted. The case study described in this paper was a recent Dutch project, part of Energy Leap (Energiesprong), an innovation programme commissioned by the Dutch Ministry of the Interior and operated by Platform31. The programme ran until the end of 2014, although parts were later extended to the end of 2015. The aim was to make various types of buildings energy-neutral and to boost large-scale initiatives. In the sub-programme LALOG (Lokaal Alle Lichten Op Groen) the owner-occupants themselves were looking for ways to challenge professionals to make their homes energy-neutral. The LALOG sub-programme provided support to groups of owner-occupants in six municipalities: Apeldoorn, Wageningen, Den Bosch, Hoorn, Amsterdam and Amersfoort. Goal was to convert at least 20 homes in each of these municipalities to energy neutral. It was a process of learning by doing by residents, builders, municipal officers, installation contractors, appraisers and other professionals. In this paper we will focus on the experiences of the Energy Expedition in Apeldoorn, also known as #ENEXAP.

2. Theoretical framework

There are basically two main bodies of knowledge relevant as theoretical framework. One is the literature on innovation management in which innovation is seen as a combined technological and economical phenomenon looking at companies (e.g. Von Hippel 1986, Chesbrough, 2006), entire supply chains (e.g. Vrijhoef, 2011) or the industry as a whole (e.g. Lundvall, 2008). Most relevant in the context of the case study are the theories focussed at upscaling from an innovative technological niche towards uptaking in the current regime (Strategic Niche Management (SNM)). The other body of knowledge relevant for this paper is the world of grassroots innovations and community action directed at fundamentally rethinking all aspects of our current society in order to build an intrinsic sustainable way of living. These two knowledge domains not only represent two different scientific communities, they represent fundamentally different groups of people with distinct discourses and practices in real life as well.

2.1 Innovation management

For innovation at the level of (a part of) an industry, the term transition is generally used. The perspective of social-technical transitions has emerged from evolutionary economics (Nelson & Winter, 1977; Dosi, 1982). From studies of former mayor changes in society e.g. the transition from horse carriage to rail and steam trains, from cottage industry to mass fabrication, insights have emerged regarding the importance of experimentation, multi stakeholder learning, coevolution of technologies, new ways of organisation, rules & regulations and financial systems. This resulted in theories of Strategic Niche Management and Multi Level Perspective (Geels & Kemp, 2007; Loorbach & Rotmans, 2006), which can be used to analyse current innovations. The rationale in these theories is that innovations start in specific niches, but their further development is highly dependent on other changes in the different societal levels (micro, meso and macro). SNM describes emerging innovative niches becoming mainstream in combined dynamic social and technological systems.

The innovation management perspective focuses on the formation of niches in which innovations can flourish. In this perspective, residents would learn to use their purchasing power to get the innovations they want, in order to be able to improve the energy performance of their homes towards energy neutral. According to Strategic Niche Management, three additional processes are important when developing a successful technological niche (Kemp et al., 1998):

- The articulation of expectations and visions that would provide direction to the learning process of parties involved. The expression of visions and expectations would also help to attract attention from the necessary stakeholders and legitimate their involvement and support.
- Construction of social networks. Interaction between different stakeholders is needed to collect the required resources (time, expertise and money) and commitment.
- Learning on multiple aspects: (1) Technical aspects and design specifications, (2) Market and user preferences, (3) Cultural and symbolic meaning, (4) Infrastructure and maintenance networks, (5) Industry and production networks, (6) Regulations and government policy and (7) Societal and environmental effects.

2.2 Grassroots innovations & community action

Until recently, the attention for innovation from the voluntary sector and local communities was not really taken into consideration despite decades of initiatives at local level. As a result, little is known about the success factors and the way these grassroots innovations take place. The innovation in these bottom-up initiatives consists mainly of social innovation. Seyfang and Smith (2007) define grassroots innovation as follows:

> *"Grassroots innovations are networks of activists and organisations generating novel bottom-up solutions for sustainable development and sustainable consumption: solutions that respond to the local situation and the interests and values of the communities involved." (Seyfang & Smith, 2007, p.585)*

Local initiatives usually construct alternative systems in which production, distribution, marketing, retail and consumption are connected in a novel way. Since the publication of the Limits to Growth report (Meadows et al., 1972) environmental movements emerged that experimented with different ways to minimize their ecological footprint. Inspired by Schumacher's 'Small is Beautiful' (1973) pioneers also addressed housing with appropriate technology, i.e. adopting a scale and complexity of technology appropriate to its setting. Seyfang and others translated the conclusions of their academic work in ten important statements directed at policymakers in relation to local energy initiatives, aiming to support innovation from these local initiatives. Community Energy is (grassrootsinnovations.org):

1. Critically important for sustainable (energy) transitions (Hielscher et al., 2013)
2. A diverse, growing, grassroots-led movement (Seyfang et al., 2013b)
3. About more than just sustainable energy (Hargreaves, 2012)
4. Thrives on local enthusiasm, but can't rely on goodwill alone (Hielscher, 2013)
5. As much about soft skills as well as hard technology (Seyfang et al., 2013)
6. Not yet being taken seriously enough by government (Seyfang et al., 2013)
7. Connected to community and sustainability networks (Seyfang et al., 2013)
8. Benefits from strong support networks and organisations (Hargreaves et al., 2013)
9. Reaches parts of society the private sector alone cannot reach (Martiskainen et al., 2013)
10. Demands flexible and tailored policy support at all levels (Hargreaves et al., 2013)

2.3 Integrated framework for analysis

The two frameworks of innovation management and grassroots community action were integrated into one integrated framework to analyse #ENEXAP:

- Articulation of expectations and visions
- Construction of social networks: (1) Diversity of actors, institutional forms and activities (2) Social capital (networks of support), human capital (skills), organisational capital (know how), financial capital (3) Contacts on local, regional and national levels an (4) Sector support infrastructure
- Learning on multiple aspects: (1) Technical aspects and design specifications (2) Market and user preferences (3) Has different meaning to the people involved (4) Infrastructure and maintenance networks (5) Industry and production networks (6) Regulations and government policy, and (7) Learning by doing, face-to-face support and mentoring.

3. Purpose & methodology

This paper will reflect on the outcomes of the collective in Apeldoorn. The subsidized #ENEXAP project ran in the period 2012 - December 2014. The period that is described in the paper is October 2013 until June 2015. The description of #ENEXAP case is based on the authors' experience as part of the initiative. Oostra was member of the #ENEXAP board from November 2013 until April 2015, Been was secretary and resident advisor for #ENEXAP from March 2013 until June 2015. The material on which the analysis is based derives from action research, board meetings, occupant meetings, meetings with Energy Leap, study meetings for the companies and conversations with people related to #ENEXAP. First a general description of the case study will be made. The next sections will be dedicated to the description of the results and the analysis of the results before ending with the summary.

4. Case description of Energy Expedition Apeldoorn

In 2011, Apeldoorn saw the launch of the Energy Expedition Apeldoorn (#ENEXAP). The municipality of Apeldoorn was curious to find out how many of its residents were interested in making their homes energy neutral, and placed an announcement in the local newspaper, 'Stadsblad'. A large group of owner-occupants came to the meeting. This resulted in a group of 33 households that started as part of the Expedition in May 2011, growing to 38 households during the process. The Expedition was supported with a LALOG subsidy from 2012 until December 2014. LALOG's direct goal was to refurbish a minimum of 20 homes making them energy neutral, taking as starting point the input from occupants. The overall ambition was to make it technically and financially feasible for owner-occupants to retrofit their home, starting with this small group and from there on boosting the local demand for energy-neutral refurbishment and encourage an appropriate supply of services. The #ENEXAP team comprised of local residents, businesses, civil-society organizations, the municipality of Apeldoorn and the local University of Applied Sciences, Saxion. These different groups al played a constructive role in carrying out the Expedition. Owners fuelled professionals with their ideas and wishes; professionals helped owners to make their wishes achievable. In the next paragraphs, the roles of the key players in the Expedition are described.

Table 1: Roles of the different stakeholders in #ENEXAP

Stakeholder	Role
Owner-occupants	*(1) The occupant-owners played an active and vital role in shaping the process. The board of #ENEXAP consisted merely of residents. After the founding of the Expedition, residents formed working groups, which were started to address different relevant issues. (2) Residents actively monitored the energy consumption in their own homes. They put a lot of effort in making their residential wishes explicit. They were guided in this by a course and a specially developed step-by-step plan. (3) Residents were actively involved in the development of solutions by professionals.*
Advisers	*(1) Several professionals brought in their knowledge on sustainability by presenting on one of the meetings for occupants or by giving a tour. Because of the innovative character of the initiative they were often willing to do so for free. (2) Additionally professional support was hired for organisational issues, but also for communication strategy and the development of a magazine. Professional support was also hired for executing three EPA Super Luxurious analyses, matching financial advice and support for the Board.*
University of Applied Sciences	*The university was asked to develop and organize two courses to the residents as well as the consortia. The first course was intended to help the occupants to articulate their requirements, how to formulate these to professionals and how to weigh different solutions e.g. financially with the principles of Total Cost of Ownership. During the course for professionals the focus was on how to deliver an integrated offer to this specific group of clients. A second course for professionals was directed at how to make an energy fingerprint of a dwelling, how to respond to a wide range of demands from clients by using principles of mass-customization and what is involved in providing a warranty on energy performance after a retrofit. The university was also part of the Board.*
Companies & consortia	*At first large contractors were linked to #ENEXAP. They dropped out because their primary interest in larger building assignments, e.g. block by block retrofitting of terraced houses with a high level of standardization. In the Expedition however, the houses are of varying types, spread around Apeldoorn. The companies that remained linked were local SME's. They made integral plans for energy neutral refurbishments, which was highly challenging for them, because of a lack of knowledge necessary for these assignments. #ENEXAP handed the SME's knowledge through courses and contact with a group of interested clients.*
Energy coaches	*The energy director helped residents to make a choice for the consortium that fitted their requirements best and helped owner-occupants in requesting quotes and the evaluations of these bids. The energy director was meant to be the intermediary between owner-occupant and companies. An auditor was appointed as supervisor to offer extra safety for the participants, by providing an extra check on the plans. In practice the roles of energy director and auditor were combined. For the residents group coached by a specific energy director the other functioned as auditor, and vice versa. Instead of 'energy director' and 'auditor' the name of 'energy coach' was therefore more appropriate.*
Municipality	*(1) The municipality proved to be an important party since they took the initiative for the start of the*

	Expedition. They decided to make an inventory of residents interested in energy neutrality. (2) They were also the party that applied for a LALOG grant (€ 285.000) that was combined with money from SLOK (€ 33.265) and money from the municipality's budget (€ 6.000). Also money from the EU project ACE was available for product development and feasibility studies (€ 84.500) (Apeldoorn, 2012). (3) The municipality was part of the Board of #ENEXAP and (4) formed the link to the national energy programme.
Energy Leap	*(1) Energy Leap organised several meetings to exchange information between the stakeholders in the municipalities involved in the LALOG programme. (2) Energy Leap also made links to other parts or parties in the Energy Leap programme that were of interest for #ENEXAP. For example the expertise was shared, that was being developed around the topic of energy performance guarantees (e.g. the standard contract) in Rapids, another sub-programme directed at dwellings. (3) Experts were invited to give presentations at either one of the occupants meetings, as part of the course made available to the local SME's or for special sessions. #ENEXAP was asked by Energy Leap to host one of the field trips for appraisers. In this field trip appraisers from around the country were asked to make an estimate of the dwelling before and after the retrofit in order to establish how an improvement in energy performance would translate in additional financial value of the dwelling.*

5. Results

The overall result of the Apeldoorn Energy Expedition was that in June 2015, after being roughly four years en route, five houses were well on their way towards becoming energy neutral. Three consortia of local SME's were formed, and residents had started to save considerably on energy.

Table 3: Goals of the LALOG program vs. results of #ENEXAP

Goals of LALOG	**Results of #ENEXAP**	**Remarks**
To put owner-occupants central in the development program	*Owner-occupants were in the lead.*	*This worked very well for focussing on the topics relevant for owner-occupants. It proved to be a hindrance for the continuation of the program after the end of the LALOG subsidy.*
De-burden occupant-owners in their search of energy neutrality	*The formation of a new consortium of companies focussed at the retrofitting of owner-occupant housing, training of 3 local consortia and the development of an approach that would fit both clients and entrepreneurs.*	*Proved to be difficult since the innovation leap required was very steep for the companies involved. These companies operated in a context were business and investment money was scarce. For them it proved to be very difficult to commit to the required product and process innovations.*
20 dwellings energy neutral	*June 2015 5 #ENEXAP houses were energy neutral or were in the process of becoming energy neutral.*	*It was not easy to reach this goal. There was only one other LALOG municipality that succeeded in realizing 5 energy neutral dwellings (Energiesprong, 2014).*
Secondary – To integrate higher comfort level, healthier indoor climate and an increase of functionality with a considerable reduction of the energy bill	*A combination with other requirements of the clients proved to be key during the program. Important additional requirements were: additional space, conversion of bathroom and/or kitchen and future proofing of the home.*	*It turned out, that the secondary goals of the LALOG program were essential to the occupant-owners. In case the consortia tried to eliminate an important secondary requirement of the client, the process came to a halt.*
Secondary - Promote the use of environmentally friendly products	*Attention was given to environmentally friendly products in presentations given at occupants meetings, in excursions and it was the expertise of one of the energy directors in #ENEXAP.*	*This was regarded as a matter of taste within #ENEXAP. To some of the occupant-owners this proved to be important, mainly because environmentally friendly products are associated with a healthy indoor environment.*
Secondary - Increase of the value of the dwelling	*This topic was not so much addressed in the sessions between occupants and companies since they themselves were not able to answer questions on this topic. Neither was the local broker.*	*This knowledge had to be developed. Energy Leap understood the importance of this question and organised two field trips of appraisers. One was hosted by #ENEXAP.*
To draw a business case for the companies to allow for continuation of energy neutral retrofitting after the duration of	*The following was developed in order to smoothen energy neutral retrofitting:* • *Step-by-step plan for the occupant-owners as a*	*The companies were focussed on making money from the start, as this is the way they are used to do business. They were not accustomed to heavily invest in the*

#ENEXAP	*means to aggregate all the information necessary about their homes and current energy consumption.* • *A financial check and a website to structure and exchange of all the information gathered.* • *Courses to help occupants to make their requirements explicit and for companies to be able to develop an integrated approach and matching offers.* • *A one-stop-shopping approach towards clients, which includes scrum-sessions at the kitchen table with all disciplines present to draw up quickly a tailor-made solution.* • *A coaching approach to support companies during their first assignments with clients.*	*development of a new (industrialised) market approach, while #ENEXAP was trying to focus on opening a bigger market on the long term for which new retrofitting concepts and approaches needed to be developed. For Energy Leap the experiences from the LALOG programme were a reason to design new subsidy programmes: Rapids Rental and Rapids Purchase.*

6. Analysis & discussion

In this paragraph we analyse the case study by confronting process and results with the integrated framework introduced in paragraph 2.3.

ARTICULATION OF EXPECTATIONS & VISIONS

The structure of the experiment was designed to support residents: the course, the interactions during kitchen table conversations, but also the discussions that emerged around presentations and excursions all helped to articulate expectations and visions. This stimulated the owners to aim high and ask for innovative solutions, be fitting their situation and demands, thereby stretching the abilities of the consortia. So the group of owners demanded innovation, but on the other hand they requested warranties on energy performance. This combination was hard on the consortia to achieve, however, the group would not let go of this high ambition.

CONSTRUCTION OF SOCIAL NETWORKS

Diversity of actors, institutional forms and activities - In a period of three years, different groups of residents, professionals and intermediaries were brought together to work on the goals set: zero energy houses and fulfilled residents wishes, while at the same time paving the road for a widespread of retrofitting in the nearby future. This required bridging the gap between residents and professionals, which both speak a different language because of different knowledge levels, perspectives and goals. During the course of several meetings, workshops and excursions residents and professionals acquired knowledge, both technical and about the perspective of the other group, and learned how to fill in their role. In the mean time, several products were developed, from which the most important one is the step-by-step plan. In working groups, residents and professionals with different expertise worked together on specific themes. There were several working groups for technical issues, EPA Super Luxurious, finances and communication. The communication group made a website to monitor progress and to serve as a discussion platform. Courses were held to support both residents and professionals in finding their way. Outcomes were that residents could better articulate their wishes and needs, a new consortium was formed and approaches were developed for the professionals to be able to make multi-disciplinary offers.

Social capital (networks of support), human capital (skills), organisational capital (know how), financial capital - There was a network of similar initiatives like #ENEXAP with initiatives in Amsterdam, Amersfoort, Wageningen, Den Bosch and Hoorn, that met once in a while. Also there were discussions with the Energy Leap programme. This provided a network to exchange ideas and inspiration. It also helped to see that others were also struggling to meet the goals set at the beginning by the Energy Leap programme. Because of the diversity of actors involved, people willing to give lectures and advise, and money from the programme to hire missing expertise, knowledge and skills needed in development were available.

Learning by doing, face-to-face support and mentoring - The goal was clear but the road to get there wasn't. This fostered learning by doing. The pilot EPA Super Luxurious e.g. turned out not to work as it was intended. The contractors did not directly translate the reports written by energy advisors into matching offers. Instead these companies either presented alternatives to the solutions proposed, or just started the work all over again. Because of the community feeling, people remained focused on the goals, although it was sometimes hard to find the right course. The social network helped to keep the parties involved on track when confronted with setbacks. The local setting, the organized activities and the energy coaches made regular face-to-face support available for both residents and companies. The energy coaches were mentoring both residents and companies on how to formulate interesting offers.

Contacts on local, regional and national level - Local contacts were organised within the Expedition and by reaching out to the expertise required. Energy Leap, the municipality, Saxion and professionals involved provided contacts on regional and national level when necessary.

Sector support infrastructure – Additionally, the municipality made hours available from a civil servant. And of course there were as well hours available from the different (professional) volunteers. This made it possible to erect an infrastructure to support interested owner-occupants in converting their own dwellings to energy neutral as well as to support local companies interested in exploring this new emerging market. Most of this supporting infrastructure is already described above.

LEARNING AT MULTIPLE ASPECTS

Technical aspects and design specifications - Technical aspects received a lot of attention in presentations at meetings, excursions and kitchen table conservations between consortia and owner-occupants. The kitchen table conversations and the first course helped in making the requirements from the occupants explicit. This formed the basis for the design specifications.

The Plugwise system was used to measure the consumption of electricity. It helped to create awareness on energy consumption necessary to operate different appliances in the home. For most people it was a complete surprise to see what the usage of a specific appliance meant, e.g. the electric boiler in the kitchen, the tap with boiling water or the electrical floor heating. This insight was essential to take further steps, e.g. changing equipment or just switching devices off.

Market and user preferences - The experiment can be seen as a way of developing a new market. #ENEXAP was an experiment, a pioneer project. The market was, and still is, learning how to accommodate clients' wishes and requirements when retrofitting individual occupant-owned houses to energy neutral in an integral way. At the same time, user preferences within this project proved to be very specific, being influenced by specific housing types and lifestyles. Therefore, every solution had to be tailor-made. For the companies involved it proved to be very challenging to develop matching supply for energy neutrality in combination with the other requirements. In board meetings it was also discussed that the consortia should integrate the wish of several occupants to think about combinations of professional work and DIY. The majority of the board saw this as a risk to overburden the consortia and the idea was therefore put aside.

The initiative has a different meaning to the people involved - The Expedition was about being adventurous: developing unexpected roads together, while enhancing sustainability. Owner-occupants had various reasons to take part in #ENEXAP. During the experiment it became clear that the idea of a sustainable, environmental friendly home with a small ecological footprint was an important driving factor, but not for all. There were also people part of the programme that were technologically interested, or focussed at reducing operational costs of living. This underlines outcomes of other research about the profile of people interested in energy neutrality (e.g. Hensen & Westerhof, 2013). For a part of the group it became a sort of hobby: improving their house, replacing e.g. lighting and refrigerator or just switching off a close-in boiler or waterbed, and sharing experiences with co-participants. The financial investment made by occupant-owners didn't need to be earned back completely by lower monthly energy costs; also the feeling of being part of this new, sustainable movement and acquiring more comfort or other functionalities were rewarding for the people involved.

Infrastructure and maintenance networks – During the training attention was given to maintenance and performance guarantees. This appeared to be very challenging for the consortia. External expertise from the Energy Leap programme was made available. In the end this did not lead to concrete offerings including maintenance and performance guaranties.

Industry and production networks - The technical innovation expected from the Expedition did not materialize. The local SME's were not equipped to create specific innovative products or designs. The industry able to come up with innovative products was not part of the Expedition. LALOG turned out to be an important lesson for the Energy Leap programme that they needed to create a different framework in order to realise the change in industry required for cost effective implementation of retrofitting at a large scale. This finally resulted in a new sub-programme: Rapids.

Regulations and government policy - The local government took their citizens seriously, since they initiated the #ENEXAP in order to reach governmental goals. Nevertheless, policies on for example permits for refurbishing were not able to provide the flexibility required right away. The local government tried to work with the occupant-owners to make the process of permit acquisition as smooth as possible. And discussions were started around topics like whether trees should be taken down in neighbourhood streets that would be blocking sunrays to reach solar panels and about the conditions necessary to meet flora & fauna legislation.

Societal and environmental effects - In the Netherlands there are approximately 7.2 million dwellings, among which a lot of terraced houses build between 1946 and 1991. The municipality of Apeldoorn has 156.960 inhabitants and consist of 67.780 households (Stadindex, 2015). To give an indication of the amount of energy that can be saved: 1.04 PJ per year by retrofitting 10 % of the Dutch housing stock to zero-on-the-meter in a period of 10 years. The average energy consumption per dwelling in the Netherlands is 1440 M3 natural gas and 3440 kWh of electricity (Nibud, 2015). This is 53 GJ per dwelling. When 10 % of housing stock will be retrofitted to zero-on-the-meter in 10 years (19,650 a year) it will represent a saving of 1.04 PJ of fossil energy per year. In the Netherlands, the gross revenue per employee per year was 310,000 Euro in 2013 (EIB, 2013). By linking the above gross turnover of 8.8 billion per year and the gross turnover per employee in the Netherlands, it will result in 28,000 jobs per year. For Apeldoorn only, the effects will be scaled to ratio of course.

Is as much about soft skills as well as hard technology - This experiment shows that technical knowledge alone was not enough to reach the goals of this experiment. The courses and the energy coaches had to guide the process and translate between both clients and companies. The road to success was not easy, mainly because next to goodwill, also knowledge both technical and process related, was needed to guide all the parties in the right direction. Also the process by which the clients were approached by the consortia, the so-called customer journey, had to be addressed by the energy coaches. Scrum sessions were introduced to speed up the process and to diminish the time needed by the companies to formulate a tailor made offer.

7. Summary & concluding remarks

The developments in the Energy Expedition addressed aspects of both views mentioned in the theoretical framework: innovation management and grass roots innovations. Both emphasize the construction of a new community, or niche, focussed at a mutual goal and room for learning. In the integrated framework this was translated in the backbone of the three pillars of the integrated framework constructed in section 2.3: goal articulation, social networks and learning. All three have played an important role in the functioning and results of the Expedition.

Starting point was the articulation of the ambition of energy neutrality. The Expedition stimulated owner-occupants to articulate their specific expectations and demands. Their high ambition level stimulated the consortia to give their best. They started developing one-stop-shop formulas and integrating existing products into customized solutions.

The programme in itself formed a coalition of occupant-owners, companies and facilitating parties. This coalition shared experiences and expectations for a period of three years e.g. during meetings, excursions and courses. This social network was the carrier and basis for the meetings, working groups and other interactions. Furthermore, the network helped to survive setbacks and to maintain drive and enthusiasm.

The new and dynamic network that was constructed around #ENEXAP provided the necessary conditions for learning. Learning was not so much on technical aspects as on social innovation, like market and user preferences, speeding up of the offer preparation process and soft skills. In relation to market preferences, it was learned that owner-occupants demanded tailor-made solutions based on their specific situation. An important lesson from this initiative is that for consortia focussing on the market of retrofitting owner-occupant owned dwellings it is essential to look at all requirements: energy performance, comfort level, future proofing of the home and other additional requirements, and to do this in an integrated way. Moreover, the owner-occupants want a warranty on energy performance. Soft skills proved to be key to bridge different knowledge levels, perspectives and goals. Finally, it can be concluded that the combination of expertise and roles necessary to upscale the retrofitting of occupant-owned dwellings requires even more integrated value chains. It also became clear in #ENEXAP, as in LALOG that disruptive product innovations are key to arrive at affordable energy retrofitting solutions necessary to realise large scale retrofitting of owner-occupant owned dwellings. New sub-programmes, Rapids Rental and Rapids Purchase were initiated to accomplish just that.

Abstract

This paper presents a housing development project in Tampere. Part of the construction of the zone will take place after 2020. The buildings constructed after that in the zone must be so-called 'nearly zero' buildings. Another significant constraint is the location in cold climate.

The project examined several different energy solutions. They differed from each other in the way heat and electricity was produced for the area. In these solutions, heat was either transferred to the area via traditional district heating, produced using heat pumps or solar thermal collectors. The electricity solution, on the other hand, was either concentrated, i.e. a power grid, or self-produced using photovoltaic panels.

Energy consumption was calculated using dynamic IDA-ICE simulation software, which used as input data hourly consumption profiles of an adjacent zone. The structures of future houses are in compliance with the energy efficiency targets set for the period in the National Energy Path. Primary energy and greenhouse gas emissions were calculated using local coefficients. The economic review covered the calculation of the payback period, the internal rate of return and the total cost.

Geothermal energy as a source for heating and electricity supplied by the network turned out to be the competitive alternative compared to traditional system, whether the decision was based on primary energy consumption, greenhouse gas emissions or economy.

Keywords: nzeb, RES, heating, electricity, economy

1. Introduction

The target area is located in Tampere. According to Köppen's climate classification, Tampere as well as Finland wholly belongs to the temperate zone with cold, wet winters with sunlight marginally. The mean temperature of the warmest month is no lower than 10°C and that of the coldest month no higher than -3°C.

The area in question is an abandoned industrial area that will be rebuild to residential use. The industrial area was sold to a property developer who has planned the area in cooperation with the city. A neighbourhood construction cooperation model known as "collaborative urban planning" (Nykänen et al., 2007) has been applied to the planning process. In the model, the planning of the residential area and town planning are carried out jointly by the construction company and the planning organisation of the city. This procedure is suitable for projects where special objectives have been set for an area, such as energy efficiency or higher-than-usual quality.

In the target area, such objectives had been set precisely for energy efficiency and customer orientation. Communications with the neighbourhood and potential residents have already been close during the town planning stage. The planning is otherwise proceeding normally with regard to background investigations and hearings that have also caused changes to the plan. Among other things, the final floor area (218 000 m^2) is lower than the first proposal.

The floor area of the residential buildings is large compared to the local housing market. For this reason, the construction is distributed over a period of ten years. This means that some of the buildings will not be completed until after year 2020, when all construction in the Member States of the European Union must be nearly zero energy buildings. A nearly zero energy building refers to an energy-efficient building as defined in the Energy Performance of Buildings Directive (2010). The required amount of energy that is nearly non-existent or extremely small should be covered to a large extent with energy from renewable sources, including renewable energy generated on-site or in the vicinity of the building.

2. Project goal

The main goal of the project has been to find a suitable energy system for the new residential area comprising near zero energy buildings. The suitability has been examined from several different perspectives. These make up the project's sub-goals or examinations from 1) the technical perspective (energy production), 2) the environmental perspective (greenhouse gas emissions) and 3) the financial perspective (investments and expenses during service life). This conference paper concentrates on sub-goal three, or financial examinations. Sub-goals one and two are discussed only to the extent to which they affect sub-goal three. It should be noted that the issue in question is the selection of a district-level energy system. Building-level solutions have been excluded, although the district systems might require their modification.

3. Research method

The energy consumption of the buildings in the area has been assumed to comply with the currently valid regulations until the year 2020, after which consumption is at the zero energy level. The hourly energy consumption profiles have been adopted from the neighbouring area, where new apartment blocks have been built over the last couple of years. The availability of light and warmth from the sun is similar in these two residential areas. It is also likely that the area will attract households of a similar type as the previously built area.

Several solutions for satisfying the need for energy have been investigated, taking into consideration the aim to increase the share of renewable energy in the buildings' energy consumption. Information on renewable energy yields has been received from both the industry and studies by our own research organisation.

3.1 Evaluation of solutions

The first financial examinations focused to the alternative decentralised solutions that use different forms of renewable energy. These calculations were done using a calculation model developed in the Renewable Energy Multitechnology Mix -project (REmix www-pages). The tool uses the basic key indicators of investment calculations (the payback period, the internal rate of return (IRR), and the net present value (NPV)). The calculation model also supports taking into consideration synergies resulting from the parallel development of several different forms of energy already from the planning stage. The model was developed to support the decision-making of, in particular, the municipal sector, so indirect effects can also be included in the calculation.

The basic idea of the model is to compare (at least to a certain extent) the solution implemented using renewable forms of energy to a "business as usual" solution comprising district heating and grid electricity. This assumption is extremely well suited to investments for replacements, where the current solution is based on district heating and grid electricity. The assumption can also be justifiably used as a comparison alternative in new construction areas, where district heating and grid electricity would be easily obtainable.

The payback period is the most commonly used investment calculation method, as it is simple to use and easy to understand. In this case the investments are made in equal parts over a period of ten years. The assumption is that the price of energy will increase and the price of technology decrease, each part of the investment will be made in a slightly different price environment.

The internal rate of return, in turn, indicates the discount rate at which the net present value of the investment is zero. The investment can, thus, be considered to be profitable if the internal rate of return is higher than the required rate of return for the capital or discount rate used by the operator.

3.2 Total cost comparison

The second calculation focused to the investment and the operating costs of all alternatives. These total costs have been calculated over a period of 25 years applying methodology framework for calculating cost-optimal levels (2012/244/EU). To be noted that the evaluations are done from the perspective of the Limited Liability Housing Companies.

4. Energy solutions and calculation assumptions

4.1 Alternative heat carriers for an energy system

Geothermal heat (GTH) is energy absorbed into the ground and water, mostly originating from the sun. GTH can be utilised with a heat pump regardless of the time of year (Lauttamäki et al., 2013). The pump collects heat from a drilled heat well that is typically around 200 m deep, or from a heat collection field installed either to the ground (depth one metre) or bottom the lake (depth two metres). The pump consumes electricity during the process, and the amount of heating energy it produces is typically around three times the amount of electricity it consumes.

Solar energy can be collected directly with **solar thermal collectors (STH)** or **photovoltaic panels (SE).** In Northern Europe, the problem in their utilisation is that the heat and electricity are generated at a different time than when they are used. Solar energy is most abundant during the summer, when its only application is heating household water (Pesonen et al., 2012). Both solar thermal collectors and PV are used as a secondary system. In order to maximise the power from the panels, they should be positioned facing south. Solar electricity is most cost effective when utilised right away. Storing electricity is not yet economically profitable due to the high price of batteries. The panels have an efficiency of around 10 to 20 per cent, which means that around 100 to 200 kWh/m^2 of the annual solar radiation energy (1,000 kWh/m^2) can be converted into electricity.

A district heating (DH) network comprises power plants and pipelines going into the heating stations of the buildings. Heat is transferred from the warm water entering the heating stations to the buildings' own heating systems. District heat can be produced most energy-efficiently in Combined Heat and Power (CHP) plants producing electricity and, as a side product, heat that is then fed into the district heating network. District heating can also utilise incinerated waste and industrial waste heat (District heating –site).

Electricity network (NE) is a basic service. The task of the electricity network is to transmit the electricity produced in power plants to electricity users.

4.2 Examined alternatives

Of the alternatives described above, five different combinations were chosen for further examination (table 1; figure 1).

1 BAU: District heating and electricity from the national network.

2A GTH, NE, STH & SE: Geothermal heat (50 per cent of the peak power requirement) and network electricity complemented with solar heat (ten per cent of the roof area) and solar electricity (an optimal amount)

2B GTH & NE: Geothermal heat (50 per cent of the peak power requirement) and network electricity

3A GTH, DH, NE & SE: Geothermal heat (35 per cent of the peak power requirement is fulfilled by collector field) complemented with district heating, grid electricity and solar power (an optimal amount)

3B GTH, DH & NE: Geothermal heat (35 per cent of the peak power requirement) complemented with district heating and network electricity

Table 1. The input of energy carriers by examined solutions.

	BAU	2A	2B	3A	3B
District heating	56 %			28 %	28 %
Geothermal heat		40 %	46 %	22 %	22 %
Solar heat		7 %			
Network electricity	44 %	43 %	54 %	44 %	50 %
Solar electricity		10 %		6 %	

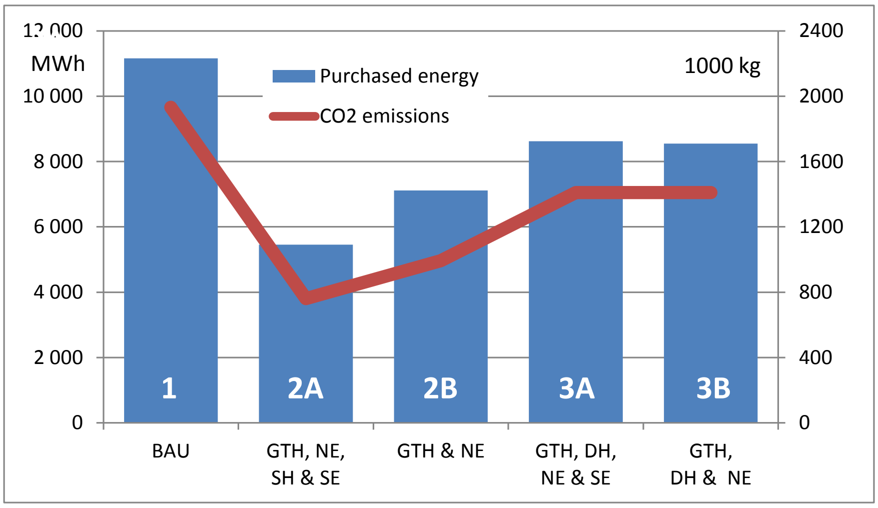

Figure 1. Purchased energy and greenhouse gas emissions of examined solutions.

Connecting the buildings to the local district heating network and the national electricity network (alternative 1) is the "business as usual" alternative. In alternatives 2A and 3A, the aim is to increase the share of renewable energy through nearby energy production. Harvesting solar energy has been eliminated from alternatives 2B and 3B.

Geothermal heat (2A, 2B, 3A, 3B) covers most of the need for heat, but their power is not enough for heating the buildings during the coldest weather during the winter. These peak consumption periods are covered by support heating. In the 2A and 2B alternatives, the support heating is produced through electricity network, and in the 3A and 3B with district heating. The primary energy consumption of the alternatives is presented in Figure 1.

The energy consumption of the buildings is identical in all alternatives. The differences in the consumption of purchased energy (figure 1) are a result of the efficiency of the energy production and how much free energy and renewable energy can be used.

4.3 Calculation assumptions

In this project, the basic assumptions and the price change scenarios were decided jointly with the research group and project's steering group. The key calculation assumptions:

- Price of district heat EUR 80/MWh including energy + monthly fees + VAT 24 % (Energy prices -site)
- Price of grid electricity EUR 120/MWh includes energy + transmission + monthly fees VAT 24 % (Energy prices -site)
- Energy price development 2 % per year and 4 % per year
- Renewable energy technology -2 % per year except solar power technology -5 % per year
- Operating and connection costs development 2 % per year
- The surplus energy produced is either wasted or used free of charge.
- Time horizon 25 years
- The residual value of the investment is EUR 0

The moderate energy price, operating and connection costs scenario (2 %) is in line with the general development of consumer prices in the near history. In the alternate scenario (4 %), the price of energy is assumed to increase faster than the general consumer prices.

Forecasting the development of energy price over a 25-year period is very challenging as it is affected by so many different factors (taxation, energy policy, state of the global economy, etc.). A 50-year horizon could also have been used, but energy price development forecasts reaching just 25 years into the future already include a great deal of uncertainty, making an even longer time period difficult to justify. Furthermore, investments usually have to pay for themselves and show profitability after a significantly shorter time period than 25 years.

A 25-year horizon is so far away that the low residual value at the end of the period does not have much impact on the calculations. Additionally, determining the residual value 25 years into the future is very challenging, as technological solutions are rapidly developing.

In the future nearby production surplus energy can naturally have its use, if selling it into the network becomes possible and/or advancements are made in energy storage technologies (e.g. batteries). In its part, this would improve the profitability of renewable energy investments.

The price trend of renewable energy solutions has been downward in the 2000s, particularly in the case of solar power. This development has been assumed to continue for the next five to ten years in the calculations.

In alternatives 2A and 2B, all investments are made in parts over a period of ten years in accordance with the demand for energy (it is assumed that construction takes place at an even pace over ten years). In reality, the construction will probably not take place at an even pace, but this assumption was made in order to make the calculation clearer.

In alternatives 3A and 3B, the geothermal system is built as a one-time investment, and the district heat and solar electricity investment (in alternative 3A) within five years in accordance with demand (it is assumed that construction takes place at an even pace). Alternatives 3A and 3B have options for starting the implementation either immediately or after five years. The solution can be deployed either in the half of the area that is completed first or the half completed last. The price environments between these options are different to such a degree that it must be taken into consideration in the calculations, too.

5. Results of examinations

5.1 Is it worth invest earlier than later?

Figure 2 depicts the payback period for the different solutions of alternative 2 for the part investments made during the first and tenth years. The payback periods of the first and last part investment differ very significantly from each other. The payback period of the investment as a whole is somewhere between these extreme values. It can also be stated in the 2B solutions, the payback period is shorter than in the 2A solutions, i.e. the solution with just geothermal heat leads to a better end result in the economic sense than when it is combined with solar heat and electricity.

According figure 2 the payback period is shorter the larger the annual increase in energy price is. Correspondingly, a part investment made in the tenth year leads to a shorter payback period than the part investment made in the first year. This is explained both by the increase in the price of energy and the decrease in the price of technology. The figure also shows that the time of the part investment (first vs. tenth year) has a clearly larger impact on the payback period than the increase in the price of energy (2% vs. 4%). The price environment is naturally most favourable with a tenth year part investment and a 4% assumed increase in the price of energy.

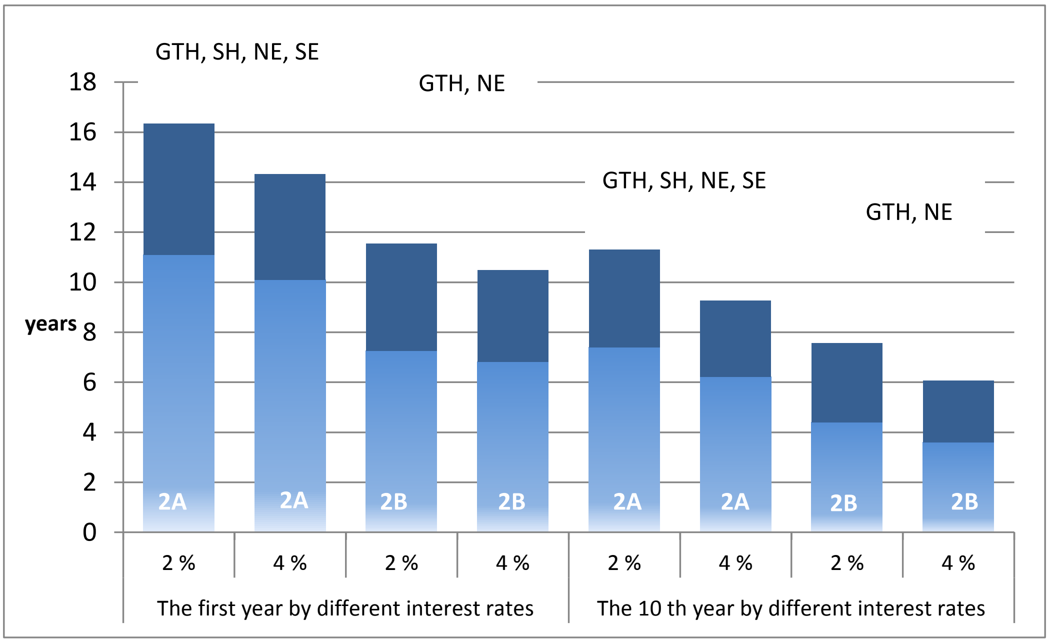

Figure 2. Payback period (years) is shorter without solar energy both in the first year's and the 10th year's investment even the price erosion has been taken account. Price range is ± 20 % (dark part of columns).

It can be seen in Figure 3 that the internal rate of return is higher the larger is the annual increase in the price of energy. The column on the right (price increase 4 %) is thus always higher than the one on the left (price increase 2 %).

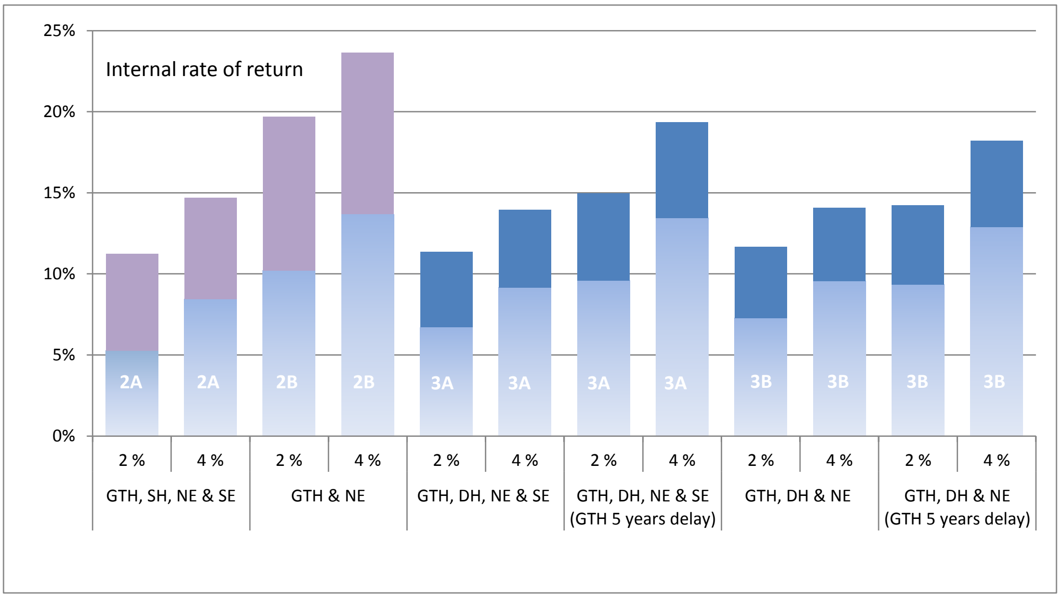

Figure 3. Internal rate of return in the different alternatives. Alternatives 2 and 3 cannot be compared with each other due for example, to different division of investments (for this reason, columns of different colours are also used in the figure). Price range is ± 20 % (dark part of columns).

The figure also shows that, in alternatives 3A and 3B, the solution implemented after five years leads to a higher internal rate of return. This is explained by both the assumed increase in the price of energy and the assumed decrease in investment costs. In other words, the investment can be made in a more favourable price environment. Thus, the difference between investments made at the present time and after five years is at its largest with the higher assumed increase in the price of energy (4%).

Extending the horizon from 25 years to 50 years will not have a significant impact on the results. There is no impact at all on the payback period, because even the longest payback period is only somewhat over 16 years. The possible residual value (e.g. 50% of the initial investment) as a rule has only a minor impact on the results, because even a 25-year horizon is so far in the future that the net present value is usually very low with these internal rates of return.

5.2 Is it worth choose centralized, decentralized solution or parallel solution?

In figure 4 we can see the total cost comparison. As could be presumed, parallel system is an expensive solution as it is in this case with the 3A and 3B, where district heating is uses as complementary system to geothermal heat. The network electricity however, is the overall cost effective complimentary energy source.

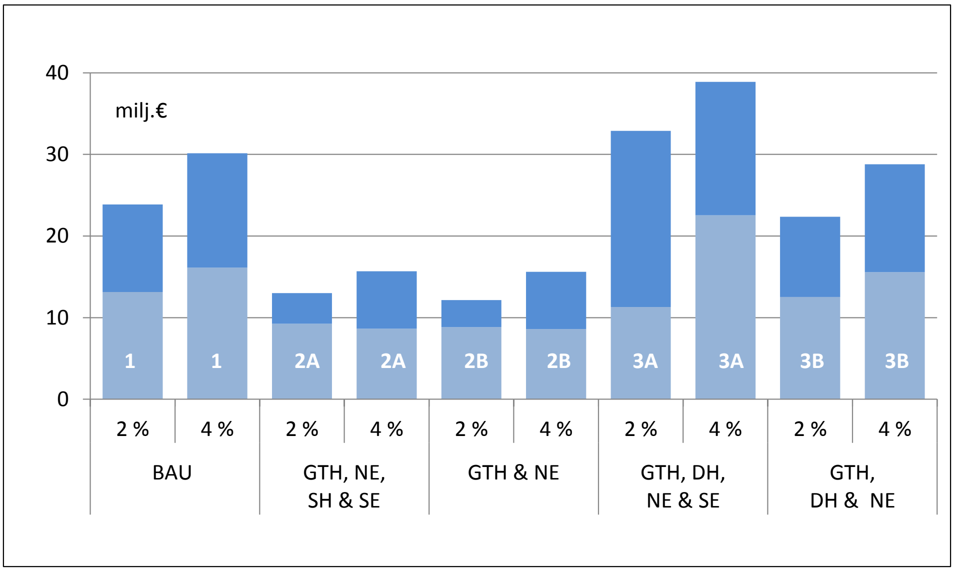

Figure 4. Total costs of energy system alternatives. Reason to high costs of 3A and 3B are a district heating system as complimentary system. Price range is ± 20 % (dark part of columns).

The calculated payback periods, internal rates of return and total costs are at such a level that solutions based on geothermal heat and network electricity (2A and 2B) would appear to be competitive alternatives. This is in line with other research results made in a similar business environment (Häkämies et al., 2015). In particular, the option 2A but also the option 2B is surveyed less GHG emissions productive when emissions are calculated by the local factors (figure 1).

Naturally, decisions depend entirely on each operator's required rate of return on the capital and the required payback period. It should be emphasised that these kinds of calculations are very dependent on several different initial assumptions, and even small changes in these assumptions can have a significant impact on the end results. Calculations should, thus, be made using several different parameters, observing their effect on the end results.

The prices and assumptions used in the calculations are largely based on the views of the research scientists and the project participants. No actual offers for these solutions have been requested. The actual prices may differ significantly, particularly due to the conditions in the area, scalability and time of implementation. Conditions in the area in this context refer, for example, to the actual price of geothermal heat depending on the geological conditions in the area. Scalability in this context refers, for example, to there being clearly more information on and estimates for geothermal heat solutions for individual apartment blocks than for an entire residential area. The prices of the technologies are also in a constant flux, and the actual price thus depends on the time of implementation.

6. Discussion

The energy system alternatives appear differently to society, the developers and the future residents of the area. In this case, society is represented by **the city**, ultimately responsible for the built environment and planning as a whole. Energy and climate objectives place binding demands on the city, among other things, in the form of agreements voluntarily made with the state (Energy Efficiency Agreement –site), and image-wise in the form of joint mayoral proclamations. Accolades received in the past also create an obligation. Indeed, from the city's point of view, the best alternative would be the one with the lowest consumption of primary energy and generation of greenhouse gases. The choice would thus be the alternative with as much renewable energy as possible (alternative 2A or 3A). On the other hand, the city owns the district heating company, so it also has grounds for adopting the traditional alternative (1). The traditional alternative is also supported by the fact that renewable energy sources can be utilised in the production of district heat. The utilisation of the existing network and production capacity saves in investment costs and is material-efficient.

It is in the **construction company**'s interest to generate profits and avoid risks, as it is bound by a ten-year guarantee on the functionality of the building. By choosing the traditional alternative (1), its investment costs and risks remain lower. On the other hand, it could be in the construction company's interest to profile itself as a frontrunner with ecological values, so the choice could turn to the alternatives involving renewable energy. These alternatives require developing the concept of an apartment block as a product. The traditional concept is that a construction company erects the building; after its completion, the building is managed by a limited liability housing company, supported by energy services that have been centralised to a great extent.

Local energy production would need to be separately organised. This would go against the prevalent development (for example energy efficiency directive 2012/27/EU), as the trend in many technological fields has rather been the opposite, towards centralisation and the benefits of the economies of scale. Based on the Smart City agenda, virtual power plants have been theorised, with this kind of local energy production bundled together and with a common operator. This would be a major regime-level change compared to the current situation.

Living as affordably as possible is in the interests of the **residents**. In this context, self-produced, free energy sounds like a tempting alternative. Indeed, when it comes to the heating of single family houses, the choice is often a property-specific system, even partial generation of one's own electricity, although its life cycle costs are currently higher. This particularly applies to countries where small-scale production of electricity has no public subsidies.

The situation is different for apartment blocks already because in the building skin there is a little space for harvesting solar power. Their choices are not made by individual households, but by the limited liability housing companies made up of individual households. For new buildings, the decisions are made by the construction company for the housing company, because only some or none of the housing company shareholders are known at the time of the decision-making. Once the housing company formed from households has been established, it is too late to influence the solutions. In order to be able to benefit from the affordability of the local production, the housing company must assume some responsibility over the system. This responsibility is, however, often outsourced to a maintenance company and it spends the economic advantage of the households.

With hybrid energy systems, the responsibility refers to, for instance, remote monitoring and the investigation and correction of any deviations detected. At this point, things move from traditional maintenance company operations to digital control rooms, where the economies of scale rule and a new breed of business ecosystems thrive.

7. Summary

The subject of this conference paper is an apartment block area comprising near zero energy buildings. The goal was to study the best way to arrange energy services for the area. The area is transitioning from an industrial area to a high-efficiency residential area.

The alternatives that were studied comprised traditional, centralised energy service, and local energy production in the area, using geothermal heat, solar heat and solar electricity. The calculated payback periods, internal rates of return and total costs are at such a level that solutions based on geothermal heat and network electricity would appear to be competitive alternatives. The solutions are area-specific, and must always be studied on a case-by-case basis.

The decision-making is rife with uncertainties. With regard to new technologies and, in particular, hybrid systems, the question are about the optimal control of the operation of the systems either on building or area level. There are examples where attempts at saving primary energy have resulted in increased consumption due to the systems not functioning properly. Utilising the benefits in full may require the development of a new business ecosystem.

The choice is also influenced by the prior choices of the target area or the city, or so-called path-dependency, which may also be a positive factor. Keeping with the traditional solution allows benefiting from the prior investments. If the energy efficiency of the city's old building stock is improved, the district heating system will have enough capacity for new customers with minor additional investments. The new area will benefit from the centralised system's investments made in on energy efficiency, renewable energy sources, and fulfilment of customer needs, remote monitoring, and large-scale hybrid solutions, including the combined heating and cooling (CHC) -technology.

Abstract

Urban renewal, as an opportunity of realizing sustainable development, can resolve numerous problems facing cities. Due to the linkage between sustainability and urban renewal, it is helpful to investigate sustainability in urban renewal context. Although there exists a consensus on the importance of sustainable development, this concept is still ambiguous, which may lead towards a deviated direction. In order to capture a better understanding on sustainability in urban renewal, thus making informed decision-making on sustainable urban renewal, some evaluation tools/methods have been proposed. However, most research focuses on a city scale or a renewal project. Sustainability assessment focusing on neighbourhood renewal is still a rarely touched area. With the aim of supporting decision-making in urban renewal, this paper proposed an indicator-based approach to neighbourhood sustainability assessment. Essential steps in this approach are introduced in detail. A case study on several neighbourhoods of Hong Kong is conducted to apply this indicator-based approach. This paper not only provides a better understanding on neighbourhood sustainability in urban renewal process, but also proposes a method of assessing sustainability of neighbourhood for supporting urban renewal.

Keywords: sustainability assessment, urban renewal, neighbourhood, decision-making

1. Introduction

Urban renewal is regarded as a two-fold sword. It can deliver a positive opportunity for realizing sustainable development and act as an antidote for urban problems (Zheng et al., 2014). There also exists some criticism including fading of local culture, destruction of social network, and segregation. Facing different voices on urban renewal, it is important to integrate the concept of sustainability into urban renewal practice. Although the concept of sustainable is accepted widely, its application in practice is not always favouring (Hunt et al., 2008). To better deliver sustainable urban renewal, it is necessary to conduct urban renewal evaluation, especially when it comes to decision-making. For example, a systematic approach with evaluation criteria on urban competitiveness quality and priority model for urban renewal projects was proposed to facilitate decision makers and developers in Taipei in reviewing urban renewal project selections (Juan et al., 2010). A model for measuring sustainability of urban regeneration at project level was proposed to assist decision-making (Peng et al., 2015). Urban regeneration performance was evaluated based on different categories (the economy and work, resource use, buildings and land use, transport an mobility, and community benefits) (Hemphill et al., 2004a; Hemphill et al., 2004b).

However, most studies on urban renewal evaluation focus on the impacts of urban renewal impacts, which are post-evaluation, minimizing the opportunities of promoting sustainability. It is more beneficial if pre-evaluation is included in urban renewal process. Pre-evaluation before urban renewal is crucial for regional policies (Greig et al., 2010). Only a few studies focusing on pre-assessment for urban renewal decision-making. For example, Ho et al. (2011) developed the Dilapidation Index under the context of Hong Kong to assess the building conditions for identifying potential renewal projects. But the Dilapidation Index only focuses on building conditions at building scale. The index of multiple deprivations, as a national matrix in the UK, is also for assessing the need for regeneration activities (Greig et al., 2010). This index is comparatively more comprehensive, yet its local context is in the UK.

Therefore, this research aims at proposing a universally indicator-based approach for sustainability assessment at neighbourhood scale for urban renewal decision-making. Four major steps are involved in the application of this approach. To better illustrate it, a case study on eight neighbourhoods of Hong Kong is employed to examine this indicator-based approach. The second section reviews previous work on neighborhood sustainability assessment and urban renewal assessment. The following section presents the conceptual framework of this approach. In further unravelling this approach, the fourth part shows the case study. The fifth section discusses limitations of this paper. And the final section concludes this paper.

2. Relevant Work

2.1 Neighborhood sustainability assessment

Sustainability has been an essential objective in city development. After it was firstly proposed in the Brundtland Report, it has been considered as a crucial issue for urban development. In order to transit to sustainable urban development, it is necessary to know where we are, what goals that we have met, and what to do next. This poses challenges and potentials on sustainability assessment. Devuyst et al. (2001) provided a definition of sustainability assessment: "a tool that can help decision-makers and policy-makers decide which actions they should or should not take in an attempt to make society more sustainable." Sustainability assessment is useful for decision-makers on determining which actions should or should not be taken for realizing sustainable development (Ness et al., 2007).

There are some internationally well-known tools for sustainability assessment for neighbourhood, including but not limited to the following ones: Building Research Establishment's Environmental Assessment Method Communities (BREEAM Communities), CASBEE for Urban Development, The Leadership in Energy and Environmental Design for Neighbourhood Development (LEED for Neighbourhood Development). Comprehensive Assessment System for Building Environmental Efficiency for Urban Development (CASBEE for Urban Development) addresses the assessment of urban areas by focusing on the phenomena of aggregation of buildings and the outdoor spaces (Haapio, 2012). BREEAM Communities focuses on the planning stage of the development process of large-scale project with the aim of making the project show their environmental, social and economic benefits to the local community (BREEAM, 2009). LEED for Neighbourhood Developments was established as a U.S. national standard for neighbourhood design which focuses on green building and smart growth. It aims at assessing the impacts of development projects based on its standards (USGBC, 2006). Although different tools have different emphases and criteria, themes applied by most tools are involved with several aspects: resources and environment, transportation, economic, location, site selection pattern and design, and innovation (Sharifi and Murayama, 2013). Through analysis of existing systems of neighbourhood sustainability assessment, locality (e.g. local culture and laws) is emphasized as a necessary aspect for adaptability of existing systems (Berardi, 2013).

2.2 Urban renewal evaluation

The importance of evaluating urban renewal/regeneration initiatives on monitoring current renewal/regeneration programs has been widely acknowledged (e.g. Peng et al., 2015; Kauko, 2012; Hemphill et al., 2004a; Hemphill et al., 2004b) . A large number of studies have been conducted in terms of urban renewal/regeneration impacts.

Some research only focuses on one certain aspect of impacts of urban renewal, like social or economic impact. For example, in order to identify social impacts of urban waterfront regeneration in Helsinki, four themes of social impacts (resources and identity, social status, access and activities and waterfront experience) were proposed (Sairinen and Kumpulainen, 2006). From economic perspective, the impacts of a public-sector-led urban renewal project on housing prices in Hong Kong were measured by a price gradient analysis (Lai et al., 2007). Some researchers explore several aspects together. Social and economic impacts of residential brownfield development in the most deprived urban neighbourhood were assessed in terms of changing housing market, residential density, population growth and economic deprivation (Bäing and Wong, 2012).

There are also studies comprehensively evaluating urban renewal initiatives. Impacts of urban renewal on socio-economic and spatial structure are often discussed together (e.g. Uzun, 2003; He and Wu, 2007; Wu and He, 2005), although different studies may use various indicators. Some scholars apply composite indicators to assess urban renewal comprehensively (Hemphill et al., 2004a; Hemphill et al., 2004b; Hunt et al., 2008; Pérez and Rey, 2013; Wedding and Crawford-Brown, 2007). To measure regeneration performance, a group of indicators under different categories (the economy and work, resource use, buildings and land use, transport an mobility, and community benefits) were proposed (Hemphill et al., 2004a; Hemphill et al., 2004b). While most studies assess urban renewal from the perspective of post-evaluation, only a few address pre-evaluation. To facilitate regeneration decision-making in Birmingham Eastside, Hunt et al. (2008) presented a series of indicators including social aspect (user comfort, form and space, access, amenity, inclusion), economic aspect (social benefits and cost, transport, employment, competition effects, viability), environmental aspect (air quality, land use, water, ecology and cultural heritage, design and operation, transport), and natural resources (materials, water, energy, land utilization, waste hierarchy).

3. Conceptual Framework

This research develops an indicator-based approach to neighbourhood sustainability assessment with the purpose of providing references for urban renewal decision-making. Figure 1 shows the conceptual framework. There are totally four steps, in which different methods could be applied. This section is to provide details in each step.

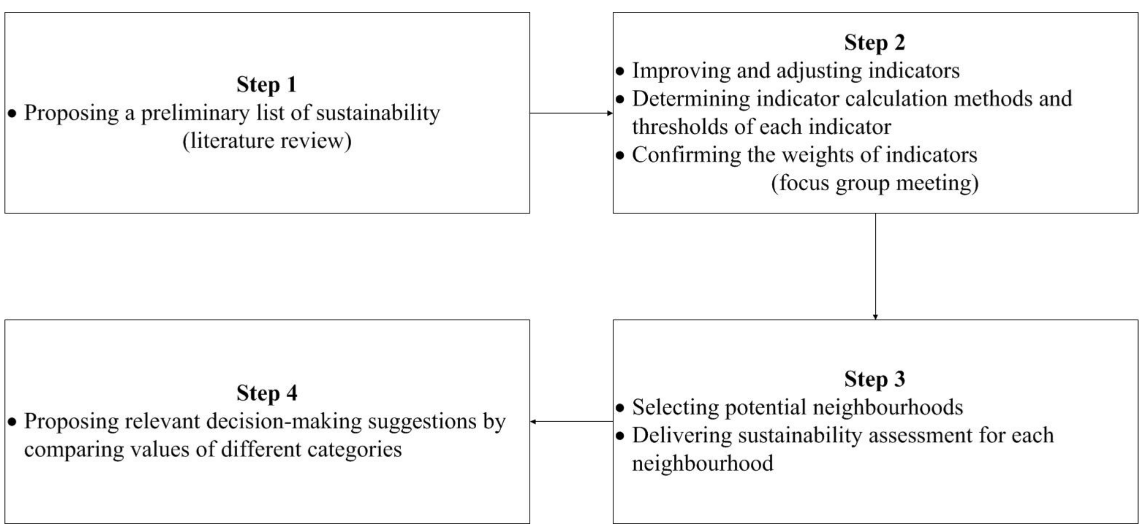

Figure 1: Major steps in the proposed approach

3.1 Step One

Various indicators have been applied in studies on sustainability assessment at neighbourhood scale. The existing tools or research can be useful resources for identifying initial indicators and their calculation methods. During this process, two other aspects need to be considered. One is the local condition. Another is what is crucial for urban renewal. In summary, the initial indicator list is a comprehensive indicator system which integrates sustainability consideration, urban renewal focus, and local conditions. Different indicators should be categorized into different themes. A hierarchy framework of indicators then can be drawn. Figure 2 shows the hierarchy framework of indicators.

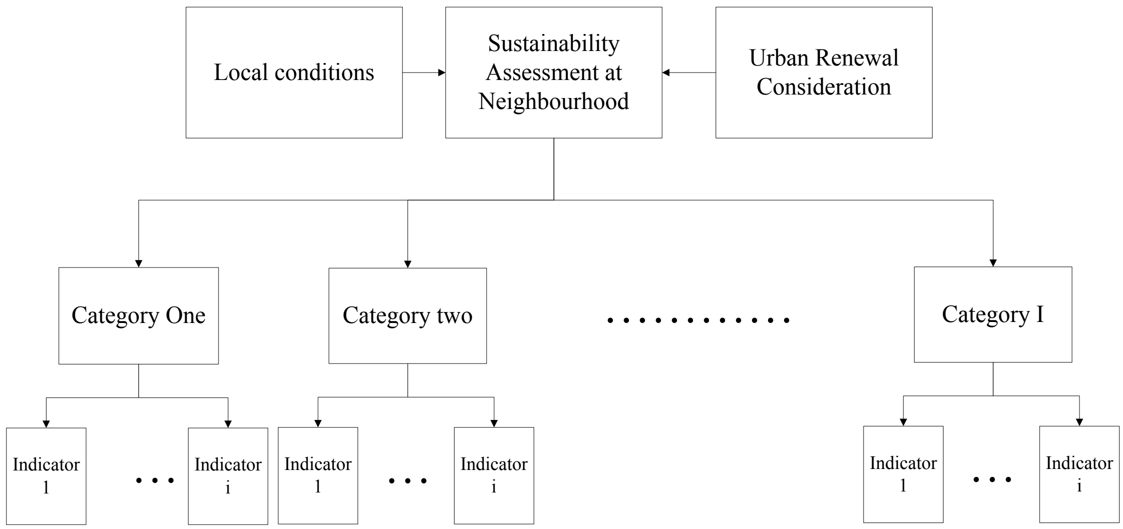

Figure 2: The hierarchy framework of indicators

3.2 Step Two

The selected indicators may be subjective, thus requiring adjustment of indicators. Focus group meeting is conducted to collect suggestions on existing indicators and to add ignored indicators selected during step one. After adjusting and improving the indicator list, it is necessary to determine calculation methods and thresholds of each indicator.

Under each category, weights of indicators is to be determined. There are different ways. For example, participants can pose specific weights for various indicators directly after discussion. Or participants judge the relative importance of each indicator, the results of which are then to be used for calculating weights by methods like analytic hierarchy process (AHP) and analytic network process (ANP). The sum of weights for indicators in each category should be 1.

3.3 Step Three

Potential neighbourhoods for renewal decision-making are to be determined during this step. Then relevant data is to be collected accordingly. The following actions include calculating values of each indicator and then obtaining the final value of each category.

Each indicator has its unique calculation method. The initial evaluation results of indicators are obtained by using different units and cannot be compared directly, thus requiring standardization before calculating values of different categories. Taking into account of the positive and negative effects of different indicators on sustainability, two formulas were applied for standardization (Pirrone et al., 2005).

Positive indicator: $y_{ij} = (x_{ij} - \min x_{ij}) / (\max x_{ij} - \min x_{ij}) (1 \le i \le m, 1 \le j \le n)$ (1)

Negative indicator: $y_{ij} = (\max x_{ij} - x_{ij}) / (\max x_{ij} - \min x_{ij}) \ (1 \le i \le m, 1 \le j \le n)$ (2)

The final value of each category is calculated by the formula below, in which S_I stands for the final value of category I, v_i represents value of indicator i, and w_i is the weight of indicator i.

$$S_I = \sum_{1}^{i} v_i w_i \quad (3)$$

3.4 Step Four

After obtaining values of various categories, relevant suggestions on urban renewal decisions can be proposed accordingly. This approach does not suggest calculating a total score of sustainability, but tends to compare each category among neighbourhoods, which can offer more detailed and specific strategies for neighbourhood renewal.

4. Case Study

4.1 Study Area and Data Preparation

Hong Kong is selected as the case study context because of its unique characteristics. Firstly, it is now facing serious urban decaying problems with approximate 4,000 buildings aged 50 years or above. Secondly, it is a typical high-density city in Asia, which experiences overcrowding and scarcity of land supply. Urban renewal can free some land for Hong Kong. Thirdly, various voices emerge in urban renewal process of Hong Kong, within which there are also some criticism such as profit-driven, fading of local culture and destruction of local network.

Eight tertiary planning units TPUs in Kowloon District of Hong Kong are selected in the case study to experiment the proposed approach (See figure 3). These TPUs, are applied by Planning Department of Hong Kong for planning purpose. A database for this research is prepared, in which both spatial and non-spatial data are included. Spatial data include land use map, road network map, the location of public facilities, and building distribution. Non-spatial data involves environmental and social aspects. The data is from different governmental departments, including Planning Department, Lands Department, Building department, Hong Kong Housing Society, Environmental Protection Department, and Census and Statistics Department. Data processing actions involve digitalizing land use map and integrating data from different sources in ArcGIS software package.

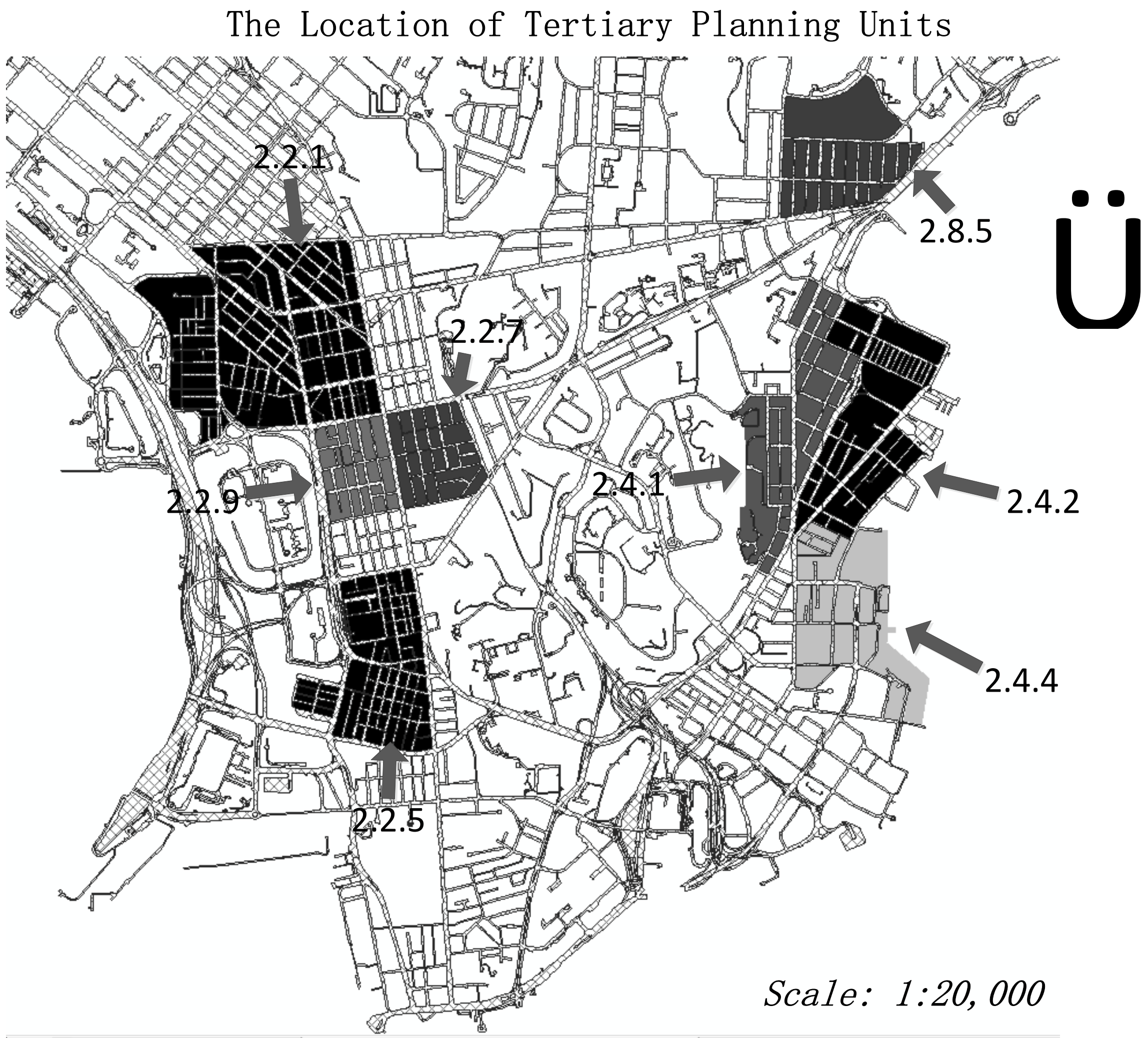

Figure 3: The location of tertiary planning units (TPUs)

4.2 Application of the proposed approach

Following the steps in the conceptual framework, the proposed approach was applied. Through literature review (e.g. Greig et al., 2010; Hemphill et al., 2004a; Hemphill et al., 2004b; Hunt et al., 2008; Boyko et al., 2012; Cheng and Lin, 2011), an initial list of indicators were proposed. This case categorized indicators into five themes, which are social aspect, environment and resources, economy and work, land use form and building conditions. Then in step two, two more indicators (Density of Small businesses with local characteristics and the fragment level of property rights) were added and calculation methods were confirmed for each indicator. To make it simple (because this study is a pilot one), each indicator is regarded contributing the same to the total value of each category; thus, the weights for indicators are the same. Several indicators were not included in the calculation because of lacking data at this scale. Additionally, this is a pilot study for illustrating this approach, it is acceptable that several indicators are not included. Table 1 presents an adjusted indicator list, which can also be referred by other contexts. Table 2 shows the final scores of different categories. Figure 2 can clearly show the comparing results in space.

Base on the results, performance of each neighbourhood can be compared directly. In terms of social aspect, TPU 2.2.1 performs the best while TPU 2.4.1 has the lowest value. As for economy and work, TPU 2.4.4 stands out with its highest value while other TPUs have similarly low values. TPU 2.2.7 obtains the highest value for the performance of environment and resources. TUP 2.2.9 shows the best result for land use form while land use form of TPU 2.2.1 presents the worst one. Building conditions in both TPU 2.2.1 and TPU 2.2.7 are satisfactory and TPU 2.8.5 presents the most serious building condition.

From these results, some issues could be found. Although some TPUs perform well in certain aspects, they may face some problems in other aspects. This phenomena reminds of a fact that values of some positive aspects may offset those negatives ones if we only refer to the overall value of sustainability. Therefore, calculating different categories respectively can avoid this dilemma in this approach. Based on the results, corresponding strategies can be proposed for each neighbourhood. For example, for TPU 2.8.5 with higher value in land use form and comparatively lower values in other categories, building rehabilitation initiatives are urgent. Then for some decaying area, comprehensive redevelopment may be an alternative for addressing various problems. It is essential to include both physical and socio-economic improvement during renewal.

Table 1: A summary of indicators and their measurement

Category	*Indicator*	*Measurement*	*Remarks*
Social aspect	*Human density*	*Population/Area of the planning unit*	*Results can be obtained through normal calculation*
Social aspect	*Age diversity*	$\frac{1}{cat}\sum_{i=1}^{cat}(1-\frac{n_{cat\_age\_i}}{n_{cat\_age\_i}^{obj}})^2$	cat *is the number of different age groups,* $n_{cat\_age\_i}$ *is the population belonging to age group* i*,* $n_{cat\_age\_i}^{obj}$ *refers to the objective population in age group* i
Social aspect	*Residential floor area per capita*	*Residential floor area/Population*	*Results can be obtained through normal calculation*
Social aspect	*Public transport diversity*	$\frac{1}{cat}\sum_{i=1}^{cat}(1-\frac{n_{cat\_trans\_i}}{n_{cat\_trans\_i}^{obj}})^2$	cat *means the number of public transportation types,* $n_{cat\_trans\_i}$ *is the number of transportation points (stops/stations) in type* i*,* $n_{cat\_trans\_i}^{obj}$ *is the objective number of transportation points in type* i*.*
Social aspect	*Facilities diversity*	$\frac{1}{cat}\sum_{i=1}^{cat}(1-\frac{n_{cat\_faci\_i}}{n_{cat\_faci\_i}^{obj}})^2$	cat *represents the number of facility types,* $n_{cat\_faci\_i}$ *is the number of facility* i*,* $n_{cat\_faci\_i}^{obj}$ *is the objective*

			number of facility i .
Economy and work	*Labor force participation rate*	*Labor force participation rate*	*Data can be obtained from statistical information*
Economy and work	*Disposable income per capita*	*Disposable income per capita*	*Data can be obtained from statistical information*
Economy and work	*Diversity of business activities*	$\frac{1}{cat}\sum_{i=1}^{cat}(1-\frac{n_{cat\_busi\_i}}{n_{cat\_busi\_i}^{obj}})^2$	cat *is the number of various business groups,* $n_{cat\_busi\_i}$ *is the population belonging to business category* i , $n_{cat\_busi\_i}^{obj}$ *refers to the objective population in business category* i
Economy and work	*Density of Small businesses with local characteristics*	*The trade of small business with local characteristics/the area of planning unit*	*Data cannot be obtained;* *This is a newly added indicator*
Resources and environment	*Waste generation*	*Total waste generation/population*	*Data can be estimated*
Resources and environment	*Waste recycling*	*Number of waste recycling facilities/area the planning unit*	*Data can be estimated*
Resources and environment	*Electricity consumption*	*Total electricity consumption/population*	*Data cannot be obtained*
Resources and environment	*Air quality*	*Air quality index*	*Data cannot be obtained*
Resources and environment	*Water consumption*	*Total water consumption/population*	*Data cannot be obtained*
Land use form	*Land use mix*	$-\sum_{i=1}^{n} l_i \ln l_i / \ln n$	l_i *is the area of land use type* i , n *means the number of land use types.*
Land use form	*Accessibility to cultural facilities*	*Number of cultural facilities within 300 meters*	*Results can be obtained through spatial analysis in GIS*
Land use form	*Accessibility to education services*	*Number of education facilities within 300 meters*	*Results can be obtained through spatial analysis in GIS*
Land use form	*Accessibility to health care services*	*Number of health care facilities within 300 meters*	*Results can be obtained through spatial analysis in GIS*
Land use form	*Accessibility to sport and leisure facilities*	*Number of sport and leisure facilities within 300 meters*	*Results can be obtained through spatial analysis in GIS*
Land use form	*Accessibility to other facilities*	*Number of other facilities within 300 meters*	*Results can be obtained through spatial analysis in GIS*

Land use form	*Accessibility to public transport*	*Number of public transport points within 300 meters*	*Results can be obtained through spatial analysis in GIS*
Land use form	*Open space coverage ratio*	*Area of open space/Area of the planning unit*	*Results can be obtained through spatial analysis in GIS*
Building condition	*Average building age*	$\sum_i^n age_i / n$	*Results can be obtained through normal calculation*
Building condition	*Number of buildings aged 50 years or above*	*Number of buildings aged above 50 years*	*Data can be obtained directly from statistics*
Building condition	*Building maintenance*	*Number of building repair cases/Number of buildings aged above 50 years*	*Data can be obtained through normal calculation*
Building condition	*Building density*	*Floor area/Area of the planning unit*	*Data can be obtained through normal calculation*
Building condition	*The fragment level of property rights*	*The fragment level of property rights*	*Data cannot be obtained; This is a newly added indicator*

Table 2: Values of neighbourhoods in different categories

	Social aspect	*Economy and work*	*Environment and resources*	*Land use form*	*Building condition*
2.2.1	*0.618491*	*0.261551*	*0.532039*	*0.231615*	*0.503037*

5. Discussion

This paper proposed an indicator-based approach to assessing neigborhood sustainability for better urban renewal decision-making. Four steps are included in the assessment. Case study facilitates illustrating how to apply this approach in practice. This approach could be applied in different contexts but be adjusted based on specific conditions. The indicator list proposed on the basis of Hong Kong context can also be referred by other studies. Changes are suggested if necessary because different contexts face different challenges and issues in neighborhood renewal.

This research has some limitations. Due to data limitation, some calculation results are estimated, which may not be accurate. And data of several indicators cannot be obtained at this scale, thus ignoring their effects on the final results. Another limitation is that weights were not developed in step two. In order to further improve it, it is suggested to include as much data as possible. It would be of great use if the weights of various indicators were obtained in step two. This approach is not aiming at making decisions directly, but to provide useful references for decision-makers. Therefore, decision-makers should combine other information and approaches when applying this approach.

6. Conclusions

With the aim of supporting urban renewal decision-making at neighbourhood scale, this paper presents an indicator-based approach for neighbourhood sustainability assessment. This approach involves four essential steps, which are illustrated in the case study. It has several shining points. Firstly, unlike some studies on assessing urban renewal, it requires a more comprehensive perspective for indicator selection, which suggests sustainability, urban renewal and local context. Secondly, its focus is neighbourhood scale, which is a proper scale for initiating urban renewal activities. This scale is regarded as an important geographic and social unit for practicing planning activities (Rohe, 2009). Thirdly, with the fact that most studies on urban renewal evaluation focus on impacts of urban renewal (post-evaluation), the pre-assessment by this approach maximizes the opportunities of applying sustainability into renewal practice. The proposed approach can benefit both theory and practice.

Institutional Development is the Key for Sustainable Water Services in the Built Environment

Tapio S. Katko,

Dept. of Civil Eng., Tampere University of Technology
(email: omraj@jarmohukka.fi)

Abstract

This paper explores the role of institutions in the development of water services – especially community water supply and wastewater. It is based on an extensive research programme on the evolution of water services in Finland that also compares our domestic development with international achievements since WWII.

The term *institution* is here used to mean the "rules of the game" while the term *organisation* is used to mean any of the "players". Institutions include both formal and informal rules, and often a large part of the latter are unseen. The paper deploys a wider view of technology development: (i) artefacts, (ii) processes, and (iii) knowledge how to apply (i) and (ii). It reminds of appropriate technology where we need a variety of criteria for technical, social, and economic appropriateness.

Water services are under continuous need of reassessment. Some changes may seem more dramatic short-term than in the longer term. Yet, they are relative and depend on the time scale used: operational (1 year), strategic (1–10 years) or visionary (20–50 years). Due to path dependence, major strategic decisions may even have an impact lasting over a century – to the futures and to the pasts.

The development paths have hardly ever been linear; on the contrary, the paths have usually divided into new development paths. In some cases, like when selecting a new raw water source, older paths may have been rediscovered. The driving forces seem to be linked to legislation and especially to water pollution control. Instead of dramatic ad-hoc reforms, overall water services evolution in Finland has mainly been based on the principle of continuous development.

In the future, we need to pay worldwide more attention to institutions as well as to management, institutional, policy, and governance issues, including the challenges of pricing and asset management of water services infrastructures.

Keywords: sustainability, institutions, path dependence, pasts, futures

1. Introduction

Water and wastewater systems are of fundamental importance to the development of communities and the welfare of people and nature. Water services – here mainly community water supply and wastewater services – will face huge challenges in the coming decades in Finland, Europe, and the rest of the world. If the current trend continues without major improvements, up to two thirds of mankind will suffer from chronic water scarcity and/or polluted water in 2050. In spite of its problems and challenges, Finland has been among the top countries in many international comparisons of water and environment management. The rapid structural change of society has also been reflected on our water services. A key challenge is to increase the weight of the invisible water services and systems in societal decision-making.

While there is a huge demand for further investments in water and sanitation systems worldwide, it is an even bigger challenge to improve the efficiency and functioning of the current systems. In both cases proper institutions, or rules of the game, are required.

Water services are managed and governed at lower levels and scale than water resources. As concerns the wider role of water in development, the International Law Association (2004) pointed out that water and wastewater services are *vital human needs* of communities. In other words, they are the most important purpose of water use (Katko and Rajala 2005). At least in the western world, water services, a fundamental, yet mostly invisible part of the community infrastructure, are taken for granted, assuming that they are available 24/7. As Golder et al. (2013) pointed out, water is one of the most taken-for-granted aspects of daily life. Yet, in most cases in developing economies, intermittent water services pose severe challenges for citizens, especially the poor.

Unfortunately, many developing and transition economies still lack water service systems, or they are inoperational, or provide service only for a few hours a day and cannot therefore be taken for granted. The World Water Development Report 2003 highlighted this major problem as follows: "Sadly, the tragedy of the water crisis is not simply a result of lack of water but, essentially, one of poor water governance" (UNESCO 2003). Accordingly, OECD (2015) reminds that "managing and securing access to water for all is not only a question of money, but equally a matter of good governance". Thus, there is an urgent need to assess recent experiences, identify good practices, and develop practical tools for assisting different levels of governments and other stakeholders for more effective, fair, and sustainable water policies.

2. Methods and approaches

This paper is based on cumulative experiences of a variety of studies by the Capacity Development in Water and Environmental Services research team at Tampere University of Technology (TUT) since 2000. The paper builds on material and research conducted by the author and the research team in some 80 research projects, 10 doctoral dissertations, and 25 MSc theses. The paper aims to explore the role and significance of institutions and their development within the overall development of water services. The paper is largely based on a project analysing the major findings on water services development within its wider institutional context after WWII and especially during the last decades, including implications for the futures. This study (Katko 2016) has been supported by several foundations and the Academy of Finland (no. 288153) which is highly acknowledged.

In this context of water services organisations, the definition of *institutions* by D.C. North, a Nobel Laureate in Economics, is here applied. He used the football (soccer) analogy and defined institutions as the "rules of the game" while organisations are the "players" (North 1990). The rules differ in size and shape. This New Institutional Economies (NIE) calls into question many ideas of the more classical schools of thought.

Andrews (2013) uses the iceberg metaphor for reminding that "a large part of institutional logic is unseen or below the water line because it is informal". He further reminds that institutional reforms can only work if they are tailored to the local context and therefore the so-called best-practice reforms tend to fail. Whereas, for instance, the World Bank links "institutional context" typically to laws and other regulations, Scott (cited by Andrews, 2013, 43) points out that institutions include regulative, normative, and cultural-cognitive elements.

Based on a sustained institutional framework, a distinction between service *provision* and *production* should be also made, as articulated by Ostrom (1990, 31) and Oakerson (1999). This distinction is important since in most countries such as Finland legislation puts municipalities in charge of providing or arranging the services, whereas services are produced or implemented by utilities or cooperatives. Yet, professional literature seldom recognises this fundamental difference (Katko and Hukka 2015).

Another key definition refers to the concept of *technology*. Here, technology is considered in a wider context which covers (i) technological artefacts, (ii) procedures, and (iii) knowledge required how to apply both (i) and (ii) (Leppälä 1998). A somewhat similar definition was presented by Jacob Bigelow (cited by Hughes 2004, 2–3) already in 1831 when he stated that "technology involved not only artefacts but also the processes that bring them into being".

Hughes (2004) further pointed out that technology is not limited to technological practices – often considered engineering – but ought to include also the processes that bring technology into being, namely invention and human ingenuity. Regarding engineering sciences, Naukkarinen (2015) identified five categories of doctoral dissertations at TUT: experimental design science, mathematical design science, naturalistic design science, explanatory inquiry, and interpretive inquiry. The categories may also overlap and they do not necessarily follow any faculty borders, showing the diversity of engineering sciences and technology development. Hukka et al. (2007) addressed the need for methodological and even philosophical diversity in water management since a single approach cannot answer to all of the research needs, and the fact that a bias in favor of a single research approach may prevent finding adequate answers to wider governance issues. Indeed, it is possible to create most valuable findings in areas that are between various disciplines.

In the late 1970s, Pacey (1977) discussed the dimensions of *appropriate technology*, and concluded that technology alone is not enough, but in addition we need a variety of criteria for technical, social, and economic appropriateness. In order to discuss technologies Pacey (1983) also introduced two major spheres: *user sphere* and *experts sphere* and argued that "good technology" should take advantage of both of these major spheres. Futures researchers have pointed out the *evolutionary nature of development.* This means that development and technology are not deterministic, but at certain points we will face bifurcation or turning points (Mannermaa 1991).

The relationships between the empirical data collected from the real world and the various theories used in this research programme and by the wider CADWES team are shown in Figure 1. Empirical data from the real world are to be tested by various methods, often according to the so-called PESTEL framework which categorizes environmental influences into six main types: political, economic, societal, technological, environmental, and legislative. The PESTEL framework has proved useful since it forces one to assess development in a wider institutional and socio-economic framework.

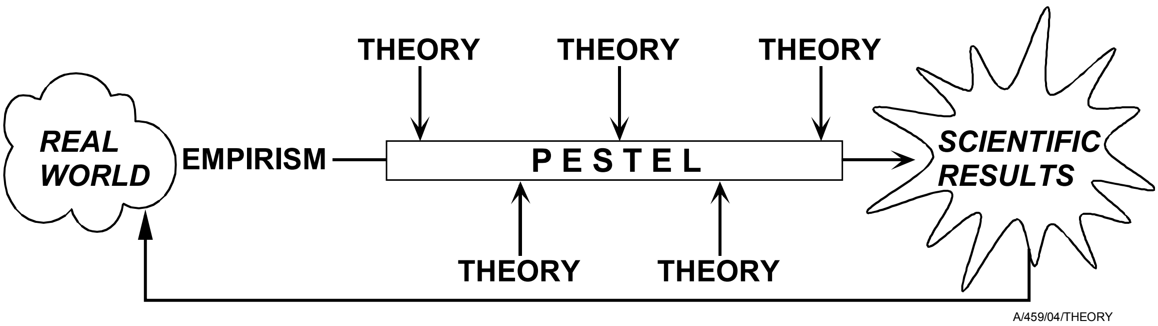

Figure 1: The major approach of the programme: relations between real word, empirism, research theories, and scientific results (Eskola 2001, 138; modified by the author)

3. Major Frameworks for Institutional Development

Water services in Finland are provided and produced at least at four different levels through various modes: from on-site to cooperatives, municipal utilities, and various types of inter- and supramunicipal arrangements (Table 1). These four levels are often connected to each other by various means. Municipal utilities are under public law whereas cooperatives are private. This diversity and multi-level governance describes both organisations and institutions. For some it may seem fragmented but in the Finnish conditions this "insdiversity" – different ways of providing services – gives flexibility to operate case by case based on local conditions. This is not to understate the challenges that they also have. In any case, the overall development is to take into account the connections between the various levels, bearing in mind the poem by Limerick (2012): "Rural and urban places, Are tangled together like laces. They´re like sister and brother, They have never been opposite cases".

As articulated by Ostrom (1990, 31) and Oakerson (1999), a distinction between service provision and production should be, however, made. This distinction is a major concern in most countries where legislation often puts municipalities in charge of providing or arranging the services which are produced and implemented by utilities. This distinction goes undetected by almost all parties involved and literature generally uses only the term "provision" without explaining its more accurate meaning.

Table 1. Four key levels of water services in Finland with their key characters (Katko 2016 forthcoming)

Level	*Features*	*No. of systems*	*Population served (%)*
On-site systems	*Dispersed rural areas*	*many*	*10*
Water Users Associations	*Villages and towns*	*1400*	*5**
Urban water and wastewater undertakings	*Water and wastewater often merged*	*300*	*50*
Inter- and supra-municipal systems	*Inter-municipal agreements* *Wholesale water* *Wholesale wastewater* *Regional water and wastewater companies****	*many*** *24* *12* *3*	*n.a.* *n.a.* *n.a.* *28*

** some 20 in large villages and towns* *** some continuous, some as reserve*
**** 2 stakehold companies owned by municipalities, 1 federation* *n.a. not available*

Through mere legislation and requirements, water services have many stakeholders and interest groups (Figure 2). Water entities at various levels produce services that in Finland are arranged by municipalities except for small and on-site systems. In fact, globally municipalities or other public authorities are owners of some 90 percent of water utilities, 95 percent of wastewater systems, and likely close to 100 percent of stormwater systems. Water utility board members are elected officials. Likely the core resource of any utility is competent personnel. Activities require economic resources obtained, ideally, by charges from customers – such as the case is in Finland – rather than through taxation. Local administration supervises the actions through regulations. The State and the European Union are in charge of legislation, policy, and regulation that are controlled by regional authorities.

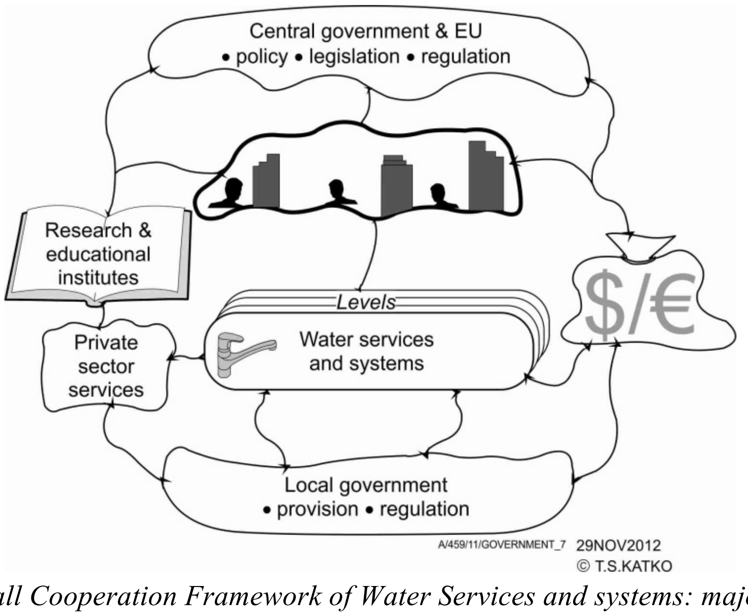

Figure 2: Overall Cooperation Framework of Water Services and systems: major stakeholders and their relationships (Katko, forthcoming 2016)

Water utilities buy services from the private sector as they have done since the beginning of the water systems (Juuti and Katko 2005). For the purposes of this study, we call this *public-private cooperation* instead of *partnership* that has been misleadingly used for the promotion of multinational companies and their long-term contracts, thus in practice reducing competition (Hukka and Katko 2003). Educational and research institutes create the basis for competences and human resources. As for lobbying for water services, the Finnish Water Utilities Association and the Association of Finnish Water Cooperatives are major actors. In addition, we have other direct or indirect stakeholders, which have their own specific roles. These include, e.g., health authorities, water protection associations, and regional councils. In any case, it is essential for each of the stakeholders to have a role that fits to the totality in the most appropriate way.

Another major feature of water services management is related to time. Nowadays futures and strategic thinking is used in many sectors for identifying and having influence on the development of services. The former "prediction" by futurologists has been replaced by futures research and forecasting that rather tend to have active influence on preferable futures and development paths. (Bell 1997) Yet, it is good to remember the argument by George Santayana (1863–1952) " those who cannot remember the past are condemned to repeat it".

Water services' futures can be explored through three different timeframes (Figure 3): operative daily actions (one year), strategic thinking (5–10 years), and visionary leadership (10–50 years). The thinner the rectangle, the less time is generally spent on it. The core of visionary thinking is that a sector or organisation tries to identify a state of futures which seems most preferable. Thereafter, from this visionary state, alternative development paths and strategies will be explored for reaching the identified state. Due to path dependence, major strategic decisions may even have an impact lasting over a century – to the futures and to the pasts (Kaivo-oja et al. 2004). Sometimes the argument "we are not interested in history, we are interested in the futures" is actually presented seriously. However, history and futures do not exclude each other. This misconception is mainly due to the path dependence of water services infrastructure development (Melosi 2000); certain strategic decisions have unavoidable long-term impacts.

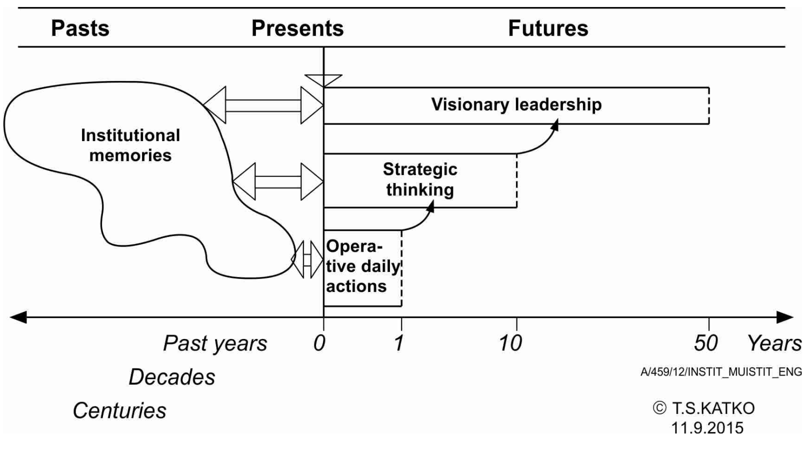

Figure 3: Timeframe for futures thinking and leadership: from operational to strategic and visionary thinking (Katko, forthcoming 2016)

At least in Finland, the selected major paths have hardly ever been linear; on the contrary, the paths have usually divided into new development paths. In some cases, such as selecting a new raw water source, older paths may have been rediscovered. The driving forces seem to be linked to legislation – especially to the requirements of water pollution control (Katko et al. 2006).

Water services are under continuous need of reassessment. In the short-term some of the changes may seem dramatic, but they are not necessarily so in the longer term. Such changes are anyhow relative and depend on the viewpoint and timeframe (Figure 4). In fact, the timeframe of water services development is exceptionally long, up to 125 years to the pasts and 125 years to the futures. Therefore, instead of one year "the quarter of water services" needs to be counted from a millennium, a fundamentally different timeframe. By no means is this to deny that daily operations are to be managed as well as possible; they should not be ignored.

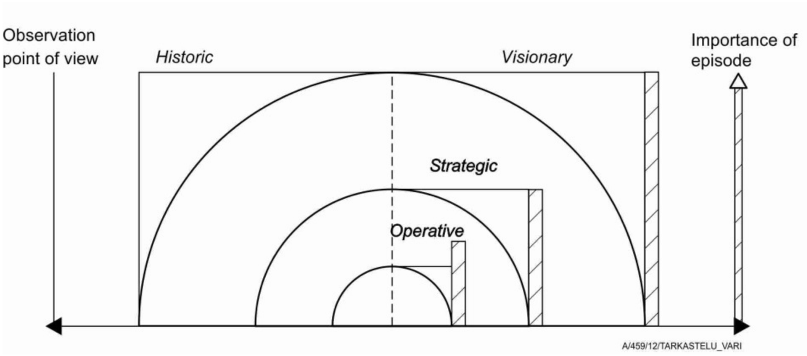

Figure 4: Suggested timeframe for water services of a quarter of a millennium: 125 years to the pasts and another 125 to the futures. The relative importance of change depends on the viewpoint and timeframe used. (Katko, forthcoming 2016)

4. Core and non-core activities of water utilities

In water services production public-private cooperation (PPC) has been practised in Finland since the early days. From strategic point of view one of the key questions is the division of core and non-core activities of utilities (Figure 5) and to what extent it is possibly feasible in various conditions to outsource the latter. Core activities may include main responsibility for required investments, strategic asset management, financial management, ownership, strategic thinking and management, bidding, business development, reputation and stakeholder management, as well as customer relations. Non-core activities, on the other hand, may include design, construction, equipment, spare and chemical supplies, vehicles and machinery, repairs, inspections, laboratory services, accounting, training, billing, meter reading, operation and maintenance, water and wastewater treatment activities, and research & development.

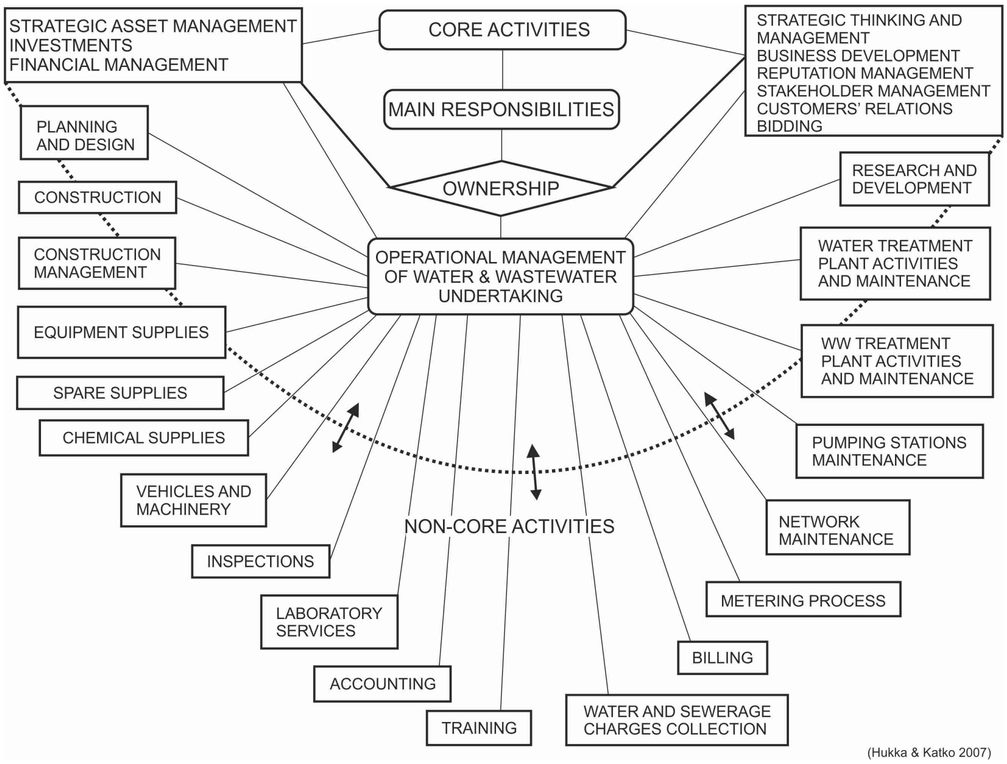

Figure 5: Core and non-core activities of water and wastewater utility (Kraemer 1998, 324; modified by Hukka and Katko 2003, modified by the authors)

Bearing in mind the difference between provision and production described earlier, the above-mentioned core and non-core activities are likely different for municipalities and, on the other hand, for water utilities. These may also be assessed through three different strategic functions: the first category being those obliged to municipalities by legislation, the second those being of major strategic importance to utilities, and the third other strategic functions.

The first mentioned core activities in Figure 5 are those closer to municipalities as utility owners. Utilities have their own strategic and operational functions. Under the latter, core activities and non-core activities can be identified. Thus, in reality the core activities and non-core activities in Figure 5 become even more complicated. In any case, it is of high importance that activities seen of strategic importance should not be outsourced.

From the point of view of education and research, it seems surprising how the current education and curriculum seem hardly to cover such strategic issues and the role of core activities. It is very obvious that these fundamental core issues cannot be left merely to continuing education and on-the-job training only. In spite of some trials on MSc Programmes or MBA programmes on Water Utilities Management, they seem not to get much ground. This is likely due to the prevailing focus on natural sciences and treatment technologies which are of course important as such. However, they are not able to give any answers to wider management, institutional, policy and governance (MIPOG) issues, such as the challenges of appropriate pricing and feasible asset management. Indeed, worldwide we have a huge challenge of proper asset management and need for rehabilitation to rates that are likely two- or even threefold compared to the present reinvestment rates. (Hukka and Katko 2015)

5. Discussion

Instead of dramatic ad-hoc (one-time) reforms that are not uncommon in developing economies, overall evolution in Finland has mainly been based on the principle of continuous development and determined policies. This has been very evident especially in water pollution control since the 1960s. On the other hand, it may be that flexibility could have been practised more. Perhaps an example of this overall finding is the Decree on Water Pollution Control in Dispersed Rural Areas passed first in 2003. In 2011 it was revised (196/201) and in 2015 it is on the Parliament table again. Changing rules of the game for several times does not sound feasible, although there might have been some obstacles in drafting the first version.

Most likely the biggest challenge of water services in the coming 20 to 30 years in Finland and also elsewhere will be aging infrastructure, especially deteriorating networks (Heino et al. 2011; Hukka and Katko 2015). The current state of the networks in Finland is satisfactory and it will get worse unless clearly more resources are directed to rehabilitation. Compared to the experiences gained from water pollution control it seems evident that we need better “rules of the game” and institutional arrangements if we want to avoid the collapse of the current water infrastructure systems. In the case of water pollution control clear requirements and enforcement were needed. In the case of aging water infrastructure more clear requirements on long-term investments will be needed, respectively. Sector professionals and utility managers also have to take this more seriously than so far in order to convince decision-makers on the matter.

As a whole, the ways of implementing water services are in any case highly dependent on *local conditions*. Available options should be always seriously considered and accumulated knowledge be used. In water services, private, non-profit systems are justified whereas international instances on profit-maximization have produced warning examples. However, the successes of any water services can finally be assessed only from the point of view of the results: how well they have fulfilled their societal objectives.

The challenge is proper asset management and need for rehabilitation to rates that are commonly two- or even threefold compared to the present reinvestment rates. In order to improve this situation it is necessary to pay more attention to institutions, the rules of the game.

6. Conclusions

The following major conclusions can be drawn on this paper:

(i) The timeframe of viable water services development is exceptionally long, up to 125 years to the pasts and 125 years to the futures, thus a quarter of a millennium.

(ii) In education and research on water services undertakings clearly more attention should be paid to strategic functions of municipalities as owners and on the other hand those of utilities.

On the whole, it is evident that to reach more sustainable futures and water services we need to pay more attention to institutions, "rules of the game", and even wider to management, institutional, policy and governance (MIPOG) issues including the acute challenges of appropriate pricing and feasible asset management.

Abstract

Water and sanitation services are basic requirements for the development of a nation. The provision of these services should necessarily be arranged by the national government through policies, and long-term and short-term plans. Moreover, follow-up of the implementation of principle in policies and plans will determine the service level on the ground. This paper is intended to explore gaps in the policy-making and implementation in the areas of water supply in Ethiopia. Review of Ethiopian water sector policy, universal access plans, growth and transformation plans and other literature are employed to achieve the objective of this paper. Moreover, the experiences of the first author that he acquired during data collection for his doctoral study are taken into account to draw conclusions. Hence, the study shows that standards set at the federal level fail to consider the actual situation on the ground and the experts at implementation level are to interpret some aspects of the policy ambiguously. Therefore, this paper recommends the policy-makers and higher officials to consult the people in charge of putting policies in effect to have contextualized and work for uniform desired-output. Service providers need to understand the notion of the receiving community in order to provide the services that satisfy the users.

Keywords: Services, policy, service provider and service producer, water supply, sanitation

1. Introduction

Well-articulated and in-depth organized policies alone cannot guarantee the achievement of the intended goals of a country. Rather, they need to be followed by systematic regulations and directives to put them into practice (Matland, 1995). Moreover, it is not only the policy-makers who require an understanding of the real problem to be solved and the mechanisms of alleviation but also every concerned member at various levels of the government, partner organisations and the receiving communities need to know to have a successful implementation. This aspect determines the thought of policy-making if it is top-down or bottom-up as explained by Matland (1995). It should also have a favourable platform to accommodate both internal and external actors.

Platforms that are provided by national policies and strategies could guide the way of actions of governmental and non-governmental organisations, and donors in a particular country. Either from the legal or logical point of view, external imposition cannot achieve a substantiated impact in terms of contributing to the developmental strategies of countries. Support in this context means helping countries to achieve their own goals, policies and strategies (MoWR, 2001b); otherwise, the effect will be retardation.

On the other hand, the detail of a national policy on a specific agenda is very critical to accommodate both local and external partners who work in a certain sector. If it lacks clarity and depth, the implementation will still be ambiguously challenging. Moreover, in the presence of excellent policies and directives, achievements might be trivial due to the way they are understood by the members of the implementing bodies both in the governmental and non-governmental organizations. Therefore, before going into a deep analysis of the situation in the country, let us see the points boldly mentioned in the Ethiopian water sector policy.

This paper is not to make a thorough critique of the entire water policies of Ethiopia, but to make a review where improvements are suggested on how to fill the gaps observed in the area of water supply and sanitation. The main question here is how accurately the policy flows down to the community though the intermediary government levels – in other words how the policy-makers control the effectiveness of the policies? Moreover, we will try to discuss the process of policy-making based on the facts in the national programmes and make conclusions accordingly.

The rationale for selecting this subject is the remarkable national effort to the development of water supply and the visible gaps in the sector. Moreover, the merit of the expertise of the authors in the field has agitated this paper. The first author has done his research on the rural water supply of Ethiopia since 2012 and the second author was involved in a project which works for the rural water supply of Ethiopia with the collaboration of the Finnish government.

The focus of this paper is to create awareness among the Ethiopian policy-makers in the way they can think of the future and how to monitor the effective policy-making and implementation. Moreover, the study is on Water, Sanitation and Hygiene (WASH) services in general with more focus to rural water supply.

2. Ethiopian water sector policy and development programmes

Based on the history of water resources development in Ethiopia, clear changes in the area of water supply and sanitation have been observed very recently (Behailu, et al., 2015). Moreover, the department, which was responsible for the water supply and sanitation, was not clearly placed appropriately until the active policy came into force in 2001. Earlier, the department was placed in different sectors where it had less attention, especially at the district level. During the years 2003-2004, when the administration of the country was decentralized, for the first time, a water desk under the natural resources department of the Agricultural development office was established at the district level (Calow, et al., 2012). In fact, currently, it is being transformed into an autonomous water office.

In institutionalizing the water supply and sanitation sector, the new millennium has a historical record. After the current active policy of the water sector enacted in 2001, several programmes and plans have been launched and are in operation to improve the life of citizens. These plans and programmes are water resources development strategy (MoWR, 2001b), Universal Access Plans (UAP, 2008; UAP-II, 2011 & UAP-III, 2011), WASH Implementation Framework (WIF, 2013), One WASH National Programme (OWNP, 2014) and Growth and Transformation Plans (I & II) (GTP, 2010 & 2015). These plans and frameworks have water supply and sanitation as a key component. Therefore, this paper will review them from the angle of water supply.

2.1 Ethiopian water sector policy and strategy

The Ethiopian water sector policy and strategy have comprehensively addressed irrigation, hydropower, drainage, water supply and sanitation. Water resources protection, management and optimization are well articulated in the policy, and in the case of limitation, water supply has been given priority (MoWR, 2001 a&b). The documents intensively describe the importance of clean water and sanitation as they are directly linked to the health problems of the country and base for the economic and social development (70% of the diseases in the country are waterborne (MoWR, 2001b).

As the focus of this paper is on water services, this section will review the policy and strategy from the angle of explaining water supply and sanitation. Moreover, water supply for urban and rural areas will be viewed differently since they have a different perspective in the documents. The role of administrating the urban water supply in Ethiopia is vested in the autonomous body consists of users or board. The board of the user council is responsible for rising investment capital and money for operations and, with a limited assistance from regional and federal governments, to seek loans in the case of large projects. In the case of urban water supply, the users are expected to cover the full cost – the initial cost and cost of Operation and Maintenance (O&M) (MOWR, 2001a).

In the case of rural[1] water supply, the source of initial investment is the government or external agents whereas O&M is the responsibility of the communities (Calow, et al., 2012; MOWR, 2001a&b). As a result, the policy stressed the need for user consultation to the development of such systems in order to create ownership feeling for active O&M. Thus, the success of rural water supply mainly depends on the availability of the government's capital budget and funds from donors and the O&M on the approach followed during implementations. This, in turn, significantly affects how the implementers understand the policy in the context of consultation and participation of the user community.

According to the Universal Access Plan, UAP (2008), the user community contribution should cover at least 10% of the capital cost of the projects, in order to motivate and create adequate ownership feeling. Moreover, users are deemed to cover the cost of operation and maintenance of their water system – cost recovery in the rural context is partial (MoWR, 2001a), only for operation and maintenance unlike to the urban water supply. The policy document has clearly pointed out water is not for sale since it is a public good. Therefore, service charges are to cover operations and maintenance costs, not for using the water resources. The cost recovery context here has been considered in different ways. Therefore, the tariff setting is left for the community and the rate is observed to be very small compared to the requirement for operation and maintenance (Behailu, et al., under review). According to national directives on policy and strategy, the role of tariff setting is left to the user community. Yet, the amount they agree to pay is not sufficient to cover increasing prices of spare parts.

To smooth the implementation of the policy, detail procedures and directions are provided in the water sector strategy. The strategy contains the ways the policy of water supply and sanitation from technical, financial, institutional, capacity building, social and environmental aspects. In general, it is more concerned to provide sustainable, effective, efficient, reliable and affordable services. Maybe due to the high proportion of the rural population, it recommends hand pumps as the best means to expand sustainable service. In practice, however, hand pumps are limited to the areas where there is shallow groundwater table and not universal in terms of availability. Moreover, it is susceptible to climate change as shallow groundwater is easily affected by the amount of direct recharge. Therefore, the strategy did not provide alternative solutions for the areas, which do not have plenty of surface and groundwater resources. Hand pump water systems that are installed in shallow wells will not guarantee sustainable services in communities with rapid population growth, areas that are affected by climate variability now and then, and water resources are in a declining trend.

In terms of finance, the implementation of water supply in rural areas is advised and supported by the local financial institutions like micro-financial institutions, local saving institutions and banks to access loans to implementation, operation and maintenance of water supply and sanitation systems. This is, actually, to supplement the external supports and government

[1] Rural in Ethiopia accounts for 84% of the approximately 100 million populations.

subsidies for water supply development. The strategy emphasises to maintain social equity by providing a subsidy for those who are not able to cover the cost of their services (MoWR, 2001b). However, the majority of rural communities are not able to finance water supply projects. Thus, this situation is making the work in water supply difficult to finance and address all in a short period.

Ensuring transparency, fairness, responsibility, and accountability in utilizing and managing of the WASH funds are the priorities of the strategy of the water sector. According to Calow, et al. (2012), the country has managed to maintain corruption on a low to medium level in rural water supply. However, the efficiency of systems requires improvement to operate at their full capacity.

In terms of training in the capacity building, the national water resources development strategy has attractive capacity building scheme (MoWR, 2001b), but it lacks the proper way to handle the existing trained staff not to migrate out. The shift of personnel from one organisation to the other does not matter to the overall performance of the sector, but there are areas that suffer heavily – rural areas where technical staffs do not like to work due to the lack of facilities and incentives.

2.2 Water supply in the Universal Access Plan I & II

The first Universal Access Plan (UAP) was for the period 2006-2012 and its target was to achieve the water supply coverage of 98% as a country including both urban and rural areas. The core of the first UAP was community mobilisation. Creating awareness among the community is crutial to handle the system sustainably. However, the plan was revised in 2011, to harmonize with the GTP.

In the revised version of the UAP, the rural and urban water supply were separated and designed to achieve 100% of coverage by 2015. However, the levels of services remained the same as in the previous plans such as 15 litres for rural and 20 litres for urban per capita per day in the radiuses of 1.5 km and 0.5 km, respectively.

In terms of the technical details, UAP-II has comprehensive plans that hold technical, financial, institutional and social aspects. Moreover, it has plans for operation and maintenance, rehabilitation and expansion. Otherwise, all documents of UAP have detailed the explanations of implementations of water supply systems both in rural and urban areas.

At the end of 2015, the objectives of any of the three plans have not been achieved. On top of that, the second Growth and Transformation Plan has already started with new standards, 25 litres for rural and 40 – 100 litres for urban water supplies. This implies that the new UAP will be expected very soon.

2.3 WASH Implementation Framework (WIF)

WASH Implementation Framework (WIF) is a framework formulated by four Ministries in Ethiopia, all directly involved in water supply and sanitation implementation. The goal of the framework is to bring fragmented efforts together to improve their impact. The Ministries involved in the framework are Health; Water, Irrigation and Energy; Education and Finance. In one way or the other, these Ministries have been taking part in the development of water supply and sanitation, thus, they sat down together to harmonize their efforts for greater impact.

The key elements in WIF are integration, harmonization, alignment and partnership (WIF, 2013). These elements are also the starting point in implementing One WASH National Program (OWNP, 2014). It means that WIF has paved a way for OWNP by creating a common understanding of the four ministries, which are involved in water supply and sanitation implementation.

The point that needs to be encouraged is the action taken to harmonize the activities of WASH in the country that was fragmented. The effort of integration in the country will, at least, reduce the cost of information, and duplication efforts in the same areas. On the contrary, actors in the sector did not give attention to local situations. It seams that they are still think that one principle will work uniformly everywhere in the country. For instance, a uniform system intended for all areas will not funcion ideally in both agrarian and pastoralist areas. In the national policy, "water supply" includes the domestic consumption and water for cattle. Therefore, water supply services in the context of pastoralist have a wider perspective than water supply for the area where their livelihood is typically agriculture. However, the framework is sticking to 15 litres per head per day as a target to achieve.

However, the commitment of the ministries to lay the foundation of harmonization and paving the way to One WASH National Program is appreciable. This is due to the fact that the experiences of many other countries still lack the concept of resource harmonization and avoiding working independently without coordination.

2.4 One WASH National Programme

The principle of one budget, one program, and one report is the motto of One WASH National Programme (OWNP). Its objective is to harmonize actors in the sector. This actosrs are including donors, partner organisation (NGOs), and governmental organisation and the private sector. In the conventional way of implementation, these actors operate separately based on their preference and hence their outputs achieved can not be measured. Moreover, different actors would have worked in the same area and caused duplication of efforts. Following the WIF, the coordination of the four ministries mentioned above created a fertile ground to establish one WASH. The national government together with regional counterparts and partner organisations should lead the development direction as outlined in the OWNP.

OWNP is launched in 2013 and is now in the implementation phase. The programme is expected to bring harmonized campaigns in the sector to address the marginalized rural, especially who are situated in the most remote areas without accessible roads.

2.5 Water in the Growth and Transformation Plan I&II

An amazing plan that has created big questions among the citizens of Ethiopians is known as Growth and Transformation Plan (GTP). It was launched in 2010 with ambitious goals that seem unachievable throughout the development sectors in the country. The plan was designed for five years and the second GPT has already started as of July 2015. Grand Renaissance Dam, Addis Ababa light train, Djibuti – Addis Ababa and Awash – Waldia – Mekkel express train projects are a few that are observed changing the image of the country. Water supply, as one of the development sectors in the country, has similar attention in the growth and transformation plan. Although the initiation of the government on the development is very appreciable, there are doubts among the citizen on the effectiveness of the plans in the short periods of the plan horizons. As indicated in Figure 1, the horizontal axis shows water supply coverage under different service levels. According to the national government, each service level has denoted by each GTP and each GTP is assumed to promote the country from one economic level to the other. In 2010, the country has designed a plan to grow from the least developed status of the lower middle income and then to the upper middle income level, before promoting to the status of the developed economy in three consecutive five-year-plans. However, it is hard to judge how many GTPs can transform a country from one economic level to the other.

Urban and rural water supply targets of the previous GTP were 20 litres per capita per day for urban and 15 litres for rural areas. Having these figures in mind the country could not achieve full coverage with this level. Nonetheless, the country again displayed a new standard of quantity supplied – 25 l/c/day for rural and 40-100 litres for urban – based on GTP 2. In fact, the service level increases through change of GTP and economic.

The point that we want to discuss at this juncture is that how the water supply systems, which were constructed for the previous standards could better fit in the new standards. Moreover, natures of the water supply schemes in the country are not in a capacity to render the GTPs proposed service level.

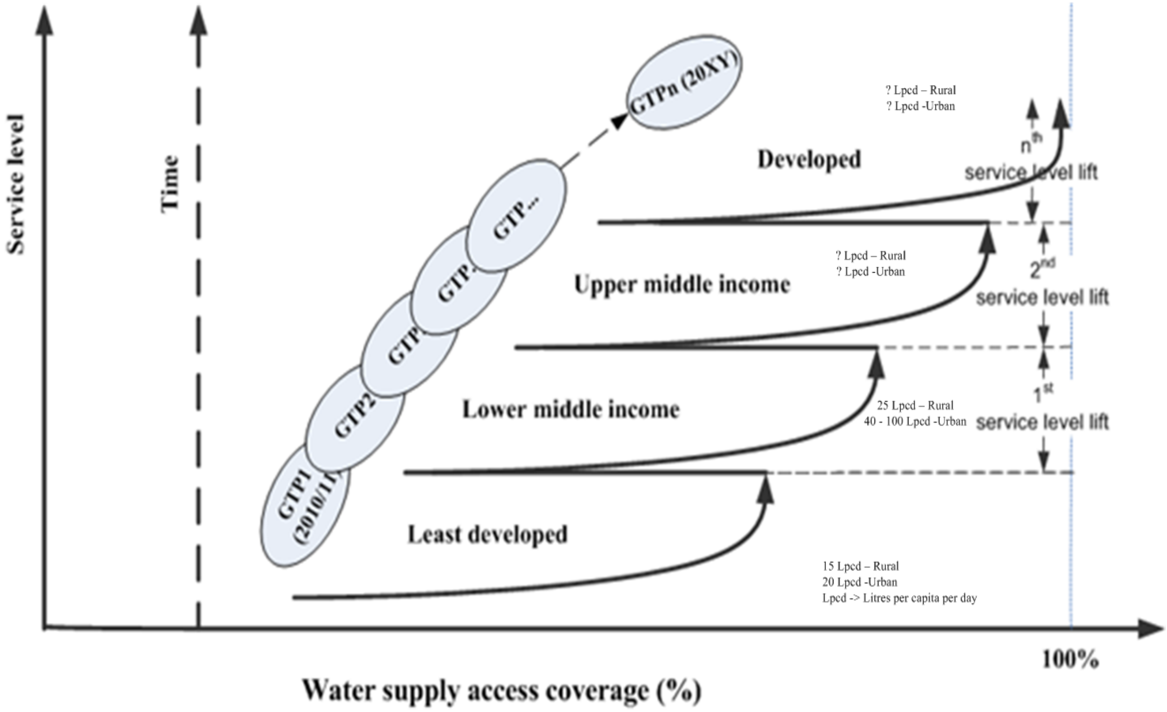

Figure 1: Tracking the Spiral Uphill Journey Path to Water Supply Universal Access to the Highest Service Level (modified from Mekonen, 2015)

3. The existing situation of services

Matland (1995) explained the top-down approach of policy-making manifested by three important drawbacks, such as lack of addressing the public objectives, excluding users and lack of a boundary between administration and policy. From these aspects, the Ethiopian water sector policy could fall under the top-down approach due to the following reasons: (1) the implementations at grassroots level are lacking pure knowledge about the policies, (2) interests of the community are not well addressed – they are driven by the consent of implementors and (3) the administration of the country is led by the political environment.

Ethiopia was celebrated for the achievement of Millennium Development Goal target 7 C in March 2015. The water supply coverage was improved by 57 % for the last couple of decades. The achievement was evaluated based on the national standard for rural and urban. The rural people are assumed to get 15 liters per capita per day and the urban 20 liters per capita per day and within the distances of 1.5 and 0.5 km, respectively (UAP, 2011). However, the study conducted in two regions of the country showed that the water supply coverage is highly subjected to insufficient service, particularly from quantity point of view. At least 40% of the populations are still without any water service. Therefore, the central point of this paper is to answer a question “How much service providers are concerned about sustainable services of the system they are in charge of?”

The served populations of the country are still uncomfortable about the service they are getting. In rural area at least 75% of the served population gets water less than 15 litres per day, which is below the national standard. Furthermore, almost all cities in the country have frequently experienced service breakdowns and a shortage of supply. For instance, Addis Ababa (the capital city); Adama, Dire Dewa, Bahirdar, Harar, Hawassa and Mekele (Regional Capitals) and other small cities usually report for residents' complaints about water scarcity. The causes of the problems might be various, but the dominant ones are poor standards of provision and production, the instability of technical personnel, and lack of commitment to feel the pain of the end user.

Ethiopia is a country that has various climatic conditions and standards of living. Some cities have a temperature low enough to freeze water in the pipelines and some have an average temperature of over 40 degree Celsius. However, the national standards do not consider these disparities. This can be good evidence of the gaps that exist between service providers and producers. The technical personnel are more concerned in discharging their responsibility than the provision of adequate services.

According to the Ethiopian governmental structure, the district level is the most important governmental entity in facilitating services to the rural communities. However, the facilities and salaries at that level cannot attract skilled manpower. Regional, federal or non-governmental organizations attract skilled manpower. As a result, staff turnover is a common and known practice in the country. One of the threats in the growth and transformation plan (GTP) is also marked as staff turnover – 60% of skilled manpower from the total required expected to be available during the plan period. The implication of this is that the service providers are not ready to understand the rural community and not significantly concerned about the sustainable services.

4. Conclusions

The last two decades have been extraordinary for the water supply and sanitation in Ethiopia. In terms of providing policy, regulations, strategies and plans many have been done since 2001. Moreover, physical implementations of services are not insignificant, although diversified plans have been introduced to improve the coverage of the services. However, from the criteria of top-down and bottom-up approaches, the policy dominantly looks fitting the top-down approach. For example, 15 litres per capita per head is a national standard of the rural community in the country with diverse climatological regions. If the policy was bottom-up, the policy-maker would understand that this amount is not enough.

From the view of creating ownership feeling, the national government has a regulation to keep the public participation to make at least 10% contribution. The basic objective of contribution is not primarily to seek money, but to retain the involvement of the users to feel ownership and make them able to manage the systems after the implementation. However, in practice, the people at the implementation level can feel it as a burden that they must provide participation level to the government to prove the involvement of the communities. In this regard, the way of participating is not achieving its target in many cases.

Therefore, the national policy needs to be extended to every stakeholder and confirmed if policies are implemented in the sense of its original objective. Moreover, service providers or producers must shoulder the responsibility of providing intended services. To materialize these, actually, there must be a forum to create understanding among users about the future of the systems.

Abstract

During winter maintenance in Norway 2014-2015, 225 445 tonnes of chemicals were used and 1 610 000 km driven while removing snow and ice on national and state roads. Despite this significant amount of chemicals and distance, winter maintenance is often omitted from current environmental studies of roads and transportation. Current studies focus primarily on vehicles, fuel technology and construction activities. This focus has been based on the fact that these are the largest source of emissions from road transportation. However, as vehicle and fuel technology advances and have less impact per unit, other aspects of transportation, such as maintenance and operation of infrastructure become increasingly important and should be included in LCA studies of roads in cold climates. In this study, life cycle analysis (LCA) is used to estimate the environmental impacts of the production, transport and distribution of chemicals during winter maintenance in Norway. The study is based on reported quantities for winter maintenance during an average winter between 2010-2015. The functional unit is set as anti- and de-icing operations on national and state roads per km during winter an average winter from 2010 through 2014. The results show that environmental impacts from winter maintenance are significant, and thus we argue that winter maintenance should be included in LCA of roads in cold climates. Further investigations on current winter maintenance methods and future options are to be conducted in order to avoid solving one problem while creating another one (problem shifting) during policy development.

Keywords: Winter maintenance, highway, life cycle analysis, environmental impact, anti- and de-icing

1. Introduction

The transportation sector is estimated to be responsible for over a quarter of greenhouse gas (GHG) emissions in the world (Chapman 2007, European Commission 2015). Direct emissions from road transport are the single largest source of GHG emissions within the transportation sector, and therefore emphasis on vehicle technology and emission reduction in the use phase has been dominant (European Commission 2015). However, GHG emissions and the resulting global warming potential (GWP) is not the only impact transportation has. Other impact categories include ozone layer depletion (ODP), acid deposition and reduced air quality in urban areas, which affect human health (Colvile, Hutchinson et al. 2001).

As transport and transportation infrastructure are essential to our society, the construction of new and the handling of existing infrastructure has become a cornerstone of sustainable development (Reza, Sadiq et al. 2014, Santos, Ferreira et al. 2015). Sustainability in transport is only achieved if all aspects are optimized. Therefore, planning and designing new infrastructure as well as maintenance of existing ones are essential as roads are rarely dismantled but rather reconstructed (Stripple 2001). To be able to take into account all aspects of infrastructure life cycle analysis (LCA) is a tool often used. LCA accounts for emissions throughout the whole life cycle of a product or a service from production to the end-of-life. Additionally, LCA is useful to avoid problem shifting.

Several LCA studies have been directed at road infrastructure. These studies focus on various aspects of the transportation sector including fuel use, road construction materials, pavement options, lighting and vehicles (eg. Birgisdóttir, Pihl et al. 2006, Zhang, Keoleian et al. 2010, Huang and Parry 2014, Huang, Bohne et al. 2015). In addition, several reports have also been published especially the report by Stripple (2001) is of importance as a practical guide to LCA inventory analysis of road construction processes. Many of the processes mentioned in the report have been studied while other processes, like winter maintenance operations, have not been sufficiently explored. It is becoming increasingly important to include these operations in LCA studies on road and transport in colder climates as vehicle and fuel technology advances have led to less impact per unit.

The aim of this study is to estimate the environmental impact of anti- and de-icing operations in Norway. The results are presented in a way that allows for further use in other studies so that anti- and de-icing impact can be included in future LCA studies of roads in cold climates.

2. Winter Maintenance Operations

The general goal of maintenance operations is to ensure mobility and traffic safety, limit environmental effects, provide good service and take care of the road infrastructure capital that exists (Statens Vegvesen 2014). One of the most important method for achieving this is friction control. Friction between the tire and the pavement is essential for control of the vehicle and effects acceleration, breaking distance and directional control. Friction control is achieved by either salting or sanding, where salting is used on roads with heavy traffic while sanding is more common on road with lower traffic (Norem 2009).

In the report *National Plan of Action for Road and Traffic Safety 2014-2017* (Statens Vegvesen 2015), where the goal of zero casualties is presented, it is shown that fatalities and severe injuries are most likely on national and state roads with total share of 37% and 45% respectively. Fatalities directly linked to weather and driving conditions were on average 16% of the total fatalities in the years 2005-2012. The category where the speed is well over the speed limits, or higher than road conditions allow for, has a share of 45% of the fatalities (Statens Vegvesen 2015). This could be directly related to road conditions. It is, however, known that drivers do not adjust their speed in proportion with reduction in road friction (Norrman, Eriksson et al. 2000). The report lists several measures to reduce incidents that include:

- Increased user awareness
- Control measures
- Motor vehicle measures
- Measures on roads.

Winter maintenance falls under the category *Measures on roads:* clearing of snow, increasing friction as well as training winter maintenance operators. Winter maintenance operations are often complicated and unpredictable and require vigilance. Of the more important tools that winter maintenance operators use are weather forecasts. However, the forecasts' quality and reliability varies, as does local situation and sudden changes in both temperature and precipitation. In a standard for operation and maintenance for roads, there are guidelines for activities that winter maintenance operators are to follow. These activities are, for example, to monitor the situation visually and through the weather forecast, use anti-icing when needed as well as de-icing and mechanical snow- and ice-removal (Statens Vegvesen 2014).

The term anti-icing is used for the action of applying chemicals to prevent wet pavements from freezing by lowering the freezing point of the water. De-icing is the act of using chemicals to remove snow and ice that have already bonded with the pavement. Additionally, chemicals are used for anti-compaction purpose where the chemicals weaken the bond between the snow crystals and prevent the snow from forming a hard crust and bonding to the pavement surface making snow removal easier (Wåhlin and Klein-Paste 2015).

In Norway, highway winter maintenance has evolved over the past decade from reactive operations towards more proactive actions. A study conducted in North America regarding operators experience shows that most winter maintenance operators felt that anti-icing and pre-wetting helped them to improve roadway safety as bare pavement was achieved more efficiently and made mechanical snow removal easier (Cui and Shi 2015). Even though salting is very helpful in winter maintenance, it is not always appropriate. In Figure 1 the temperatures and precipitation (in mm water equivalent per hour) where salting is advised, not advised or should be done with caution are presented.

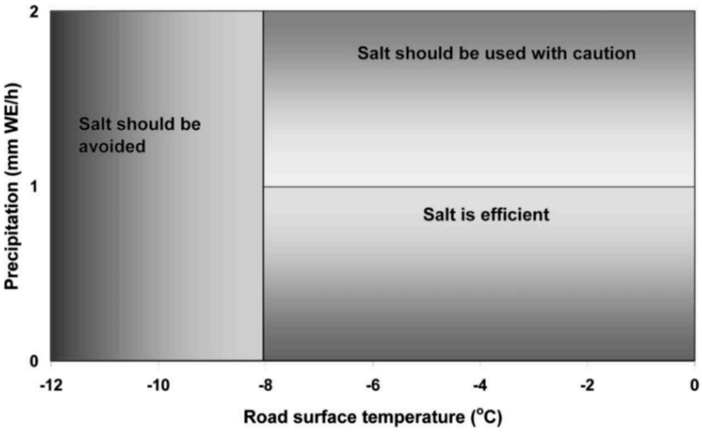

Figure 1: Weather situation and salting efficiency (Norem, 2009 p. 115)

The lower the temperature, the higher the concentration of salt must be in order to efficiently prevent ice formation and to reduce the risk of bonding between both snow crystals and snow crystals and the pavement surface. Therefore, the salt quantity is highly dependent on these weather situations shown in Figure 1 where the highest consumption is then when the weather is cold and with precipitation while salting is most efficient for temperature -8 to 0 degrees Celsius with fairly low or no precipitation (Norem 2009).

Other factors affect the amount of salt on the road are dependent on three physical processes: the initial loss, the dissolution of salt and the loss of salt (Lysbakken and Norem 2011). The initial loss of salt occurs when it is spread to the roads by wind or turbulence from the winter service vehicle (WSV) itself or because of the speed of the vehicle and spreader. The initial loss can be reduced by pre-wetting or by spreading brine. Other factors such as road surface conditions and texture as well as wind also affect the initial loss of salt. Dissolution of salt in water or brine on the road surface is mainly affected by the solubility of the chemical used and the dissolution rate. The process of salt loss includes several process where the salt leaves the road surface. These processes include salt lost by traffic as either blow-off (dry) or spray off (brine) and finally the runoff (Klein-Paste 2008). It is important that winter maintenance operators are aware of these physical processes.

3. Method

LCA is often used in assessing environmental effects from products and services in order to avoid problem shifting. LCA is therefore a very suitable tool in assessing environmental impacts of winter maintenance operations. An LCA study is conducted in four phases. First, goal and scope are defined; this includes defining the functional unit and system boundaries. Then inventory analysis is conducted where all physical products that go in and out of the system are accounted for. Environmental load of these flows are then calculated to form an impact assessment and finally the results are interpreted (International Standards Organization 2006). During each of these phases, the previous and next phase should be reconsidered in order to make any necessary changes that are revealed during the investigation. The LCA software SimaPro was used for this study, with the ecoinvent database (Weidema, Bauer et al. 2013) and calculations made with CML baseline impact assessment method.

It is very important that the inventory is carefully executed and accurately reflects use of any equipment, materials and energy. Poor inventory will only lead to high inaccuracy and maybe even wrong environmental impact results at a later stage.

3.1 Goal and Scope

The goal of this study is to map and analyse the activity of anti- and de-icing operations in Norway. The system boundaries are limited to winter maintenance operations; specifically anti-icing, de-icing and anti-compaction for increased friction and making ploughing easier. Within the system boundaries are material production and transportation as well as storage but also equipment and energy use. However, the chemicals effect on the environment after distribution is left outside the system boundaries due to lack of data.

By mapping the activities, a detailed inventory can be made to realize resource intensity. The study covers average winter maintenance operations in Norway for winters 2009/2010 through 2014/2015, from now on referred to as winter 2010 through 2015, on national and state roads. Mechanical snow removal is however outside the scope of this study.

The results are intended to be available for use by other LCA practitioners as well as winter maintenance personnel. Therefore, the results will be set up systematically, making it possible to contribute to other LCA studies that have results per kilometre to give an indication of the environmental impacts of winter maintenance.

3.2 Functional Unit

The functional unit is the very corner stone of any LCA but finding a suitable functional unit within the transportation sector can be difficult. This difficulty stems from large variations in design, location, material use, geographical profile, transportation distances and traffic load. In this study, the functional unit is the *anti- and de-icing operations on national and state roads per km during winter an average winter from 2010 through 2014*.

4. Life Cycle Inventory

The inventory for winter maintenance is quite complex and different from a more common product based inventories. It is different in the way that there is no standard recipe for achieving safe roads during the winter season. Therefore, it is necessary to base the calculation on an average. Whether it is most suitable to have an average based on the previous winter or if the last five should be used, is debatable. In this study the average of the last 5 winters was chosen as they are believed to be well documented and give good representation of an average winter in Norway. These averages will then have to be presented per kilometre for all different types of equipment, materials and transportation distances. There are few things that are constant, or could be assumed constant, between seasons. Locations of the distribution storage for example, where the ships dock and the salt is unloaded and stored, can be assumed to be fairly constant as the biggest importers have the same or similar locations (Aslaksen 2015, Heggedal 2015). In the following section, necessary equipment and materials needed for winter maintenance are listed along with important background information.

4.1 Equipment

Equipment in winter maintenance mainly refers to the winter service vehicles (WSVs) such as trucks and their extra equipment. Extra equipment includes tanks, salt/sand spreaders and the different types of blades and ploughs. However, it also includes information about storage facilities for the salt and sand regarding type of storage, the location and possible energy use. In Norway, the most commonly used WSV is a truck or a tractor with mounted a spreader, plough, grader or loader. For highways, trucks with a mounted plough or a grader and salt spreader are the most common. These vehicles mentioned are used during and right after a weather event. Additionally, other WSV might be needed soon after a weather event to clear areas of snow for example to improve visibility or to remove compact snow and ice from the road. (Sivertsen 2015). The WSVs are owned and run by the contractors that are awarded contracts for approximately 5 years at a time. The quantity of vehicles in use during winter season is therefore difficult to determine.

Storage facilities are located at or near the shipping docks near the largest cities. These places are assumed to have storage facilities, which are warehouses with a roof and four walls. As they are assumed to have no heating and are used for a long time, they are insignificant in terms of emissions. The storage is therefore omitted from the inventory analysis.

4.2 Materials

Winter maintenance materials includes the chemicals used for anti- and de-icing. According to major importers of road salt and the largest contractors for winter maintenance operations on national and county roads, the largest share of salt is used in the south, west and mid-Norway to around the area of Trondheim. Information about the storage locations are obtained from Mesta (Heggedal 2015) and GC Rieber (Aslaksen 2015). Table 1 presents major storage facilities as well as quantity of salt in each location and percentage of the total imported salt.

Table 1: Location of salt storage facilities, quantities and share of total imported salt

Quantities / *Location*	*Salt [tonnes]*	*Percentage*
Oslo	*65 282*	*32%*
Arendal	*53 408*	*26%*
Stavanger	*52 511*	*26%*
Ålesund	*11 192*	*5.5%*
Trondheim	*11 192*	*5.5%*
Harstad	*4 602*	*2.3%*
Hammerfest	*4 602*	*2.3%*

The quantities of salt that are estimated to be at these locations are based on documentation from Norwegian Public Roads Administration (NPRA) and supported by information from importers and contractors. Reported quantities of salt used in Norway seem to be stable the last years and variations can be explained by changes in weather. However, when looking farther at years prior to the years included in the study, we can see that the use of salt has increased drastically. This increase is due to salt now being used on a larger portion of the road network (Sivertsen, Lysbakken et al. 2011). As mentioned previously, anti- and de-icing operations are beneficial within a range of approximately 0 to -10 degrees Celsius. This reflects well in the information from both importers, contractors and NPRA where salt quantities are lower per kilometre in the northern and in inland regions.

Note, that the impact assessment method used does not account for the salt itself during production. Which means that the production phase accounts for materials and energy used during production as well as equipment but not any effects of salt on the local environment at the excavation site. Additionally, there are no available LCA information about the effects salt has on the environment after distribution. Therefore, effects of salt after distribution are not included in the results. However, there are few things that should be mentioned.

The focus of available environmental impact studies are on the effect of salting on the ground, surface water, soil contamination and stress on vegetation (Fitch, Smith et al. 2013). Environmental impacts of salt are localized and are dependent on various aspects such as road location and weather where precipitation, temperature and wind are of importance. The salt mainly goes directly into roadside lakes, with run-off water to nearby lakes and streams or to roadside vegetation and soil (Ramakrishna and Viraraghavan 2005). During winter, road salt is released into nature in pulses, which can lead to a rapid change of salt in the surface water. This rapid change can have deteriorating effects on the water quality. It has been shown that chloride levels in roadside stream increase dramatically and is carried downstream. With a continued build-up of chloride in lakes, it can have serious effect on the use of the water in the future. Additionally, a large proportion of the salt can leach into the groundwater where drinking water supplies can be effected by the chloride concentration. Salt contaminated run-off water may impact surface water in several ways. It can alter both physical and ecological characteristics of lakes with insufficient mixing of denser deeper layers and fresher upper layers. Seasonal mixing is essential for oxygen transfer in the lake that is necessary for continued animal and plant life in lakes. Toxic metals in sediments can also be release as a result of high salt concentration in water bodies. Release of toxic metals such as mercury can lead to lake stratification which again effects animal and plant life (Ramakrishna and Viraraghavan 2005)

The effects of salt on soil are not as serious as the effects on water. However, it has the potential to increase overland flow, surface runoff and erosion while decreasing soil permeability and aeration. The impact of salt can therefore be assumed to potentially increase emissions that contribute to categories like fresh and marine water aquatic ecotoxicity and terrestrial ecotoxicity.

4.3 Transportation

Transportation of salt is an important factor as the distance are significant. Transportation starts at salt excavation point where it is transported to the harbour. From the harbour, the salt is transported on freight ships to Norway, specifically to the locations introduced in Table 1. To estimate the freight transportation distance an online tool was used (McGraw Hill Financial 2015) and the results can be viewed in Table 2.

Table 2: Shipping distances to the different storage facilities

Origin / Destination	*Spain*	*Tunisia*	*Germany*
Oslo	*4812*	*5274*	*963*
Arendal	*4513*	*5076*	*680*
Stavanger	*4410*	*5052*	*789*
Ålesund	*4621*	*5441*	*1248*
Trondheim	*5252*	*5712*	*1698*
Harstad	*5941*	*6276*	*2385*
Hammerfest	*6536*	*6628*	*2982*

It can be assumed that around 35% of the salt comes from Germany in the form of salt stone, while the remaining 65% come from Spain (25%) and Tunisia (40%) and are from salt lakes. To be able to calculate the environmental impact of the transport, it is important to find the average distance a kilogram of salt travels. Here the distance travelled with a freighter is 3620 km on average for each ton of salt.

The large centralized storage facilities are natural pick-up points for operators. The operators often collect salt on 30-tonne trailers (with a hanger) and either take the salt straight to distribution or drive to de-centralized storage for later use. Additionally, some of the salt is transported on smaller boats to local operators' storage facilities. The transportation distance from the central storage to a de-centralized storage is not taken into account, since commonly distributed directly.

4.4 Distribution

To be able to estimate the distribution distance, the salt quantity, which lies between 15-40 gr/m^2 (Statens Vegvesen 2015), was assumed 20 gr/m^2. The distribution distance can then be roughly calculated from the reported salt quantities used in each region. The result from these calculations are shown in Table 3. The table shows the distribution distance in kilometres for each region for year 2010-2015.

Table 3: Calculated kilometres driven during distribution of salt in each region

Year / Region	2010	2011	2012	2013	2014	2015	Average
East	*426 668*	*501 768*	*433 676*	*477 357*	*470 163*	*488 178*	*466 302*
South	*391 471*	*335 939*	*320 923*	*380 691*	*434 672*	*425 230*	*381 488*
Vest	*340 356*	*501 045*	*394 496*	*387 557*	*205 079*	*421 931*	*375 077*
Mid	*150 203*	*207 287*	*165 165*	*140 706*	*116 555*	*179 360*	*159 879*
North	*56 125*	*54 197*	*59 319*	*70 142*	*59 091*	*95 620*	*65 749*
Total	***1 364 823***	***1 600 236***	***1 373 578***	***1 456 463***	***1 285 560***	***1 610 318***	***1 448 495***

The average distribution distance is then used to calculate the emissions per kilometre. When mechanical snow removal is conducted, which is not included in this paper, salt is most often also distributed at the same time. However, the distance calculated here is assumed to be attributed only to salting. This is done instead of reducing the distance by attributing some of it to mechanical snow removal and then adding extra distance to account for distance driven during observation.

5. Results

The results are presented for 11 impact categories. The impact categories and the origin of the emissions are shown in Table 4, where it is clear that distribution of salt in Norway is the major contributor to all impact categories, with more than 99% share of total emissions.

Table 4: Impact results per kilometre road in Norway during one average winter

Life cycle stage / Impact category	Production	Freight transport	Distribution	Total emissions
Abiotic depletion [kg Sb eq.]	*0%*	*0%*	*100%*	*2.42*
Abiotic depletion [MJ]	*0%*	*0.02%*	*99.98 %*	*1.4×10^{7}*
Global warming [kg CO2 eq.]	*0%*	*0.02%*	*99.98 %*	*8.8×10^{5}*
Ozone layer depletion (ODP) [kg CFC-11 eq.	*0%*	*0.01%*	*99.99 %*	*0.16*
Human toxicity [kg 1,4-DB eq]	*0%*	*0.01%*	*99.99 %*	*4.0×10^{5}*
Fresh water aquatic ecotox. [kg 1,4-DB eq]	*0%*	*0.01%*	*99.99 %*	*1.1×10^{5}*
Marine aquatic ecotoxicity [kg 1,4-DB eq]	*0%*	*0.02%*	*99.98 %*	*2.7×10^{8}*
Terrestrial ecotoxicity [kg 1,4-DB eq]	*0%*	*0.01%*	*99.98 %*	*1.4×10^{3}*
Photochemical oxidation [kg C2H4 eq.]	*0%*	*0.07%*	*99.93 %*	*1.5×10^{2}*
Acidification [kg SO2 eq.]	*0%*	*0.11%*	*99.89 %*	*3.0×10^{3}*
Eutrophication [kg PO4--- eq.]	*0%*	*0.05%*	*99.95 %*	*7.1×10^{2}*

The only impact category that is slightly different from the others is acidification where freight transport contributes more than to the other impact categories. However, the main source of emissions is, like in distribution, the direct emissions of burning fuel during transport.

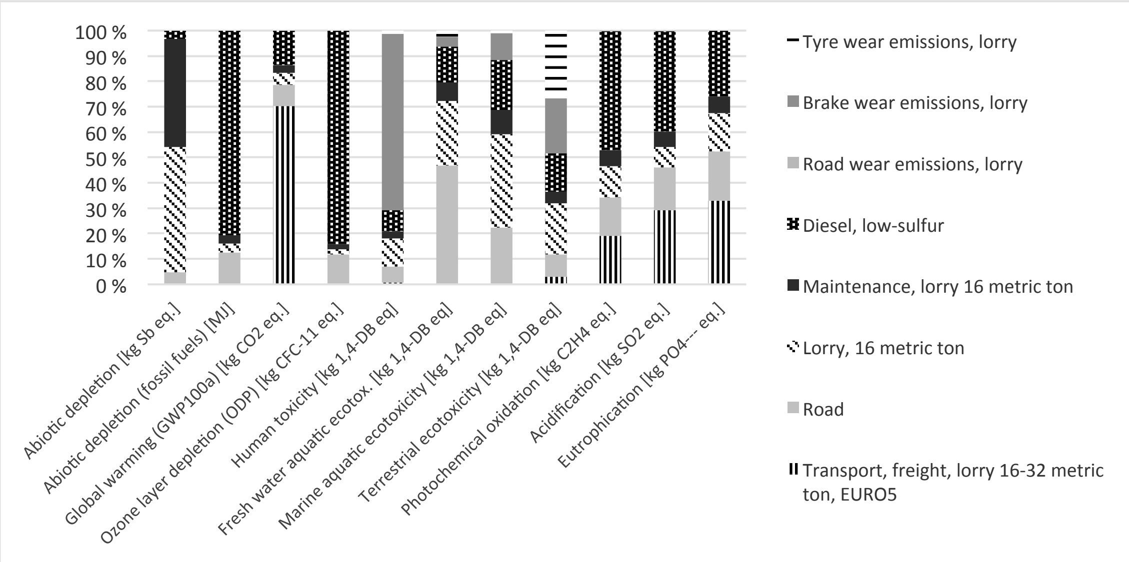

Figure 2: Emission source for the different impact categories.

Looking more closely at salt distribution shown in Figure 2, they are divided into 8 activities that contribute to the different impact categories. Towards global warming, the main contributor is the direct emission of burning fuel under transport while the production and maintenance of the truck are almost exclusively the source of abiotic depletion. The production of diesel is responsible for over 84% of the impact towards ozone layer depletion but also the largest contributor towards photochemical oxidation. Surprisingly, break wear emissions from the truck is responsible for approximately 70% of the emissions towards human toxicity.

For comparison, a Euro 5 personal vehicle would have to be driven over 2.7 million kilometres to reach the same emissions levels for global warming as is estimated emitted by salting operations in Norway.

6. Discussion

As expected, the results show that the highest impact from salting operations is from distribution in Norway. Because environmental effects of winter maintenance are highly linked to driving distances of the WSVs and material use it is important to reduce loss of salt as much as possible by optimizing speed of the vehicle and the spreader. Training and awareness of the winter maintenance staff can also contribute to less loss of salt and better winter road service. The quantities and the driving distance are however also very dependent on temperature and precipitation during the specific winter.

Furthermore, other efforts to reduce impact from winter maintenance are to focus on vehicle and fuel technology. Fuel efficiency combined with optimization of anti- and de-icing methods could potentially reduce emissions substantially. However, it should also be kept in mind that winter maintenance operators report that especially using anti-icing is beneficial as it makes mechanical snow removal easier and results sooner in clear and safe roads. Making mechanical snow removal easier can in itself be a method of reducing emissions during winter maintenance.

7. Conclusions

Life cycle analysis (LCA) was used to estimate the environmental impacts of the chemicals used during winter maintenance and their distribution. Results on the functional unit of *anti- and de-icing operations on national and state roads per km during winter an average winter from 2010 through 2014* show that environmental impacts from winter maintenances are significant. Therefore, we argue that winter maintenance should be included in LCA of roads in colder climates. The results are presented per kilometre so it can be used in other studies to roughly include the impact of anti- and de-icing.

Further investigations should be conducted on fate of salt after salting. In addition, mechanical snow removal and future options in winter maintenance will be investigated further within the current project. By doing so, enough information should be available for decision makers to avoid problem shifting.

Between Domestic and Public: Women's use of space in low–income urban settlements, Surabaya, Indonesia

Sarah Cahyadini

Newcastle University, United Kingdom
(email: s.cahyadini@ncl.ac.uk)

Abstract

Urban development has brought many changes to our built environment. Despite the changes, various values remain attached to certain places, especially in the *kampung*, an indigenous urban settlement in Indonesia. The *kampung* is a self-help settlement, where houses are built incrementally by people and the community, predominantly of low and middle income groups. It has distinct features such as heterogeneity and preservation of traditional culture. Kinship is highly valued and maintained in these settlements, which is promoted by community gatherings. The limited space in each house does not necessarily limit the interaction between residents, as they use the immediate front, side or rear part of the house as a gathering space. Women in the *kampung* play a significant role in the use of these spaces, as they connect private and public space by inhabiting these areas for their activities. This paper will elaborate on the settings and features of spaces in and around the houses that support women's relationships in the community by applying observation and interview methods. These features have proved to be successful in creating a harmonious society in the low-income urban settlement.

Keywords: domesticity, public space, women, kinship, low-income urban settlement

1. Women in Human Settlements

Women are one of the leading actors in development. Their contributions through everyday life activities are extensively recognised by scholars, principally in the context of developing countries. Moreover, the empowerment of women and their full and equal participation in political, social, ecological and economic life are essential in relation to achieving a sustainable human settlement.

1.1 Global and National Perspectives

It is now almost forty years since the initial international commitment for housing development was completed in 1976 via the UN-Habitat conference. As a commitment, it is continued to be shared in relation to different focus; one of them being the needs and contributions of women. The commitment to sustainable development as stated in Agenda 21 (1992) recognised the requirement to strengthen the role of specific groups, such as women, children and youth, so as to generate sustainable and equitable development. The beginning of the 21st century also reaffirmed the goals of gender equity and the empowerment of women through Millennium Development Goals (MDGs). From the United Nation's report (2015), the endeavour of MDG have been able to increase the number of girls enrolling in primary to tertiary education by 30%, whilst also enhancing the number of women in parliament. However, gender inequality still persists, principally in connection with access to economic assets and participation in private and public decision making. Furthermore, women remain the greatest number of urban poor compared to their male counterparts.

In the recent years, with regards to Indonesia, MDG have accomplished their particular aims in relation to the education sector. Consequently, there has been equal participation of boys and girls in primary education (BAPPENAS, 2015). The number of women members in the House of Representatives and moreover women's contribution in the non-agricultural sector are gradually increasing. However, the development is not equally distributed, especially in the eastern part of Indonesia. More importantly, there needs to be an improvement related to the quality of women's lives apart from education, labour force and political participation. Thus, to achieve sustainable and equitable developments, housing and human settlements could be part of the way forward.

1.2 Kampung in Surabaya

It is worthwhile indicating that a kampung is not a slum (Funo, 2002), nor a marginal settlement (Silas, 1989). To a certain extent it is an urban village developed incrementally by the inhabitants and which has certain characteristics. These features are defined by Funo (2002) as variety, heterogeneity and autonomy, consisting of a highly serviced society, preservation of traditional culture and complexity of ownership relations and mutual aid system. By variety, it means that there are various characteristics of a kampung related to its establishment, such as the migratory background of the inhabitants, economic activities, spatial layout, and so on. For example, based on the geographical situation (distance from the city centre) a kampung can be divided into three types: urban, fringe and rural kampung.

Kampung have been an important part of the development of Indonesian cities, especially in Surabaya, the capital of East Java province and second largest city of Indonesia. Approximately 70% of the settlements in Surabaya are self-built by the community. There is a practice called '*gotong royong'* (working together), which is deeply ingrained in the lives of the kampung's inhabitants. This might be one of the reasons that community based programmes, such as the Kampung Improvement Programme (KIP) undertaken from the 1970s to the 1990s were well received and organized by themselves.

1.3 The Research

This study is part of a PhD research about women and housing in a low-income urban settlement. It was conducted in two kampung communities in Surabaya; Jambangan and Rungkut Lor. With regards to the geographical situation, Jambangan is a fringe kampung, while Rungkut Lor represents an urban kampung. The different location (urban or fringe) means that there are differences (to a certain extent) in terms of density and infrastructure. Based on economic activities, most of the inhabitants in Jambangan are traders and public or private employees, whereas in Rungkut Lor, residents are mostly industrial workers from Surabaya's neighbouring city. The different conditions of these two kampung might provide different backgrounds for women in using space especially at the neighbourhood and urban level.

This paper examines how women use the space in and around the house to perform their activities which relates to social relationships through gender perspectives. Observations and interviews are applied in conjunction with photographs and drawings. In dealing with the private and personal data, it is compulsory to obtain consent prior to the interview, so that every participant gave their permissions to publish the data. This includes using their real name in the document. The participant list in Table 1 describes only the women that are part of the discussions in this paper, but not all of the participants in the study. It is worth noting that there are two main activities which connect these women together as participants; environmental activity (recycling) in Jambangan and economic activity (making snacks) in Rungkut Lor.

Table 1. List of Participants

No.	Name	Age	Kampung	Notes
1.	Bu Mustaqim	44	Jambangan	a mother of two, sister of bu Bayu, active in recycling centre
2.	Bu Bayu	49	Jambangan	a mother of two, sister of bu Mustaqim, sells traditional drinks for additional income
3.	Bu Nur	47	Jambangan	a mother of two, neighbour of mbak Fitri, active in recycling centre
4.	Mbak Fitri	39	Jambangan	a mother of three, neighbour of mbak Fitri and cousin (by marriage) to bu Riana, active in recycling centre
5.	Bu Riana	49	Jambangan	a mother of three, cousin (by marriage) to mbak Fitri, runs a juice stall in the food court nearby
6.	Bu Pri	50	Rungkut Lor	a mother of three, a grandmother, neighbour of bu Latifah

7.	Bu Latifah	43	Rungkut Lor	a mother of two, neighbour of bu Pri, earning income from sewing clothes
8.	Mbak Titin	30	Rungkut Lor	a mother of one, selling traditional snacks.

2. Space and Social Relationships

We use space in many ways, as it serves many purposes. Lawson (2001) suggests that through space we can express individuality or support solidarity, gather people together or set them apart, while also conveying sets of rules within society. One of the many relationships that space can accommodate is the kinship network; while at the same time the kinship relation may shape how space is used. Space as it was traditionally defined by architecture is the space determined by architect or designers, whilst in gendered discourse, space is rather as it is found, used, occupied and transformed through everyday activities (Rendell et al., 1999:101). Public and private realms, kinship networks and social relations of exchange have been particularly important in examining the differing spaces men and women are allocated culturally, and the particular role space has in symbolising, maintaining and reinforcing gender relations (Ardener in Rendell, 2002:9).

2.1 Domesticity: Public and Private Realms

> *…women's experience in the city is not one of creating boundaries, drawing limits, or establishing categories; it is one movement in the margins, between and through categories, connecting rather than distinguishing and relishing contradictions rather than rejecting them (Andrew, 2000:158).*

Public and private are only one of the dichotomies related to the use of space, among others such as outside/inside, economy/family, work/home, duty/love (Jarvis et al., 2009:10). These separate spheres are usually associated with male and female respectively. However, as Andrew (2000) mentioned above, the use of space by women is not neatly patterned; instead it is more likely intersections between multiple identities. Women have different roles as wives, mothers, sisters, neighbours, and income earners. These roles are juxtaposed in the efforts of creating home comfort. Therefore, the role of women in defining home comfort is predominant. Rybczynsky (1987) suggests that privacy is one of the principal attributes in relation to home comfort in 17th century Europe. In this context, the idea of privacy is closely related to domesticity, as they both deal with the intimate part of a house. Subsequently, the notion of comfort then developed historically, and now has multiple layers of meaning, which include leisure, pleasure, efficiency and convenience. Modern discussions on domestic architecture are more broadly related to house and dwelling, the architecture of the everyday, as it challenges the notion of domesticity, which refers to the idea of the division between work and home, between male and female spheres, public and private space, regarding the difference between genders (Heynen and Baydar, 2005).

As domesticity changes meaning through time, it also varies culturally. In the case of traditional Madurese settlements in East Java, Indonesia, domestic activities such as cooking and bathing may take place outside the house, in a compound setting (Faqih, 2005). Although more often than not in modern settlements the kitchen and bathroom are located inside the house, the traditional custom of cooking outside the house is still conducted in the urban settlement, especially in the kampung, where women use the alley or front terrace to cook. In this sense, domesticity is not connected to privacy, but more in relation to the role of gender, where domestic spaces relate to women's use of space.

Bu Nur's house is one example of this. When the family renovated the property in 2010, she decided to have the kitchen at the front instead of at the back. Consequently, it occupies the space of front yard of the old house. The kitchen is connected to the front terrace by a stable door (Figure 1), which makes it practical when she bakes biscuits every year during the Islamic festive months, assisted by her neighbour. The large oven for the biscuits will be placed on the front terrace and any activity requiring kitchen utensils can be easily accessed straight from the front terrace. More than a practical reason, this example also gives an idea of how domesticity is played out in the house. The activity of cooking as one of the 'private' activities of the household has shifted into a more public domain, driven by economic motives.

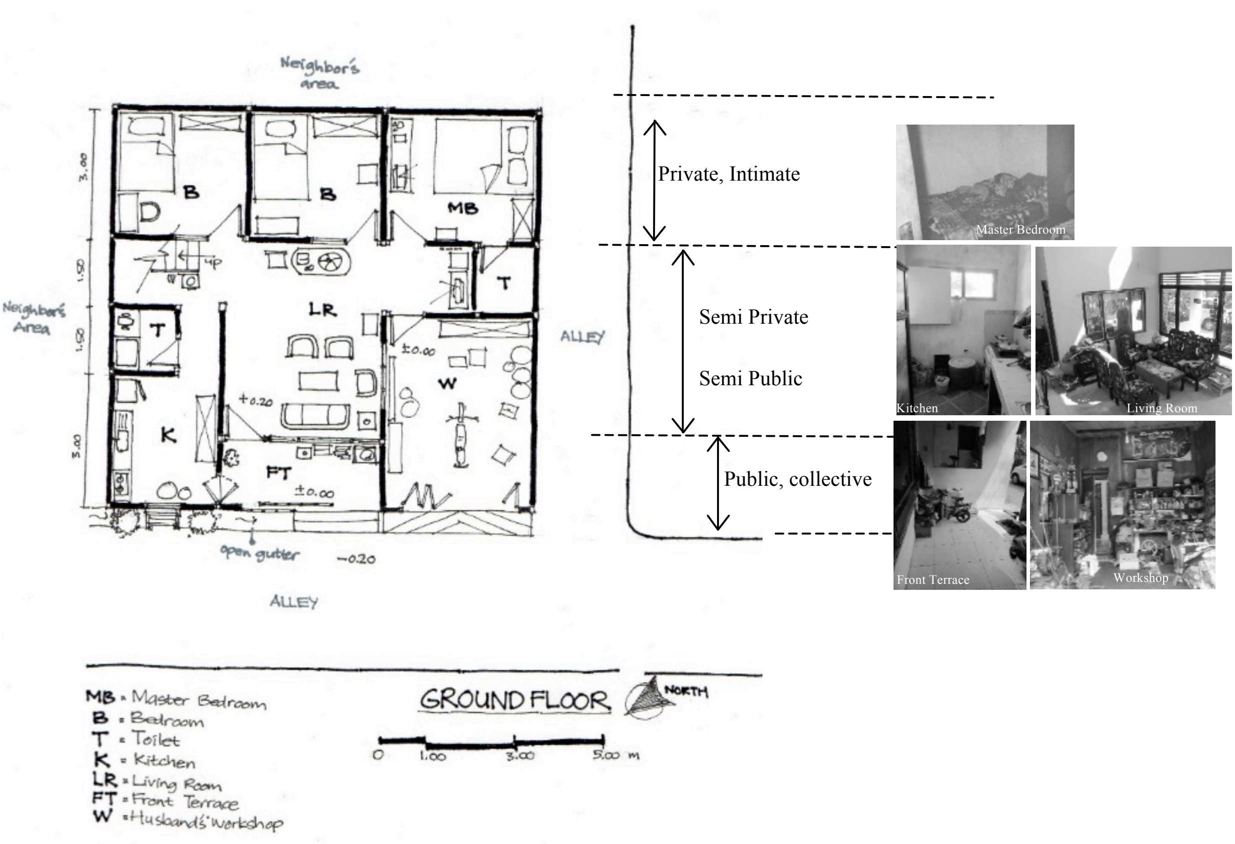

Figure 1. Bu Nur's house plan, the kitchen and terrace are connected by a stable door

2.2 Kinship: Biology and Culture

Discourse on kinship, principally from the anthropological point of view has tended to rest on the distinction between the biological and the social, the natural and the cultural (Carsten, 2004). Kinship as proposed by Sahlins (2013) is the **mutuality of being,** in which people are intrinsic to one another's existence. It is socially constructed, aside from consanguinity or affinity relationship. This is evident in many cultures, especially in Southeast Asia via a study by Rosaldo in 1980, where the Ilongot society in the Philippines share 'blood' through a history of migration and through research conducted by Carsten in Malaysia in 2004, which observed the sharing of food and co-residence in forming kinship (Sahlins, 2013: p.8).

In Javanese social structure, the nuclear family is the most important part of a kinship unit (Geertz, 1989:4). Therefore, we can observe the relationship between people through how they identify each other. Moreover, Geertz also suggests that social security within the family is significant for the functioning of Javanese society as a whole. By social security it means that in case something happens within the nuclear family (for example, parents become ill) a support system is provided by the surrounding community. This condition is still relevant today as almost all of the participants have family or relatives within the area.

A participant in Rungkut Lor, Mbak[1] Titin, lives in rented rooms near her parents, who also rent a house in the neighbourhood. She first moved to Rungkut Lor in 2005 due to the work she had at a factory in Rungkut Industrial park. Later on, her parents moved into the area to live closer to their children (their other daughter lives in Tenggilis, a neighbouring settlement located about two kilometres from Rungkut Lor). By having parents who live nearby, it is easy for Mbak Titin to go to training and other activities conducted away from home, since she can leave her 2 year old daughter under her parents' care. Bu[2] Pri, another participant in Rungkut Lor also has a son who is married and rents a room nearby. She will then gladly looks after her granddaughter during the day while her son and daughter in-law are working.

The research participants in Jambangan share different forms of kinship, from biological to cultural. For example, Bu Mustaqim and Bu Bayu are siblings. They live nearby on the same plot of land, although in different houses. Bu Riana and Mbak Fitri are related by marriage, as their husbands are cousins. In addition, more than being just a biological relationship, kinship is culture. Bu Nur and mbak Fitri's relationship evidently demonstrates the notion of kinship that is shaped by human engagement, rather than naturally given.

The different forms of social relatedness in some ways affect the way women use space (between participants). For example, in the first case, during one interview with bu Mustaqim, she told her first son to park the motorcycle in bu Bayu's place because the usual parking space

---

[1] mbak is used as a form of politeness when calling an older – although there is not a huge age gap- woman, and literary means sister.
[2] 'bu' is the abbreviation of 'ibu', and literary means mother. It is often used before the forename in Indonesia to show respect to an older lady and is similar to the use of Mrs.

was being used for the interview. On another occasion, Bu Mustaqim kept some stuffs for bu Bayu in her house. Thus, this reveals that both of them use their separate house space in various ways as one unit, where they can interchangeably use each other's space without having to first ask for permission. This practice of shared space is not evident in the second case of bu Riana and mbak Fitri. The practice of sharing spaces is also evident in the third case of mbak Fitri and bu Nur, where they do not share a biological relationship, but share activities and experiences. The difference with the first case is that this shared space operates on a mutual basis, rather than equality, as can be noted in the first case. These three examples of relationships demonstrate the different practices incorporated in shared space, used by women.

Bu Nur and mbak Fitri have both lived in Jambangan since they married. As women who married a local man, they both have to live with the in-laws during the first years of their marriage[3]. This experience forms the basis of their relationship. Afterwards, both of them became involved in the same activities, such as the recycling centre, *posyandu* (children's healthcare) *arisan* (community gathering) and community savings. Simple everyday life activities, for instance baking biscuits and grocery shopping enabled their relationship to grow stronger and thus, they are like sisters. Furthermore, Mbak Fitri's son and daughter call bu Nur and pak[4] Slamet, *Budhe* and *Pakdhe*. This is how nieces and nephews call aunts and uncles in Javanese. Their close relationship can be perceived, as they mention it in the interview:

> *"…when we renovated the house, we did not move, we only used the existing two rooms, and when the new rooms were done, we used them while the builder worked on the other rooms. It lasted for two months, so we used the bathroom of bu Slamet (bu Nur) during that time. We still have some stuff there (in bu Nur's house) because now our space is so limited. Bu Slamet is always suggesting that my son should use their upstairs bedroom later when they finish renovating the house. But I still feel reluctant..."*
>
> *[Fitri, 39 years old, 10 June 2015]*

In the interview with me, mbak Fitri referred to bu Nur as bu Slamet (her husband's name) to show her courtesy and respect; while in daily interactions, she will call her 'mbak' Nur. It shows her close relationship with bu Nur, while at the same time maintaining the highest respect for her in front of me, the researcher. This courteous manner is also shown in her reluctance to let her son sleep in bu Nur's house. This reluctance however is not evident as she allows her first daughter to live with her brother-in-law's family in another city. In fact, this confirms evidence of how in Javanese culture, the concept of family is still closely related to blood relations.

As for bu Nur, mbak Fitri is a source of support in many ways. She assists her not only in community activities such as the recycling centre and children's healthcare, but also in her

---

[3] It is common practice in the Javanese patriarchal system that the oldest or only son of the family will stay in the parents' house after marriage to look after them.
[4] Pak is the abbreviation of 'bapak' and literary means father. It is often used prior to the forename in Indonesia to show respect to an older man and is similar to the use of Mr.

economic activity (baking biscuits to sell), in particular when she became more dependent on her after the motorcycle accident that affected her ability to travel as easily as before:

> *"…the accident was about two years ago, and happened right in front of the house. I wanted to go to buy porridge for my husband's sister, as she was sick, when all of a sudden I fell and could not get up. I then realised I couldn't see my knee, and I screamed. The neighbours started coming, and among the first to come is Mbak Fitri's husband […] since the accident, I go with mbak Fitri to the market…"*
>
> *[Nur Isaroh, 47 years old, 10 June 2015]*

Bu Nur lives in a two-storey house with 4 bedrooms (the second floor was under construction, one room is used to store mbak Fitri's belonging), while mbak Fitri occupied one room in the family-owned rented rooms (Figure 2). In addition, their houses are only about 20m apart**.** Mbak Fitri's son is voluntarily helping pak Slamet (bu Nur's husband) in the construction of the house, helping to carry the bricks, cement, and other materials. In this case, the use of space in another person's house is exchanged with other forms of activity, when house space is limited or not available to other party.

Figure 2. Bu Nur's house (left) and Mbak Fitri's house (right)

2.3 Settings and Features of Kampung that Supports Kinship Values

In general, two types of space are occupied by women in the *kampung* which supports their social relationship. First is the space that was built or occupied on purpose, whereas the second is the immediate space in or around the house. The first space is primarily used by the women at certain times and for specific activity, while the second differs through time and activities.

2.3.1 Time and Activity-based Settings

The first type of space is promoted by the same primary activity, such as recycling in Jambangan and making snacks in Rungkut Lor. To accommodate this activity, each woman's group makes the effort, in order to have a specific place. Beyond the main activity, the relationships between these women also involve the social, cultural and economic aspects of their everyday life. For example, while doing the recycling and making snacks, they share information on raising children, community savings, undertaking the daily shopping with the cart seller that passes by or just by sharing stories. In another way, this relationship develops kinship as they have become mutually related. Thus, kinship configures how the space is used.

In Jambangan, this type of spatial configuration was evident in the recycling centre. This particular activity was first initiated in 2012, when the kampung participated in an environmental programme; 'Green and Clean' initiated by the city council. It started as a simple greening activity, and then developed into a recycling centre. With the recycling activity, more space was needed to store the recycled objects before they were collected by partner recycling agents. This facility was established as the woman's group asked the district office to provide them with more space for their activity and is constructed from very simple materials. On one occasion during the election campaign, the woman's group secured a donation to upgrade the building, as is shown in Figure 3. In Rungkut Lor, this type of space was a rented room, paid for by the cooperation of women who conduct the business. Here in the rental space, they receive purchase orders, receives guests and buyers, bake some of the biscuits, and also hold meetings. Both the spaces are relatively small, approximately 30 m2; nevertheless they are adequate enough to accommodate the women's activities.

Figure 3. The recycling centre in Jambangan (left) and Kampung Kue Secretariat inRungkut Lor (right)

2.3.2 Immediate Space around the House (Time-based)

The second type of space appropriation is the immediate space in or around the house. It is the space that is available in the first place, although it can be used in different ways, based on certain times and activities. For example, the terrace of a public reading room in Rungkut Lor was utilised at dawn to sell snacks and cakes not only for the neighbourhood buyers but also by other traders within the surrounding traditional market, as revealed in Figure 4. Aside with public facility, a number of people used the immediate space adjacent to or in front of their own houses (Figure 5).

Figure 4. The use of public reading room in the kampung at dawn (left) and noon (right)

Figure 5. The use of immediate space in front of the house for economic activity at dawn (left)

Another feature in the kampung that also has a significant role in creating and maintaining the social relationship between women in this setting are the benches (Figure 6). These come in different shapes and materials - from simple wood planks to more permanent concrete blocks and are usually located in front of the house. In general, they tend to be used from the afternoon until dusk (between 4 to 6 pm). This is the time where most of the women in the kampung have spare time (they watch children play, water the plants, exchange tips on cooking or tell each other interesting stories). It is also the most convenient time in relation to tropical weather to be outdoors.

Bu Latifah who spends most of the time inside the house because she sews clothes to make ends meet, recalls the ritual afternoon meeting on the benches as one way for her to strengthen her relationship with her neighbour during the first months of her stay in 2010. Nowadays, it is also a way for her to release stress after spending hours inside the house.

Figure 6. Different types of bench in Jambangan and Rungkut Lor

2.3.3 Immediate Space of the House (Activity-based)

The most common space in the house used by women to perform community activities is the front terrace. The activities comprise: *arisan* (monthly gathering), *pengajian* (weekly Qur'an recital) and *posyandu* (fortnightly children's healthcare). These spaces were used by prior arrangement, depending on the activities schedule. One example is the children's healthcare activity (Figure 7). In Jambangan, it was organised on every first and third Wednesday of the month. At the time the activity took place, children aged less than 5 years old were weighed, their height measured and on occasions they were given vaccines by a health practitioner.

Figure 7. Children's healthcare activity occupying the front terrace of the house

3. Moving Beyond Binaries

The examples above reaffirmed that women's use of space, principally in kampung, is not that of using separate spheres, but instead moves beyond the binaries of public/private, work/home, outside/inside, and even duty/love. We can see from the aforementioned examples that domestic space in this context is gender related and is less associated with the private sphere; thus it can occupy a public sphere. This might informs a different notions of domesticity as in most European and North American literatures which mostly relate with home and privacy (Rybczynski,1987; Kent,1990; Lane, 2007).

A further interesting finding is how a certain space is used primarily by women, despite its location in public areas. It appears to indicate the strong agency of women in claiming their own space. Women use space not only depandant on activities, but also on social relationships. Therefore, kinship relations plays an essential role in how these spaces are used, while at the same time these spaces with their different activities can nourish and strengthen the social relationships between women. In the context of low-income urban household, where the limited space of the house may encourage more shared use of public space, this interrelationship is therefore determinants in creating a harmonious urban settlements.

4. Acknowledgment

The author is a lecturer at ITS Surabaya who is now studying at Newcastle University, UK.This paper is part of ongoing PhD research of women and housing, under supervisory of Dr. Peter Kellett and Prof. Rose Gilroy, which aims at exploring the use of space by women in low income urban settlements. The research is funded by Directorate of Higher Education (DIKTI), Ministry of Research and Technology (Kemenristek) of Indonesia.

INTERNATIONAL COMPARISONS OF CONSTRUCTION LABOUR PRODUCTIVITY

(email: chiafc@utar.edu.my)

Abstract

Comparing productivity of industry between countries is a crucial information base for research in comparative analysis and policy making. This comparison enables identification of shortcomings in one place and then look for ways to deal with them. The construction industry is characterised by heterogeneity and uniqueness of its product, complexity of its delivery process and industry structure and the country specificity of construction products. Aggregate quantity measures of construction are normally done with monetary value of construction output. The monetary value of construction output are normally converted with the market exchange rates into the same currency for comparisons of construction production across countries. The comparison is always distorted by the volatility of market exchange rate. An alternative is using Purchasing Power Parity (PPP). PPP is a neutral way of stating the ability of one nation's currency to purchase goods in different nation costs recorded in various national currencies in a single currency. Newly published Purchasing Power Parity data from the World Bank's International Comparison Program 2011 and employment statistics maintained by the International Labour Organization (ILO) are used to generate comparable data of the construction labour productivity (CLP) of 93 economies and the Construction Labour Productivity Indexes (CLPIs). The CLPI is the standardised index of the construction labour productivity of an economy relative to the world average. CLP tends to be higher in the high economies than the low income economies. CLP measures of the two methods are tending towards convergence as the economies grow from developing to developed status. CLP shows a relatively stronger correlation with nation's economic growth based on exchange rates. Construction industry is changing from being a long-established non-international traded industry to a more complex international traded industry.

Keywords: Productivity, Construction industry, International comparisons, Purchasing power parity

1. Introduction

GDP per capita, a common measure to provide an assessment of the performance of the market economy and to monitor cyclical fluctuations, is simply labour productivity multiplied by the proportion of the population that works. In the absence or difficulty to construct a perfect alternative metric, GDP is still being commonly used to understand what makes countries rich and the underlying causes of productivity change. A country's productivity is the average of its industries productivity weighted by its size. Therefore to understand what makes countries rich is best achieved by evaluating the performance of individual industries. Such a micro approach reveals the importance of industrial productivity (Lewis, 2006).

Construction is an important industry because its output is large and it represents a significant part of the economy. It produces investment goods which are vital for the wellbeing of any economy. In most countries, construction provides about half their gross domestic fixed capital formation (Hillebrandt, 2000). The world construction industry stands at 5.5% of world Gross Domestic Product (GDP) in 2013 (United Nation Statistics Division, 2014).

On the other hand, low productivity in the construction industry has been a constant concern. To raise economic performance, it needs to focus on the causes of productivity differences among companies, industries, sectors, and countries. The international comparisons form a crucial information base for research in comparative analysis and policy making. It is difficult to compare construction products between economies because the construction industry of each economy is basically unique. The complexity and the country specificity of its products results with no two economies build exactly the same kind of house or power station (The World Bank, 2015). The most commonly used method for such international comparisons is to express the GDP of the countries concerned in the same currency unit so that the differences in the economies are readily identifiable. There are long recognized shortcomings in GDP as a measure of economic performance such as home production, technological obsolescence and environmental degradation or depletion of natural resources are excluded in the measurement of GDP (Stiglitz, et.al. 2009). This comparison is exaggerated when the economy's foreign-exchange rates is used to convert its national currency. An alternative approach to overcome volatility of market exchange rate in the comparison is to replace exchange rate with purchasing power parity (PPP) as conversion factor (Todaro & Smith, 2015). PPP is the ability of one nation's currency to purchase goods in a different nation. It compares how different currencies function in the same country, rather than trying to compare different currencies in different countries (Taillard, 2013).

The following section highlights in more detail the problems of making international comparisons, introducing the concept of PPP and International Comparison Programs by the World Bank and summarising the PPP approach to construction expenditure by the World Bank's International Program. It explains the different productivity measures and justifies the single factor gross output measure used. The next section provides details of the sources of data for the construction expenditure and construction employment statistics of the different economies. Sections 4 compares the results the construction labour productivity and

Construction Labour Productivity Indexes (CLPIs) of 93 economies computed in this study. Section 5 discusses the productivity differences between the economies based on PPPs and exchange rates. Section 6 concludes the findings of the study.

2. International Comparisons

International comparisons of levels and more importantly of rates of growth play a very important role in the policy design. It enables structural reforms to import the "best practice" of the country performing the best in terms of productivity, if the productivity of the two countries are computed in the similar way. Reported National Accounts are good sources of data to be drawn for international comparisons. Comparisons are indeed possible if the procedures and definitions used to compute the accounts are comparable, but there are still large differences in the ways National Accounts calculations are carried out (Stiglitz, et.al. 2009).

The main issue in the international comparison is the inconsistency of definitions used in national measures of construction activity. In addition, the output of construction is so heterogeneous, aggregate quantity measures of construction is not feasible, and using monetary values is the only option (Meikle & Gruneberg, 2015). Often costs are converted to USD (or any other currency) in order to compare costs between countries. The supply and demand for currencies are influenced primarily by factors such as currency speculation, interest rates, government intervention, and capital flows between economies. A high exchange rate will make local costs look high against the comparison country. A low exchange rate will do the opposite (Turner and Townsend, 2015). Comparing national economies via measures such as gross domestic product (GDP) using exchange rates can be very much distorted by price-level differences between countries (Best & Meikle, 2015). The differences between the levels of GDP in two or more economies reflect both differences in the volumes of goods and services produced by the economies and differences in the price levels of the economies. They do not reflect the relative purchasing power of currencies in their national markets (The World Bank, 2015).

Many goods and services such as buildings, government services, and most household market services are not traded internationally (The World Bank, 2015). The volatility of exchange rates can distort a country's construction costs compare with others in international comparisons of construction activity (Meikle & Gruneberg, 2015).

2.1 Purchasing Power Parity

PPP removes the impact of volatility of exchange rates (Turner and Townsend, 2015). The International Comparison Program (ICP) conducted under the charter of the United Nations Statistical Commission (UNSC) provides globally comparable economic aggregates in national accounts (The World Bank, 2015). It is the principal source of data on the PPPs of currencies, real domestic product and real per capita income. The latest round of the ICP 2011 participated by 199 economies provides the full set of results for 177 economies, accounts for about 97 percent of the world's population and 99 percent of the world nominal GDP (The World Bank, 2015). The participating economies report their expenditures that are valued at national price levels in national currencies i.e. nominal expenditures. These nominal expenditures are converted to real expenditures (i.e. expenditures that are valued at a common price level) by PPPs (The World Bank, 2015). Real expenditures reflect real or actual differences in the volumes purchased in economies and provide the measures required for international volume comparisons (The World Bank, 2015).

ICP comparisons are designed to compare the volumes of goods and services that enter GDP at specific points in time. They are not designed to measure the relative rates of growth in GDP between these points. Each ICP comparison produces indexes of real GDP that show the relative volume levels of GDP among participating economies for the reference year. When the indexes for consecutive reference years are placed side by side, they appear to provide points in a time series of relative GDP volume levels over the intervening years (The World Bank, 2015).

PPPs are calculated in stages: first for individual goods and services, then for groups of products, and finally for each of the various levels of aggregation up to GDP (The World Bank, 2015).

2.2 Purchasing Power Parity of Construction Expenditure

Construction expenditure is one of the 25 sub aggregates expenditure reported in ICP 2011. It includes capital expenditure on the construction of new structures and renovation of existing structures. Gross fixed capital formation in construction is broken down into three basic headings: residential buildings, non-residential buildings, and civil engineering works (The World Bank, 2015).

The economies of Eurostat-OECD used the bill of quantities approach in comparison. All the economies are required to price the Bill of Quantities of a common set of standard fictitious buildings and civil engineering projects on the basis of the actual structures and materials and methods commonly used in their construction. Each economy was expected to price 7 out of 11 standard construction projects specified using prices of successful tenders submitted during the reference year. The price includes the contractor's mark-ups for general site costs, head office overheads, profit and cost of employing professional architects and engineers. The PPPs for construction are calculated using the overall prices of the projects (The World Bank, 2015).

The Commonwealth of Independent States (CIS) economies used a modified version of the bill of quantities. These economies were required to provide unit prices for 66 inputs covering materials and labour for the regional coordinating agency in order to price simpler and less complete bills of quantities of an extensive range of model structures. The PPPs for construction were calculated using the overall prices for the model structures (The World Bank, 2015).

Other participating economies were required to collect unit prices for 38 kinds of basic building materials, the hourly cost of hiring five types of building equipment with and without an operator. The economies were also asked to include the hourly rate at which compensation was paid to construction workers across 7 occupations and for a common set of 55 inputs. They had to indicate the types of structures for which each of the inputs was commonly used and the average resource mix for each of the three basic heading. PPPs for the basic heading were obtained by aggregating the PPPs of its subheadings with subheading expenditure weights (The World Bank, 2015).

2.3 Labour Productivity

The productivity measures can be classified as single factor productivity or multifactor productivity. The single factor productivity relates a measure of output to a single measure of input, whereas the multifactor productivity relates a measure of output to a bundle of inputs (Organisation for Economic Co-operation and Development, 2001).

These measures capture the movements of output with gross output or value-added. When measured as gross output per unit of labour input, labour productivity rises as a consequence of outsourcing and falls when in-house production replaces purchases of intermediate inputs. This does not reflect a change in the individual characteristics of the workforce and a shift in technology or efficiency. The efficiency gain as a consequence of input substitution will not be captured (Organisation for Economic Co-operation and Development, 2001).

Value-added based labour productivity measures tend to be less sensitive to processes of substitution between materials plus services and labour than gross-output based measures. When outsourcing takes place, labour is replaced by intermediate inputs. This will reduce value added and hence lead to a fall in the labour productivity. At the same time, outsourcing means less labour input needed, this will lead to a rise in the labour productivity. Because labour productivity measures reflect the combined effects of changes in capital inputs, intermediate inputs and overall productivity, they do not leave out any direct effects of embodied or disembodied technical change. The embodied technical change enhances production possibilities for a given set of inputs, while the disembodied technical change operates via capital goods and intermediate inputs (Organisation for Economic Co-operation and Development, 2001).

The choice of productivity measures depends on the purpose of productivity measurement and the availability of data. Labour productivity relates to the single most important factor of production, is intuitively appealing and relatively easy to measure. It partially reflects the productivity of labour in terms of the personal capacities of workers or the intensity of their efforts and how efficiently labour is combined with other factors of production. It also reflects how many of these other inputs are available per worker and how rapidly embodied and disembodied technical change proceed (Organisation for Economic Co-operation and Development, 2001).

3. Research Methods

This paper used single factor productivity measure, based on gross output. It is simply the ratio of the quantity of gross construction output to quantity of labour input. The construction expenditure found in the ICP 2011 is used as the proxy for gross construction output. The expenditure includes capital expenditure on the construction of new and renovation of existing residential buildings, non-residential buildings, and civil engineering works. The quantities of labour input is obtained from the International Labour Organisation's central statistics database (ILOSTAT). ILOSTST provides recent labour data for over 100 indicators and 165 economies. Employment by construction that are used as proxies of quantity of labour input are extracted from the section of *Employment by Economic Activity and Occupation* of the databases (International Labour Organization, 2015).

There are 93 matching pairs of economies found in the employment statistics of ILOSTAT and construction expenditure in ICP 2011. They account to 82.5% of real construction expenditure and 89.9% of nominal construction expenditure. The computed construction labour productivities and Construction Labour Productivity Indexes (CLPIs) based on PPPs and exchange rates of these 93 economies are available in Appendix I. The construction labour productivity of different economies needs to be expressed in the same currency unit so that the differences in productive levels of different economies are readily identifiable.

The CLPIs are standardised indices expressed by the construction labour productivity of an economy relative to the world average productivity level, which is set at 100. Economies with CLPIs greater than 100 shows their construction labour productivity levels are higher than that of the world average. Economies with CLPIs less than 100 indicates their construction labour productivity levels are lower than that of the world average.

For analytical purposes the World Bank classification of economies is used in the discussion. The World Bank classifies economies as low income, middle income, or high income. As of 1 July 2011, low-income economies are those that had average 2010 incomes of nor more than \$1005; lower-middle-income economies had average incomes of \$1006 to \$3975; upper-middle-income economies had average incomes of \$3976 to \$12 275; and high-income had average incomes of \$12 276 or more. Low- and middle-income economies are commonly referred to as developing economies (World Bank, 2011). There are 49 high economies, 26 upper middle income economies, 16 lower income economies and two low income economies.

4. Results

It is apparent from Table 1 that CLPs of 80 economies are higher based on PPPs measurement method, leaving CLPs of 13 economies are higher when based on exchange rates. The former are low, lower middle, upper middle and partially high income economies and the latter are all high income economies. It suggests that developing economies tend to understate the construction labour productivity if based on the exchange rates measurement.

Table 2 shows the top 10 construction productivity and CLPIs of high income economies. CLPs of all the selected economies are higher based on PPPs with exceptions to Finland, France and Sweden. CLPI of Belgium is slightly below world average based on exchange rates, but appears as two times of world average when measured by PPP.

***Table 1**: Comparison of number of economies with higher CLP based on different measurement methods*

World Bank classification	*Number of economies*	*Number of economies with higher CLP based on PPPs*	*Number of economies with higher CLP based on exchange rates*
High income	*49*	*36*	*13*
Upper middle income	*26*	*26*	*0*
Lower middle income	*16*	*12*	*0*
Low income	*2*	*2*	*0*
Total	*93*	*80*	*13*

***Table 2**: Top 10 CLPIs of high income economies*

Economies	*Nominal consumption (based on exchange rates)*		*Real consumption (based on PPPs)*	
	Construction expenditure/ construction employment	*CLPI (world = 100)*	*Construction expenditure/ construction employment*	*CLPI (world = 100)*
Norway	*164 883*	*140.20*	*239 836*	*335.36*
Australia	*127 261*	*108.21*	*227 640*	*318.30*
Switzerland	*152 675*	*129.82*	*224 479*	*313.88*
Canada	*192 678*	*163.83*	*213 732*	*298.86*
Finland	*199 997*	*170.05*	*194 469*	*271.92*
Netherlands	*169 527*	*144.15*	*191 795*	*268.18*
Denmark	*179 506*	*152.63*	*184 002*	*257.29*
France	*206 154*	*175.29*	*183 479*	*256.56*
Belgium	*110 622*	*94.06*	*168 909*	*236.18*
Sweden	*183 807*	*156.29*	*157 615*	*220.39*

Table 3 shows the top 10 construction productivity and CLPIs of upper middle income economies. CLPs all the selected economies are higher based on PPPs. CLPIs of Romania and Albania achieved approximately two-third of world average when measured by exchange rates. But they performed marginal higher than world average when based on PPPs. Kazakhstan's CLPI is lower when based on PPP.

Table 4 shows the top 10 construction productivity and CLPIs of lower middle income economies. CLPs all the selected economies are higher based on PPPs. CLPIs of Indonesia is about half of world average when measured by exchange rates, it appears 35% higher than world average if it is based on PPPs. The CLPIs of Armenia, Georgia, Moldova and Ukraine are lower when based on PPP. Bhutan's CLP appears to be the highest among the 93 economies but it has a relatively smaller size of construction industry. Its construction expenditure in 2011 was USD 720 million and employed 4500 construction workers.

***Table 3**: Top 10 CLPIs of upper middle income economies*

Economies	*Nominal consumption (based on exchange rates)*		*Real consumption (based on PPPs)*	
	Construction expenditure/ construction employment	*CLPI (world = 100)*	*Construction expenditure/ Construction employment*	*CLPI (world = 100)*
China	*122 119*	*170.76*	*361 219*	*307.14*
Seychelles	*93 528*	*130.78*	*213 840*	*181.83*
Romania	*47 420*	*66.31*	*134 817*	*114.63*
Montenegro	*47 336*	*66.19*	*103 673*	*88.15*
Mexico	*46 035*	*64.37*	*88 701*	*75.42*
Albania	*44 298*	*61.94*	*128 236*	*109.04*
Colombia	*42 678*	*59.68*	*89 253*	*75.89*
Turkey	*41 891*	*58.58*	*102 283*	*86.97*
Kazakhstan	*41 736*	*58.36*	*56 466*	*48.01*
Costa Rica	*35 380*	*49.47*	*76 702*	*65.22*

***Table 4**: Top 10 CLPIs of lower middle income economies*

Economies	*Nominal consumption (based on exchange rates)*		*Real consumption (based on PPPs)*	
	Construction expenditure/ construction employment	*CLPI (world = 100)*	*Construction expenditure/ Construction employment*	*CLPI (world = 100)*
Bhutan	*159 595*	*223.16*	*680 664*	*578.77*
Indonesia	*34 681*	*48.49*	*158 391*	*134.68*
Mongolia	*33 156*	*46.36*	*112 181*	*95.39*
Armenia	*31 598*	*44.18*	*37 377*	*31.78*
Georgia	*24 015*	*33.58*	*29 674*	*25.23*
Sri Lanka	*19 897*	*27.82*	*83 397*	*70.91*
Senegal	*15 806*	*22.10*	*45 437*	*38.64*

Morocco	*14 853*	*20.77*	*75 983*	*64.61*
Moldova	*14 770*	*20.65*	*18 098*	*15.39*
Ukraine	*13 742*	*19.21*	*20 002*	*17.01*

Table 5 shows the construction productivity and CLPIs of the two low income economies, Ethiopia and Zimbabwe. Both CLP and CLPI of the two economies are higher when based on PPPs.

***Table 5**: CLPIs of low income economies*

Economies	*Nominal consumption (based on exchange rates)*		*Real consumption (based on PPPs)*	
	Construction expenditure/ construction employment	*CLPI (world = 100)*	*Construction expenditure/ Construction employment*	*CLPI (world = 100)*
Ethiopia	*9,225*	*12.90*	*55 759*	*47.41*
Zimbabwe	*6,398*	*8.95*	*17 111*	*14.55*

Table 6 shows in low income economies, CLP is 4.7 times of exchange rate when based on PPP. Ratios of CLP based on PPPs to CLP based on exchange rates are gradually narrowed to 3.5, 2.6 and 1.3 times in lower middle income, upper middle income and high income economies respectively.

***Table 6**: Average expenditure per capita and construction labour productivity based on PPP and exchange rates group according to economic development status*

World Bank classification	*Average expenditure per capita based on*			*Construction labour productivity based on*		
	PPPs	*Exchange rates*	*PPPs/ exchange rates*	*PPPs*	*Exchange rates*	*PPPs/ exchange rates*
High income economies	*39 692*	*38 750*	*1.02*	*140 865*	*107 176*	*1.31*
Upper middle income	*14 367*	*7 497*	*1.92*	*97 196*	*37 471*	*2.59*
Lower middle income	*6 727*	*2 809*	*2.39*	*89 689*	*25 597*	*3.50*
Low income	*1 296*	*524*	*2.47*	*36 435*	*7 811*	*4.66*

It is apparent from Figures 1 and 2 that, there is a strong correlation between construction labour productivity and expenditure per capita when they are based on exchange rates. Figure 1 shows that the coefficient of determination (R^2) of construction labour productivity and the expenditure per capita is 0.10 when they are based on PPP. However, the coefficient of determination (R^2) increased to 0.60 when based on exchange rate (Figure 2). This is equivalent to correlation coefficient (R) of 0.77.

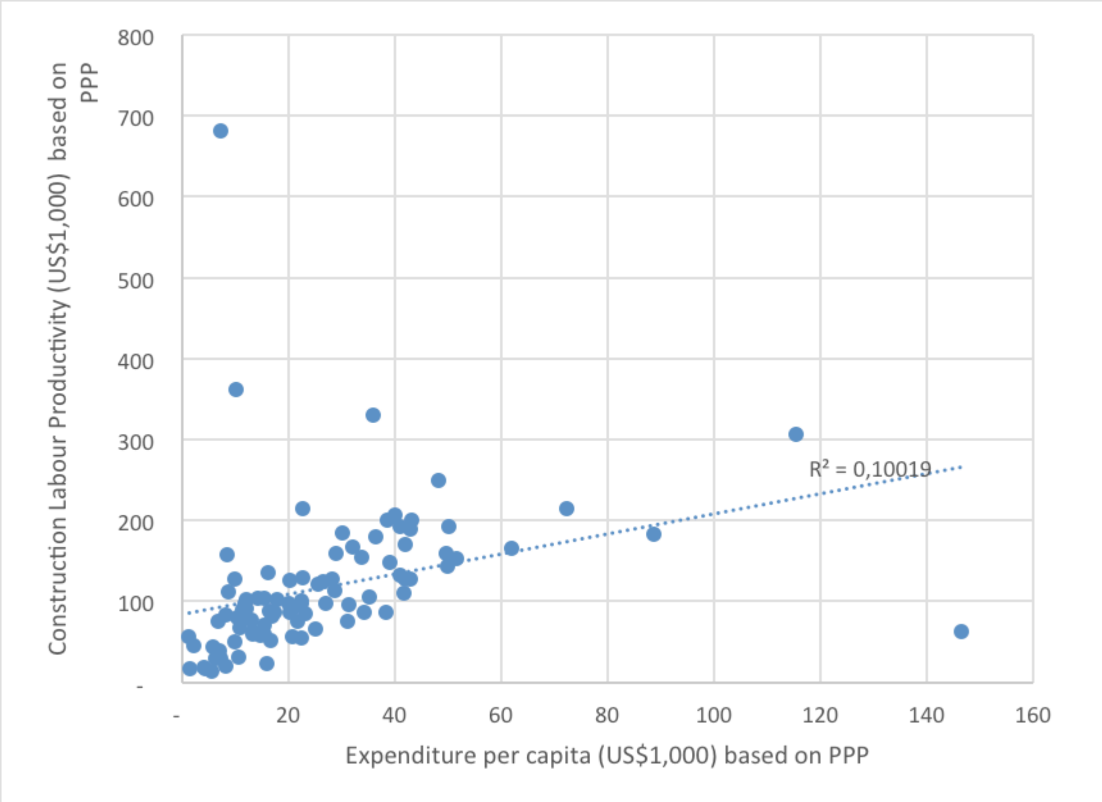

***Figure 1**: Construction labour productivity and expenditure per capita based on PPP*

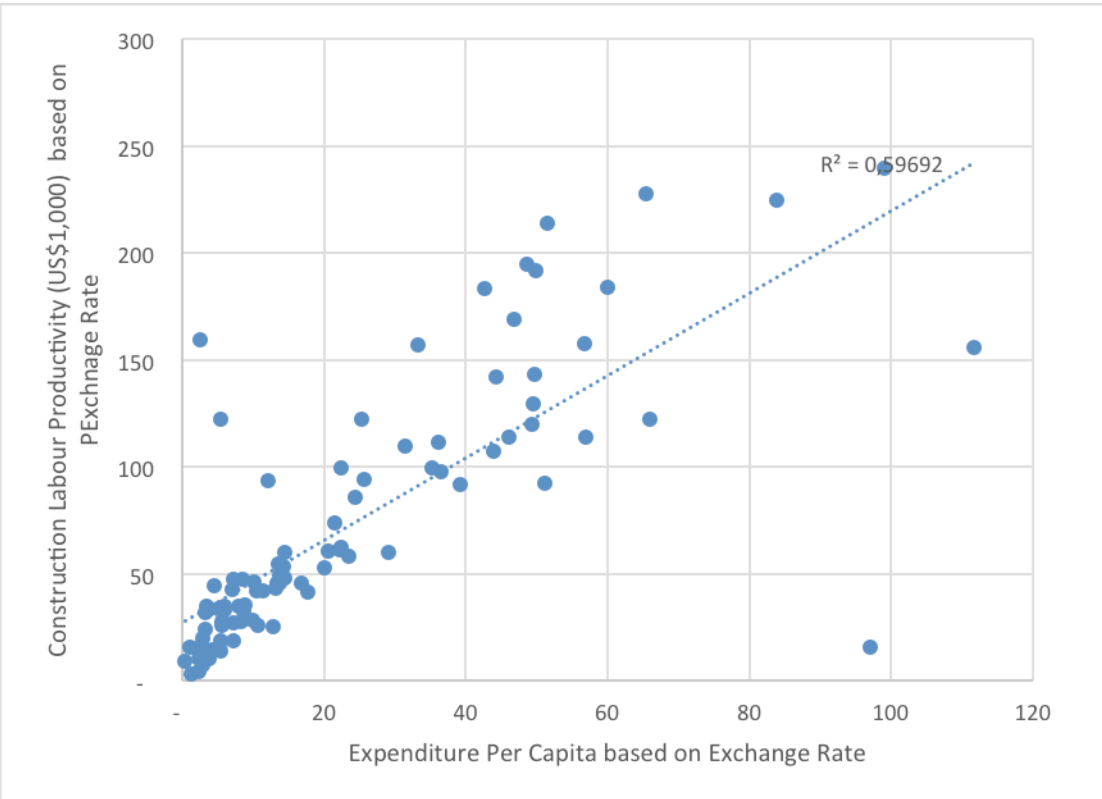

***Figure 2**: Construction labour productivity and expenditure per capita based on exchange rate*

5. Discussion

The above analysis shows exchange rates measurement of construction productivity tends to understate the CLPs. It is mainly because construction is an industry relying mostly on the local supplying of resources, such as materials and labour and it also depends on local demand for its output.

CLP tends to be higher in the high income economies than the low income economies. One possible reason for this is that construction industry in the higher income economies have a better opportunities for capital investment and replacing on-site manual works with mechanisation and off-site production.

In higher-income economies, the differences between CLP measures in PPPs and exchange rates are less compared to the low-income economies. The two methods of measurement are tending towards convergence as the economies grows from developing to developed status (Table 6). CLPs and economic development shows stronger correlation when based on exchange rates (Figure 2). This suggests that CLP will eventually be strongly influenced by the exchange rates. Construction industry is changing from being a long-established non-international traded industry to a more complex international traded industry. With the globalization of the world economy, today's construction business is fast becoming an internationally interdependent marketplace. According to the ENR (2014), the Top 250 International Contractors had USD 543.97 billion in contracting revenue in 2013 from projects outside their home countries, up 6.4% from USD 511.05 billion in 2012. Data published by ENR shows that ENR's top 225 international contractors in 2011 earned USD 453 billion in revenue from construction projects outside their home countries, which represents more than a two-fold increase over the USD 189.4 billion recorded in the last ICP 2005. In addition, with the rise of modern industrialized countries, increasingly complex civil engineering projects are being procured, and the increased scale of these projects has provided a launching pad for international construction. Advanced technology, fast transportation, convenient communications, effective knowledge transfer, integrated markets and trade liberalization have all helped to lower traditional barriers and transform construction into a fiercely competitive international marketplace where construction companies ebb and flow (Lu, et al., 2015).

6. Conclusions

Statistical analysis is subjected to alternative interpretations because they serve a multiplicity objectives. Policies and best practices may be drawn from inferences of statistical analysis. This paper attempt to compare the productivity of the construction industries of different economies in order to identify the high and low performance economies to uncover their underlying determinants of productivity performance in the further studies. Further researches need to be aimed at taking stock of what already been done, and assessing the strengths and weaknesses of these practices in order to shape the industry's future policy.

Influence of construction time on the productivity of construction works

Christian Hofstadler
Institute of Construction Management and Economics, Graz University of Technology
(email: hofstadler@tugraz.at)

Abstract

Construction time has a major influence on the economically viable execution of construction works. Any short (or very short) construction period will severely affect the effective utilisation of production factors, which influences not only elementary (labour, materials, equipment and machinery) but also discretionary (project managers, site managers, technicians etc.) production factors. Clients often do not recognise this effect, or even deny it. Productivity is adversely affected not only by too short but also by exceedingly long construction times.

This paper demonstrates the basic correlation between construction time and productivity. Own approaches and methods known from pertinent literature are presented and critically reviewed to be able to quantitatively assess losses of productivity. This paper illustrates the influence of construction time on costing and, consequently, the actual construction process. Construction managers will be made aware of the necessity to closely monitor those construction-related factors that have an influence on construction time.

Another factor that deserves increasing attention is the gradual ("notional") shortening of construction time. Very often, more work needs to be performed than originally agreed upon whereas the construction period remains the same, and the contractor has to cope with a deterioration of the conditions under which work is to be executed. In most of these cases, contractors are forced to accelerate processes "incrementally" to adhere to the agreed-upon construction period, which partly incurs significant additional costs to be covered by the contractor if the client is not notified of the related disruptions based on the merit of the individual case.

Overall, this paper should create a better understanding of factors that promote or inhibit productivity whilst raising awareness of disruptions to the construction process, with the aim to further improve the effective utilisation of production factors but also to identify, and subsequently evaluate, thresholds of productivity losses more easily.

Construction time influences both the quality of individual processes and work steps and the overall quality of the project, as well as the number of construction process disruptions and thus the amount of additional costs claimed.

Keywords: construction time, productivity, production factors, costs, construction process disruptions

1. Introduction

Construction management is characterised by a combination of production factors. Pricing is essentially determined by defining which production factors to combine in which way and at what points in time. As part of the zero-base costing exercise (i.e. calculating cost-covering prices of construction works to be performed at a later point in time, excluding speculative elements), the expected costs of construction works must be determined. The costing exercise uses various construction work scenarios that are "played back" as a mental "construction film". The type and combination of production factors required for the construction work scenario that is considered most likely at the time of bid costing are applied.

Costs result from the consumption of production factors that is measured in monetary amounts. The intensity of this consumption is essentially driven by the time available for construction. The final bid pricing should always be determined on the basis of a zero-base costing exercise. At the very least, this approach makes bidders aware of the risk/opportunity range in which their quoted final prices lie. If the client specifies a construction period that is shorter than normal, and if the bidder then decides to quote a price that is, say, 20% lower than the zero-base level, the bidder should at least be fully aware of the fact that it runs a very high project risk. In such a case, it is often no longer possible, even if production factors are combined in an optimal fashion, to make up for this deficit that exists already at the beginning of the construction phase.

2. Production system

In construction management, production factors include elementary (labour, equipment and machinery, materials) and discretionary factors (project managers, site managers, technicians etc.). Production factors are particularly influenced by environmental and ambient conditions. Any effective or efficient construction process is characterised by combining these production factors in an optimal fashion. This optimal combination is reached if and when production factors can be employed at a "normal productivity" level (cf. Hofstadler (2014); Produktivität im Baubetrieb; pp. 13).

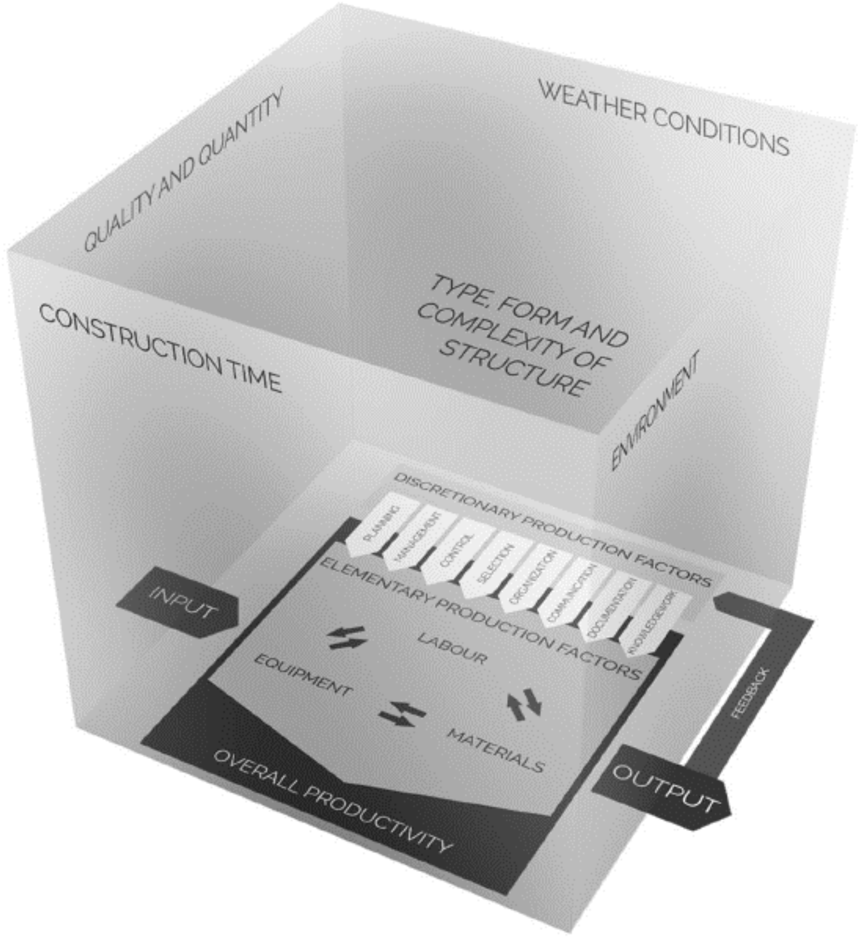

Figure 1: Influence on total productivity

The way in which production factors can be combined in a cost-effective fashion essentially depends on the type, shape and complexity of the structure as well as on the conditions governing work performance (see Fig. 1). Furthermore, achievable total productivity is determined by the required quality features and quantities, construction time, the site environment, and – last but not least – by prevailing weather conditions.

Any new construction project will always be subject to different boundary conditions; production factors must be adjusted to the specific circumstances of the project.

3. Importance of construction time

Construction time influences the project in many different ways. This parameter is relevant not only in terms of construction management and economics but also from a legal point of view. Construction time influences individual quality features as well as total quality and the number of disruptions to the construction process, and thus additional cost claims.

Generally speaking, sufficiently long periods must be scheduled for preparing quotations and construction activities and for actual work performance on the job site. Additional factors to be considered when determining normal construction time include seasonal effects and specific site conditions as well as other influential factors and difficulties.

Whenever short construction times coincide with a specified high quality standard of the building or structure and adverse weather conditions, this setting leads to a particularly unfavourable situation.

4. Specification of construction time

Construction time is usually specified by the client or principal. Contractors use this information to derive the utilisation of production factors required to fulfil their contractual duties. Labour consumption rates serve as a baseline indicator for all labour-intensive activities; labour consumption rates are subsequently used as key input variables to calculate output values. Bidders use labour consumption rates as an important basis for their costing and final pricing exercise.

How do production factors and productivity develop over the period of construction? This question is crucial for both preparatory project measures to be implemented by the client and for the costing exercise carried out by bidders and contractors asl well as for work execution and the billing of construction works. Clients are well-advised to thoroughly deal with the question of which intensity of production factor utilisation is most appropriate and useful to prevent any risk to achieving their project targets (quality, completion date, costs etc.). As a matter of course, clients are free to neglect this issue and to rely on a comprehensively worded construction contract. However, this approach might be associated with major disadvantages in terms of the project outcome (including cost overruns, quality issues and construction delays) because, obviously, any building or structure will always be constructed not by virtue of a mere contract but by an appropriate combination of production factors. It is the purpose of the construction contract to provide a proper framework for performing and billing construction work as well as rules for conflict resolution. It would thus also be advisable for the client to deal with the change in productivity and production factors over time. Bidders and contractors are bound to do this anyway because they would otherwise not be in a position to prepare a source-based costing exercise and to write the “optimal screenplay” for executing construction works (including spatial, temporal and intensity-related progress of work steps). In this context, the following question needs to be answered: Which trend should be assumed with regard to productivity and production factors during the construction period?

There will always be fluctuations in productivity because it will not remain constant over the entire period to project completion. When evaluating productivity, the individual project phases must be considered in relation to work performance (see Fig. 2). The following basic distinction can be made:

- Productivity during the ramp-up phase (D_{RU} = duration of ramp-up phase)

- Productivity during the main construction phase (D_{MC} = duration of main construction phase)
- Productivity during the final phase (D_{FP} = duration of final phase)

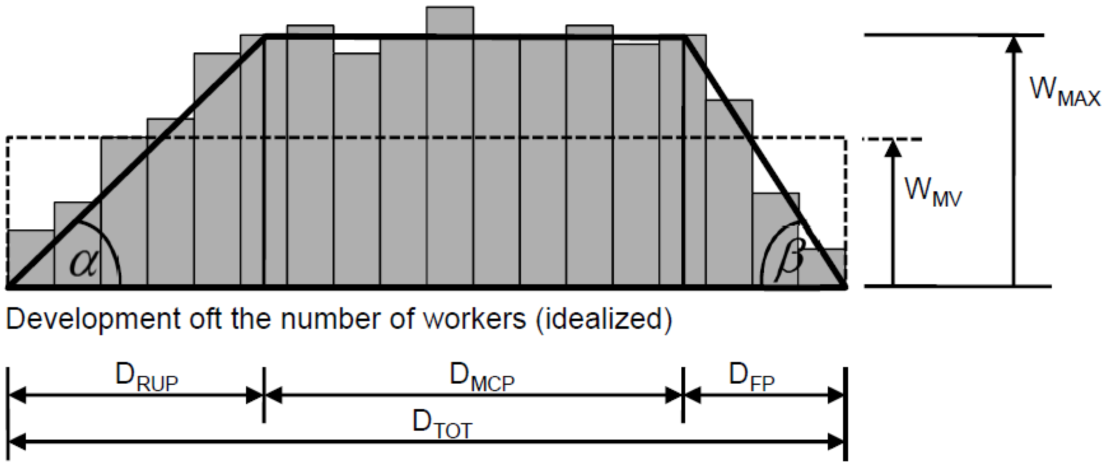

Figure 2: Number of workers on the construction site; see Hofstadler (2014), p. 14

Disruptions to the construction process are particularly disadvantageous in the ramp-up and final phases because optimally adjusted resources are not yet or no longer allocated to site operations.

4.1 Significance of construction time for the construction contract

By specifying construction time, the client exerts a direct influence on costs, and thus on construction prices. Construction times that are too short lead to losses of productivity and to higher costs. In the short term, higher costs are incurred, for instance, if the planning-ahead process does not work as intended or if other circumstances related to work performance (within the scope of the client) have changed. At a later stage, this situation will lead to issues caused by poorer structural quality as well as medium to long-term obstructions of use due to changed maintenance and repair scenarios. Limits for losses of productivity are still partially unknown or open to dispute.

Provided the client specifies normal construction times, contractors are in a position to optimally combine their production factors so as to perform their work owed under the contract at the lowest possible construction cost whilst adhering to the allocated budget (see Fig. 3). Thus, there is a lower risk of non-compliance with the specified construction time and cost as well as the agreed-upon quality standard.

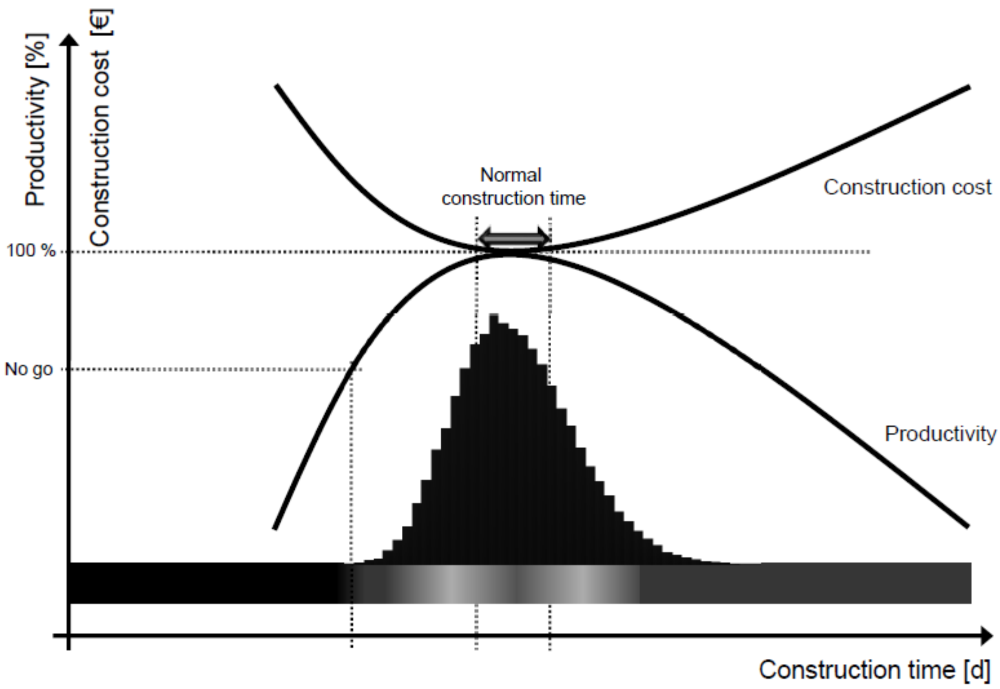

Figure 3: Relationship between construction time and costs; see Hofstadler (2014), p. 39

When determining construction time, the client usually considers limiting boundary conditions with an influence on site operations and management only to an insufficient extent, or not at all. These limiting factors result, for instance, from structural and operating conditions and have a major influence on the parameters that determine work output, such as the maximum number of usable workers or the maximum number of usable pieces of equipment.

A major issue in the context of calculating construction time is the linear nature of currently applied methods. In most cases, linear construction management-related correlations are used for the calculation process although these do not reflect reality. Any over- or underrun of thresholds or limits will lead to losses of productivity when capacities increase or decrease; these losses have a significant influence on calculation results. To accurately determine construction time, the various influences of productivity, such as limited available space for construction equipment, on production factors must always be considered.

Hruschka stresses that any calculation or optimisation of construction time must consider the mutual obstruction of the existing potential to prevent unrealistically short construction times. The construction time of a project cannot be shorter than permitted by the working capacity of the maximum installable transport equipment (Hruschka, 1969, p. 165).

Blecken states that the assumption of a deterministic production process leads to an oversimplification of the production model. Linear methods are chosen although most correlations of the combination of construction factors do not follow a linear pattern. He considers the additional application of stochastic methods to be a key tool to achieve significantly improved outcomes.

4.2 Definitions of construction time

The concept of construction time designates the calculated construction time prior to considering any buffer (assumed by the contractor). After determining construction time and considering the boundary conditions related to construction management and economics, the client should additionally account for a buffer to be able to compensate for any delays within its scope of responsibility.

Construction times are generally categorised as follows according to Hofstadler, 2014 (p. 57):

- Extremely short construction time
  Construction time is determined in such a way that the number of workers and pieces of equipment to be utilised productively exceed the corresponding maximum values (= thresholds to losses of productivity) by 20%.

- Very short construction time
  Construction time is determined in such a way that the number of workers and pieces of equipment to be utilised productively exceed the corresponding maximum values by 10%.

- Short construction time
  Construction time is determined in such a way that the number of workers and pieces of equipment to be utilised productively represent the corresponding maximum values. Any disruption to the construction process may immediately lead to losses of productivity when adhering to the construction time target.

- Normal construction time
  Construction time is determined in such a way that the number of workers and pieces of equipment to be utilised productively are 10% lower than the corresponding maximum values.

- Long construction time
  Construction time is determined in such a way that the number of workers and pieces of equipment to be utilised productively are 25% lower than the corresponding maximum values.

5. Influence of construction time on productivity

The qualitative correlation between construction time and productivity has been outlined above and is also reflected in the current literature pertaining to construction management. The missing piece, however, is the quantitative correlation between productivity and construction time. It is important for all parties involved in the project to find out how productivity changes in the event of deviations from “normal construction time”.

5.1 Construction time and losses of productivity

How can reliable data be derived that quantitatively describe the correlation between construction time and productivity in a generic rather than project-specific manner? Any *ex post* analysis will be difficult because massive changes in the type and circumstances of work performance will have occurred at least to a certain extent, and additional works or services will have been commissioned, compared to the situation when the construction contract had originally been entered into. The originally agreed-upon construction project does no longer correspond to the actually completed building or structure. It is virtually impossible to arrive at a source-based differentiation to determine whether losses of productivity were caused by changes in construction time and/or changes in the type of work, the circumstances of work performance, or contracted additional works or services.

For this reason, subsequent studies were based on *ex ante* considerations as a practicable alternative.

To generate valid data, an expert survey was conducted at Graz University of Technology to determine the quantitative correlation between construction time and labour consumption rates, and thus productivity. A total of 35 experts working for construction contractors were interviewed (both from construction trades and industry; survey period from August 2012 to April 2013). Respondents had an average work experience of 17 years (minimum experience: five years; maximum experience: 43 years).

Experts were asked to estimate increases in labour consumption rates or losses of productivity to be expected if deviations from the optimal construction time occur from a construction management and economics perspective (first stage: questionnaire completion; second stage: discussion of the questionnaire with the expert). "Normal" construction time serves as a reference where production factors can still be utilised without losses of productivity.

Prior to analysing data from the expert survey more thoroughly, an exploratory analysis was carried out to get an overview of collected data. This step was necessary to check plausibility and distributions as well as to identify any outliers. Box plots of the variables were prepared as part of the analyses to graphically represent distributions. A box plot describes the location and spread of a distribution and indicates any existing outliers. Outliers and extremes may significantly distort arithmetic means depending on the distance from the box plot whisker. This phenomenon was prevented by applying the M-estimator method, which made it possible to move existing outliers/extremes closer to the "main mass" of data by assigning a lower weighting to them. Arithmetic means and M-estimators were used as a basis for preparing diagrams and trend curves for increases in labour consumption rates and losses of productivity.

The differences in the increases in labour consumption rates for shorter or longer construction times are reflected in the diagram shown in Fig. 4 to consider the influence of construction time at the costing stage or in the process planning phase. The x-axis represents the extension/shortening of construction time relative to normal construction time as a percentage whereas the y-axis shows the percentage increase in the labour consumption rate for reinforced concrete works.

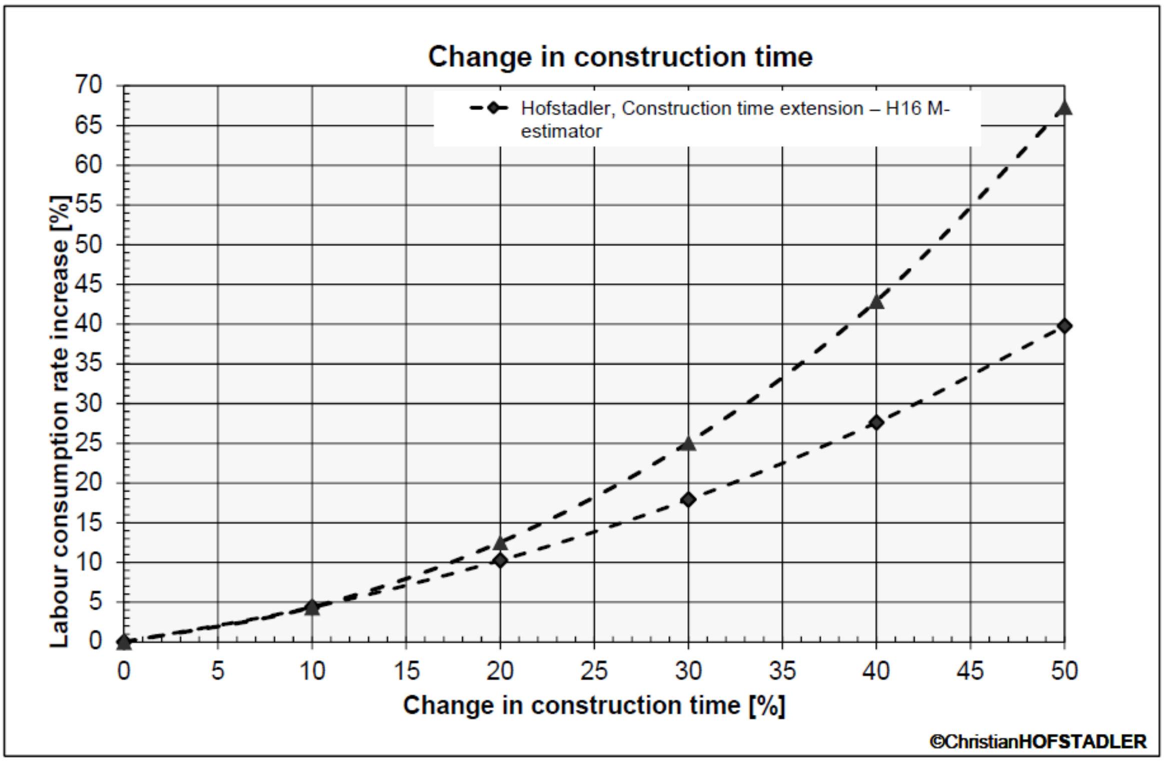

Figure 4: Trend curve for labour consumption rate increases – comparison between extension and shortening of construction time for reinforced concrete works (Hofstadler, 2014, p. 445)

The two curves are almost identical up to a 10% change in construction time. Only from the 15% threshold do the two curves deviate from each other. For instance, a 50% reduction/increase corresponds to a difference of about 27.6 percentage points. At a 50% shortening of construction time, the labour consumption rate increase amounts to about 67.4% and is thus 69.4% greater than in the case of construction time extension [= 67.4% * 100% / 39.8% -100%].

This comparison clearly demonstrates that a shortening in construction time is associated with greater labour consumption rate increases compared to an extended construction period. It is commonly known that shortened construction times lead to superimposed disruptions to productivity, particularly in the event of underruns of minimum available workspace and crane capacity.

There is a trend towards several different losses of productivity occurring simultaneously in the case of shorter construction times compared to construction time extensions.

5.2 Comparison with pertinent literature

The diagram shown in Fig. 5 compares the values cited in the pertinent literature to the results of the expert survey. This diagram represents the effects of shortened and extended construction times and the resulting losses of productivity. Oberndorfer, Petzschmann and Reister subsequently introduced generic limits and ranges for plausible productivity losses. Prior to using these limit values, care must be taken to ensure that the concept of productivity losses as interpreted by these authors is fully understood, as well as the calculation methods applied by them.

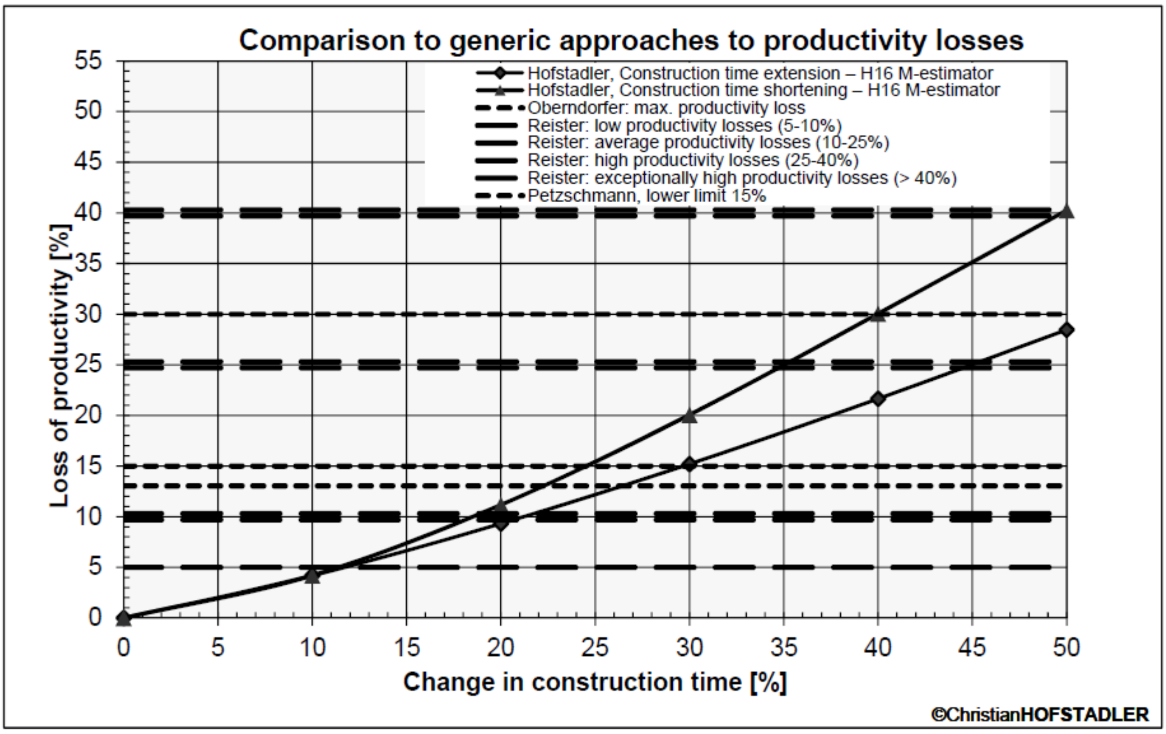

Figure 5: Trend curve of labour consumption rate increases – comparison between extension and shortening of construction time for reinforced concrete works (Hofstadler, 2014, p. 479)

The comparison with the limit defined by Oberndorfer shows that this limit is equivalent to the losses of productivity that would occur at a construction time shortening by about 22% and a construction time extension by about 27% as determined in the study conducted by Hofstadler.

In the event of simultaneous disruptions to the construction process, Petzschmann indicates a potential loss of productivity that ranges from 15% to 30%. The 50% productivity reduction according to Petzschmann is roughly equivalent to a 24% construction time shortening or a 30% construction time extension.

When considering the upper limit of 30%, the construction time shortening amounts to 40% whereas the construction time extension exceeds 50% (there is no point of intersection of the two curves in this case).

Reister considers ranges that cover the entire area of losses of productivity due to construction time extension or shortening. When considering a 45% construction time extension, it becomes apparent that the associated 25% productivity loss precisely coincides with the terminal average and initial high losses of productivity according to the categorisation applied by Reister.

For the 50% construction time shortening, the associated 40% loss of productivity precisely coincides with the terminal high and initial exceptionally high losses of productivity according to Reister.

The comparison of current results of the expert survey with the limit defined by Oberndorfer shows that this limit need not necessarily be applied, and that higher losses of productivity might occur. The limits stated by Petzschmann appear to lie within a plausible range. The ranges defined by Reister appear to be fairly plausible from a construction management perspective, depending on the extent of changes in construction time.

6. Conclusions

The correlation between construction time and productivity was shown both qualitatively and quantitatively on the basis of the new study published by Hofstadler. The effects on productivity and labour consumption rates to be expected if construction time is shortened or extended compared to the “normal” period were demonstrated. Related input data were collected directly in the expert survey. Arithmetic means were complemented by robust mean values calculated using the M-estimator method, which made it possible to systematically underweight any existing outliers and extremes in the calculation. The curves shown in the diagrams are thus very robust and reliable.

Any construction time that leaves sufficient room for considering all relevant construction management aspects will be beneficial for both parties to the contract. On the one hand, if the client specifies a normal construction time, this creates the preconditions for a construction process with very few disruptions. On the other hand, bidders can be highly confident in being able to utilise their production factors at their planned “normal productivity” level if a normal construction time is specified. Any disruptions can be overcome more easily compared to a construction process that had been disrupted already when work commenced due to an exceedingly short construction time.

Abstract

Performance measurement has been applied systematically in many different sectors to drive improvements in productivity. Attempts have been made to establish measurements and benchmarking in the construction sector, but we still have not reached a situation where performance is measured systematically and consistently along the construction process. This paper reviews performance measurement theory pertaining to the construction sector to understand how performance is currently measured. Using participative workshops and interviews, we have mapped requirements of different stakeholders toward a performance measurement system. Based on literature and collected data, we outline issues to consider when attempting to develop further mechanisms for measurement. We also report briefly from a study to analyze different measurement and benchmarking systems to understand strengths and weaknesses of these initiatives. Based on this analysis, we have in Norway established a project to systematically test the CII 10-10 system to see whether it can meet measurement requirements at several levels in the construction sector.

Keywords: Performance measurement, benchmarking, productivity, construction sector

1. Introduction

The word of mouth says that the construction industry around the world has great potential for improvement in productivity and performance, and this impression is supported by current research (Abdel-Wahab and Vogl, 2011, Ingvaldsen et.al., 2004). Multiple efforts have been launched to address this issue in recent years, but the main challenges for the industry are to document the real performance of the industry, understand where improvements are needed, and document whether improvement efforts have had the effect they were supposed to have. The fact is that the construction industry does not have a common measure, nor a common tool to measure, how productivity and performance improves or falls over time. This paper will argue that the construction industry should drop *productivity* as a measure and instead adopt *performance* measurement in order to support performance improvement efforts. The paper will also illustrate how a comprehensive performance measurement system should be constructed to address five different performance levels, and it will outline an ongoing effort to test the suitability of one performance measurement tool on the project level.

Today, productivity is the dominating indicator for performance in the construction industry. Productivity is the only measure available on an overall level in most countries, which is also the case in Norway, the country we have studies the most closely. The Norwegian Central Bureau of Statistics, SSB, provides annual productivity statistics. These statistics are based on the annual economic reports provided by all organizations registered doing business in Norway.

Figure 1 illustrates how productivity for the construction industry has declined, using the productivity in 1995 as a benchmark. By comparison, the productivity for non-construction has nearly doubled in the same time span. The statistics are, however, flawed and certainly not 100% reliable. First of all, not all organizations in the construction industry are represented in these statistics. Some organizations are included in other industries, such as oil and gas, since they have projects within both industries. Second, these figures are very high-level and fail to capture activity-level improvements. It is also a major problem that improvements that entail moving toward industrial production, i.e., off-site prefabrication of building modules, often has a double negative effect on construction productivity; this production is often transferred from construction to manufacturing in industry statistics. This means that the most productive activities are removed from the construction statistics, leaving the industry worse off than before the improvements were implemented.

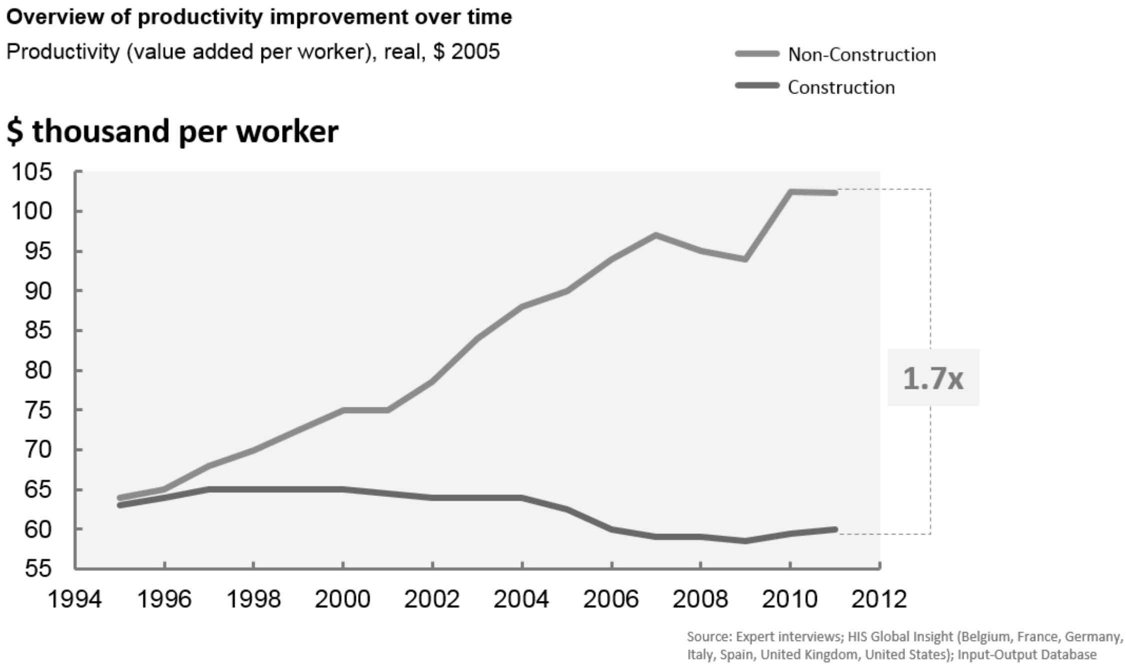

Figure 1 - Comparison of productivity improvement over time

Why, then, is it so hard to measure performance and get reliable measurements? Some of the answers are found in the characteristics of the industry itself. The construction industry comprises a large number of small construction firms, and a few larger contractors. A typical construction project consists of several small or medium-sized organizations temporarily working together, and they normally do not have any long-term relationship or partnership lasting longer than the duration of the project. They usually apply a contract model that does not give incentives for carrying out improvement efforts that will result in improved performance or increased value creation for other organizations. In other words, most improvement efforts are focused on increasing value for one single organization, and they do not necessarily find it interesting to help other organizations in the same project to increase their profits from that particular project. These characteristics results in sub-optimization and makes it harder to establish common measures and tools for performance measurement.

The long-term objective for the research project presented in this paper is to establish a set of tools that will support structured performance improvement efforts in the construction industry. The first step in this research effort is to select and test one tool for performance measurement in a range of Norwegian construction companies representing different actors in the project value chain. In addition, the first step will make sure that the experiences gained by each company is documented and shared between the companies.

2. State-of-the-art

According to Vogl and Abdel-Wahab (2015), in their review paper on the topic, there are not many papers that attempt to synthesize the existing literature in productivity research. Some attempts have been made (Yi and Chan, 2014; Dolage and Chan, 2014; Panas and Pantouvakis, 2010). Thus, it is difficult to find authoritative overviews of approaches and methods used to measure productivity/performance in construction. The fact that the approaches employed originate from quite different academic fields further complicates efforts to provide such an overview.

Notice that we deliberately wrote "productivity/performance", since these terms are often used either interchangeably or simultaneously (and then having somewhat different meaning) in publications. Many authors have discussed these terms, e.g., Page and Norman (2014), stating that "productivity measures how efficiently inputs are used to produce outputs" whereas "performance measures how well something achieves its intended purpose." Takim et al (2003) defined performance measurement as "the regular collecting and reporting of information about the inputs, efficiency and effectiveness of construction projects… used to judge project performances, both in terms of the financial and non-financial aspects and to compare and contrast the performance with others, in order to improve program efficiency and effectiveness in their organizations". These and many other definitions emphasize that performance is more detailed, with productivity often being seen as one aspect of performance.

Roughly, two main fields have contributed to the body of literature:

- Economics, discussing different ways to measure (and compare) productivity at a national and sector level.
- Operations management, looking at mechanisms to measure (and improve) performance at a business process and project level (both fields have also touched upon enterprise level measurements).

Under the economics approach, there are again two primary approaches; single-factor and multiple-factor models (Crawford and Vogl, 2006). The most widely applied single-factor model is the measurement of (average) labor productivity, which is typically applied by national statistics bodies in many countries. The calculation is done by dividing the aggregate output/value created by the labor input spent to produce the output. Multi-factor models attempt to explain productivity by considering factors beyond labor productivity, such as capital, technological progress, management, skills, etc. There are advantages and disadvantages of both approaches (ibid). Single-factor models require less data and allow cross-national benchmarking due to their widespread use, but at the expense of accuracy. Multi-factor models provide better insight through more fine-grained measurements, but require more data that can be difficult to collect. Extensive criticism has also been raised regarding the accuracy of high-level economics models, for example lack of suitable data (Allmon et al., 2000), that available statistics are unable to determine whether productivity in reality has decreased or improved (Rojas and Aramvareekul, 2003), and that a trend from on-site building to offsite manufacturing shifts this activity from the construction to the manufacturing sector (Haas et al, 2000). Irrespective of which economics model is applied, there is little relevance in terms of application at an operational level, in projects and companies and actors in the sector have therefore pursued alternatives (Harrison, 2007).

The operations management field offers bottom-up approaches, often termed "activity-level" measurement, based on measuring individual construction activities/processes. Equal to economics-derived approaches, also here different mechanisms have been developed. Back in 2000, Allmon et al described how economics-based measurements could be replaced by activity-level measurements, but still relying on publically available statistics (Means' Building construction cost data, published by the R.S. Means Co. Inc. from 1960-1997 in the US and deflating costs using the Consumer Price Index). A different approach to operational performance measurement builds on so-called performance measurement frameworks, defined by Brown et al (1997) as "a complete set of performance measures and indicators derived in a consistent manner according to a forward set of rules or guidelines." According to Yang et al (2010), the primary frameworks applied in the construction industry are excellence models (e.g., the European Foundation for Quality Management excellence model), the Balanced Scorecard framework (Kaplan and Norton, 1996), and key performance indicators models (e.g., the KPI framework developed through the Construction Best Practice Program in the late 1990s (Lin and Shen, 2007)). As we show later, systems based on key performance indicators seems to have become more prevalent lately, as seen in the operational performance measurement systems currently available.

Goodrum et al. (2002) outlined some advantages of activity-level measurement over traditional aggregate measurement; by measuring output in real quantities (e.g., square area of building spaces or volume of materials) the issue of price indexes is eliminated, by measuring labor effort in terms of labor hours there is no need for using cost-index-based deflators, and it is easier to compare input and output changes over time. More importantly, while high-level productivity measurements at best capture a very few factors that affect the performance of the sector and its projects, there are a number of issues that affect the long-term viability of the sector. One set of such factors was proposed by Page and Norman (2014), factors such as building to quality the market needs, maintaining health and safety standards, developing and maintaining skills, adopting technology, innovating, etc. According to Harrison (2007), the key disadvantage of more detailed activity-level measurement is that assembling a complete sector view would require summing up all tasks in some manner, while it would be easy to omit tasks. And for all tasks, large amounts of high-quality data are required.

A last topic of relevance when it comes to activity-level measurements is at which level such measurements can target. Yang et al (2010) reviewed performance measurement studies undertaken in the construction sector and found three levels being discussed; the project level, the organizational level, and the stakeholder level. Of these, project level measurements came first (Lin and Shen, 2007), and encompassed a large numbers of different dimensions of performance, e.g., environmental performance, human resource performance, procurement performance, safety performance, technology innovation, etc. (many of these coincide with Page and Norman's factors (2014)). For enterprises in the construction sector, project-level measurements are valuable but the need for more aggregate company-level assessments induced efforts to measure performance at the organizational level (as reported by for example Bassioni et al, 2005). Such measurements cover both financial, as would be expected, and non-financial aspects (Bassioni et al, 2004). The third level, stakeholder-focused measurements, is arguably also important, as project success is ultimately judged by different stakeholders. Wang and Huang (2006) found that the owner's, supervisor's, and contractor's performances were significantly related to the different criteria of overall project success. According to Yang et al (2010), there has been less work at this level of measurement.

We have so far briefly mentioned some more specific models/systems for performance measurement. To conclude this chapter, we outline in some more detail a selection of such models/systems, based partly on previous studies and partly on mapping undertaken ourselves. Going back to 2003, Takim et al reported from work to synthesize systems of measuring project performance in the United Kingdom, the USA, France, India, Hong Kong, Saudi Arabia and Malaysia. They found that these systems had different aims and focus of measurement; measuring both productivity and performance at a project level, assessing project viability, as well as targeting project quality. As far as we have been able to ascertain, few of these systems are still in use today, and we therefore conducted a renewed search for existing performance measurement systems. Table 1 lists the systems found that we judged to be most relevant for further investigation (we make no claim that our search was exhaustive).

Table 1: Overview of selected existing performance measurement systems

Performance measurement system	Country of origin	Measurement purpose	Data providers
Construction Industry Institute: 10-10 program	USA	Assess project performance at the end of each project phase through performance measurement and benchmarking	Project manager, project participants
Construction Industry Institute: General Program	USA	Detailed performance analysis after project completion using benchmarking	Project owner
Constructing Excellence: KPIzone	UK	Detailed performance analysis after project completion using benchmarking	Project owner
Benchmark Centre for the Danish Construction Sector: KPI System	Denmark	Evaluation of contractors in the form of a scorecard as a basis for more informed future choice of contractors and contractor improvement	Project owner
Performance Based Studies Research Group: Performance Information Procurement System	USA	Evaluation of contractors to allow selecting future contractors based on other criteria than price	Project owner
Project Norway: Health Check/Project Evaluation	Norway	Assessing performance throughout the life cycle of a project	Project participants
BRE: Key Performance Indicators for Construction Industry	UK	Performance measurement for a set of performance indicators that can be compared across projects or companies	Project participants
Customer satisfaction measurements	In use in different countries	Measurement of client/end-user satisfaction with the completed building	Client/end-user

We will refer to Table 1 and these systems in the discussion section of the paper.

3. Methods

The research presented in this paper has developed slowly, from an idea presented and discussed at a formal search conference in the Norwegian industry to identify ways to improve the performance of the sector. This turned into a research project, started in 2013, and currently has funding until 2017. The mentioned search conference prioritized performance measurement as one of six initiatives to be undertaken, as a means to truly knowing the current status, verifying whether improvement efforts have an impact, and undertaking industry analyses. The Norwegian Directorate for Building Quality (DiBK) funded an initial study to document the challenges facing the industry when trying to implement performance measurement and use the data to improve their performance. In turn, the first study laid the foundation for a secondary study, where the aim was to select and test one specific performance measurement tool in order to gain experience in both how that tool worked, what proper handling of the tool demanded of the organization using it, and how structured performance measurement should be carried out in practice. The main project started in august 2015, and will be carrying on until summer of 2017. The long-term objective for the whole portfolio of research effort is to develop a set of tools for performance measurement in the construction industry in order to support future efforts for continuous improvements in the industry.

A combination of different methods for data collection and data analysis formed the methodical framework for the research presented in this paper. Data collection was carried out using interviews, focus groups and expert panels. In addition, document studies were used as well as existing descriptions and documented experiences in using the different performance tools under evaluation. The representatives from the construction industry also participated in workshops where the findings were discussed and scrutinized. To a large extent, the same methods were used to analyze the data, especially focus groups, expert panels, and workshops. The integrity and validity of the data were ensured through triangulation, both researcher triangulation (using more than one researcher to analyze the same data) and the application of different types of data.

We have made some choices regarding methods, research approach and sample selection. First, we have not been able to identify and review a complete sample of tools available for performance measurement in the construction industry. Hopefully, our sample is satisfactory and encompasses the most frequently used systems that are publicly available. Second, the organizations involved come from the Norwegian construction industry. Still, our research has shown that there are many similarities internationally in the construction industry. Our findings could therefore be valid for other countries, even though this has not been the aim for this study, Finally, the research is still ongoing so our findings are not finalized yet, and the results should be reviewed in this perspective.

4. Results and Discussion

As chapter 2 showed, measurement of productivity and performance has been extensively discussed in relation to the construction sector. However, although many countries measure high-level productivity and several performance measurement framework and systems have been developed, we still have not reached a situation where performance is measured systematically and consistently along the construction process. As briefly discussed in chapter 3, as part of the research project aimed at investigating a possible new, operations-focused measurement system, we mapped the needs of different stakeholder groups in terms of measurement and measurement data. This led to the identification of five characteristics to consider when designing a performance measurement system (and based on these five characteristics, the subsequent development of a framework for evaluating a performance measurement system in terms of fulfillment of measurement requirements). The five characteristics are:

- *Level of measurement*; at which level of construction sector activity the measurements are undertaken, as discussed by Yang et al (2010) and treated in more detail below
- *Who undertakes the measurements*; who is responsible for collecting the measurement data, e.g., the project owner, engineering consultants, contractors, authorities, external actors, etc.
- *Dimension of performance measured;* the performance measurement literature suggests a wide range of aspects of performance that can be measured, spanning dimensions like time, cost, quality, flexibility, SHE, communication, innovation, learning, environmental impact, and ethics
- *Project phase targeted*; construction projects can be divided into a number of different phases and the measurement needs will typically vary across phases (this is for example evident in how CII has chosen to link the 10-10 performance measurement and benchmarking system to five project phases)
- *Type of project/building/infrastructure*; not surprisingly, we found that the usefulness of the selection of performance indicators applied vary from project type to project type, e.g., office building, laboratory facility, rail line, etc.

Regarding the first of these dimensions, the sector/activity level addressed by the measurements, for activity-level measurements, Yang et al (2010) identified three levels; the project level, the organizational level, and the stakeholder level. In our mapping of measurement stakeholder groups, we found five distinct groups that also logically correspond with measurement levels:

- *The country level;* by this, we think of the economics-type measurements undertaken at a high level of aggregation, typically for the whole construction sector of a country. This level of measurement has many stakeholders with highly differing needs for measurement, but some key measurement purposes can be to demonstrate the importance of the construction sector in society, promote the reputation of the sector, improve competitiveness, feed national and supranational statistics to allow tracking of trends and benchmarking.
- *The project/value chain level*; we have combined the terms *project* and *value chain* to clearly communicate that this level addresses whole projects and their (often multiple) value chains that contribute to delivering the project (this corresponds to the project level

identified by Yang et al (ibid). To measure and promote better performance of projects, this level of measurement must be able to assess the performance across individual actors to determine how well they collaborate to perform the project. Such measurements should provide detailed insight into the performance of the projects, especially which performance drivers affect overall performance, as well as stimulate behavior that create win-win situations.

- *The company/organizational level*; meaning the individual (private) company or (public or non-profit) organization participating in the construction project (corresponding to the organizational level discussed by Yang et al (ibid). Many measurements at this level are required by authorities or for accounting purposes, but other measurements that aggregate results from the organizations' projects are also important.
- *The construction process level*; academic sources and practitioners apply different terms to the lowest activity level of a construction project, e.g., construction processes, business processes, work processes, and we refer to these processes, for example land acquisition, production of drawings, electrical installation, etc. These measurements serve several different purposes; provide a platform for fact-based improvement efforts, promote an end-to-end view on processes to counter sub-optimization, assess effects of changes in processes, etc.
- *The user level*; this last one is not as clear a "level" as the other four and could even be argued is a phase of the project rather than a level of measurement. What we mean here is the users' perceived performance of the project and its deliverables, an important aspect of performance often overlooked in existing literature, and one that can only be measured after completion of the project, ideally even only after some period of use, this indicating that this is a matter of project phase. However, we could also argue that this is a singular instantiation of the stakeholder level outlined by Yang et al (ibid), and we have therefore chosen to include it as the fifth level. The purpose of these measurements are to assess whether the delivered building or infrastructure fulfills it purpose (usability), to understand the long-term life cycle performance of it, evaluate user satisfaction, etc.

Put together, the five characteristics of a performance measurement system can be construed as spanning a five-dimensional matrix. Every single cell in such a matrix would represent a unique measurement context be populated, and in an absolutely complete performance measurement system, each cell would be populated with at least one performance indicator serving a unique purpose. In reality, the different combinations carry highly differing relevance, and a "complete" measurement system would be extremely complicated and contain many measurements of little interest. To identify cells of the matrix that seem to have the highest potential for delivering relevant measurements, we defined a set of criteria to use when mapping measurement requirements among sector stakeholders:

- Is there a measurement need and purpose?
- Is there sufficient availability and quality of the data required?
- How much effort and cost will be involved in establishing the measurement?
- Do other established performance measurement systems undertake this measurement, thus allowing benchmarking?

Regarding the issue of data availability and quality, it is obvious that any performance measurement system and regardless of which exact performance indicators are defined, will require a fair amount of performance data. An effective construction sector system should strive to exploit lessons learned from other sectors when it comes to data collection, where we see that there a number of "archetypes" of measurement approaches that pose different opportunities:

- Manual or automatic harvesting of data from public records, e.g., industry statistics, accounting systems, license data, etc.
- Automatic data collection from different sensors or sources. This is an area with a large potential for effective data collection. Approaches can include collecting measurements from sources like moisture sensors, drone-mounted cameras, scanners, step counters on smart phones, etc. See Akinci (2015) for a presentation of some opportunities different technologies provide for data collection.
- Exploiting so-called crowdsourcing where large numbers of users cooperate to populate databases with relevant data. An example of this approach is the Danish construction scorecard system where public sector project owners score suppliers according to a number of performance dimensions, where this data is later made available to other project owners.
- Establishing a structured database for benchmarking, where users are encouraged to input performance data by allowing them to compare their own data against others'. Several of the performance measurement systems listed in Table 1 build on this principle.

Irrespective of the chosen performance measurements and which approach is used to collect the performance data required, the purpose of any measurement effort is obviously to give users of the system new insight. A fundamental analysis is to identify relationships between so-called *outcome measures/result indicators* and *performance drivers* (Kaplan and Norton, 1996). Result indicators say something about the end performance level of an activity or process, for example quality expressed by user satisfaction or warranty costs, productivity expressed as the portion of craft hours spent on value-added activities, or safety expressed as recordable incidents or time away due to injuries. These are the results of different performance drivers, characteristics about how the processes are designed or other contextual factors, for example the level of involvement of building contractors in the engineering phase, degree of prefabrication, distance between storage and work area on site, etc. Important insights can be gleaned from investigating whether changes in results indicators can be explained by differences in performance drivers, as this can help identify good practices that will improve performance.

The identified characteristics of performance measurement systems and assessment criteria presented here can be combined to either evaluate existing systems or as guidelines when designing a new system. In the end, the criteria we developed and that were used to evaluate the systems mentioned in Table 1 are those shown in Table 2 below. The table also shows our assessments of each system, and we underline that these were subjective assessments made considering our requirements for a measurement system to be pilot implemented in Norway.

The conclusion was that there is not one single system that meets all requirements. However, we found that the CII 10-10 system seems best suited for adaptation into a national construction industry system for Norway as it had the best score of all the systems presented in Table 2. This system will be tested in a number of companies and at the aggregate level during the next two years.

The 10-10 system provides benchmarking of project performance based on anonymously surveying project management team members and collected facts on project progression. 10-10 surveys by phase instead of at completion, and uses five distinct but overlapping phases (front-end planning/programming, engineering/design, procurement, construction, commissioning/start-up) using simple statement-based questions. In addition, the system uses ten leading indicators (input measures) and ten lagging indicators (outcome measures) to collect facts, hence the name 10-10. A project benchmarks its performance with other projects in the same phase, and it is possible to see how the performance of the project develops during the project life cycle. A more thorough description can be found on the CII web site[1].

5. Conclusions

This paper reports from a study undertaken on the use of performance measurement in the construction sector, a study that addressed several issues that need to be resolved for such measurements to be meaningful and have an effect. Previous studies have investigated different levels measurements can be undertaken at, typically distinguishing between country/industry and project/activity level measurements. We have found that in order to provide a comprehensive set of measurements that serve a number of different purposes, an extensive measurement system is needed that addresses five levels; the industry/sector level, the company level, the project level, the process level, and the user “level”. Furthermore, the range of issues targeted for measurement must also be expanded, from pure labor productivity assessments and a narrow set of project level factors to a wide set of performance indicators that can be used to facilitate understanding, improvement, and aggregation to higher levels.

Having looked into existing measurement systems and evaluated these against a set of requirements, it seems clear that there is no extant system that meets all requirements. It is probably not likely that one unified system ever will exist, but we see that it is crucial that if several systems must be used, these must be linked and allow aggregation of data across the different measurement levels.

In the Norwegian construction sector, we have found the CII 10-10 system to be the one existing system that promises to meet the most of our requirements. Together with about twenty organizations in the industry, we will initiate extensive testing of this system to see how well it manages to serve both process and project level improvement efforts, analyses into performance drivers and their effects, as well as industry-level statistical needs. We will report from this work in future papers, and in the mean time hope other countries experiment with other measurement models and systems so that we jointly can move the industry forward.

Abstract

The primary aim of this research is to examine the interplay between formal and informal networks in construction project-based organisations (PBOs), with a view to understanding its impact on project performance. PBOs, as an organisation form, have been widely adopted to organise works in various industries, especially construction, information communication technology, automobiles, film-making and the media, and so on. Previous studies have recoginised the importance of formal institutions (e.g. hierarchies, contracts) while that of informal institutions (e.g. social network, culture) has yet to be well documented, or at most, merely treated as a supplement to the formal ones. This study goes beyond that by arguing that the interplay between the formal and informal institutions has a significant effect on project performance. It does so by conceptualising PBOs as social networks, including formal and informal networks, which are representations of the formal and informal institutions, respectively. Three PBO case studies in the construction industry are conducted. With the help of Social Network Analysis (SNA), the graphical and mathematical presentations of both formal and informal networks in three PBOs are explicated. It is found that the greater the extent of "fit" between the formal and informal networks/institutions of a PBO, the better the project performance will be. The research contributes to the knowledge body in two folds: (1) methodological innovation through integrating PBO, SNA and institutional analysis, and (2) examination of the impact of interplay of formal and informal networks on project performance.

Keywords: Project-Based Organization, Social Network Analysis, Fit, Construction

1. Introduction

PBOs as an organisation form have been widely adopted to organise works in various industries, especially construction, information communication technology, automobiles, film-making and the media, and consulting and professional services. According to Sydow et al. (2004), PBOs refer to a variety of organisational forms that involve the creation of temporary systems for the performance of project tasks. Here, a project can be defined as a temporary organisation to which resources are assigned to undertake a unique, novel and transient endeavour (Turner and Miller, 2003).Winch (1989) classed PBOs as 'intra-firm' and 'inter-firm' organisations. Intra-firm PBOs, e.g. in-house projects, are still under the ambit of a single economic unit or firm. The operations of intra-firm PBOs are normally governed by hierarchical relations. By contrast, inter-firm PBOs are a coalition of multiple firms with divergent economic and social interests (Winch, 1989). Project governance in inter-firm PBOs is mainly through contracts, and more recently has seen a shift of focus to informal institutions such as relations, trust, and culture.

The advantages of PBOs include less inertia associated with permanent organisations, better processes, higher output quality, increased ability to respond to customers' needs and innovation in collaboration with clients and suppliers. However, the downside is that PBOs bring new challenges to knowledge management, human resource management, and strategic management. Researchers have endeavoured to explore how to maximise the advantages while overcoming the downside of PBOs.

The construction industry has been consistently used as a typical institutional setting for inter-firm PBOs research and practice. It is an industry in which the forms of PBO have long been taken to be the norm across a significant swathe of activity (Morris et al., 2011; Bresnen et al., 2004; Gann and Salter, 2000; Winch, 1989). Without PBO, the industry may not have developed so many roads, bridges, offices, housing projects and the like, which are instrumental in influencing human health and social behaviour as well as cultural identity and civic pride (Pearce, 2003). The industry is said to be the largest industry employer globally (WTO, 1998), accounting for around 10% of the world's GDP, and yielding an output of approximately US$ 4.8 trillion per annum (Flanagan et al., 2007). Nevertheless, the industry has also received its fair share of criticism for its widespread problems such as late delivery, budget overruns, and lacklustre performance (Li et al., 2009). For example, in 2004, the Construction Industry Institute of the US estimated that 57% of money spent on construction in the USA is non-value-added and is therefore wasted (Eastman, 2008).

MacLeamy (2008) attributed the above problems to a fatally flawed system: design, bid, and build (DBB). Under the DBB system, professionals such as architects, engineers, surveyors, and contractors are separately contracted to do a parcel of the work. Although under the same umbrella as PBOs, they are not necessarily involved in the whole project lifecycle. As such, they do not always work together efficiently and, in fact, can have competing interests (MacLeamy, 2008). This is well known as the fragmentation and discontinuity that exists in construction PBOs. With such structural problems, it is not uncommon to see issues such as risk-aversion, short-termism, silo thinking, lost information, and ineffective communication. It is no exaggeration to say that the construction industry has witnessed almost every downside that a PBO could have. Responding strategies have been explored, e.g. encouraging communication (Dainty et al., 2006), promoting relational contracting, emphasising the importance of culture and trust (Rowlinson and McDermott, 1999), and advocating design and build integration (Walker, 2007) and public private partnership (Li and Akintoye, 2003).

There are many formal institutions of PBOs in the construction industry, such as ownership, financing modes, contractual relationship, outsourcing and sub-contracting, strategic alliancing, etc. These formal institutions have a great effect on the project performance. While recognising the importance of formal institutions associate with a PBO (e.g. organisation structure, hierarchies and authorities, and contractual arrangement), researchers increasingly start to examine the importance of informal institutions. For example, Pauget and Wald (2013) reported a vivid case of a French hospital construction project, in which relational competence in complex temporary organisations was investigated. While formal institutions define the "normative system designed by management" or the "blueprint for behaviour" (Scott, 1981), informal institutions define the actual behaviour of players. Informal institutions are largely shaped by soft factors such as players' mindset, trust, Guanxi, or project manager's charisma. They may or may not be in line with the formal institutions with the constraint of the specific PBO environment. Krackhardt and Hanson (1993) metaphorically describe the informal network is "the central nervous system driving the collective thought processes, actions, and reactions of its business units", and must be matched with the formal network, which is the skeleton of an organization, only by that the productive engine of the organizations can be fully steamed. However, as a whole, the importance of informational institutions in construction PBOs has not been well documented. Too often, they are treated as exogenous factors, which only passively responded to alternative formal institutions (Zenger et al., 2002). They go further and theoretically discussed the interplay of formal and informal institutions in organizations, and argued that it would have significant impact on the organizational performance (Zenger et al., 2002). Nevertheless, empirical studies on the interplay in construction PBOs are few and far between.

The aim of this research is to examine the interplay between formal and informal networks in construction PBOs, with a view to understanding its impact on project performance. The research question of this study is "how does the interplay of formal and informal networks associate a PBO affect project performance?", and the main research hypothesis is as H: *The greater the extent of "fit" between the formal and informal institutions associated with an innovative procurement system, the better the project performance will be*. The article is organized in the following way. Subsequent to this introduction section is the methodology, whereby construction PBOs are conceptualised as social networks, including formal and informal networks, which are representations of the formal and informal institutions, respectively. SNA is then employed as the main analytical tool, followed by the description of three case studies. Then, the results of data analyses are presented and discussed. Finally, conclusions, implications and limitations are provided.

2. Methodology

A mixed method comprising of case study, interview, survey/questionnaire, archival study, field study, and social network analysis are integrated to answer the research question. There are many possible ways to collect the data for mapping the SNs, such as the use of questionnaires, interviews, participant observations (Scott, 1991), and ethnographic methods (Hartmann and Fischer, 2009). However, these methods often rely heavily on personal judgment of the informants and are very time-consuming. This study collected relational data of informal institutions, which is often "off-the-record", thus requires considerable skills in interviewing, ethnographic studies that can interrogate real relations from those relations bearers. In this study, the information of informal networks occurred in workplace of a PBO was collected to characterize the informal institutions. Particularly, this study introduces a novel method, which is able to develop a set of SNs from timesheets. Case studies of three PBOs set the framework and boundary for this study. Interviews, survey, archival study and field study are the direct methods used in the data collection process, while SNA and related correlational analysis are employed in the data analysis.

2.1 Theoretical foundation

The relationships amongst the project team members in a PBO can be understood by treating them as a 'socio-technical system', which is a systems approach to complex organizational design that recognizes the interaction between people and technology in workplaces (Tavistock Institute, 1966). However, Winch (1989) argued that it has only limited analytical use in construction PBOs. Schweber and Harty (2010) thus proposed the "socio-technical networks" to examine the relationships. Notably, researchers have conceptualised PBOs as social networks (SNs), which consist of a finite set or sets of actors and the relation of relations defined on them (Wasserman and Faust, 1997). Loosemore (1998) investigated interpersonal relationships in PBOs under crisis conditions using SNA. Nohria and Eccles (1992) asserted that all organisations are SNs and therefore need to be analysed in terms of networks of relationships. Following this line of thought, Pryke (2005; 2012) suggested that a construction PBO can be represented as a multi-layer of interdependent networks. Chinowsky et al. (2008; 2010) also clearly stated that project organisations are SNs. Drawing upon these theories, it is appropriate for this proposed study, by emphasising the embeddedness of project management in a social context, to take the theoretical stance that PBOs are SNs.

If we accept that a PBO is an SN, then our understanding of the effects of formal and informal institutions interplay in a construction PBO can be related to the analysis of the network by using the established SNA approach. As an academic discipline introduced by Moreno (1960), SNA has matured over the past decades (Wellman et al., 1988). It is concerned with the structure and patterning of relationships over time and its purpose is to examine how the relationship structures impact behaviours, and to identify both their causes and effects (Wasserman and Faust, 1997; Scott, 1991). SNA is a new "language" to represent and understand PBOs (Pryke, 2012). Mead (2001) underscored the value of SNA in visualising project teams. The translation of PBOs into SNs also enables SNA to be applied, particularly its mathematical and sociological methods, to study project relationships in a manner that will inspire both academic and practical interest (Hughes, 2012).

2.2 Social network analysis

The collected data include data about formal networks and that about informal networks. The former mainly embrace contractual relationship and organizational structures, while the later contains self-reporting of the real-life communication and/or archival records of the work-related interactions. Data collected in all the three case studies are preliminarily edited, coded, and translated into SNA language. As shown in Figure 1, according to the information of the links, the collected data about formal networks are conversed into adjacent matrix, which is the SNA data input format used in *Ucinet* and *R*. Similar conversion method can be performed based on the collected data about the communication information. The validation of the networks is crossed checked and rectified through further enquiry by email, phone or face-to-face talk.

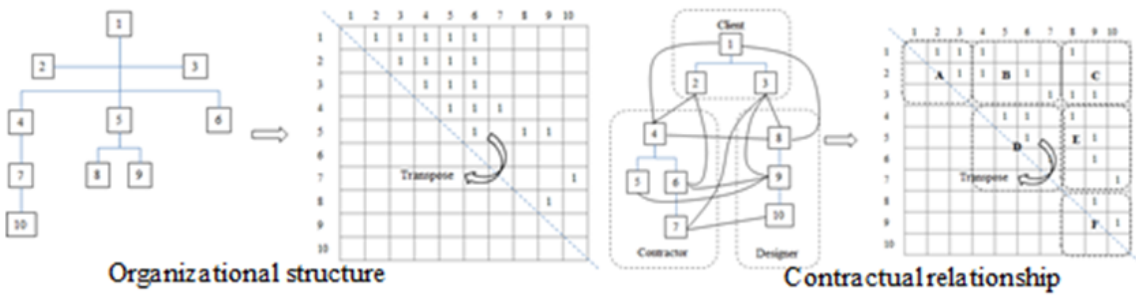

Figure 1 The illustration of the method to converse the collected data into adjacent matrixes

When the data are ready, it comes to the further data analysis, which constitutes of two phases. The first phase is the graphical and mathematical presentation of social networks to characterize the formal and informal institutions. SNA is carried out through the SNA software *Ucinet* and *R*. The visualization function in the software is able to convert the adjacent matrixes into various graphs of networks. The key actors, network density and clusters can be observed within the vivid images. It helps the researchers to get a big picture of the networks, and to gain the preliminary sense of the patterns of the data. The mathematical presentation of the social networks includes a set of metrics, e.g. network density, diameter, average path length, degree / closeness / betweenness centrality, clustering coefficient, etc. The metrics can be utilized to reveal the hidden patterns and trends in the data. Particularly, the physical meanings of the metrics, as explicated in Table 1, will be analysed and discussed in the rich context of the three case studies.

2.3 "Fit" between the formal and informal networks

To measure the fit of formal and informal institutions surrounding a PBO, a simple instrument was developed based on two main principles. First is the complementary/rival nature of a network metric. If a network metric is complementary, it means that an increase in the fit index leads to higher level of fit; if rival, an increase in the fit index leads to lower level of "fit" and it is expected to result in poorer project performance. Second is the benchmark, as set by the metrics of formal social networks. Here, the closer the fit index value is to 1.0, the more similar the formal and informal social networks are. In the context of PBOs, "fit" can be understood through the discrepancy between informal and formal institutions.

The fit index of a metric *X* at the individual level is assigned as the proportion of the average value of *X* in the informal network, denoted as $Average\ (X^I)$, and that in the formal network, denoted as $Average\ (X^F)$. The equation is shown as below:

$$Fit\ index = \frac{Average\ (X^I)}{Average\ (X^F)}$$

The fit indexes of the metrics at the network level are calculated according

$$Fit \quad index = \frac{Informal}{Formal}$$

Where, given a particular metric X, Informal stands for the value of X of the informal network and Formal stands for the value of X of the formal network. Two main principles behind when the author developed the concept of fit index are as follows:

1) The nature of complementary of a metric

The value of the fit index for a given SNA metric is expected to be closer to 1 in order to achieve a better project performance. By saying complementary, it means that the increase of the fit index leads to higher level of fit. Similarly, a fit index is rivalry means the increase of its value is expected to result in a poorer project performance.

2) Benchmark: the metrics of formal social networks are set as the benchmark.

As shown in the equations, the fit of formal and informal institutions are measured by the comparison of the formal and informal social networks. The closer the value of a fit index is to 1, more similar the formal and informal social networks are.

The level of fit between the formal and informal institutions is interpreted by Discrepancy of Fit (*DoF*) between the designed formal network and the actual informal network, which is equivalent with the extent of being close to 1.0. The discussion applies to both the SNA metrics at network level and individual level. Mathematically, *DoF* is measured in Equation 5.3, which is the same as Equation 4.2. Given a metric, the value of *DoF* is usually larger than 0, unless there is a perfect fit between the formal and informal networks in terms of the metric.

$$DoF = | Fit \quad index - 1 |$$

According to extensive literature review, the metrics selected for this study are grouped into *network level metrics*, including network density, diameter, average path length, global clustering coefficient, and *individual level metrics*, including degree / closeness / betweenness centrality, and local clustering coefficient. Totally, eighth metrics are employed to develop the main hypothesis (*H*) into eight respective sub-hypotheses, where the extent of "fit" in (*H*) is measured the metrics.

2.4 Case studies

The description of the three case studies is shown in the Table 2. Project Alpha is an infrastructure project in Hong Kong with four separated contracts. It is a complex construction project, with a huge amount of financial investment of about 36 billion HKD. Project Beta includes two public housing projects done by the same government department in Hong Kong. Project Gamma is a building project in Germany, with a relatively small financial investment of 180 million HKD. This project is the only one that is private funded. The network boundary of SNA is set to be active PBOs in the three case studies respectively (for the time being of data collection), with the actors the main project participants and the links the formal or informal "interactions" aforementioned above.

Table 2 Description of three case studies

Project Ref	*Alpha*	*Beta 1*	*Beta 2*	*Gamma*
Project type	*Infrastructure*	*Public Housing*	*Public Housing*	*Building*
Duration	*8 years*	*3 years*	*4 years*	*21 Months*
Financial size	*36,0000 Million HKD*	*470.0 Million HKD*	*610.4 Million HKD*	*180 Million HKD*
Financing method	*Government appropriation*	*Government appropriation*	*Government appropriation*	*Private fund*
Physical size	*4.5 km long trunk road, 3.7 km long tunnel and 3 km approach roads*	*11,950 m2*	*11,871 m2*	*14,800 m2*

3. Data analysis and results

There are totally 4 PBOs in the three case studies, 1 for Case Alpha, 2 for Case Beta, and 1 for Case Gamma. The main outcome of preliminary data processing mainly is the adjacent matrixes for both formal and informal networks. The two matrixes are imported into *Ucinet* to have the network visualization and into R to calculate the SNA metrics. Figure 2 is the graphical presentation of the formal and informal networks in Case Beta 1. The size of a node is proportional to the node's degree, and the displace rule of the two graphs in Figure 2 is trying to highlight the "important" actors in the middle. Hypothetically, the formal network shall set up the basic structure for the informal network, since the former shows the designed working relationships among actors within the PBO, while the later one is the actual interactions occurred during the project delivery process.

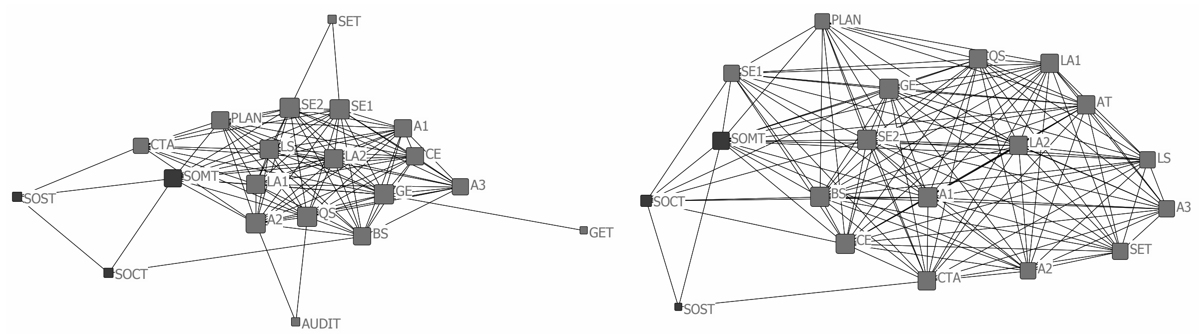

Figure 2 The graphical presentation of the formal and informal networks of Case Beta

The 'fit' of formal and informal networks will be examined at two levels, namely, individual level and network level. The former concerns the investigation of fit of formal and informal networks surrounding an individual, e.g. the degree centrality, and the clustering coefficient, while the latter concerns the overall fit between the formal and informal networks, e.g. density, average path length, and diameter. It is expected that to do so will allow a comprehensive understanding of the interplay from both a micro and macro perspective. The fit index of a metric X at the individual level is assigned as the proportion of the average value of X in the informal network, to that in the formal network. The fit indexes of the metrics at the network level are calculated as the proportion of the value of the metrics in the informal network to that in the formal network. The results of the SNA metrics of the four PBOs are presented in Fig. 3 and Table 2, respectively.

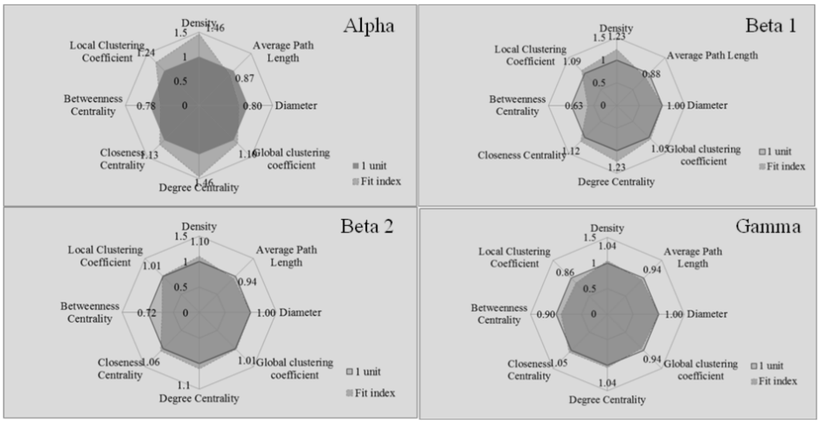

Figure 3 The spider diagrams of the fit indexes in the four PBOs

Table 2 A summary of DoF and project performance

			Alpha	*Beta 1*	*Beta 2*	*Gamma*
DoF	*Network level*	*Density*	*0.46*	*0.23*	*0.1*	*0.04*
		Average Path Length	*0.13*	*0.12*	*0.06*	*0.06*
		Diameter	*0.2*	*0*	*0*	*0*
		Global Clustering Coefficient	*0.1*	*0.05*	*0.01*	*0.06*
	Individual	*Degree Centrality*	*0.46*	*0.23*	*0.1*	*0.04*

	level	*Closeness Centrality*	*0.13*	*0.12*	*0.06*	*0.05*
		Betweenness Centrality	*0.22*	*0.37*	*0.28*	*0.1*
		Local Clustering Coefficient	*0.24*	*0.09*	*0.01*	*0.14*
Performance		*Time*	*4.00*	*4.25*	*4.50*	*4.10*
		Cost	*3.75*	*4.25*	*4.50*	*3.86*
		Quality	*4.13*	*4.25*	*4.50*	*4.44*
		Working Environment	*4.00*	*4.00*	*4.00*	*4.89*
		Health & Safety	*4.00*	*4.50*	*4.50*	*5.00*
		Total Performance	*3.96*	*4.25*	*4.43*	*4.36*

The data about the project performance of the four PBOs were collected through secondary empirical data and subjective assessment. The secondary empirical data from archival documentations and published materials are preferred to objectively measure the project performance and soliciting project staff and asking them to report their self-perception on project performance is also adopted as an alternative data collection method. After the collected data were edited, cross-checked, coded and standardized, a correlational analysis is carried out to discuss the interplay of the formal and informal networks and its impact on the project performance of the PBOs, followed by the qualitative discussions. The correlational result is shown in Table 3.

Table 3 Correlation between the fit indexes of the SNA metrics and project performance

DoF of SNA metrics	*Time*	*Cost*	*Quality*	*Work-En*	*H&S*	*TOTAL*
Density	*-0.27*	*-0.59*	*-0.40*	*-0.13*	*-0.32*	*-0.96*
Average Path Length	*-0.60*	*-0.35*	*-0.76*	*-0.23*	*-0.37*	*-0.87*
Diameter	*0.17*	*-0.84*	*-0.07*	*0.20*	*0.00*	*-0.93*
Global Clustering Coefficient	*0.11*	*-0.89*	*-0.41*	*0.54*	*0.38*	*-0.90*
Degree Centrality	*-0.27*	*-0.59*	*-0.40*	*-0.13*	*-0.32*	*-0.96*
Closeness Centrality	*-0.63*	*-0.30*	*-0.72*	*-0.32*	*-0.46*	*-0.84*
Betweenness Centrality	*-0.91*	*0.62*	*-0.50*	*-0.94*	*-0.94*	*-0.03*
Local Clustering Coefficient	*0.22*	*-0.94*	*-0.30*	*0.60*	*0.44*	*-0.88*

Note: the closer DoF to 0, the less discrepancy between the designated formal network and the actual informal network, i.e. the fitter.

The results in Table 3 show that the *DoF* of density has a negative relationship with the total project performance, with the correlational coefficient of -0.96. Furthermore, the negative relationship is confirmed in all five aspects of project performance. Therefore, H is accepted.

4. Discussions

This study explored the interplay of formally designed working network and the actual network of informal interactions. By using SNA, the graphical and mathematical presentations of formal and informal networks are compared to reveal the interplay of formal and informal networks. According to the result of correlational analysis and the implications of SNA metrics explicated, the impact of the interplay of formal and informal networks on the project performance could be probed.

The density of a network measures the extent to which actors are extensively interacting with each other. The smaller the network density in a PBO-based network, the better the project performance shall be. Smaller *DoF* of the network density in a PBO is equivalent to better fit of formal and informal networks in terms of density, which is confirmed to have a positive impact on project performance. This supports the hypothesis that higher density of formal or informal networks does not necessarily lead to better project performance; it also depends on the level of fit between the two.

Both average path length and diameter reflect the level of interaction convenience for actors within networks. They share a similar implication in organizational research in that a smaller value leads to more convenient interactions. The main difference is that average path length measures the average reachability, while the diameter describes the maximum distance of all node pairs. The smaller *DoF* of the average path length (or diameter) in a PBO is equivalent to the better fit of formal and informal networks in terms of path length (or diameter), which is confirmed to have a positive impact on project performance.

Degree centrality, closeness centrality, and betweenness centrality are the three measures of centrality at the individual level in SNA, which relates to individual members' influence and power within a PBO. These measures indicate that an individual with higher centrality has a more important role in the organization. Smaller *DoF* of either centrality measure in a PBO is equivalent to the better fit of formal and informal networks in terms of centrality, particularly in the consideration of average effects. However, the hypothesis for the Betweenness centrality is rejected with a non-significant correlation coefficient. Betweenness centrality is a reflection of the mediating effects in controlling and transmitting information flows within the network.

In the vocabulary of organizational studies, the four concepts are closely related to organizational cohesion (relevant SNA metrics including but not limited to density, average path length, degree centrality, and global clustering coefficient), organizational efficiency (relevant SNA metrics including average path length, diameter, and closeness centrality), and organizational effectiveness (relevant SNA metrics including degree centrality, betweenness centrality, and local clustering coefficient). By employing SNA, the formal and informal networks of PBOs were deciphered as a series of vivid graphs and quantitative numbers, and then their interplay is confirmed to perform an important role in the achievement of better project performance.

5. Conclusions, implications and limitations

The above discussions point to the conclusion that the higher extent of 'fit' between formal and informal network could be conductive to a better the project performance of PBOs, under the condition that the individuals of PBOs have relatively stable and normative working behaviours. The method used in this study provides a new perspective for the management board to probe into the informal working networks, to evaluate the original organizational design and collaboration mechanism, and then to more efficiently steer the operation of the PBOs. In reality, the working behaviours of individuals are also changeable under proper guidance. A good manager shall be able to make instrument for a more collaborative and trust organizational culture through the upper-down structural design of the PBO, and meanwhile be able to get a clear view of the informal networks, e.g. through the bottom-top feedback.

Within the boundaries of PBOs, formal networks set up the organizational skeleton for interaction and information exchange between project members, while the informal networks reflect the actual communication patterns and information flow. A denser informal network is perceived to be more cohesive, as long as the fit between formal and informal networks has reached a certain level. A project manager could diagnose organizational effectiveness by checking the fit of network density between the formal and informal networks. When a low level of fit is discovered, a project manager could take one of two intervention approaches. One is to investigate the formal institutions to see whether the work task-related communications among the corresponding professionals are sufficient, and if not, missing or long-distance information channels may be bridged at the organizational structure level, e.g. by using facilitating technologies. The other approach is to initiate informal institutions (e.g. project team camps).

This study is conducted in an innovative way to integrate SNA approaches, institutional thoughts and project management theories together, and the findings are limited to some factors, which shall be aware and improved in the future research activities. Firstly, the number of the case studies is relatively small, and the generalization of the findings in this study needs more evidence to decode the interplay of formal and informal networks and its impact on the PBO performance. Secondly, the significance level of the statistical analysis is marginal, and hence they are better treated as “indicative” instead of “decisive”. The quantitative analysis should be understood in conjunction with the qualitative analysis. Thirdly, SNA is a promising research method in providing a big toolkit for the organizational study scholars to explore, however, as to the authors’ knowledge, the exploration is just a corner of the iceberg. Particularly, the bridge between graphical / mathematical presentations of SNA and practical implications in organizational study is yet to be shortened.

Direct Cost of Rework - A Subcontractor's Perspective

Phillip Barlow,

Abstract

While it is widely recognized that additional costs due to poor quality have a significant impact on construction project success, limited research has been conducted to determine the direct cost of quality. When studies were conducted on the direct cost of quality (rework) they were usually from the perspective of the general contractor or owner and not from that of the subcontractor, where quality improvement would be most impactful. This study identifies the previously published work on the direct cost of rework; their data sources, perspectives, and calculations in an attempt to compare and contrast these investigations and add new data generated as a part of this research. An analysis of the inspection failure rates of subcontractors on California hospital projects was conducted and through a targeted survey the subcontractor's average cost of rework was identified in order to develop an additional cost analysis approach when calculating the true direct cost of rework. Previous research identified that the direct cost of rework typically ranged from 2.1% to 6.6% of the total project contract value with a mean of 4.2%. Utilizing a direct cost of rework calculation from a subcontractor's perspective, a cost percentage of 0.55% was calculated based on the total subcontractor contract value. These results delineated a clear and significant difference in the direct cost of poor quality depending on one's project perspective. This paper contributes to the study of quality by recognizing the true cost of rework from a subcontractor's perspective which assists industry in better understanding the motivations to improve quality. By recognizing the true cost of rework, steps can be taken to identify and reduce rework cost and ultimately further enhance construction project cost performance.

Keywords: Quality, Hospital Construction, Inspections, Direct Cost of Rework, Subcontractor

1. Introduction

The three criteria for assessing the success of a construction project are known as the 'iron triangle' of time, cost, and quality (Atkinson 1999). The first two objectives are relatively straightforward to define and measure: a subcontractor is either ahead or behind schedule, either over or under budget. Quality, the third objective, is much more difficult to assess and has received only limited attention in academic literature (Morris and Hough 1997). Quality control (QC) is the consensus term for a construction inspection process that verifies the quality of construction projects after work has been completed. This is in line with Crosby (1980) who defines quality succinctly as the conformance to established requirements.

This measureable description of quality is the foundation on which third-party quality control inspections are based for general contractors and more importantly for subcontractors whose perspective this study purports. Failed third-party inspections and the resulting direct cost of rework (also termed deviations), have been one cause of unnecessary construction costs attributed to lack of quality or cost of quality (COQ). If construction quality fails to meet the established criteria (applicable codes and contract document requirements) then additional resources must be spent (or wasted) on quality costs to make corrections. One goal of the construction process is to decrease the number of failed inspections (quality failures) and thus decrease the direct cost of rework or the direct cost of poor quality (DCOPQ). Being able to accurately and consistently calculate the DCOPQ across varying project types is an important factor in finding solutions.

While the cause of rework is an important topic and one which has garnered some attention, purporting and calculating the cost of rework has been widely inconsistent. A study was conducted on the quality inspection results from six California hospital construction projects. A survey was employed in an effort to uniquely calculate the Field Rework Cost (FRC) from the perspective of subcontractors. Based on this investigation a new calculation for the DCOPQ or direct cost of rework was developed and discussed to better understand and consider the entire concept of construction rework cost.

2. Background

2.1 Construction Rework Cost

For the purposes of this research, rework is seen as a negative term best defined by Rogge et al. (2001) as an activity in the field that has to be done more than once or activities that remove work previously installed as part of the project. A study conducted by Love and Edwards (2004) summarized most of the prior research conducted on the cost of construction rework. Their study emphasized the small amount of work done on the subject to date and the large disparity in the results. It was hypothesized that these variations were a result of researchers using different scope assessments, data collection methods, inconsistent calculations, and varying definitions of the term quality. A continuation of Love and Edward research can be found in Table 1 which is partially inclusive of their work and additional research found since their 2004 publication.

Table 1: Summary of reported total direct cost of construction rework studies.

Author	*Descriptor*	*Cost %*	*Formula*	*Data Source*	*Perspective*	*Country*	*Project Type*
Hwang (2009)	Field Rework Factor	2.12%	Total Direct Cost of Rework / Construction Cost	Project Reports	Owners and General Contractor	Various	Various Types
Love (1999)	Direct Rework Cost	2.40%	Rework Var. + Non-Var. + Defects / Contract Value	Single Case Study	Owner and General Contractor	Australia	Industrial
Burati (1992)	Deviation Cost	2.50%	Construction Deviation Cost / Total Project Cost	Nine Case Studies	CII Data Collection	USA	Industrial
Simpeh (2012)	Direct Rework Cost	2.93%	Direct Cost of Rework / Orignial Contract Sum	Survey	Construction Professionals	South Africa	Various Types
Ledbetter (1994)	Rework Cost	3.10%	Rework Cost Design + Construction / Project Cost	Single Case Study	General Contractor	USA	Heavy Industrial
Love (1999)	Direct Rework Cost	3.15%	Rework Var. + Non-Var. + Defects / Contract Value	Single Case Study	Owner and General Contractor	Australia	Residential
Wilis (1996)	Quality Deviations	3.30%	Deviation Correction Cost / Project Value	Single Case Study	General Contractor	USA	Chemical Plant
Barber (2000)	Quality Failure	3.60%	Quality Failure Cost / Contract Value	Single Case Study	General Contractor	UK	Highway Project
Mills (2009)	Defect Cost	4.10%	Defect Cost / Contract Value	Owners Claims	Ower - Housing Guarantee Fund	Australia	Residential
Josephson (2002)	Direct Rework Cost	4.40%	None Conformance Cost / Total Project Cost	Seven Case Studies	Owner and General Contractor	Sweden	Various Types
Josephson (1999)	Defects	4.85%	Defect Cost / Production Cost	Seven Case Studies	Owner and General Contractor	Sweden	Commercial
Love (2010)	Direct Rework Cost	5.07%	Direct Cost of Rework / Orignial Contract Value	Survey	Various Contractors and CM Co.	Australia	Heavy Civil
Hammarlund (1991)	Quality Failure	6.00%	Quality Failure Cost / Contract Value	Single Case Study	General Contractor	Sweden	Commercial
Love (2002)	Direct Rework Cost	6.40%	Direct Cost of Rework / Total Project Cost	Survey	Senior Construction Prof.	Australia	Various Types
Love & Edwards (2005)	Direct Rework Cost	6.40%	Mean Direct Cost of Rework %	Survey	Design, Contractors, & Consult	Australia	Various Types
Barber (2000)	Quality Failure	6.60%	Quality Failure Cost / Contract Value	Single Case Study	General Contractor	UK	Highway Project

This updated summary of reported rework cost studies reinforces the continued wide variation of descriptors, calculation formulas, data sources, and project types which researchers have utilized. These disparities and their lack of cohesion only adds to the confusion when rework cost comparisons are made between studies. As Love and Edwards (2004) reported and the results of Table 1 support, "while the calculation of rework can be an arduous and time-consuming task, there is an imperative need for rework definition and measurement before an accurate assessment of direct costs can be made" (p. 208).

Regardless of the descriptors used or how the calculation were formulated, all the research generated to this point analyze a version of the total direct cost of rework divided by the total project value or contract value. Undoubtedly construction research would benefit greatly from these values being calculated identically, so they can be directly compared industry-wide regardless of specific project circumstances. Unfortunately, the driving force when identifying the cost of rework and the formulas used have often been dictated by the data available. When this existing data is summarized a mean cost of 4.2% is calculated based on some determination of total cost of rework versus some total contract value.

2.2 Subcontractor Perspective

On commercial construction projects general contractors have typically subcontracted to specialty subcontractors as much as 75% to 100% of the work (Schaufelberger and Holm 2002). Despite the fact that subcontractors complete a large portion of most construction project, issues concerning subcontracts are seldom acknowledged or discussed. As Arditi and Chotibhongs (2005) confirmed, “little research has been conducted and little information is published on this topic” (p866). Efficient subcontracting (increased inspection success and reduced rework) would benefit all parties involved in the construction process including the general contractor, the owner, and the subcontractor.

Most research conducted in the areas of quality, quality control, and cost of quality has been from the perspective of the general contractor or the owner (Barlow 2015). A focused literature review on this topic as summarized in Table 1 confirms the lack of attention to subcontractor rework cost. Methods that improve the chances of subcontractor success by ensuring that all aspects vital to a subcontractor go well should be put in place (Boynton and Zmud 1984). This paper focused on the true cost of rework from a subcontractor’s perspective where the final quality of a construction project is truly determined. Unlike previous calculations of rework. the formula supported by this study is the direct cost of rework from a subcontractor’s perspective:

$$\frac{\text{Subcontractor's Total Direct Cost to Correct Inspection Failures}}{\text{Total Subcontract Contract Amount}} = \text{Field Rework Cost (FRC)}$$

In order to decrease quality inspection failures, which is the direct cause of rework, one must start with the subcontractor. The subcontractor carries the primary responsibility of obtaining quality success on a project, all others exist to support their efforts. Only by understanding and measuring subcontractor inspection success can we hope to decrease the amount of rework, decrease the DCOQ, and thus decrease the total cost of rework on any construction project.

2.3 California Hospital Construction

In California, healthcare construction projects are subject to a separate design review and construction inspection process due to their specialized nature and importance to the public. The California Office of State-wide Health Planning and Development (COSHPD) performs the regulatory oversight. In particular, the Facilities Development Division (FDD) of COSHPD reviews and inspects all healthcare construction projects in California. The FDD conducts plan reviews; issues building permits; confirms seismic compliance; performs construction observations and inspections; and interprets regulations, building codes, and policies.

In 2014, the FDD had over $20 billion worth of healthcare projects either under plan review or in construction (OSHPD 2015). In addition, the amount of anticipated healthcare construction to occur in California during the next ten years is predicted to be over $100 billion dollars. Alfeld (1988) advanced the view that construction, due to its magnitude alone, promises a greater payback for performance improvement than almost any other industry. Any small step in the direction of reducing the COQ due to inspection failures and rework in this field will likely save millions of dollars. The resources wasted on failed construction inspections could otherwise be spent on more desirable aspects of the healthcare cost ledger, such as lowering consumer costs for healthcare or saving lives.

3. Research Methodology

3.1 Mining Existing Data

This study first mined existing third-party construction quality inspection data generated by the FDD on six major California hospital projects. The data quantitatively revealed COSHPD inspection successes and failures at a subcontractor level over the entire project. The existing data were extracted and downloaded into MS Excel spreadsheets for further sorting and analysis. The data were gathered remotely and after-the-fact, eliminating any form of bias and avoiding what is known as the Hawthorn effect (Franke and Kaul 1978), referring to the tendency of individuals to perform differently when their performance is being measured or observed.

All six hospital projects were constructed in California under the review and supervision of COSHPD. All projects were completed between 2009 and 2014, varied in total construction cost between $260 million and $550 million, and varied in total area between 28,000 and 60,000 square meters validated continuity of the data. No further information about the projects is provided in this study to keep the identity of the projects, the owners, the architects/engineers, general contractors, and subcontractors confidential. COSHPD generated data had several advantages over other possible sources of quantitative inspection data generated by architects, engineers, general contractors, and privately hired consultants. All healthcare construction projects were required to accommodate continuous on-site inspections by the FDD, thus normalizing the inspection data. The FDD's policies and procedures for inspections, data gathering, and record keeping were standardized across all hospital projects, required by law, and conducted over the entire construction process.

COSHPD quality control inspection data were obtained and analyzed from forty-one (41) different subcontractors spanning six different California hospital projects. The breakdown of the forty-one subcontractors by trade, number in each trade, and designated reference number is shown in Figure 1. In order for a particular subcontractor who worked on one of the six hospital projects to be chosen for this research, a minimum of 150 inspections conducted by a COSHPD inspector was required. This minimum number was used to distinguish between subcontractors who had a significant role in the project and those who were ancillary.

Framing & Drywall (7 each); FD1, FD2, FD3, FD4. FD5, FD6, FD7*

Electrical (6 each); EL1, EL2, EL3, EL4, EL5, EL6

Structural Concrete (5 each); SC1, SC2, SC3, SC4, SC5

Wet Mechanical (5 each); WM1, WM2, WM3, WM4, WM5

Fire Sprinklers (5 each); FP1, FP2, FP3, FP4, FP5

Dry Mechanical (4 each); DM1, DM2, DM3, DM4

Ceiling Panels (3 each); CP1, CP2, CP3

Insulation (2 each); IN1, IN2

Fire Stopping (2 each); FS1, FS2

Exterior Framing (1 each); EF1

Glass & Glazing (1 each); GG1

* FD7 exists because one of the six hospital projects used two framing and drywall subcontractors due to the size of the contract.

Figure 1: Subcontractors by trade, number, and designation.

Table 2 below shows a breakdown of the forty-one subcontractors, the hospital projects on which they worked, and the number of inspections that they conducted. Inspection success was later converted into percentages to normalize the comparison between subcontractors who had varying numbers of inspections.

Table 2: Subcontractors by project, designation, and number of inspections.

3.2 Subcontractor Survey

Data reliability is related to data source and is therefore inextricably linked to the position held by the person who completed the questionnaire (Oppenheim, 1992). An individual survey was sent specifically to the subcontractor's field project manager in-charge of the project and from which the above existing mined inspection data was obtained. The survey was returned fully completed by thirty-nine of the original forty-one subcontractors; two subcontractors were not available or unwilling to participate. The survey focused on the actual cost of a failed third-party quality control inspection. The survey questions were as follows:

SQ1 – What was your total subcontract amount?
SQ2 – How many man hours were required to correct an inspection failure?
SQ3 – How much in material costs were required to correct an inspection failure?
SQ4 – How much equipment cost were required to correct an inspection failure?
SQ5 – How many man hours were required for the re-inspection process?

Figure 2: Subcontractor Survey Questions

4. Results

4.1 Data Mining Results – Total Inspections

A total of 61,070 COSHPD inspections data points were analyzed from six hospital construction projects spanning forty-one subcontractors. Major subcontractors on a significant California hospital project could generally expect that nearly 1,500 inspections might be required of them on any particular hospital project. This piece of data may not particularly useful, knowing that the average number of inspections required for any particular subcontractor will vary greatly. Subcontractors of a particular trade, however, could benefit from the results shown in Figure 3, which identifies the average number of inspections broken down by subcontractor trade. Figure 3 brings into focus the wide variation in the number of inspections possible depending on the subcontractor trade. The values listed represent the number of subcontractors representing a particular trade, the mean number of inspections, the minimum, and the maximum number of inspections respectively.

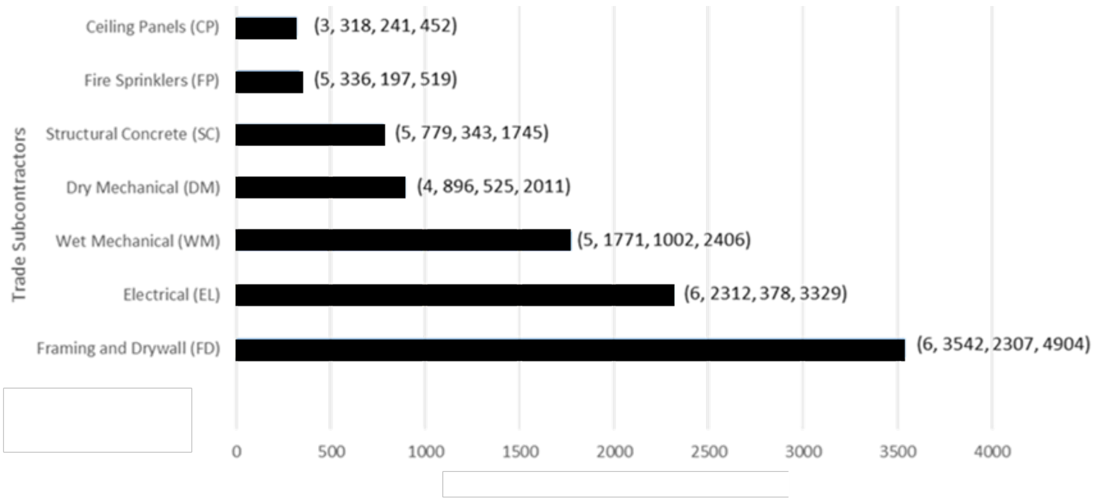

Figure 3: By trade and (number of subcontractor's, mean, minimum, and maximum number of inspections).

4.2 Data Mining Results – Failed Inspections

The percentage of COSHPD re-inspections (or failed inspections) versus total inspections revealed that 9.07% of all inspections conducted resulted in a failed inspection. The range of results was a minimum percentage (best subcontractor performance) of 2.02% and a maximum percentage (worst subcontractor performance) of 21.82%. As a result of a failed inspection, the work inspected was redone (re-work), a re-inspection was requested, and a new inspection was conducted by COSHPD. The overall re-inspection percentage number is based on over 60,000 inspection attempts with a standard deviation of 5.55%.

Subcontractors were then ranked based on percentage of failed inspections, ranking high achieving (low percentage of re-inspections) to low achieving (high percentage of re-inspections) as shown in Table 3. A re-inspection rate range of 2.02% to 21.82% was observed, as was a fairly even distribution of trade types along the spectrum. This would indicate that re-inspection rates had no particular correlation to the type of subcontractor trade being inspected.

Table 3: Ranking of subcontractors by percentage of re-inspections.

Subcontractor	Re-inspection Rate %	Subcontractor	Re-inspection Rate %
1. FD7	2.02%		
2. WM5	2.16%	22. WM1	7.98%
3. EL6	2.18%	23. EL2	8.33%
4. SC5	2.34%	24. DM3	9.06%
5. FD2	2.98%	25. DM1	9.58%
6. WM3	3.20%	26. FS2	9.86%
7. SC2	3.46%	27. FD4	9.88%
8. FD3	3.81%	28. IN2	10.07%
9. DM4	3.81%	29. FP2	10.96%
10. FD1	4.48%	30. FP3	11.95%
11. SC1	4.55%	31. IN1	12.11%
12. SC3	4.66%	32. FS1	12.38%
13. EL5	5.29%	33. CP2	13.05%
14. FD5	5.93%	34. GG1	13.82%
15. CP1	6.11%	35. CP3	14.94%
16. FP5	7.11%	36. EL4	15.28%
17. FP4	7.17%	37. WM4	17.71%
18. EL1	7.23%	38. FP1	19.33%
19. EF1	7.30%	39. WM2	20.28%
20. DM2	7.86%	40. SC4	21.76%
21. EL3	7.98%	41. FD6	21.82%

4.3 Survey Results

To determine the subcontractor's direct cost to correct each failed inspection (rework), questions SQ1-SQ5 (see Figure 2) were asked as part of a survey. The responses were analyzed and the mean amounts are shown below (Figure 4) based on an N=39.

SQ1 Total Subcontract Amount	$28,468,384 (US$)
SQ2 Man Hours to Correct	6.3 Man Hours
SQ3 How Much Material Cost	$238 (US$)
SQ4 How Much Equipment Cost	$96 (US$)
SQ4 Man hours to Re-inspect	3.8 Man Hours

Figure 4: Mean results from subcontractor survey.

Direct Cost of Quality (DCOQ) per failed inspection was calculated (see Figure 5) for this sample (N=39) subcontractors. The cost per man-hour rate, including workers' compensation insurance and overhead, was estimated at $80.00/hour (based on the 2015 RS Means Carpenter/Foreman/ Superintendent blended rate for California, USA).

Labor Cost Correct (6.3MH x $80/hr)	= $ 504
Material Cost Correct	= $ 238
Equipment Cost Correct	= $ 96
Labor Cost Re-inspect (3.8MH x $80/hr)	= $ 304
Subcontractor's Average Cost per Inspection Failure	= $1,142

Figure 5: Failed inspection calculation.

From the mining of inspection data results discussed earlier, it is estimated that significant subcontractors on California hospital projects averaged approximately 1500 inspections per project at a 9.07% inspection failure rate. Based on these numbers, a subcontractor could typically expect to incur (1500 x 9.07% x $1,142) = $155,369 of direct re-work expense (DCOQ) from a subcontractor's perspective. At an average subcontract amount of $28.5 million per project, the percentage of DCOQ for a substantial subcontractor working on a California hospital project is approximately ($155,369 / $28,500,000) = 0.55% Field Rework Cost (FRC). This percentage is lower than that found in other studies which calculated the DCOQ based on the entire construction project.

5. Discussion and Conclusions

Previous studies on the topic of construction quality have primarily focused on the cause of quality failures, the cost of quality due to rework, and identifying the reasons for project success. These studies are all from a primary stakeholder's perspective, most notably the general contractor. Interestingly, there were no studies found that examined the issue of quality from a subcontractor's perspective in an attempt to document inspection failures, improve inspection success, and decrease the DCOQ. This study assessed the construction quality of California hospital projects from the perspective of subcontractors in the field and through COSHPD third-party quality inspection data. The old adage, "you can't manage what you don't measure" (Deming 1986), is a rudimentary goal of this study. This research aimed to create measurements and benchmarks where none existed to assist subcontractors and project teams to better manage the quality inspection process on construction sites.

This study found that the DCOQ from a subcontractor's perspective was only 0.55%, far below the project wide calculations. While there is a wide variation when comparing these results, they may both be correct, because the total DCOQ for the total project with general contractor costs, mark-ups, etc. included may justify the higher percentage range as compared to the just subcontractors direct cost of rework. The motivation to decrease the additional cost of rework on large construction projects from a general contractor's and owner's point-of-view are clearly understandable at 3% to 6% of total project cost, especially when the significant indirect costs associated with poor quality are also considered. At 0.55%, and with very little additional indirect costs, what is the motivation for the subcontractors to decrease their amount of rework and DCOQ? Subcontractors may be very comfortable with a percentage such as this. General contractors and owners might find it difficult to motivate subcontractors to decrease this percentage further when it is such a small amount to begin with.

Gathering, analyzing, calculating, and benchmarking quality inspection data at a subcontractor level was unique to this study. For the first time, using our approach, subcontractors and the rest of the construction project team can utilize measureable quality inspection data to gauge the relative success of the quality obtained in the field. This new approach when applied early on in the construction process can alert project teams when a quality issue exists and action by management is required to rectify either the quality management process, quality assurance program, and/or the quality control program responsible for the relatively poor inspection results.

By applying this study, subcontractors could more accurately calculate the direct cost of rework due to failed quality inspections to determine the actual DCOQ for their particular trade and company. Depending on the results, a subcontractor can determine if taking corrective action for quality assurance is necessary or if the rework percentage is acceptable and simply a cost of doing business. General contractors and owners might choose to further motivate subcontractors financially to decrease rework and the DCOQ with various incentive programs if subcontractors are unwilling to take additional quality assurance action on their own. Future studies should look at the reason for these failed inspections and why they were not corrected prior to a formal inspection process. Indirect costs resulting from inspection failures such as lost productivity, acceleration costs, and work flow disruption is an issue which should also be further explored.

A Study on the Factors of Completion Time for Road Construction Projects

Ifte Choudhury
Texas A&M Choudhury
(email: i-choudhury@tamu.edu)

Abstract

Studies indicate that there is a relationship between project cost and construction time for different construction types. The purpose of this study is to validate the time-cost relationship model developed by Bromilow et al. in context with road construction projects in Florida. The model was extended to include contract types to determine whether the variable also has an effect on project duration. Data related to 235 road construction projects was obtained for the study. SPSS® program was used for analysis of the data. The statistical technique used for the analysis was stepwise linear regression. The results indicate that both actual construction cost and contract type have a statistically significant relationship with construction time for road construction projects in Florida, at the level of significance (p-value) of <0.0001. A prediction model of construction time was developed based on the results of the study. This model will be useful to both graduate and undergraduate students taking courses related to cost estimating and construction project scheduling, and also to professionals involved with the construction industry.

Keywords: Construction Time, Construction Cost, Contract Type, Road Construction, Regression Analysis

1. Introduction

1.1 General

Construction time for any type of project is related to a wide range of variables including construction cost. Time and cost have been typically used as important criteria for determining project performance globally. A relationship exists between the time taken for construction of a project and the cost incurred to complete it. Project cost has been identified as a correlate of construction time in many regions of the world (Bromilow et al., 1980; Choudhury & Rajan, 2008). In the construction industry, contractors usually use previous experiences to estimate the project duration and cost of a new project. In general, the more time it takes to complete an activity, the more human resources have to be engaged for the task, resulting in a higher project cost.

A correlation between completed construction cost and the time taken to complete a construction project was first mathematically ascertained by Bromilow et al. (1980). The authors analyzed the time-cost data for a total of 419 building projects in Australia to develop the model. The equation defining the mean construction time as a function of project cost was found to be:

$$T = K*C^{B} \qquad (1)$$

Where

T = duration of construction period from the date of possession of site to substantial completion, in working days

C = completed cost of project in millions of dollars, adjusted to constant labor and material prices

K = a constant indicating the general level of time performance per million dollar

B = a constant describing how the time performance is affected by the size of the construction project measured by its cost.

The model indicates that the duration of project time of a construction project is basically a function of its total cost. It provided a basis for all parties concerned with the construction procedure to establish a fairly accurate probable duration of a project in days, given the estimated cost of the project. The authors also analyzed the overruns on cost and time that provided a measure on the accuracy of the industry's time and cost prediction.

The model also indicates that relationship between duration of a construction project and time required to complete it is non-linear. A hypothetical scenario of such relationship, developed by the author, is shown in Figure 1. In order to perform data analysis using a linear model, the variables need to be transformed into their natural logarithms.

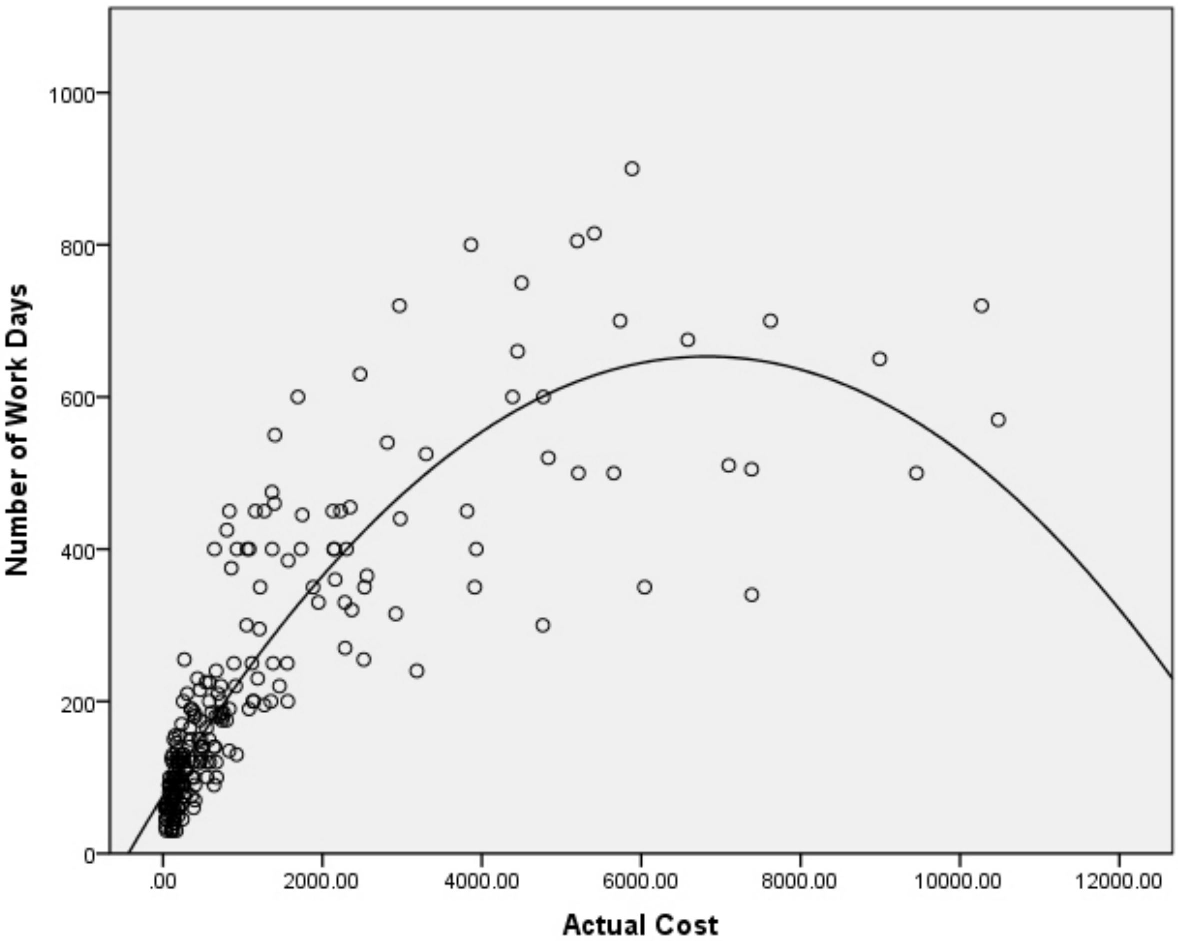

Figure 1: Non-linear relationship between construction cost and time

Several other studies have been performed around the world to make similar predictions for either a specific sector of construction or construction industries, in general. Ireland (1985) replicated the study to predict construction time for high-rise buildings in Australia; Kaka & Price (1991) conducted a similar survey both for buildings and road works in the United Kingdom; Chan (1999) investigated the effect of construction cost on time with particular reference to Hong Kong; and Choudhury & Rajan (2008) conducted a study on residential construction projects in Texas. Hoffman et al. (2007) used Bromilow et al.'s (1980) time-cost model to analyze data collected for 856 facility projects. They, however, included certain other variables such as project location, building type, and delivery method in the model.

Gritzka & Labi (2008) conducted a study on factors of time delay, specifically for road construction projects. Findings of their study indicate a statistically significant relationship between longer-duration projects and cost overrun.

All these studies found that the mathematical model developed by Bromilow et al. (1980) is applicable for prediction of construction time when the cost of construction is known.

1.2 Other Possible Factors of Road Construction

A critical issue in road construction that affect project delivery, experienced almost worldwide, is cost overrun (Bhargava et al., 2010). It generally results from factors that occur during various stages of life-cycle of a project. Studies on highway projects have been conducted by quite a few researchers to seek the extent of this particular problem.

Findings by several authors indicate that it is associated with project design, project environment, and project size (Akinci & Fisher, 1998; Hinze et al., 1992); project size, of course, is directly related to overall construction time.

Construction procurement is the process of obtaining services and supplies for efficient and timely delivery of the end product. The major project delivery methods include (1) Design-Bid-Build, (2) Design-Build, and (3) Construction Management at Risk. Studies indicate that project performance is affected by project delivery method (Choudhury & Pitkar, 2007; Ling et al., 2004; Chan et al., 2002).

The trend in the use of project delivery system is changing rapidly. Project delivery system has evolved over the years. The medieval master builder was hired by an owner to design, engineer, and construct an entire facility. This system was common until the early 20th century. With changing technologies, it was necessary to change the type of delivery system that gave way to the Design-Bid-Build method. As the specialization of services increased, it was found that the interaction during design phase was extremely poor which resulted in inefficient designs, increased errors and disputes, higher costs, and ultimately longer schedule. This led to the Construction Management at Risk delivery system to improve the interaction among parties concerned and to overlap the design and the construction phases. Eventually, it was found necessary for owners to resort to a single source Design-Build contracting (El-Wardani et al., 2006). There is an increasing trend toward the use of the Design-Build delivery method in the public sector (Choudhury & Pitkar, 2007; Tulacz, 2006; Yakowenko, 2004).

It is thus possible that project delivery method could play a role in construction performance time. The likelihood of an impact of delivery method on construction time of road projects was ascertained by including it in the time-cost relationship model.

1.3 Hypotheses

From a review of literature, it is hypothesized that

1. (H1) The mathematical model developed by Bromilow et al. (1980) holds good for prediction of construction time for road projects.
2. (H2) The actual completion time of road construction projects in Florida is affected by actual construction cost.
3. (H3) The actual completion time of road construction projects in Florida is affected by estimated construction cost.
4. (H4) The actual completion time of road construction projects in India is affected by contract type or delivery method.

2. Methodology

2.1 Data Collection

Data for 235 completed road construction projects undertaken by Florida Department of Transportation (FDOT) was obtained from secondary sources. All construction works were completed within last five years.

2.2 Variables

Actual Construction Time (TIME): It is the actual time measured for the completion of a road construction project. It was measured in days. This variable was labeled as LNTIME after being transformed into its natural logarithm.

Actual Project Cost (ACOST): It is the total cost of construction works of a road construction project. It was measured in units of 1000 US Dollars. This variable was labeled as LNACOST after being transformed into its natural logarithm.

Estimated Project Cost (ECOST): It is the total cost of construction works of a road construction project, estimated by FDOT prior to construction. It was measured in units of 1000 US Dollars. This variable was labeled as LNECOST after being transformed into its natural logarithm.

Contract Type (CONT): It is the type of contracting used for delivering a road construction project. This was a dummy variable consisting of two categories: (1) Design-Build (DB), and (2) Others. This variable was labeled as LNCONT after being transformed into its natural logarithm. It was assigned a value of 1, if the contracting method was DB; if not, a value of 0 was assigned.

3. Results

3.1 Analysis

The time-cost relationship model developed by Bromilow et al. (1980) defines only the relationship between construction time and actual construction cost. Since the present study hypothesizes relationships to exist also between (1) construction time and estimated construction cost and (2) construction time and contract type, the model had to be modified. Following model encompasses both the variables that may have an effect on construction time performance:

$$TIME = K*ACOST^{B1}*ECOST^{B2}*CONT^{B3} \qquad (2)$$

A stepwise linear regression analysis was used to perform the first step of analysis (see eqn. 3). It is a semi-automated process of building a model by successively adding or removing variables based on the *t*-statistics of their estimated coefficients. Therefore, the variables had to be transformed into their natural logarithms.

$$LNTIME = LNK + \beta_1 \, LNACOST + \beta_2 \, LNECOST + \beta_3 \, LNCONT + \varepsilon \qquad (3)$$

Where LNK = natural logarithm of K; β_1, β_2, β_3 = regression coefficients; and ε = error term.

The results show that two independent variables were retained by the model: actual construction cost (LNACOST) and contract type (LNCONT). Estimated contract cost (LNECOST), not being statistically significant at the level of 0.5, was were excluded. The results are shown in Table 1.

Table 1: Stepwise Linear Regression Analysis for LNTIME

Variable Retained	*Intercept (LNK)*	*Regression Coefficient*	*t*	*p<|t|*	*Critical Value of |t|*
Intercept	*1.827*		*15.976*	*<0.0001*	*1.96*
LNACOST		*0.529*	*29.976*	*<0.0001*	
LNCONT		*-0.131*	*-2.234*	*0.026*	
F-value of the Model = 459.471	*p>Model F=<0.0001*	*Model R^2 = 0.89* *Adjusted model R^2 = 0.80*			

3.2 Interpretations

The *F*-value of the model used for multiple regression analysis was found to be statistically significant at less than the 0.0001 level. This provides evidence that a relationship exists between construction time and at least one of the independent variables used in the model. The results indicate that construction cost (p>0.0001) and contract type (p>0.026) are correlated to construction time. The other variable, estimated construction cost, was not found to be significant at level of significance of 0.05; hence, it was automatically excluded by the statistical program from the model.

An important aspect of a statistical procedure that derives model from empirical data is to indicate how well the model predicts results. A widely used measure the predictive efficacy of a model is its coefficient of determination, or R^2 value. If there is a perfect relation between the dependent and independent variables, R^2 is 1. In case of no relationship between the dependent and independent variables, R^2 is 0. Predictive efficacy of this particular model was found to be moderately high with an R^2 of 0.89, and an adjusted R^2 of 0.80. It means that at least 80 percent of the variances in construction time of projects are explained by actual construction cost and contract type.

Based on the findings, research hypothesis (H1) regarding application of Bromilow et al.'s (1980) model for prediction of construction time for road projects could not be rejected; F-value of the model was statistically significant .Research hypotheses (H2) and (H3) related to relationships between actual completion time and cost of road construction projects (Figure 2) and actual completion time and contract types for road construction projects in Florida could not also be rejected; relationships of both these variables with actual construction time were statistically significant. However, hypothesis (H4) indicating a relationship between actual completion time and estimated construction cost for road projects in Florida had to be rejected, because relationship of this variable with construction cost was not found to be statistically significant at the 0.05 level.

The relationship between time and cost was found to statistically significant at the level of less than 0.0001. The relationship between time and contract type was found to be inverse at the level of less than 0.026. It means that construction duration was less using design-build type of contract.

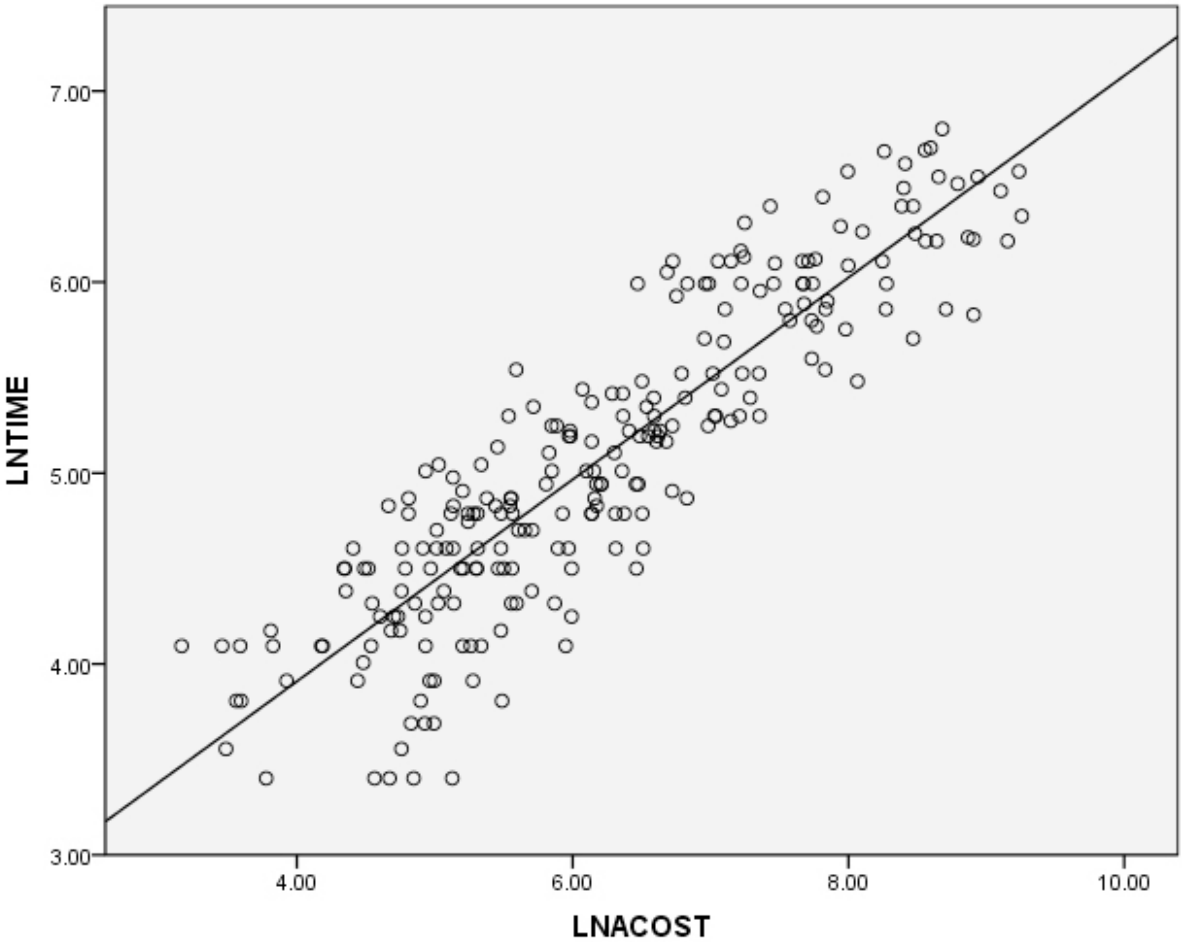

Figure 2: Relationship between LNTIME and LNCOST

The prediction model for road construction time in Florida was developed using results of the analysis. Bromilow et al.'s (1980) model was modified by adding contract type to the equation. The value of LNK and LNCONT were required to be transformed to K, using an exponential function [exp(LNK)] and [exp(LNCONT)] respectively, for expressing the model in its original form (Equation 4). The model may be expressed as follows:

$$TIME = 6.215*ACOST^{0.529} *CONT^{-1.31} \quad (4)$$

This model can be used to predict the road construction time in Florida when the gross floor area in known. For example, if the actual construction cost of a road project is, say $5,000,000, the predicted construction time for the project would be about 494 days.

4. Conclusions

The results of the study provide evidence that a modified version of the mathematical model developed by Bromilow et al. (1980) is applicable for prediction of time for road construction projects in Florida. Apart from cost, contract type was also included in the model.

The results of the statistical analysis indicate that for a road construction project in Florida, an increase in construction cost results in an increase in total construction time. The results also indicate that contract type has a statistically significant effect on actual construction time of the projects. It takes less time for completion of a road project in Florida using design-build method of delivery.

The model will be useful for students of construction science, taking courses in construction project scheduling. It will also be useful for all parties associated with the construction industry to predict the mean time required for the delivery of a road project. It provides an alternative and logical method for estimating construction time, both by bidders and clients, to supplement the prevailing practice of estimation predominantly on individual experience.

This study has been conducted using data for construction of road projects in Florida. The construction industry can benefit from the results of the study by applying the model in predicting construction time for similar projects. Such models may be developed by collecting historical data either from the owners or the constructors. However, the model documented in this study applies only for road construction projects in Florida and cannot be generalized beyond the sample size.

Lean Sustainable Indices: A case for South African Public Infrastructure Sector

Rasheed Isa,
Central University of Technology, Free State
(email: risa@cut.ac.za)
Fidelis Emuze,
Central University of Technology, Free State
(email: femuze@cut.ac.za)

Abstract

The interwoven nature of the goal of lean and sustainability points to synergy that can be created for industry, and societal benefits. The paucity of studies, which dwell on the impact of lean and sustainability on construction project performance is however notable. This is the case of public sector infrastructure projects (PSIP), which form the focus of this research. This exploratory study assesses the indices required for measuring the integrative implementation of lean and sustainability concepts in an infrastructure project. The study is qualitative in nature, based on interpretative theoretical framework that is grounded in lived experiences of project stakeholders. Emergent findings indicate that although the generic internal project key performance indices (KPI) of cost, time and quality is of major concerns to the stakeholders, indices required for integrative implementation of lean and sustainability are more broader in satisfying various stakeholders concerns, which would match business and environmental excellence, energy efficiency and optimum indoor environment, minimized resource consumption, minimized emissions, increase health and well-being, user productivity, reduced noise and dust pollution, stakeholders collaboration, and community social benefits. Such benefits include employment and enhanced industry competitiveness. It can be argued that a focus on these indices could lead to project delivery with limited impact in terms of sustainable development.

Key words: Construction, Lean, Infrastructure, Sustainability, South Africa

1. Introduction

The last decades witness a lot of innovation and transformation in its expedition for an improved built environment. Infrastructure development is crucial to drive the economy and advance civilization (Mirza, 2006). Achieving a sound and well-functioning infrastructure is essential for continuous economic growth, international competitiveness, public health and overall quality of life, as demanded by the current generation within the available social and natural context. However, this interrelationship between social and natural boundaries could alter the ecosystem. Environmental symptoms such as worsening climate change and huge emission of greenhouse gases (GHG), as a result of the depletion of natural resources because of the need to consumption is a global reality. As a result, sustainability has emerged in construction lexicon (Abidin and Pasquire, 2007).

The World Commission on Environment and Development (WCED, 1987) propounded the definition of sustainable development. The definition, which has been widely adopted by multiple agencies, says that sustainable development is meeting the basic needs of the present and the right for a better life without compromising the ability of future generations. The import of this definition is placed on the balance between social development, economic development, and environmental sustainability (Shen et al., 2007). Based on this, the primary goal of infrastructure development has now expanded from been mere economic viability to social and environmental concerns. Major infrastructure procurement now involves expert considerations regarding major spheres of sustainability. The triple bottom line (TBL) of economic, social and environmental dimensions qualifies for legislative, financial, and professional backings necessary for procurement success (Opoku and Ahmed, 2015). Infrastructure sustainability has grown from being technical based perspectives into social-political dimensions, attracting the attentions of multi-disciplinary experts, nations, and pressure groups in an attempt to negotiate the best way for sustainable development. This has been furthered by the recent adoption sustainable development goals (SDGs) by the United Nations (UN). The goals are premise on the need to build safe and resilient infrastructure, and combats climate change. The goals also include sustainable use of resources, promotion of inclusive and sustainable industrialization, which foster innovation.

This new concept focuses on the impacts of infrastructure development and resource use. The focus is on how efficient management can be brought to bear on energy consumption, dust and gas emission, noise pollution, waste generation, water discharge, water use, land use and pollution, and consumption of non-renewable natural resources, and its effect on the needs of current and future generations (Ghosh et al., 2014). Various researchers have shown that the construction industry and its activities have significant effects on the environment (Ding and Lanston, 2004; Griffith, et al., 2005; Low *et al*. 2009). Several work (Kibert, 1994; Hill and Bowen, 1997; Madu and Kuei, 2012) have proposed the thinking that underpins sustainability for the construction industry in order to engender wastes minimization and prevention of environmental hazards through basic principles of 5Rs (rethink, reduce, reuse, recycle and report) to achieves long-time economic and social benefits. Sustainability goals can only be achieved if construction activities are informed and directed by new thinking, new resources and expertise. Some of this comes in the form of innovative practice, tools and enhanced process models, but much will have to come from situated and contextual appreciations of sustainability goals and local practices in the industry (Pathirage et al., 2007).

Similarly, lean as a concept was developed as an industry process of eliminating waste by adapting production process in construction to enhanced performance (Howell, 1999; Forbes and Ahmed, 2011). Rybkowski et al. (2013) look at lean construction as respecting stakeholders in the value chain through a holistic pursuance of continuous improvement, while minimizing waste and maximizing value to the customer. Howell (1999) sees lean construction as a production process that mainly redresses project KPIs balance by 'increasing value while reducing waste' in construction. This production process is often anchored on waste reduction and normally practiced in the segregation of construction process breakdown of project life-cycle. Most works on lean construction have been premised on the five principles of lean thinking that serve as a pathway for continuous improvement. These principles are: value, value stream mapping (VSM), flow, pull, and perfection (Pasquire and Connolly, 2002; Terry and Smith, 2011). These principles are used to mitigate the current practices in infrastructure procurement that often hinders the attainment of the criteria for sustainability (Vieira and Cachadinha, 2011).

The interwoven nature of the goal of lean and sustainability points to a synergy that can be created for industry, and societal benefits. Construction industry can leverage on the synergy between lean and sustainability to achieve infrastructure development. Lean concepts align with sustainability concept of doing more with less. What is not clear though and is worthy of further investigation is; how can lean and sustainability indices be used to promote stakeholder engagements in the built environment? The paucity of studies which dwell on the impact of lean and sustainability on construction project performance is notable (Novak, 2012; Campos *et al.*, 2012). This is the case of public sector infrastructure projects (PSIP), which form the focus of this research. Monitoring progress towards lean and sustainability (LS) practices, thus, requires the identification of operational indicators that provide manageable units of information on economic, environmental, and social conditions that can be measured. A full disclosure of this new paradigm and the ability to fully map out its performance indices will be beneficial to the industry, and enhanced the process of continuous improvement and attainment of ecosystem equilibrium for sustainable development. The proposed will assist developers and others stakeholders gain a more comprehensive view of the lean and sustainability in the construction context.

2. Sustainability in Construction

Over the last three decades, sustainability concept has been growing in significance in the areas of developments in the built and natural environments (Edum-Fotwe and Price, 2009). After probing for answers to the challenge of sustainable development, most nations refocus their attentions on the construction industry. The construction industry is important to the achievement of the sustainable development agenda. The South African government has made progress in establishing policies that favour energy savings in the built environment. Appreciation of the major impacts of construction activities on sustainable development has led to the development of various management approaches and methods to guide construction participants in achieving better project sustainability performance in South Africa (Du Plessis, 2007; Thomson and El-Haram, 2011).

Kibert propose 7 principles to implement sustainable construction practice in 1994. These principles cover most aspects of the TBL and the concept of "doing no further harm" to the built environment. These construction principles speak to: conserving, to minimise resource consumption; reuse, to maximise reusable resources; renewing/recycling, to optimise renewable or recyclable resources; protecting, to conserve the natural environment; eliminate toxic materials, to create a healthy and non-toxic environment; economic benefits, to apply life cycle cost analysis; and technical, to provide quality products. Adopting these principles will ensure the reduction / elimination of adverse effects of construction activities on the built environment through efficient use of resources. The outcomes of sustainability principles could be regarded as a vital ingredient of improved competitiveness in construction industry (Opoku and Ahmed, 2015). Sustainable construction fosters interaction and protection of natural and social environments and ultimately helps to reduce energy usage, enhanced healthy and improved condition of living, and promote stakeholders productivity.

3. Lean in Construction

Stakeholders' concern about inefficiency in the construction industry is well known. The monumental wastes accompanying the use of resources (energy, water, materials, and land) have contributed immensely to climate change. Business as usual can no longer be sustained in the construction industry, if the industry is to assure biophysical sustainability while maintaining competitiveness (Womack and Jones, 2003; Holton et al., 2010). Lean offers an alternative that allows construction activities to thrive within environmental and social-economic constrains. Based on lean principles, major sources of waste, inefficiencies and pollution within the construction processes are identified and eliminated through collaborative approaches and processes to create value. For instance, planning, measurement, adjustment, and improvement ("Plan, Do, Check, Act") have also prove to be a veritable framework for value creation beyond specification (Ng et al., 2012).

Various lean principles and tools have been developed for use in construction with varying degree of success. San Martin and Formoso (1998) state that lean performance indicators include value chain efficiency, process efficiency, production flexibility, improved skills, material diversity, standardization, and optimization of components weight. Generally, the collaborative and continuous improvement principles inherent in lean practices made it not only a wastes reduction philosophy, but catalysts for business competitiveness, productivity and profitability. Lean principles engender effectiveness and efficiency in production processes by systematically examining the value chain for non-value activities through critical thinking and planning improved projects performance (Corfe, 2012; Novak, 2012).

4. Lean and Sustainability in Construction

The emergence of sustainability issues calls for a more innovative approach for the world to survive within the present constrains. The construction process generally contributes to the total energy use, GHG emission, and waste generation. Utilizing lean tools bring forth the predicted variable of efficiency and waste reduction, and the responsive variable of environmental benefit through reducing construction wastes at source, minimizing resource depletion, and preventing pollution. Integrative deployment of lean and sustainability could increase the pace of broader enhanced value (Larson and Greenwood, 2004; Ghosh et al., 2014).

Despite the sustainable construction drivers reported in the literature - resource efficiency, competitive advantage, reputation, increased productivity, reduced wastage, reduced materials cost, and preservation of natural environment (Yates, 2003; Zhou and Lowe, 2003) , the uptake of sustainability is still limited in the industry. This limitation may not be unconnected with the complex and fragmented nature of the construction industry. Common challenges perpetrating the limitation are the lack of understanding, perceived costs, and inadequate expertise (Opoku and Ahmed, 2015). However, lean reputation for promoting collaborative working arrangements, coordination, waste and cost reduction, and continuous learning and improvement serves as an opportunity for the industry to mitigate barriers to sustainable construction and create value beyond specifications.

The opportunity for value beyond the specifications has emerged as construction process with highly developed lean practices have reliably broken through the traditional project constrains and serve as catalyst for sustainability and enhanced added value in meeting the needs of sustainability (Nahmens and Ikuma, 2009; Novak, 2012). Lean practice covers a wide range of infrastructure procurement practices: planning and risk management, collaborative working, problem definition and solving, and value stream efficiency. These lean approaches demonstrate the value stream (benefits in terms of cost, time, and sustainability) for infrastructure sustainable development that span the project life cycle. It is on this premise that governments are urging the industry to leverage on lean thinking for real value delivery whilst simultaneously achieving improved competitiveness and the objectives set out in the strategy for sustainable construction (HM, 2009 cited in Corfe, 2013). It follows that lean thinking could form a central part of organisations' sustainability strategies, as it could deliver sustainability objectives.

Lean sustainable construction therefore can be conceptualized as 'a proactive approach to project delivery practice that meets a broader sustainability concerns of environmental, economic, social and technical perspectives by leveraging on available effective and efficient concepts to attain sustained productivity'. Sustained productivity here means to exceed the status quo of project delivery practice and achieve infrastructure beyond specifications. This has been achieved through efforts to enhance infrastructure project performance, reduce resource use and reduce costs through lean tools such as BIM, just-in-time, 5R, 5W (Scanlon and Davis, 2011; Ahuja et al., 2014).

5. Research Methodology

The aim of this study is to develop holistic indices of integrative implementation of lean and sustainability in terms of infrastructure development. The indices could allow a better understanding of stakeholders' way of assessing public infrastructure project performance. Within the construction context, the understanding of KPIs serves as benchmark for improved productivity, and it is vital to the success of project goals. To resolve this challenge, an exploratory study was conducted in Bloemfontein, South Africa. The study relies on interpretative theoretical framework that is grounded in lived experiences of project stakeholders (Creswell, 2013). Purposeful sampling in which the participants are selected according to a defining characteristic that makes them a role player was utilised in the study (Nieuwenhuis, 2007; Leady and Ormrod, 2010).

In particular, nine stakeholders in infrastructure development were interviewed in six different entities (department of works, project managers, consultants, policy administrator, community representative and the academia) with semi-structured questions that were initially sent to them by e-mail and a follow up telephone call was used to confirm the actual date of the interview for consistency. The interviews were conducted over a period of two weeks. Interviews, generally, were between 20 to 30 minutes in duration. At the start of the interviews, each participant was reminded of the research question and of the interview process. Each interviewee was then provided with a covering letter to read, and a confidentiality agreement to sign; on demand. This process was then followed by the actual interview during which the interview protocol was utilized as a guide. Each interviewee was asked about his / her experience and perceptions of infrastructure performance indicators related to: economic, environmental, and social conditions. All interviews were recorded and transcribed. The emerging findings were then collaborated with a comprehensive literature review to explore the phenomenon in South Africa. Nine interviewees took part in the exploratory study. The interviewees were two women and seven men between the ages of 30 and 56. The educational levels of the participants ranged from a national diploma to a doctoral degree, and construction industry experience ranged from 3 to 32 years (Table 1).

Table 1: The demographic of interviewee

Descriptions / *S/N*	*Highest Level of Education*	*Entities*	*Designations*	*Years in Industry*
1	*Bachelor's Degree*	*Works department*	*Project supervisor*	*3*

8	*Honours Degree*	*Community rep.*	*User*	*8*
9	*Honours Degree*	*Policy administrator*	*Director*	*32*

6. Research Findings and Discussions

The findings are herein presented and discussed in line with natural and social concerns about biophysical, economic, technical and social dimensions of sustainability in order to cater for the concern of different stakeholder. This provides a platform to integrate the primary data and the literature for meaningful interpretation for the right indices to emerge.

7.1 Indices for Biophysical Dimension

Most environmental concerns appears to be the highly researched sustainability dimension, some of the issues of the environment are predicated on the interaction between natural and social issues. Most interviewees suggest that resource use is a global issue as concerns for global warming are not localised. Sustainable resource use and environmental impact assessment are considerations in any developmental agenda, where the goal is to achieve sustainable extraction of fossil fuels and minerals resources at a rate lesser or equal to the slow replenishment of the inert resources, and to reduce the use of 4 generic resources of energy, water, materials, and land.

An attempt to maximise resource reuse and / or recycling, use renewable resources in preference to non-renewable resources, minimise air, land and water pollution, minimized emissions. So as to maintain and restore the earth's vitality and ecological diversity; and minimise damage to sensitive landscape in order to achieve the expected continuum (Shen, et al., 2007). Interviewees were unanimous in saying "we all know the rate at which we depletes the natural resources is certainly not sustainable, and a stable weather condition is not only good for our health, it also good for future planning". This echoes the current unpredictable nature of the biosphere and it impact on the environment. The interviewees express preference for facility with efficient energy, good indoor environment, and limited noise and dust pollution that can aid productivity.

7.2 Indices for Economic Dimension

Cost and value for money are the main determinants between internal and external stakeholders in any potential infrastructure development of scale. The management of the inherent trade-offs between these parties determine the viability of the project. Most interviewees agree with Shen et al. (2007) that intending user's affordability, employment creation; enhanced competitiveness, environmentally responsible supply chains, and the capacity to meet the needs of future generations are the main fulcrum for economic sustainability. Interviewee 5 says "yes, we all want to put up an energy efficient building or green building as you call it, but those technology are beyond the reach of common man", while interviewee 8 says "any user will like to rent a sustainable built environment because it ultimately reduces energy and maintenance costs of the properties". These quotes demonstrate the significance of energy use to the economics of the stakeholders. Other economic aspects mentioned by the interviewees relate to: having a competitive edge over their industry rivals through organizational learning, innovative ideas, technological advancement; improved productivity for enhanced profits; and stakeholder's collaboration for sustained harmony that engendered business and environmental excellence.

7.3 Indices for Social Dimension

The social dimension of sustainability has been growing in importance as a criterion for evaluating the viability of projects in the construction sector, especially in developing nations where basic needs of life and the right skills for quality job remains a challenge. Social sustainability in construction is mostly premises on the need for improve quality of human life through implementation of skills acquisition and capacity enhancement of the disadvantaged, to seek fair or equitable distribution of construction social costs, and to seek intergenerational equity (Shen, et al., 2007; Edum-Fotwe and Price, 2009). This social cost, according to the interviewees pertains to the health and well-being of the community. Most interviewees agree that "a lean sustainable project should be able to contribute to the community through local employment and improved skills development". A segment of the interviewees also echoes the need to match business goals with environmental excellence. This can only be attained through stakeholder collaboration and community involvement/development, proper site layout to reduce noise and dust pollution for work place harmony.

7.4 Indices for Technical Dimension

Quality is one of the traditional KPIs in construction management. Although relative in nature, it depends on technical competence and it outputs express 'value for money'. Sustainability in technical terms is to construct durable, reliable, and functional structures, which creates the built environment; humanize large buildings; and revitalize the existing urban infrastructure (Shen et al., 2007). Most interviewees agree with Emuze (2015) that the new model of sustainability must include regenerative, adaptive and resilient initiatives in order to achieve a broader sustainability agenda. The quality of the design, material selection, production process and the level of finishes most at times determine the functionality and the price clients are willing to pay for the products. Also, poor quality of work in projects may lead to reworks which certainly compromise other performance indices.

7.5 Indices for Lean and Sustainable Projects

The traditional KPIs have evolves overtime from the dated tripod of cost, time and quality. Projects success are now evaluated through performance measures to include critical factors of; health and safety and related sustainability criteria (Khosravis and Afshari, 2011; Kylili, Fokaides and Jimene, 2016). The broader sustainability indices have been widely reported (Shen et al., 2007; Edum-Fotwe and Price, 2009; Emuze, 2015) to encompass the natural and socio-economic aspects of infrastructure development and its effect on various stakeholders in the industry.

These cut across the project value chain in relation to processes, resources, leadership, people, financial, environmental and the entire ecosphere through project lifecycle. Lean principles as a waste reduction tools, is an effective ways of enhancing the various spheres of KPIs for infrastructure development (see sections 3 and 4). It can then be infer that indices for lean and sustainability (LSI) are those indices that can be seen as a standard of judgement by which lean and sustainable values can be measured. Hence, the LSI went beyond traditional indices to accommodate external inclusiveness that address industrial harmony and the need of future generations. As illustrated in Table 2, these indices set a benchmark for measuring project performance holistically and provide significant insights into developing a comprehensive base for future developments.

Table 2: Stakeholders project performance indices

Types / Indices	*Traditional*	*Lean (L)*	*Sustainability (S)*	*LSI*
Cost	✓	✓	✓	✓
Time	✓	✓	✓	✓
Quality	✓	✓	✓	✓
Health and Safety	✓	✓	✓	✓
Environmental responsible value chain		✓	✓	✓
Energy and resource consumption		✓	✓	✓
Pollution and emission		✓	✓	✓
Matching Business and environment		✓	✓	✓
Social cost/benefit			✓	
Industry competitiveness		✓	✓	✓
5R / Renewable resources		✓	✓	✓
Flexibility and adaptability		✓	✓	✓
Organizational learning		✓	✓	✓
Dispute	✓	✓	✓	✓
Stakeholders collaboration		✓	✓	✓
Employment and Skill development		✓	✓	✓
Continuous improvement		✓	✓	✓
Planning and risk	✓	✓	✓	✓

management				
Value stream efficiency		✓		
Technological advancement		✓	✓	✓
Affordability		✓	✓	✓
Indoor environmental quality			✓	

Adopting these new sets of performance measures as a base for planning and executing future projects could lead to evolution of sustainable built environment. To do so, a clear understanding of the LSIs, as a sub-set of biophysical, economic, socio and technical dimensions will be needed. This can come to fruition through further research and stakeholders' engagement in term of standardizing LSI measurement methods (Ali, Al-Sulaihi and Al-Gahtani, 2013).

7. Conclusions and Recommendations

The purpose of the research reported upon in this paper is to develop lean sustainability indices that are grounded in stakeholder's projects experience with the view of creating a consistent and holistic way of assessing public infrastructure project performance. The compilation of the indices is relevant as projects performance criteria are often hedged around the traditional KPIs and TBL of sustainability, measured both objectively and subjectively, in order to achieve success expectations. To sum up, the emergent findings indicate that although generic project KPIs of cost, time and quality is of major concern to the stakeholders, indices requires for lean and sustainability are however, broader and far reaching in engendering efficiency and effectiveness in infrastructure development. These include matching business and environmental excellence, energy efficiency and good indoor environment, minimized resource consumption, minimized emissions, increase health and well-being, user productivity, reduced noise and dust pollution, stakeholders' collaboration, community social benefits, and enhanced industry competitiveness. It can therefore be argued that a focus on these indices could benefit project delivery with limited whole life cycle impact in terms of sustainable development. The indices could provide all stakeholders the same information and knowledge of the overall goals, creating cooperation, coordination and better understanding of the key issues affecting the value chain, towards achieving better project performance.

Abstract

The current construction industry in Hong Kong faces severe challenges in relation to increasingly stringent regulations, aging workforce and skills shortages and their triggered high labour costs, and the transition of development from the fast-speed to sustainability-oriented mode. Lean construction has been recognised as an effective approach to improving productivity, hence offering a potential for the Hong Kong construction industry to prosper in the challenging circumstance. The aim of this paper is to examine the current practices and explore the future development of lean construction in Hong Kong. The research was conducted through 30 semi-structured interviews with established professionals in the industry. The results indicate a low level of awareness of the lean concept although some lean construction techniques were already embedded in practices implicitly. A wide range of benefits were identified, which were centred on reduced input, increased output and reduced impact, offering a potential for productivity improvement. However, challenges were also revealed at individual, organisational and industry levels, markedly people's mind-set and reluctance to change, a lack of demonstration of the benefits, and a weak knowledge base of lean. While some regarded lean as today's solution and therefore a must-to-have, others speculated an uncertain and dynamic future of lean construction in Hong Kong. Recommendations were identified for promoting lean construction in Hong Kong, fundamental to which was collaboration engaging government, industry and institutions.

Keywords: lean construction, productivity, industry development, Hong Kong

1. Introduction

The construction industry has long been criticised in many countries and regions for low levels of performance in relation to cost and time overruns, poor quality, disputes, and other problems leading to impaired efficiency and waste. It has also been argued as one of the weakest sectors in innovation, with piecemeal adaptation of modern technologies (Woudhuysen and Abley 2004). Much of the research in construction has attributed the lag-behind performance to the nature of the industry that is highly fragmented in structure and complex in operation, and has reached a consensus on the urgent need for reform and innovation in the industry (Dubois and Gadde 2002; Woudhuysen and Abley 2004; Goodier and Pan 2010).

Productivity is an essential component of industry performance which can be illustrated by a ratio between output and input (Park et al. 2005). The need for improving productivity is a great concern in the construction industry. In Hong Kong, the seminal Henry Report 'Construct for Excellence' (Construction Industry Reviews Committee – CIRC 2001) proposed 'an integrated construction industry that is capable of continuous improvement towards excellence in a market-driven environment'. More recently, the Hong Kong's Construction Industry Vision 2020 (Hong Kong Construction Association – HKCA 2012) has set the target of improving by 50% productivity by 2020 against 2012 benchmarks. However, in parallel with the ambitious goals, there are pressing challenges facing the Hong Kong construction industry to meeting these targets. One of the most significant issues is the ever increasing demand for manpower, accompanied with skills mismatch and the ageing labour force (Wong et al. 2015; Ng and Alan 2015). The great shortage of skilled labour poses significant risks to the fulfilment of a productive industry. In addition, safety is a thorny problem that the accident rate of the construction industry ranked the top among all sectors in Hong Kong (Wong et al. 2015). The impact of construction on the environment is also critical in Hong Kong, in terms of the large amount of carbon emissions and wastage demolition (Hong Kong Green Building Council – HKGBC 2014). To tackle these challenges and thrive in the dynamic circumstance, the adoption of modern technologies and innovative ideas is of great importance in the Hong Kong construction industry.

Lean construction has been widely recognised as an effective approach to improving productivity in the construction industry, e.g. in the UK (Egan 1998; Wolstenholme 2009), US (Salem et al. 2006; Song and Liang 2011), and Canada (Mao and Zhang 2008). Koskela et al. (2002) defined it as "a way to design production systems to minimize waste of materials, time, and effort in order to generate the maximum possible amount of value". Lean Construction Institute (2015) described it as "a new way to design and build capital facilities whilst the reliable release of work between specialists in design, supply and assembly assures value is delivered to the customer and waste is reduced". The many definitions and descriptions of the concept of lean construction in literature, albeit varying from each other, indicate the underlying common purpose of value maximization and waste minimization in construction projects. Along with the development of lean construction globally there have emerged numerous lean construction techniques and tools, with a trend attempting to address the emerging concepts and practices in the construction industry, such as building information modelling (BIM), sustainability, advance planning, and visualisation. For examples, Salem et al. (2006) studied six lean construction techniques: last planner, increased visualisation, first-run studies, huddle meetings, the five S's and fail-safe for quality. Song and Liang (2011) developed a vertically-integrated scheduling system tool for implementing lean thinking to improve project cost and time performance as well as reducing environmental impact of construction. Sadreddini (2012) described in detail two lean construction tools, i.e. collaborative planning and visual management, and considered them to be the first two commonly used to ensure quick wins and start a roll-out of lean and culture change. All these studies emphasise the importance of selecting and applying appropriate tools in a given situation.

However, the take-up of the lean approach in the Hong Kong construction industry appears to be low, coupled with few lean construction tools and technologies in use. Understanding of lean construction may reside with individuals in the industry and academic domains (e.g. Li et al. 2012), while such body of knowledge is fragmented and insufficient. Leung and Tam (2008) identified that the term "lean construction" is not commonly applied by practitioners in the Hong Kong construction industry. These factors not only expose the Hong Kong construction industry to risks and uncertainties when facing the rapidly evolving technologies and innovations, but hamper further take-up and future development of lean construction for achieving the construction industry vision and productivity improvement target.

The aim of this paper is thus to examine the current practices and explore the future development of lean construction in the Hong Kong construction industry. Following this introduction and methodology, the paper examines the perspectives of lean, the status quo of lean construction in Hong Kong, and achieved and potential benefits of and challenges for lean construction. It then explores the future development of lean construction in Hong Kong and identifies relevant recommendations, before conclusions of the paper are drawn.

2. Research Methodology

This research aimed to examine the lean thinking and applications in the Hong Kong construction industry. Semi-structured personal interviews were carried with established professionals in the industry. The interviewees were selected using the cluster sampling strategy, and covered the key stakeholder groups of lean construction in Hong Kong, e.g. developer/client, contractor, specialist contractor, architect, engineer, manufacturer and supplier, government, institution. Previous research (Warren 2002) argued that interview-based research should target between 20 and 30 interviewees for academic publication purpose. Therefore, this study targeted 30 interviews, achieved from 43 invited professionals with a response rate of 70%. Each interview took around 45 minutes, guided by a number of questions in three aspects: the status quo of lean construction in Hong Kong; benefits of and challenges for lean construction in Hong Kong; and future development of lean construction in Hong Kong.

The interviews were audio recorded with permission. The transcripts and notes taken during the interviews were analysed following the process of identifying codes, themes and patterns with the aid of NVivo software.

3. Results and Analysis

The background information of the 30 interviewees is provided in Figure 3. The interviewees together, by their primary affiliated organisations, covered all of the eight main stakeholder groups in the Hong Kong construction industry identified for this study, which were institution (30%), contractor (17%), consulting engineer (17%), developer/client (13%), government department (10%), manufacturer and supplier (7%), specialist contractor (3%) and architect (3%). The interviewees together also well covered various groups of stakeholders by their working experience. Nearly half of the interviewees (46%) had more than 30 years of experience in the construction industry, followed by those with 10-19 years of experience (20%) and then those with 20-29 years of experience and those with less than 10 years of experience.

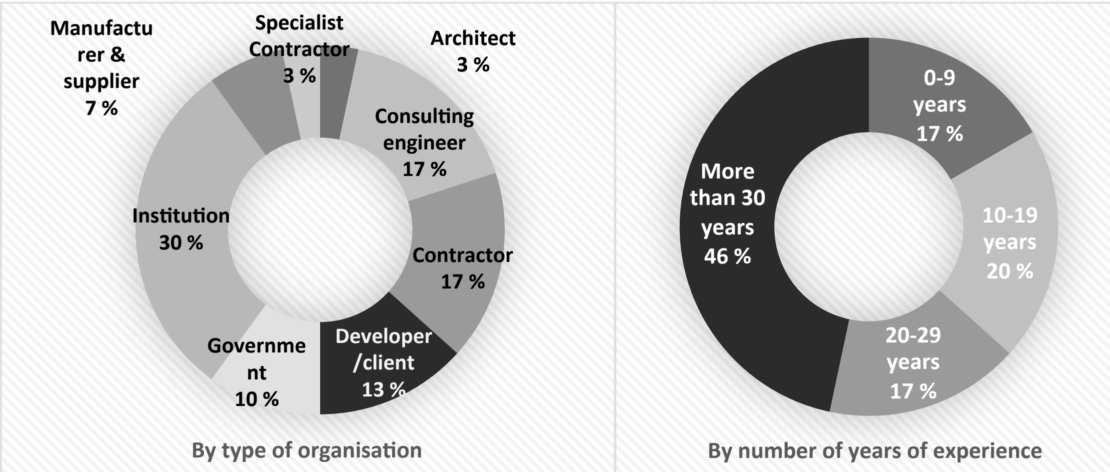

Figure 1 - The demographic information of the interviewees

3.1 Status quo of lean construction in Hong Kong

3.1.1 Understanding of the term “lean construction”

The term “lean construction” was still considered new and uncharted in Hong Kong. More than half of the interviewees (53%) were not familiar with the term. Some of those who knew about the term had not actively adopted the lean construction approach in their practices. Removing those interviewees from institutions (including universities) and consulting engineers (who were assumed to have devoted more efforts in knowledge exploration and exploitation and might have had more exposure to lean), only 12% (2 out of 16) were familiar with the term. It is worth noting that those stakeholder groups who are ignorant of lean are the main actors in the industry. These results suggest that the Hong Kong construction industry is not familiar with the term “lean construction”. The identified perspectives of the concept of lean are summarised below.

Lean construction is from lean production

Over one third interviewees (11/30) commented that lean has its origin in manufacturing such as Toyota automobile production. Applying lean thinking in construction was recognised as a result of cross-industry benchmarking. Hong Kong heavily relies on imported goods while most construction-related manufacturing facilities have been relocated to Mainland China. Therefore, manufacturing-based innovation like lean may not diffuse well in the construction industry. Thus, the limited awareness of lean explains the poor understanding of lean in construction.

Lean construction is to reduce waste in construction projects

It has been widely reported that applying lean in construction is conductive to the reduction of multifaceted waste in construction projects, including time waste, on-site construction waste, labour waste and other forms of wastages. This was a consensus among the interviewees. Some highlighted only certain kinds of waste, while others had a more comprehensive perspective covering all potential non-value-adding matters within the projects. Besides, it was also brought forward that the construction industry faces different wastage issues from manufacturing and has more on-site wastes. Therefore, although the concept of lean construction was recognized to have originated from lean production, the actual implementation of lean in construction operations is different.

Lean construction is to minimise resources in construction projects

As pointed out by some interviewees, an essential feature of lean is to finish the project with fewer resources in terms of budget, schedule, material, labour, land and other required assets. This perspective is in line with the fundamental lean idea that "lean is to maximise the value", but emphasizes only the value of the industry itself not the final customers. In Hong Kong's construction market, the supply, especially housing, has largely failed to keep pace with the demand, which results in a less attention from the industry on the value of end customers, compared to manufacturing or construction market in other competitive places, like Mainland China. These results suggest a missing link in connecting the interests of industry stakeholders and end users in the Hong Kong construction industry.

Lean construction is an integrated approach of life-cycle process management

Lean construction was also viewed as a pillar of project management, with a focus on the integration of processes. Most interviewees considered lean based on the beneficial targets, e.g. reduced waste and minimized resources. Therefore, this perspective offers a slightly different view that concentrates on the pathways to achieve lean. The integration of works at the project level, or more specifically, integrated project delivery (IPD), do put the lean principals into practice. Nevertheless, this perception was only proposed by a few industry experts in the interviews. Indeed, the construction industry is characterised as a competitive and loosely-coupled system (Dubois & Gadde, 2002), while market conditions in Hong Kong are even competitive (HKTDC, 2015). In this respect, the efforts to manage and improve industry performance are more often aimed at individual level rather than enhancing the total project performance, and the power and importance of collaborative integration have often been ignored in the industry.

Lean construction is an overarching theory of project management

Some participants argued that lean construction should be understood as an overarching theory of project management, which covers a range of principles, tools and techniques. They suggested that the lean concept should be promoted to help achieve a systemic understanding of lean for improving the multiple performance aspects of construction projects. It was argued that the promotion of lean can facilitate the application of lean tools and techniques. Based on these arguments, it was acknowledged that the promotion of the concept of "lean construction" should be important and valuable for the Hong Kong construction industry.

3.1.2 Relevant lean construction practices in Hong Kong

Although the term "lean construction" was not much used in the Hong Kong construction industry, relevant lean practices were identified for improving construction performance.

BIM: a promising but not well-applied technique in Hong Kong

There has been a global transition towards smart and virtual construction, and Hong Kong is of no exception. BIM as the most representative digital technology exerts a tremendous fascination on construction companies. All the interviewees agreed that BIM is an innovative and beneficial practice in the construction field. However, whether it is a lean approach is not clear. Some confirmed that BIM is useful and favourable to achieve lean with the powerful visualization and integration, but others argued that it can be a lean tool only if applied wisely and correctly, e.g.

> *"There is no button or promise in BIM to tell us when we do something not lean, so to me it's just a tool and whether it is lean depends on the user. If the user's mind-set is not lean but mean, I don't think BIM alone can create lean construction."*

The use of BIM in Hong Kong, although having been highly promoted, was still considered poor. The BIM use has been largely restricted to the design and planning stages. Some interviewee commented,

> *"Projects labelled with BIM may only exist in names, that they do have BIM consultants come periodically but may have no impact on the real construction works, resulting in a waste of time and resources rather than being lean."*

In this regard, the wide-spread take-up of BIM in Hong Kong would be slow and challengeable.

Low or zero carbon building (L/ZCB): a promotive but uncertain area in Hong Kong

L/ZCB is being promoted in Hong Kong. The first ZCB in Hong Kong has been developed with a collaborative effort across the industry, to showcase the modern energy-saving building technologies and raise the awareness of low carbon living in Hong Kong. However, the possibility of a wide take-up of ZCB in Hong Kong was doubted by some interviewees. One argument was lined in the uncomfortableness a zero carbon environment may offer in such a hot and humid city. Another was concerned with the uncertain feasibility of L/ZCB in the high-rise high-density urban environment of Hong Kong.

L/ZCB was considered not an approach for lean but a scenario for lean application. Whether or not the zero carbon blueprint is a feasible target in Hong Kong, lean techniques were recognized to play a crucial role in reducing carbon footprint and fulfilling building energy saving schemes.

Prefabrication/modular construction: a widely adopted approach in Hong Kong

Prefabrication and modular construction were agreed to be a long-term and well-adopted practice in the Hong Kong construction industry, especially in the public sector. Also, it was seen by almost all the interviewees as an effective lean approach itself and also a useful scenario for embedding lean strategies. Actually, the strength of prefabrication use in Hong Kong was the main supporting argument taken by the interviewees who commented,

> *"Hong Kong does not use the term "lean construction", but moves in the same direction to improve construction performance."*

While the use of precast units and modular construction is not new to the industry, there is still room for improvement and being much leaner, as noted by some interviewees. First, better planning is needed involving the usage prediction of precast units, logistics and on-site arrangement. Second, the extent of prefabrication use can be increased. It was reported that around one third of the concrete elements used for public housing in Hong Kong were prefabricated, but the extent for private buildings in the city was much lower. An increased use of prefabrication was therefore suggested. Third, some interviewees suggested that Hong Kong should bring back its precast yards from the Mainland due to the increasing land and labour costs in the Mainland, and time and carbon emissions in transportation.

Look ahead planning tools: an untapped method in Hong Kong

Unlike the other three themes which were widely known, only a few interviewees were well informed with look ahead planning. As look ahead planning is a specific lean approach, this finding is not surprising. It reveals that although interviewees have argued that the Hong Kong construction industry has applied lean practices without labelling the term, a gap still exists in applying some specific lean techniques. An even poorer awareness was identified of Last Planner System, which is one of the most important and far-reaching construction-specific lean techniques that covers look ahead planning as one step. This finding again suggests that advanced lean construction tools and techniques, with the potential to improve construction productivity, are still largely untapped in Hong Kong.

Other techniques undertaken for improving productivity

While employing a formal lean approach is rare in the Hong Kong construction industry, advanced practices to increase efficiency have been adopted in different firms for a long time. During the interviews, industry experts and researchers mentioned a number of other related techniques and methodologies for improving productivity. Examples of such techniques and methodologies include quality control, critical path method, knowledge sharing platform or knowledge transfer system, collaborative delivery methods, data management, design software, reuse of resources, and 5S.

3.2 Benefits of and challenges for lean construction in Hong Kong

A wide range of achieved or potential benefits were identified, which can be grouped under three themes in alignment with the industry-wide concern of improving productivity and competitiveness, namely, reduced input, increased output and reduced impact (Table 1).

Table 1 Identified benefits of lean construction in Hong Kong

Theme	*Identified benefit*	*Example quote*
Reduced input	• *Reduced cost* • *Saved resources* • *Reduced project schedule* • *Saved labour* • *Saved spaces*	*'Time and cost are the benefits since lean helps the management to reduce the resources and result in faster projects.' [from institution]* *'If use wisely, it can reduce the number of waste and the number of manpower.' [from developer/client]*
Increased output	• *Higher quality construction* • *Better customer satisfaction*	*'We use some machineries and prefabrications, so by using these lean construction tools or techniques or designs, productivity will be enhanced, waste has been reduced, and quality has been improved.' [from institution]*
Reduced impact	• *Reduced construction waste (reduced environmental impact)* • *Improved safety (reduced accidents)*	*'Reducing waste in landfill, which I think is a very big issue in Hong Kong' [from consulting engineer]*

Six themes of the challenges were identified, grouped at the individual, organizational and industrial levels, leading to the uncertainty and dynamics of its future development (Table 2).

Table 2 Identified challenges for lean construction in Hong Kong

Level	*Identified challenge*	*Example quote*
Individual level	• *People's mind-set* • *Reluctance to change*	*'Number one is the concept. People have to have that concept.' [from government]*
Organizational level	• *Lack of demonstration of the identified benefits* • *Lack of support from the leader* • *Lack of time to learn*	*'You need to convince all the big boss to approve of implementing such kind of approaches.' [from supplier]*
Industrial level	• *Lack of knowledge/training in the market* • *Constraints in the regulatory framework*	*'Also the policy, I mean the procurement, is not really conductive to innovation.' [from institution]*

3.3 Future development of lean construction in Hong Kong

The need for improving construction productivity in Hong Kong was made clear in the interviews, but whether or not to achieve that by promoting lean construction was considered to be uncertain. Some believed that lean is today's solution to tackling the identified challenges, such as labour shortage, environmental concerns and low productivity. Some argued for a dynamic future of lean construction development in Hong Kong, i.e. the future development of lean construction will be associated with uncertainties and diversity. The others considered that the adoption of lean construction may still be stagnant in Hong Kong in the near future. Overall, the future development of lean depends on what challenges exist and how such challenges can be solved, as well as the efforts exerted in the promotion among industry stakeholders.

A number of recommendations were identified from the interviews to addressing the identified challenges and promoting lean construction in Hong Kong. The recommendations are:

- There is an urgent need for more education and training on lean construction.
- Successful cases of utilising lean are highly required to promote and demonstrate the benefits of lean construction.
- Government policies and incentives for adopting lean are impactful.
- Collaboration is critical to utilising lean for improving productivity.
- The establishment of a lean construction organisation in Hong Kong should be useful.

Fundamental to all these recommendations is government-industry-institution collaboration.

4. Discussion

The results from the interviews reveal that lean construction as a philosophy is not well understood in the Hong Kong construction industry as a whole. Although some more established approaches and techniques (some being lean related) have been widely utilised for improving productivity, the adoption of modern lean tools and techniques is limited. The promotion of lean therefore has the potential to broaden the horizon of the industry and facilitate the take-up of innovation, boosting up construction productivity.

The identified benefits of lean construction are primarily of reduced cost, resources and time. These results echo the fundamental principle of lean in waste minimization that unnecessary and repetitive wastage in various forms can be eliminated by applying lean (Womack 1996). Higher quality was also identified, but only by a few interviewees, whereas better customer satisfaction was considered as another benefit by even fewer participants. This result is believed to be presumably due to the severe problem of housing shortage in Hong Kong (Yip 2014), which dilutes the customer focus in the marketing strategy of many construction companies. However, lean is a customer-centric philosophy (Howell 1999). This finding suggests that the little awareness of lean construction in Hong Kong might be attributed to the lack of customer value emphasis in the industry. Along with an increasing global concern on sustainability and low carbon, the Hong Kong construction industry is now exerting more efforts on waste management and carbon footprint reduction (Pan and Ning 2014). It was also considered that the approach of lean construction can be promoted in Hong Kong under relevant sustainability schemes with its beneficial effects on the reduction of construction waste and resource consumption.

Despite the many identified benefits, challenges for lean are thorny. The results show that a large proportion of construction practitioners in Hong Kong are quite conservative and accustomed to conventional methods of construction. Owing to insufficient labour in Hong Kong (Wong et al. 2015; Ng and Alan 2015), some seldom fear the unemployment crisis and do not see the necessity of applying lean approaches or other innovative methods. It was recommended that more education and training is required to address this ideology. However, as the lean philosophy is really culture and value-laden, education per se may hardly fulfil that purpose. Besides, as the construction industry is fundamentally profit-driven, to fully demonstrate the benefits of lean by using successful project cases will be very important to encouraging construction organisations to take up lean. In this respect, pilot projects demonstrating how lean can help to improve performance are highly recommended. However, due to the lack of knowledge and expertise in the Hong Kong construction industry, pilot cases may be difficult to be developed. Increasing the industry's knowledge base of lean is vital, but the key issue resides with how to build such a knowledge base in this lean-insulated area. Recommendations on government and institutional support and industry-wide collaboration are only effective when industry stakeholders have achieved a comprehensive understanding of lean. Thus, it might be a more effective way to establish a specific lean construction organisation in Hong Kong, which may draw lessons globally, explore lean knowledge attentively, and create a collaborative platform for lean projects formation.

5. Conclusions

This paper has examined the current practices and explored the future development of lean construction in Hong Kong. The paper concludes that lean construction as a philosophy is not familiar to the Hong Kong construction industry at large. Relevant practices, however, have been conducted. BIM and L/ZCB are emerging areas and have received increasing attention in Hong Kong, but still being partial or immature. Prefabrication is a long existing practice and yields great benefits in the Hong Kong construction industry. Look ahead planning tools which are specific for lean construction are still untapped in Hong Kong.

The paper also concludes that wide-ranging benefits of lean construction are available, markedly reduced input, increased output and reduced impact. Examples identified include minimised project input of money, materials, time, labour, land and other kinds of resources, maximised value of the project output in higher quality and customer satisfaction, and reduced impact of construction in terms of less environment related wastage and accidents. Co-existed with the benefits are a number of challenges at the individual, organisational and industry levels. Typical examples of the identified challenges include people's mind-set and reluctance to change, the lack of demonstration of the benefits, insufficient support from the leaders of construction organisations, and the paucity of knowledge and expertise of lean in the industry.

The paper further concludes that to address the challenges and accelerate the uptake of lean in the Hong Kong construction industry, recommendations are proposed in terms of policy promotion and incentives from the government, knowledge support from institutions and universities, and collaboration across the whole industry. The establishment of a lean construction organisation in Hong Kong should provide an effective way to explore the knowledge and facilitate the future development of lean construction in Hong Kong. Such organisation should aim to disseminate lean related knowledge, develop learning from international practices for the wide industry, provide a collaborative platform for government-industry-academia initiated pilot lean projects, and organise events to support stakeholder communications and engagement.

Industry Practitioners Quality Perceptions of Built Environment Graduates at Entry Level in the South African Construction Industry

Ephraim Zulu
(email: ephraimzulu2000@yahoo.co.uk)

Theodore Haupt
(email: haupt@ukzn.ac.za)

Abstract

Entry level graduates in the construction industry have been criticised for failing to meet the expectations of the industry. Gaps have been reported between competences possessed and those demanded by industry. These deficiencies impact on the ability of the graduates to acquire employment, maintain the employment, progress in their careers and get a new job when the need arises. Information on the extent of the problem of deficiencies in factors that impact on employability is scanty, if not altogether missing. This research therefore sought to establish the perception of employers in the South African construction industry on the level of preparedness of university graduates entering construction practice. A quantitative survey design approach was used. Data were collected through a structured questionnaire circulated to a purposively selected strata of general contractors registered with the Master Builders Association in the construction industry in South Africa. Descriptive statistics, reliability coefficients and the Kruskal Wallis test were computed and used to identify skills, knowledge, competences and attributes which employers felt were lacking in entry level graduates. The results show that the employers are not satisfied with the quality of graduates from universities in South Africa. Graduates are found to be deficient in knowledge of construction, financial aspects of construction, problem solving, professional practice, oral communications skills, written communication skills, health and safety, self-directed learning, ethics, team working, punctuality, legal and risk aspects of constriction, reading and understanding of documents and professional conduct among others. Attributes found to be deficient include negotiation skills, vision, practicality, entrepreneurial attributes, leadership, forward thinking, critical thinking, problem solving, and communication skills among others. On a positive note, graduates were rated fairly well in the desire to learn and information technology skills. The results suggest that employers are very highly expectant of the skills, knowledge, competences and attributes which graduates should bring with them to construction practice from the university. However, while it is important that graduates possess the relevant skills, knowledge, competences and attributes, the employers perception of the relevant extent to which graduates need to demonstrate these at entry level may be overrated.

Keywords: Built Environment Graduates, South African Construction Industry, Graduate Quality, Construction Education, Industry Perception

1. Introduction

The extent to which graduates entering the construction job market are competent for practice has come under question on several occasions. Several deficiencies have been reported including failure to apply practical construction knowledge, absence of problem solving skills, poor communication skills among many other skills critical for the efficient functioning of construction industry practitioners (Aryakwa et al., 2011; Love and Haynes, 2011). Similar deficiencies have been reported in some sections of the South African construction industry (Smallwood and Emuze, 2011).

These deficiencies impact on the ability of the graduates to acquire employment, maintain the employment, progress in their careers and get a new job when the need arises. The ability to achieve these is described as employability. Information on the extent of the problem of deficiencies in factors that impact on employability is scanty if not altogether missing. For example, the British Council (2014) noted the severe lack of information on employability skills that graduates possess and that while employer perspective surveys are usually sources of such information, even these are often absent in some countries. It is consequently difficult to compare employability information across contexts and through time (Ibid). For Sub-Saharan Africa, the absence of such information creates challenges for evidence based policy. The absence of evidence is in fact a global challenge with only a small number of high-income countries having adequate data on employability (Ibid).

This research therefore sought to establish the perception of employers in the South African construction industry on the level of preparedness of university graduates entering construction practice. Three measures were used to assess the level of graduate preparedness. Firstly, a single item measure, were respondents were asked to rate their extent of agreement, was used. Secondly, respondents were asked to rate several items which comprise of skills, knowledge and competences desired in construction graduates and an aggregate score was computed from the items. Thirdly, respondents were asked to rate attributes which make a good construction graduate. In achieving the objective, the paper first presents a background to the research by reviewing literature on deficiencies and employability of construction graduates generally and in South Africa in particular. The methodology adopted for achieving the objective is then presented and the results analysed and discussed after which conclusions are drawn.

2. Background

There has been widespread concern about the extent to which university graduates are ready for the workplace. The construction industry has equally expressed displeasure at the quality of graduates entering the industry. For example, while analysing the perception of the Ghanaian construction industry on the performance of industry entry level graduates, Ayarkwa et al. (2011) noted that graduates lacked practical building knowledge, problem solving skills, communication skills (inter-personal skills in generally) among several other skills and competences. Love and Haynes (2011) equally noted the absence of all these skills and competences in a survey of construction manager and construction companies in Australia.

Shafie et al. (2014) also reported a gap in the competences of construction graduates in Malaysia.

The competence gaps identified among the construction graduates have an effect on the employability of the graduates. Employability has been defined as gaining employment, maintaining employment and obtaining new employment if required (Lees, 2002 citing Hillage and Pollard, 1998). Harvey (1997, cited in Lees, 2002) defined employability as the propensity of graduates to exhibit attributes that employers expect will be necessary for future effective functioning of their organisation. Employability and employment differ in that employment is only about having a job while employability is possession of the qualities needed to get a job and maintain and progress in the workplace (Lees, 2002; British Council, 2014). Employability therefore depends on the possession of relevant knowledge, skills and attributes and how these are used and presented to potential employers (Lees, 2002).

Copper and Lybrand (1998, cited in Lees, 2002) suggested that employability skills fall in four broad areas of traditional skills, key skills and personal attributes, knowledge of organisations and how they work. Quite similarly, Zou (2008) classified the employability attributes into three categories of attributes, skills and knowledge (ASK) shown in Figure 1. Employers are generally satisfied with the disciplinary knowledge of graduates but perceive significant weaknesses in information technology skills, reliability and transferable skills such as team working and problem solving (British Council, 2014).

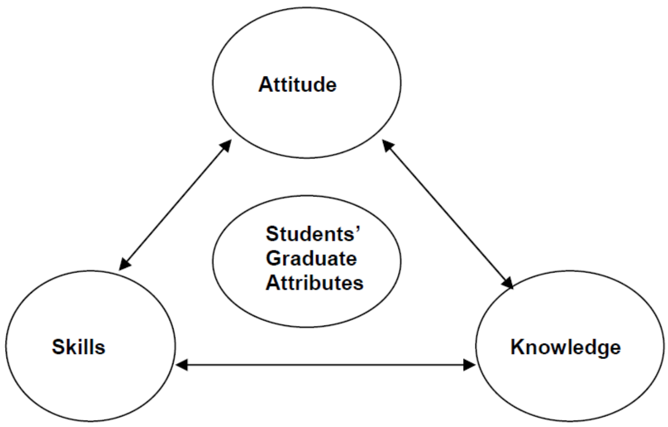

Figure 1: ASK Acronym for Graduate Attributes (Zou, 2008)

The range of skills, competences and knowledge areas identified as important for construction graduates is very large. While assessing employers expectations of the performance of construction graduates, Davies et al. (1999) found that strong interpersonal skills, team players who can also lead a team, information technology, language ability, good commercial awareness, problem solving skills among others were the skills employers expected from graduates. Shafie et al. (2014), while assessing views of employers and expectations of soft skill competences of quantity surveying graduates in Malaysia, identified communication skills, problem solving skills, leadership, team work, professional ethics and moral self-confidence as skills necessary for quantity surveying graduates. Technical skills like measurement, contractual aspects and project management among other competences are also necessary for a well prepared quantity surveying graduate (Ibid). Adams (1998) established that important topics for contractors in developing countries included accounting and financial management, entrepreneurial studies and project management among many others. Ahmed et al. (2014) identified five skills as important for construction management programmes and these are health and safety regulations, interpreting contract documents, listening ability/giving attention to detail, knowledge of building codes and regulations and time management. Acheampong (2013) and Sedighi and Loosemore (2013) also reported deficiencies in construction graduates.

Inadequacies in the relevant skills, knowledge, competences and attributes desirable in construction graduates have been reported in the South African construction industry. For example, while assessing the performance of diplomates and graduates entering the South African construction industry Smallwood and Emuze (2011) noted that the perception of industry is that the performance is almost inadequate in every learning outcome. The biggest gaps were found in project and site management, construction technology and skills, knowledge of the importance of key issues in construction, communication, people skills, leadership, problem solving and team work. In a survey on the difference between perceptions of importance attached to different skills by graduate employers in South Africa and the employers' level of satisfaction with the actual skills of graduates the British Council (2014 citing SAGRA Survey, 2013) also reported deficiencies in graduates employability albeit not specific to the construction industry. Significant deficiencies were reported in all skills surveyed including willingness to learn, team working, problem solving, interpersonal skills, commitment, proactivity, oral communication, flexibility, planning, numeracy, self-awareness, self-promotion, customer orientation, leadership, networking and business acumen. The graduates were perceived to be well prepare in IT/Computer literacy and foreign language.

Producing graduates who are employable requires the delivery of a university academic experience which imparts the relevant knowledge, skills and attributes that define employability in any particular field. Lees (2002) posited that it is likely that employer's criticisms of the weaknesses of graduate recruits are not necessarily resulting from failure in the curriculum but rather a failure in the transfer process. Lees further suggested that chosen teaching methods assist students to develop the employability skills to varying limits. Ahmed (2014) concluded that an integrated curriculum presenting the distinct parts of the construction process synergistically in a project environment is likely to equip graduates with better construction project management skills.

Notwithstanding the literature suggesting that graduates lack employability skills, Davies et al. (1999) concluded that graduates are actually not as poorly-prepared for the workplace as would be suggested by anecdotal evidence from employers. The British Council (2014) also noted that there is rather weak evidence suggesting that there is a gap in skills between the skills which the graduates possess and the ones that are required in the job market.

3. Research Methodology

A self-completing questionnaire was favoured firstly because the survey was preliminary and conducted to validate the extent of the problem of inadequately prepared graduates in the South African construction industry and since a census was not possible due to the very large number of construction industry practitioners. Graziano and Raulin (2007) suggest that it is appropriate to conduct a survey rather than a census unless the population of interest is small.

3.1 Population and Sampling Technique

Practitioners in the South African construction industry including Quantity Surveyors, Construction Managers, Construction Project Managers, Civil Engineers and Architects were targeted for inclusion in the sample. The respondents were drawn from a purposive sample of Master Builders Association (MBA) members in two of their regions. The selected regions were MBA Kwazulu-Natal (KZN) which covers the province of KZN and MBA North which covers Mpumalanga, North West and Limpompo districts of South Africa. While the MBA registers contractors of different specialisation, only contractors registered in the general contractor category who had valid email addresses on record were targeted for inclusion in the sample because they are more likely to employ graduates of Quantity Surveying, Construction Management and Architecture. While a random sample including all the different MBA regional offices would be more appropriate for external validity and therefore generalisation (Bryman and Bell, 2003), a purposive stratified sampling technique was instead favoured because of the exploratory nature of the research and the convenience of dealing with the selected MBA offices. Greenfield (2002) suggests that it is acceptable to use a non-probability sampling technique when access to elements in a population is prohibitive. However, it should be noted that the resulting sample may contain bias and therefore affect external validity and consequently reduce the power of generalisation (Bryman and Bell, 2003).

3.2 Survey Instrument and Data Collection

The questionnaire was designed to investigate the respondents' perception of the level of preparedness of the graduates from traditional South African universities and universities of technology whom the respondents had worked with. The questionnaire also sought to establish the extent to which the university education programme prepared graduates for specific educational attributes. In achieving these objectives, two scales were prepared. The first scale had 31 items with phrases about characteristics of graduates which were measured using a five point Likert scale with 1 = "Strongly Disagree", 2 = "Disagree", 3 = "Neutral", 4 = "Agree" and 5 = "Strongly Agree". The characteristics ranged from personal attributes to knowledge possessed by the graduates. The second scale was used to measure the extent to which university educational experience impart a range of attributes desirable in graduates using 22 attributes.

3.3 Implementation

The survey instrument was circulated to the target sample as an e-mail attachment by the MBA using their register of general contractors with a letter explaining the survey, its use and noting that participation was completely voluntary, results would be aggregated and therefore no individuals would be linked to any specific response and that respondents had the right to accept or refuse participation. While the use of questionnaires attached to e-mails is not yet common place, web-based survey instruments are becoming common place. Denscombe (2006) and Calbring et al. (2007) concluded that there is little evidence of a mode effect linked to web-based questionnaires compared to paper based ones. While a questionnaire attached to an e-mail is different from a web-based survey, they share a number of commonalities including the electronic nature of the interface as opposed to a paper interface and the use of the internet to communicate the responses among others. It can therefore be assumed that the two modes of survey dissemination should share similar advantages and disadvantages and can be concluded also that evidence suggests that the use of e-mail in surveys does not create any errors or biases that can be attributed to the mode of questionnaire administration.

4. Results and Discussion

The respondents were general contractors registered with the MBA KZN and MBA North who employ university graduates in construction. A total of 55 responses were received and analysed.

4.1 Graduate Preparedness

Table 1 indicates that the construction industry practitioners do not feel that construction graduates entering the South African construction industry are adequately prepared for the construction industry practice. The average score of 2.40 from the scale ranging from 1 through to 5 with 1 being strongly disagree, 2 being disagree, 3 being neutral, 4 being agree and 5 being strongly agree that the graduates are well prepared for construction practice indicates that the employers are not satisfied with the work readiness of the graduates upon entering the construction industry practice. This finding is consistent with other findings from South Africa such as from Smallwood and Emuze (2011) and also from the British Council (2014) and Shafie et al. (2014) and Aryakwa et al. (2011).

Table 1: Descriptive Statistics for "Graduates are well-prepared for immediate engagement with the world of work"

	N	Mean	Std. Deviation
Graduates are well-prepared for immediate engagement with the world of work	55	2.400	0.852

Rather than rely on a single item measure of the concept of industry perception of graduate preparedness, the 31 item scale was analysed. Firstly, the 31 items were tested for uni-dimensionality and to find the factors which consistently measure the same underlying construct. Cronbach's alpha was used and a resulting score of 0.908 was achieved after deleting some items so as to achieve the highest possible reliability index shown in Table 2. Cronbach's alpha measures the reliability of a data set which represents the degree to which the observed values measures the 'true' value and is thus error free (Hair et al., 1998). Weimer (1987) defines reliability simply as the probability that the estimate is correct. The computed Cronbach's alpha of 0.908, shown in Table 2 suggests that there is a 90.8% probability that the error of the estimate is at most 0.05.

Table 2: Reliability Statistics

Cronbach's Alpha	N of Items
0.908	18

The descriptive statistics of the 18 selected items measuring the construct of graduate preparedness are shown in Table 3. Based on the mean scores, respondents felt that graduates have a desire to learn as indicated by the mean score which tends towards the agree score of four. The desire to learn new things is contrary to the report by the British Council (2014 citing SAGRA Survey, 2013) on the employability of South African graduates who were reported to be reluctant to learn. However, the reported survey was aggregating results from different disciplines. The findings here therefore suggest that the construction graduates differ in their propensity towards learning new things as compared to the rest of the South African graduate population.

The rest of the items have mean scores tending towards three indicating that the respondents do not feel that graduates perform well in these areas. Other findings have indicated deficiencies in most of these areas. For example, Ayarkwa et al. (2011) found that graduates lack practical building knowledge in the Ghanaian construction industry consistent with the item indicating that graduates have inadequate knowledge of construction. Graduates lack the ability to define and solve problems consistent with the item indicating that graduates are unable to propose solutions to problems and substantiate and justify their position (Ibid).

Table 3: Graduate Preparedness Descriptive Statistics

	N	Mean	Std. Deviation
Graduates demonstrate a desire to learn new things	36	4.056	0.754
Graduates are able to work in a multi-cultural environment	20	3.650	0.813
Graduates are able to work in a team	55	3.455	0.835
Graduates are able to work methodically to finish an assigned task	12	3.417	0.996
Graduates conduct themselves ethically at all times	55	3.382	0.757
Graduates are able to learn on their own/autonomously	20	3.250	0.786
Graduates are knowledgeable about health and safety	12	3.167	0.835
Graduates are technically well-skilled	55	3.164	0.996
Graduates are assertive and willing to accept responsibility on projects	20	3.150	0.875
Graduates understand consequences of their actions	20	3.150	0.988

Graduates are able to communicate effectively in writing	55	3.127	1.139
Graduates are assertive	12	3.083	1.084
Graduates are able to communicate effectively orally	55	3.055	1.061
Graduates are respected by their seniors/those they report to	12	3.000	0.953
Graduates possess an adequate set of skills for professional practice at entry level	20	2.750	1.020
Graduates are able to propose solutions to problems and substantiate and justify their position	55	2.673	1.037
Graduates understand the financial aspects of construction	12	2.667	1.231
Graduates have adequate knowledge of construction	55	2.618	0.972

Table 4: Graduate Preparedness Descriptive Statistics

	N	Mean	Std. Deviation
Average	55	3.157	0.633
Valid N (listwise)	55		

While a total of nine items were not considered in computing the aggregate score of Graduate Preparedness, they were notwithstanding individually compared with the computed Graduated Preparedness score in order to identify any trends among the deleted items. The average scores of each of the deleted items are shown in Table 5. All the deleted items fall below the agree point except for the item “Graduates are able to use technology and software packages” to which the respondents agree that the graduates are well prepared to do. This finding is consistent with Ayarkwa et al. (2011) on construction graduates in Ghana and with the British Council (2014 citing SAGRA Survey, 2013) on South African graduates generally who found that the computer literacy of graduates was acceptable to employers.

Employers feel that graduates are not well prepared in the rest of the items shown in Table 5. Most of the deficiencies are consistent with several other findings.

Table 5: Descriptive Statistics

	N	Mean	Std. Deviation
Graduates are able to use technology and software packages	12	4.083	0.515
Graduates conduct themselves ethically at all times	55	3.381	0.757
Graduates are able to defend themselves in terms of a position they take which might be different	12	3.250	0.754
Graduates always conduct themselves professionally	55	3.182	0.905
Graduates respect authority	12	3.167	1.030
Graduates demonstrate sensitivity to needs of others they interact with at work	20	3.150	0.671
Graduates are able to read and understand documents	12	3.000	0.853
Graduates understand the legal and risk aspects of construction such as standard forms of contract	12	2.667	0.888

Graduates understand punctuality and are punctual themselves	12	2.583	0.669
Valid N (listwise)	12		

4.2 Graduate Attributes

Respondents were asked to state the extent to which they agree that the university experience offered to graduates imparts in them attributes desirable in a graduate. The resulting reliability index for the construct of graduate attributes is shown in Table 6. The attributes of the graduates exhibit a high level of internal consistency.

Table 6: Reliability Statistics

Cronbach's Alpha	N of Items
0.934	22

The descriptive statistics for the scale of graduate attributes are presented in Table 7. The mean scores range from 3.40 to 2.40 indicating a general disagreement that the graduates possess the desired attributes.

Table 7: Graduate Attributes Descriptive Statistics

	N	Mean	Std. Deviation
Employable	46	3.435	1.128
Knowledgeable	46	3.413	0.777
Responsible	45	3.356	1.004
Adaptable	46	3.304	0.963
Socially responsible	46	3.283	0.958
Lifelong learner	46	3.283	0.981
Planner	46	3.239	1.099
Pro-active	46	3.217	1.073
Independent thinker	46	3.217	1.073
Skilled professional	45	3.133	1.057
Culturally aware	45	3.133	0.991
Communicator	46	3.130	1.024
Problem solver	46	3.087	1.029
Critical thinker	46	3.087	1.112
Informed	46	3.087	1.112
Human skills	46	3.044	0.918
Forward thinker	46	3.000	1.174
Leader	45	2.911	0.949
Entrepreneur	46	2.848	0.942
Practical	46	2.848	1.010
Visionary	44	2.773	1.138
Negotiator	46	2.413	0.909
Valid N (listwise)	41		

A new variable measuring the graduate attributes was computed from the mean scores of all the individual items investigated. The resulting descriptive statistics for the aggregate variable are presented in Table 8 which also shows that the respondents are not altogether satisfied with the university graduates entering the construction market.

Table 8: Descriptive Statistics

	N	Mean	Std. Deviation
Graduate Attributes	47	3.117	0.692
Valid N (listwise)	47		

4.3 Associations among the Variables

In order to identify any relationships among the variables, the variables were tested for associations among them. Firstly, a normality test was performed to establish whether to use parametric or non-parametric tests of association. The Kolmogorov-Smirnov statistic is used to test for normality for a sample size exceeding 2000. The Shapiro-Wilk test (shown in Table 9), which tests the null hypothesis that the data are drawn from a normal distribution for a sample size not exceeding 2000, suggests that the "Graduates are Well-prepared for Immediate Engagement" data does not follow a normal distribution while the "Graduate Attributes" data and "Graduate Preparedness" data follow a normal distribution. Since one of the variables does not follow a normally distributed, non-parametric tests were preferred.

Table 9: Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Graduate Preparedness	0.114	47	0.157	0.955	47	0.066
Graduate Attributes	0.069	47	0.200*	0.983	47	0.738
Graduates are well-prepared for immediate engagement with the world of work	0.274	47	0.000	0.865	47	0.000

*. This is a lower bound of the true significance.

a. Lilliefors Significance Correction

The Kruskal Wallis test, a non-parametric test exploring differences in mean scores, was computed to establish whether the mean scores of the computed "Graduate Preparedness" variable differ significantly with the single variable item which inquired whether "Graduates are well prepared for the immediate engagement with the world of work". The resulting chi-square statistics ($c^2(2, N=55)=13.165$, $p=0.001$) and the Spearman's rho correlation statistics ($r=0.629$, $N=55$, $p=0.000$) suggest that the two variables are associated with a fairly strong positive correlation.

The Kruskal Wallis test statistics were also computed relating the computed variable of "Graduate Preparedness" with the computed variable of "Graduate Attributes" to establish whether the two variables are also associated. The resulting chi-square statistics ($C^2(3, N=47)=20.817$, $p=0.000$, and Spearman's rho correlation statistics ($r=0.764$, $N=47$, $p=0.000$) suggest that the perception of graduate preparedness is strongly associated with the perception of the attributes possessed by the graduates with a very strong correlation coefficient.

The three measures used to assess level of preparedness of construction graduates for construction practice all correlate strongly and significantly with each other at an alpha of 0.001. The significant and strong correlations, which confirm that the three measures are related, confirms that the three measures are all valid measures of the perception of the respondents about the level of preparedness of the graduates and also validate the internal consistency of the instrument. The internal consistency of the instrument is also validated by the high Cronbach's alpha of the three measure shown in Table 10.

Table 10: Reliability Statistics

Cronbach's Alpha	N of Items
0.802	3

5. Conclusions

Employers in the South African construction industry feel that construction graduates entering the construction practice are inadequately prepared by the university education experience they are offered consistent with other findings from the South African construction industry and also from other countries surveyed. All three variables used to assess the perception of employers of the level of preparedness for construction graduates entering the South African construction industry consistently demonstrate that employers feel that university graduates are not adequately prepared for practice.

Skills, knowledge and competences perceived to be lacking in the graduates include knowledge of construction, financial aspects of construction, problem solving, professional practice, oral communications skills, written communication skills, health and safety, self-directed learning, ethics, team work, punctuality, legal and risk aspects of construction, reading and understanding of documents and professional conduct among others. Attributes found to be deficient include negotiation, vision, practicality, entrepreneurial attributes, leadership skills, forward thinking, critical thinking, problem solving, and communication among others. On a positive note, graduates were rated fairly well in the desire to learn and IT skills.

While the scenario regarding the extent to which graduates of construction programmes from South African universities based on the findings of this research looks rather bleak, it is worth noting that the research is based on the perception of employers about the graduates. The results therefore also point to a very highly expectant set of employers who may not adequately appreciate that university programmes need to provide a firm theoretical grounding for the graduates to develop into a career of choice within the industry. Therefore, while it is important that graduates possess the relevant skills, knowledge, competences and attributes, the employers perception of the relevant extent to which graduates need to demonstrate these at entry level may be overrated. Also worth noting is that other research has established that there is in fact weak evidence suggesting that there are gaps between competences possessed by graduates and those required in the job market.

Abstract

This research paper investigates how maintenance performance measurement is utilised to measure Condition-Based Maintenance (CBM) in petroleum pipelines (PPs) in the Oil and Gas (O&G) industry. The paper is written using the findings of an extant literature review. The paper reviews various concepts of performance measurement (PM) and issues in relation to CBM in the O&G Industry. The paper discusses in-depth, the use of performance measurement in Condition-Based Maintenance in the Oil and Gas industry. The findings highlight the importance of performance measurement in CBM as a system that ameliorates pipelines maintenance and synergises O&G workforce to achieve a well-defined work procedures in CBM. This paper identifies performance measurement as a possible sub-system of strategic maintenance in petroleum pipelines (PPs). Performance measurement is in fact a return to the fundamental concept of CBM, and is a means of ensuring that the lifecycle of PPs is well managed and maintained. Based on the findings of this study, the paper develops a conceptual model for measurement of efficiency of actions in condition-based maintenance in pipelines. In order to improve workers performance, motivation, good information management, collaboration, and

Keywords: Condition-Based Maintenance (CBM); Performance Measurement (PM); Oil and Gas (O&G); Petroleum Pipelines (PPs), Strategy

1. Introduction

1.1 Condition-based maintenance in pipelines

The nature of maintenance work in the Oil and Gas (O&G) sector has change in recent decade from strictly preventive or corrective maintenance to condition-based maintenance as a result of huge increase in the number of petroleum pipelines (PPs) to be maintained. The term condition-based is used to discuss and interpret problem, situation and circumstances causing a particular or whole section of PP disorder, and assist management to decide the maintenance action to be performed. Facility maintenance in the O&G sector require improvement in the strategic and operational function. Because Oil and Gas (O&G) is considered as the backbone of the global economy, which involve a rigorous operation such as: exploration/extraction, refinement, transportation, and marketing of the petroleum products often by petroleum pipelines (PPs) (Duncan and Wang, 2014). There are several ways in which O&G can be transported, e.g. ocean moving vessels, tankers, rail transportation and pipelines. Yet, PPs remain the easiest, economical, resilient and robust way of transporting O&G in the petroleum industry (Ai-Khalill, 2005; Anifowose, 2012; Duncan and Wang, 2014; Shafiqur and Al-Hadhrami, 2014). PPs profitability cannot be overemphasised as it tends to be an indispensable component in the O&G industry (Ossai 2012; Bandinelli and Gamberi 2011). PPs can be defined as an integrated tube used to transport O&G liquid to demand point.

Despite the profitability or value in the use of PPs, PPs has not been without flaws. Equally, industries using pipe either as a storage facility or as a source of transporting O&G may face different challenges (Enyiche2 2011; Qian et al., 2011; Anifowose et al. 2012). Many of the challenges often occur as a result of improper maintenance, vandalism, corrosion or rupture and ageing. For example, ageing pipelines, i.e. those pipelines near the end of their useful remaining life or exceeding their original design life (Anifowose et al. 2012; Ossai, 2012). There is an increasing requirement around the world to defer their replacement or extend their remnant life (Clausard, 2006; Okamoto et al., 1999). Problem within this ageing PPs if unnoticed, can lead to catastrophic consequences at the time of deterioration (Bogue, 2013; Barabadi, 2014). Some example of major pipelines incidences in Nigeria alone include: such as, the 1998 Jesse pipeline explosion in Nigeria that almost claimed an entire village, burning to death over 250 people; the Ijegun 2008 PPs explosion in Nigeria damage more than 15 homes and 20 vehicles as construction workers incidentally broke the underground PPs; and, the 11th July 2015 PPs explosion in Bayelsa State Nigeria killing 12 workers, the 27th March 2016 O&G pipelines explosion killing operators (Aroh et al., 2010, The Guardian, 2015, Punchng.com, 2016). Consider: “it is such examples as the above that necessitate an improvement in the level of PPs”

1.2 Maintenance concepts and Strategies

Certainly, improved maintenance concepts and strategies could guarantee O&G pipelines robustness and reliability. Literature indicates that, improved maintenance has the capability to influence resources or maintenance operation in several monitoring levels (Alabdulkarim et al. 2014; Prajapati et al., 2012). On the other hand, inadequate maintenance plan may trigger system deterioration and cause disaster (Aboelmaged, 2015). In contrast, Dey et al. (2004) argue that most pipeline workers ensure that during the installation PPs, safety provisions are created to provide a theoretical minimum failure rate for the life of the pipeline. Kadafa (2012) argues that, despite the safety provision in place, several failures have been inevitable in PPs operation. Hence, strategic maintenance is important in the improvement of PPs maintenance. It can reasonably be argues, therefore that issues of strategic maintenance cannot be overlooked in the process of pipelines maintenance. Also, the role planning and adequate implementation play in the achievement of pipelines maintenance projects or the methods by which they are obtained is well documented in the "literature review". See (Oliver Schwarz 2005; Paranjape et al. 2006; Greenough and Grubic 2010; Prajapati et al. 2012; Platfoot 2014; Goyal and Pabla 2015). Beside the practice of CBM, there is a need to understand other maintenance function and what constitute pipelines maintenance and how to perform the assigned task successfully and this is discussed in the next section

2. Maintenance Types and Practice

The oil and gas (O&G) industry often practice several pipelines maintenance types in order to prevent pipelines from failure (Achebe et al., 2012; Agbakwuru, 2011; Gomes et al., 2013). Most of the maintenance practice include: preventive maintenance, corrective maintenance, turn around maintenance, reliability centre-maintenance, total productive maintenance, risk-based maintenance, shut-down maintenance, opportunistic maintenance, computerised maintenance management system, total quality maintenance and condition-based maintenance (Bousdekis et al. 2015; Fraser et al. 2015). However, preventive and corrective maintenance describes a wide range of activities designed and performed in order to improve the overall reliability and availability of a system (Moghaddam and Usher, 2010). Regardless of the specific pipelines system, preventive and corrective maintenance activities can be categorised in one of two ways, which is either repair or replacement (Öhman et al., 2015; Platfoot, 2014; Van Horenbeek and Pintelon, 2014). Preventive maintenance has been derived from a level of repair analysis to determine the maintenance allocation for a given system or subsystem (Prajapati et al., 2012). Corrective maintenance if often referred to as run to failure practice or maintenance task performed after failure has occurred or in the process of occurring. Corrective maintenance constitutes repair, refurbishment or replacement of sectional breakdown, or other remedial work to restore pipelines system to its original state as it was in new condition (Prajapati et al., 2012; Reza Golmakani and Fattahipour, 2011).

Equally, opportunistic maintenance, RCM, risk-based maintenance and other maintenance types are often seen as extra maintenance activities performed to enhance the overall performance O&G facility. Their activities consist of inspection, cleaning, lubrication, adjustment, alignment, and replacement of O&G pipelines facility that is wear-out or faulty. However, aforementioned maintenance types are usually done to elongate PPs lifespan or retain their serviceability (Al-Khalil et al. 2005; Liu et al. 2010; Sahraoui et al. 2013; Duncan & Wang 2014). Despite the numerous maintenance types, corrosion, sabotage, improper maintenance still persists. The prevailing issues in the Nigerian context are corrosion attack, improper maintenance and sabotage. Corrosion fatigue consists of cracking of material due to changing cycle, stress or as a result of corrosive environment. Improper maintenance issues may occur as a result of poor management, sociotechnical inordinate behaviour, social factors, and lack of motivation, poor communication within upstream and downstream section, lack of technical knowhow and the use of low quality materials. Sabotage involves third party meddling and obliteration of pipelines reliability (Bagkavos, 2008). However, this study assumed that sabotage and obliteration caused by third party may prompt corrosion outbreak and other unwanted issues in pipelines maintenance. These issues often interrupt the firm approach in the practice of preventive or corrective PPs maintenance activities in the Nigeria O&G sector.

Prajapati et al., (2012) argue that, adopting strictly preventative or corrective maintenance approach leads to inefficiencies in the use of manpower, subsequently causing downtime of PPs systems, economic loss and other wastefulness. At the heart of any pipeline integrity management system (PIMS) is having an understanding of the likely condition of a pipeline and confidence in the data generated from any inspection programme conducted to validate this understanding (Clausard, 2006; Fink et al., 2004; Okamoto et al., 1999). Based on the data generated on PPs inspection programmes, an Operator can go forward and make decisions related to the current and future integrity of a pipeline, remaining life assessment with the help of condition-based maintenance philosophical viewpoint to appropriate corrective and preventive maintenance action (CAPA) and to monitor activities that will improve pipelines performance.

CMB can be defined as an instrument that managers use to underpin efficiency and effectiveness of action in pipelines maintenance by helping managers to deal with issues related to functional safety, environmental and operational failure modes. CBM helps managers to plan and formulate a workable strategy through historical and current data (Al-Najjar, 2012; Fraser, 2014; Prajapati et al., 2012). In this instance, CBM seeks to discover the root cause of the failure and performs the detailed analysis of the reliability of the system components and the system as a whole (Al-Najjar, 2012; Bousdekis et al., 2015; Prajapati et al., 2012). Bousdekis et al. (2015) argue that, CBM can only detect emerging failures before their occurrence through diagnostic and prognostic techniques. CBM uses condition monitoring techniques to assess, control and investigate pipelines whether a problem exists and to determine the life cycle usefulness before failure occurs (Garg and Deshmukh, 2006; Prajapati et al., 2012).

Furthermore, Prajapati et al. (2012) state that, CBM enables the automotive, aerospace, military, and other industries to understand values of maintenance network bandwidth, data collection and retrieval, data analysis, and decision support capabilities for large data sets of time series data. In contrast, CBM forms the basis of all types of maintenance (Zhou et al., 2015). For instance, CBM function can be done either as in preventive/corrective maintenance, or condition monitoring. Consequently, the real uptake and implementation of CBM often improve the maintenance concept in the O&G industry. As a result, a comprehensive maintenance definition should embrace the CBM philosophical view. Taking this into consideration, maintenance is defined as a process of assessing assets condition and to know the current state and improve its condition using CBM elements to determine the necessary maintenance either about preventive, corrective, reliability centre maintenance or other maintenance actions needed to underpin or improve PPs condition monitoring in order to possess the assets.

Moreover, the effectiveness of CBM requires a comprehensive maintenance management system. Being that the enterprise-wide information management and business planning has become a norm rather than an exception (Garg and Deshmukh, 2006). Combined with a review of the pipelines maintenance management activities, e.g. review of internal and external issues in pipelines maintenance and management, CBM monitoring correlation with the inspection findings, will enable the integrity management strategy to proactively diagnose the likely causes of corrosion and discuss other related issues. On this basis, individual maintenance performance can be improved using lesson learned in order to obviate unwanted event that may decline PPs performance. Based on the determined corrosion or sabotage rates, accurate monitoring and prediction of future repair together with mitigation requirement can be determined via CBM historical data.

The search for materials and identification of issues using extant literature involved a rigorous process of selecting materials from databases such as: Emerald Insight, Google scholars, Science direct and Scopus. Performing combination of key words like performance measurement approach in pipelines integrity management, performance measures in condition-based maintenance in pipelines, maintenance performance measurement in the O&G industry result to many qualitative and quantitative materials. Applying the grounded theory approach, the materials gathered were narrowed down and focus on qualitative materials pertinent to this study. The Glaser and Strauss 1960s approach enable this study to perform constant comparison of different pipelines issues and incidences, to assess individual perceptions about pipelines maintenance, the role performance measurement plays in the maintenance of PPs. Also, the grounded theory approaches enable a clear identification of the key issue affecting CBM in pipelines. The process of identifying the discrepancies, contradictions, gaps in the CBM in pipelines activities and to formulate the emerging consensus that will improve the maintenance process also involve another rigorous process.

The practical relevance about grounded theory is that researchers do not know the outcome, until it emerges by investigating issues. However, the procedures of assessing worst-case hypothetical conditions and for the analysis of the consequence of any given pipelines failure are beyond the scope of this paper. Besides, pipelines failure and maintenance hypothetical characteristics and consequences vary with each pipelines sizes, also the environment vary were pipelines operation are done on daily basis (Anifowose et al., 2012; Okoh and Haugen, 2014; Shukla and Karki, 2016; Sylvestor et al., 2004). Pipelines failure and related issues tends to be a global problem. Though, several rules and regulation are in place to ensure adequate performance of CBM in pipelines. But, in the current time, the full benefits of CBM in pipelines maintenance can be realised through performance measurement plan do check act (PDCA) model, a techniques that enable managers to assess the effectiveness and efficiency of action in facility maintenance engineering/management. Undoubtedly, performance measurement approaches has enable some industries to outperform their equals in business. The next section will be discussing the intrinsic values about performance measurement

3. Performance measurements

There is a need for manager to analyse CBM activities in PPs and how to utilise the full benefits of CBM in PPs maintenance. Equally, literature review justified the need to perform measurement with an adages “you can’t manage what you can’t measure and what get measured gets done” these elements underpin PPs maintenance managers to safeguard working environment. The change in the operating context cause maintenance managers to concentrate on effectiveness of actions within PPs routes. Performance indicators are needed to give maintenance managers in charge of operation a qualitative information on the extent to which these goals are reached and the next actions to take to improve CBM operations. Performance indicators are a means to achieve maintenance control, so that maintenance costs can be reduced, productivity can increase, safety of the process can be achieved and environmental regulations can be fulfilled (Arts et al., 1998). For instance, in the UK, Liyanage and Egbu, (2008); Njuangang et al., (2015) develop some key performance measurement improvement concept to underpin the improvement of hospital facility maintenance management. Similarly, Parida et al., (2015) exemplify the importance of performance measurement across industries, whit emphasis on performance indicators, leading and lagging indicators, and the identification of “performance drivers and killers”, in maintenance operation. Moreover, performance measurement often involves a comprehensive approach linking strategy to action, motivating employees, supporting budget and controlling resources in order to overcome the strictly approach to the traditional practice of the engineering maintenance management in the industries. In this aspect, performance measurement allows benchmarking process to be performed in order to eliminate the out-dated management style, which does not support the current technological improvement in pipelines maintenance (Al-Najjar and Kans, 2006; Kutucuoglu et al., 2001; Lee et al., 2013; Simões et al., 2011). Another area to be addressed through performance measurement is the sociotechnical inordinate behaviour, a factor that often limit the effectiveness of action in pipelines maintenance. In fact, social issue can significantly influence maintenance performance. For example, pipelines conflicts between department and poor collaboration might prevent operators from passing on important information.

Inadequate information often result to neglect or abandonment of PPs maintenance in long-distance location. Most time, it lead to corrosion attack, leakages and environmental depredation. Also, causing counter accusation, political oversight and communities meddling due to environmental depredation. Though, literature indicates that issues like this can only be overcome through performance measurement. Hajjari, (2012) explain that, at the organisational context, maintenance contains several aspects that can affect the maintenance activities and cause undesirable adverse effect in maintenance processes. Therefore, performance measurement is required to refine the maintenance culture and to lead in the process of planning and monitoring maintenance. Performance measurement approach can be used to determine assigned job and monitor the efficiency and effectiveness, improve communication system, improve decision-making process and assess workers behaviour. Even in the decommissioning process when a particular route or section is no longer viable or required performance measurement can support CBM activities to achieve success in the operation.

Performance measurement practice can be plausible when management utilised the key performance indicators to assign task and monitor individual performance. Individual performance can also be monitored through a defined work order model as shown in table 1. The essence of work order is to guide operators about the maintenance activities/action and together with the role individual must perform in order to achieve target.

Table 1: CBM detailed work-order guide (source: (Platfoot, 2014)

PM function	Condition based maintenance pipeline work-order Mandatory	Documentation guide
Elements in work order	Date work requested, KPI to prioritise work; status of work, open, approved, work in progress, completed or cancelled, area to be worked on/location of work, specification of work to be done	Date work closed; date work scheduled commence, actually date work commenced, amount of resource/crew, summary of maintenance job plan
Work description or specifying the type of work	Work order type; priority of work order (e.g. emergency, periodic inspection, constant monitoring etc.).	Maintenance activity type; priority of original request Total
Cost of work	Actual amount/Prorated	Total cost (estimated and actual), labour hours (estimated and actual), materials and other miscellaneous costs/ coherent cost code
Performance evaluation	Monitor performance	Recommend

Applying the performance indicators or maintenance performance indicators according to (Parida et al., 2015), the work order can be fully defined and utilised. The issues of vagueness and inadequacy about measures can be obviated through this method.
Given a clear focus in the measurement of efficiency and effectiveness of pipelines maintenance within the upstream and downstream pipelines distribution network. In this aspect, performance measurement indicators enable managers to compare the actual operating conditions with a specific set of reference conditions and to ensure managers achieve target in the following ways:

- Establish solid technical justification for using the set objective and articulate the reason for not using other objective for assessment techniques to assess the pipeline section (Nidd et al., 2007).
- Establish active data management system to ensure security of data that will allows integration and manipulation for further improvement (DeWolf, 2003)
- Ensure that all data provided are sufficient for long-term planning and helping to achieve acceptable statistical conclusions (Nidd et al., 2007)
- Monitor the technical function to ensure that the collected data and results are accurate within acceptable industry tolerances.

- Ensures that all personnel involve are fit-to-work, trained and qualified and all certifications are documented, perhaps organise periodic medical check-up for workers.
- Ensures that CBM activities are achieved in a timely manner.

Literature indicates that, performance measurement and CBM support decision-making. Amalgamating the two elements will holistically address facility maintenance issues without discrepancy and helping to incorporate and regulate the relevant maintenance elements into the organisational management cycle. In the aspect, Armstrong (2006) exemplifies five basic performance measurement elements, which includes: agreement (i.e. incorporating operators to synergy in order to achieve organisational goals), measurement of efficiency and effectiveness, quality data collection and feedback, positive reinforcement and dialogue performance output. In this aspect, performance measurement can be fully utilised in CBM in pipelines as shown in figure 2.

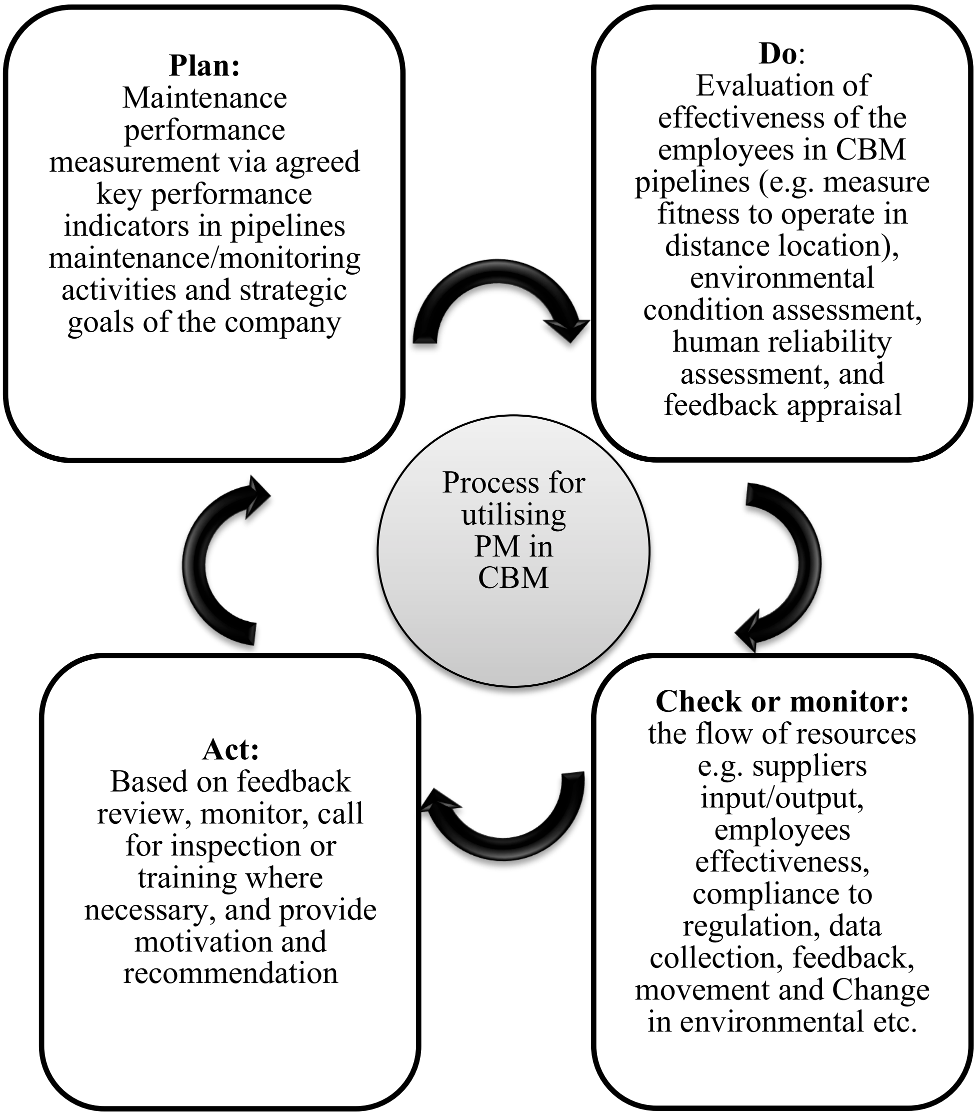

Figure 1: Condition-Based Maintenance Plan-Do-Check-Act model

In addition to the work-order as discussed in Table 1 above, measurement of performance can be realised through the PDCA model. The PDCA facilitate the work-order procedure, by help operators to understand their role in the pipelines integrity management programme before the performance of that role can be fairly assessed (Huprich, 2008; Kutucuoglu et al., 2001b; Parida and Chattopadhyay, 2007; Simões et al., 2011). Though, individual or maintenance team goals should to be defined before the commencement of work, to enable the field supervisor aligns the operators' objectives with the organisational goals (Huprich, 2008).

In pipelines maintenance, operators' role cannot be overemphasised, because they provide continuous assessment and feedback for the improvement of goals and to determine individual performance in PPs maintenance. In this form, PDCA can positivity influence measure, to determine safety compliance and ensuring adequate maintenance within the upstream and downstream sector is achieved. The PDCA justify the link between CBM and performance measurement as a single entity, their separation may result to catastrophic effect in pipelines maintenance. The union are power for decision-making in pipelines maintenance. Also in terms of monitoring, repair, replacement and improvement and decommissioning of pipelines system. Based on the different categories of issues discussed, the study can conclude that the identified issues can be used in extracting new performance indicators for condition-based maintenance in pipelines (i.e. extra indicators has been added to extant performance measurement indicators that is currently in operation for driving the performance of pipelines maintenance plan). Further research may consider defining contextual issues using real case scenarios for deriving performance measurement in pipelines maintenance project.

4. Conclusion

This paper exemplifies the importance of performance measurement and how to utilised performance measurement in condition-based maintenance in pipelines in various way. For instance, the application of plan-do-check-act (PDCA) and work-Oder in complex pipelines maintenance job and to monitor issues opposing pipelines performance. Another reason for this research is to establish plausible performance measurement method that will underpinning pipelines integrity management and justify values created by means of utilising performance measurement indicators for the improvement of facility maintenance and environmental protection at workplace.

The study also demonstrates the influence of using grounded theory to critically examine issues that requires improvement. It is clear that the combination of CBM and performance measurement is beneficiary and valuable, it rewards pipelines deficiency positively they merge corrective, preventive, and condition monitoring types of maintenance to address pipelines issues in a logical manner. As the research develops, the details of the model will be expended, and further study will be exploring issues relating to maintenance model being implemented that is designed for use within pipelines maintenance management involving life project scenario.

Research Roadmap for Safety and Health on Construction Sites

Michael Behm
East Carolina University
(email: behmm@ecu.edu)

Ciaran McAleenan
Ulster University
(email: c.mcaleenan@ulster.ac.uk)

Abstract

The proceedings paper details the initial roadmap process, data collected, and summarizes steps forward for the Working Commission on Safety and Health in Construction (W099) to produce a complete research roadmap. A preliminary consultation report was developed in 2013. Data collection included an initial web-based survey sent to W099 members and registered W099 2015 conference attendees. The survey was completed in August before the September conference. At the conference special plenary sessions were organised to define and shape the research roadmap and goals. Seven brainstorming sessions were held around themes important to the CIB W099 and building off the survey results. The sessions were audio recorded, transcribed, and summarised. Future directions for finalisation of the roadmap are discussed with the goal of validating the roadmap during a workshop at the 2016 Word Building Congress.

Keywords: Roadmap, research, safety, health, construction.

1. Introduction

Occupational health and safety (OHS) is the science of the anticipation, recognition, evaluation and control of hazards arising in or from the workplace that could impair the health and well-being of workers. (Finneran and Gibb, 2013). Occupational health and safety is both an interdisciplinary and a multidisciplinary science clearly connected to and built on many other disciplines (Aven, 2014). Aven further contends safety science is also a discipline in itself. A 2014 Special Issue of the journal *Safety Science* sought to define, better understand, and operatinalise safety science. Various leading safety researchers provided input. Hollnagel (2014, pg. 24) for example, writes that "the object of safety science is accordingly how people are able to provide the required performance under expected and unexpected conditions alike." Hale (2014, pg. 67), discussing research in safety science comments that "Practitioners and their financial masters are too willing to follow safety intervention fashions and to accept anecdotal evidence that something will work, rather than asking for that more rigorous levels of proof to raise the probability that their investment is worthwhile."

Globally, construction is one of the most hazardous industry sectors with many thousands of workers being killed and seriously injured each year. While some regions have been making progress over the years there is still a long way to go to reach the vision of an industry where people return home at the end of a shift healthier than when they arrived (Finneran and Gibb, 2013).

There exists a great need to frame a research and practice oriented path forward in construction safety and health. CIB W099, the Working Commission on Safety and Health in Construction, is taking up this challenge alongside many CIB Working Commissions with the goal of positively affecting the global construction community. This proceeding paper is not a research roadmap. Rather, this is the summary of the initial discussions about the development of the CIB W099 research roadmap. Therefore, the paper does not contain a critical analysis of all the data.

2. Background

The goal of CIB W099 is to complete a research roadmap to better engage with and impact the global construction industry. The Roadmap has four specific aims:

1. To identify research which is important in construction safety and health.

2. To identify research gaps in the field of construction safety and health.

3. To suggest research priorities in the field of construction safety and health.

4. To identify ways that CIB W099 can contribute to these research priorities in the next 10 years.

3. Methodology

The W099 research roadmap is currently in process and is building off a preliminary consultation report (Finneran and Gibb, 2013). This proceeding paper reports on the data collected through December 2015 and specifically two sources of data. The first was an on-line survey taken in August before the most recent W099 conference and meeting in Belfast. The survey was sent to W099 members and registrants of the September Belfast W099 conference. They were asked to forward the survey on to colleagues and encouraged specifically to send to colleagues in industry and governmental agencies. The second data source wee the brainstorming sessions held at the Belfast W099 conference which followed up on the on-line survey summaries.

On-line Survey

In the survey we asked almost primarily opened ended questions to allow respondents to write freely and express their ideas around the questions. The questions were generally around three main themes. In addition we asked demographic information and also listed construction safety and health publications to determine their importance, via a Likert scale, to respondents' research.

Firstly, we assessed research and practice priorities in the respondent's country by asking the following two open-ended questions.

> What are the top three construction health and safety practice issues in your country?
>
> What are the top three construction health and safety research priorities in your country?

Secondly, we followed up on the three main findings from the Finneran and Gibb (2013) consultation report. We restated those three main findings and asked the respondent to list up to three additional topics deserving of research in each area. The language is below.

The 2013 CIB W099 Consultation Report surveyed industrialists and researchers from leading regions and identified three areas that were seen as key to moving from the current situation to the ideal OSH state.

The first was: "More responsible client behaviour – to adopt procurement approaches that support the integration of health and safety into project decision making and drive this so that it happens.

The second was “Health and safety becomes a professional responsibility of everyone in the industry. At the moment it is perceived to be the health and safety professional’s job. Health and safety professionals are generally not architects, engineers etc. They don’t make decisions. They act as advisors. The decision makers need to step up and take professional responsibility.”

The third was "Closer and more effective links between industry and academia. There is a need for a more evidence-based approach to construction health and safety. Companies need to know with certainty what works and what doesn’t. Managers are easily persuaded when there is evidence but skeptical when there is none."

We asked three questions, one for each main finding. For example, for main finding #3 we asked the question in this manner: What topics do you feel are the most deserving of priority research in the area of “Closer and more effective links between industry and academia”? Please list up to 3 topics.

For each question in this section we reiterated the definition of research priority. “Priority research” is defined as an area of research that requires priority funding and scientific interest in order to advance the construction safety and health in the coming years. When listing your topics, please be as specific and explicit as possible.

Thirdly, we asked open ended questions assessing what the future of CIB might look like. Those questions were as follows.

> What other Construction Safety and Health topics are important and should be included in future analysis and discussions in preparation of a Research Roadmap? Include as many as you like. Include Health and Safety topics (ergonomics, etc.), type of construction where there might be a need (housing, etc), or general construction industry issues (small and micro organizations, etc).
>
> What should CIB W099 be doing to better support your research and practice in construction safety and health?

Brainstorming Sessions at W099 Belfast Conference

The results of the survey were presented at the W099 conference in Belfast in September 2015 and discussed with the attendees. Attendees were broken into 6 brainstorming group with leaders assigned. Groups were assigned one of the following questions.

1. How well does education, training, and professional development prepare design professionals in the provision of inherently safe(r) designs?
2. How can the research into safety and health deliver improvements in workers conditions and their quality of life?
3. What progress towards achieving vision zero is likely to be brought about from current OHS research across all jurisdictions?

4. What are the opportunities for creativity and innovation in the delivery of safe design?
5. How can gender equality, cultural diversity and inclusivity be promoted in the design of safe(r) workplaces?
6. Are the ethical and moral challenges understood around the globe and addressed appropriately in OSH research projects?

In addition all Groups discuss these two questions:

1. Future scenario: The roadmap will unfold a vision on where we want to be in the future, e.g. in ten years' time including the stakeholders' opinions on required/envisaged future systems, processes and technologies, preferred future practices and skills etc.
2. Development strategy: What is needed in terms of knowledge, information, tools, concepts and applications to enable the respective systems, processes and technologies to develop from where we are today to where we want to be in the future?

Groups were allotted 50 minutes to discuss these questions. All discussions were audio recorded and transcribed into MS Word for analysis. Each group leader gave a report on the closing day of the conference.

4. Results and Discussion

On-line Survey

An overwhelming majority of the 48 survey respondents (39) came from academia. See Table 1. We were hoping to receive more responses from industry and government agencies. This limits the results of the survey. However, as will be noted later, stronger ties with industry and governmental agencies are important goals for W099. Table 2 shows there was a decent spread of respondents from across continents; the majority were from Europe. Noticeably absent for the survey were South American respondents. W099 has historically not had good attendance at its conferences and meetings from South America. Finneran and Gibb (2013) analysed authorship from past CIB W099 conferences and noted South America was very much underrepresented at the conferences. However, where the conference was held in Brazil in 2003 the majority of papers were from that region. One action being discussed within W099 leadership is targeting South America for a regional construction safety and health workshop or conference by 2020.

Table 1: Survey Respondents – Employment

	N	***%***
Academic	*39*	*81.2*
Industry	*5*	*10.4*
Government	*2*	*4.2*
NGO	*2*	*4.2*
Total	*48*	*100*

Table 2: Survey Respondents – Continent

	N	***%***
Europe	*21*	*43.8*
Africa	*10*	*20.8*
Australia	*5*	*10.4*
Asia	*5*	*10.4*
North America	*5*	*10.4*
Missing	*2*	*4.2*
Total	*48*	*100*

In the initial part of the survey we asked about respondent's top three research and practices in their country. Tables 3 and 4 summarize the top findings. Safe design emerged as one of the top priorities in both questions indicating the need to better understand this concept which many believe has promise to positively affect construction worker safety and health. Work at height was the top priority for practice whereas reducing falls was important for research but not listed very high. This might indicate a gap in research to practice for reducing falls from working at height. Health related issues and small and medium organizations showed up in both lists indicating possible areas to explore.

Table 3: What are the top three construction health and safety practice issues in your country?

Practice Issues	***Number of times mentioned***
Work at height	*11*
Safe Design	*9*
Client awareness / role	*7*
Health related hazards	*6*
Small and micro organizations	*6*
Safety culture	*5*
Motor Vehicle accidents	*4*
Language / literacy / foreign workforce	*4*

Table 4: What are the top three construction health and safety research priorities in your country?

Research Issues	***Number of times mentioned***
Safe Design	*11*
Cost benefit Analysis / business case for safety	*6*
Skills, competency, and training of workforce	*5*
Leadership / culture	*5*
Occupational health	*4*
More effective regulation	*4*
Better statistics, more rigorous research	*4*
Small and micro organizations	*3*
BIM potential	*3*
Supply chain	*3*
Reducing falls	*3*
Musculoskeletal disorders / human factors	*3*

In the second part of the survey we followed up on the three main findings from the Finneran and Gibb consultation report. The first question had to do with "more responsible client behaviour". Many comments had to do with demonstrating that safety and health does not cost more or demonstrating the cost-benefit. Some extended the thinking from green buildings which initially had the cost barrier but now eventually is viewed as cost effective. Some key comments include:

- Prove that S&H does not increase construction costs / Produce safer but also faster and with less initial costs - prefabrication?
- Money! The analogy with regards to green building can be extended further. Green buildings generally speaking cost a lot more than the alternative, if the client wants it then they pay for it as it has some intrinsic benefit to them.
- Focus on OSH prominently within the general subject of CSR. Putting it within CSR gives it a larger dimension and makes more of an impact.
- OHS is not a priority - it is pushed downstream - how to make it a priority upstream and educate developers they can be an influence.
- Learning from exemplar clients re their influence on construction H&S

The second point from the consultation report asked respondents to consider how "Health and safety becomes a professional responsibility of everyone in the industry. At the moment it is perceived to be the health and safety professional's job. Health and safety professionals are generally not architects, engineers etc. They don't make decisions. They act as advisors. The decision makers need to step up and take professional responsibility." Some interesting responses questioned education and the role of the traditional OHS professional and a few are provided below.

- Broad-based multi-disciplinary H&S Undergraduate Education that ensures that all graduates understand that H&S is their responsibility.

- Research into the efficacy of health and safety professionals. Some national bodies run into tens of thousands of members. Does this contribute to a positive outcome or does it negate the ability all professionals (and employees) to exercise their responsibilities for safety and health?
- Supervisor education and OHS integration needs to be improved.
- This is a self-perpetuating myth. We all know that it is everybody's responsibility, but H&S specific professionals earn their money by trusting that very few others actually care and think they can immediately transfer risk and responsibility to the person with the title for responsibility.
- What is the paradigm of the "safety professionals" and how they are in conflict with the other professions?
- In the UK, the bold move made by the Regulators was to embed the old CDMC role in the new Principal Designer role. This should move the responsibility from the 'consultants' to the lead designer, PM or D&B Contractor. A before and after survey of this change (intervention) would be interesting.
- I agree with the statement in quotes above. I have reservations about the proliferation of OSH specialists because surely it should simply be embedded in the everyday work of managers and supervisors? More research on how OSH is actually seen by managers and supervisors would be helpful.

The third and final main point from the consultation report asked respondents to consider ideas for closer and more effective links between industry and academia. Many of the responses indicated the difficult nature of this problem. Some of the more interesting responses are highlighted below.

- There is a need for a more evidence-based approach to construction health and safety. Companies need to know with certainty what works and what doesn’t. Managers are easily persuaded when there is evidence but skeptical when there is none.
- Meaningful links between academic and industry are difficult to achieve, even when both parties are keen. As a construction site manager who became an academic, I have always striven to work with the industry, but this has been challenging because academia is driven by different career determinant from industry. Perhaps we need some good research to tell us what works and what doesn't when trying to make links?
- Evidence of safety is really problematic – because it's a non-event! So perhaps a way of exploring/researching/framing this that is readily understood by practice that doesn't need stats or other traditional measures of 'impact'?
- I cannot say what deserves of priority research but how research is conducted by the universities seems all too often to be in respect of the needs of students to get a masters of PhD with little reference to the needs of the industry generally. This results in similar or even repeat research projects being carried out year after year. Maybe a priority research project is into research projects themselves to ascertain their relevance, innovativeness, dissemination and standard of research.

Respondents were asked about the importance to the following publications to their research. It was good to see the W099 conference proceedings ranked second. Table 5 summarizes those results.

Table 5: Importance of publications

Publication	***Ranked Importance***
Safety Science	*4.73*
CIB W099 conference proceedings	*4.63*
Construction Management & Economics	*4.55*
Journal of Construction Engineering and Management	*4.55*
Engineering, Construction and Architectural Management	*4.18*

The final two questions of the survey were open ended asking respondents what else could be done by CIB W099. The first of those questions asked "What other Construction Safety and Health topics are important and should be included in future?" There was a variety of answers including looking at organizational issues, psychological issues, nanomaterials, residential construction, and new concepts such as Safety-II. One of the most interesting responses sums it up with "Ask industry what it wants, ask the workers on site what they want, ask those who work, live and play within or on or under the things that we construct. I mean really ask, with a passion simply to eradicate work place and home death and serious health issues caused by preventable circumstances."

The final question asked respondents to assess W099 and give advice, "What should CIB W099 be doing to better support your research and practice in construction safety?" The most popular advice centred on W099 being a venue to ensure collaboration among researchers from different countries, and engage in meaningful collaboration between conferences. Specific quotes included:

- The standard of research is inconsistent, judging from papers submitted to W099 conferences. Some are of a high standard and others are, in my opinion, barely meet degree level standards much less PhD standards.
- CIB W099 like many academic commissions/groups needs to live outside of its own membership and make a real and meaningful impact beyond the publication of its proceedings.
- More interaction between conferences.
- Try to enhance more collaboration between researchers from different countries - measure the amount of co-authored papers by researchers.
- Increase the number of developing countries' researchers at conferences. It's the same group of countries attending.
- Have a review of the proceedings of CIB W099 over the last five years and as a panel of people both academic and industrial to mark each paper for its relevancy and impact on

real life. How likely is it that lives have been directly saved or improved by the outcomes of the research?
- Organize more regional conferences.

Others were complimentary:

- I think W099 works really well! A communicative, welcoming, open and sharing group of researchers who are most willing to help and support each other. The annual conference is very good for ensuring a vibrant network, so nothing much to add here.
- Continue as you are. The aims and programme are excellent.

Brainstorming Sessions at W099 Belfast Conference

In essence it was hoped that this was a turning point conference. Each attendee has thoughts about the future of construction OHS, and now W099 must put these thoughts into action. The pre-conference debate featured four academics against four local construction industrialists examining the value and relevance of research. A Day 1 plenary session entitled "Bashing the heads of Bunny Rabbits" explained the story of the eradication of smallpox and served as an inspirational example of achieving what seemed to be an insurmountable task. Both sessions fed into the brainstorming sessions.

In this section the brainstorming sections are summarized and pertinent quotes provided. In a sense the questions provided each small working group were primer questions to get the conversations going. In the end, most sessions focused on the last 2 questions about the future scenario and development strategy. The summary of the brainstorming sessions in therefore focused on those two questions. For the sake of brevity, this section is concise.

1. Future scenario: The roadmap will unfold a vision on where we want to be in the future, e.g. in ten years' time including the stakeholders' opinions on required/envisaged future systems, processes and technologies, preferred future practices and skills etc. Comments around this theme include:
