Figure 1: Approaches to safeguarding sustainability requirements, external and internal.

Bröchner (1999) as well as Mokhlesian and Holmen (2012) among others make the point that competence is at the heart of a successfully implemented environmental system. Building on this notion, one might take it further and state that the given EMS that the client organization uses is merely a reflection of its competencies. The more competent the organization and the individuals who partake in it, the more pertinent the environmental systems ought to be for its intended purposes. Therefore, it would seem that the optimal solution would be one that incorporates the different systems that are available to the client. It is not a singular holistic approach, but rather a diversified strategy that employs different systems where they are appropriate. This line of thinking goes against what seems to be the prevalent paradigm for clients in the Swedish construction sector where sustainability is often regarded as a monolithic issue, as made evident by the common structure of having widely different areas such as energy efficiency, toxicity, safety, social sustainability and cultural sustainability in the same division.

The latter two are particularly difficult to grasp as they seem to involve a subjective dimension which is more difficult to comprehend.

> It is as you say, a lot more difficult [to manage social/cultural sustainability]. It seems to be about primarily perceived values that are much more difficult to grasp than if one has used this type chemical or not, that's more black and white. (*Development Manager of Energy and Environment for PubClient*)

> You have no metrics [on social/cultural sustainability] what so ever. It is a bit of trumpery, really! The energy issues are a lot easier […] it is easier to place a metric on it. (*Environment and Energy coordinator for the Municipality*)

A proposed response to this is to specify separate personnel that deal exclusively with those issues or the more preferred option of creating an environment in which these sustainability considerations become an accepted part of the project manager's role.

> I feel that everyone still needs a lot of support in regards to environmental and energy related issues and [they] regard it as a separate issue whereas I would argue that it is a natural part of any type of role. In the long term, I would say that we need far less support for capabilities in those areas. As project managers, most environmental issues should be obvious. (*Development Manager of Energy and Environment for PubClient*)

This shift in mentality would essentially reduce or do away with specialized organizational units that deal with these issues. Instead opting for a solution where the project managers are expected to possess the capabilities needed to safeguard sustainability requirements themselves. This can also be viewed in light of the past changes that has occurred in the construction industry in regards to environmental concerns. Initially, such questions were often met with resistance by actors in the industry who questioned the soundness of more sustainable ways of building.

> The trend is essentially the same in the construction industry or the real estate industry. Although the public sector had even prior to this had it easier in discussing these types of questions, I think that there is a huge difference today. For example, energy-efficient construction, when we started there were many who did not believe in it at all, [claiming] you would construct bad buildings. That debate is surely not as prevalent. […] Now, I'd say that there's a great upswing regarding all these environmental issues for everyone. No one thinks it's weird to talk about biodiversity anymore which if you were to mention it in 2008, it was almost a bit nonsensical. But certainly in public organizations, I do not think that there is a single public [organization] that we have contact with, a property owner, who is not working with these questions and considers them important. (*Development Manager of Energy and Environment for PubClient*)

There are two notes that relate to this quote, firstly that although public organizations may be working with these issues, it would seem that the private sector has a more organized way of working as evident by one interviewee saying:

> Large [contracting] companies have worked with sustainability questions in a more structured way. (*Sustainability strategist for a municipal company*)

Secondly, that the state of the sustainability issue went from being something that is questioned to something that is obvious and part of every task in the organization. What occurred beyond this, however, shows a rather peculiar shift. Once environmental concerns had become a natural part of the organization, it was no longer viewed as a differentiating attribute of that organization. Initially, PubClient's project managers were fully cognizant of the importance of keeping sustainability in mind in all matters as this was a core issue that permeated much of the organization.

> There are a lot of new project managers [of ours] who can barely understand that we build the most energy efficient buildings in Sweden! We have very clear instructions and requirements [internally] and so on which they adhere to, but they do not get an understanding for what it is and what it really means. (*Development Manager of Energy and Environment for PubClient*)

From this, there seems to be an indication that as the organization becomes more capable in working with sustainability related issues, the more fluent it is in formulating stipulations and requirements to adhere to sustainability requirements. However, once the organization has worked with these issues for a sustained amount of time, they become part of the everyday mode of operation as opposed to something novel. This shift may then result in the members of the organization working with these issues in a perfunctory fashion without much forethought in why the work is carried out in the way that is.

Another reoccurring theme in the interviews was the tendency to regard the sustainability issue as one that could be easily managed if there was more awareness of the issue. The interviewees mostly rejected the notion that there was a lack of capability in the organization for how to work with the sustainability. There seemed to be an insistence on downplaying the technical skills required to work with sustainability related issues. Instead, they would point to a lack of awareness as the primary issue that needed to be addressed.

> Yes, I think so (i.e. that the organization is capable to handle sustainability issues). However, I do think that if one wants to get more results then there is a need for more people to work with these matters […] I mean it's not a difficult science […] I believe that the capability exists, that's my experience at least. If you look at [client organizations] in the city, I think there is tremendous capability […] we have knowledge, I think everyone knows what it is about. I don't think we can get more knowledge, it is about finding more in the organization and really go through with it and receive enough resources and

money to be able to go through with it. (*Environment and Energy coordinator for the Municipality)*

Instead of viewing the challenge of sustainability as a capability issue, perhaps it should be viewed as a questions of resource allocation. In order to work with this issue in an efficient matter, more resources, basically, need to be allocated to it. Or, by embedding sustainability in everyday work it becomes a discreet capability, it becomes something that is simply a part of the everyday work's starting point.

5. Concluding thoughts

Sustainable construction is essentially an umbrella term that contains a wide range of different activities that aim to improve the production and the outcome of construction projects in a way that ensures that long term effects are considered. Not only with respect to the environment but also to society. Although issues such as waste management, noise reduction and preserving the biodiversity of a local ecosystem could all fall under sustainable construction, these issues have few things in common both in their technical details as well as their strict relevance to construction. This invites one to ask: does it make sense to feature social sustainability, cultural sustainably and environmental sustainability under the same department? Much of environmental sustainability can be measured in hard figures, particularly with respect to pollution, and could essentially fall under quality assurance, whereas social and cultural sustainability cannot be measured easily and are handled using more qualitative assessments.

This study would also suggest that although the capability required to manage sustainability issues does not necessarily need to be extensive, there is however a need for increasing the resources required for managing sustainability in a more efficient manner.

The construction industry's fragmented structure dictates that any change that occurs needs to do so in the entire supply chain of actors for it to have any fruitful effect on the industry as a whole. It would similarly seem that a multifaceted approach for managing sustainable construction would too require that the different actors be involved. Environmental issues are treated as constraints, a necessary evil that must be addressed instead of a factor of equal importance to that of financial concerns and project delivery. At the same time, it is important not to downplay the shift towards a more sustainability-driven thinking that has slowly but unrelentingly found its way into the practices of the construction industry. From energy efficient houses to methods of production that involve burning fewer amounts of fossil fuels. This is all commendable and few would argue the contrary. The point of interest lies in finding ways to continue the trend of incorporating and embedding sustainably to the operations of the organization. However, what this study shows is that when the client organization does so and working with sustainability issues becomes part of the established modus operandi, there is a risk that the members of the organization work with these issues in a perfunctory way without understanding what they are doing and why they are doing it. If this is a development that should be regarded as troubling or merely the expected culmination of incorporating sustainability in all affairs remains to be seen. What can be said however is that the increased incorporation of sustainability will significantly alter the way in which that organization operates and the way that it is structured.

Abstract

Vacant commercial facilities are an increasing concern in many developed countries. Despite the low occupancy rates in existing facilities, new commercial facilities that better accommodate the needs of modern end-users are constantly developed. In addition to financial concerns, under-utilized spaces are a great environmental burden, as buildings account for approximately one third of the global energy demand. One of the most effective ways to reduce the greenhouse gas emissions associated with buildings is to increase space-efficiency, namely, reduce the use of space. Repurposing existing facilities for a new use or a different end-user, does not suffer from the embodied energy and material use associated with new construction and major refurbishments. However, it can be argued that even a repurposing project may lead to significant waste of financial, natural and human resources if the project is unsuccessful, i.e., the facility remains under-utilized after the attempted adaptation. This study examines two Finnish repurposing projects with special focus on stakeholder management and engaging end-users. Both projects are investigated starting from the early design phase. The data comprises stakeholder interviews, and observation in a planning workshop. As the researchers actively participated in the workshop, the research is also partially action-based. This paper presents a model for identifying and engaging end-users to a repurposing project. The key finding is that, active participation in the design phase leads to a sense of ownership of the space, which in turn is thought to promote the efficient use of space and improve occupancy. End-user engagement and higher occupancy together would support all three dimensions of sustainability: social, environmental, and economic.

Keywords: repurposing, end-user engagement, project management, stakeholder management, sustainability

1. Introduction

Vacant commercial facilities are an increasing concern in many developed countries. For instance in the Helsinki Metropolitan Area the occupancy rates reached a record low level of 82% in 2014 (KTI 2015). Despite the low occupancy rates in existing facilities, new commercial facilities that better accommodate the needs of modern end-users are constantly developed. Moreover, new construction carries with it significant embodied greenhouse gas (GHG) emissions. Therefore, in addition to financial concerns, under-utilized spaces are a great environmental burden, as buildings account for approximately one third of the global energy demand. One of the most effective ways to reduce the GHG emissions associated with buildings is to increase space-efficiency. Numerous companies have adopted this measure in their sustainability program, in the form of reorganizing facility portfolios. The popularity of the measure is largely due to the relationship between cost-efficiency and space-efficiency, but the reduction in GHG emissions is also evident.

Repurposing existing facilities for a new use or a different end-user, is gaining support globally and is considered a more sustainable option than new construction (Bullen 2007; Bullen and Love 2009, 2010; Langston et al 2007). Repurposing does not suffer from the embodied energy and material use associated with new construction and major refurbishments. However, it can be argued that even a repurposing project may lead to significant waste of financial, natural and human resources if the project is unsuccessful, i.e., the facility remains under-utilized after the attempted adaptation. In line with the Toyota Production System (TPS) definition (Liker 2004), a failed project is considered 'waste' (Silvius and Schipper 2014). Therefore, and for the purpose of this study, a repurposing project is considered sustainable if it succeeds in engaging the intended end-users and, consequently, improving occupancy levels. Based on previous literature, a sustainable project requires proactive stakeholder management and engagement early on in the project (Aaltonen 2010, Bai et al. 2013). Consequently, this study looks at repurposing projects from the point of view of stakeholder engagement in the design process.

This study examines two Finnish repurposing projects, which both place special emphasis on end-user engagement in the project design phase. The primary data sources comprise stakeholder interviews, and observation. As the researchers actively participated in the workshop, the research is also partially action-based. A model for identifying and engaging end-users to a repurposing project is presented. The study finds that, active participation in formulating a joint vision and participating in the design phase leads to a sense of ownership of the space, which in turn promotes the efficient use of existing commercial buildings. However, based on the findings, end-user engagement in the early phases of the project is not enough, but engagement should continue throughout the project and during operations also.

The remainder of the paper is structured, as follows. The next section introduces the theoretical background for the research. The following Section 3 describes the study design, including a description of the cases, data collection and analysis. The findings of the empirical analysis are presented in the fourth section. The fifth section discusses the findings further, and the sixth and final section provides conclusions and suggestions for future research avenues.

2. Theoretical background

This paper utilizes two separate streams of research as a theoretical background for the study. First, literature on sustainable adaptive reuse of buildings is introduced. Second, the paper draws on previous work that has integrated sustainability into project management.

2.1 Sustainable adaptive reuse of buildings

Repurposing of facilities, where existing facilities are renovated for a new use or a different end-user, is gaining support globally and is considered a more sustainable option than new construction (Bullen 2007; Bullen and Love 2009, 2010; Langston et al 2007). Bullen (2007) identified several sustainable outcomes of an adaptive reuse process, including: reducing resource consumption, reducing energy use and emissions, extending the useful life of a building, cost-efficiency compared to demolition and rebuilding, reclaiming embodied energy, and revitalizing existing neighbourhoods, to name but a few (Bullen 2007).

Langton at al. (2007) discuss the obsolescence of a building and bring up six different types: physical, economic, functional technological, social, and legal obsolescence. The cases studied in this paper best suit the description of the functional obsolescence, where the buildings are no longer needed for their original purpose, and social obsolescence. Social obsolescence was particularly visible in the case of the new learning environment, where behavioural change had lead to changes in space requirements. When buildings become obsolete, Langston et al (2007) argue, they require either demolition or refurbishment. Bullen and Love (2009) develop a viability process model to aid the decision making process of building owners on whether to demolish or refurbish the buildings. The overall conclusion is that the decision should always be based on the individual characteristic of the building, and that no consensus exists whether adaptive reuse is always the most sustainable option (Bullen and Love 2009).

This paper utilizes the theoretical framework recognising the sustainability of reuse of existing facilities. Nonetheless, neither of the case projects represent the type of major renovations that are described in the previous sustainable adaptive reuse literature. The presumption is that, minor repurposing projects are always innately sustainable, as they require even less energy, materials and other resources than major refurbishments. It should be further noted that better occupancy rates and space-efficiency along with avoiding new construction make the repurposing of buildings sustainable regardless of whether sustainability per se is a stated goal of the project. In other words, the motivation behind a repurposing project need not be achieving sustainability, but underlying motivations are in fact, most often economic.

2.2 Sustainability in projects

Recently, issues related to sustainability have received only minor attention in project management literature. Much of the discourse is emphasizing the role of stakeholder management, linking proactive stakeholder management to sustainability. Unlike sustainability, stakeholder management has received increased attention in project management literature in recent years. Special attention has been placed on the significance of proactive stakeholder management early on in the project, and stakeholder identification (see e.g. Aaltonen 2010). This approach is also found to promote project sustainability (Bai et al. 2013).

Both stakeholder management and sustainability management are crucial in large built environment projects, which inherently carry great environmental, social and economic impacts. Eskerod and Huemann (2013) argue that currently project managers falsely engage in “managing-of-stakeholders” rather than “managing-for-stakeholders”. The former simply attempts to make the stakeholder adjust to the project, while the latter is considered more sustainable as it proactively considers the diverse needs of the different stakeholders.

Silvius and Schipper (2014) define nine dimensions of sustainability in projects: Balancing the triple bottom line, balancing short-term and long-term orientation, balancing local and global orientation, considering values and ethics, considering transparency and accountability, stakeholder participation, risk reduction, eliminating waste, and consuming income rather than capital. They also list identification of the key stakeholders, stakeholder involvement, communication, project handover, and selection and organization of the project team as one of the relevant impact areas of projects. Successful handover and organizational learning are also seen as key components in sustainable project (Silvius and Schipper 2014).

Using the terminology and philosophy developed by Liker (2004) for the Toyota Production System (TPS), Silvius and Schipper (2014) consider a failed project to be ‘waste’. Waste of materials and resources is of course inherently unsustainable. Therefore, and for the purpose of this study, a repurposing project is considered sustainable if it succeeds in engaging the targeted end-users. Bai et al (2013) have developed a six-stage process for achieving sustainability in project through stakeholder management. The six suggested stages are: 1) identification 2) relating stakeholders to sustainability targets, 3) prioritization 4) managing 5) measuring performance 6) putting targets into action. The six stages approach requires that the project set measurable sustainability targets. It is therefore not applicable as such, as this study argues that a repurposing project is innately sustainable.

3. Study Design

The research approach is qualitative and explorative, with two cases studies. Case study research with a small number of cases allows studying phenomena rigorously and in-depth in their real-life context. For this research, both studied cases provide rich information on the phenomenon under study. The main source of data comprises interviews with key informants from both cases, participating in a planning workshop and development meetings, and archival data of the two projects. The in-depth, semi-structured interviews ranging between 60 to 90 minutes in length included questions about project stakeholders and the development process. Despite the extensiveness of the interview data, also archival data such as email correspondence were used as additional data sources. Moreover, observations by the researchers complement the data and provide also investigator and method triangulation. Finally, utilizing two separate cases for the study provide an opportunity to compare the cases and provides a richer empirical data base. Limiting the number of cases to two allows for in-depth analysis of both cases

This study examines two Finnish repurposing projects with special focus on stakeholder management and end-user engagement. The first case study is a private health care and wellness campus in Helsinki. The project was initiated because a major occupant is re-locating offsite. The vision of the property owner is to revitalise the campus by leasing the excess vacant space to several smaller, commercial tenants. The facility is a heritage building with conservational value, and even though restrictions do not apply to the interior or space design, only minor refurbishment is planned. Potential future occupants were invited to participate in a workshop and submit ideas for the new campus. The other case is a learning environment on Aalto University campus in Espoo, Finland. Several campus facilities suffer from low occupancy rates and are potentially subject to major renovations or demolitions. Simultaneously, new ways of working and learning continue to make traditional classroom settings obsolete. The second case project combines the need for new type of learning environments to the need to improve space efficiency on campus. The repurposing project transforms an old machine hall into an innovative networking and learning space for students. This exceptional project utilizes co-design techniques with students to create an innovative space.

Table 1: Description of the two cases

Case / *Theme*	*Case Energy Garage*	*Case Wellbeing Campus*
Facility type	*Alternative learning environment on campus*	*Full-service health and wellbeing campus*
Project type	*Developing a new learning space, refurbishing unused space*	*Improving space efficiency, energizing campus with new tenants*
Data sources	*Primary data source* • *19 stakeholder interviews (recorded and transcribed)* *Other data sources* • *80 archived documents including email correspondence* • *Observation during meetings and other site visits*	*Primary data source* • *Workshop* *Other data sources* • *14 stakeholder interviews (recorded and transcribed)* • *Observation during meetings and other site visits*

Based on previous literature, special focus of analysis was placed in the early project phases and how the first contact with stakeholders was managed. The distinct processes of the two selected cases are mapped, analysed and compared particularly from the perspective of stakeholder management.

4. Findings

The findings are first presented separately for each case, through introducing a project outline with detailed descriptions and quotes about events. Then, the findings are synthesized to form a suggested model for end-user engagement in a repurposing project.

4.1 Case Energy Garage

The development path of the learning environment Energy Garage has been described in detail in previous research (Kyrö and Artto 2015). Different phases, each with a different focus and different key stakeholders, arose from the analysis. The project has its origin in a research initiative, which in 2013 was decided to re-focus on students and learning. The project shifted from a faculty-driven research initiative to a student-led social learning environment.

Even though the project was initiated at the top management of the university, the project had a goal of bottom-up management. The university wanted to provide financing and support, but not micromanage the project. Instead, students were invited to be active members of the design team and a student was selected as a project manager. As one member of faculty put it: "*adults were left out of the design process.*" An experienced designer of learning spaces led the design efforts, however. Four interactive design meetings were organized. The lead designer stated, that her role was to be *"facilitating, instead of planning for the students"*. After the start of operations, students had the main responsibility of day-to-day management of the space. Additionally, a board consisting of student and faculty representatives meets every quarter to discuss user needs.

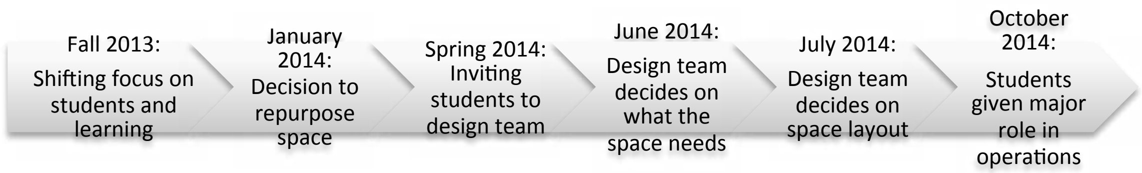

Figure 1: Timeline of Case Energy Garage repurposing project

The benefit of this kind of a co-design process was identified to be an enhanced sense of ownership experienced by the design-team. However, students are a problematic end-user group as they tend to graduate and move on, quickly. New students may have completely different ideals of an innovative learning environment.

4.2 Case Wellbeing Campus

The second case takes a different approach to the campus development, and utilizes a new form of an ideating workshop to catch the attention of potential new end-users and gain fresh insight. Ideating was sought with a distinct and novel workshop method. Potential end-users were first invited for a workshop on campus. Invitations were sent to private, public and third sector actors both from the health and wellbeing sector. Altogether 13 participants were present at the ideating workshop, aided by five facilitators and three persons assisting in documenting the workshop for future research use.

During the workshop, participants were first asked to recall a recent pleasant memory related to health and wellbeing. This was thought to focus the participants to the workshop theme in a positive way. For the remainder of the workshop the participants were divided into three separate groups. Each group member first considered which actors and activities they would prefer to locate on the campus, and present their suggestions to the group. At this point the participants were not allowed to select the organization they were presenting as a future campus end-user. During the second phase the group was to combine the best suggestions from each member to come up with a new unique set of actors and activities on campus. Once the activities were agreed upon, the next phase required the group to design the campus layout on a general level by placing the different activities on campus. Finally, the groups were asked to come up with a name and slogan for the campus. During the entire workshop the participants were reminded that they were not restricted by any existing physical of economic constraints of the campus. The freedom to innovate produced a range a truly special ideas for the future use of the campus.

The innovative workshop method produced a number of ideas for the campus development, and a few were selected for further implementation. The strength of the workshop method, the 'no restrictions' principle, also entails a challenge, as the unique, innovative ideas cannot be executed as such. However, the method was extremely successful in capturing novel ideas. As the instructions distributed to all workshop participants read: *"You will be able plan the campus with your peers in a good atmosphere and without any restrictions… Together we will create a business model concept of dreams. The results can later be compared to more traditional or implemented plans"*

Consequently, the ideas have been taken into account when planning the campus with existing tenants present. Moreover, the participants of the first ideating workshop remain stakeholders of the campus development project, albeit in a minor role.

4.3 Cross-case analysis

Next, some key features of the two projects are identified and listed in Table 2. Also the handover of the projects, which is known to be of significance to overall project sustainability, is discussed.

Table 2: Findings from the two case projects

Case / *Theme*	*Case Energy Garage*	*Case Wellbeing Campus*
Target	*Create a new learning environment for the students* *Improve occupancy*	*Energize the campus with new activities and end-users* *Improve occupancy*
Approach	*Proactive end-user (student) engagement starting from the early design phase* *Bottom-up management approach*	*Proactive inclusion of potential future occupants (public, private, third sector) in the early design phase*
Process	*Co-design team meetings*	*Single ideating workshop*
Strengths	*End-users experience ownership of the project and space*	*Innovative, 'out-of-the-box' ideas emerge*
Challenges	*Students as an end-users group change; the design team no longer represent the end-users at the operations phase*	*Financial constraints limit possibility to realize ideas* *Workshop participants do not represent end-users as such*
Handover	*Continued engagement of student groups during operational phase, e.g. membership in the board*	*Internal workshops with final end-users to refine the ideas to more realistic ones*

As seen in the table, the projects differ somewhat in their respective process, and therefore strengths and challenges. The strength of a long-standing, co-design process involving a group of selected end-user representatives meeting several times, is the enhanced sense of engagement and ownership of the space that the group was identified to feel. On the other hand, the innovative ideating workshop method, where participants were specifically told to leave all physical and economic constraints, produced a number of great, out-of-the-box ideas. However, as many ideas will not be realized, the process might lead to lowered sense of empowerment of the participants. It is noteworthy that both project faced the challenge of a change in the actual end-users compared to the originally planned. Due to this, the importance of stakeholder engagement also later on in the project is highlighted.

5. Discussion

This study sought out to increase understanding on how the repurposing of building could bring about environmental, social and economic sustainability. The results indicate that the most significant challenges are connected to the identification of the right stakeholders. Interestingly, both cases witnessed a change in the end-users compared to what was planned. Previous literature suggests that stakeholder engagement its crucial at the project frond end. However, based on these findings, engaging end-users early on in the planning phase is not enough if the end-users change and the management does not respond to the change. Instead, sustainable repurposing projects require stakeholder engagement throughout the project lifecycle. The importance of continuous, lifecycle management has previously been discussed earlier in the context of shopping centre facilities (Artto et al. 2015).

Based on the findings, a model adapted from the six-stage process for achieving sustainability in project through stakeholder management, inspired by Bai et al. (2013), is developed. The suggested model for repurposing projects comprises five separate phases, as follows.

1) **Identification of desired end-users.** This stage was handled differently in each case project, but nonetheless received significant emphasis on both. The identification was based on careful analysis of the desired future use of the space *(e.g. modern learning environment or energizing campus ecosystem)*
2) **Engaging potential end-users to the project.** This stage is particularly crucial for the further success of the projects primary goal, namely, improving occupancy at the end of the repurposing project. Despite different approaches in each case study, both cases place special emphasis on engaging the end-users through inviting them to participate in the joint planning activities.
3) **Formulating a shared vision with potential end-users.** Both cases were promoting a certain vision of the future space already before the joint planning activities, however, both openly allowed jointly ideating a new vision. This stage aids the sense of empowerment and ownership of the space.
4) **Co-design of activities and space.** End-users were also engaged in the actual design of the physical phase and activities that should be included. In both cases, this stage requires compromising between the different actors.
5) **Engaging final end-users to operations.** This stage is a requirement for the continued sense of ownership and end-user satisfaction. For both case studies, problems were identified as the final end-users differ from the potential end-users who participating in the previous phases.

The five stages are presented as a continuous project lifecycle in Figure 3.

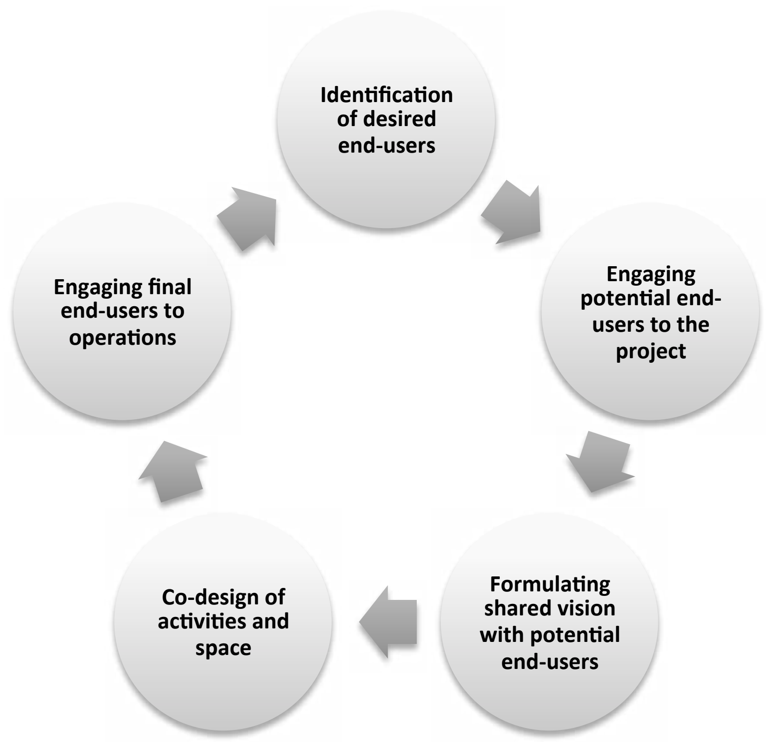

Figure 3: End-user engagement model for repurposing projects

The practical contributions may be used by real estate professionals in planning for repurposing projects, and utilized in the design process introducing these co-design principles. As new learning environments and campus retrofitting projects are becoming more and more common (Eriksson et al. 2015), the practical contributions are particularly current and relevant.

6. Conclusions

This paper has introduced the common goals of, and enhanced understanding of the concepts of stakeholder engagement, repurposing, and sustainability. Engaging stakeholders and managing sustainability have previously been linked, as have repurposing and sustainability, but all three combined provide a more thorough view of sustainable repurposing project.. It should be noted that improved occupancy rates and space-efficiency make the repurposing of buildings sustainable regardless of whether sustainability per se is sought after in the projects. In others words, the motivation behind a reuse project need not be achieving sustainability. This paper draws on empirical data of two exploratory case studies, and makes no attempt at statistical generalisation. In the future, analysing a number of case studies with available quantitative occupancy data after repurposing projects would provide interesting findings. The proposed, integrated stakeholder engagement model could be validated through these types of mixed method studies. Another potential future research avenue would be to study the relationship between sustainable repurposing and city planning policies.

Abstract

Many different sources have reported on the looming shortage of labor for the construction industry. Simultaneously, veterans who are returning from deployments and transferring into a civilian career are facing significantly higher unemployment rates than the general population. This paper proposes that these issues can be partially solved by forming a working relationship between the two populations. To find relevant information and opinions on this topic, interviews were conducted with three different groups. These three groups were contractors, veterans who are currently working in construction, and groups or organizations who are working to promote the partnership of the construction industry and the veteran population. Since the data gathered was mostly opinions and experiences, qualitative data analysis techniques were used to find trends in the data. Comparing and contrasting these different groups gave an informative insight to the issue. This paper concludes that while there are many challenges to overcome, the veteran population is a sustainable source for future employees for the construction industry, which can, in part, help to lessen the forecasted shortages for both skilled labor and construction professionals. However, there are multiple steps that need to be taken before veterans will have the opportunity to easily transfer their skills into the construction workforce. Some of these are cultivating lasting relationships between contractors and local military bases, provide opportunities for veterans to learn about and connect with contractors, and offer targeted veteran training programs that allow veterans to gain trade specific skills before they leave the military.

Keywords: veterans, workforce development, construction industry, United States,

1. Introduction

In 2011, in the United States, it was estimated that there will be approximately 300,000 veterans exiting the military in the next year, and this number will continue to grow in the years to come (VetPop 2011). These men and woman who have served the country are returning home to another battle, the adjustment to civilian life. Veterans who have fought in post September 11, 2001 wars (known as Gulf War II – era veterans) face an unemployment rate that is roughly three percentage points higher than the average (Army Times 2013).

The construction industry in the United States, on a whole, is experiencing a shortage of labor (AGC, 2013). This shortage applies to both construction professionals and trade workers. As the US economy is recovering from the downturn that began in 2007, construction projects are once again in high demand. Almost three quarters (74%) of construction companies report having trouble hiring qualified workers to meet the demand for their increasing work (AGC, 2013). This is an issue that is not just a current one, but one that will persist long into the future if new avenues of finding laborers and employees are not established and continually sustained.

This paper proposes that these two issues can be solved simultaneously. Veterans need sustainable careers and construction firms need trainable, responsible workers. Yet, there still seems to be a disconnection between the companies and these potential employees. This study investigated if and why veterans were a good fit to work in construction and what is currently being done to pair these two populations together and what can be done in the future to increase awareness on both sides of the issue. This research aimed to explore the opportunities in, benefits of, and barriers to construction as a civilian career for recent veterans and to investigate how this population could help to solve workforce issues in the construction industry. The objectives of the research were to (1) assess the need for renewed and continual workforce development in the construction industry, (2) discover what skills, experiences, and training veterans of the U.S. Military have that have been and would be applicable in the construction industry and (3) to discover what efforts are currently being made to pair contractors with veterans and to suggest future actions to this end.

The study used qualitative research methods and techniques. Interviews were selected as the main method of data collection because of the personal nature of the issue at hand. The collected data was analyzed by summarizing, coding, narrative and comparative analysis methods.

2. Literature Review

2.1. Construction Workforce Issues

In 2013, the Associated General Contractors of America (AGC) released the results of a nationwide survey that revealed issues companies were having with finding suitable workers. Over eighty percent of the firms surveyed answered that they had expanded their professional or craft workforce in the past year and that they had trouble or are still having trouble filling those positions (AGC, 2013). This survey determined that 65% of the firms considered the quality of the available construction crafts workers was below average or poor whereas 77% of the firms considered the quality of general construction professionals as either average or less. Contractors are pushing more for higher productivity rates from their craft workers. This higher demand for quality and productivity is being opposed by the lack of proper training pipelines for future construction workers (Pace, 2003).

According to a leading management consulting and investment banking company for the engineering and construction industry (FMI), in a detailed 2010 report on construction trade demand, the estimated number of jobs that needed to be added by 2014 to fulfil the estimated amount of work was 1.5 million. Another source, the Construction Labor Research Council (CLRC) predicted that a minimum of 185,000 new construction jobs will have to be added annually in the next decade to keep pace with the demand for construction services. It was also predicted in 2010 that by 2014 almost twenty percent of the current construction workforce would retire or be on the verge of retiring. All of this comes at a time when the market for construction is finally climbing out of a six year recession (NCCER, 2013).

All of these facts point to, what is commonly referred to as, the “skills gap.” This skills gap highlights the growing break between the construction workforce and the skills and training that are needed for one to join the workforce and the general population. High school aged kids and other young people are not receiving or are not interested in receiving the proper training to enter a construction trade as a career. Over fifty percent of high school graduates are now attending college. Very few are attending trade schools. This shift in the US culture is leading to less funding for the secondary career and technical schools, which in turn leads to fewer workers and less ways for a hopeful employee to receive proper training (AGC, 2014).

The AGC released a workforce development plan in 2014 which outlines a number of ideas on how to combat the aforementioned problems about labor shortages and a lack of proper training programs (AGC, 2014). One section of this plan discusses how giving training opportunities to veterans can be a great source of future workers. There are already many programs in place that could help veterans gain the needed skills to enter the construction workforce, if they receive more funding and are grown into a national effort. The AGC also mentions that extending the Work Opportunity Tax Credit, which helps cover certain costs of hiring veterans for companies, would encourage more companies to actively seek out the veteran population as a potential market for future employees.

2.2. Veteran Unemployment Status

Bureau of Labor Statistics publishes the data for unemployment rates for veterans. The statistics for the unemployment rate for vets by period of service show that while many periods have lower rates than nonveterans, the Gulf War era II, which is defined as veterans who have served post 9/11/2001, is the youngest generation of vets and has the highest unemployment rate. The Gulf War era II generation is also comprised of a much larger population of women than previous veteran generations.

2.3. Veterans in Construction

The idea of pairing veterans with construction companies is not new, but it is one that still has plenty of potential to help both sides. There are multiple organizations and programs that have this goal in mind: V2C, Helmets to Hardhats, VIP, Veterans Build America, and V.I.C.E. or Veterans in Construction Electrical are just a few such programs (Jones, 2013). However the effectiveness of many of these programs is hard to quantify. If they truly are making a difference in the labor force as a whole has yet to be determined.

"Helmets to Hardhats" has been helping veterans find jobs in the construction industry since 2003 but recently lost its funding from the federal government thus greatly impacting its effectiveness (Cronin, 2013). V2C is a much smaller and much newer program. It has been developed and run thus far with no funding. The founding members of the program have essentially volunteered their extra time to run V2C, but they feel that to begin making a larger impact, funding must be procured soon (Jones, 2013).

VIP is the most different program from the previously mentioned ones. This is because VIP does not simply try to pair veterans with jobs, it actually provides the necessary training to become an apprentice in the plumbing and pipefitting industry for free. This program is twenty weeks long and guarantees job placement upon completion of the program. The program includes eighteen weeks of intensive training that takes place while the veteran is still stationed on base and then two weeks of transition assistance to assure the veteran a smooth shift back to a civilian life and career. All of these services are provided free to the veterans and paid for by the local UA (United Association of Plumbers, Pipe Fitters, Welders and HVACR Technicians). This program started on Joint Base Lewis-McChord in Lacey, WA and has spread to multiple other bases including Camp Pendleton, California and Camp Douglas in Wisconson (Terven, 2011).

The percentage of veterans working in construction is significantly less than other industries such as: automotive/mechanic, aviation, government, health-related services, security, and transportation (Abt, 2008). There is limited data on the make-up of the construction labor force and what percentage of workers and professionals are veterans.

A survey by the *Military Times* entitled "Best for Vets 2013: Employers" ranked the top 53 employers for veterans. Of the 53 companies listed none were from the construction industry. There are two contractors listed on the 2014 list of "Best for Vets: Employers." The decision was based on data such as percentage of employees who were veterans, percentage of veteran executives, and percentage of recruiting budgets dedicated to veterans. This survey suggests that the construction industry as a whole could improve its outreach towards veteran.

3. Research Methodology

The study was conducted using qualitative research methods and techniques. Interviews were administered to collect the data from three different groups consisting of twelve people in total.

The collected data was analyzed using qualitative methods such as summarizing, coding, narrative and comparative analysis. The answers from each group were examined individually, as a group, and comparatively across all groups.

Group One- General and Specialty Contractors. This group consisted of a representative or group of representatives from selected construction firms in the Southeast of the United States. These firms and individuals were chosen using convenience sampling methods.

Group Two- Veterans. This group was comprised of people who were currently working for a company that was involved in the construction industry and also had previously served in any of the branches of the United States military. This group was selected using both convenience and snowball sampling methods.

Group Three- Programs that are currently working to pair the veteran population with the construction industry. This group contained people in leadership positions in a group or organization whose goal is to pair the veteran population with the construction industry through a variety of different methods. These organizations and individuals were chosen using convenience sampling methods.

3.1. Interview questions

Group One was asked eight questions, Group Two were asked ten questions and the third group responded to six questions in total. Following questions were asked in the interview:

a) Interview Questions for Group One (Construction Company representative)

1. Does your company have or participated in any special hiring/training program for veterans? If so, please explain. If not, would you consider creating and or joining one?

2. Does your company actively participate in any kind of workforce development program? If so, please explain.

3. What are some positions that veterans currently hold or have historically held in your company?

4. In your experience, have veterans had more, less, or a comparable amount of applicable training than non-veterans who you have hired for similar positions?

5. Has your company experienced any difficulties in finding and or hiring veterans onto your workforce? If you have, please explain.

6. Has your company experienced any direct or indirect benefits of hiring veterans i.e. government relocation assistance or other paid expenses? If so, please explain.

7. Is there any specific factor that is keeping your company from actively recruiting and hiring veterans?

8. For your company, what would make the process of recruiting and hiring veterans a simpler and more regular occurrence?

b) Interview Questions for Group Two (Industry Veterans)

1. Were you involved in construction in any way during your time in the military?

2. Did you receive any construction related training while in the military?

3. Why did you get into construction?

4. Did you have any connections in the industry? If not how did you get in touch with construction companies?

5. Did you participate in any program or organization that helped veterans find jobs in construction or other fields?

6. Do you believe that the training you received from the military prepared you for a civilian career after you had finished your service?

7. Do you know of anyone that you served with who is now working in the construction industry?

8. What was your knowledge of and perception about construction before you started to work in the industry?

9. Did you consider any other careers outside of the construction industry?

10. Would you recommend a career in construction to a fellow recent veteran?

c) Interview Questions for Group Three (Veteran Program Representatives)

1) How/why did your program get started?

    a) Why do you think vets and construction are a good match?

2) What is the goal/mission of your program?

    a) Has it evolved at all?

    b) If so. Why?

3) What kind of progress has your program made and how has it changed?

4) What has been the biggest impediment to the mission of your program?

5) What is the biggest factor(s) that will help promote the partnership between vets and construction?

6) Where will your program go from here?

4. Results and Analysis

4.1. Data Trends

In this section of data analysis, the collected interviews were transcribed into written form. The interview transcripts were then comprehensively read multiple times. Trends in answers to the questions were identified and recorded as codes. The tables are reported below from each group with the codes as found in the text. This paper defines a trend as a topic that was mentioned by two or more (40%) of the interviewees in a certain group. The interviewees wording did not have to exactly match another's to be considered a code or trend, rather it was the topic of idea spoken which determined the trend. There are three fields in each of the tables below:

- Description—a brief description of the idea or topic that was repeated by multiple interviewees

- Mentions—This is the number of times the identified topic or idea was mentioned by the interviewees, this includes multiple mentions by a single interviewee, but at least two separate interviewees had to mention the idea before it was considered a trend

- Marker—this is the highlighted color of the trend (Table ,1 2, and 3)

Table 1: Contractors' responses

Marker	Respondents	Mentions	Description
(pink)	5	17	Veterans are hard to contact as a group
(yellow)	4	10	Veterans have the type of work ethic or attidue we are looking for in an employee
(dark blue)	5	8	We would like to hire more veterans
(red)	3	5	Veterans have the leadership skills we need in our workforce
(green)	2	3	Veterans thrive in teamwork enviornments

As demonstrated in Tables 1, 2, and 3, there were many trends found throughout the collected data. One of major takeaways from this form of analysis is that one of the main hindrances in advancing the relationship between the construction industry and the veteran population is the difficulty in finding, or lack thereof, established lines of communication between these two groups. A separate trend discovered in all three groups was that of how military training prepares veterans for their civilian careers. While most interviewees agree that the trade specific training is absent, the soft skills that military service men and women develop such as, work ethic, attitude, trainability, leadership, and teamwork combine to make veterans a great candidate for any job in construction.

Table 2: Veterans' responses

Marker	Respondents	Mentions	Description
	5	14	I gained skills in the military which helped me later when I got a civillian job
	4	13	I had a Family or Friend Connection in the Construction industry
	3	11	Construction is hard work
	4	8	I did not particpate in construction while in the military
	5	6	Construction is a hard field to get into if you do not have any connections with a company

Table 3: Responses from veteran construction programs

Marker	Respondents	Mentions	Description
	2	6	Online job sites are not the answer, there needs to be a more tangible solution
	2	6	The Military and Government are hard to work with
	2	5	These types of programs are good for the veteran community
	2	5	Veterans are hard to contact as a group
	2	3	Construction is a fragmented industry
	2	2	Veterans have the type of work ethic, attidue, and leadership skills we need in our workforce
	2	2	Veterans are trainable

4.2. Comparative Analysis

The diagram below (Figure 1) illustrates how the data trends from all three groups align with each other. This diagram shows that there were many interrelated issues mentioned by two or even all three groups. By representing the data in this way it is easy to spot the main issues and ideas for the entire collection of interviewees.

As illustrated above, one trend that stood out from all interview groups was the topic of communication. This theme was brought up by the interviewee in almost every interview. Every time communication was mentioned the tone was negative. The difficulties of trying to reach out from one population to the other or the lack of communication between populations were pointed out as the biggest obstacles in the way of the goal. All contractors had experienced indirect benefits of hiring veterans through their attitudes about work, and their abilities to thrive in team oriented environments. This idea was to back up all of the veterans' belief that the leadership and teamwork skills they developed during their time in the military were the cornerstone to their successful careers in the construction industry. The notion of veterans having the skills needed to be successful in the construction business was further reinforced by the fact that all three programs in this study were started by veterans who believed the same thing so strongly that they decided to do something about it, in a big way.

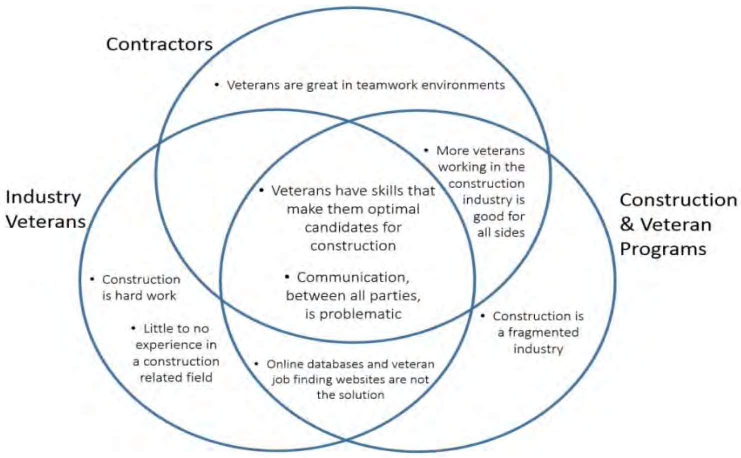

Figure 1: Conceptual alignment of data trends

The most prevalent difference between the group of contractors interviewed and the group of veterans interviewed was their outlook on veteran employability in the construction industry. Although all parties agreed that there are many similar skills needed and many parallels in the lines of work, the veterans were split evenly between recommending a career in construction to a fellow veteran, while contractors were unanimous in their desire to employ more veterans. While this result cannot be extrapolated to the populations as a whole, it certainly points out a gap that must be filled if the construction industry truly wants to recruit more veterans in the future.

5. Conclusions and Recommendations

There is no doubt that workforce development in the construction industry is a topic that needs to be addressed. Amid forecasts of labor shortages and the public's rapidly deteriorating attitudes about working in the construction trades, no contractor is denying this need. However, what the strategy will be to truly develop the workforce remains largely to be determined. Several different national contractors and industry groups have proposed plans of how to accomplish this task. As revealed through the interviews performed for this study, this issue cannot be solved with a singular solution or by a one contractor. Conversely, it must be handled through multiple avenues of attack and via an industry wide effort. The conclusions and recommendations of this paper alone are not enough to solve the construction labor shortage, nor are they intended to do so. To be successful, the following tactics must be accompanied with a heightened sense of awareness from all contractors and industry participants and a comprehensive, realistic plan of action from collaborative industry groups, unions, construction nonprofit groups, and individual contractors.

Ultimately, hiring a veteran is a business decision and as with any business decision, it is about return on investment. Veterans have been proven to have the intangibles needed to succeed in the construction industry in positions from trade apprentices all the way to senior management and owners. With the addition of increased awareness of the construction fields, opportunities to make personal connections with contractors, and readily available training programs, the veteran population could prove to be a renewable source of future employees for the construction industry for years to come. More importantly, these training programs and other opportunities will provide reliable avenues for service men and women to develop the skills and connections needed to smoothly transfer from active duty service into a prosperous civilian career. As a result of the research in this paper, the authors make following recommendations for the construction industry:

1) Begin the process of building a relationship with the veterans before they become veterans.

The construction industry is a fragmented industry with thousands of individual contractors spread across the country. Very few of the contractors have the time and or resources to individually establish a working relationship with the military. Likewise the veteran population, once separated from the military, is disjointed and near impossible to reach as a whole. Because of the conditions of these two populations it is important for a significant number of contractors, acting through local industry groups, such as the state chapters of the Associated Builders and Contractors, begin the process of building a relationship with the veterans before they are discharged from their final military stationing.

2) Recruit people with connections on both sides to become a liaison

This can be done firstly by recruiting someone with a strong network of connections in the military bases in the local community to be a part of this initiative. These connections are critical because, similar to construction, knowing who to talk to is half of the battle.

3) Establish a presence on local military bases

With the aforementioned connections in place it will be easier to establish a presence on the base. The idea is to get veterans to begin thinking of construction as a viable career. The most obvious groups of veterans to begin this campaign towards are those with construction related experience from the military i.e. the Navy Construction Battalion, or the Army Corps of Engineers. This group may prove to provide the best immediate return on investment, however, as revealed through this study veterans who were not assigned to these units can and will still make great employees for any contractor.

4) Offer construction specific career fairs and information sessions

To begin reaching out to these groups and establishing a credibility with the base command, groups should begin with relatively low cost, high yield strategies such as construction specific career expos. V2C has already begun this process and hopefully the rewards to all parties will be evident. Once these types of events have been successful it will become easier for individual contractors to reach out to these bases when they want to recruit more veterans. This strategy will diminish the largest complaint of both the contractors and veterans interviewed, which is the high level of difficulty experienced in trying to reach out and make personal contact with the other population.

5) Start a military specific training program

VIP has established a very effective training program specifically for veterans to gain the skills necessary to enter the welding and pipefitting trade. They have set up these programs to be run on base for active military personnel who are about to be finished with their military service. This is the optimal time to train the service men and women because of multiple reasons. Firstly, these men and women are highly trainable at this stage in their military careers and can absorb the trade knowledge and gain the necessary skills efficiently. This allows for training programs to be condensed, saving everyone involved time and money. Secondly, as they are still employed by the federal government, their living expenses and housing arrangements are fully taken care of by the military. This means that the veterans do not have to try and support their families by working a night job or by taking unemployment benefits form the government. This gives the veteran the ability to fully concentrate on the training program, which again saves everyone involved time and money.

The program that VIP has created is an accelerated eighteen week training regimen that is completely free to the veteran. The UA pays for the training which amounts to $15,000 per person. At the end of the program every veteran is guaranteed a job in the industry and also must join the UA. That amount of money may seem daunting at first, but not when one considers the thousands of dollars in union dues the graduates will pay back to the UA and the tens and possibly hundreds of thousands of dollars of work the graduates will produce in quality craftsmanship over the lifetime of their careers. It is important that the framework for this strategy continue to be developed and expanded into as many construction trades as possible. As of now, the UA is the only group with such a training program and the program is only available on a limited number of USMC bases. Unions and other trade groups, as well as general construction industry groups must find ways to finance, implement, and expand these types of training programs.

Abstract

Across Europe, some 200 million people live in suburbs in great need of modernization and social uplifting. The JPI Urban Europe SubUrbanLab project has examined how these suburbs can be modernized and socially uplifted together with the residents and other stakeholders using the Urban Living Lab approach.

This paper proposes a plan for the evaluation of six Urban Living Labs. The Urban Living Labs were real life development actions implemented in two suburban areas using different Urban Living Lab methods: Alby in Sweden and Peltosaari in Finland. The evaluation plan is divided into two sections 1) evaluation of the Urban Living Lab methods and 2) evaluation of the implemented modernization and social upgrading actions.

The evaluation of methods provides insights into the appropriateness of using an Urban Living Lab approach for involving users and stakeholders in less valued suburbs. This evaluation is designed to include the whole process of developing, planning, implementing and following-up an Urban Living Lab. The evaluation of actions is carried out using both quantitative (e.g. CEA, physical indicators) and qualitative (e.g. online questionnaires and interviews with residents, municipal representatives, practitioners and other experts) methods. The evaluation focuses on how the implemented actions have contributed to these suburbs' attraction, sustainability and economic viability.

Keywords: modernisation, urban living labs, neighbourhood, people involvement

1. Introduction

Across Europe, some 200 million people live in suburbs in great need of modernization and social uplifting. The JPI Urban Europe SubUrbanLab project (2013-2016) has examined how these suburbs can be modernized and socially uplifted together with the residents and other stakeholders. The project developed and set up six Urban Living Labs (ULLs): three in Alby, Sweden and three in Peltosaari, Finland. These ULLs were arenas for co-creation of innovative urban solutions: a means to develop new forms of experiences on involving the residents and stakeholders into development in an urban context. The long-term goal is to turn these suburbs into more attractive, sustainable and economically viable urban areas.

2. Urban Living Labs methods

Urban Living Labs are development environments that integrate residents and other stakeholders to develop and test new solutions in their daily life. The users of the new services or solutions are active partners in the whole development process, which happens in the real urban context. Urban Living Labs utilize various co-design methods for understanding the needs, generating solution ideas, presenting ideas and evaluating the solutions in practice. In addition, citizen participation methods are used for participation in decision making and taking action. Voytenko et al. (2015) defined the characteristics of urban living labs based on a study of the ongoing research projects in Europe as follows:

- ULLs are placed in geographical area
- ULLs represent a specific form of experimentation, including processes of innovation and learning
- Participation and user involvement
- Leadership and ownership

In this project we have defined an Urban Living Lab as a forum for innovation and dialogue that integrates the residents and other stakeholders to develop and test new ideas, systems and solutions in complex and real contexts in order to solve challenges in the urban area (see e.g. Friedrich P. et al. 2013). The research and development are intertwined in a “living laboratory” – in the middle of people’s everyday living environment. An ULL includes the following features (Friedrich P. et al. 2013, Ståhlbröst & Holst 2013):

- it integrates researchers, public organizations, residents and companies to co-develop new solutions;
- the users of the developed services or solutions are active partners in the development work during the whole process;
- the solutions will be developed and evaluated in the real use context;
- besides producing the concrete solutions, the aim is to learn and exchange knowledge among the partners;
- the activities are encouraging and rewarding for all participants;

Before starting Urban Living Lab activities, several things have to be checked and planned. First of all, understanding the context is important. This understanding can be obtained by interviewing people from different backgrounds, observing the environment and familiarising oneself with earlier reports written about the area and its challenges. The next tasks is to define the goals for the development project based on the needs of different target groups, identify the residents and other stakeholders who should participate in the project and involve them in defining the aims, clarify the roles in the Urban Living Lab and define a transparent decision making process. Finally, the methods for the specific actions and the communication process should be planned.

Friedrich P, et al. (2013) have defined general boundary conditions and methods for successful Urban Living Lab implementation based on existing literature on citizen participation and consumer behaviour change. Additionally, municipality employees, active residents and participants in previous citizen participation projects were interviewed in the target areas of the project: Botkyrka municipality in Sweden and the city of Riihimäki in Finland. A summary of the defined methods with short descriptions (when necessary) and their suitability for face-to-face or online use is presented in

Table 1. More detailed descriptions for each method are presented in Friedrich P. et al. (2013).

Table 1: Participatory methods grouped based on their purpose and art of implementation

Purpose	*Method (description)*	*Face-to-face*	*Online*
Understanding people and issues	*Interviews (both open-ended and individual follow-up questions)*	*x*	*x*
	Observation	*x*	
	Questionnaires	*x*	*x*
	Focus groups (structured discussion groups led by a facilitator)	*x*	*x*
	Diaries (e.g. blogs telling stories and sharing observations around a certain topic)	*x*	*x*
	Cultural probes (a specific diary method consisting of inspirational material packages and tasks)	*x*	*x*
Generating ideas	*Workshops (including variations such as "rotating table", "dialogue café", "Open Space")*	*x*	*x*
	Walkshop (a workshop implemented by walking)	*x*	
	Brainstorming	*x*	*x*
	Idea competition		*x*
Presenting and evaluating solutions	*Scenarios (textual stories of possible futures)*	*x*	*x*
	Storyboards (a visual story of a planned service or solution, e.g. in a form of a comic)	*x*	*x*
	Films (further developed form of storyboards)	*x*	*x*
	Mock-ups (light weight prototypes illustrating aspects of the solution as a tangible object)	*x*	
	Field tests (testing new services/solutions in the real world context)	*x*	

Participating in decision making	*Dialogue meetings / forum (moderated meetings around a certain topic)*	*x*	*x*
	Citizen panels (regular meetings for selected participants to give input and feedback on a certain service/solution)	*x*	*x*
	Chat (real time on online discussion after or instead of a face-to-face meeting)		*x*
	Voting	*x*	*x*
Taking action	*Citizen parliament (a forum where the citizens take action themselves)*	*x*	
	Mini pilots (citizen driven projects sponsored by the municipality)	*x*	
	Change agents (voluntary citizens informing and activating their peers to change their behaviour)	*x*	

Online focus groups, workshops, panels etc. should be arranged in existing online forums that the target groups already use instead of introducing new tools that need to be advertised to the participants according to Brandtzæg et al. (2012). Also face-to-face methods should utilize already existing networks.

3. Implemented Urban Living Labs

Six Urban Living Labs as real life development actions were defined and implemented in Alby and Peltosaari districts during 2014-2015 as a part of the normal living and operation of neighbourhoods. Within the Urban Living Labs, residents and other stakeholders were involved using different Urban Living Lab methods in developing and implementing innovative solutions to increase the social, economic and environmental sustainability in these areas in great need of modernisation and social uplifting.

The first Urban Living Lab in Alby, "Shape your world", provided children and young adults (age 12-18) with the opportunity to increase their knowledge and understanding of sustainable development and urban gardening while participating in renewing their urban environment.

The second Urban Living Lab in Alby, "New light on Alby Hill", focused on how using new LED technology and light installations can transform a walkway on Alby Hill, an area that the residents earlier have perceived as insecure, into a more attractive and safe area.

The third Urban Living Lab in Alby, "Vacant Space Alby", involved a broad range of stakeholders, including residents, in the design and planning of temporary activities (time span 10 -15 years) to be implemented on a vacant 18 000 m2 space in central Alby. The stakeholders were involved in design of activities, based on local needs, using workshops and web-based co-creation tools.

The first Urban Living Lab in Peltosaari, "Energetic co-operation", focused on finding ways in collaboration with residents and the housing company for decreasing the energy use of rental apartment buildings. Discussion events with residents and other stakeholders were arranged to find out energy saving ideas and best ways to share information about energy efficient living.

The second Urban Living Lab in Peltosaari, “Sustainable decisions”, brought together decision makers and municipality representatives to find out ways for taking into account better and more actively the city’s energy and climate targets in the everyday decision making. Workshops were arranged for activating dialogue and co-development, and ideas for improving practices were gathered.

The third Urban Living Lab in Peltosaari, “Together more”, involved residents in the planning and development of their environment and provided local activities and meeting places for the residents. The goal was to improve the appreciation of the area and to increase the communal feeling among the residents. Several types of activities were piloted and residents were invited to discussion events to influence the plans concerning the area.

4. Evaluation of the implemented Urban Living Labs

4.1 Goals and evaluation process

The goals for each Urban Living Lab were formulated in a dialogue between different stakeholders and project partners, depending on the planned scope of the work. It has been important that both the involved project partners and the stakeholders have common expectations and goals for the Urban Living Lab from the beginning. Nevertheless, the individual goals of different stakeholders and partners need to be recognized. The goals defined for each Urban Living Lab concern both the modernization actions and the participation of residents and stakeholders.

The evaluation of the implemented Urban Living Labs is twofold: First, each ULL is evaluated regarding its contribution to environmental, social and economic sustainability in the area where the Urban Living Lab has been implemented. Secondly each Urban Living Lab is evaluated with respect to how it has lived up to the definition of an Urban Living Lab (the Urban Living Lab principles). The evaluations of each Urban Living Lab are hence focused around the following two parts:

1. Evaluation of the Urban Living Lab’s contribution to environmental, social and economic sustainability
2. Evaluation of fulfilment of general Urban Living Lab principles (Urban Living Lab definition)

The evaluation plan for each Urban Living Lab is specific to that particular Urban Living Lab, as the Urban Living Labs are focused on different actions, using different methods and set in different contexts with different users.

4.2 Evaluation of the Urban Living Lab's contribution to environmental, social and economic sustainability

The evaluation of contribution to sustainability depends on the goals of the particular Urban Living Lab but also on the local goals or views on social, environmental and economic sustainable development in the particular suburb. The evaluation of sustainability mainly takes its point of departure from goals set up for each Urban Living Lab and sustainability as seen from the context of the particular suburb, but will also discuss contribution to sustainability from a broader point of view. Some aspects of sustainability were not covered by local views/goals on sustainability or by the specific Urban Living Lab goals, but they will also be evaluated. As an example, the evaluation of contribution of sustainability will, as far as this has been possible, evaluate the economic viability (economic sustainability) for the Urban Living Labs.

In the evaluation of contribution to sustainability, both quantitative (e.g. CEA, physical indicators) and qualitative (e.g. online questionnaires and interviews with residents, municipal representatives, practitioners and other experts) evaluation methods will be used, depending on the specific Urban Living Lab. The evaluation focuses on how the implemented actions have contributed to the attraction, sustainability and economic viability of the target areas Alby and Peltosaari.

The evaluation can be based on a focus group or reference group that, after the project has been finished, discusses how the Urban Living Lab has contributed to local sustainability goals. For social sustainability, a before-and-after-survey can reveal changes over time concerning e.g. interest to contribute to the local society and commitment to sustainability. All Urban Living Labs will also, as far as this is possible, be evaluated with respect to the Urban Living Labs contribution to increased social cohesion and increased commitment among residents and other stakeholders to sustainability.

Relevant evaluation questions concerning the social issues and attraction are e.g. what kind of role do the implemented actions play in order to attract people and businesses to the suburbs? Have the actions increased the willingness of people to live in these suburbs? Do more businesses want to invest or get established in these suburbs due to the actions undertaken? Have the actions increased the willingness to cooperate with local stakeholders? Do the Urban Living Labs bring lasting and deepened commitment among residents regarding environmental matters and sustainability? How do the Urban Living Labs increase social cohesion? Are the developed Urban Living Labs mature to continue actions after the SubUrbanLab project ends? Are the responsibilities between different stakeholders clear for further collaboration?

Relevant evaluation questions concerning the environmental sustainability and economic viability are e.g.: How have the implemented actions contributed to environmental, social and economic objectives e.g. leading to improved environmental performance and creating new local jobs? Have the actions been implemented in a cost-efficient way? What is the added value, (even monetary) of Urban Living Labs in getting the benefits?

Economic viability refers to how cost-efficient the Urban Living Lab has been, e.g. compared to more traditional ways of implementing the same actions. Where possible, the project will use cost-effectiveness analysis (CEA) in order to evaluate the cost-effectiveness of the different implemented Urban Living Lab actions and to compare the different alternatives. Here the VTT-CEA tool (Tuominen et al. 2015) will be used for evaluating energy efficiency investments done in the case areas. The evaluation of cost-effectiveness is done to measure the performance and effectiveness of a project. From a public policy point of view, the main argument for evaluating the costs and benefits of projects is for ascertaining whether public support for the project is a sound investment.

4.3 Evaluation of the Urban Living Lab methods (participation of residents and other stakeholders)

The evaluation of methods provides insights into the appropriateness of the selected Urban Living Lab methods for involving users and stakeholders in less valued suburbs. This evaluation is designed to include the whole process of developing, planning, implementing and following-up an Urban Living Lab.

In practice, Urban Living Labs can make use of different co-design methods both face-to-face and online to involve all relevant stakeholders in the process of planning, designing, developing and evaluating new solutions. The evaluation of the Urban Living Lab approach will therefore especially focus on how residents and other stakeholders have been integrated to solve challenges in the urban areas or, in other words, how the knowledge, experience and input from the involved residents and stakeholders have been used in the whole process of the Urban Living Lab - when setting up and developing the Urban Living Lab, when planning the Urban Living Lab and when implementing the Urban Living Lab. Other aspects of the Urban Living Lab approach, such as the learning between partners and how invited participants have experienced their participation, will also be discussed.

To be able to evaluate this, documentation, such as meeting minutes, is vital during whole process of all Urban Living Labs. Interviews with and questionnaires among participating residents and stakeholders have also been important methods to be able to evaluate their involvement.

Inhabitants and other stakeholders were engaged to the implemented development actions through different participatory methods such as online Owela tool developed by VTT (Friedrich 2013), face-to-face meetings, workshops, interviews, questionnaires, field tests and mini pilots. The implemented Urban Living Labs used mainly traditional face-to-face-methods, such as workshops, discussions, surveys and questionnaires as these turned out to be suitable ways of co-creation with the target groups. Face-to-face meetings and discussions with the residents were focal in raising interest and creating commitment whereas use of digital tools for participation was not regarded natural by many of the residents.

Relevant questions concerning the evaluation of methods are for example: Were the relevant people able and willing to participate through the method? Was the group involved in the activity sufficiently representative of the targeted stakeholders? Did the contributions gained using the method have an impact on the activity? Did the method support interaction and mutual learning among the participants? Did the method provide equal opportunities to participate for different kinds of people? Could the method be adjusted based on the needs of the activity? Was the method laborious and/or complicated for the organizers or participants?

4.4 Preliminary evaluation results of two Urban Living Labs

The evaluation work is ongoing during the time of writing this paper. Here some preliminary evaluation results of the second Urban Living Lab in Alby, "New light on Alby Hill" and the second Urban Living Lab in Peltosaari, "Sustainable decisions" are presented (Karlsson et al. 2016b).

Alby Urban Living Lab "New light on Alby Hill" focused on how using new LED technology and light installations can transform a walkway on Alby Hill, an area that the residents earlier have perceived as insecure, into a more attractive and safe area. The sustainability objectives of this Urban Living Lab were: 1) Renewing the urban Environment, 2) Modernising Alby's identity and 3) Trying out new working methods at the municipality.

Several methods were used to evaluate the contribution to sustainability. Questionnaire surveys targeting the users of the pathway were carried out before and after the implementation of the new lightning. The energy use before and after the implementation was calculated including also the reduction of GHG-emissions. A focus group interview was carried out with the representatives of the municipality, private housing company Mitt Alby, Collage of Arts and the research partner IVL to discuss the contribution to sustainability objectives on different levels. A Cost Effectiveness Analysis (CEA) was conducted to examine the economic sustainability. All phases of the Urban Living Lab were continuously documented and reported in project reports "Selection of Urban Living Labs in Alby and Peltosaari" (Karlsson et al. 2015) and "Establishment and implementation of Urban Living Labs in Alby and Peltosaari" (Karlsson et al. 2016a) to be utilized in the evaluation process.

The contribution of the Urban Living Lab to social sustainability is here presented as an example. The contribution to social sustainability was evaluated by estimating the increase in the sense of security and participation and engagement.

The increase in the sense of security was evaluated using the results of the questionnaires. According to the results the new lighting on the pathway increased the sense of safety to some extent, especially amongst the women. The amount of women feeling unsafe or sometimes unsafe using the pathway during dark hours was reduced from 79% to 55%. The pathway was experienced to be better and lighter with the new lighting system but a high proportion of the respondents still felt sometimes insecure despite of the new lighting.

The residents’ involvement and participation was evaluated to be high in the project. The number of people participating in the project either through the Residents Council, by submitting images for the competition, by voting on their favourite picture or by participating in the opening ceremony was counted to be 160 people, but there has been some overlapping (for example both contributing pictures and voting). The specific Urban Living Lab website was visited by nearly 400 people. The residents on Alby Hill were also informed about the project via info leaflets and there has been also other information sharing utilizing e.g. posters and the municipality´s website. According to the results of the questionnaires, the amount of respondents feeling that they can influence changes in their outdoor environment raised from 31% to 52%.

Peltosaari Urban Living Lab “Sustainable decisions” brought together decision makers and municipality representatives to find out ways for taking into account better and more actively the city’s energy and climate targets in the everyday decision making. Workshops were arranged for activating dialogue and co-development, and ideas for improving practices were gathered. The sustainability objectives relevant for this Urban Living Lab were: 1) Support decision making on energy efficient and sustainable investments and 2) Develop and experiment with new practices in the municipality to enhance collaboration and communication.

The methods used to evaluate the contribution to sustainability were e.g. questionnaires and surveys to participants before and after the seminars. The contribution of the Urban Living Lab to environmental sustainability is presented here as an example. The impact of the workshop was evaluated by the number of people reached through the workshops. Besides the persons actually participating in the workshop, the invitations and the presentation materials distributed after the workshops reached a much wider group of people. The workshops were considered worthwhile participating and especially discussions were highly valued. The workshops were also regarded as a good way to enhance interaction and communication. The results of the questionnaires and surveys showed that the energy efficiency and life cycle perspectives are not well integrated into the current decision making in the municipality, despite of the goals and commitments of the city. This fact further emphasises the need for developing new ways to take these issues better into account in the future. Based on the discussions with the representatives of the City of Riihimäki some impacts of the workshops have already been noted, such as:

- Life-cycle projects will be taken to be considered in some upcoming investments
- PV panels will be included in some future alternatives
- Representatives of other departments have been invited to some meetings to enhance the flow of information in the organisation.

5. Discussion

This paper has concentrated on the evaluation plans of different Urban Living Labs. The impacts of each Urban Living Lab differ from each other and therefore impact evaluation has to be planned separately for each Urban Living Lab but also common elements have been identified. It is also challenging to evaluate the impact of one single Urban Living Lab as the city has several ongoing activities and sustainability goals having similar kinds of effect. Also, many impacts can be noticed and/or measured only after several years, as for example changes in attitudes and processes, which happen slowly and are simultaneously affected by several external factors. It is however difficult to identify at that point how an ULL has affected that development.

Key success factors for Urban Living Labs are the early and continuous involvement of the affected people, clear goals and expectations, and experimenting in real context instead of discussing. The methods must be adapted to the goals and participants. On the other hand, an intrinsic part of the ULL approach is that course of an activity may change during the process, based on the contributions and decisions among the participants. This further complicates the evaluation since the goals may be adjusted during the process. At its best, people can participate in the Urban Living Lab activities as a part of their other activities and see the effects of their participation shortly afterwards. The participants should have the ownership to the project, create content and express themselves (Brandtzæg et al. 2012).

There are different ways to realise Urban Living Labs depending on the stakeholder group, boundaries, and existing groups/networks in the neighbourhood. It is important to identify different types of existing development projects, networks and stakeholders, with which to link the Urban Living Lab actions as utilizing relations to other activities brings win-win advantages. Urban Living Lab should be planned to support broader development targets and projects in the municipality or area.

From a public policy point of view evaluation methods are needed for assessing a project's level of success and for being able to compare the project to its alternatives. Currently decision makers clearly need more evidence on the impacts and benefits of co-creation and co-design. How can we measure the impact and value of the learning process and show that the monetary investment has been profitable? The common factor in all Urban Living Labs is thus estimating the impact of co-creation, which lacks methods and indicators.

The preliminary evaluation results emphasize the need for careful planning of the measures and methods for evaluation but also the necessity to update them during the course of work, due to adjustments and changes for the scope of the work that often take place as a result of the contributions from the stakeholders.

Furthermore the results indicate that the value of using Urban Living Lab approach needs to be considered more extensively than the generally used quantitative measures, such as costs and number solutions that are taken into use. Benefits of engaging residents in developing and piloting solutions often follow from "avoided costs", such as early identification of non-working solutions or potential bottlenecks, improved acceptance of a new solution among the users, and faster start-up and active use of a solution. Additionally the approach intrinsically supports learning and self-efficacy among the participants and improves co-operation between the partners, and thus provides benefits that are not necessarily expressed as specific goals of the activity but nevertheless are valuable. Successful engagement as such should be weighted as a valuable result.

The preliminary evaluation results also emphasize that the motivation for using Urban Living Lab approach should be based on different kinds of criteria than simple cost-efficiency of implementing concrete actions. Engaging people and co-development processes require resources and take time but on the other hand the outcomes of all Urban Living Labs of the study were significantly affected by the participation: similar results could not have been achieved without the Urban Living Labs. Maybe even more importantly, the Urban Living Labs were seen to have numerous "secondary effects" on the participants and the area that would not have been accomplished without Urban Living Lab approach. Examples of these are learning, enhanced opportunities for self-expression, increased awareness of relevant issues in the area, improved collaboration between partners and feeling of being able to influence.

The set of evaluation questions formulated in this study provide a good basis for conducting systematic evaluation of an Urban Living Lab. Further development of methods and ways for assessing benefits of different scales in parallel are however still needed to be able to demonstrate convincingly the profitability of Urban Living Lab approaches.

6. Conclusions

The overall conclusions of the paper are following:

- It is vital to be able to demonstrate the benefits of Urban Living Labs and thus approaches for evaluating impacts systematically are needed
- The SubUrbanLab project with six different Urban Living Labs provides a good basis for developing a general evaluation "framework"
- This paper proposes division of evaluation into different categories and suggests questions that can be used as a basis for evaluating Urban Living Labs

7. Acknowledgements

The work is part of the SubUrbanLab project (Social uplifting and modernisation of suburban areas with Urban Living Lab approach), which is funded by TEKES and VINNOVA through Urban Europe Joint Program Initiative. Funders are acknowledged. Project partners are VTT Technical Research Centre Ltd., City of Riihimäki, City of Botkyrka, and IVL Swedish Environmental Research Institute.

Abstract

This study aims to develop and test a paradoxical link between corporate social responsibility (CSR) and corporate financial performance (CFP): CSR may be detrimental to financial performance in the short-term term (e.g. by adopting carbon reduction schemes, or taking account of fair trade) but will be conducive to improving performance in the long term (e.g. by developing reputation, or improving business relationships). Using panel data of international construction companies derived from various sources, the hypothesis is confirmed. The traditional notion that CSR will have an immediate and unchanging impact on CFP is probably flawed. In the international construction business, a short-term, negative effect of CSR on CFP is witnessed, but a positive effective of CSR on CFP can be developed if effectively involved in CSR programme for long. It takes time to materialize CSR in terms of financial performance. This research helps explain the CSR dilemma, whereby business executives' hesitate to fully engage in CSR for long, given their pressure to effectively maximize profitability for shareholders. The research thus provides support to business executives who should be relieved from short-termism when devising proper CSR strategies in international business.

Keywords: Corporate social responsibility, Corporate social performance, Corporate financial performance, CSR-CFP relationship, International construction

1. Introduction

Since the phrase corporate social responsibility (CSR) was coined by Bowen and Johnson (1953), it has been and remains the subject of contentious debate. Friedman (1970), for example, famously argued that socially desirable goals, if at the expense of profitability, should be disconnected from a company's fiduciary responsibilities; "if managers used corporate resources for any cause other than profit maximization, it would constitute a form of theft". On the other hand, Porter and Kramer (2006; 2011) advocated 'creating shared value', which involves creating economic value in a way that *also* creates value for society. They advocated raising societal issues from the periphery to the core of a business. The two schools seem form a debate spectrum with Friedman on the one end while Porter on the other, although both share the same component to emphasize profitability of a business. The majority of the debaters tend to take an eclectic position in the spectrum by accepting that nowadays companies have an obligation to assume social responsibilities while pursuing business success (Lu *et al.*, 2014). This school of CSR thought reflects the changing social and political climate around the world, indicated by the decline of *laissez-faire*, the increase of government intervention, the vogue for stakeholder theory, the deepening of globalization, and the emergence of sustainable development (Green, 2009).

CSR has increasingly become the Quadruple Bottom Line (QBL) by broadening the traditional Triple Bottom Line (TBL), which requires societal, environmental, and economic reporting in business. This echoes with Porter and Kramer's (2006) observation that CSR has emerged as "an inescapable priority for business leaders in every country". Yet, the extent to which a company actually engages itself in this CSR trend is vigorously disputed. At times, business executives are allegedly myopic in assuming social responsibility (Painter-Morland, 2006). CSR needs to have a genuine economic foundation to be sustained in a competitive business world (DTI, 2002). Without evident benefits for companies, CSR may not continue to flourish as CSR programs are costly and detract from companies' limited financial resources (Wang *et al.*, 2008).

To provide this CSR legitimacy, researchers have endeavoured to search for a link between CSR and corporate financial performance (CFP). This CSR-CFP link has become a non-trivial issue that is widely debated amongst management theorists and business executives. Margolis and Walsh (2001) identified 95 empirical studies on the CSR-CFP relationship published since 1972. Orlitzky *et al.* (2003), in their milestone review, critiqued that Margolis and Walsh's (2001) study used the so-called 'vote-counting' technique, whereby studies are simply coded as showing significantly positive, negative, or statistically non-significant results, and conclusions are likely to be false. They used meta-analysis, viewing it as a more robust statistical method, and reported with greater certainty that CSR is positively correlated with CFP. Empirical research on the CSR-CFP relationship continues, irrespective of the call for a moratorium on it made by Margolis and Walsh (2001). Lu *et al.* (2014) identified 84 relevant empirical studies on the CSP-CFP relationship published during 2002 and 2011.

One notable research trend is that researchers have gradually recognized the CSR-CFP nexus as not being static but changing in a non-linear fashion, e.g. U-shaped curvilinear relationship (Barnett and Salomon, 2006; Park and Lee, 2009). The causality between CSR and CFP may occur in a certain time lapse. It is a significant advancement to consider time lags in the CSR-CFP nexus research, since decision-makings and resource allocation are time-consuming in practice. Though this kind of view is partly reviewed by Orlitzky et al (2003), convincing empirical studies remain few and far between. Inoue and Lee (2011) reveal that each decomposed CSR aspect had a different effect on both short-term and future profitability of companies in tourism-related industries. There seems to be two hypotheses, one positing the short term effect between CSR and CFP, and the other concerning the long term relationship. While contemporary researchers have acknowledged both hypotheses, no one, to the best of our knowledge, has attempted to integrate the two into a refined theory capable of accounting for their seemingly paradoxical dynamics.

The aim of this paper is thus to offer and test a refined theory on the dynamic and sophisticated relationship between CSR and CFP by considering time lags. The main hypothesis is that a paradoxical link exists between CSR and CFP: *CSR is detrimental to CFP in the short-term but will be conducive to CFP in the long-term.* The distinction between the expected short-term and long-term effects of CSR on CFP enables the falsification of the theory. The research in this paper has profound academic and practical values. Academically, the research provides fresh answers to the moot question regarding the CSR-CFP link. It helps divert researchers' attention from the allies-and-adversaries dichotomy to the paradoxical dynamics between CSR and CFP. It may lead to a breakthrough towards a refined theory of the CSR-CFP nexus. Practically, it could help explain some CSR dilemmas, such as executives' hesitation to fully engage in CSR despite the rhetorical exhortations of its benefits; back to the board room, they are under pressure to effectively maximize profitability for shareholders in short-term. The research provides support to business executives to be relieved from short-termism when they devise proper CSR strategies to achieve business success.

2. Constructs and measures

2.1 Corporate Social Responsibility (CSR)/Corporate Social Performance (CSP)

There is no agreed-upon definition on what is meant by CSR. Dahlsrud (2008) identified 37 definitions of CSR. Carroll and Shabana (2010) advised that there are many other academically derived definitional constructs. Carroll (1979) proposed four kinds of social responsibilities constitute total CSR: economic, legal, ethical, and discretionary (philanthropic) responsibilities; the CSR firm should strive to make a profit, obey the law, be ethical, and be a good corporate citizen. Carroll (1979) further suggested depicting them as a pyramid, which has been known by many scholars as the CSR pyramid. While a consensus of CSR definitions remains an issue, other similar concepts such as corporate social performance (CSP) have emerged. Many empirical papers reviewed by Margolis and Walsh (2001), Orlitzky *et al.* (2003), and Lu *et al.* (2014) actually examined the relationship between CSP and CFP. Although some researchers (e.g. Margolis *et al.*, 2007) use CSP and CSR interchangeably in empirical studies, others attempt to distinguish the two concepts (Lu *et al.*, 2014). According to Carroll (1991), CSR emphasizes obligation and accountability to society, while CSP emphasizes outcomes and results. Maron (2006) suggested that CSP is a way of making CSR applicable and putting it into practice. Beurden and Gössling (2008) pointed out that CSR is not a variable and therefore it is impossible to measure; CSP, on the other hand, though difficult to measure too, can be surrogated by the use of proxy measurable variables.

The proliferation of definitions makes it difficult to measure CSP. The challenge is to identify and measure CSR initiatives that are prevalent amongst companies. Carroll's (1979) CSR taxonomy provides the theoretical guideline from which CSR initiatives can be identified. Many companies also issue CSR disclosures, in which they explain their dedication to CSR and highlight successes. By following all these, CSR initiatives can be identified and measured. It is also noticed that studies that explored the empirical CSR-CFP link often circumvented the measuring problem by adopting a pragmatic approach. They used aggregated CSR indices that were established by other parties, such as the Council on Economic Priorities (CEP) index, the Kinder, Lydenberg, Domini (KLD) index, and the FTSE KLD 400 Social Index, or the World's Most Admired Companies, annually published by *Fortune* magazine, as a CSR index.

2.2 Corporate Financial Performance (CFP)

Performance means different things to different stakeholders. Nevertheless, in contrast to the pluralism of CSR/CSP, measures of CFP in academic research have largely converged into the trichotomy of CFP proposed by Orlitzky *et al.* (2003), namely, 1) market-based, 2) accounting-based, and 3) perceptual CFP measures. Market-based measures of CFP, such as price per share or share price appreciation, reflect the notion that shareholders are a primary stakeholder group (Cochran and Wood, 1984). Beurden and Gössling (2008) added more market-based measures in their review work, including stock performance, market return, market value to book value, and others. Alternatively, accounting-based measures consist of profitability measures, asset utilization, such as return on asset (ROA) and asset turnover, and growth measures. Cochran and Wood (1984) aruged that accounting-based indicators, such as the firm's return on assets (ROA), return on equity (ROE), or earnings per share (EPS), capture a firm's internal efficiency in some way. Lastly, perceptual measures of CFP ask survey respondents to provide subjective estimates of firms' financial performance (Conine and Madden, 1987). Amongst the three generic CFP measures, the accounting-based measures are objective and audited, market-based measures are partly objective, and perceptual are largely subjective based on the survey respondents' perceptions (Lu *et al.,* 2014). Given that both CSP and CFP are already broad constructs that are difficult to be measured, Lu *et al.* (2014) suggested a general principle of using more objective CFP measures and secondary data in future empirical studies. The selection of CFP measures is also subject to data accessibility, and their suitability to the characteristics of an industry within which companies are operating.

3. Hypotheses

To reiterate, the aim of this paper is to investigate the causality of CSP on CFP. Instead of trying to identify a static and linear positive, neutral, or negative causal effect between CSP and CFP, the main premise in this paper is that a paradoxical link exists between CSP and CFP. There are, in effect, two hypotheses: one that posits a short-term, negative effect of CSP on CFP, and the other that proposes a lagged, positive effective of CSP on CFP:

H_1: The link between CSP and CFP in the long-term is positive.

H_2: The link between CSP and CFP in the short-term is negative.

The intention is to identify how CSP affect CFP in the short and long-term. The hypotheses can be conceptually illustrated in Fig. 1.

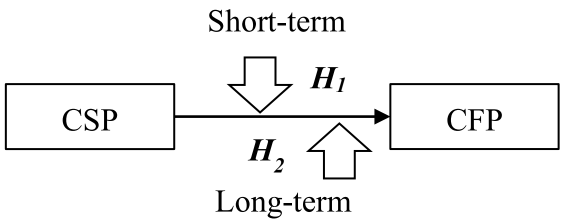

Fig. 1 Illustrated Conceptual Model

The hypothesized paradoxical relationship between CSP and CFP in this paper is different from those studies exploring a curvilinear (U-shaped) or an inversely U-shaped curve between CSP and CFP (e.g. Barnett and Salomon, 2006). For example, although Barnett and Salomon (2006) recognized that the basic issue concerns whether the costs of social responsibility are offset or exceeded by financial returns over some period of time, they hypothesized and tested the curvilinear relationship between CSP and CFP by using an ordinary least squares test without considering the lead-lag effects. The research is also different from those studies looking at the nexus between sustainability and financial performance, or in entertaining words 'when does it pay to be green'. The difference lies in the fact that the terms, CSR or sustainable development, are different, although when operationalizing the concepts, managers tend to treat them as similar, if not entirely identical (Lu *et al.*, 2014).

4. International Construction Business

The hypothetical paradoxical link between CSR and CFP will be tested within the context of 'international construction business (ICB)'. According to Ngowi *et al.* (2005), international construction is defined as the part of construction business that is undertaken by companies working on projects outside their home country; it concerns when a company resident in one country performs work in another country. Once seen as a local activity, the construction business today is fast becoming an internationally interdependent marketplace (Yang and Lu, 2013). To give an example of the scale of this business, *Engineering News-Record* (ENR) statistics show that the ENR Top 250 International Contractors (TIC 250) lodged US$511.05 billion in contracting revenue in 2012 from projects outside their home countries, along with US$813.55 billion in revenue from domestic projects (Tulacz, 2013). Advanced technology, fast transportation, convenient communication, effective knowledge transfer, integrated markets, and trade liberalisation have all helped construction companies transcend traditional national boundaries and enter the international arena (Yang and Lu, 2013).

When looked at in the context of CSR debate, probably no industry offers up as many paradoxes as construction CSR (Lu *et al.*, 2015). On the one hand, the construction industry has an inherent social responsibility; it materializes the built environment, making an important contribution to the national economy, and providing a large number of jobs (Hillebrandt, 1984). On the other hand, construction is intrinsically 'irresponsible'; it competes with the natural environment and can have an adverse impacts upon it, including land degradation, greenhouse gas emissions, resource depletion, waste generation, and various forms of pollution (Ofori, 1993). The conjunction of these paradoxes has brought CSR to the fore. CSR it is now growing in prominence as a core issue confronting the construction industry and its organizations (Murray and Dainty, 2008).

The above paradoxes relating to CSP-CFP nexus are particularly evident in international construction. CSR practices travel with international construction companies (ICCs) and influence other countries with the increasing globalization of construction business. Indeed, in analysing top ICCs' CSR disclosure trends and future prospects, Lu *et al.* (2015) discovered that the firms spent great deal of efforts on CSR when they conducted international business. Yet, the difference of cultural/institutional background between the home and host countries further complicated the paradoxes. ICCs from economically developed countries are normally required "central compliance". The ICB is certainly a positive development in terms of value creation, knowledge exchange, and resource configuration and optimization. However, the ICB is also criticized as being relatively irresponsible, given the embodied energy and the carbon emissions associated with mobilizing resources across continents. It thus provides an interesting lens through which the paradoxes of CSR can be fruitfully investigated.

5. Data, Samples, and Measures

The data used to test the hypotheses was collected from several sources. The initial sample came from the Environmental, Social and Governance (ESG) Intangible Value Assessment (IVA) index tracked by the Morgan and Stanley Capital International (MSCI). MSCI offers kinds of products and services indexes, such as the IVA indexes, to provide research and ratings of corporate management of environmental, social risk factors, and other CSR activities. Companies from industries related to construction were selected according to the Global Industry Classification Standard (GICS) developed by the MSCI. This included ICCs such as Hochtief AG from the construction and engineering industry, CRH plc from the construction materials industry, and Cummins Inc. from the construction and farm machinery industry. The MSCI began to rate ICCs in 2002. The amount of firms rated was small at the beginning bit it increased steadily. Our starting sample represents a balanced panel of 34 ICCs from 2006 to 2013, i.e. 34 ICCs over the period of 2006-2013 have been consistently rated in terms of their CSR performance by the MSCI and the data was realised via the ESG IVA index.

Secondary data was collected from various sources for measuring ICCs' CFP. Basic financial data for each firm were gleaned from their annual reports or financial reports. These reports were retrieved from their websites or other databases like Morningstar.com and Bloomberg.com, since most of the ICCs are publically listed companies in various stock exchange markets and they have to reveal data and maintain the integrity of the data to its shareholders to comply with the law. When we matched the financial data with the MSCI ESG data, we lost four firms due to missing data. This left us a final usable sample that is a balanced panel of 30 ICCs from 2006-2013.

CSP is used as a measurable substitution of CSR. The majority of CSP-CFP studies uses CSP databases developed by third parties, so does this study. MSCI rate firms' CSP based on three criteria: environmental, social, and governance pillars. For the environmental pillar, the MSCI considers carbon emissions, toxic emissions and waste, and opportunities for clean technology as the key issues. Corruption and instability, and health and safety are regarded as the key issues for the social pillar criterion. Key indicators of the governance pillar criterion include audit, board structure, shareholder rights, compensation, and transparency. The weights of key issues in each GICS sub-industry are set according to the industry's relative contribution to the externality of each issue, as well as the time frame to internalize these costs. According to the MSCI industry report of the construction industry, for example, the Construction & Engineering industry ranks above the 90th percentile of all sub-industries in terms of employee accident and fatality rates, which is thus categorised as a High Contribution (MSCI, 2015). Firms receive weighted average scores every year based on the performance scores and weights of the three criteria. The score range for a firm's CSP is within 0-10.

CFP measurement remains the subject of contentious debate in CSP-CFP nexus research. Orlitzky *et al.* (2003) list various CFP measures in 52 studies, and the widely used profitability measures include ROA (return on assets), ROE (return on equity), profit margin, EPS (earnings per share) etc. They converge the CFP measures into three broad subdivisions, namely market-based (investor returns), accounting-based (accounting returns) and perceptual (survey) measures. Following Lu *et al.*'s (2014) suggestion to use more objective CFP measures and depending on data availability, we selected accounting-based indicators, such as the firm's return on assets (ROA), return on equity (ROE) or earnings per share (EPS) and market-based indicators, such as the stock return (SR) or price-earnings ratio (P/E). Following many researchers, such as Waddock and Graves (1997), Barnett and Salomon (2012), we finally choose the ROA as the major CFP measure in this paper.

Control variables are needed for the CSP-CFP nexus analyses, given that CSP will not explain all the variations in CFP across companies. Andersen and Dejoy (2011) summarized that size, industry, risk, RD and advertising expenses are the most commonly used control variables in explaining the CSP-CFP relationship. Lu *et al.* (2014) found that capital structure is often adopted as control variable in the paper under their review. All the firms in the sample are from the construction industry so industry as a control variable makes little sense. Mainly for practical reason, firm size and capital structure are selected as the control variables in this study. Market capitalization of stocks is usually adopted as the measure of firm size. The stocks of large, medium and small companies are referred to as large-cap ($10 billion plus), mid-cap ($2 billion to $10 billion), and small-cap (less than $2 billion). We define debt/equity ratio as the firm's total debts divided by equity to control the capital structure of the firm. This ratio can reveal the managers' preference of financing as well as measuring the risk of the firm. In this regard, risk is also considered a control variable in this study.

6. Results and Analyses

The panel data model is analysed by R software (R Development Core Team 2008), which is an open source statistical analytical software program. The "plm" package in R software is chosen for the panel data analysis.

6.1 Stationarity test

Before the panel data analysis, the first step is to test the stationarity of the variables. A stationary process has the property that the mean, variance and autocorrelation structure do not change over time. If the data of the variable contains a trend, the results of regression could not be fully credibility without isolating the effects of the trend. Stationarity of the variables is tested by a unit root test (Maddala and Wu, 1999), which is one of the common ways to perform the task. Maddala-Wu unit root test model is chosen for this study. Maddala and Wu (1999) proposed that use of the Fisher (p_λ)

test which is based on combining the *p*-values of the test-statistic for a unit root in each cross-sectional unit. In *R* software, *purtest* implements several testing procedures that have been proposed to test unit root. The results are shown in the Table 1.

Table 1 Stationarity test of the panel data using the Maddala-Wu unit root test model

	Maddala-Wu unit root test						
Variables		***Chi Square***	***Degree of freedom (df)***	***Order***	***method***	***p-Value***	***Results***
CFP	*ROA*	*52.5334*	*2*	*0*	*trend*	*3.913e-12*	*Stationarity*
CSR	*CSP*	*49.4894*	*2*	*0*	*trend*	*1.793e-11*	*Stationarity*
Control Variable	*D/E ratio*	*29.7743*	*2*	*0*	*trend*	*3.425e-07*	*Stationarity*
	MC	*28.7758*	*2*	*0*	*trend*	*5.642e-07*	*Stationarity*

Notes: 1. ROA=return on assets; D/E ratio=debt/equity ratio; and MC=market capitalization. 2. Alternative hypothesis of test is stationarity.

The results in Table 1 show that Maddala-Wu unit root test with the method of trend is used and the null hypothesis is non-stationarity. Since the *p*-values for all the indicators are smaller than 0.001, they indicate that the variables in the panel are stationary and ready for the further analysis.

6.2 Results of long-run equilibrium relationship

To test *Hypothesis 1*, panel data models are used directly to estimate the equilibrium relationships between CSP and CFP in the long-term. The equation for testing the long term equilibrium relationship between CSP-CFP is shown as follows:

$$CFP_{it} = CSP_{it} \times \beta + DE_{it} \times \alpha + FirmSize_i \times \gamma + Z_i \times \theta + \varepsilon_{it} \qquad \text{Eq. (1)}$$

(i=1, 2… 30; t=2006, 2007… 2013)

where the subscript i indicates individual firm, t represents the time (years), CFP_{it} is the dependent variable (using ROA as the indicator), CSP_{it} is the independent variable, DE_{it} and $FirmSize_i$ are two control variables, DE_{it} is the Debt/Equity Ratio while $FirmSize_i$ is represented by Market Capitalization, β, α and γ are the coefficients of CSP_{it}, DE_{it}, and $FirmSize_i$, $Z_i \times \theta$ is the heterogeneity term, Z_i could be a constant term or a group-specific constant term or a group-specific random element, θ is the coefficient of Z_i, and ε_{it} is the error term.Various available panel data analysis models are compared using the results of the three tests (Lagrange Multiplier Test, f test, and Hausman Test) mentioned above. By strictly following Kunst's (2009) comparison method, the fixed model is tested to be better for estimating the impact of CSP on CFP, i.e., ROA in the long run. Results of the long-run equilibrium relationship using the fixed model are shown in Table 2.

Table 2 Results of long run equilibrium effects of CSP on CFP

Dependent variable: ROA (fixed model)				
	Estimate	*Std. Error*	*t-value*	*p-value*
CSP	*0.0056*	*0.0019*	*2.9000*	*0.0041***
D/E ratio	*-0.0009*	*0.0021*	*-0.4008*	*0.6890*
MC	*0.0013*	*0.0004*	*3.1651*	*0.0018***
R-squared: 0.1004 Adj. R-squared: 0.0866 F-statistic: 7.7014				
*p-value: 6.663e-05 Signif. Codes: 0 '***', 0.001 '**', 0.01 '*', 0.05 '.'*				

CSP is found to have a positive and statistically significant (*p*-value= 0.0041) impact on ROA in the general model with β equal to 0.0056, which means CSP in general would improve the financial performance, represented by ROA. Therefore, the general equation for the long-term equilibrium relationship between CSP and ROA (Eq. 1) can be written more specifically in *Eq.(3)*. The *p*-value of the long term model equals to 6.663e-05, which is much smaller than 0.001, showing good results in testing *Hypothesis 1*. The hypothesis that CSR will be conducive to improving corporate financial performance in the long term is thus supported.

$$ROA_{it} \sim 0.0056 * CSP_{it} + 0.0013 * FirmSize_i \qquad Eq.(3)$$
$$i = 1,2,\dots,30, t = 2007,2008,\dots,2013, CSP \in [1,10]$$

6.3 Results of short-run effects test

To test *Hypothesis 2*, interactive effects of CSP in each year are added into the panel data analysis, which indicate the effects of CSP in specific year on CFP. The equation is shown as follows:

$$CFP_{it} = CSP_{it} \times \beta_0 + \sum Factor(year) \times CSP_{ij} \times \beta_j + DE_{it} \times \alpha + FirmSize_i \times \gamma + +Z_i \times \theta + \varepsilon_{it} \qquad Eq.(2)$$

(*i*=1, 2… 30; *t*=2006, 2007… 2013; *j*=2007, 2008… 2013)

where the subscript *i* indicates individual firm, *t* represents the time (years), *j* represents the years using interactive effects (all years except 2006, which is regarded as the basis year), CFP_{it} is the dependent variable (using ROA as the indicator), CSP_{it} is the independent variable, $Factor(year) \times CSP_{ij}$ is the interactive items of each year times CSP, DE_{it} and $FirmSize_i$ are two control variables, DE_{it} is the Debt/Equity Ratio while $FirmSize_i$ is represented by Market Capitalization, β_0, β_j , α and γ are the coefficients of CSP_{it}, the interactive items, DE_{it}, and $FirmSize_i$, $Z_i \times \theta$ is the heterogeneity term, Z_i could be a constant term or a group-specific constant term or a group-specific random element, θ is the coefficient of Z_i, and ε_{it} is the error term. Various available panel data analysis models are compared using the results of the three tests (Lagrange Multiplier Test, f test, and Hausman Test). The fixed model is tested to be the best for estimating the impact of CSR on CFP (i.e., ROA) in the short term. Results of the short-run effects test using the fixed model are shown in Table 3.

Table 3 Results of short-term effects of CSP on CFP

Dependent variable: ROA (fixed model)					**Dependent variable: ROA (fixed model)**				
	Estimate	*Std. Error*	*t-value*	*p-value*		*Estimate*	*Std. Error*	*t-value*	*p-value*
CSP	*0.0053*	*0.0021*	*2.5326*	*0.0121**	***Factor(2011) *CSP***	*-0.0017*	*0.0010*	*-1.7219*	*0.0866`*
Factor(2007) *CSP	*-0.0002*	*0.0010*	*-0.2249*	*0.8223*	***Factor(2012) *CSP***	*-0.0024*	*0.0011*	*-2.2157*	*0.0278**
Factor(2008) *CSP	*-0.0002*	*0.0010*	*-0.2171*	*0.8283*	***Factor(2013) *CSP***	*-0.0034*	*0.0011*	*-3.1438*	*0.0019***
Factor(2009) *CSP	*-0.0030*	*0.0010*	*-2.9855*	*0.0032***	***D/E ratio***	*-0.0026*	*0.0021*	*-1.2531*	*0.2116*
Factor(2010) *CSP	*-0.0023*	*0.0010*	*-2.2350*	*0.0265**	***MC***	*0.0015*	*0.0004*	*3.5127*	*0.0005****
R-squared: 0.1887 Adj. R-squared: 0.15725 F-statistic: 4.6518									
p-value: 5.7636e-06 Signif. Codes: 0 '', 0.001 '**', 0.01 '*', 0.05 '`'***									

As shown in Table 3, all the interactive items, representing CSR in each year, show the negative impacts on ROA, which means CSR implementation in short-term is detrimental to CFP. Thus, *Hypothesis 2* is supported.

7. Discussions and Conclusions

Owing to its theoretical and practical significance, the intellectual debate on the nexus between corporate social performance (CSP) and corporate financial performance (CFP) is incessant. It is hardly new for existing studies to recognise the positive, negative, neutral or even the non-linear, dynamic, and multidirectional relationships between CSP and CFP. However, it seems that no one has attempted to integrate the CSP-CFP nexuses into a refined theory capable of accounting for their seemingly paradoxical dynamics. Originated on the both sides of the Atlantic, CSR has travelled with construction business when it traverses traditional national boundaries into the international arena. International construction companies nowadays use it as a 'soft power' for market penetration. This paper, by focusing on the international construction business sector, found that indeed CSR is slightly detrimental to CFP in the short term but will be conducive to CFP in the long term. At the beginning, CSR programmes are in the nature of competing scarce resources possessed by the firms, such as capital, entrepreneurship, manpower, time, and management efforts while the benefits might not be able to be cultivated in short term. After a certain period of time, the CSR programmes, though competing scarce resources too, may bring long-term benefits, e.g. after experienced the learning curve, by developing reputation, or improving business relationships.

The research provided a fresh perspective to the moot question regarding the CSR-CFP link. With the introduction of time into the equitation, the traditional negative and positive relationships are now conceived as complementary rather than opposing. It goes beyond the allies-and-adversaries dichotomy towards a theory of paradoxical dynamics between CSR and CFP. The research can also enrich the classic discussions of firm's boundary. Particularly, new institutional economics asserts that certain economic tasks, if add to the transaction cost, should be excluded from the boundary of a firm, and they should be performed by the market (Coase, 1930; Williamson, 1991). Given the fact that CSR does consume firm's resources, many scholars thus believe that CSR should be excluded from the boundary of a firm. Many have misunderstood Friedman, assuming he was against CSR as he famously argued that socially desirable goals, if at the expense of profitability, should be disconnected from a company's fiduciary responsibilities (Friedman, 1970). This research shows that with discretional management, CSR could reduce transaction cost, e.g. by developing a harmonious relationship with stakeholders so as to guarantee key resources, or by developing a reputation. Business executives should focus no more on "whether conducting CSR or not" but on how to properly manage CSR as the allies of CFP.

A significant practical use of this research is that it provides to business executives to be relieved from short-termism when they devise CSR strategies to achieve business success. Most contemporary firms are set up and governed based on old firm theories, such as profit maximization, and shareholders' profits are protected by law while stakeholders' benefits, though important too, are bound by 'social contracts'. With these firm-related ideology, it is a natural thinking for shareholders to emphasize maximizing their profit effectively and efficiently. In a competitive business world, this is translated to the perpetual burden of business executives to justify their CSR strategies with higher CFP. This research suggests that CSP may not immediately lead to higher financial performance. Instead, at the beginning, CSP may jeopardize a firm's financial performance. Shareholders should take a long-term stance to their CEO's CSR strategies.

Abstract

Occupant questionnaire data were collected both before and after retrofitting of 38 Finnish multifamily buildings and eight control buildings. One adult per apartment (an average of about five apartments per building) was asked to fill in a questionnaire about occupant perceived housing satisfaction, health and wellbeing, as well as occupant behaviour. A total of 234 occupants (response rate 94%) answered to the first questionnaire (baseline), and 187 (75%) answered to the second questionnaire (follow-up). In this paper, we aim to describe occupants' perceptions on their housing and self-reported health symptoms, and to assess the effects of retrofits improving energy efficiency of the buildings on occupants' perceptions if indoor environmental quality and health.

Keywords: apartment buildings, indoor environmental quality, noise, thermal comfort

1. Introduction

Collecting information directly from the occupants is an important part of building and indoor environmental quality (IEQ) assessments. Overall, collecting information from the occupants using structured interviews or questionnaires can be useful when assessing ways to improve occupants' satisfaction with their housing conditions, and also in larger scale population studies where sample size is sufficient for group level (statistical) analyses. Limitations of occupant surveys include that they provide subjective measures prone to bias (e.g., misclassification, self-selection bias), and dependent errors (Rothman et al. 2008).

There exist a few energy retrofit intervention studies, which have included assessments of health outcomes. In UK, a review of the impacts the Warm Front program provided evidence of that the home energy improvements conducted were accompanied by appreciable benefits in terms of use of living space, comfort and quality of life, physical and mental well-being (Gilbertson et al. 2006). In Germany, Frankfurt housing intervention study concluded that renovation and insulation activities did not appear to be in conflict with the health of residents (WHO 2008).

Outside Europe, a cluster randomised study was conducted to evaluate effects of insulating existing houses on health in New Zealand. It was reported that insulating houses led to a significantly warmer, drier indoor environment, and resulted in improved self-rated health, self-reported wheezing, days off school and work, and visits to general practitioners as well as a trend for fewer hospital admissions for respiratory conditions (Howden-Chapman et al. 2007). In addition, a recent study from the US assessed low-income housing development renovated in accordance with green healthy housing improvements, reporting improved self-reported general health among adults (Jacobs et al. 2015).

This paper focuses on results from housing and health questionnaires collected from Finnish apartments as a part of INSULAtE-project (www.insulateproject.eu).

2. Material and methods

Study buildings were drawn from several regions in Finland (Tampere, Hämeenlinna, Imatra, Helsinki, Porvoo, and Kuopio). Participating multi-family buildings were chosen among buildings with planned retrofits improving energy efficiency during the project (2010-2015). In addition, some control buildings, which had no plans for retrofitting, were included. Recruited apartments were selected from volunteering occupants, who did not receive any compensation for their time participating in the study. The study plan was evaluated and approved by the National Institute for Health and Welfare's Ethical Research Working Group in Finland.

About 80% of the buildings were constructed between 1960 and 1980, and majority of them had mechanical exhaust ventilation (<10% had natural ventilation). Most common retrofitting activities included changing windows, adding heat recovery to the ventilation systems, adding thermal insulation to the building envelope, and changing heating systems.

Information about housing and health was collected from the occupants by questionnaires developed based on previous studies (Turunen et al. 2010). The questionnaire comprised of 49 questions related to the building and living environment; physical, biological, and chemical conditions; hygiene; occupant behaviour, health and well-being; and background information. One adult per apartment was asked to fill in the questionnaire on two occasions: first at the baseline (corresponding to the situation before retrofits in the study buildings) and second (follow-up) questionnaire usually about one year later (corresponding to the situation after retrofits in the study buildings). A total of 234 and 187 people (response rates 94% and 75%) answered to the first and second questionnaires, respectively. In addition to the questionnaires, comprehensive IEQ assessments were performed by trained investigators, who conducted measurements in each apartment (data not shown). Table 1 shows some background characteristics of the respondents and their apartments.

Table 1: Questionnaire respondents' background characteristics.

P-values shown in the tables are referring to the statistical testing of group level differences between first and second questionnaires using chi-square test. The test does not take into account the dependency between the samples, i.e. the fact that in most cases the respondents were same at the baseline (1st questionnaire) and follow-up (2nd questionnaire). Therefore, the test results are only used for screening purposes. With respect to selected variables, where significant differences were found on the group level, the results were further analysed using General Estimating Equations (GEEs). These multivariate models were fitted with unstructured covariance structure and binominal link-function. In the models, individual responders and buildings, as well as time of questionnaire were identified by the ID-, building-, and time -variables, and respondents' gender and age were included.

We also tested the differences between the control and study buildings using chi-square test, but these results should be treated with caution due to small number of respondents from control buildings. At the baseline (1st questionnaire), a larger proportion of the respondents in the study buildings were females, and kept furry pets indoor less frequently than the respondents in the control buildings. On the other hand, the respondents in the control buildings were significantly more often tenants, they were younger, and had lived in their current apartment a shorter period of time, and had less children living in their apartments. Mechanical air supply and wood burning fireplace were more common in the control buildings. At the follow-up (2nd questionnaire), the differences between study and control buildings remained significant for tenure status and number of children living in the apartments. In addition, the respondents from the study buildings reported exercising more frequently.

Based on the preliminary screening, the respondents from the study buildings reported higher proportion of apartments having covered balcony, trickle vents, and mechanical supply air after retrofits (2nd questionnaire) as compared to the baseline (1st questionnaire), which changes are corresponding with the targeted energy retrofit actions. Also saunas were significantly more common in the study buildings after retrofits.

3. Results

Results related to occupant self-reported thermal conditions are shown in Table 2. Occupants from the control buildings reported significantly less opening windows daily in the living room as compared to the occupants from the study buildings at the baseline (1st questionnaire), and a similar (non-significant) trend was seen in the winter. At the follow-up (2nd questionnaire), occupants from the study buildings reported significantly higher temperatures during heating season as compared to the occupants from the control buildings.

* Further analysed with GEEs

In the study buildings, the respondents reported slightly higher indoor temperatures after retrofits as compared to the situation before retrofits, but the group level differences were not significant. Similarly, reporting too hot summer temperatures was less frequent among respondents from study buildings after retrofits, as well as reporting of draught during winter.

There was a significant pre - post retrofit difference among respondents in the study buildings in reporting opening windows daily for temperature control in summer in their living room. The difference remained significant in the GEE model including respondents' age and gender. The trend was similar for other rooms and also during winter in the study buildings, whereas an opposite trend was seen among the respondents from the control buildings.

Table 3 shows results related to dampness and mould, odours, lighting, and noise. At the baseline, respondents from the control buildings reported significantly less frequently odours related to food, and daily noise disturbance related to traffic or industry, as compared to the respondents from the study buildings. At the follow-up, respondents from the study buildings reported odour related to tobacco smoke significantly less frequently.

* Further analysed with GEEs

Reporting of odours appeared to become less frequent after retrofits in the study buildings. The group level differences were statistically significant for odours of tobacco, stuffiness, and sewage smell. The differences for stuffiness remained significant in the GEE model including respondents' age and gender. Daily noise disturbance related to the dwelling and HVAC systems appeared to become more frequent, whereas disturbance related to traffic or industry was reported significantly less frequently. These differences were statistically significant in the GEE models including respondents' age and gender.

As indicated in Table 4, occupants from the control buildings were more satisfied with indoor air quality (IAQ) and maintenance at the baseline, and they reported less upper respiratory symptoms and eye symptoms. They also related symptoms to home environment less often than the occupants from the study buildings. They missed days from work or school less frequently. At the follow-up, the differences between the control and study buildings appeared to diminish.

*[a] Daily / weekly [b] within the last 12 months * Further analysed with GEEs*

The respondents in the study buildings were significantly more frequently satisfied with IAQ and maintenance than before retrofits, and they were less frequently planning to move, whereas an opposite trend was seen in the control buildings. Respondents in the study buildings reported significantly less weekly upper respiratory symptoms and a similar trend was seen for lower respiratory symptoms. Reporting of respiratory infections, doctor visits and missed work or school days were also reduced. The differences with respect to satisfaction with IAQ and upper respiratory symptoms remained significant in the GEE models including age and gender.

4. Discussion

Drawing conclusions based on questionnaire data requires careful analyses and interpretation. Occupant self-reporting is subjective and prone to reporting bias. There are, however, some ways to increase objectivity: e.g. using questions that specifically ask about matters that can be validated, such as doctor diagnosed diseases, and missed work/school days due to illness.

Due to numerous factors that influence human health and well-being, a large enough sample size is needed to draw conclusions about the empirical relationships between housing conditions and occupant health. The required sample size is primarily based on the need to have sufficient statistical power. There are many methodological difficulties inherent in assessing the health effects of housing that need to be carefully considered. For example, response rates are often low, which can limit the possibility to draw conclusions and generalize the results.

On the group level, our sample size appears to be sufficient to detect relatively large differences (>10% difference in the prevalence values) between the sub-samples. However, group level comparisons may be inconclusive, as there are many confounding factors that have to be taken into consideration. It appears that our sample size with respect to questionnaire data may be limited with respect to drawing definite conclusions on the potential effects of energy retrofits on occupant health and wellbeing, but it could be used to develop tools to follow-up effects of national programmes and policies that are aiming to improve energy efficiency of buildings, particularly with respect to occupants' satisfaction. Future analyses will also provide additional information about associations between occupants' self-reported and measured IAQ, which can be used for validation purposes.

National Institute for Health and Welfare has also conducted so called "National housing quality, health and safety survey", where questionnaire data have been collected from random samples of 3000 household-dwelling units in 2007 and 2011 (Anttila et al. 2013, Pekkonen & Haverinen-Shaughnessy 2014). The results of the survey can be useful as reference material, regarding to housing and health conditions in Finland.

5. Conclusions

INSULAtE-project has developed a comprehensive assessment protocol aiming to demonstrate how improving energy efficiency in buildings impacts on indoor environmental quality and health outcomes. The protocol includes occupant questionnaires, which could be utilized when assessing the effects of improving energy efficiency of the housing stock. Changes were observed in occupant satisfaction with the dwelling and IAQ, perception of odours, daily noise disturbance related to HVAC systems and traffic or industry, as well as respiratory symptoms and missed work or school days, which could be related to the retrofits, although further studies are needed to verify the associations.

Acknowledgements

INSULAtE-project is co-financed by EU Life+ -programme and Finnish Energy Industries. The authors would like to thank the occupants who participated in the study.

Abstract

The goal of this paper is to provide an overview of the defensive and supportive projections of users towards perspective of social usability during the change processes of an academic workplace. The significance a university's staff attributes to relational aspects during the change process of a workplace was studied at the University of Jyväskylä, in a situation where a faculty and a research institute were moving into a new building. The workplace process was carried out through co-designing. An interview survey of the key persons (N=12) was conducted. These persons acted as mediators of information between employees, architects and designers. The results revealed several tensions relating to social usability and the importance of experiencing safety and trust during the process. Also professional identity is reflected during the workplace change. End-user satisfaction is closely related to the individuals' experiences of relational factors attributed to communication and collaboration. It is especially important in the change process of a workplace. Moreover, it is very culturally sensitive both to express and interpret who knows the needs of the users "best". Therefore, it is a very complex phenomenon: attempts to improve the culture of working needs those who lead the way of change. Otherwise it is too tempting to remain stagnant within a comfort zone. The agents of change partially exist inside the working community, but for the most part, the need for change can be found from the group consisting of the built environment professionals, the employer and the owner of the property.

An academic community is naturally accustomed to influencing its professional field but is much less so when dealing with factors beyond that field. Keeping this in mind, we must note that the arena of influencing the built environment that should reflect your professional expertise is a new one. Therefore, an academic community may at first have problems influencing these environments in an expedient manner. Research-based knowledge and a deeper understanding of the processes that build mutual trust are crucial. Therefore, a better base of knowledge and understanding of social processes is required.

Keywords: usability, user experiences, change within an academic workplace, co-creation

1. Introduction

Even though they carry the considerable weight of tradition, universities and academic workplaces are in a state of transformation. They must reflect and support the skills and attitudes needed in the 21st century. The requirements and need are not easily defined without the perspective of a future-orientated user. According to den Heijer (2011) the most important considerations that the campus of the future should incorporate/reflect are e.g. less individual territory and more shared space as well as considerations in terms of place independency: due to developments in ICT, people can work wherever is best for them. Various generic models are suggested for academic offices for example as 'studies, quarters, clusters, hubs and clubs' but that an appropriate workplace solution should be developed 'based on an in-depth understanding of the work activities of the people involved' in the workspace (Harrison and Hutton, 2014, 163).

Especially when considering the scenarios of the work and work environments of the future, the space should be seen as a multi-dimensionally structured one, containing social, emotional, physical and intellectual features. Existing spaces seldom support all these levels of work in the future. The future of academic workplaces needs dynamic communities that offer participative and collaborative spaces for knowledge sharing, creativity and learning. (See Jääskelä, Klemola, Kostiainen and Rautiainen, 2012; Rautiainen and Kostiainen, 2015.) Therefore, a fresh evaluation of usability of places from the perspective of social usability, meaning the usability of the social place, is worth to investigate: how the diverse features and artefacts of a built environment support emotional experiences and relational processes. The aim of this paper is to explore the defensive and supportive projections of users towards the perspective of social usability during the change processes of an academic workplace.

2. Theory

2.1 Perspective of Social usability

The International Council for Building Research and Documentation (CIB) working group on the usability of workplace (W111) has been exploring concepts, methods and tools, developed in the evaluation of all kinds of consumer products, applied to the built environment (Alexander, 2006; 2008; 2010). The intention has been to identify and evaluate how to design and manage the relationship between activities and space. Usability in the built environment is context dependent and related to user experience, social relations amongst users and to the interaction between users and facilities. Usability has found to be strongly related not only to relationships between people and physical settings, but also to clarify strategies for the organization regarding work and the use of facilities. Usability is 'a cultural phenomenon that can only be improved through better understanding user experience, considered as situated action in a specific context' (Alexander, 2008, 6). Usability is social by its nature and the perspective of social usability focus on user experience and understanding the relationship between individual, place and social community connected to the context. Language and communication are important factors in studying the user experience and understanding the social layout of the place (Airo 2014; Airo, Rasila and Nenonen, 2012).

2.2 The social dimension of work

Finnish organizations and university campuses are increasingly building multifunctional spaces (e.g. Future Campuses, 2011; Ruohomäki, Lahtinen, Haapakangas and Reijula, 2014). When considering the perspective of social usability of the workplace – especially the sense of community, knowledge sharing and meanings given to it – it is noticed in previous research that multifunctional spaces increase social interaction (Davis, Leach and Clegg, 2011; De Croon, Sluiter, Kuijer and Frings-Dresen, 2005; Vos and van der Voordt, 2002) and perceptions of forthcoming workplace changes also seem to focus on spaces where collaboration is supported (Ruohomäki et al, 2014, 709). The social dimension of the work and the meaning of interaction, collaboration and competence in communication become clear when we examine how work is performed in today's knowledge-intensive work culture. Academic work that is based on shared expertise, knowledge processing, networking, mobility and globalisation, poses a serious challenge to the meaning and relevance given to a social dimension of the work: communication and collaboration are not merely a tool – they are rudimentary requirements for work.

Jobs require comprehension and control of processes that are fundamentally communicative: collaboration is how work is done - e.g. work is done through teams or networks, or is performed interactively. Knowledge and understanding is created and shared and the work result - instead of concrete products or performance – is increasingly in the form of pooled ideas, and is the outcome of collaboration (e.g. specialised problem solving). Work no longer speaks for itself (work is not a material product), and an employee must be able to uphold the "results" of his or her work, often consisting of abstract ideas or shared processing of data (see Kostiainen, 2003). The origination, distribution and approval of common meanings - and learning what is new - are based on interaction, so that work performance requires multi-faceted familiarity with and confidence in collaborative processes both nationally and globally (e.g. Curtain, 2000; FinnSight 2015, 2006). However, collaborative orientation to work does not 'transfer' with employees from old environment to new or form an essential part of the work employees do, unless its meaning becomes relevant to them. Although interaction is permanently part of employee routine, it is too often taken for granted that people at work can communicate or collaborate, and is rarely given profound consideration. Therefore a fresh perspective of social usability of the workplace and its evaluation - meanings university staff attribute to collaboration and knowledge sharing – is called for in the studies concerning the forthcoming changing of the workplace.

3. Method

3.1 Research questions and data description

Previous research on usability has used case-studies in order to define the concepts of usability and to support the process of usability research (e.g. Alexander, 2008, 7-8). This case-study aims to improve the understanding about defensive and supportive relational processes and defining concepts related to the perspective of social usability of workplace. This study seeks to answer the following questions:

1) What are the defensive and supportive projections towards relational processes and experiences during the design-phase of the new work space?
2) What phenomena could explain the perspective of social usability?

An interview survey of the key informants (N=12) was conducted. The study included a total of ten interviews (two pair-interviews) with people from the University of Jyväskylä. The interviewees were chosen as module co-ordinators by the facility team consisted of faculty administration and construction team. All module co-ordinators had been involved in the planning of their own module (dice) - the section of the new building where the particular group of employees were placed. They were acting as key persons who were mediators of information between employees and architects and designers.

The interviews were carried out as semi-structured qualitative interviews using an interview guideline with about 25-30 questions divided into seven themes: (1) the overall expectations as well as expectations related (2) to work, (3) to the new building and space, (4) to collaboration, (5) to wellbeing and enthusiasm, (6) to the image of their own organization and (7) experience of possibility to influence. Questions were framed as open as possible. All interviewees were asked the same questions, but ordering the questions was flexible and followed the progression of the conversation. Additional questions were asked dependent on what interviewees brought into question. Each interview lasted about one hour and were recorded. Blakstad et al (2010, 23) states that in order to gain useful information about the usability of the building it is important to relate the users' experiences to certain space or place and to specific physical surroundings. In this case study, the new building was under construction and some of the future users had had an opportunity to visit the construction site. In the interview situation, all interviewees had a copy of a floor plan where they and their colleagues are going to move within one year. Just before the interviews the employees had got information about their placement in the new building.

3.2 Data analysis

The thematic analysis frame of Braun and Clark (2006) was used in data analysis. The data was analysed step-by-step consisting of three interactive sub processes. The first, data reduction phase consisted of generating initial codes where the process of systematic coding (Miles and Huberman, 1994) was applied. The second phase of the analysis was searching for themes and all the codes were collated into potential themes. Also the comprised themes were reviewed against the first phase initial codes' themes. Finally, defining and naming themes and the drawing of conclusions were implemented (see Table 1). In the first, data reduction phase the qualitative interview data was reduced into a manageable form by generating initial codes by using an ATLAS.ti analysis program. The codes were used as the units of organizing the qualitative data in a way that the initial codes were formed through the re-reading of the data. The data was coded according to defensive, supportive and neutral projections concerning social usability. After categorizing the data into these three dimensions the qualitatively different ways of experiencing the phenomena either positively, negatively or neutrally were the more detailed units (e.g. sentence or phrase) of analysis (see Marton, 1994). As a result of the first analysis phase altogether thirteen sub-code categories were created to which interviewees' experiences were interpreted as connecting (see Table 1).

Table 1: The phases of analysis

Phase 1: Generating initial codes			***Phase 2: Searching and reviewing themes***	***Phase 3: Defining and naming themes***
Supportive projections	*Defensive projections*	*Neutral projections*	*Thematic tensions between experiences and expressions*	*Interpretation, identifying the central findings*
Social orientation, collaboration			*Need for change – the claim/concern of stability* *The sense of ownership – the sense of detachment* *Efficiency – inefficiency* *The sense of being heard – the sense of being dismissed* *The sense of being valued – the sense of being valueless* *Rationality – sensibility* *Social – privacy*	*Experience of safety (high – low)* *Experience of trust (high – low)* *Professional identity (individual – collective)*
New possibilities, innovations				
Clean and healthy work environment				
Enthusiasm				
Privacy, peace and quietness	*(Lack of) privacy, peace and quietness*			
The sense of ownership	*(Lack of) ownership*			
Stability	*Stability*			
Status, hierarchy	*Status, hierarchy*	*Status, hierarchy*		
Informing, instructions	*Informing, instructions*	*Informing, instructions*		
Work practices	*Work practices*	*Work practices*		
	Various fears, anxiety			
	Placement	*Placement*		
	Physical space, layout			

The first phase analysis revealed that the same matters, occasions or events could have both supportive and defensive as well as neutral projections. Although the interviewees experienced certain matters either largely positively or negatively it was apparent that in the same interview the same matters could be expressed both defensively or supportively. As a consequence of this finding, the thematic tensions between experiences and expressions were studied in the second phase of analysis. Analysis revealed in total seven thematic tensions. Finally, in the third phase defining and naming the meta-themes was the systematic process of interpretation, identifying the central findings, the conclusion drawing of the organized data. Three meta-themes behind the thematic tensions were identified as experience of safety (high-low), the experience of trust (high-low) and the professional identity (individual-collective). These cross data findings – the thematic tension between experiences and expressions (Chapter 4.1) and interpretative meta-themes (Chapter 4.2) are reported in the results.

4. Results

4.1 Social usability as supportive and defensive tensions

The interview survey of the key informants who were mediators of information between employees and architects and designers revealed several tensions relating to social usability in the process. These tensions could be named to following themes: 1) Need for change – the claim/concern of stability, 2) the sense of ownership – the sense of detachment, 3) efficiency – inefficiency, 4) sense of being heard – sense of being dismissed, 5) sense of being valued – sense of being valueless, 6) rationality – emotionalism and 7) social – privacy.

Need for change – the claim/concern of stability. The analysis of the data raised either the need for change or the claim of stability. Also those who wanted some changes expressed their concern about excessive stability. They saw that the possibility to change is maybe not utilized in its possible entirety. Both desire for change and fear for change are essential elements which generate experiences of feeling comfortable at future work and work space. Therefore it is important to take these opposing orientations into consideration. The need for change and the concern of stability are shown in the next exemplars:

> ”I also believe that they are sort of burdened by tradition. I think that they should gather an outside perspective on things and switch things up accordingly. It should be the basis for trying new things bravely. We should try to find ways to save some space if it helps in keeping a few more people employed at the location. I don't think the concept of saving always has to mean that things are taken away from you. It can also be the spark for trying out new and different things.”

> ”I probably somehow disagree with the notion that the work of a researcher requires a peaceful atmosphere for thinking. If we consider the kind of phenomena that we're researching and the direction we're heading to, I think we need […] a sort of shuffling of ideas. A kind of collision of minds. Meetings where different ideas are tossed around. Then after such meetings, there are places for you to kind a withdraw to […] where you can mull over your own thoughts. But the thought of going through an entire process like that in isolation, that 'I came up with this research idea, I'm going to look into it, I will advance and I will develop'...no way, such thinking belongs in the past.”

> ” I don't think it's going to become any better or worse than what we've had here or anywhere else.”

”If I had to say one word, for me it would be, like, an opportunity to do something differently. But unfortunately I have to ask that has it also been a wasted opportunity? I mean, it's still somewhat possible, but it also carries the danger of getting too comfortable and safe.”

The sense of ownership – the sense of detachment. The data also revealed a tension between the ownership and sense of detachment. Users' expectancies mirror the idea that the users themselves mould the new space to be their own. Some of them could already express that 'this is my place here' (pointing out one spot from the floor plan) or this is going to be 'our get-together space'. Experiences related to at least some level of ownership create the feeling of safety. Next citations exemplify the joint or personal feeling of ownership:

”On the other hand, I feel we're not even expecting to get everything, like a physiotherapy station […]. So our wishes display the atmosphere that we would want there. […] If there won't be an egg chair, then there'll probably be an exercise ball or something else then. There's a drive present, that we're going to make this great.”

“At least my own feelings about the building are really positive. My kids are utterly tired of hearing about it when we drive past it. Like look, there's mommy's house! The entire building is so beautiful already.”

Other hand, there are also uncertainty originating from the sense of detachment and 'free-floating'. Within the co-design process all the users were not always certain were their planning the space for themselves or for some more undefined user. Also, the placement of users lived during the process and experiences of ending up with someone else's ready-made plan was frustrating. Moreover there is lots of speculation whether there is an own or a changing working place or whether it is possible to bring any material of their own and personal things or not. Moreover there is uncertainty whether the forthcoming working community is familiar or re-formed of stranger people. The elements of the sense of detachment emerge in the next quotations:

”So in a way, for quite a while it was designed for the needs of people who are not here anymore. We are no longer interested in what was being taken there but now we are going to live with the decisions that they made on our behalf.”

”Somehow I feel that there won't be a kind of personal space for me or anyone else. The reality will probably be that, considering how few people we have overall, in the end we will designate personal desks for everyone. So those will be the personal spaces where you can bring your own photograph or potted plant if you feel like doing so. But during the planning phase the overall picture we have received has been quite impersonal, that everyone is going to switch places constantly and you don't really have this little space of your own.”

Efficiency – inefficiency. One essential tension expresses the desire to be efficient and productive in the new work space. This tension was mainly connected to the discourse involving the private rooms or the working area in an open space. Especially the conditions where people do not have their own space were seen a great threat to efficiency. The following statements exemplify this approach:

”But if we look at the nature of this job, we have people who are doing eight to ten hours of work daily at their own work station in their office. I think it is a difficult proposition to place those individuals into an open space like this and expect that the efficiency of their work doesn't suffer.”

”Well, there are a lot of doubts connected to these developments. If everything that has been suggested during the planning phase is implemented, I believe that overall well-being will suffer. That not having a space of your own will immediately increase stress levels. […] In any case, this change of scenery, this big moving project will at first disrupt the working rhythm people have developed. I guess after six months or so we may begin seeing these factors settle down.”

Also, an opposite impression can be seen which is considered productive ways of doing work. For part of the users, the threat of working alone or placement in a private room would be more ineffective. The next exemplar illustrates this point of view:

> ”So how much do we know about ergonomics. How much do we know about creativity, producing new ideas and the importance of cooperation? I think it's a genuinely dreadful thought that I should go into a box, inside four walls, to work by sitting in that same spot.”

The sense of being heard – the sense of being dismissed. One of the most discreet tensions addressed the problem the sense of being either heard or dismissed in different phases of the co-design process. Some of the users find that their ideas and thoughts have been taken into consideration very well. Also the awareness of different experiences seems to be shared especially in informal discussions. The next quotation reveals the comparison of different experiences of being heard:

> ”And a trusting feeling, there's this notable feeling that this group […] trusts that they will be heard in comparison to these others. I mean, if we haven't been heard, we have designed this die but it doesn't turn out in practice according to those designs, somehow this feels different. I could of course be wrong, but maybe we have a more decided feeling of being heard here.”

The experiences of being dismissed are usually connected with assumptions that the decisions are fixed on in advance and there are not any possibilities to influence. Moreover users think that they have been promised certain solutions (e.g. private room) or things (e.g. extra walls) and these promises are not heard and taken into proper consideration. The following statements exemplify these thoughts:

> ”Somehow I feel that there's not much use discussing anything here. These things have already been decided. [--] I think at least in our dice the final conversations will revolve mainly around fighting for who gets to be in a smaller room and who in a bigger open space, etc. Or maybe fighting is too strong a word, but people will try to make their cases for needing exactly a certain type of work space.”

> ”Then the negative feelings that relate to our dice or that may not even be connected to any of the dice in particular, but to my feeling of how poorly we've been listened to. Even though we were promised the opposite. We assumed that we would have a bigger influence on this process and we are disappointed because we didn't.”

The sense of being valued – the sense of being valueless. Also the sense of being valued or valueless is one of the crucial features when evaluating the social usability of work space. Part of the users feel extremely privileged in the situation of having a brand new building and allowing to be part of the exceptional co-design process. Experiences of being valued are expressed in the following statements:

> ”Well, I feel it is like, once in a lifetime. A brilliant, but probably also a very rare, opportunity to be designing your own future work spaces.”

> ”I think that at least having this great building, at such a beautiful location, it makes me feel that it'll be nice to invite in guests from other universities or such places. That the building is a great business card of sorts, that we can proudly display to others.”

The sense of being valued or valueless can be fastened on an individual level as well as on a professional level or it can be fastened on status. Part of the users find it highly dismissing if their own work or opinions seem not to be valued during the process:

> ”What has kind of happened here, in my view, is that the work of the designers has been shifted onto us. That we could somehow nicely refine the most important questions and deliver them to the architects so that their valuable working hours wouldn't be wasted. […] Thinking about this inversely, this may mean that our working hours aren't the most valuable ones around.”

> ”This process has somewhat clarified the fact that the statements of some are valued more than the statements of others, because they tend to follow the basic ideas that the architects have set out. Those statements tend to be valued more than the ones that have criticized those basic ideas. […] It's obvious that some people are listened to more than others, I feel it's blatantly obvious.”

Rationality – sensibility. The data did not reveal any extreme expressions of happiness or satisfaction towards the new working space or its social climate. When users brought out some positive aspects or features even then they described the awareness of critical atmosphere and siege mentality at the same time. Quite a rational and moderate attitude was usual when describing the new work space and the ways of working there:

> ”I think that this is a common mission for us all. […] I relay the information and wishes and organize what is needed, but if folks are not going to get on board, I don't feel like it's my responsibility to lure people in. We're all grown-ups here. […] Whoever comes in, comes in [to the design meetings] and their opinions will be included in the decision-making process. Everyone else will simply adapt.”

> ”People have had a long while to digest this move to [the new building]. They have seen the blueprints, they know approximately what awaits them and thus should know how to ready themselves. I don't believe there will be any notable problems beyond that.”

Where there was not a noticeable enthusiasm in users talk there was considerable amount of negative toned emotions towards the new working space and the interpersonal relations there or even towards the location of the property itself:

> [Is there something inspiring there?] “It's terribly depressing if you say no, but in my mind it's just a space we occupy. I don't think there's anything particularly inspiring in that.”

> [What is the negative feedback centered on?] ”It's centered on the other staff members. People seem to fear the thought of an open workspace, figuratively sitting like chickens on a roost where everyone can see and hear what you're doing with no personal peace for your work. Maybe this fear is based on not knowing what this transition to something new will lead to, leading at first to negative feedback.”

> ”The property that [the new building] is built on is absolutely horrible, what with all the motorways crisscrossing around it. When you take a look at any of the university buildings, none of them are on such an inferior property.”

Tensions between social – privacy. Further, the tension between social and privacy was evident in users' expectations. Especially the entrance hall and lobbies on each floor were expected to function as various social encounters, more than their own working spaces. The wish for various social happenings and the chance for fruitful random and casual encounters were expressed:

> ”I think people should arrange all kinds of events in the main lobby, such as christmas parties or something more regular. It could work as a great meeting place, so I think it could also work as an event space for the townspeople.”

> ”I was actually allowed to visit the building back in August and in my view, the shared spaces and the ground floor and the entrance, right by the cafeteria and the large lecture hall, I think they're going to be brilliant. The entrance looked really nice. And I absolutely loved the cafeteria!”

> ”This dice in itself isn't all that important. What's much more important is the space in between the dice. I can imagine that in that space lots of happy or even random gatherings can take place. ”

The tension between social and privacy was often expressed through the talk of quietness and peace. The privacy-talk was mainly attached to the wish to have a decent peace to work. The concern of losing the ability to concentrate was very evident at the expense of those possibilities the new building could offer. There was even a very strict demand for being silently which causes also distress:

> ”There's a lot of talk about arranging the workspace culture in a way that gives people silence when they need it. I would have personally maybe wanted more discussion about how to co-exist while also frequently talking to our colleagues. [--] Silence, silence and calmly and silently like mice within the walls and you should never say anything or make any sounds. Even if you start eating your lunch, you should try to make sure you don't rustle any papers or otherwise cause noise in the process.”

> ”The biggest issues have revolved around peace for working. I think the demand for this kind of peace and silence has drowned out attempts to innovate and bring in new ideas and viewpoints concerning our jobs.”

4.2 Social usability as an experience of safety, trust and professional identity

As a result of the third analysis phase three meta-themes behind the supportive and defensive thematic tensions were identified: 1) experience of safety (high-low), 2) experience of trust (high-low) and 3) the professional identity (individual-collective). These phenomena and their relations can in part be attached to explain the concept of social usability. The relations between these meta-themes can be placed at a fourfold table as seen in Figure 1.

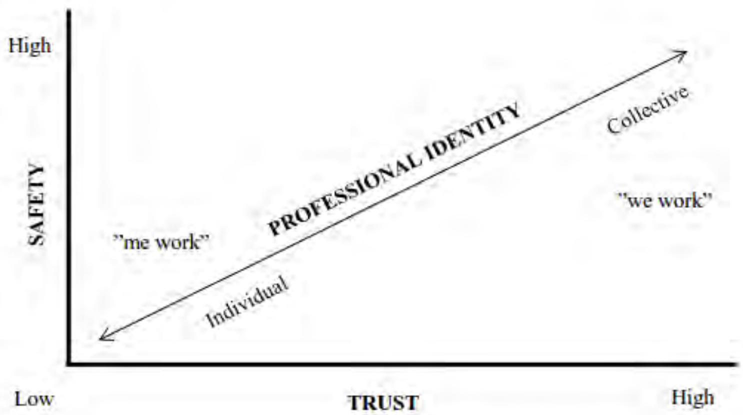

Figure 1: Relations between experiences of safety, trust and professional identity

It seems that during the change process of an academic workplace the experiences of individual workers can fluctuate in the continuums of experiencing low trust to experiencing high trust as well as experiencing low safety to high safety. The trust (e.g. experience of being heard and valued) is not only experienced at an individual level but it is a shared feature – what you hear and assume others to think and behave moulds also subjective experiences. Further, experience of safety seems to be attached to relational factors, how and to what degree an individual expects he or she is able to preserve ones privacy as well as factors connecting with ownership to ones' work and various personal things. Experience of low trust and low safety can be erupted into high defensive emotionalism. Moreover this can have a link to the fear of low productivity which emphasis is apparent in an academic work. At the same time, the professional identity can be seen either more individual or collective or the desire to be more one or the other remains either quite stable or varies depending e.g. on the new placement and its possibilities. Experience of high trust and high safety can predict desire to work more collectively.

5. Discussion

In the workplace change process it is very culturally sensitive both to express and interpret who knows "best" the needs of users and therefore it is a very complex phenomenon. In the transition phase and especially just before the concrete change – in our case before moving into a new building – the suspicious and defensive projection tend to be overpowering compared with supportive and trusting projection. However, being aware of this emphasis attempts to improve the working culture needs those who lead the way of change, otherwise remaining in the comfort zone is too tempting. The transition from customary or traditional work culture towards something new is not easy and it is crucial to understand how users are able to make the sense of the change (Bean and Eisenberg, 2006, 210). Employees' expectancies and prejudices tend to colour their mental image of forthcoming work space (whether physical, social or virtual in nature), have an impact on motivation and wellbeing and therefore non-instrumental, especially social needs must be better understood, defined and operationalized (e.g. Airo, 2014; Kojo and Nenonen, 2012; Hassenzahl and Tractinsky, 2006). During the change process it can be considered if a place and perspective of social usability can be understood as an interactive product: interactive processes should be planned carefully both before, during and after the workplace change.

We need to notice that an academic community is naturally accustomed to influencing its professional field but is much less so when concerning factors beyond that field. Keeping this in mind, we must note that the arena of influencing the built environment that should reflect your professional expertise is a new one. Therefore, an academic community may at first have problems influencing these environments in an expedient manner. Partly the agents of change exist inside the working community, but for the most part the need for change is displayed by built environment professionals, employer and the owner of the property. In academic settings there is a long tradition to be or to move in ready-built environments. Nevertheless when there is a possibility to influence not only in ones' professional field but also in the built environment which should reflect your professional expertise it is a new arena to express the expertise. Therefore understanding the processes building mutual trust are crucial.

6. Conclusions

The results revealed several supportive and defensive tensions relating to the perspective of social usability during the change process of an academic workplace. Eventually, the experience of trust and safety and the perception of being heard and valued during the change process seem to be essential.

Experiences of trust and safety mirror the satisfaction among the users and support the trend that more qualitative indicators are needed in real estate business (e.g. den Heijer, 2011; Kärnä et al, 2013).

End-user satisfaction is closely related to the individuals' experiences of relational factors attributed to communication and collaboration in the workplace (Airo, Rasila and Nenonen, 2012; Kivimäki et al, 2000) and especially in workplace change processes (Laframboise, Nelson and Schmaltz, 2003; Qian and Daniels, 2008). Further, experience of trust and safety can enhance the collective professional identity, which is seen to support the skills and attitudes needed in the 21st century. In all, research-based knowledge and deeper understanding about the processes building mutual trust are crucial.

Review of end users' role in facility management in university environment. A basis for a complementary approach to enhance interaction between end users and professionals

Kirsi Taivalantti (Ms.), PhD-student
School of the Built Environment, University of Salford
K.M.Taivalantti@edu.salford.ac.uk

Abstract

The aim of this literature review is to explore ground for including institutional and socially constructed understanding of the end users' role in facility management processes. This is applicable especially in strongly institutional settings, such as universities.

In facility management of universities, economic efficiency and effectiveness, such as utilization rates and appropriate use of premises, is a recognized object for development. The usual attempts are to survey end users' needs and satisfaction, or to establish interactive bodies and processes between facility management, organizational management and the end users. However, the interaction between the facility managers and the end users is still a challenge.

This research is carried out by a literature review of current study about the role of end users in facility management. The literature review is focused on university buildings' internal end user groups, students and staff, but includes a wider overview of service buildings in general.

First, previous study shows needs for development and implementation of practical methods of interaction between facility management and end users. Secondly, there is a lack of recognizing the need for inclusion of end users in the everyday practices. Thirdly, there is an insufficient understanding of the end users as definitive stakeholders, that have their own concepts and understanding of the facilities they work and study in. Fourthly, in dynamic university campus environments, the connection between the facility management and its' added value function in academic outcomes is recognized, but hard to measure.

Since facility management can be defined as a type of workplace management, a different interpretation of the environment should be considered on the side of the technical and the service-business-oriented view. Socially constructed understanding of the institutional settings is already a common approach in the field of organizational studies. This approach can facilitate interaction and improved understanding between the professionals and the end users. Higher level of mutual understanding can contribute to the value adding function of the facility management.

Keywords: end user, facility management, interaction, university

1. Introduction

The aim of this literature review is to explore ground for including institutional and socially constructed understanding of the end users role as stakeholders in facility management processes. This is applicable especially in strongly institutional settings, such as universities. The literature review concentrates on current research papers on the end users' role in facility management.

Chapter two presents end users' role in whole cycle of construction design and use. The objective is to find out how end user involvement in this cycle is presented in the literature. Facility management has a value adding function for the core operation. The end user is one key actor for this value adding function.

Chapter three reviews current research of end user role in facility management in university environment. Research of the subject can be divided in two groups: first the research concerning end user satisfaction, and secondly the research concerning campus management processes.

Chapter four reviews research papers concerning current practice in the facility management research, as well as a few recent academic openings that aim for understanding users' original definitions in the field of facility management.

Chapter five discusses the findings and introduces the idea of socially constructed and institutional understanding as a complementary approach in the field of facility management research. Chapter six present conclusions of this literature review.

2. End users' role and involvement in facility management

2.1 End users in design and using phases

In facility management of service buildings, economic efficiency and effectiveness, such as utilization rates and appropriate use based on core functions and individual and social needs, are often a challenge. The practical developmental actions are for example to survey end users' needs and satisfaction, or to establish interactive bodies or processes between the professional facility management, the user organization management and the end users. The common factor between these different tools is the need to increase interaction. However, often not the whole process from design to actual end use is covered. The using phase and the actual outcome of the design process is not necessary the object of concern. (Hansson et al. 2010, 37.)

In Scandinavian countries, based on the democratic welfare-state-ideology, hearing of citizens is a part of official processes in land use and urban planning. In the house building industry this is not regulated and thus not a practice. However, in the design phase of buildings, end users seem to be involved increasingly. Reasons for this are both practical and political. There is a genuine need to obtain information as the base for technical solutions. Another reason is to overcome differences in values and interests, as well as resistance for change, to reach commitment of the parties involved (Pemsel et al. 2010, 24). Literature presents a number of different methods to include end users in a design process. It is still uncertain, how well these methods are used, and also, how well they can be adopted in real life projects (Pemsel et al. 2010, 24; Hansson et al. 2010, 37). Many of the methods are also criticized for not offering guidance for how to act upon the outcome from the method (Hansson et al. 2010, 13). Different methods tend to seek increasing communication between the stakeholders, and to improve the understanding of end users' real needs and requirements. However, they are built on quite complex systems and based on data gathering and analysis (ibid.) Methods seem to be built on professional base of knowledge and concepts of the industry.

In previous research about end user inclusion in both public building projects, as well as in private office building environment, the writers argue that a traditional cost-based property management doesn't still acknowledge end users' level of awareness of for example sustainability factors or long-term maintenance cost (Nousiainen & Junnila 2008, 275; Wihlborg & Laurell 2011). In public building projects end user inclusion in the process in early states benefits society's cohesion and decision-making processes (Wihlborg & Laurell 2011, 367). End users knowhow and interest seems to be underestimated.

Social and cultural barriers between the professionals and the end users cause communication failure and hinder the effectiveness of the planning tools used, even though some methods are based on interaction (Pemsel et al. 2010, 25). The end users are still seen merely an obstacle, than a stakeholder of great importance in design phase, which causes setbacks and conflicts in hand-over phase (Lehtiranta 2015, 571). Understanding operational performance of the project should be a combination of technical focus in construction and emotional basis of customer experience (ibid. 573–574). There is a need for a better understanding of issues like cultural and social habits and highlight the importance of putting effort into ensuring a productive and trustful relationship and communication among all participants (Pemsel et al. 2010).

2.2. Value adding function of facility management

Few tools that concentrate on the end users, even though used in design phase of construction projects, cover the whole cycle and different phases from the user point of view (Hansson et al. 2010; Lehtiranta 2015). In using phase of the building, the professional body present is the facility manager. Facility management should have an elementary relationship with the strategic core of the operation, since it organizes and maintains the whole physical environment of peoples' work and other operative actions (Barrett 2000). Even though design phase has major impact on the quality and functionality, few decisions are totally irreversible (Finch 1992). Facility manager is in key position to make adjustments, both in risk management as well as to improve functionality, safety, aesthetics and overall satisfaction of end users.

Based on the strategic positioning of facility management, with relation to the core functions of the organization and operational core, facility management should be suited to the environmental characteristics rather than adopting a universal best practice (Chotipanich 2004, 367; 371). Both internal and external factors should be considered in the management practices (ibid.). This is due to the understanding of facility management as a strategic and a value adding function to the core operations, rather than just a cost factor (Anker Jensen 2010). Conceptualizing the value adding impacts, four different stakeholders for added value for the organization can be defined: society, customers, staff and owners (ibid. 182). It is also important, that facility management professionals are capable of explaining the benefits of their actions to their clients, customers and end users of the services they provide (ibid. 186). Facility management should be acknowledged as relationship management. The value of the function is produced in these relationships and is subjectively dependent of the other parties' experiences. So it is important to take into account the views and interests of different stakeholders, including the significant groups of end users in the facilities. (Anker Jensen et al. 2012, 211–212.)

This paper is concentrating on internal end users in university facilities, which are students, academic staff and administrative staff. By an end user in facility management can be meant "a person receiving facility services" (Coenen & Kok 2013, 343). In public buildings, like universities, where there are a groups of everyday end users, like staff or students, as well as groups of persons that receive facility services on more random base, such as visitors, this should be more focused. End user can be defined as a person within the core organization receiving facility services. The ideas about added value by facility management (Anker Jensen 2010; Anker Jensen et al. 2012) are based on this grouping, dividing internal (staff, students) and external (visitors) dimensions.

Facility management is in charge of organizing the physical settings for the operational needs of end users. In addition to physical needs, the purpose of the facilities is also to provide for a social setting where people meet and interact. The physical setting provides cues for social situations and communicates meanings. Thus, facilities management can create value for organization by setting the physical environment according to organizational goals and desired behaviour by the end users. (Coenen & Kok 2013, 345.) For that, not only organizational goals, but also actual personal understanding of the facilities functions are required. Cross-functional cooperation between different end user groups and facility management can create balanced setting for the operation, as well as help the facility management in their service function (Kok et al. 2015).

Considering end users as a significant factor in a facility management process can influence both the satisfaction of the end user, as well as their actions, in a profitable way (Junnila 2007; Awg Husaini & Tabassi 2014). The end users should be involved in the process of shaping their workplace environment. People occupy workplace as their territory. If they are involved in the processes of management and maintenance of that physical setting, they will commit themselves also to changes required. (Kaya 2004, 251.) Too often in practice the appearance of the facility management happens and is interpreted as a sudden, uninformed and unwanted change by the end users. This causes non-communication and misunderstanding. (Rayle 2006, 54.) If the end user responses were understood better, it would be much easier to develop effective and efficient processes (Rasila & Gersberg 2007). If changes are planned together beforehand, stress could be decreased and changes carried out with less time and resources.

Even though the end user involvement is considered in some tools of design the whole process and using phase is left out for less attention (Hansson et al. 2010). Based on the idea of facility management as strategic and value adding function for the core operation (Anker Jensen 2010; Anker Jensen et al. 2012; Valen & Olsson 2012; Coenen & Kok 2013), there is a need for further development of assessment tools that include the evaluation of added value and how the user experience the buildings (Valen & Olsson 2012, 298–299).

3. End users and facility management in universities

3.1 End user satisfaction

In university environment, research seems to concentrate especially on students' comfort and satisfaction. Student surveys about facilities' technical quality and functioning show that the students do understand and articulate such concepts as sustainability (Nousiainen & Junnila 2008; Lehtiranta 2015).The aim is to point out the significance of end users as stakeholders in process of sustainable facility management (Hebert & Chaney 2012, 469). A survey applying customer satisfaction model to the research on campus facility management showed that both students and university staff emphasize overall appearance, tidiness, as well as safety. Indoor air quality is also an essential factor for satisfaction. (Kärnä, Julin & Nenonen, 2013.)

About space use and learning environment, students see informal settings and ad hoc spaces for learning important on the side of the formal learning environments and situations. Technology access, as well as collaborative space are important for students. (McLaughlin& Faulkner 2012, 148.) The most effective strategy to improve student satisfaction with the space management would be the emphasis on the social areas, such as auditoriums and libraries (Hanssen & Solvoll 2015). Also, facilities, as physical environment, seem to have some impact on student choice of university (Price et al. 2003).

There are differences between students and staff satisfaction factors. Public spaces and campus accessibility are in an essential role for the students. For academic staff, factors related to teaching and research facilities have the main contribution to the satisfaction. (Kärnä & Julin 2015.) For research staff, possibility to carry on working without interruptions caused by moving or other facility changes seems to be of importance (Hebert 2012). Considering the ongoing pedagogical change and virtual access requirements in the universities, expectations of the end users are that physical and virtual access is flexible and that facilities will reflect what is available in other aspects of students' lives socially, professionally and personally (Todhunter 2015).

However, it seems that the articulation of the needs and key issues addressed to the facilities, by the individual end users, is not clear. There are different views between individuals, and there is not necessary a clear and common articulation of organizational visions and strategies, as well as pedagogical approaches, to lean on. (Todhunter 2015.) There can also be a lack of recognizing facilities as strategic issue in organizational level, usually caused by lack of information and representation, or by managements' viewpoint of facilities as operational cost rather than strategic issue (Kamarazaly et al. 2013, 143).

3.2 Campus management

Campuses are physical working and studying environments that are arenas of interaction between different groups, as well as objects for a constant change. Therefore, a process perspective including both internal and external influences has to be considered. Social, physical and virtual facilitation should thus be seen as a systemic entity. Rather than seeing the campus as a set of stable facilities, the emphasis should be on managing flows and communities. (Rytkönen 2015.) There is a demand for a holistic approach for facility management to create learning environments of today (Rytkönen et al. 2015).

This holistic approach sets pressure to new methodologies and approaches involving end users as stakeholders in university environment, in addition to surveys and interviews, such as referred previously in this chapter. One approach could be to include experience-oriented methods that look the facilities also from the user's perspective from both technical, social and virtual viewpoints. (Rasila et al. 2009.) Another suggestion is to implement future-oriented modelling tool, which can provide a systematic and a collaborative design approach (Rytkönen & Nenonen 2014).

The added value structures of facility management are space quality, efficiency and utilization, quality of education and research, as well as collaboration-competition aspect (Rytkönen & Nenonen 2014, 148). This suggest that facility management has influence upon academic achievement (Kok et al. 2011, 260). The added value of facility management in educational environment can be conceptualized by defining facility services and coordination as settings, knowledge transfer as process and educational achievement as an outcome (ibid. 256). However, the route from optimizing facility services (the settings) the best way, to achieve the best possible academic achievement (the outcome), is still unclear. Subsequent research is required on the subject. (ibid. 259-260.)

4. Challenges in facility management research

The specific object of facility management defines it as a service business that has focus on workplaces and their management (Tay et al. 2001, 361; Jughans & Olsson 2014). According to a review of academic research of facility management (2007), researchers emphasize the need for valid quantitative data analysis techniques, as well as rigorously conducted qualitative research. It is also suggested that in order to develop, the field of facility management should exploit both approaches and theories of such fields as social science and human resource management. (Ventovuori et al. 2007, 235–236.) Within the Nordic countries, the main trends and development challenges in the field of facility management seem to differ significantly between the four countries (Anker Jensen et al. 2014). In Finland, the facility management research is influenced by the recent innovation policy that emphasizes the needs of customers in product and service development, the systematic use of economic incentives, as well as the participation of end-users in the innovation process (Nenonen & Sarasoja 2014, 65). In a Swiss research is was stated that, from the value adding point of view, more empirical evidence of economical, ecological and social aspects is required to develop facility management further (Windlinger et al. 2014).

A few researchers have approached towards qualitative and socially constructed understanding of facilities, in terms how people define the change in the physical environment in discourse (Airo et al. 2012.) There is no clear difference whether the space people discussed about was actually physical or symbolic, but it is stated that the method of discourse analysis could be more widely used in the field of facilities management. (ibid. 299.) The methods of narrative and discourse analysis are not very widely used in research of general workplace management. The use of linguistic methodology could help to reach a holistic way of studying and developing workplaces. (Airo & Nenonen 2014.)

The concept of space in the field of organizational studies and the facilities' role in workplace management can be approached in the light of organizational creativity. The way of organizing the physical space plays a significant role in the emergence of organisational creativity. As a concept, aspects related to physical space and the organisational culture are brought together. (Kallio et al. 2015.)

Engineering and management, in terms of both research and practice, tend to lean towards procedural concepts and leave declarative approach for a smaller emphasis. On the other hand, from the end user's point of view, the challenge is to understand why something is done and what the consequences are. The importance of qualitative data and approach is also important to reach such taxonomic and ontological concepts that can reach this declarative dimension, in addition to the procedural (Rasila et al. 2010; Che Hassan 2013, 111).

5. Discussion: Opening for an institutional approach

There is evidence of social and cultural barriers and communication failure between the professionals and the end users (Pemsel et al 2010; Hansson 2010). There are also challenges with the tools used in these processes. Tools and practices, as well as the recognition of the importance of the end users, seldom reach beyond the design process into using phase of the buildings (Pemsel el. al 2010, 24; Nousiainen & Junnila 2008; Hansson et. al 2010; Lehtiranta 2015). Thus, the first challenge of recognizing end users in the field of facility management is the lack and applicability of suitable tools of interaction between the professionals and the end users.

The value adding function of facility management understands end users' significance for the process. End users can be defined by terms of external (for example clients) or internal (for example staff or students). (Chotipanich 2004; Junnila 2007; Anker Jensen 2010; Anker Jensen et al. 2012; Coenen & Kok 2013; Awg Husaini & Tabassi 2014; Kok et al. 2015.) Still, there are challenges of how well the end users are included and informed for example in projects of change. Thus, lack of commitment from the end user side occurs (Kaya 2004; Rayle 2006; Rasila & Gersberg 2007). The second challenge is the real inclusion of the end users in everyday practice. This could also be seen as a consequence of the first challenge.

End users in university environments are often considered as customers, whose satisfaction factors are surveyed and interviewed in order to develop service practices (Price et al. 2003; Hebert & Chaney 2012; McLaughlin& Faulkner 2012; Kärnä, Julin & Nenonen 2013; Hanssen & Solvoll 2015; Kärnä & Julin 2015; Todhunter 2015). There are also openings towards more explanatory, individualizing research (e.g. Hebert 2012; Todhunter 2015). The third challenge is the still insufficient understanding of the end users as definitive stakeholders, that have their own concepts and understanding of the facilities they work and study in.

There is a lean towards a holistic approach to campus management practices, due to dynamic aspects of todays' campuses (Rasila et al. 2009; Kok et al. 2011; Rytkönen & Nenonen 2014; Rytkönen 2015; Rytkönen et al. 2015). The roots of this holistic view about university campuses are also in the pedagogical field. The connection between the facilities and the academic outcomes, in terms of added value, is recognized, but not easily measurable. The fourth challenge is the difficulty to show the complicated structures between the physical environment and actual efficacy in academic outcomes.

Mainly due to the value adding function, field of facility management is recognized as a type of workplace management (Tay et al. 2001; Ventovuori et al. 2007; Jughans & Olsson 2014; Nenonen & Sarasoja 2014; Windlinger et al. 2014). Workplace management can also be attached to the field of organizational studies. There is a recognized understanding of organizations and workplaces in a cultural and institutional context, together with other approaches (e.g. Morgan 2006; Hatch & Cunliffe 2006; Czarniawska 2008). Having facility management understood as workplace management, some recent attempts to approach that tradition of social constructionism (Berger & Luckmann 1966) are to be found (Rasila et al 2010; Airo et al 2012; Che Hassan 2013; Airo & Nenonen 2014; Kallio et al. 2015). However, based on both the writers' own statements, as well as the theoretical frames used in the articles, these studies are merely testing and exploring the cultural and constructionist aspect in the field of facility management, rather than applying the cultural and socially constructed frame in the research as such.

There is also an indisputable understanding of universities as strongly institutional organizations (e.g. Millett 1962; Weick 1976; Brubacher 1978; Becher & Trowler 2001). As such, they are built on regulative, normative and cultural-cognitive basic framework (Scott 2008). By definition, this means that institutional setting and these basic structures direct the actions and reasoning of the people working and studying in them (Berger & Luckmann 1966, Weick 1995; Czarniawska 2008).

The challenges and recognized state of the art in facility management found in the literature suggest that opening the door wider for cultural and institutional based understanding in the field of facility management could be an additional new approach. Exploring this possibility could help with the challenges of interaction between the facility management professionals and the end users.

6. Conclusions

Four different challenges that cause problems in end user and professional facility management interaction were defined based on literature research. First, lack and applicability of suitable tools of interaction between professionals and common users. Second, mistakes in understanding of end users as occupants in their own territory that have also knowledge of their physical surroundings, and lack of recognizing the need for inclusion and interaction in the processes. This can be caused by the lack of tools. Third, still insufficient understanding of the end users as definitive stakeholders, that have their own concepts and understanding of the facilities they work and study in. Fourth, in dynamic environment, such as university campuses, the connection between the physical environment and its' value adding function for academic outcomes is hard to measure and show.

Studies of the facility management show the nature of the discipline as a branch of workplace management. In addition to widely implemented approach of service process development, there could be other directions of organizational management research applied. Some recent attempts have been taken towards cultural and socially constructed understanding of facilities as space for social interaction. Exploring this approach in future research could give a new insight and ideas to the development of interaction and interactive tools between the professional facility managers and the end users. As strongly institutional environments, universities would be a fruitful ground to start to conduct such research.

Abstract

In the recent years several Finnish school buildings are facing renovation needs, which force municipalities to relocate the activities of schools to temporary facilities. Often the problem is solved with container schools. The usage of the temporal space may last for several years, therefore it is essential to design them as functional as possible. Furthermore, the temporary settings can provide a platform to develop new knowledge practices and promote school engagement.

The aim of this paper is to identify the spatial borders and affordances, which affect school engagement and learning experience in temporary container school. This is examined in a case of a temporary upper school facilities. The spatial effects on school engagement and learning experience of pupils were researched by mixed method -approach, which included survey, four workshops and a user journey observation with the employees and the pupils of the school. The result were analyzed with FOA-framework consisting of three components of flexibility, ownership and accessibility of space.

Spatial borders and affordances from the perspective of the school engagement were identified and labelled under the major components. The results of this study can be directly utilized in the design of future type temporary school concept but also in designing complete new school buildings.

Keywords: Learning Environment; School Engagement, Learning Experience

1. Introduction

In Nordic countries the school buildings are in desperate need of renovation. Temporary facilities are used in order to maintain the basic education standards. While the actual building stock is going through extensive rebuilding, the pedagogical needs are faced in temporary facilities.

Simultaneously the emphasis of primary education is shifting from teacher-centred education, towards inquiry-based and student-centered forms of learning (Kumpulainen et al, 2010; Litmanen et al., 2012; Lonka, 2012; Lonka, 2015). Accordingly learning processes have become more collaborative and activating including a variety of different forms of working and ICT-based knowledge practices (Hakkarainen, 2009; Lonka, 2015). This puts the traditional and rigid learning environments truly under test. The contemporary learning activities challenge the physical learning environments by knocking on the doors and bouncing from wall to wall (Lonka et al, 2013).

While the new views on education are faced in the old premises of school, a clash of cultures are about to take place. As the renovation of old facilities forces the users of school to relocate to temporary premises, an opportunity to test different kinds of spatial solutions emerges. This provokes the question: what kinds of spatial solutions enhance the new needs of learning and teaching?

In this paper the effects of temporary spatial solutions to school engagement and learning experience are investigated. The following questions are asked

1. What is the role of temporary space in learning experience
2. How does the spatial design effect to school engagement
3. What kind of spatial solutions enforce the positive learning experience and school engagement.

The results of this paper give insights to the design of future type temporary school concept but also in designing complete new school buildings, which enhance the new ways of learning.

2. School Engagement and Learning Experience

Despite the flattering PISA-results in Finland (OECD, 2013), there seems to be a worrying lack of school engagement and positive learning experience. Latest research indicates, for instance, that school exhaustion (Salmela-Aro & Tynkkynen, 2012) and school-related cynicism and inadequacy has increased among students on an academic track (Salmela-Aro et al, 2008). Furthermore, in the latest measurement by OECD (2013) the students' school engagement in Finland fell exceedingly beneath the OECD average. This is one crucial factor why improving learning methods and environments are topical as they can promote pupils' motivation and wellbeing.

The concept of school engagement can be defined in three ways: to behavioral, emotional and cognitive. The behavioral engagement draws on the idea of participation; it includes involvement in academic and social or extracurricular activities and is considered crucial for achieving positive outcomes. Emotional engagement encompasses positive and negative reactions to social sphere, school and is presumed to create ties to an institution and influence willingness to do the work. Cognitive engagement draws on the idea of investment; it incorporates willingness to exert the effort necessary to comprehend complex ideas and master difficult skills. (Fredricks et al, 2004).

As Fredricks et al claim the engagement is seen more of a mental issue. Its' connection to physical space and the experience of space is still an unknown territory. However the school engagement and learning experience are connected not just to social but also to physical gathering of things. (Airo, 2014). Wang and Holcombe (2010) state that adolescents' school engagement can be seen as school participation, school identification and use of self-regulation strategies. In this research particularly the school identification is discussed in connection to spatial attributes of learning environments.

Measuring actual learning and experienced learning can differ. However there is a body of evidence that relationship of the two is positively correlating. It is stated that learning is enhanced through active involvement in personally meaningful experiences accompanied by processing for meaning and future use (Luckner, et al 1997).

3. Learning Environments

Learning environment is a wide concept that consists of multiple dimensions from which the context of learning emerges. Usually at least three dimensions are acknowledged: physical-, social- and digital (Lodge, 2007; Nuikkinen, 2009; Piispanen, 2008). Also cultural and pedagogical dimensions are mentioned (Manninen, 2007; Kuuskorpi, 2012). However, it's not about how we divide the concept in pieces but how we form a functional and engaging unity out of these dimensions, so that the surroundings and its multidimensional affordances really promote 21st century learning. In addition, the school's organizational culture and leadership practices plays a huge role in pushing the educational practices toward 21st learning and thus utilizing the corresponding learning environments (Vaara, 2014). Furthermore, this cultural shift also set its own demands on learning environments: new co-working and communal practices require more informal and flexible spaces to foster straightforward collaboration (Vaara, 2014).

Self-determination theory (SDT) assumes that the degree to which students perceive that the school context meets those psychological needs determines the level of students' engagement in school (Wang, 2010). In this sense the perceived school environment also in physical sense, would enhance their engagement to school and learning experience. In addition the physical design of the school has been seen both as an enabler and prohibiter in pupils learning process.

Physical school environment also reflects the policies of governments' pedagogical views. They are political and public places, which often lack private rooms and enclosed space for pupils. It has been quite critically stated that sometimes school buildings resemble hospitals, factories or even prisons, in which the individual does not have a freedom for privacy or individuality.
(Vuorikoski & Kiilakoski 2005, 312–313.) In addition the traditional classroom represents hierarchy between teachers and pupils. Teacher is allowed to move and control the space, whereas the pupils are forced to sit still (Gordon 1999, 106–107.).

School and learning environments are not just restricted to internal spaces. Also the yard and network of learning places can be seen part of the learning environment. School is often separated from the other cityscape by fences etc. The aesthetics of the external spaces have been seen as important part of the pupils' wellbeing. However they often contradict with safety regulations and ideals, which would acknowledge the needs and behavior of young pupils (Gellin et al, 2012, 143).

In this paper the school engagement, learning experience and learning environments are defined always in relation to the spatial design and its' features. The actual learning outcomes are not discussed. Neither is the overall school experience other than its relation to the temporary school facilities.

4. Flexibility, Ownership and Accessibility of school environment

The school engagement and the learning experience in temporary school facilities was investigated with a so called FOA - framework, in which the concepts of flexibility, ownership and accessibility of space were used to both gather and to analyze the data. Flexibility of space refers to the range of usage of the space. That is how well does the space alter to variety of usage. The ownership refers to identity of the space. In other words, how well do end-users, the staff and pupils identify with their school and how much they have a freedom of using it. Accessibility refers to usability and comprehensiveness of the school building and infra.

The FOA-framework was derived from literature focused especially to the research of usability of built environment. The researchers argue that usability as a core concept for managing organisational ecology (Alexander et al 2013). It is stated that usability is a cultural phenomenon that can only be improved through a better understanding user experience, considered as situated action in a specific context" (Alexander, 2008). A building's performance can never be seen or understood in isolation from an organisational and technical perspective.

Alexander (2010) argues that school facilities should be considered in the context of the communities they serve and as a prime means of transforming education. Effective learning environments successfully combine appropriate social and digital environments with the physical environment (Beard, 2012). Creating quality learning environments, which are more broadly accessible in the community, can also play a catalytic role in regeneration.

Usability evaluations are based on different user's experiences and assessments on how well the buildings perform regarding different parameters. The dutch standard NEN 8021:2014 (Valuation of User Requirements and Performance of Non-Residential Buildings) defines nine usability criteria: which are comfort, safety, sustainability, flexibility, use of space, representativity, services and accessibility. NEN 8021 helps both the users to determine their needs and wishes regarding the building and also helps providers to compare their products to it (Anon 2014).

In this study the concepts of usability defined by NEN8021 were applied in forming the FOA-framework by focusing in flexibility including the use of space, representative especially from the perspective of ownership of the space and accessibility. The other criteria like comfort and safety where also discussed but the three parameters were the most significant for this research.

The flexibility, ownership and accessibility i.e. FOA-framework was applied in analyzing both quantitative and qualitative information. That is, the discussions, answers and observations were placed in the thematical FOA-framework. In addition the different kind of data (qualitative and quantitative) were cross analyzed in a matter of how they correlated or differed. In addition it was looked are they any extra data, which would differ from the original FOA-concept.

5. The Methods

The temporary School environment was investigated with mix-method approach, that is both qualitative and quantitative methods and data were utilized. The qualitative methods included four workshops and a user journey observation.

Self-report questionnaire

To map the prerequisite for the co-creative learning environment intervention a preliminary self-reported questionnaire was conducted among all seventh graders of the school (n =100). The seventh grade was chosen, because of potential follow up-measurements in close future, since the seventh graders would stay at the school for two further years and therefore also experience the school's transfer to the new school building in fall 2016. For this purpose a questionnaire including 22 statements about the conceptions on learning environment and school work was prepared by applying partly statements used in the self-report questionnaire of the Mind the Gap Between Digital Natives and Educational Practices -project (2013-2016) funded by the Academy of Finland (Mind the Gap, 2014, Hietajärvi, 2014).

However, more specific statements concerning learning environments were invented and added to the original Mind the Gap *How do you experience your school and schoolwork?* –instrument, which was a learning environment centered section in the self-report questionnaire. This decision was made, because the orginal Mind the Gap instrument included only a few more general statements about learning invironments, for example *my school feels safe* and *the learning environment of my school feels comfortable*. Therefore, more precise statements concerning physical learning environments were added, for example *my school building is comfortable from the inside* and *the spaces of my school help me to focus on the current task*. Furthermore, the statements in the questionnaire were set in an order that would reflect the daily cycle of pupils' school experiences, by starting with statements about entering the school area, then proceeding to the interior design of the school building and finally to more general school experiences (see table 1).

This so formed Flexible Learning Spaces-instrument (see table 1) was then set in a 5-point Likert-type scale. The statements were set in an order that's in line with the users' daily cycle of observations: starting with statements about entering the school environment, proceeding to the inner surrounding, first in more general and then in more specific, and then measuring the users' overall conception about their school.

User journey-observation

Part of the qualitative data was gathered with user journey observation. Observation tells something about the things that people actually do, not what they think they do. Conceptualizing of a space is based on user actions and researcher's interpretation. Spaces as such are not conceptual entities but they become one when combined with human reasoning and action (Lefebvre, 1974). Thus both the users, their actions and the space were observed.

The actual observation was based on Dale Cobb's (2008) customer journey framework. The idea of Dale Cobb's customer journey was originally an idea of a conceptual journey becoming a customer. Observation applied a model of the different concrete "journeys" users make in the building and in the space. The researchers observed the school building and the yard by all the functions that took place in school such as entering school, acting in breaks, eating in cafeteria and being in the class room. The observations were conducted both from the teachers and from the pupils' point of view. This was done by walking first with the teachers throughout the school facilities. The pupils' perspective was first investigated in workshops and later with taking the observation walkthroughs with the pupils.

Workshops

During the project four workshops were arranged: the first workshop focused on user experience about existing physical spaces and surroundings of the school and the thus collected data were then combined with results of the user-journey observation. Later one workshop was then arranged to participate the users, both pupils and teacher, into the design process of a new engaging learning space which was supposed to demonstrate the key findings and principles of the project and offer a testbed for the school to adopt new educational practices to foster 21st learning. In this later workshop pupils sketched preliminary spatial layouts which were then reviewed and improved by the teachers and researchers.

Additionally two workshops were executed to introduce new digital solutions to the pupils and teachers. The aim of these workshops was to foster the integration of ICT into the learning environment and learning processes, which is an important factor in 21st century learning. Furthermore, it was to make sure that the new devices provided by the project would successfully blend into the daily practices performed especially in the new learning space.

6. The Results

The aim of this paper was to identify the spatial borders and affordances, which affect school engagement and learning experience in temporary container school. Based on mix-method approach following key results can be identified.

The results of the self-report questionnaire indicates that the physical learning environment in the temporary school settings are not experienced by the users as comfortable or engaging (see table 1, 8.2, 8.3, 8.4). However, the results indicate that the overall working culture and communality is seen as rather engaging and positive (table 1, 8.11, 8.17,). The pupils also felt the overall school environment safe (table 1, 8.1.). Furhermore, the results show that the pupils experienced their work at school as activating, collaborative and the teachers' guidance supportive (table 1, 8.9, 8.12, 8.14). In all, the pupils considered the role of their working environment as significant (table 1, 8.16).

Table 1. Results of the self-report questionnaire.

Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
a8.1 My school area feels safe	100	1,0	5,0	4,070	,9239
a8.2 My school yard is comfortable.	98	1,0	5,0	2,357	1,1238
a8.3 My school building is comfortable from the outside.	99	1,0	5,0	2,242	1,0888
a8.4 My school buiding is comfortable from the inside.	99	1,0	5,0	2,697	1,1469
a8.5 The spaces of my school foster collaboration.	98	1,0	5,0	2,592	1,0633
a8.6 The spaces of my school foster my own learning.	99	1,0	5,0	2,828	1,0977
a8.7 The spaces of my school help me to focus on the current task.	99	1,0	5,0	2,626	1,2002
a8.8 The classrooms enable a variety of different working forms.	98	1,0	5,0	2,837	1,0619
a8.9 During the lessons the pupils have an active role.	99	1,0	5,0	3,667	1,0102
a8.10 It's peaceful during the lessons.	97	1,0	5,0	2,866	1,1513
a8.11 The pupils in my class enjoy being together.	97	1,0	5,0	4,041	,9345
a8.12 During the lessons the teachers encourage me to express my opinion.	99	1,0	5,0	3,636	,9944
a8.13 The teachers are interested in how I'm doing.	98	1,0	5,0	3,378	1,0890
a8.14 The teachers treat us pupils righteous.	99	2,0	5,0	4,051	,8497
a8.15 I feel that the school's ICT helps me to learn.	98	1,0	5,0	3,367	,9238
a8.16 The surrounding working environment plays a significance role.	97	1,0	5,0	4,021	1,1178
a8.17 There is a good atmosphere at our school.	98	2,0	5,0	3,816	,9454
a8.18 It's easy to work in my school.	99	1,0	5,0	3,667	,9476
a8.19 I feel my school's spaces as my own.	98	1,0	5,0	3,276	1,1468
a8.20 I know how I can influence the matters at my school.	97	1,0	5,0	3,278	1,0776
a8.21 I feel myself happy in this school.	99	1,0	5,0	3,717	1,0789
a8.22 I'm proud about my school.	98	1,0	5,0	3,367	1,1158
Valid N (listwise)	86				

6.1. Role of space in learning experience

The results of the qualitative approach complimented those of quantitative. Based on observation and workshops the effects of spatial attributes to learning experience were often concentrated to physical hindrances of the temporary container school.

> "The classrooms are noisy. It is impossible to listen the teacher, when it is raining and the water hits the ceiling so hard" Pupil 15 years.

The hindrances were mostly connected to audio, such as the noice of the rain, ventilation or to the light structures of the facility. It was also claimed that the trembling of the facility and its' vulnerability to external factors such as passing cars or slamming doors affected to concentration of the pupils.

It was not only the physical structures, but also the temporary gathering of the spaces that impacted to pupils overall spatial experience and behavior. Walls, visibility and access to different spaces affected for instance to the amount and grouping of students and teachers in certain places:

> " There is gasstation across the road. All the pupils are running there all the time. I can't see all the students all the time, since the yard does not have a shared area and the containers are sort of a labyrinth" Teacher

and

> "All the pupils are gathered in front of doors under the rain shelter, like penguins" pupil, 13 years.

These comments illustrate how certain corridors or lack of them affects to the way pupils are teached, managed and taken care of. Also they affect to the social order of the groups. Who is going where, who is the first in line, who has to stay out in the rain etc. Of course similar structures can be seen in every school building and built environment in general. However, the temporary schools this is rarely acknowledged.

6.2 Spatial effect to school engagement

Spatial design has both straightforward causal effects on engagement and indirect effects which are connected to overall experience of school building and wellbeing within the school. For instance dysfunctional basketball field may arouse constant discomfort of the students, which accumulates to misbehavior within the classroom.

> “ The older pupils govern the whole yard by playing basketball in the center. It is hard to cross the yard to other side without interfering the game and causing annoyance” pupil 13 years

On the other hand the common distress of the students and teacher unites them and enforces the engagement to the organization. In this sense it is challenging to separate the role of space in overall experience of the school.

> “ This is our school. This is the only memory I will have about my school, when I grow up. When I am an adult I don’t have my school anymore. I can’t say to my children that, there is the school, where your mom went to” Pupil, 14 years.

Based on these aforementioned findings the spatial design of the school building whether temporary or permanent solution should acknowledge the identity of the school by either creating new symbolic artefacts or bring old ones from previous premises.

> “We have this old counter, which is the designated place for 9 graders. My dad asked, do we still have. He also used to have it when he went to same school” Pupil 13 years

The temporal nature of the space affected to school engagement also by lack of certain key spaces such as gym hall.

> “we do not know where to go, if we have a party. We do not even have a gym hall. We always have to go somewhere else and it takes time” Pupil, 13 years.

In addition the fractured nature of container school in small and bigger perspective affects to time management within the school life. If pupils have to go far for eg. gym lessons, they do not have time to come back to next lessons, which generates pressure to curriculum plans.

7. Conclusion

The borders and affordances of temporary school facilities can be categorized in terms of flexibility, ownership and accessibility. Learning experience and school engagement is affected in following ways:

The temporary school facilities such as container schools are often ready made mass products, which lack the quality of the permanent school. On the other hand, as not being so fixed they can and especially should be adjustable to differing needs for learning.

The results of the preliminary self-report questionnaire also indicates that the positive and safe atmosphere and collaborative school culture, at least in the context of this study, could foster an experimental approach into co-creating new pedagogical practices and adjustable learning environment solutions to turn the otherwise non-engaging temporary environment into an engaging testing ground of new kind of learning.

The ownership of the temporary school is endangered by its temporary nature. As indicated in work shops it appeared that no-one cares to take responsibility of a school that is not permanent. On the other hand the shared experience of the temporarity strengthens the engagement to the community. The lack of quality in physical conditions contribute to school engagement and identity by bringing the staff members and pupils together. The accessibility of the container school is often overlooked, which creates unusable and almost dangerous situation in school yard. On the other hand the lack of internal spaces such as corridors, forces pupils to move and interact with each other and within the space.

Based on results it can be said, that whether in design of a temporary school or a permanent school following suggestions should take into consideration, when planning new learning environments: Facilities should be planned primarily in terms of functions they could gather avoiding for instance the setting of different disciplines. Utilization of gamification as part of the learning and working (eg. Avatars, listing their achievements, gathering experience points, immediate supportive feedback). The school can be a interface of learning in itself.

Sets of furniture are such that they can be easily grouped into different forms to support and control the gathering of spaces. This can be also supported with a rhythm of curtains and other movable space dividers between the various rooms. Private spaces should move towards public spaces: the user should feel intuitively the nature and purpose of the different spaces and is able to act accordingly. The building should be easy to expand, if necessary, outside the classrooms, eg. In the lobby, courtyard, or in some other open environment. Spaces are teaching platform in their self: for example, green walls, showrooms, solar panels.

The interaction between the users and the environment, strengthens the school engagement (eg. events, concerts). The border of a temporary school building is often a lack of communal space. This is a weakness in formulating the engagement. Various events increase ownership and promote the takeover of the operating culture and spaces. Creating a themed space with a variety of identities, which are suitable for different learning processes give the users feeling of freedom and creativity. The engagement can be supported artifacts which encompasses a certain meanings.

Users should be included in the design of new environments and be given the opportunity to customize their own environment. Projects made together: for example, the wall paintings as part of the arts exercises, school logo design contest. The ownership of the building encourage students to move out of the recess. The external space of courtyard is extremely important and should be acknowledged. The gathering of spaces guides also the gathering of groups and social order.

Integrated learning for students in the Built Environment

Daphene Koch, PhD,
Purdue University
cyrd@purdue.edu

Abstract

The purpose of this study is to assess the transformation of integrated learning in one course related to the built environment. Research on college teaching and learning provide evidence active learning and collaboration is more effective than traditional lecture (Kuh, Kinzie, Schuh, & Witt, 2005; Pascarella & Terenzini, 2005). Applying this research to improve undergraduate education a transformation is occurring by incorporating more effective pedagogical techniques across disciplines. This paper will outline the changes which have been applied to one course that includes many different majors connected to the built environment. Data collected in this course and at the university will show if the integration changed the students' perception of learning climate, basic psychological needs or knowledge transfer. The results of this study will show the impact of the different elements of active learning in a classroom across disciplines.

Keywords: Assessment; Active Learning; Integrated Learning; Transforming learning

1. Transforming Education through Integrated Learning

Decades ago, King (1993) in his research, encouraged faculty to move from being a ‘‘sage on the stage’’ to more of a ‘‘guide on the side’’ in their teaching approaches. A university wide transformation program took this concept and applied current pedagogy to develop faculty training to change one course at a time. To improve higher education pedagogies, Instruction Matters – Purdue University Academic Course Transformations program (IMPACT) was based on research in pedagogy to improve student learning. The mission of the program is “to improve student competency and confidence through redesign of foundational courses by using research findings on a sound student-centered teaching and learning” (IMPACT Management,, 2014a,b,c). Through the development it was shown that redesign of courses needed to include innovation, implementation and assessment to be successful (Arthur & Zelda, 1987; Levesque-Bristol, Weaver, & Parker, 2012). The experts leading this initiative created tools for assessment based on The Self Determination Theory. This tool was used in all courses associated with IMPACT. One course that was transformed is an introductory course in the built environment (BCM10001). The transformation included the development of new learning outcomes, utilization of an active classroom and creation of active learning modules. Data collected over three semesters show the impact of the all courses at the university and the specific course related to learning climate, psychological needs and perceived knowledge transfer.

2. Review of Literature

2.1 Curriculum Development

Curriculum development was based on the research related to student success. One beginning set of tools includes the seven principles of good practice in undergraduate education by Chickering and Gamson, 1987. More current research includes the evidence of collaboration / team work and active, student-centered learning as increasing student success (Kuh, Kinzie, Schuh, & Witt, 2005; Pascarella & Terenzini, 2005). Blooms taxonomy was used to transform the learning outcomes into more students centered objectives (Anderson, L. W., Krathwohl, D. R., & Bloom, B. S. (2001).
John Dewey is believed to be the father of experimental learning and it is from his ideas that researchers have developed the self-determination theory (SDT). Each course transformation was unique, but it was important to have a common assessment tool. The experts leading the university wide curriculum researched leading publications and found the Ryan and Deci model was not only proven to be valid and reliable, but also aligned with their mission statement. This tool is utilized to measure students’ perception of learning climate, basic psychological needs and knowledge transfer (Ryan & Deci, 2000b). Self-determination theory has the potential to address learning problems such as student attrition in the active learning environment (Chen & Jang, 2010). As Neimiec and Ryan (2009) stated in their research, the STD higher learning can be improved by helping a student develop interest to want to learn because of interest in developing their own knowledge. This theory is based on the ideas that there is a need for autonomy (self-choice), the need for competence (mastery learning), and the need for relatedness (related to real world) (Ryan, Connell, & Deci, 1985). Figure 1 illustrates the concept of moving students towards self-determination and increasing

their intrinsic motivation to learn. The transformation of courses was based on this type of theory and as an assessment tool was developed to measure the effectiveness.

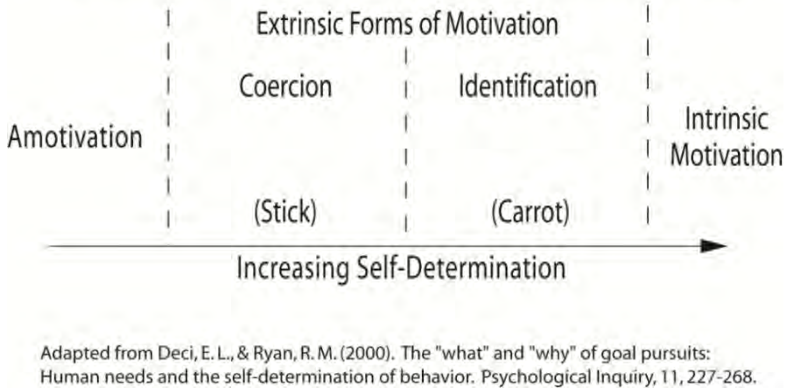

Figure 1: Continuum of Self Determination Theory

The goal of the project is to develop instructional pedagogy that engages students in learning activities that apply knowledge but also allows them to develop higher levels of cognitive learning. The activities create an engaged student that work at their own pace and continually grow as information is interpreted and applied to authentic interactions in the classroom (Grabinger & Dunlap, 1995; Prince, 2004).

2.2 Learning models

The IMPACT program was designed to utilize active learning through different course transformations techniques. There are three main models that were introduced to faculty to assist in their course transformation. The goal is to make a more student centered learning instead of the traditional lecture model where students listen and take notes during the entire class time. A supplemental model adds materials online which assists the students in applying the knowledge of the course. This could be videos over current events related to the class that assist the students in transferring the knowledge from the classroom to life. The idea is that when the students are in class, there can be activities integrated into the lecture to assist the students in applying knowledge and building cognitive skills.

The next method is the replacement model where parts of the lectures are replaced by online content to allow for more in class time for activities. Students come prepared for class and have reviewed materials which allow them to expand their participation in the class. The final method is known as the flipped method. This can be used for a fully online course or can be developed to eliminate the need for lectures and create a fully active student-centered teaching. For example, students read and do homework before coming to class and then review assignments in class instead of listening to a lecture that they were not prepared to hear. They read material and view videos on the assigned chapter before coming to class and then engage in active learning strategies such as debates on current issues during class (Gilboy, Heinerichs, Pazzaglia, & Chester, 2014). The idea that students must be self-motivated to learn before coming to class and that class time is used more for clarification of information. A hybrid model of this would be when some information is given in class like a mini lecture but still utilizes the class time more as a work period.

The supplemental model is the middle ground between the fully flipped and the traditional lecture. These types of pedagogical approaches have been utilized to transform classrooms.

Figure 2 illustrates the connection to active learning and the increase in student success measured by a lower Drop, Fail or Withdrawal (DFW) rates and increased GPA in courses. The ultimate goal is to increase retention and decrease time of degree completion to ultimately lower overall cost of education.

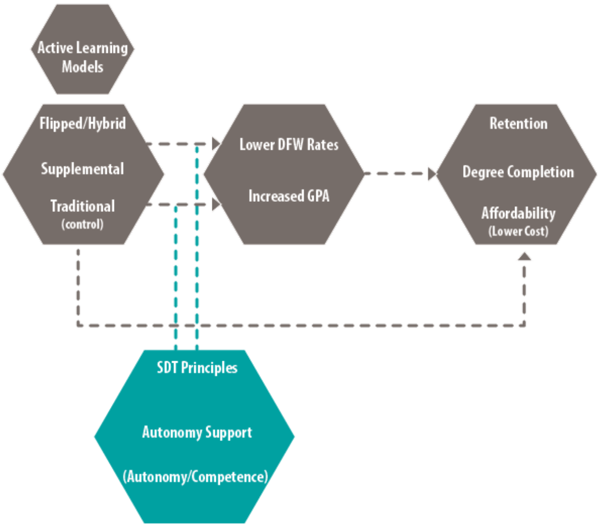

Figure 2: Active Learning Model Measurable Outcomes.

3. Specific Pedagogical Changes

The BCM10001 Introductory course was first transformed in spring 2013 with assessments collected in fall 2013, and spring and fall of 2014. The instructor has made the following changes to the course:

- Met in an active classroom with moving tables and chairs (shown in Figure 3)
- Developed an online textbook with pre and post tests for each chapter
- Implemented modules with pre work and in class activities
- Created community based group service project to apply knowledge.
- Instant feedback in class tests
- Limited lecturing with emphasis on activities in classroom

This university allows faculty to own the curriculum for each course while outside accreditation agencies validate each program. The outcomes of courses are required to be measurable for assessment purposes of each department. The changes in this course have evolved with continuous improvements added after each semester. The initial major changes were developed with the guidance instructional designers, literacy professionals and information technology experts.

Figure 3: IMPACT Active Classroom

3.1 Transforming Outcomes

The initial learning outcomes for this course were based on the American Association of Construction Education (AACE) accreditation standards. As these standards are moving towards outcomes based assessment, it seemed logical to also align courses to follow these standards. The original outcomes were as follows:

1. Introduce students to the Building Construction Management (BCM) department including: Faculty, staff, concentrations, program, history, career opportunities, student opportunities, and department events.
2. Review the history of the construction management industry through the current trends for the future. (LEED, Sustainable, Green)
3. Evaluate the campus resources available for students' success (Online writing lab, libraries, Academic Success Center (ASC), College of Technology Tutoring, BCM Mentors, etc.)
4. Identify and define materials, methods and construction vocabulary related to the CSI divisions by numbers.
5. Explain the various sectors of the construction industry and career opportunities for the students.
6. Utilize computerized software to overview topics including: project delivery types, contract documents, plan reading, bidding, estimating, pre-planning, scheduling, codes, and safety.
7. Reveal the roles and of the major players in construction industry and how they work as a team.
8. Identify the general concepts and applications of Building Information Modeling / Management (BIM) to construction plans and specifications.
9. Expose the opportunities for lifelong learning in the construction industry (certification programs per state, CPC, AIC, Site Supervisor Cert. etc.)

Over the semester long IMPACT workshop, the faculty and team refined the outcomes for the course to include only these four main points:

1. Review the past, present and future of the construction management industry.
2. Identify resources for student success and lifelong learning at Purdue and beyond.

3. Demonstrate competencies in using computerized software to overview topics in Construction Management.
4. Differentiate between material uses and applications on a construction project.

Each outcome for the course were then aligned with objectives which were mapped to an assessment technique. Table 1 shows a sample of two objectives related to outcome # 1. The first objective uses exam questions to assessment the recall level of Blooms. The next objective is assessed through a project and expects the student to analyze this topic area.

Table 1: Mapping of BCM10001 Course objectives to Blooms Taxonomy

	Remember/ Recall	Understand	Analyze	Apply	Evaluate	Create	Activities
1.a.i Define construction related technical vocabulary	x						Exam questions
1.a. ii Differentiate between LEED, Sustainable, and Green using materials as examples			x				Project

Further improvements in the course were created based on the pedagogies introduced in the classes. As replacement model of course design was utilized. Improvements to the course aligned with Checkering's principles of increasing student success in the classroom. The physical space of the classroom with rolling tables and chairs that can be configured into endless configurations assist the faculty and student connections. This allowed students to collaborate and work in groups and have the faculty walk around and sit with the students. Activities related to the built environment include: design process, team building, scheduling, estimating, communication, and professional development. Modules which include professional development assist the students with understanding how their career path integrates into the built environment.

One specific example of an active day is a mock career fair that occurs each semester during classtime. It is one part of a career development module that begins with a resume review. The Mock Career Fair was developed to increase the self-efficacy of students related to interaction of industry partners. Students are given information on how to dress, what to say and specific companies to research. Typically 6 – 9 companies with 1 – 3 representatives for each company attend the mock career fair the class before the real department career fair. Students are required to dress appropriately and interact the company representatives as if it is a real career fair. They received points by reporting out on the feedback, positive or negative, from the industry partners. Feedback from this has been positive from the student's and the industry partners. There is an overall belief that this class increases students' confidence and preparedness for the larger career fair event.

Some of the larger more technical course projects include a mini design project. This project has been done as an individual and group activity. The students are applying knowledge of roles in the built environment by finding flawed designs and outlining the major players in the owning, design, building, or maintain the particular infrastructure issue on the campus.

After this identification, the students had to come up with a plan on how to fix the design flaw thereby encouraging creative thinking as well helping students apply the knowledge obtained.

To understand project scheduling, students are required to bring a list of activities that they do in preparation for getting ready for school each morning. During class time, a full class discussion is facilitated by the instructor to help the students understand if each of the items on their list is actually an activity. Does it take up time or resources? After this discussion, students are introduced to a bar chart format for visualizing the data. They then work individually, but can talk with each other, to make each of the bar charts for this daily tasks. It is then that the students begin to understand concurrent and predecessors and successor types of activities. The goal of this assignment is to assist the students in understanding basic concepts of scheduling. Additional assignments included interpreting an actual construction schedule and developing a schedule related activities assigned.

4. Data collection to assess course transformation

Students in the course represent many areas of the built environment including designers and management. Table 2 below shows the typical distribution of majors attending the class. This course fulfills the requirements of a general education elective for the university and therefore is taken by all majors across the university. It is a required course for all students in the School of Construction Management majors and minors. The exploring students are undecided in a career choice and have not declared a college major.

Table 2: *Demographics by Major Typical for Course*

College Major	Typical Percentage in Class
Construction Management	51%
Liberal Arts	9%
Engineering	4%
Management	6%
Exploring	15%
Science	4%
Technology	11%

The diversity of the class allows for richer experiences for students to work in groups and share information. As an introductory course, there is a higher number of first year students, but also students who are upper level. Figure 4 shows the typical distribution by years enrolled in college.

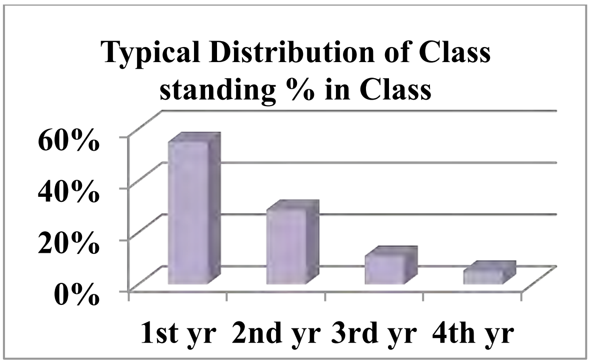

Figure 4: Typical Demographics of Class by Year

4.1 Methodology

Data was collected by the IMPACT team using an online survey instrument made up of questions on a Likert scale ranging from 1 (Strongly Disagree) to 7 (Strongly Agree). The survey instrument was made up of sections that aligned with the outcomes for the assessment (learning climate, psychological needs and perceived knowledge transfer). The survey instrument based on the STD research explained in the review of literature is one which has been proven over many years of research. This version of the survey has been utilized in all of the transformed courses since 2010. Some of the details which have been included in the questions are outlined below.

Learning Climate questions are used to determine the students' perception of the active learning. Sample questions include:

My instructor understood my perspective.

My instructor encouraged me to ask questions.

My instructor listened to how I would like to do things.

Basic Psychological Needs pertains to the extent to which students are confident about mastery of content material as well as the feelings of being connected, intellectually and emotionally, to other students in the class, as well as to their instructor. They include the areas of autonomy, competence, relatedness, and self-regulation questions listed below:

I am free to express my ideas and opinions in this course.

I feel like I can pretty much be myself in this course.

I have been able to learn interesting new skills in this course.

Most days I feel a sense of accomplishment from this course.

Perceived Knowledge Transfer is the student perception of if the course content is important to their future learning or life. Sample questions in this area include:

I feel confident in my ability to apply the course material in my professional life.

I feel as if the material covered in this course is relevant to my future career.

Information learned in this course will inform my future learning experiences.

I believe that it is important for me to learn the information included in this course.

4.2 Results

The goal of this study was to examine the effects of infusing active learning elements and integration into a course related to the built environment. The results will show the individual semesters that were surveying. The instrument consisted of three sections that align with the objectives of the study:

1. Learning Climate
2. Basic Psychological Needs
3. Perceived knowledge transfer

Descriptive and inferential statistics and selected variables were used to explore the research. Analyses were conducted to examine the experiences of the students who had chosen the course.

1. Learning Climate refers to students' perceptions of the student-centeredness of the learning environment. Results for the course and overall campus numbers are shown in Figure 5. Fall 2013 semester was lower due to being the first semester and having the least amount of activity. It is logical that as the faculty member becomes more familiar with the new pedagogy it would improve the learning climate. The lower numbers in Fall 2014 are probably because of a new online textbook that was implemented for the first time.

	Fall 2013	Spring 2014	Fall 2014
BCM 10001	5.72	6.4	5.85
IMPACT Mean	5.11	5.51	5.32

Figure 5: Comparison of average Learning Climate score

2. Basic Psychological Need is based on the Self Determination Theory as mentioned earlier. Figure 6 illustrates summary data for SDT in area of autonomy, relatedness, and competency as determinants of motivation. The highest learning climate provided the lowest Basic Psychological Needs satisfaction although the result was not significantly different from that of Fall-2014. This is finding is in accordance with Niemiec & Ryan's research and indicates that the infusion of active learning elements into learning climates can possibly undermine the Basic Psychological Needs of the students (Niemiec & Ryan, 2009).

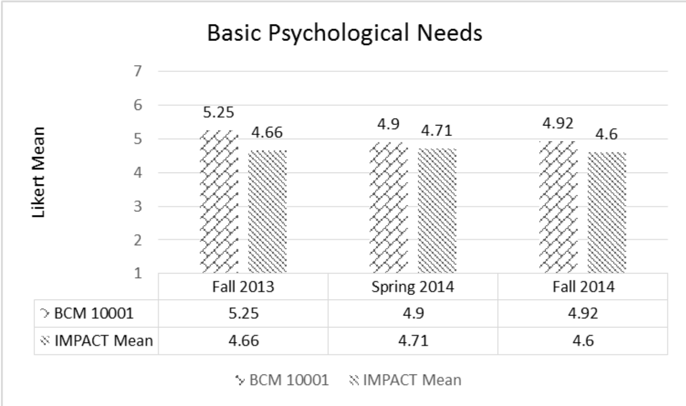

Figure 6: Comparison of Average Basic Psychological Needs Score

3. Perceived Knowledge Transfer is the engagement in higher levels of Bloom's taxonomy may improve the students' perception of knowledge transfer (King, 1993; Mazzolini & Maddison, 2003). Upon comparing the results of Fall-2013, Spring-2014 and Fall-2014, it was found that there was no significant difference in the way the students perceived their knowledge to be transferred. Figure 7 shows the overall comparisons for each semester.

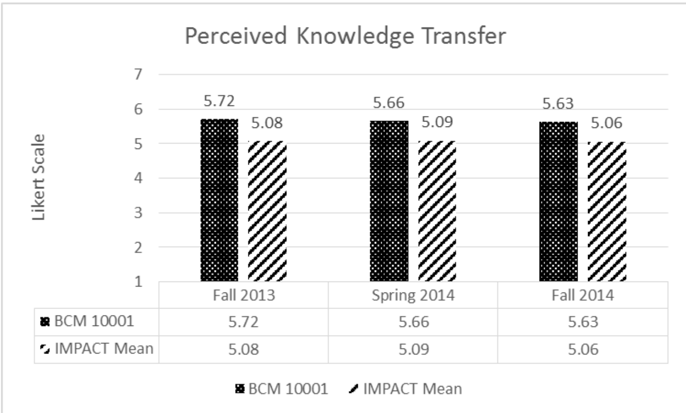

Figure 7: Comparison of average Perceived Knowledge Transfer Score

5. Conclusions

Overall the changes to the course showed to be very positive. Since the changes have been made to the course, the number of students taking the course has doubled. Industry partners are now commenting on the maturity of the students as the becoming employees in areas of the built environment. The active learning modules create a platform by which students learn materials, but also grow more motivated and excited about the career path and college major that they have chosen. Real world activities create an autonomous environment which increases student interaction. A gallop poll done in 2014 with over 30,000 college graduates around the United States showed that the top 6 outcomes align with the transformation ideas:

1. I had a professor who made me excited to learn (63%)
2. My professors cared about me as a person (27%)
3. I had a mentor (22%)
4. I worked on projects (32%)
5. I had an internship (29%)
6. I was active in extracurricular activities (20%) (Paul, 2015).

Unfortunately, only 3% of those surveyed had experienced all 6 areas. Those who were reporting were also reporting success in the workplace to further show that the extra effort by faculty to create an integrated learning environment might that transfers to lifelong learning. Figure 8 shows a summary of the three semesters for this course in comparison to the overall average for the campus. With n=170 for the course and n=7,000 for the overall campus, this gives a good indicator that the research of active learning is supported by this course.

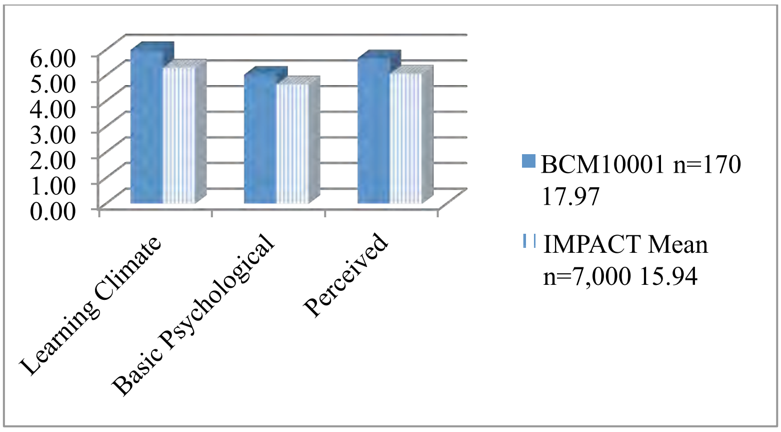

Figure 8: Overall Comparison of course and campus.

Abstract

The future learning environments are not based on standardized design solutions like lecture theatres for 100 persons or classrooms for 40 persons. As new technology and new ways of studying are being developed new demands are put on university environments. At the same time utilisation of resources in form of both teachers and university facilities is challenged by development of integration of learning, teaching and the spaces where it takes place. The challenges are shared among users and owners of campus, where retrofitting is needed too. This paper aims to describe Campus Retrofitting (CARE)- methodology for user-centric and co-creative campus retrofitting processes. The campus development research in Nordic countries and co-creation in retrofitting processes are discussed. The campus retrofitting cases in different countries are described by emphasising especially the methods they used. Based on the analysis of the methods the framework for Campus retrofitting (CARE) - methodology is presented and discussed. CARE-methodology is a tool to capture new logic to learning environment design. It has three key activities: co-creating, co-financing and co-evaluating. The integrated methodology and the formulation of the guiding principle of the CARE-way of sustainable retrofitting of university campuses opens up an agenda for investigating a new methodology for sustainable urban retrofitting in a Nordic context.

Keywords: universities, space management, facilities management, space design

1. Introduction

The Nordic countries have much in common, historically, culturally and linguistically. They have had a common labour market and strong co-operation in many areas for many years. The Nordic welfare state model is based on the rights of individuals to a decent life and equal opportunities for social promotion, often achieved through education. Higher education is a part of their large public sectors and has been influenced by a powerful nation-state in which regional policy considerations and the social thesis of equal educational opportunity have played an important role (Fägerlind et al. 2004). Nordic countries have a strong research and development drive in campus development. The challenge is to apply the research results to campus retrofitting practices: how and what kind learning environments to develop. Nearv et al. (2010) claim that the intelligent estates director, from a position of blindly reacting to academic demands and maintaining the existing stock, has taken a pro-active role in contributing to the academic and business planning process by presenting options, identifying under-utilised resources, and mapping out pathways to achieving academic aspirations. Also Nielsen et al (2012) emphasise the significance of interactive co-creation between an actor and stakeholders surrounding the actor as a way to develop future learning environments and in particular for sustainable retrofitting of universities.

The future learning environments are not based on standardized solutions. Universities are under pressure to expand, change and find greater efficiencies. They have recognised the value of their estate both as a real estate asset and vehicle to open up opportunities for innovative teaching. All Nordic university property management organisations emphasise, that their operations need to be sustainable from economic, environmental and social perspective. There is a need to preserve the cultural heritage, since the university properties are often culturally valuable and reflect the society in general (Anon. 2010).

This paper aims to describe Campus Retrofitting (CARE)- methodology for user-centric and co-creative campus retrofitting processes. First the campus development research in Nordic countries and co-creation in retrofitting processes are discussed. Then the campus retrofitting cases in different countries are described by emphasising especially the methods they used. Based on the analysis the framework for Campus retrofitting (CARE) - methodology is presented and discussed.

2. Campus Retrofitting

2.1 Need to Retrofit Learning Environments

A university's campus is seen as a huge learning environment, which creates possibilities for learning – also across the university's academic environments (Anon. 2013). The last thirty years have witnessed dramatic developments in higher education. In Danish literature it is stated that an important parameter in world-class universities is a vibrant and challenging physical research and study environment. Physical planning is of great significance to the quality of the study and research environment at and around universities. (Anon. 2009) New methods of learning, new creative work environments, internationalisation, digital possibilities, and not least urban development and more stringent energy requirements continually increase the demands concerning the physical setting (Anon. 2013). In Norway thirty projects, which address such issues as the future of the prototypical greenfield campus were collected in order to understand how inner city campuses are transforming the urban context and include prominent corporate enclaves and their ideological underpinnings (Hoeger and Christiaanse 2007).

In Sweden Karolinska Institute and Stockholm County Council (SLL) had a research and development project about Future Learning Environments in 2010-2012: How Space Impacts on Learning. They used the concept of the learning landscape to explore the range of learning environments needed at multiple scales to better align with changes in the medical education curriculum. Four key scales that correspond to important types of learning spaces are identified: the classroom, the building, the campus and the city. "In- between" spaces were identified as growing in importance given changing patterns of learning and the use of information technology. The focus from singular spaces to networks of inter-connected virtual and digital environments was considered as a critical shift. The need for higher levels of engagement of faculty, administrators and students in defining the briefs for the design of new kinds of medical education environments was highlighted (Nordquist and Laing 2015). By using more sociological perspective (Leijon 2012) states, that space shapes interaction, but interaction also shapes space; thus, it is essential to consider space in relation to negotiation and transformation (Leijon 2012). According to Nenonen and Lindahl (2014) inter professional interactivity and boarder zones between the traditional hierarchy, space segments and organisational structures as learning environment need to be identified, especially in the context of medical education.

Similar topics were touched in Finnish research about academic identity. User identity has a significant effect on how users experience a campus area and its buildings. Despite this, user identity does not necessarily meet the image of the organization. The strategic planning of spaces need to be done without forgetting the history and own identity of the users. (Airo and Rytkönen 2015). This finding has been published as a part of the large research and development program The Future learning environment 2011-2014 led by University properties of Finland. The learning environments of the future were investigated from the perspectives of campus co-operation, sustainable development, co-creation and multi-disciplinary learning. In the begin of the research program the expectation was to collect the new typologies for learning environments but at the end of the project it was found out that that equally important as the new solutions are the processes how they are realized together with users. E.g. the transition to sustainability is often seen as a top-down governing challenge, but it can include pioneering bottom-up ways to create change. Bottom-up actions in innovation should be given recognition and nurturing, as the bottom-up initiatives often challenge systems that resist change (Pulkkinen and Staffans 2005).

The existing premises of campuses possess a huge potential to be turned into lively urban centres that support learning and research of the future. Hence, the existing buildings can be seen as platforms for novel architectural solutions and stages for presenting the universities' state-of-the-art education and research. Radical, extensive changes would most likely create the biggest impact on behaviour and functionality. However, not all changes need to be massive and expensive. Like acupuncture, which releases energy by the point of a needle, so could the campus spatial structure be energized through small changes, which have a bigger impact than their size (Poutanen et al., 2015). According to Eriksson et al. (2015) retrofitting as technical and spatial solutions covers only part of the process. The activity-based retrofitting consists on multidisciplinary collaboration and learning processes where the diverse users have different roles during the retrofitting process. This will be discussed in the following chapter in terms of co-creation.

2.2 Need to Co-create in Campus Retrofitting Processes

Campuses are pioneers in facing the built environment challenges. The retrofitting processes are the additions of new technologies, features and functions to existing built environment systems. In university campuses this means the development of embedded learning environments, new space typologies, variety of platforms (both digital and physical) supporting collaboration within the university and in connection with diverse stakeholders. It means upgrading or replacing technical elements but also the changes in user activities and practices. Nevertheless it is connected also to service concepts and the new ways to produce services. (Eriksson et al., 2015) The purpose of user involvement in retrofitting processes means making fuller use of user knowledge and experience. Action and use of facilities is strongly related to experiences of the users and thus their possibility and will to perform. People create their own places in the facilities – they are socially constructed. Both technical and psychosocial systems are important when retrofitting campus. Co-creation allows and encourages a more active involvement from the users of the campus to create a value rich experience. Interpretation and analysis of the built environment and support services based on how it is socially constructed will enable integration of organisational use and the facilities provided to arrive at an understanding of usability of built environment (Alexander et al., 2013). The question is how retrofitting processes are conducted.

Sanders (2008) has been investigating the history of co-creation and stated that in Norway, Sweden and Denmark the Collective Resource Approach was established to increase the value of industrial production by engaging workers in the development of new systems for the workplace. The approach put together the expertise of the systems designers/researchers and the situated expertise of the people whose work was to be impacted by the change. The approach, thus, built on the workers' own experiences and provided them with the resources to be able to act in their current situation. In the broadest meaning of user participation it could be called "collective design" which was launched in early 1990´s. Collective design is something more than contributory influence and just participation. It is a process where knowledge and values confront, complete and modify each other leading to something new. All actors in the process are regarded as experts and their participation is therefore based on their relevant knowledge rather than on their roles as representatives for different interests. (Granath et al., 1996) Over the past ten years, together with increasing attention to the importance of front-end activities in general (Ryd, 2008; Blyth and Worthington, 2010), new interest in user involvement is emerging; though a change in focus is noticeable. The purpose of user involvement has shifted from mere participation to co-designing, making fuller use of user knowledge and experience (Sanders and Stappers, 2008; Erikson et al., 2014).

CIB Work Group 111 on Usability of workplaces - with a significant amount of Nordic researchers and practical case studies - has been exploring concepts, methods and tools, developed in the usability of built environment, including also learning environments. A key product of the Nordic research project REBUS (User- oriented Benchmarking for Usability in Real Estate) was a process description, detailing how building owners and facilities managers can gather user experience from existing buildings as a basis for improving them, as input when designing new buildings, or as a reference when choosing new premises. (Lindahl et al. 2011). The universities comprising of the students, researchers, professors, lectures and other staff are the users of the universities properties. The university occupiers' needs vary from other commercial properties (e.g., offices) with needs regarding, i.e., lecture halls, laboratories and other special space. The university properties are often relatively large, made for a special purpose and can be difficult to convert to other usage. (Alexander et al. 2013)

To sum up it seems to be crucial to understand more the characteristics of co-creation methods in campus retrofitting processes in order to find out the ways for constant, future-orientated way to develop learning environments. Leaning on Nordic tradition on user-involvement we make the following analysis of campus-retrofitting cases.

3. Nordic studies about Campus Retrofitting

Campus Retrofitting (CARE) -project focused on innovative retrofitting of Nordic University Campuses. The goal was to develop and demonstrate scalable retrofitting, CARE-concepts for sustainable built environment management. The emphasis was in developing the systematic and continuous Campus retrofitting methodology, which is a system of broad principles or rules, from which specific methods or procedures may be derived to solve campus retrofitting problems in the context of developing future learning environments.

In Sweden, Denmark and Finland the Campus retrofitting studies were connected to developing new concepts for learning environment especially by understanding the diverse needs for informal learning. In Norwegian studies as well as in some Finnish studies the emphasis was in evaluation of the retrofitting concepts. In Norway especially in terms of the use of energy efficient solutions and in Finland in terms of the usage rates, indoor environment quality and user satisfaction of the solution.

The Danish study aimed to develop future learning environment together with users. The method used in Danish study was participatory workshops in DTU (Danish University of Technology) Campus Service – building client function for developing future learning environments. Instead of the usual approach: study tours they wished to get inspiration from ”learning researchers”. They conducted an action research process in spring 2015 with four workshops and participants were campus service representatives, teachers, students and users of Learning lab. The themes for the workshops were: Dream learning environment; What do we know about learning spaces and what are the new typologies; Relations between learning space, technologies and learning and Performing University Spaces. The outcome was a new and different dialogue, which was engaging, strategic, open. It opened the bigger picture for participants and created the idea of a ”longitudinal community” to supplement existing organisational structures. The facilitators and experts of the workshops represented e.g. anthropology and business sciences. The approach was multidisciplinary by its nature.

The Swedish study aimed to build meeting places within the university designed to create and implement social responsibility and sustainability framework of Chalmers Real Estate Ltd. The method used in this study was based on best practice mapping by using the approach of human geography and urban sociology. They developed a manual for the meeting place builders called “Building Meeting Places - an introduction to strategic inter structure supply”. In parallel with the manual also a digital tool for inventory and analysis of the meeting places have been developed. Additionally the training of staff was part of the project. An inventory of meeting points on the Chalmers campus has been made during the spring of 2014, which formed the basis for future development with the physical environments. The manual includes a reviews of the meetings and venues evolved historically, trends that are relevant to today's and tomorrow's meeting place realization, models and theories to analyze and describe the meeting places' anatomy and character, as well as a number of concrete strategies and tools to develop and strengthen the different types of meeting places. The first demonstrations were made during the Campus Retrofitting process.

The Finnish study included 26 demonstration projects on different campuses of Finland, conducted by University Properties of Finland. Co-creation, realization, co-inesting and finally evaluation of activity based, multifunctional learning, research, and working environments were typical for the demonstrations. The retrofitting in case Musica, a building at Jyväskylä University Campus dedicated for education and research of music, aimed to plan a living room and learning/research spaces for the students by using Charrette-method. During the five day Charrette-process the new end-user goals were recognized and linked with the strategic principles of the facility department of the university, and the needed planning documents were created. Small scale campus retrofitting demonstrations concerning future learning and working environments in universities was the effective way to test new, unknown solutions and concepts. The costs were shared between user and property owner. (Naaranoja et al 2015)

In Tampere University of Technology, Finland students were in active role when redesigning under-used lobbies into a lively social and informal learning space. The halls and corridors, which are located in popular areas on campuses, have great potential as redesigned into novel social and informal learning spaces. Learning spaces located in circulation spaces reach students from all faculties, which also intensifies the use of the spaces as those compose typically up to 22% of the total floor area of Finnish university buildings. Campus-wide Wi-Fi and the culture of Bring Your Own Device (BYOD) enable all secondary spaces for informal and social activities. The three cases were novel learning spaces created in a lobby, a renovation of a campus café, and co-created learning spaces in an academic library. All of these demonstrations were successful in both attracting people and increasing the popularity of the space. Also the indoor environment measurements provided evidence of sufficient comfort factors. Economically the demonstrations were inexpensive due to the fact that they were made by innovative student projects. Traditionally the renovation budget is used to return the facilities to the same level than they used to be – campus retrofitting demonstrations focus on developing the facilities for responding to the needs of future. (Poutanen 2015).

The Norwegian study focused on energy-efficiency improving methods for non-residential buildings and linked master student education with an on-going research project on energy efficiency improvement of non-residential buildings. They mapped the implementation in Norway by developing and conducting a MINDER survey with focus on existing methodologies. They learning environment was extended to visit and study energy-efficient buildings in its real life context. The students were invited to visit the buildings, analyse building documents, conduct interviews with practitioners and meet in the university classroom to present and discuss their findings. Best practice examples represented the most relevant building types and user organisations towards energy-efficiency improvement and were selected from the local municipality's energy-efficiency award. The students developed and presented findings with focus on innovative solutions for energy-efficient buildings' management. The aim was to analyse and improve the methods for innovative approaches for energy-efficient operation of energy efficient buildings. The survey cooperation with practice contributed to getting information and develops a deeper understanding about user-behaviour in energy-efficient maintaining of buildings next to technical facts and figures.

Additionally a Living lab case study have been followed up. The case was a single-family house at NTNU Gløshaugen campus in Norway with a gross volume of approximately 500 m^3 and a heated floor area of approximately 100 m^2. The house consisted of traditional residential spaces such as living room, kitchen and two bedrooms and it was used as a living lab. The ecological drivers for activities were low energy demand, passive and active use of natural resources and independency from the energy grid and lowering the environmental impact of the second home sector. Living Lab was developed in cooperation with industrial partners inside the Research Centre on Zero Emission Buildings (ZEB). The design included a wide range of components that can be adjusted according to users' needs and desires, functional program distribution and climatic context (envelope, furnishing, and technical system). The users interacted with buildings characterized by high indoor comfort conditions and low energy demand. The monitoring system of the use of the building has been designed in order to be flexible, expandable and easily reconfigurable. In addition sensors have been integrated in the building as it would be in a real house and chosen among those that can be installed in a real-world application - i.e. on- purpose-made sensors have been avoided as much as possible. The Living lab involved students, researchers and industry partners to develop sustainable solution and behaviour. (Finocchiaroa et al. 2014)

The analysis of the methods used in different Nordic studies was made by comparing the following aspects: How the users were involved to the studies and demonstrations, how the campus retrofitting process/project was realized in practice and economically and how the demonstrations were evaluated. The summary of analysis is presented in Table 1.

Table 1: Summary of campus retrofitting methods

Analysis focus \ Country	*Denmark*	*Sweden*	*Finland*	*Norway*
User involvement	*Active role in workshops – source of ideas and information*	*Staff trained to meeting place manual*	*Active role in workshops – source of ideas and information*	*User behaviour in testing focus*
Realization	*Longitudinal community for on-going development was established for creating the future learning environments*	*Inventory of meeting points in campus and development of meeting place strategy for campus*	*Future learning environment demonstrations with co-funded budgets of owner and user. Partly realized as student projects*	*Producing and testing energy efficient solution with focus on user interface*
Evaluation	*Not yet*	*Not yet*	*Sensors for indoor environment, interval cameras, observations, user feedback surveys*	*Testing user-interface in Living lab Case studies on using and maintaining the energy efficiency of buildings*
Other remarks	*Trans disciplinary approach*	*Trans disciplinary approach*	*Diverse participatory methods*	*Integrating master student education and research*

4. Results

Based on the analysis the campus retrofitting methodology includes the following elements:

1. Active user participation and co-creation process: Campus retrofitting methodology indicates the importance to understand users and their needs as well as diverse activities, which set requirements for the future learning environments. The user was in all cases the main informant and also co-creator. The users were challenged to provide insights about their activities now and in the future. They were set to the active role also in designing the solutions. This activity based understanding is the basis of co-created and co-designed solutions.

2. **Commitment to share economical costs among stakeholders - co-financing:** The active stakeholders in Danish, Swedish, Norwegian and Finnish studies were the property owners or facility managers. They need to provide good university facilities and at the same time take care of the economical issues in order to achieve sustainability, sufficient usage rate of university facilities and efficient use of spaces. The economical structure was based on co-financing the projects by the university and by the property owners. The engagement of user and owner create cost-efficient ways to retrofit campus facilities.

3. Follow-up measurements - co-evaluation: Evaluation together with users and owners as by using diverse methods (e.g. user surveys, using sensors, interval camera and user feedback, user interface testing) to ensure the success of demonstrations was important in all cases. Co-evaluation provides evidence about effectiveness of the solution and material for learning and developing. It provides a longitudinal perspective for retrofitting processes and solutions.

The qualitative methods in connection with more traditional quantitative and objective methods together provided the valid process for proof of evidence in Campus Retrofitting (CARE)-demonstrations. The Norwegian study included survey, where the intention was to combine the technical data with the user data and enlarge the scope of fully technical approach to energy efficiency. In the Living lab case the user interface was the in user-test and both technical and user-data was gathered. The Finnish studies connected to campus lobby demonstrations included the measurements of usage rate and user satisfaction provided also quantitative data. In Danish, Swedish and other Finnish cases the methods were more qualitative by their nature including e.g. participatory workshops.

It was notable that the besides the different stakeholders the use of multidisciplinary approach was typical for the cases. E.g. Finnish charrette-process is based on method used traditionally in urban design. In the Swedish study the manual was based on human geography and urban sociology approach. In the Danish study anthropology and business sciences, e.g. management were part of the content of the workshops. The synergy between different disciplines and different actors provide material for new solutions.

5. Discussion

CARE-methodology has three key activities: co-creating, co-financing and co-evaluating. CARE-methodology can be framed and illustrated with the following Figure 1.

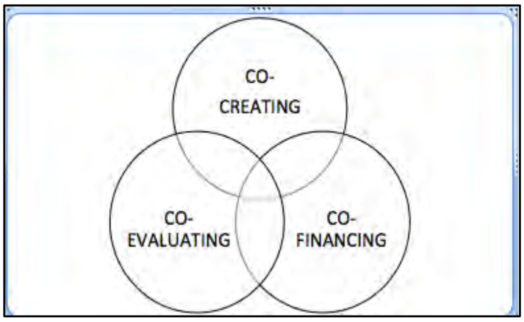

Figure 1: CARE-methodology

CARE-methodology consists on sharing: the vision, costs and results of retrofitting are shared between users and owners of campus in order to develop the future-orientated and sustainable agenda. The iterative processes of campus retrofitting differ from traditional linear technical projects. The activity based campus retrofitting is the on-going process and not limited to the certain phase of the retrofitting as a financial or technical process.

The Nordic studies provided material of planning itself but also new ways to provide continuity for the development of learning environments: it is important to provide proof of concepts and to engage different stakeholders. In order to use the CARE-methodology in practice the following steps are recommended: 1. Set the vision for the retrofitting process. 2. Identify the diverse actors for sharing the vision. 3. Define the budget among diverse actors and agree about the shared economy 4. Involve users to co-creation by using different methods. 5. Update user needs continuously, not only in the one dedicated, often predefined phase like e.g. specification of needs. 6. Decide and realize the user-centric evidence collection of the process and the solution. 7. Learn and develop continuously: there is not such a thing as "finished solution".

CARE-methodology can be a tool to capture new logic to learning environment design. The Nordic studies were chosen because they represent new and actual on going, experimental co-creating strategies at the universities, and we expected to gain new insights from these innovative processes, where the universities deviated from their standard practice. This has led to identification of new methods and contributions to the current literature on retrofitting of universities and learning environments. The two-year long project did however not allow longitudinal studies beyond one year or further co-creation processes. And this we recommend for future studies.

6. Conclusions

Nordic universities have been investigating campus retrofitting case-studies, which include a wide spectrum of methods how interaction and co-creation between students, teachers, researchers, real estate and FM staff as well as industry can take place in campus retrofitting processes. The wide user group represents a broad cross section of perspectives and experiences and provides a platform for fruitful discussions of the studied demonstration projects. The applied methodologies and the formulation of the guiding principle of the CARE way of sustainable retrofitting of university campuses could be applicable in the larger context of urban retrofitting. The methodology is not depending on learning environment or university campus context as such but it seems to be more transferable by its nature. It opens up an agenda for investigating a new methodology for sustainable urban retrofitting in a Nordic context.

Acknowledgements: The CARE project is co-funded by Finnish Funding Agency for Technology and Innovation as well as the authors' universities. We would like to thank our project partners Olli Niemi, University Properties of Finland; Jacob Steen Møller, DTU and Tore Haugen, NTNU and their colleagues for the many stimulating CARE conversations.

How to Manage Corporate Real Estate and End-Users Engagement into Smart Workplace Change Strategies: A Case Study

Chiara Tagliaro,

(email: chiara.tagliaro@polimi.it)
Andrea Ciaramella,
ABC Department, Politecnico di Milano
(email: andrea.ciaramella@polimi.it)

Abstract

Progressively, the spacial demand of workplaces is modifying, together with the habits of workers. How can companies react to the change of perspective that is affecting the traditional ways of working? What does 'Intelligent Built Environment' mean for corporations?

For several years at international level, it has diffused a new conception of the office: flexible spaces, shared desks and informal areas that can accommodate different activities as needed. Even in Italy this phenomenon is spreading rapidly: some firms have started to abandon cellular offices and open-plan offices, and to experiment with flexible work settings. A new demand is emerging with specific characteristics. The most significant drivers seem to be economic efforts (big and expensive buildings affected by low daily occupancy) and organizational reasons (teamwork, part-time work, teleworking, network strategies, etc.). Nevertheless, even external factors such as competition, globalization and corporate image can influence the motivation for change.

The authors have collected data on new ways of working and workplace change strategies in the brand new Italian headquarters of a company active in the technology hardware & equipment industry, with around 1,000 employees. The investigation involved both quantitative and qualitative research methodologies. By matching the results obtained, it has been possible to elaborate some considerations regarding benefits and risks of flexible workstations and the way of integrating smart working into corporate real estate strategies. What kind of data is valuable to retrieve about the use of workspaces? Which methodologies would be the most suitable for such a scope? When and how should consultants support their clients? And, most of all, to what extent can an 'intelligent building' support human activity in daily life?

The knowledge acquired can be useful to companies, both for managing the functioning of existing buildings and for orienting future projects towards the objective of becoming more 'intelligent'.

Keywords: Smart Working, Employees' Satisfaction, Workplace Change Management, Corporate Real Estate, Intelligent Office Building

1. Introduction

More than 30 years ago, Ronald Goodrich (1982) was considering that "now, as a result of the growing importance of office work, the introduction of office automation, the changing character of work, and the economics of office buildings, the office environment is becoming more intimately linked to the psychological needs, performance, and well-being of its users." The same consideration, with the due differences, seems to be valid today as well. The importance of office work has now partially been revised, office automation is evolving everyday, new ways of working are rising, office buildings are changing their form and function, and the office environment requires being linked more than ever before 'to the psychological needs, performance, and well-being of its users'. New working activities, new technologies with which we do them, new organizational structures and new ways people work together generate new requirements from the users' side, that reflect on the space, the building and the built environment.

The opportunities, offered by a world that is more technology-driven everyday, lead to new ways of communicating, informing and networking affecting life and work style (Corso, 2005). Due to the advancements in the Information-Communication Technology field, some main consequences are emerging: a) new ways of communicating and expressing likes/dislikes are diffusing; b) new ways of working are developing; c) new data is available and suitable to create value. These aspects converge in the workspace that should, therefore, change and evolve taking into account people expectations. This probably means that, along with the workplace features, configuration and layout, even the methodologies currently used to assess the workplace quality might be adapted. As the most recent RIBA 'Plan of Work 2013' suggests, the fine-tuning of building quality against users' requirements, expectations and opinions is recognized as a fundamental part of the construction process and the users are important stakeholders within it (RIBA, 2013). But, despite the many Post-Occupancy Evaluations that have been conducted worldwide, it seems there is still the need to find a way to transfer that process into a form that can be meaningfully put into everyday practice (Mallory-Hill, et al., 2012). Moreover, it is fundamental to make the user-centered approach (Vischer, 2008) more widely diffused – e.g., in Italy there is still lacking circulation in the academia and a shortage of applications in the professional sector.

For these reasons, there is growing interest in studying the interactions between the working environment and users' perception. What features should characterize the workspace according to the new ways of working? How can we assess them? How is it possible to fine-tune the quality of the workplace? These questions affect all the stakeholders taking part in the process. Among them, Corporate Real Estate departments are particularly interested in those issues, since they are in charge of workplace change management, together with the Human Resources and Facility Management. Companies are taking up new ways of working in order to attract and retain talent, be competitive and successful in the globalized world (Heather, 2003). Architecture and built environment can be the enabler for the competitiveness of regions and cities, the success of companies and the well-being of workers and citizens. How is it possible for an office building to take the role of enabler? What is an 'intelligent office building' meant to be?

2. Background

Corporations that need new buildings should pay attention to creating solutions that correspond to real requirements, in order to obtain major cost savings with the best quality. Moreover, it is important to fine-tune building performances continuously, according not only to corporate strategies, but also to pragmatic human experiences. By involving the end-users of office buildings, in fact, it is possible to build an effective decision making process. For these reasons, an integrated approach to the design, delivery and management of buildings and built environments is necessary nowadays. The objective is to reach the best results in terms of employee commitment, satisfaction and productivity (Miller, et al., 2014).

To this end, an international company was interested in conducting a post-occupancy study on their brand-new Italian headquarters. The firm had recently invested in the construction of new premises. The initiative entailed a radical re-layout of the work settings, according to the smart working approach (Methodos, et al., 2015) and looking at the 'Intelligent Building' model – i.e. high-tech building with flexible office space and advanced control technology (Preiser & Schramm, 2002). The application of a hot-desking solution (Knight & Haslam, 2010) was embraced in order to optimize space utilization and encourage employees' interaction. Only 30 employees out of almost 1,000 can use an enclosed office, different business units are grouped in some open-space areas, which are dedicated generically to one organizational function, but nobody has an assigned workstation. A proportional number of meeting rooms, varied for capacity (from 4 to 25 seats) and equipment (projectors, screens, teleconference and videoconference tools, etc.), concentration rooms and phone booths are located on each floor, beside some free space for informal meetings, breaks etc.

The study began 6 months after the move in, in order to allow the occupiers to start using the space and get accustomed with the new way of working. The previous workspace setting was arranged as a traditional open plan, with fixed workstations and a very low density rate. Therefore, the working experience radically transformed in the new building and some resistance to change emerged among employees. The objective of the management, including Corporate Real Estate (CRE), Human Resources (HR) and Facility Management (FM) departments, was to accompany the employees through the workplace transformation, to verify the pre/post-transfer impacts and to harmonize the new spaces with their requirements.

3. Research Methodology

The investigation involved both quantitative and qualitative research methodologies, in line with the approach suggested by Jick (1979) and referring to Post-Occupancy Evaluation techniques, as recommended by Costa (2014). The first methodology implied processing on quantitative data provided by the company and a questionnaire administration. The qualitative approach consisted of a field observation campaign, some semi-structured interviews with the management team and a few focus groups with employees.

As the exploratory phase began, a large documentation was revised about the characteristics of the building, completed by a non-structured observation with the walk-through of one of the HR managers. In addition, numerical data concerning the accesses of employees to the building and meeting rooms' reservation was analyzed. Actually, FM and HR departments pick up this data on a daily basis, but leave it at a raw stage of elaboration, so it needed cleaning and preparing before use.

Semi-structured interviews with the management team, including CRE, FM and HR managers, were conducted, with the goal to bring together impressions, intentions and sentiment from the stakeholders responsible for fine-tuning real and perceived building performances.

The structured observation was carried out on 2 different workdays, considered representative of the standard ones, given the firm's characteristics and different business units' habits. This methodology was applied to map and monitor the way people use spaces, according to the behavioral mapping approach typical of environmental psychology studies. In addition, qualitative considerations about where and how workers performed several activities were annotated and later compared with workers' perception. Four researchers, in two groups, walked through specific zones of the building (selected as a representative sample of the whole premises), making sure to observe each space once per hour. Overall, 62% of the workstations and 87% of the meeting rooms were observed. Supported by a detailed checklist, the observers punctually registered the number of:

- employees seating at desks;
- personalized desks;
- employees occupying the meeting rooms;
- employees using concentration/phone booths;
- people present in the break areas.

These records have been intersected with:

- total number of accesses;
- total number of desks;
- capacity of the meeting rooms;
- number of phone booths;
- number of break areas.

In the end, 3 focus groups were organized to directly meet with the employees and listen to their thoughts. The HRs selected the 50 people sample – divided into smaller groups. The sample represented overall almost all the business units inhabiting different zones of the premises. A questionnaire was administered during the sessions, with the aim of systematically collecting some information and better organizing the meetings, since they involved a large number of employees. This covered several aspects and was composed of seven questions about workers' perception, four of which, more in detail, regarded – see Appendix (Survey questionnaire):

1. their doubts or worries before the move compared to their feelings after the move;
2. their presence at work during the 'typical working week' (time spent in the office building);
3. their activities at work during the 'typical working day' (time spent on different activities and in different areas of the building);
4. the level of importance and relative satisfaction they attribute to some factors that affect work quality and effectiveness (on a typical Likert scale from 1 to 5).

The questionnaire was used as a template for open discussion. After answering one question, the people were invited to talk about the same topic and discuss between each other. The interviewers wrote down several annotations during the conversation, suitable for further comments. Finally, information gathered through the application of the methodologies above mentioned have been matched together.

4. Findings

Useful findings have been built up thanks to the integration of several methodologies, none of which can bring trustworthy results if taken in isolation. Quantitative data retrieved about the use of the workspace (e.g. number of accesses per day, employees sitting at the desk, personalized desks, employees occupying the meeting rooms, employees using concentration/phone booths, people present in the break areas) need to be verified against qualitative information. Only through this integration, is it possible to get 'what' is happening and explain the reasons 'why' this is going on and, therefore, find a strategy to correct eventual mismatches.

The chapter will summarize the main insights obtained on flex office implementation, workspace management and employees' satisfaction, with respect to the move in process and the brand new office layout.

4.1 Pre/post Transfer Impact

With regard to the employees' issues about moving to the new premises, most of the focus group participants found their worries were ill-founded. Out of 49 interviewed employees, between 60 and 70% confessed they:

- were afraid of wasting time while they were looking for a free work station;
- were concerned there could be problems in working relationships with colleagues;
- suspected they would lose their normal efficiency in their daily work activities.

Overall, they found that these matters were not a problem. Respectively, 100% of them were satisfied with finding a free workstation, 85% of them were fine with working relationships and 78% had no problem with work efficiency. In more detail, during the open discussion, specific reasons for concern in work efficiency emerged, which lowered the employees' level of satisfaction. Among these reasons, the main ones were associated with noise and distractions in an open space setting, sense of privacy, and climatic discomfort. Regarding these problems, a deeper understanding has been provided thanks to the field observations and the further points faced in the focus groups, where additional issues connected to the quality and effectiveness of the daily work came to light.

4.2 Adaptation to flex office

Even though the majority of the people who were afraid of wasting time while looking for a free workstation admitted to having no problem in this instance, some complaints about contract conditions arose. Against expectations, indeed, contracts require most of the employees to work in the office (*"I thought flexible space meant a more flexible management of work. I thought I would really be able to work from home, but this is not happening now"*). The ratio of people who have a telework contract and employees with a traditional contract is very low (*"about 1:9"*) and in some cases has been further reduced compared to the previous situation (*"many colleagues had a 3-days-at-home-2-days-in-the-office contract. Now contracts are renewed in the opposite sense"*). As a result, the risk of overcrowded spaces increases proportionally with the rigidity of contracts. Besides, there is the threat this company policy is upsetting employees, who perceive a considerable lack of alignment between architectural/layout choices (*"it is all in flexible logic"*), on the one side – which aims at establishing a model of flexibility in settling and working, and contract conditions, on the other – which are perceived as working against that model. In this regard, it is noted that a good workplace strategy should be managed with the full involvement of the human resources and real estate functions, that should work in an integrated manner (Martin & Black, 2006).

In addition to this consideration, the questionnaire shows that most of the interviewed employees can represent their working hours in a 'typical working week', where over 90% of them say their daily work is performed in the office. Only a very small minority believes their activity does not follow a regular pattern and admits they are often away from their work desk. This minority includes employees of those business units that are typically more mobile, such as the customer service unit and the marketing department in particular.

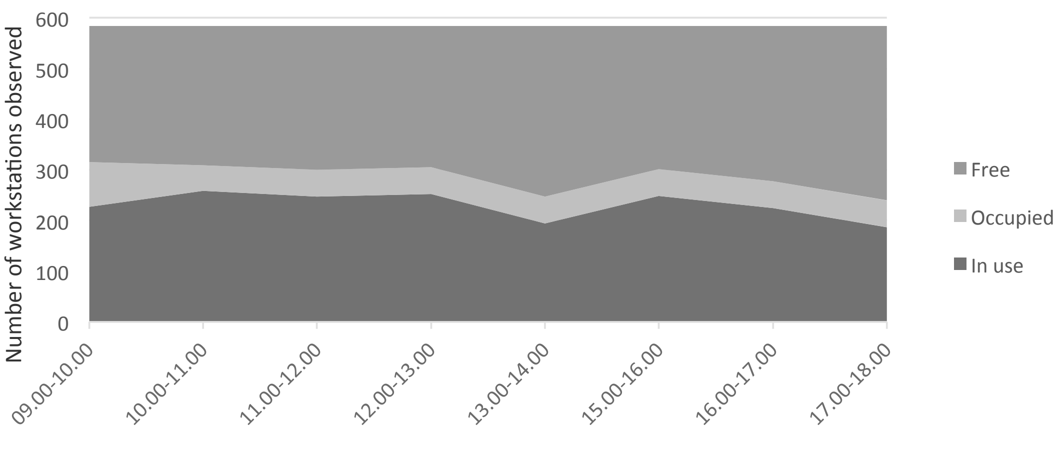

Figure 1. Number of workstations in use, occupied and free (source: observation)

Comparing the issues that emerged during the focus groups and the questionnaire answers with the numerical records retained by the HRs and the field observations, it is possible to correctly weigh the accuracy of the statements reported by some workers. According to them, in certain conditions it is difficult to find a free desk (*"on some days there is not enough room for everybody, teleworking does not fit in properly"*). The quantitative data obtained from monitoring badge swipes at the entry turnstiles, during the period January-June 2015, reveals that the average attendance level of the total number of employees is around 75%, reaching 81% as its highest value. Therefore, employees' perception about their daily presence in the office doesn't correspond to real data. Moreover, field observations reveal that the percentage of attendance at the workstations is even lower (Figure 1). Only around 40% of workstations were in use (an employee was physically present at the desk), on average, and 15% of them were occupied by an employee being not physically present (he/she could be involved in a meeting, conference call or other activity). Therefore, almost 50% of the workstations resulted in being effectively free.

This kind of count is actually more accurate than the mechanical count performed by turnstiles activated by badge swiping, because it detects the continuous presence of an individual in a building. However, a margin of error is possible because of eventual misinterpretation of traces on the workstation at the time of observation. Although, numbers make it evident that it is unlikely for employees to encounter real difficulties in finding a free seat.

Furthermore, with regard to the multiple-choice question "Which of the following statements best describes your work station in your company?", most employees answered that they worked in an open space setting, whereas only 13% specified they worked in different, non-assigned work stations. This means that most employees do not perceive they are hot-desking. They still have a more traditional concept of open space, which they conceive as a collective space shared with colleagues, in which everyone has the exclusive use of one workstation. This feeling explains also the tendency to 'sedentism' and personalization that affects their behavior. During observation rounds, on average 1 workstation out of 4 was marked in some way with personal objects. This trend might compromise the flex office model, but it is not equally distributed among all the functional areas. In fact, some business units tend to mark the space less strongly than others do. These correspond to those functions that are more suited to a flexible workstyle, for example the sales areas. On the contrary, some business units are more settled as a vocation, such as finance, legal, procurement, quality and others. Not surprisingly, it is exactly here that the most numerous territorial signs, e.g. identity-oriented markers (Brown, 2009), have been found. It is also significant that almost 20% of those desks not assigned to any business unit, i.e. theoretically free from personalization, presented some marks. The objects typically found on the desks may affect more or less significantly the image and functionality of the workstations. Among them it is worth mentioning: toys, photographs and posters; calendars, post-its, reminders; plants; pen holders; documents. Coherently with the trend registered, according to the questionnaire, 44% of interviewees would appreciate the possibility to personalize the desk in order to feel more comfortable at work.

4.3 Work Activities and Spaces

Beside more traditional activities such as 'PC, reading, writing' and 'talking/meeting', that employees estimate can take up, respectively, around 45% and 15% of their typical working day, other activities such as 'phone' and 'conference call' seem to be very significant, as revealed by the questionnaire, occupying 27% of the typical working day. This is coherent with recent research saying that thinking, talking and brainstorming create the most value for an organization (Colpaert, et al., 2014). Today, the time spent at work in some type of conversation is up to 50-80% of the overall working day. It is common belief that by talking together, people come up with new solutions in the shortest time that probably neither single person could have developed alone. The key activities in today's work are both concentrated (solo) and collaborative (together). On one side, concentration, observation, research, imagination, testing and planning require concentration. On the other hand, brainstorming, interviews, workshops, co-creation, debate and delivery require collaboration. These attitudes impact the traditional features of the workspace and how people perceive it.

Referring specifically to the employees' assessment, the activities performed in a typical working day can be carried out collectively or individually in the following proportion:

- collectively or in groups, 40%;
- individually, 47%;
- both collectively and individually, 13%.

It is therefore possible to claim that the distribution of the workstations in the new headquarters is correctly planned; in fact, the number of open space workstations and the number of workstations in meeting rooms is almost the same.

When considering the above, it is necessary to bear in mind the importance of the spaces and technological facilities used to manage meetings and calls. It is crucial to implement the appropriate measures to disturb as little as possible other employees who are involved in activities that require particularly high levels of concentration (e.g., PC, reading, writing).

4.4 Strengths and Weaknesses

Focus group participants were asked to express their opinion on the importance of, and satisfaction with, a number of factors that can affect the quality and effectiveness of their work (on a scale from 1 – not at all important/very dissatisfied, to 5 – very important/very satisfied), regarding physical (Roeloofsen, 2002) and psychological (Alker, et al., 2014) issues (Figure 2)

It is interesting to read the weight of the difference between the level of importance given to one factor and the corresponding level of satisfaction. In this way, it is possible to become aware of the most critical issues and establish intervention priorities accordingly.

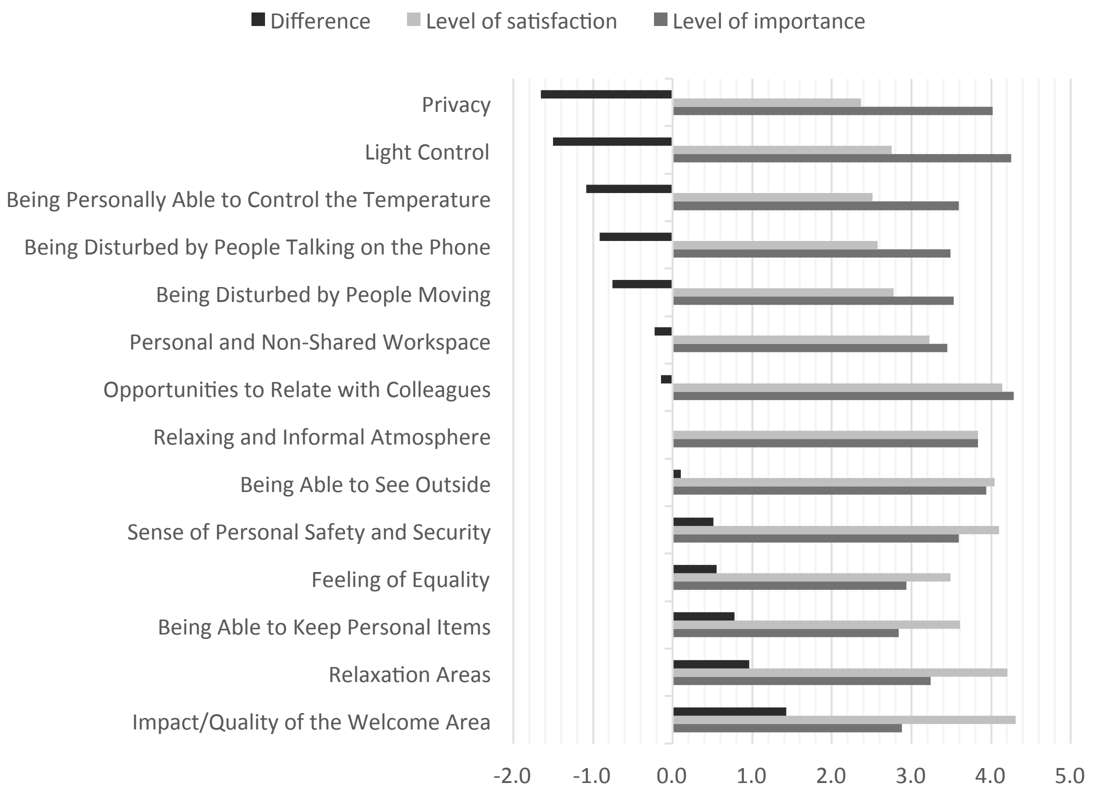

Figure 2. Level of importance/satisfaction regarding the factors that affect work quality and effectiveness (source: questionnaire)

The factors that received the highest score (≥ 4 points) for importance include: opportunities to relate with colleagues; control of light; privacy.

With regard to satisfaction, the highest ranking factors (score ≥ 4) include: impact/quality of the welcome area; relaxation areas; opportunities to relate with colleagues; sense of personal safety; being able to see outside.

It is important to note that for some of the listed factors the level of satisfaction is equal to or exceeds the given level of importance. These factors can be considered 'strengths' (Table 1). On the contrary, in some cases, there is a significant deviation regarding the level of satisfaction (< 3 points), so these factors must be interpreted as 'weaknesses' (Table 1), which require urgent intervention measures.

Table 1: Strengths and weaknesses

Strengths	*Weaknesses*
- *impact/quality of the welcome area* - *relaxation areas* - *being able to keep personal items* - *feeling of equality* - *sense of personal safety* - *being able to see outside* - *informal and relaxing atmosphere*	- *privacy* - *control of light* - *being able to personally control the temperature* - *disturbance caused by the use of mobile phones* - *disturbance caused by people moving around*

Lastly, there are some aspects that have a slightly negative difference but the related level of satisfaction is good or excellent (≥ 3 points), e.g., personal and non-shared workspace. In this case, it is reasonable to suppose that the changes in working conditions have had a certain impact on employees, who have yet to absorb it all. It is likely that over time the level of satisfaction may increase, even without making significant changes to the surroundings, simply as a result of people becoming used to the new conditions.

From the direct discussion about factors listed above it is possible to claim that the general sentiment seems to be very positive ("*I like it here*", "*it is a 100 million times better than in the past*", "*everything is much more efficient*"). In most cases, the expectations regarding the new open space layout are positively satisfied ("*before joining this company I worked in an open space setting. In the old premises I felt I had taken a step back, now I feel things are normal again*"), and in some cases they have actually exceeded improvement expectations. About one third of interviewed employees have switched from a closed office to an open space layout with a generally favourable attitude (*"I had a closed office but I have grown used to it - now there is more contact with colleagues"*). It is clear that the opportunities for social interaction, for exchange and for establishing new relations have increased (Blakstad, et al., 2009), which everybody considers a positive aspect ("*we know each other better, we have met new colleagues*"). Among other things, this element was considered the most important factor (score of 4.3) that can affect the quality and efficiency of work ("*The new layout improves interaction among colleagues and helps us feel more part of a team*").

The outward image of the premises is considered one of the best factors. The architectural features employees are most satisfied by are the equipment in the meeting rooms, common areas for guests ("*the company image has gained a lot*", "*I always receive compliments from guests*") and quality of light (not be confused with 'control of light', which is related to the quantity of light and being able to manually adjust its intensity). On the contrary, the inward image seems to have some issues, especially regarding the feeling of equality ("*we were told we were going to the new premises so we would all be equal, 'Break down the barriers, no more status quo!', then it turns out not to be true*"). Some employees complain about disparity caused by closed offices assigned to people who do not actually need them ("*there is a problem of equality,* *actually there are closed offices for colleagues who could integrate with everybody else*"). However, these considerations can be rated as 'overcome' by the answers recorded in the questionnaire completed by the focus group participants, who on the whole gave the feeling of equality a positive assessment in terms of satisfaction (3.5), which actually exceeded the expectations compared to the given level of importance (2.9).

5. Discussion

The study has demonstrated the success of the project in terms of overall employees' commitment, satisfaction and productivity, as declared by themselves. The new workspace features have been introduced in order to react to the change of perspective that is affecting the traditional ways of working. The update of the office setting according to the new trends – including hot-desking, encountered the favor of building occupants, despite initial doubts. Thanks to occupants' consultation, it was possible to assess the appropriateness of the new configuration and to fine-tune the quality of the intervention. The users gave warnings of discomfort during the focus groups, so that some technical problems emerged, such as the control of light and temperature. These were reported to the management who planned a prompt intervention. About work efficiency, most of the concerns could be attributed to incorrect or improper habits on the users' side (disturbance caused by the use of mobile phones, disturbance caused by people moving around and privacy related issues). These are likely to be resolved simply as a result of people becoming used to the new conditions and thanks to a good communication and education strategy implemented by the HRs.

Particularly crucial to this extent was the phase of reporting findings. At a first stage, a written report was delivered to the management, providing all the details about research methodologies, conclusions and possible actions to implement with indications for prioritization, in order to support the decision-making process. Afterwards a presentation was organized, inviting all the employees who took part in the focus groups. Here the main outcomes of the research were explained in an understandable way, trying to focus on those behavioral aspects that could positively affect the working experience. Moreover, the real estate and facilities managers introduced the actions they were going to undertake in light of consultants' recommendations. Involvement of employees in decision-making is likely to foster a sense of common identity and to promote motivation and commitment. In this phase the evaluator assumed the role of mediator, helping communication and negotiation of consensus (Preiser & Schramm, 2002).

In the end, it was confirmed that the most important worries troubling the employees before the move were mostly inconsistent. No waste of time while looking for a free workstation, no problems in relations with colleagues, and no loss in normal work efficiency was seriously detected. In fact, many free desks are always available and enhanced relationships with colleagues are reported as one of the most satisfactory factors. The risks of implementing flexible workstations with open-space and hot-desking were positively faced and brought benefits in terms of interactions, feeling of equality and informal working atmosphere. All these aspects characterize the new ways of working and should be endorsed by the office environment. This is the extent to which an 'intelligent office building' can have a meaning for corporations. It should be able to adapt every time to the changing necessities of the company that it hosts and to provide the occupants with the right backing for their multiple activities. Then, of course, an office building is not intelligent by itself, just for its architectural configuration and technical infrastructure, but it is primarily the way it is managed that makes the difference.

6. Conclusions

The present research should be considered one of the few efforts in the post-occupancy studies conducted in Italy. Therefore, it represents one of the actual best practices in workplace change management in an Italian context, which will contribute to building a cross-cultural framework of evaluation data on building types like intelligent office buildings. Moreover, hopefully it will encourage the evaluative stance throughout the building delivery process. The implementation of a post-occupancy study is important both for verifying the results of a project after its completion, which is needed in building management, and for gathering data suitable for further interventions. Particularly, the phase of reporting findings to the end-users brings the immediate outcome of making them feel important stakeholders within the office building and to keep them well-informed about the objectives of the project and its results. This process itself enhances engagement and satisfaction among workers. In addition, it is an important occasion for communicating messages able to turn behaviors into positive attitudes and good habits. The related consequences will be visible after some months, when, for that reason, it will be important to perform further surveys.

With regard to this specific case study, the main objectives to accompany the workers through the workplace transformation and to verify the pre/post-transfer impacts towards the harmonization of the new spaces with their requirements were met.

An external consultant's job can be important for helping companies switch from a traditional way of working to a smart working model and conveniently match the workspace with the organization's new objectives and values. Ideally, this accompanying function should last from the very beginning of the project until the delivery of the building, and even afterwards with a continuous monitoring activity. Through the whole duration of that period, it is possible to understand the initial intents and to verify them against the everyday operation of the workspace. This long and complex process is the only means to fine-tune the quality of office buildings. Most of the time, because of a lack of resources or motivation, it is not possible to carry on this preferential relation with the company. Nevertheless, it would be useful, at least, to retrieve some data about the use of the workspaces, since they are suitable for keeping the building value under control. Going into more detail, it seems valuable to monitor space occupancy rates, employees' habits concerning their ways of working (presence during the week and activities during the day) and occupants' perception on how the workplace affects work quality and effectiveness. These are the main variables that reflect if an office building is working properly or not. Some professionals should be in charge of collecting them and to promptly adopt the best measures for adjusting the space features according to these changing variables. Today, thanks to sensors and portable devices it is not difficult to gather some of them. Nevertheless, some room for innovation exists especially where occupants' involvement is required – in light of the new ways of sharing likes and dislikes – and in assembling qualitative shades with quantitative assumptions. More research would be interesting to understand how to combine this information in everyday practice.

In fact, on the basis of our experience, while relying on only one source of information could have produced misleading results, matching both quantitative and qualitative data through the triangulation of different methodologies helped obtain consistent outputs. On one side, it is important to remark that the role of a consultant needs to be supported by internal sectors. On the other, it is evident how different skills (the consultants' know-how, with the CRE, HR and FM experience) have collaborated to generate key insights valuable for driving the management of the new premises and for informing eventual future corporate projects. This case study also suggests the necessity of complementing real estate and facility management with human resources policies and underlines the importance of devoting proper attention to internal communication. May it be necessary to appoint a new professional who is able to apply an integrative approach as such?

An 'intelligent office building' is one that successfully relates to its occupiers, being able to adapt according to the changing needs of its users. That is the extent to which an 'intelligent building' can support human activity in daily life at work. This can depend, on one hand, on the technological devices installed with advanced control technology and the architectural features characterizing the work setting, as a flexible office space. But, on the other hand, it depends on the organizational structure and managerial intentions. The work conducted demonstrates how not only the result of a post-occupancy evaluation is important, but the process itself is very helpful. Using a user-centred approach, employees feel more engaged, know they are part of the stakeholders and, consequently, become more conscious and responsible for their behaviour. Their contribution can make buildings function better. Only through this kind of attitude, can it be possible that an office building takes the role of enabler for the well-being of workers, the success of companies, and the competitiveness of regions and countries.

Appendix (Survey questionnaire)

The appendix shows part of the questionnaire that was administered to the participants in the focus groups. The intent was to induce the interviewees to reflect on some key points, on the basis of which the debate was developed. This method was useful also to quantitatively collect some data considering the large number of people involved in the meetings.

1. What of the following aspects correspond to doubts or worries that you had before the move to the new premises?
   Which of them were positively solved and are no problem at present? Which ones, instead, are effectively cause of annoyance to you?
   For instance:

Table 2: Question 1 of the questionnaire

	Pre-transfer doubts/worries	*After-transfer feeling*	
		Positive matching	*Negative matching*
☐	*Efficiency in daily work*	☐	☐
☐	*Time spent looking for a free workstation*	☐	☐
☐	*Working relationships with colleagues*	☐	☐
☐	*Others: ………………………………………*	☐	☐

2. In your ‘typical working week’, what days do you usually work in the office?

Table 3: Question 2 of the questionnaire

	Weekday	*Morning*	*Afternoon*
☐	*Monday*	☐	☐
☐	*Tuesday*	☐	☐
☐	*Wednesday*	☐	☐
☐	*Thursday*	☐	☐
☐	*Friday*	☐	☐
☐	*Saturday*	☐	☐

3. In your ‘typical working day’ in the office, how much time do you usually spend in the following activities?
   Among them, what are the activities that you do individually and what require collaboration with other colleagues?

Table 4: Question 3 of the questionnaire

	Activity	*Individual*	*Collective*	*Percentage of time*	*/100%*
☐	*PC, writing, reading*	☐	☐		*/100%*
☐	*Storing, filing, paper handling*	☐	☐		*/100%*
☐	*Phone*	☐	☐		*/100%*
☐	*Conference call*	☐	☐		*/100%*
☐	*Video conference*	☐	☐		*/100%*
☐	*Presentation*	☐	☐		*/100%*
☐	*Meeting/talking*	☐	☐		*/100%*
☐	*Learning*	☐	☐		*/100%*
				100%	*TOT.*

4. Express the level of importance (from 1 = very low, to 5 = very high) that you attribute to the following factors, reflecting if they can influence or not the quality and effectiveness of your daily work.

Table 5: Question 4 of the questionnaire

	Factors	*Not important*				*Very important*
		1	*2*	*3*	*4*	*5*
1.	*Personal and non-shared work space*	☐	☐	☐	☐	☐
2.	*Impact/quality of the welcome area*	☐	☐	☐	☐	☐
3.	*Being personally able to control the temperature*	☐	☐	☐	☐	☐
4.	*Relaxing and informal atmosphere*	☐	☐	☐	☐	☐
5.	*Privacy*	☐	☐	☐	☐	☐
6.	*Being able to see outside*	☐	☐	☐	☐	☐
7.	*Being disturbed by mobile phones*	☐	☐	☐	☐	☐
8.	*Being disturbed by people moving*	☐	☐	☐	☐	☐
9.	*Feeling of equality*	☐	☐	☐	☐	☐
10.	*Being able to keep personal items*	☐	☐	☐	☐	☐
11.	*Relaxation areas*	☐	☐	☐	☐	☐
12.	*Sense of personal safety*	☐	☐	☐	☐	☐

Abstract

Infrastructure lies at the very heart of social and economic development of a country and the world at large. Yet, despite its importance the delivery outcomes of infrastructure projects have been far from satisfactory. Infrastructure projects face issues of cost and schedule overruns as well as failure to realise expected benefits. Research in the field of project management has emphasized the importance of a 'strong owner' to the success of projects. To act as strong owners, public sector clients that deliver infrastructure projects need to have project capabilities to perform various roles. This paper presents an initial framework on how public sector clients can develop ‘owner project capabilities’, so as to improve infrastructure project delivery outcomes. The theoretical perspective of dynamic capabilities is employed to study how these public sector clients can develop the requisite ‘owner project capabilities’. It is suggested that learning is the mechanism by which owner project capabilities are developed, based on the concept of routines development, and argues for the incorporation of the organizational learning theory within the dynamic capabilities framework. Theoretically the paper contributes to the extension of the current application of organizational capabilities into the public sector infrastructure context. Additionally, it also provides initial insights into the relationship between owner project capabilities and (organizational) learning; and the difficulties faced by public sector clients during the process of capability development.

Keywords: infrastructure development, client capabilities, project capabilities, project owner, project learning

1 Introduction

Infrastructure lies at the very heart of social and economic development of a country and the world at large (Stevens *et al*., 2006). It serves as the bedrock of a nation's competitiveness, economic development, and social well-being (World Economic Forum, 2014). Notwithstanding the importance of infrastructure, most countries experience difficulties in providing for their infrastructure needs, in addition to ensuring that delivered infrastructure provides planned benefits. Whilst the advanced or developed countries face the challenge of maintaining extensive transport, energy supply, water, and telecommunications network as well as upgrading and modernizing them, developing countries face the challenge of meeting their basic infrastructure needs such as access to water and sanitation, electricity, roads and health facilities (McKinsey Global Institute, 2013). The result is an increasing infrastructure deficit, or 'gap', estimated at US$ 1 trillion per annum (McKinsey Global Institute, 2013; World Economic Forum, 2014).

This expanding infrastructure gap comes at a time when public sector clients, around the world, are increasingly being questioned regarding their ability to achieve value for money, and face the grinding pressures of improving infrastructure project delivery while cutting administrative costs. In short, they are being asked to do more for less, i.e. produce more public value with fewer resources. Key issues, frequently brought up, include the lack of appropriate levels of procurement skills that will allow them engage with their private sector supply chain partners on equal terms; sub-standard efficiency and productivity in the production phase; and unnecessarily large organizations with high administrative costs. Furthermore, cost and time overruns are increasingly highlighted (Flyvbjerg *et al*., 2003; Miller and Lessard, 2000; National Audit Office, 2009) and subjected to public scrutiny.

This paper sets out to investigate how these public sector clients charged with project delivery could develop capabilities they need to improve on project delivery outcomes. The paper starts by reviewing the outcomes of completed infrastructure projects and draws attention to the role of the project owner to these outcomes. It argues that to improve project outcomes, project owners need to become strong owners by having the capability to perform various roles. We then review the literature on organizational capabilities with particular focus on addressing the capabilities subset of project capabilities. It is suggested that project owners need 'owner project capabilities' made of three distinct subsets to act as strong owners. The rest of the paper is devoted to answering the question of how public sector clients may develop the desired level of owner project capabilities. In answering this question, the theoretical framework of dynamic capabilities, which focuses on how organizations undertake change by creating, extending or modifying its resources is reviewed and suggested as an appropriate lens to study how capabilities are developed by public sector clients. In particular, how routines - the building blocks of capability – develop and evolve is suggested as giving an insight to capability building. We then give an initial insight into how routines could be developed via project learning and some difficulties that are faced by public sector clients during this process. The paper concludes by arguing that there is no 'one-size fits all' capability set for public sector clients, and that it is a matter of knowing the scope of capabilities they need to manage their projects and how to develop it. Additionally it also suggests that there is also the need for further insights into the relationship between capabilities and learning so as to better understand how capabilities are built.

2 Project Outcomes and the Importance of a Strong Owner

As noted above, the delivery outcomes of infrastructure projects worldwide have over an extended period been poor and far from satisfactory. This has led to increasing scrutiny and questioning of the performance of project owners and operators by their stakeholders. Typically, project owners are being questioned on: their commercial capabilities, i.e. their ability to interact on equal and professional terms with the private sector (e.g. National Audit Office, 2009); project assurance capabilities, i.e. their ability to independently and objectively verify whether a project is on schedule, within budget and will meet future performance (e.g. National Audit Office, 2010, 2012); and their project delivery capabilities (e.g. LEGCO, 2014). Such accusations are supported by a plethora of studies conducted on completed infrastructure projects. These studies show that projects are usually subjected to substantial cost and schedule overruns, fail to realise expected benefits and meet projected demands (Flyvbjerg *et al*., 2003; Flyvbjerg, 2014; Merrow, 2011; Morris and Hough, 1987). For example, in a series of studies on transportation projects in different jurisdictions, Flyvbjerg (2014) suggests that nine out of ten projects face cost overruns, while the demand and benefit side of the projects were out of forecast by between 20-70%. Indeed, it seems that issues of cost and schedule overruns and, failure to derive expected benefits are the norm rather than the exception in infrastructure delivery (Flyvbjerg, 2014; Flyvbjerg *et al*., 2009).

Perhaps the most influential work on the poor outcome of infrastructure projects in recent times has been that of Bent Flyvbjerg and colleagues (e.g. Flyvbjerg *et al*., 2003; Flyvbjerg *et al*., 2009; Flyvbjerg, 2011). This work has done much to clarify project escalation, and how optimism bias and strategic misrepresentation contributes to cost and time overruns on many projects. However, these two concepts have a higher degree of explanatory power in economic infrastructure than in social infrastructure, and it remains the case that many projects experience cost and time overruns without optimism bias or strategic misrepresentation being present (Love *et al*, 2012). Other studies have instead identified factors such as the inability of the project owner to: properly control the front end definition; shape project strategy and cope with political, economic and social turbulence and outside institutions; drive the project and deal with partisanship and contractual turbulence, as factors that affect project delivery outcomes (e.g. Merrow, 2011; Miller and Lessard, 2000; Morris and Hough, 1987). Ultimately, what many studies, on this topic have in common is the conclusion that causes of project failures usually lay in areas that are within the remit of project sponsors rather than that of project execution or implementation by the project supplier or contractor (see Flyvbjerg *et al*., 2003; Meier, 2008; Miller and Lessard, 2000; Morris and Hough, 1987).

In consequence, there is now a growing body of work focusing on the owners and sponsors of infrastructure projects. Although it is still the case that majority of the project management literature is supplier focused. A major scholarly contribution in this regard has been the work of Peter Morris (Morris, 1997, 2013; Morris and Hough, 1987). Arising out of his research on major projects he advocated for the concept of a 'strong owner' as a dimension of project success (Morris and Hough, 1987). This perspective of the role of project owners has recently been reinforced by Merrow (2011), who also advocates for a strong, distinct owner team that will be able to interface authoritatively with the supply side. This view is succinctly summarized as: "The contractor's job is to deliver a project as specified, on time and on budget. The owner's job is to specify the right project" (Merrow, 2011, p. 126). This basically means that the contractor cannot do the owners' work, and *vice versa*, as they have different sets of roles, goals and expectations on the project. This conclusion is supported by the findings of Hui, Davis-Blake, and Broschak (2008) who showed that project owners who demonstrated or exhibited high 'owner dominance' tend to achieve better outcomes.

2.1 The role of the infrastructure owner

Infrastructure projects are delivered within a temporary organization domain created by the coalition of two principal types of organizations: the relatively permanent owner and operator that supplies capital resources to the project and the relatively permanent project-based firm (supplier) that provides human and material resources to the project organization (Winch, 2014). In general terms, the difference between these two organizations is that the latter are project based and work predominantly on projects, while the former are not. The relatively permanent owner and operator on infrastructure projects, is usually a public sector organization in the form of Governmental agencies, departments, municipals, counties, bureaus or any such similar designation that owns and operates completed infrastructure. These permanent owners and operators may also be referred to as 'public sector clients'. Generally the core concern of such 'public sector clients' is that of operations and maintenance of completed infrastructure such as the regular supply of power, ensuring roads are in good condition for transportation purposes, etc. (Winch, 2014). As such, they tend to develop competencies or capabilities in areas core to their operations other than that of infrastructure delivery. However, it is the case that these public sector clients engage in the delivery of infrastructure projects on a periodic basis as the need for them to extend their infrastructure base arises. This may be due to ongoing business concern such as the need to grow, perceived inadequacies in existing infrastructure, or policy initiatives (Winch, 2014). To do so, they are required to define the project thereby delineating its scope and specifications. They are also required to procure and manage project suppliers to ensure project is delivered to specifications, set up internal control measures to ensure the project is completed within budget and schedule, and integrate the completed infrastructure into existing operations. Achieving the above objectives for these infrastructure owners is, however, fraught with challenges. A prime challenge is how to make use of their limited existing resources to develop and promote infrastructure projects whilst maintaining core capabilities necessary to operate and maintain delivered infrastructure. In effect, public sector clients face the tension of using limited resources to develop and maintain capabilities for infrastructure delivery while also performing their core duties of operating and maintaining completed infrastructure.

2.2 Owner capabilities

Organizational capabilities are commonly defined as the particular combination of skills, competences, resources, routines, and behaviours, which enable effective performance and generate competitive advantage. The capabilities literature is vast and varied but is usually divided into two main types: 'operational capabilities' which capture the day-to-day, month-by-month ability of the organization to deliver on its mission; and 'dynamic capabilities' which capture the ability of the organization to change and develop in order to meet new challenges. In other words, operational capabilities deal with the ability of the organization to deploy its resources and to efficiently execute its daily activities; whilst dynamic capabilities deal with how the organization could undergo change and in the process extend its resource base (Helfat *et al*., 2007; Winter, 2003). What is either an operational or dynamic capability is an issue of context and very much dependent on the core activities of the organization. Thus, what may be an operational capability for one organization may be a dynamic capability for another.

A sub-set of the capabilities literature is that of 'project capabilities' stemming out of research on innovation in complex product systems and the project-based organization. These project capabilities refer to the specific knowledge and experience required to engage with internal and external customers, develop bids and implement and execute projects, and can be summarised as the appropriate knowledge, experience and skills necessary to perform pre-bid, bid, project and post-project activities (Brady and Davies, 2004; Davies and Hobday, 2005). The conceptualisation of project capabilities and associated empirical studies has mainly been supplier focused. However, as the literature in the previous section shows, the project owner needs to act as a strong owner for successful delivery of projects. To be a strong owner the project owner may have to perform roles such as being able to manage its interface/interaction with the project supplier, defining the project, and setting up internal control measures among others during project delivery. This ability of the owner organization to mount temporary projects may be viewed as its project capabilities - '*owner project capabilities'* (Winch and Leiringer, 2016*)*. Owner project capabilities are made up of three conceptually distinct sets: of capabilities: '*Strategic capabilities*, *Commercial capabilities*, and *Governance capabilities* (Winch and Leiringer, 2016). *Strategic capabilities* are those which the owner needs in order to successfully implement its investment projects and required at the strategy or front end stage of a project. *Commercial capabilities* are the set of capabilities needed to manage the interface between the owner organization and the project based supplier firm. It is mainly outward facing as it focuses on the interaction between the owner organization and project supplier. *Governance capabilities* are those needed to manage the interface between the owner organization and the temporary project organization involved in the project.

A major question that arises, and the one that is of main interest in this paper, is how the desired level of owner project capabilities can be developed. The answer is by no means straightforward. Investment in infrastructure assets is inherently lumpy compared to managing operations, and therefore poses a number of challenges. To further complicate things different sets of capabilities are acquired in different ways, and the process is heavily influenced by historical factors (i.e. path dependent). Some capabilities can be seen as the outcome of learning through repeated interactions and will follow different learning trajectories depending on if, for example, they concern formal or trust based relations. Other capabilities are the result of specific human resource investments. This means that some capabilities can be developed rather quickly whilst others can only feasibly be developed over time. It also follows that where the investment programme is particularly lumpy or where the size of the client organization is restricted, as will be the case if attempts are made to reduce head count and cut overhead costs, there might be a strong temptation to use third party consultants. However, the use of third party consultants entails the risk of failing to develop adequate in-house capability, even if it is viable (Merrow, 2011). Possessing adequate owner capabilities in-house and the process of developing these capabilities is useful for public sector client organizations if they are to act as strong owners and in the process improve project outcomes.

3 Dynamic Capabilities

In answering the question of how the desired level of owner project capabilities could be developed, the theoretical framework of dynamic capabilities, which focuses on how organizations rely on internal resources to undertake change, offers itself as a useful theoretical lens. Infrastructure projects, which are temporary in nature, fundamentally, are about change in the client organization, as they either extend in scope the existing operational capabilities or create new ones to meet new challenges.

As such it is possible to view the view owner project capabilities as the permanent organization's ability to mount temporary projects by making use of internal resources to undertake this change.

Dynamic capabilities, defined as "*the capacity of an organization to purposefully create, extend, or modify its resource base*" (Helfat *et al*., 2007, p. 4), explains how organizations renew competences and undergo change in order to achieve congruence with changing environmental and business conditions (Teece *et al.*, 1997). In general, organizations renew their competencies, develop new capabilities and undergo change by modifying their resource base – the tangible, intangible and human assets the organization owns, controls or has access to on preferential basis and enables it undertake its activities or routines (Helfat *et al*., 2007). This ability to purposefully create, extend, or modify the resource base is very much dependent on the 'managerial' and 'organizational' processes available to the organization as these are the mechanisms by which organizations either develop or put dynamic capabilities to use (*ibid)*. These processes show how things are done, and are used to achieve two main functions: search and selection procedures – decision making; and configuration and deployment of selected decision – implementation. The search and selection procedure is more of a managerial process whilst the configuration and deployment of selected decision combines both the managerial and organizational processes. Managerial processes specifies strategic paths of decision making during search and selection procedures. The combination of managerial and organizational processes specifies which routines will be used to undertake change processes such as creating new routines, extending or modifying existing ones (*ibid)*. Integral to the deployment of organizational processes are strategic routines such as *resource integration routines; resource configuration routines; routines to gain and release resources; and exit routines* which are used in undertaking the change process (Eisenhardt and Martin, 2000).

In addition to the processes available to an organization, the development of dynamic capabilities is very much dependent on its current 'position' and the 'path' it has taken (Helfat *et al*., 2007). Positions form the base of any future capability development as they represent investments made by the organization over the years. This includes current specific endowments of technology, intellectual property, complementary assets, customer base, and its external relations with suppliers and complementors (Teece *et al*., 1997). Renewing the existing capabilities of an organization without regard to the prior investments it has made has significant implications. There are substantial cost elements involved in discarding existing positions in addition to the fact that some positions, which give the organization its current capabilities and performance advantages, are difficult to replace. Furthermore, capabilities are largely cumulative and rely on previous knowledge. As such, the path travelled by an organization determines its existing capabilities, as well as possible future ones. Thus, past investment may either enhance or constraint the future direction of the organization. This has led to the general notion of capabilities being seen as path dependent and subjected to historical factors (Helfat *et al*., 2007; Teece *et al*., 1997). Accordingly, the paths and positions of an organization guide and shape up the processes during capability development.

3.1 Development and Evolution of Capabilities

The actual process of developing capabilities is by no means a trivial affair. This is partly due to the organization specific nature of capabilities where a collection of routines and resources gives an organization its unique capabilities. Also, the unobservable nature of capabilities in addition to embedded tacit knowledge makes it difficult to observe how they develop. A perspective that gives an initial insight into capability development is the process of how routines develop. Routines are argued to be the fundamental unit or building block of organizational capabilities. As such, capabilities are sometimes defined in terms of routines. Winter (2003) for instance describes capabilities as a high-level routine or collection of routines that enables an organization produce an output. Understanding how routines develop within the organization may give an insight into capability development.

Routines encompass the accumulation of knowledge. Organizations accumulate and/or gain knowledge, leading to the development of routines, by engaging in learning to retain practices or activities that improve efficiency and are deemed beneficial to existing operations; or searching for new knowledge that brings in new practices and development of new routines. Various learning mechanisms, or processes, guide the type of knowledge that is accumulated. Notwithstanding the type of learning mechanism(s) engaged in, one of two major outcomes results: a change or modification of existing routines (and capability), or an improvement of existing routines (and capability). To improve existing routines, organizations undertake *exploitative learning* where they learn from practice, trial and error (experiential learning), and selection and retention of behaviours or routines that are beneficial to the activities of the organization (Zollo and Winter, 2002). This leads to the development of routines that are highly patterned, repetitious or quasi repetitious in character (Gavetti and Levinthal, 2000). Developing new routines in contrast represents a change in how the organization operates, and requires the organization to use *exploratory learning* mechanisms to bring in novel knowledge into the organization to enable the generation of new routines (and capabilities). This is achieved through engaging in a purposeful action and learning, so as to gain new knowledge (Pandza and Thorpe, 2009).

Dynamic capabilities is known to cause change or modification to the existing routines or resource base. This suggests that organizations have to rely more on exploratory learning mechanisms during the development of dynamic capabilities as novel knowledge is what is needed to change existing knowledge trajectories and routines (Pandza and Thorpe, 2009). This has, however, not been the general perspective taken in research that has sought to establish linkage between dynamic capabilities and learning. Existing research seeking to link the two concepts has focused mainly on exploitative learning arising out of experiential learning and knowledge transfer mechanisms with less emphasis on how novel knowledge that leads to the development of new routines and knowledge is brought into the organization. For example, Zollo and Winter (2002) suggest that dynamic capabilities evolves via three learning mechanisms: behavioural learning mechanisms of *experience accumulation*; and more deliberate cognitive processes of *knowledge accumulation* and *knowledge codification* derived from reflection on past experience. Similarly Eisenhardt and Martin (2000) identified the experiential learning mechanisms of: *repeated practice, mistakes, and pacing of experience.* This perspective could, however, be questioned, as the change role nature of dynamic capabilities makes it unlikely that experiential learning is solely responsible for dynamic capabilities development (Pandza and Thorpe, 2009). Instead, it could be argued that the focus should be on integrating into the dynamic capabilities framework an organizational learning theory that has both exploratory and exploitative concepts.

4 Learning for Public Sector Clients

It is evident from the discussion above that learning plays an important role in the development of dynamic capabilities. Learning is, however, a broad concept consisting of different types (or subsets) based on the context and organizational type. The type, or subset, of learning used by public sector clients to develop their project capabilities is that of 'project learning' defined as "… that which encompasses the generation, capture and transfer of learning by individuals and groups within project settings" (Scarbrough *et al*., 2004a, p. 492). Project learning thus occurs: from and in between projects; within and between the temporary project organization and the permanent parent organization; and across various levels such as individual, group (project) and the organizational levels (Artto *et al*. 2011; Scarbrough *et al*., 2004a). The different ways by which project learning occurs may usefully be classified into two main categories: intra- project learning and inter-project learning (Swan *et al*., 2010). Intra-project learning occurs during interactions with other actors on a project and may lead to the generation of novel knowledge. Inter- project learning in contrast occurs when the novel knowledge, or efficient ways of undertaking existing activities, is deployed within the wider organization and on various projects sites. This type of learning leads to improvement in existing routines.

It is commonly stated that the multidisciplinary background of the various actors on a project allows for cross disciplinary problem solving which enhances learning. However, despite the assertion that project environments are appropriate for learning the evidence suggests otherwise – it is generally difficult to engage in project learning (Edmondson, 2003). This is due to a multiplicity of factors such as: the one off and non-recurring nature of projects which makes it difficult to apply knowledge gained from one project to another (Hobday, 2000); the lack of formal structures and incentives to enable learning be institutionalized (Ekstedt *et al*. 1999; Scarbrough *et al*., 2004b); and the decentralized nature of organizations engaged in projects where knowledge gained by one unit is not transferred to others (Eriksson 2013). The multi-level layer of project organizations also affects learning as they tend to act as learning boundaries. This arises when learning at one level generates new shared practices that are different from practices elsewhere in the organization (Scarbrough *et al*., 2004b). This may result in a situation where the transfer of learning from one context (level) to another becomes more arduous due to the need to transfer practices which are completely different to the wider organization.

Public sector clients in particular face other challenges that affect their ability to learn and subsequently develop capabilities. They commonly do not possess all the resources needed to undertake the project. Thus, rather than deploy its own resources and in the process engage in learning, they are forced to outsource and use consultants for duties that are not core to their domain. Outsourcing, although having some positive effects especially in the short term, has long term implications as it affects the ability of public sector clients to engage in learning and subsequently develop capabilities. Consultants and suppliers become repositories of knowledge, as well as are the direct recipients of experience on a project, with the client having no technical input to the project. Furthermore, even where public sector clients decide to engage in learning, they may find it challenging to value, assimilate and exploit the new or novel knowledge being brought into the organization due to a lack of prior related knowledge for infrastructure project delivery. Or put somewhat differently, they may not have sufficient absorptive capacity (Cohen and Levinthal, 1990). Additionally, where the public sector client organisation is able to engage in learning, it faces the challenge of maintaining and making use of the knowledge so it does not atrophy due to infrequent use.

5 Concluding remarks

Many countries presently face massive investments in social and economic infrastructure. The economic role of social and economic infrastructure in modern societies is well understood; and the many contemporary pressures put on the scarce resources available, such as citizens' rising expectations, ageing infrastructure, urbanisation, and sustainability are well rehearsed. What has received significantly less systematic research attention is the role of government bodies in the execution of the projects through which they acquire such infrastructure assets. In this paper, we have tried to take a first step in partially rectifying this imbalance by investigating the public sector organizations charged with the definition and delivery of large infrastructure projects, what capabilities they need and how they can develop the capabilities they need to do so.

History has shown that it is neither feasible nor desirable to establish client organizations that are literally one-stop shops. Thus, it is not a matter of adding extra capabilities to the organization just for the sake of it. However, the whole cycle of making a capital investment infrastructure through ensuring that funds and human resources are available; engaging with suppliers of vital inputs to the new infrastructure and stakeholders with interests in that infrastructure; engineering the facility and coordinating the project to deliver it; and sharing the knowledge gained both within the program of projects to deliver the strategic initiative and capturing it for future investment projects, demands that sufficient resources are allocated to do so. There are many willing suppliers of the specialist services required to move through this life-cycle, but they all demand managerial attention. Further, various procurement types and client organization may demand different combinations of capabilities to manage the whole life cycle. Thus, it is not the case that client organizations should possess all owner project capabilities, but rather knowing the scope of capabilities it will need to manage projects, i.e. what capabilities it may need in-house based on its own unique case, in addition to how it can develop such capabilities to properly manage its suppliers and resources.

We have attempted to demonstrate that approaching the evolution, or development, of dynamic capabilities from the perspective of wholly integrating organizational learning theory will ensure that there is a better understanding of how novel knowledge is brought into the client organization as well as the various learning mechanisms needed at the exploratory and exploitative stages of learning. There is, however, the need for further insights into the relationship between owner project capabilities and learning. This means conducting empirical research on how client organizations undertake learning leading to capability development. These findings will help unravel various learning mechanisms that public sector clients can use to develop their project capabilities.

Proceedings of the CIB World Building Congress 2016

These proceedings (Volume I - V) bring together papers presented at the **CIB World Building Congress 2016**. The CIB World Building Congresses have for several decades been the leading global events on construction research and innovation.

The theme for CIB World Building Congress 2016 was "Intelligent built environment for life". It highlights the importance of build environment and its development to the society. This triennial congress focused on the intelligent processes, products and services of construction industry:

- How can research help to improve the contribution of constructed assets to digitalizing world and service needs?
- How will the research community meet emerging new needs of the users?

CIB is an association whose objectives are to stimulate and facilitate international cooperation and information exchange between governmental research institutes in the building and construction sector, with an emphasis on those institutes engaged in technical fields of research. CIB is a world wide network of over 5.000 experts from about 500 member organisations with a research, university, industry or government background, who collectively are active in all aspects of research and innvation for building and construction.

Preface

This volume III of the WBC16 proceedings is focusing on the building-up and shaping of intelligence into our built environment for life. In total, the 61 papers with the 735 pages are advancing such intelligence in diversified contexts across the globe.

In Section I, firms, business operations and knowledge embedded within the building and construction sector are being built up in terms of business development, market creation, strategic differentiation, competitiveness, knowledge, organisational learning and social responsibility.

In Section II, life-cycles and sustainability within the built environment are being built up in terms of building adaptability, life-cycle maintenance, virtuous and economic sustainability, green business modelling, performance based building, manufactured green buildings, concrete facades renovation, construction materials stewardship, live energy and urban water management.

In Section III, building information modelling (BIM) is being shaped in terms of business value delivery, BIM with Lean Construction, BIM with GIS, data-driven projects, perceptions among clients and users, overcoming barriers, meeting challenges, implementation, predictive semantic inferences and knowledge acquisition.

In Section IV, many novel solutions based on information and communication technologies (ICT) are being shaped in terms of Big Data, integrated and quasi-automated procurement, augmented reality onsite, text mining, virtual reality headsets and smart safety vests.

In Section V, contracting forms, risks and legal issues are being shaped in terms of a “Next Step”, highly economic alliancing, organisational economics, PPPs, risk sharing, extra contractual, context-specific concerns, the concurrency and analysis of delays as well as the adjudication of payment claim disputes.

In Section VI, construction project management (CPM) is being shaped in terms of PM design, stakeholder management, safety design and constructability, time management and space charts as well as cost control via Kaizen and contingencies.

The Business Development Management Function: Processes at the Front of the Front End of the Management of Projects

Hedley Smyth,
Bartlett School of Construction and Project Management, UCL
h.smyth@ucl.ac.uk

Abstract

The strategic front-end of the management of projects is where the construction is scoped, defined and designed client-side prior to engagement with main contractors on the supply side through procurement. At the front of the front end on the supply side is the business development management (BDM) function, the euphemism for sales. BDM is claimed to be isolated from other processes along the project lifecycle. Applying marketing theorization around securing work and delivering value for the analysis, this paper addresses BDM in ten major contractors to examine the extent of integration. Marketing offers three theoretical lenses: the transactional marketing mix, the more transformational relationship marketing and the current emergence of the service-dominant logic. Each lens facilitates conceptual evaluation of BDM in terms of current practice at the front of the front end, the extent of integration in the project lifecycle from its own theoretical position, and the rigor of value propositions and delivery. This is complemented at a detailed BDM level by an interaction sales approach. The findings show elements of all theories across the main contractors and in BDM processes in each contractor. A lack of integration is evident using all three analytical lenses and value propositions and delivery are constrained as a result. Management awareness of theory and applied configurations in BDM are thin and provide an explanation for the low integration, resulting in firms constraining their ability to effectively articulate and differentiate value propositions, deliver value propositions to clients and constrain growth in a competitive market.

Keywords: Business Development Management, Marketing Mix, Relationship Marketing, Service-Dominant Logic, Value Propositions

1. Introduction

The strategic front-end of projects is where construction is scoped, defined and designed client-side prior to main contractor engagement. At the front of the front end on the contractor side is the business development management (BDM) function, the euphemism for sales. Projects are specific assets, where selling occurs prior to production to contract. A long period of selling is typical whereby BDM is engaged with selling prior to a specific project and then BDM is injected into the project front end once the specific project is identifiable.

The sales function includes securing sales and delivering value. The emphasis between the two varies conceptually according to the underpinning marketing theorization. There is broadly one transactional approach, the *marketing mix*, and two transformational approaches, *relationship marketing* and the *service-dominant logic*. The transformational approaches place more emphasis on value. The sales function has been neglected in the extant management and marketing literature, especially in regard to value (e.g. Jones et al, 2005; Haas et al, 2012). Sales or BDM has received minimal attention in construction (Smyth, 2000). Marketing and BDM are claimed to be isolated in the project domain (Pinto and Covin, 1992; Turner, 1995). This paper tries to address BDM operations. It investigates: (i) range of activities conducted within the function and related to this (ii) the extent of integration with other functions along the project lifecycle. Applying marketing theorization around securing work and delivering value for the analysis. At a detailed level of BDM an *interaction sales approach* is employed (Haas et al, 2012).

Methodology and methods are interpretative and qualitative. The empirical evidence is drawn from 10 main contractors to examine the way selling is conducted and how value is addressed for delivery and realization. The findings show elements of all three theorizations underpinning BDM processes across the contractors, yet selling is largely conducted without strategic and tactical guidance. Integration is minimal, affecting value propositions, relationship management and practices of co-creation of value. Contractors therefore constrain their service provision from the outset of the project lifecycle. The paper concludes that management lack awareness of theory and a systematic approach to BDM. This constrains selling capabilities, configuring valuable propositions and value realization by clients post-completion. Construction firms therefore curtail potential market growth.

Structure of the paper is traditional: a literature review, methodology and methods, findings and analysis followed by the conclusions and recommendations on BDM in construction.

2. Literature Review

2.1 Marketing Theorization and the Strategic Project Front-End

The management literature has emphasized the business model concept in recent years (e.g. Zott and Armit, 2008). Business models embody strategy, structure and processes with an associated earning logic of revenue and profit. The marketing strategy, of which selling forms a part, is part of the model, even though the mainstream management and marketing literature have few overt connections. Marketing and sales has two main components: securing work and delivering value in order to grown and sustain a reputable business. Although the theoretical approach to marketing affects the emphasis between selling and value, both are necessary to secure new and repeat business, especially project markets (Smyth, 2015).

Marketing has developed three main theoretical lenses: the transactional *marketing mix* (MM) (Borden, 1964), the more transformational *relationship marketing* (RM) (Berry, 1983) and the current evolution of the *service-dominant logic* (S-DL) (Vargo and Lusch, 2004). There are other important contributions, for example entrepreneurial marketing (Morris et al, 2002) and the RM variant of project marketing (Hadjikani, 1996). The lens applied will be largely limited to the three mainstream theorizations. Entrepreneurial marketing has hardly been addressed for projects and in construction, while the status of project marketing has been addressed elsewhere, including the extent to which it is a theorization (Smyth, 2015), yet it will be referred to where relevant.

The marketing mix or MM arose from economics around the exchange process and was founded in reference to mass market consumer goods. The emphasis is upon key inputs (McCarthy, 1964) on the assumption suppliers know what they want and choose from predetermined offers on the market. The customer is largely passive until active at the point of exchange. The emphasis is upon selling products and services, value being largely determined from the inputs. In construction, application is conceptually limited because main contractors have few controls over the key inputs apart from price. Additionally, sales occur ahead of production and the exchange occurs over the project lifecycle. However, it was used extensively within the conceptual limits as means to secure work based upon past inputs, that is track record by sector and building type (Smyth, 2000).

Relationship marketing or RM was founded in the market for intangible business-to-business (B2B) services (e.g. Grönroos, 2000). The emphasis is on process. Selling is conducted through organizational and network relationships, supported by systems and procedures to manage the process. The customer or client and other stakeholders are active and relationship management extends into operations in support (e.g. Ford et al, 2003). Relationships are conceived as delivering value and content is negotiated and customized. RM conceptually aligns with construction. Clients are to be managed as much as projects and between projects to manage the sleeping relationship (Hadjikani, 1996), for example through a key account management (KAM) function (Smyth and Fitch, 2007). RM adoption in construction is partial and has lagged many sectors, commitment being incremental (Smyth, 2015).

The service-dominant logic or S-DL emerged a decade ago (Vargo and Lusch, 2004). The emphasis is on value outcomes. Customers are most active, conceived through the axiom of the *co-creation of value* (Vargo and Lusch, 2015). Value is co-created through organizational resources being combined. In projects informs the configuration of value propositions that can optimize value realization in use and in context (Akaka et al, 2013, 2015). Theoretical development has identified co-creation occurring through dialogue (Ballantyne and Varey, 2006) and interaction (Edvardsson et al, 2011). Interaction brings forward some the RM tenets again. In projects, value in context and use echoes the renewed call for a focus upon benefits delivery and impact (Morris, 2013). In construction, the S-DL implies a medium-to-long term view, which is at odds with the short-term incentive structures of management, financial and stock markets (cf. Smyth and Lecoeuvre, 2015). It accords with addressing client organizational problems or servicing the core business for which valuable projects are the solution. It also addresses total asset management, facilities, whole life cost and potentially responding to climate change issues. Marketing theorization can both articulate the current state (Vargo and Lusch, 2004) and carry normative content (cf. Prahalad and Ramaswamy, 2004). The S-DL has yet to be picked up prescriptively in construction practice.

Changing theorization has shifted the approach to value. From the tangible input focus pre-determined by the supplier to a perceptual primary outcome focus realized value in use and context, marketing has increasingly been decoupled from the exchange with price as the measure of value. Yet the emphasis upon price through competitive bidding for construction, the bidding process is also largely decoupled because the bid price typically has little to do with the incurred cost at the time of the final account when the exchange process is complete.

BDM involvement occurs prior to any project. This is part of client management or KAM and operates at a programme management level of the contractor to maintain the relationship, manage service consistency and workload continuity (Smyth, 2000). This is particularly the case where potential and repeat business clients are perceived as valuable to the supplier in terms of growth and profit. The *client lifetime value* derived the project value of work over, say, 7-10 years is significant to project businesses although many contractors retain the transactional focus upon projects as the main unit of financial consideration (Smyth, 2015).

BDM engages with projects at the front-end where the investigation of client needs and configuring solutions is explored in the main contractor. Previous research has pointed out that marketing occupies an isolated position in regard to project management (Pinto and Covin, 1992; Turner, 1995). Yet somewhat paradoxical, there is an argument claiming BDM is a subset of project management, for example applying a funnel approach to link them (Cooper and Budd, 2007). This raises analysis of BDM at a more detailed level.

2.2 *Business Development Management in Construction*

Selling in the extant management and marketing literature has been neglected (Jones et al, 2005; Haas et al, 20102). The sales literature is generally presented as linear, for example: production à sales à marketing à partnering (e.g. Weitz and Bradford, 1999). For projects selling occurs prior to production. While there has been research into the BDM at general level (e.g. Preece et al, 2003), the detailed analysis of the function has been neglected, especially around configuring value propositions in preparation for and in bid management. It requires firm support to align the inputs, develop the relationships and understand the potential value in use. It requires different degrees of organizational and marketing capabilities to conduct this with effect (Möller, 2006).

Selling is a prime emphasis under MM. Selling and delivering value through relationships have similar weighting under RM. S-DL has focused upon conceptual development and refinement with little or no consideration of selling in the role of service provision and value realization. A recent exception is an *interaction sales approach* for the co-creation of value (Haas et al, 2012). The approach develops the line of argument that BDM becomes part of value co-creation through face-to-face interaction. Thus selling and value creation become intertwined. It re-introduces RM tenets through a relational value creating process to the sales function: *the sales function reflects a role of sales as creator of relationship value* (Haas et al, 2012, p. 95), which becomes part of the service value and thus contributes to the ability to sell too. Haas et al (2012) brings forward 4 conceptual categories to understand the sales process:

1. *Jointness value* – resources are combined dyadically and in the network, in the case of projects at the project front-end as well as during construction (cf. Ballantyne et al, 2011). BDM initiates i) identification of the key relations and relational processes, ii) configuration of the value proposition and service delivery, iii) the co-creation of value.
2. *Balanced initiative* – customers are active (e.g. Levitt, 1983), providing preconditions for innovation, collaboration and combining resources to co-create value (e.g. Tuli et al, 2007). In construction, the client is active and the contractor reactive, for example in developing procurement routes and other innovation (Smyth, 2006). This implies support from organizational capabilities and programme management to guide BDM action.
3. *Interacted value* – relationships provide a means to identify and configure value propositions, which hold potential for the client and end-users to optimize value realization in use (Haas et al, 2012). Win strategies emerge from creative dialogue and by committing to reciprocal promises (Ballantyne and Vary, 2006). BDM initiates the process, implying functional integration (Smyth, 2015).
4. *Socio-cognitive construction* – value is phenomenologically and subjectively realized from the functional and symbolic content in use (Vargo and Lusch, 2015). Thus value is

as much behaviourally derived from the specific assets, following the idea that action shapes interpretations (Weick et al, 2005). In construction, BDM has focused upon value as past performance through track record and current execution regarding time, cost, quality and scope, underplaying benefits delivery and impact (cf. Morris, 2013) and educating clients accordingly (Smyth, 2000) – see Figure 1 for further details.

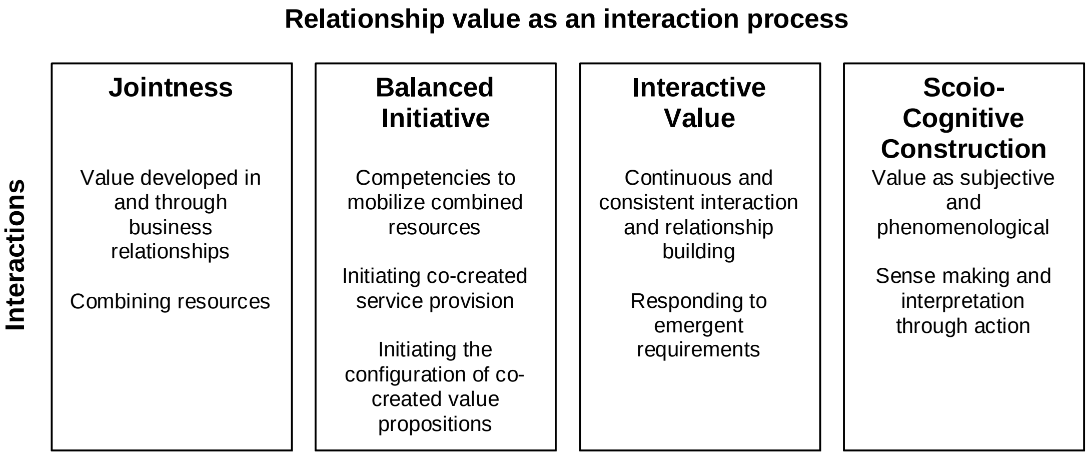

Figure 1: An Interaction-based Framework of Sales' Value Creating Tasks in Projects (developed from Haas et al, 2012)

BDM has a pivotal role at the front of the front-end, connecting the contractor with the client and forming the interface with the project. It has been argued that successful outcomes are dependent upon strategically addressing the front end on the client side (Morris, 1994, 2013) and on the supply side (Smyth, 2015). There are two implications that arise for BDM. First, the interaction sales approach brought forward by Haas et al (2012) has to be conceptually subdivided into the strategic and tactical sales levels of operation to reflect the contractor-project interface and the front end, and the project lifecycle from the front end to the realization of value in use. Second, the long exchange period in construction from post tender negations, through the stage payments to the final account mean that value in use clearly becomes twofold: a) the execution experience as service provision over the entire project lifecycle from the front of the front end to the final account, b) the project content value in use post-completion for the client and end-users. These provide a theoretical contribution to be evaluated through the empirical analysis.

In order to apply the interaction sales approach in detail, the BDM effort to *understand client needs* in order to sell the service and configure value propositions involves a number of potential levels: (i) collecting information on the project and requirements, (ii) knowing the motivations and considerations of the key decision-makers, (iii) understanding client business solutions or organisational purposes the project is addressing, (iv) understanding the client's own core business to get to the bottom of what they perceive as valuable. The MM approach only requires the first level. RM requires the second and third levels. S-DL requires all levels to secure a comprehensive understanding of use value.

3. Methodology and Methods

An interpretative methodology was applied to respect value judgments, subjectivity and information provided in context (Denzin, 2002). Respecting key actors perceptions enriches understanding of attitudes present, the strengths and weaknesses of organizational artifacts, processes and behaviour, yielding meaning to generate patterns of events, draw out experiences, draw attention to outcomes of significance (Smyth and Morris, 2007). The researcher is also interpreting evidence, producing a layered approach (see Table 1). In this research the data comes from 30 semi-structured interviews with those in business development management roles (BDMs) across 10 main contractors. Ownership varied: 4 UK-owned contractors, 4 mainland EU-owned contractors, 1 other European contractor and 1 Antipodean-owned contractor. Sectors of operation included civil engineering and infrastructure, building, refurbishment and fit out, although sector activities did not appear material in how BDM practices were conducted. The period covered is the constrained European market from 2009.

Table 1: Interpretation Levels in Qualitative Research (adapted from Wells and Smyth, 2015)

Levels of Interpretation	Agent	Stage of Interpretation
1.	Interviewee in the main contractor organization	Interviewee interprets events (including processes) as they occur – a sense-making activity
2.	Interviewee in the main contractor organization	Interviewee with other actors moderate their interpretation – an iterative sense-making activity
3.	Interviewee in the main contractor organization	A degree of post-rationalisation as a result of subsequent events, also moderated by social and other contextual factors
4.	Interviewee as informant	Recall moderation in context of interview – interpretative selectivity
5.	Interviewee as informant	Responsiveness to the perceived research agenda and selectivity as to what the actor perceives the researcher wants to hear
6.	Researcher as data collector	Selectivity of information according to values and research context in note-taking and analysis post-interview
7.	Researcher as analyst	Researcher interprets events as perceived in the analysis – a sense-making activity

4. Findings and Analysis

The findings and analysis are presented from the strategy level through the project lifecycle.

4.1 Marketing and Sales Strategy in the Main Contractors

The marketing strategy was variably developed across the firms. It was arguably the most developed in BranCo, applying RM, yet some BDM practices were rooted in MM pipeline selling. Across all the contractrs with marketing plans other functions were largely unaware of the content, for example EuroCo’s procurement department was both unaware of the plan and had no dialogue with BDM to coordinate value propositions in the supply chain. In BritCo marketing was cut post-2008. Marketing” was consigned to a backroom function of processing market information and BDM was absorbed into bid management. UKCo did not have an explicit marketing strategy, seeing BDM as a pipeline of information collection and response – it was reported as *marketing on the run*. EUCo put in place its first marketing plan in 2008 and subsequently developed strategies for key customers, which were presented to board level. Primary content was a strong emphasis on forward work planning. EuroCo customer plans were frequently out of date and not referred to at functional levels (cf. Smyth, 2013). A KAM capability has been introduced for consistent client management. It was poorly resourced and largely operated at project rather than programme management levels.

A strategic intent of jointness to combine resources was absent, despite client demands for collaborative practices in the infrastructure sectors. Contractor perceptions around competitive advantage and intellectual property were constraints to jointness for the co-creation of value through knowledge sharing, innovation and collaborative working. RhoCo and BudCo particularly emphasized these points, but these two organizations were among the most focused on transactional and operational cost. They were defensive rather than transformative to drive dynamic and incremental performance improvement around value.

Procedures to guide BDMs for relationship building and understanding client needs were absent, affecting balanced initiative and interactive value. This represents a lack of strategic support for the tactical BDM operations. BudCo operated a transactional pipeline approach with a strong input-price connection maintained throughout. ElecCo, FinCo and BritCo were also highly transactional and closely adhered to MM practices. Value was perceived as technology and expertise. In EuroCo, management capabilities for innovation and service provision were not recognized. Yet many clients, especially in the public sector were reported to have lost capabilities post-2008 and thus need more strategic support and advice. This was recognized and presented relationship building and co-creation opportunities for FinCo and EuCo, although the latter was better placed and selectively took the opportunity as a type of balanced initiative and interactive value creation.

Overall, strategy development for BDM has improved over the last 15 years (cf. Smyth, 2000), yet remains weak against the theoretical lenses apart from MM.

4.2 BDM at the Strategic Project Front-end

The BDMs sought a mix of high value and high profile clients, with some trade margin offs if the client profile was thought to reinforce sector track record and the ability to secure other new work. This was particularly found in FinCo for public sector and for BranCo for some private sector work. Mid-recession, trade-offs challenged the RM strategy in BranCo. New clients were difficult to secure, especially in new sectors. There was around 10% experimentation in BDM activity for entering new markets and anticipating new markets – an important substitute for market research because contractors reside near the top of the ‘food chain’ (cf. Smyth, 2000). BranCo followed this strategy. One BDM in EuroCo reported that it was difficult to secure resources to prime new sectors even where tasked with the objective. EUCo and BranCo admitted that they were weaker on value than selling. EuCo was the only company that drilled down to all five levels of to *understand client needs*, albeit sporadically and not always succeed in injecting the understanding to value propositions. Initiatives were not always balanced (cf. Haas et al, 2012). BranCo was the only company to employ a *client lifetime value* as a measure, which helped to reinforce interactive value in selling.

Mapping of the key decision-makers helps understand client need as part of RM, namely knowing the motivations and considerations of the key decision-makers.. BranCo was the most effective case company, yet inconsistent practices were also present. Some BDMs conducted formal mapping for their own purposes at organisational, programme and project levels among clients and their representatives, while a few logged their maps on the CRM system, Salesforce®. Engagement with CRM was low across the companies. A number relied on informal processes, mentally mapping people by role and influence. Mapping competencies support interactive value in interaction selling (cf. Haas et al, 2012).

There was a lack of strategic resource commitment and criteria. AntCo tactically committed resources based upon time and effort at project level. Finance management and commercial directors were said to be predominantly transactional. It restricted client engagement and combining resources through jointness.

Customers frequently seek high interaction levels, for example to have a large say in the members of the project teams (Haas et al, 2012; Smyth, 2015). Management awareness of theory and applied configurations are thin with the consequence of low levels of resourced interaction and integration. Practices were uneven and varied. The lack of strategic support was tactically echoed as a lack of guiding procedures.

4.3 BDM Tactics at the Front-end

In the general absence prescribed systems and procedures, routines and action were left to individual responsibility (cf. Smyth, 2015). In FinCo client interaction was cut back following 2008 with reliance upon telephone contact to solicit information to feed the work pipeline, and employing a highly transactional around the bid and contract process: *We tend to be office based. We don't go out and meet the clients*. BudCo are predominantly transactional, claiming to be good at managing high-level relationships yet weak down the hierarchy and into operations. There were similar procedures for internally qualifying project opportunities. These were generally qualified against resource inputs rather than the potential of combined resources to manage risk and create value, that is, through jointness. For example, UKCo classified project opportunities as follows:

1. Platinum – must win;
2. Gold – resources committed to investigation, but the decision to proceed taken;
3. Silver – interesting but no resources committed;
4. Bronze – promising yet too early to know.

In EuroCo opportunities over a threshold cost went to the main board for risk assessment.

Some RM tenets had been absorbed by the BDMs, who were building relationships even if these were left unrecorded CRM IT software. An EUCo BDM summed it up: *its all about people and relationships*; and, *it boils down to some trusted relationships* according to an AntCo BDM. Some BDMs built relationships to improve pipeline information quality and processing. This sales approach overlooked value delivered through relationships or co-creation, including in BranCo. To progress relationships, BranCo made resource commitments against key clients, yet to configure value, non-contractual promises could not be made as the procedures did not exist to deliver against these. Imbalanced initiatives and interactive value were compromised. Cost and risk management mainly drove out value. Even when value was addressed, it was seen in terms of cost, RhoCo pursuing this for efficiency using Six Sigma. Some clients reinforced the transactional approach. However, one client set BDMs "homework" to gauge commitment, offering opportunity to co-created value at the front end. Overall, configuring aligned value propositions proved to be a tactical challenge due to the lack of strategic support.

Some EUCo BDMs perceived value as inputs determined at prequalification. Value was perceived as standard inputs. Prequalification and bidding documents were put together on a cut and paste basis rather than being tailored to context. Many BDMS had no involvement in bid management. FinCo, BritCo and BranCo did, the former two from an MM perspective and the latter from an RM perspective. Yet, BranCo BDMs tended to hand over prospects after pre-qualification. BDM lifecycle involvement, even through a "watching brief" was widely cited as important: *they need a common link* and the *willingness to partake in dialogue*, yet implementation was inconsistent. BranCo was more effective at developing "win strategies" during bid management, influenced by BDM yet not derived from promises due to the lack of integration. BudCo claimed to have an effective link between BDM and bid management, which fed into value propositions. BranCo BDMs were most vocal on this point and it is summed up in EUCo as the challenge of *getting the theme running through*. Bid managers and project managers were largely left unaware of understanding about value or were not required account for this. BDM remains isolated in relation to project management (cf. Turner, 1995).

ElecCo has a different approach, predefining specialist inputs supported by breadth and depth of expertise. This was offered as exchange value in the knowledge of a high degree of client dependency even though there may be customized solutions to context. Realized value in use could be quite high, but it not was not directly co-created. Overall value propositions were high value yet transactional.

Collaboration, early contractor involvement and open dialogue are formal mechanisms for combining resources in joint problem solving that can feed into balanced initiative and interactive value delivery. These measures were mentioned by a number of BDMs across the cases and especially in UKCo. Collaboration was present in infrastructure, driven by clients with service and value in mind.

A lack of integration was evident, despite interactions, and value propositions were suboptimal. Evidential patterns were mostly identified in terms of a lack of systems and procedure for BDM.

4.4 BDM Tactics in Execution and Post-completion

Delivery is constrained by low integration both in service provision for execution and realizing potentially valuable propositions post-completion. Sporadic involvement of BDMs was reported during execution. This was across two types of contact for value delivery: externally the client contact and internally the project team contact. The internal relationship includes key performance indicators and lessons learned fed into configuring future value propositions. BudCo reported limited knowledge feedback to tweak "win themes". EUCo BDMs were charged with making contact twice with site during execution. Where feedback occurred, it was inconsistent and intermittent, and described by one UKCo BDM as being managed "quite randomly". Summing this up, a BDMs reported feedback as important, yet, *in practice it never happens*.

The BDMs were contributing to the function being isolated (cf. Turner, 1995), belying any conceptual argument that BDM is part of project management (cf. Cooper and Budd, 2007).

BDMs, indeed the companies, were disengaged from monitoring value alignment and value realization post-completion, even though the final account is closed long after practical completion on site. Benefits delivery and impact was neglected by BDMs and by the case study firms. Overall, sales interaction falls away and the monitoring of and support for the co-creation of value is low – low jointness, balanced initiative and failure o understand socio-cognitive construction.

5. Conclusions and Recommendations

The sales function has been neglected in the extant management literature, especially in regard to value (e.g. Jones et al, 2005; Haas et al, 2012). BDM has received little attention in projects and construction (Smyth, 2000). The paper set out to review BDM practices on the ground. It investigated the range of activities conducted within the function and related to this the extent of integration with other functions along the project lifecycle. Low integration was prevalent, confirming previous findings (Smyth, 2015). Marketing and BDM have been claimed to be isolated from other processes in the project domain (Pinto and Covin, 1992; Turner, 1995). This is still the case to an extent but there are more touch points and interactions than might be expected from past research, especially at the front end. The notion that marketing is to be subsumed into project management has no current basis, the future aim being to integrate rather than for either function to absorb another.

The informal BDM activities were diverse and inconsistent in supporting a single theoretical lens or the interaction sales approach (cf. Haas et al, 2012). This was the consequence of low strategic investment and commitment for BDM rather than the development and delivery of differentiated value propositions. BDM strategic support in the firm hierarchy was an underdeveloped, including programme management to support BDM prior to any project and at the front end of construction projects. Overall, the transactional *marketing mix* or MM was still prevalent despite the ill-theoretical fit. *Relationship marketing* or RM principles were applied piecemeal, and aspects of the *service-dominant logic* or S-DL were present by implication rather than strategic design. The activity to *understand client needs* only served MM. Selling dominated value within marketing and BDM, and risk and cost dominated value. In summary, selling is largely conducted through BDM without any conceptual underpinning and strategic guidance.

The paper has made a contribution by analyzing BDM using the interaction sales approach conceptually and conceptually added the strategic and tactical analysis. It also investigated BDM at a more detailed level of activity. There is scope to dig down further in future.

The recommendations for practice could be numerous at the level of activity, but the big picture for management at senior level and for marketing and BDM is that there needs to be increased awareness of theory and a systematic approach to BDM. Implementation needs resourcing and commitment with a transformational emphasis upon growth the market.

Research recommendations show clearly that asset specific markets and project businesses in particular require mainstream marketing concepts to be translated into context for these to have use value. Thus care is needed in appropriating and applying marketing theorization in construction.

Abstract

The primary tool to bridge innovations and the market is the business model concept, i.e., the logic of creating and capturing value. Although business model is regarded as a boundary-spanning unit of analysis, most of modern business model frameworks are firm-centric and less suited for analyzing the interdependent nature of organizations residing and evolving in same innovation ecosystems. Through the business model approach, also urban ecosystems are able to build sustainable competitive advantage. However, an ecosystem can cross a variety of industries and encompass a variety of organizations, which makes the identification of its exact boundaries both theoretically and practically difficult. Hence, contributing to ecosystem level business model discussion, this study applies a business model approach to analyze how an ecosystem may innovate and build competitive advantage as a whole.

In particular, this paper focuses on how business model approach can be viewed as the way for leveraging value from innovations in the urban area development context, and explores how urban area development may contribute to new market creation. The Finnish spatial planning system, spanning from strategic spatial planning to physical land-use planning, provides a context for researching innovative opportunity and advantage exploration and exploitation behaviors. Particularly, contributing to the opportunity exploration for new market creation is called for within Finnish urban area development practices. Drawing from Activity Theory and business model literature, in the context of ecosystems, we suggest an ecosystemic business model approach in urban area development. The corresponding analysis of three urban area development cases show how new unofficial spatial planning practices relate to ecosystemic business model approach and new market creation.

Keywords: business model approach, innovation ecosystem, large-scale project, market creation, spatial planning

1. Introduction

Today's business environment incorporates a diversity of innovation stakeholders, ranging from public organizations, research institutes, large and small firms onto individual users and citizens (Lappalainen et al. 2015, Gobble 2014). Hence, the concept of innovation has spread from the internal parameters of corporations to include also the wider ecosystem (Durst & Poutanen 2013, Ahokangas et al. 2015). Relying on open innovation (Chesbrough et al. 2014), also cities have started to utilize e.g., public-private-people partnerships (Lappalainen et al. 2015). Innovation ecosystem thinking is therefore useful in seeking to understand the dynamic relationships between different industries, private and public organizations and governments (Lappalainen et al. 2015, Papaioannou et al. 2009, Durst & Poutanen 2013) when they are building new markets.

The primary tool to bridge innovations and new market creation is the business model concept, i.e., the logic of creating and capturing value (Chesbrough 2010, Teece 2010). The business model is a boundary-spanning unit of analysis (Zott et al. 2011) that connects an organization with its environment, customers, competitors and larger society (Teece 2010). In ecosystemic contexts value creation and capture are embedded within the whole ecosystem of players, meaning that value is co-created and co-captured (Ahokangas et al. 2015, Lehto et al. 2013). The business model concept serves as an open innovation platform, connecting focal organization with other organizations, communities and individuals for joint development of innovations (Saebi & Foss 2015). Through the business model concept, also urban ecosystems can be seen to be able to build sustainable competitive advantage (Lappalainen et al. 2015).

However, most of modern business model frameworks are firm-centric and less suited for analyzing the interdependent nature of organizations residing and evolving in a same innovation ecosystem (Iivari et al. 2015). Therefore, business model research needs to consider also ecosystem level business models (van der Borgh et al. 2012). Contributing to this view, this study regards the business model as a tool to build synergy among the ecosystem members for determining how the ecosystem innovates and builds competitive advantage as a whole (Jansson et al. 2014, Iivari et al. 2015).

Specifically, this paper explores how business model approach can be viewed as the way for leveraging value in the urban area development context. Urban development agencies may provide opportunity exploration scenes (Oosterlynck et al. 2011, Hirvonen-Kantola et al. 2015). Particularly, enhancing the opportunity exploration for new market creation is called for within Finnish urban planning and development practices. Thus, this research enquires *how business model approach can contribute to new market creation in urban area development?*

Now, we will introduce the concepts of innovation ecosystem and ecosystemic business model. Then, we suggest an ecosystemic business model approach to be applied in our analysis on urban area development. We also show how urban planning and development practices relate to the innovation ecosystems' business model approaches and their life cycle, in three urban area development cases.

2. Theoretical framework

2.1 The emergence of innovation ecosystems

The notion of ecosystems has gained increasing attention in academic literature as a concept to understand and explain the complexity and the interconnected nature of modern business environment (Durst & Poutanen 2013). The ecosystemic perspective is considered to reflect a fundamental change in the way we think of business in general, particularly in relation to innovations (Gobble, 2014). The term business ecosystem was first introduced by James Moore (1993) who calls a business ecosystem an economic community supported by a foundation of interacting organizations and individuals—the organisms of the business world (Gobble 2014). Ecosystems are focused on commonly created value, renewal, and constant innovation in order to achieve a sustainable competitive advantage in their business environment (Ahokangas et al. 2015, Lehto et al. 2013).

Ecosystems are partly intentionally formed and partly a result of accidental emergence (Moore 1993). Business ecosystems are hence characterized with high complexity, interdependence, co-operation, competition and coevolution (Iansiti & Levien 2004, Jansson et al. 2015). Moore (1993) states that firms create a new business ecosystem based on four evolutionary stages from birth, expansion, leadership, and self-renewal. At the birth stage, it is essential for the ecosystem members to go beyond just satisfying their immediate customers. At the expansion stage the scale-up potential of the business concept of an ecosystem is tested. At the leadership stage the business ecosystem reaches stability and profitability. The final stage, self-renewal or death, is caused by the threat of rising new ecosystems. Hence, there is a continuous life-cycle process of the ecosystem members taking place within an ecosystem (Hirvonen-Kantola et al. 2015).

The underlying thought behind ecosystemic perspective is to expand the capabilities of one actor beyond its own boundaries and transfer knowledge into innovation through collaborating with others (Adner 2006). The joint utilization of complementary capabilities in pursuit of new innovations is hence highlighted within ecosystems, and in this way, ecosystemic thinking closely relates to open innovation (Chesbrough et al. 2014). Although open innovation originates from corporate R&D, its application has expanded beyond inter-firm collaboration (Chesbrough et al. 2014). Also cities and regions have started to seek the benefits of openness and ecosystemic thinking through public-private-people partnerships based on quadruple helix model (Lappalainen et al. 2015).

The ecosystemic thinking is particularly relevant for the smart city concept, which refers to cities themselves acting as innovation drivers (Schaffers et al. 2012). A city can be considered ‘smart’ when investments in human and social capital and traditional and modern ICT-based infrastructure fuel sustainable economic growth, high quality of life and wise management of natural resources through participatory government (Schaffers et al. 2012). Test-beds, living labs, collaborative platforms and testing environments provide good development opportunities for innovation creators and help them to bring their solutions to the market (Launonen & Viitanen 2011). Launonen and Viitanen (2011) stress that innovations need to be designed for real life situations in order to have commercial value. However, urban area development in this context is still bound to traditional land-use planning based on zoning, which makes fast responding to changes and the free development of new markets challenging.

2.2 The concept of ecosystemic business model

The business model is the primary tool for leveraging value from innovations (Chesbrough 2010). The business model bridges innovations and new market creation, i.e., the logic of creating, capturing, delivering and sharing value (Teece 2010, Amit & Zott 2015). Value creation and capture are based on opportunities that require business models for the successful exploration and exploitation of those opportunities and the subsequent competitive advantage (Ahokangas & Atkova 2015, Teece 2010). In ecosystemic contexts value creation and capture are embedded within the whole ecosystem of players, meaning that value is co-created and co-captured (Ahokangas et al. 2015, Lehto et al. 2013). Collaboration of the focal firm with its ecosystem is one of the defining factors of business model openness (Frankenberger et al. 2014). However, the ecosystemic business model can also be regarded as the business model of an ecosystem with mutually connected opportunities. Thus, in an ecosystemic context, the business model functions as an open innovation platform that connects an organization with other organizations, firms, communities, individuals and larger society for joint development of innovations (Saebi & Foss 2015). Therefore, the business model is a boundary-spanning unit of analysis (Zott et al. 2011).

Casadesus-Masanell and Llanes (2011) discuss open source, open core, open edge and proprietary business models. Within ecosystemic smart city contexts this categorization can be interpreted to concern the roles of the city as the focal player of the ecosystem with the rest of the ecosystem when innovating new offerings and creating new markets. With an open source business model the ecosystem jointly co-creates value for its customers whereas in proprietary mode the focal player tries to control value or market creation activities of the ecosystem. In open core business model the focal player remains open whereas the rest of the ecosystem players run their activities independently. In the open edge mode the city as the focal player defines the rules of collaboration allowing the rest of the ecosystem act within the established rules.

Through the utilization of the business model concept, urban ecosystems are capable of building sustainable competitive advantages (Lappalainen et al. 2015). The business model is a tool to build synergy among the ecosystem stakeholders in order to determine how the ecosystem innovates as a whole (Jansson et al. 2014, Iivari et al. 2015). Most importantly, however, within the ecosystemic business model approach, cities may thrive for new market creation by enabling the innovation ecosystem to shift from an evolutionary stage to another (Moore 1993). In addition, cities may allow for the logic of creating, sharing, delivering, and capturing value to develop freely or in a defined manner. Hence, the ecosystemic business model approach needs to consider also business model's viability, evolution and its place in the product or service lifecycle, which in this research refers to spatial planning practices (see also Demil & Lecocq 2010). With the emergence of the idea that the built environment is a source of competitive advantages for urban regions (Hirvonen-Kantola et al. 2015), the question of how business models may boost new market creation is particularly relevant for innovation ecosystems that are nowadays being catalyzed in different cities in Finland, in the urban area development context.

3. Research strategy and methodology

3.1 The context of urban area development

The urban area development takes place within the Finnish spatial planning system, spanning from strategic spatial planning to physical land-use planning, and provides a context for researching innovative opportunity and advantage exploration and exploitation behaviors (Hirvonen-Kantola et al. 2015). However, our spatial planning system is a normative and multilevel system based on land-use planning. Although, the attention has been paid to the European discussion on urban policy as creating prerequisites for urban development (Jauhiainen & Niemenmaa 2006).

In Finland, local planning authorities have been granted an independent role, and the system has offered opportunities for strategically active municipalities. As the ecosystem's facilitator we may thus identify at least the municipality with active land policy and local planning monopoly, as these are portals to opportunities. Here, the most important mechanism of control is the Land Use and Building Act (LBA, Maankäyttö- ja rakennuslaki 1999/132). The land-use planning system is a functionalist and rationalist hierarchical system in which general planning ideally guides detailed planning, and which aims to produce legally binding plans that enable development and implementation.

Municipalities draft their own master and detailed plans, and the powers of approval and ratification are given to the local municipal councils, which makes the local government central stakeholder in the ecosystem. Detailed plans regulate development by defining building rights, efficiencies, dimensions and functions in detail, attached to land-owning information. Plans can be initiated and paid for by both landowners and municipalities, that is, by diverse ecosystem stakeholders. Indeed, the planning practice seldom conforms to formal planning hierarchy, since landowner rights are well protected in the LBA. In addition, investors and the Ministry of the Environment expect speedy preparation of detailed plans, although business considers urban planning slow.

Diverse Public-Private-People partnerships are applied in urban planning and implementation, and any interested party participation is emphasized. The planning authority must publicize planning information so that interested parties are able to follow and influence the planning process (LBA 62 §). Here, openness is a competitive advantage to the innovation ecosystem reaching for new market creation. When launching the preparation of a new plan a Participation and Assessment Scheme has to be drawn up and publicized. It should cover participation and interaction procedures as well as processes for assessing the plan's impacts (LBA 63 §).

However, the business impact assessment with value propositions and competitive advantage identifications is typically neglected, and the content of ecosystemic business model unformed.

In recent years, planning has advanced from top-down government to negotiations with developer-contractors, setting common goals and tying in the ecosystem stakeholders at the beginning of planning projects. The implementation of plans has been integrated with planning, and the detailed plan has become a type of project plan. In order to plan in neo-liberal conditions some cities have developed unofficial practices, which are central instruments in spatial planning. In fact, the three urban area development cases that we will study next, point out the role of unofficial urban planning and development practices, in approaching new market creation as the business opportunity for the ecosystem with mutually connected opportunities arising from the urban area development context.

3.2 Ecosystemic business model approach

Building on the literature review, we will apply a business model approach in exploring how urban area development may contribute to new market creation. Drawing from Activity Theory (Engeström 1987, 2001) and business model literature, in the context of ecosystems, we first suggest a new ecosystemic business model approach in urban area development (Figure 1), to be applied in our analysis.

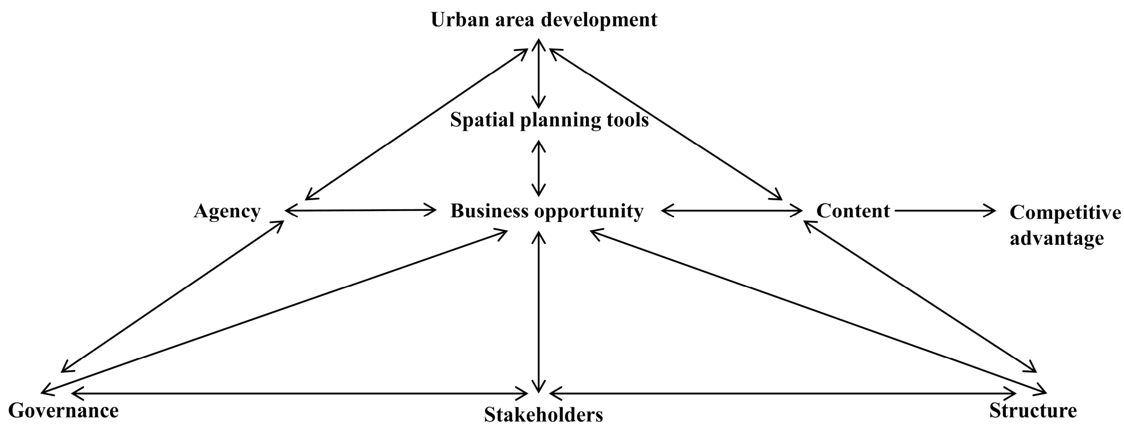

Figure 1: Ecosystemic business model approach in urban development.

In our model, a business opportunity is set as the focal sense—meaning—which affects directly all the other key factors. These are the subject, object, outcome, rules, community, division of labor, and tools included in the human activity system (Engeström 1987). Hereby the structure is transformed into a business model framework. As opposed to the human activity system just mentioned, we consider the urban area development as context to define business opportunities, and thus we add context on top of the model. We also regard spatial planning tools as mediating artefacts.

The model covers the opportunity, stakeholders, content, context, structure and governance of the ecosystem. Starting with agency, it can be seen as the subject of the ecosystem, holding a portal to opportunities, or being responsible for facilitating the activities and interaction within the urban ecosystem. The other side of the coin, the stakeholders including government, industrial/business, academia and citizens form together with the city the community of the ecosystem. Second, the context of the ecosystem can be viewed from innovation perspective as renewal and new market creation can be seen as the key co-creation activities of the ecosystem players. The structure, i.e., the configuration of the ecosystem then defines and delimits the scale and scope, plus division of labour of the units involved. Third, the governance and mechanisms of control as rules relate to the openness of the ecosystem business model, varying from open source to proprietary. This can also be seen in the content of the ecosystem activities that form the basis for the value proposition as the object of the ecosystem as well as its competitive advantages as outcome.

In this paper, three urban area development cases in progress are noted as the hot spots (Gratton 2007) applying the ecosystemic business model approach for new market creation. These cases utilize different types of urban planning and development practices, and they are regarded as one of the most important strategic urban development projects (Salet & Gualini 2006, Oosterlynck et al. 2011) in their cities as they are set to integrate the aims of the local land-use planning, and business and industrial policy. The data concerning the cases was gathered through various forms of primary, participatory (Wallerstein & Duran 2003) data collection methods, e.g. following up the urban area development processes, participating in quadruple collaboration, workshops and meetings, as well as follow-up interviews with focal actors.

All the elements included in the ecosystemic business model framework were identified in the three urban area development cases, and depicted in Figures 2–4. Then, it was analyzed if any of the elements had risked the innovation ecosystems' openness and evolution, in search for new market creation.

4. Analysis

4.1 New market creation in urban area development

Cities may strive for new market creation by enabling the innovation ecosystem's evolution. Moore (1993) states that firms create a new business ecosystem based on four evolutionary stages: birth, expansion, leadership, and self-renewal. At birth, the ecosystem members go beyond just satisfying their immediate customers. At expansion, the scaling up potential of the business concept of an ecosystem is tested. At leadership, the business ecosystem reaches stability and profitability. Finally, rising new ecosystems results in self-renewal or death.

The following analysis on three urban area development cases in progress—the development of the Hiukkavaara Arctic smart city, urban regeneration of the Karjasilta school area in Oulu, and the future Vehkala business and enterprise area in Vantaa—show how urban planning and development practices relate to the innovation ecosystems' business model approach and the ecosystems' life cycle. To start with, INURDECO-SWC quadruple collaboration project aimed at creating the Hiukkavaara Arctic smart city innovation ecosystem (Figure 2), and a detailed plan for Hiukkavaara center, energy efficient block concepts, plus an operational model for Hiukkavaara living laboratory including innovative real property conveyance for threshold projects testing energy-efficient solutions.

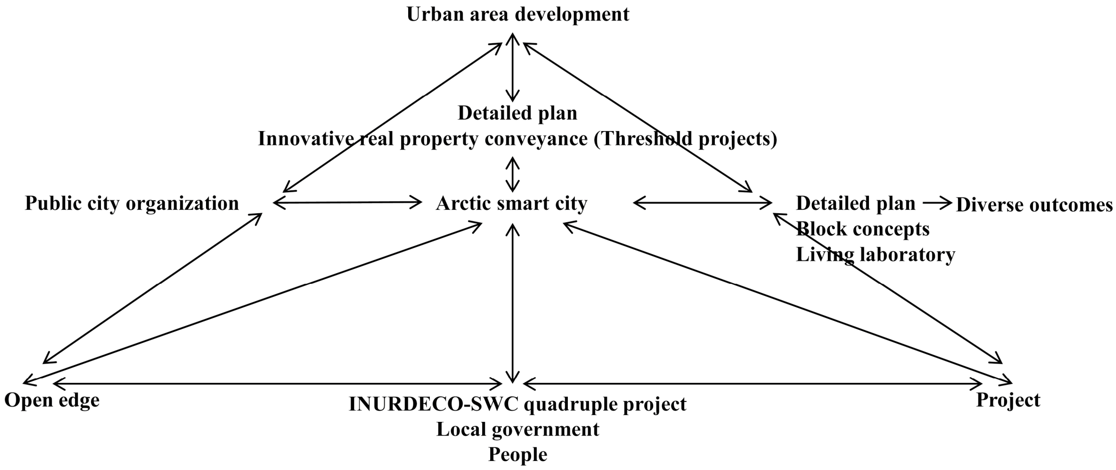

Figure 2: Ecosystemic business model approach in the Hiukkavaara Arctic smart city.

Ideally the ecosystem would have had a business model approach with an open source, in which the ecosystem jointly co-creates value for its customers (Casadesus-Masanell & Llanes 2011). In practice, it had open edge governance with detailed planning channeling the ecosystem's interaction process. However, with multiple content and diverse scales and scopes, the innovation ecosystem lost synergy, which derives from insufficiently identified business opportunities. In the end, the Arctic smart city living laboratory sustains a test-bed by a continuous innovative real property conveyance process, with motive for knowledge. For the capability for self-renewal of the ecosystem's remaining part, the ability to update the threshold project parameters is vital. As such, the life cycle of the innovation ecosystem in the Hiukkavaara Arctic smart city ceased along with the finalized detailed planning project.

Whereas in the Karjasilta school area regeneration related innovation ecosystem, the sight for the expansion stage was built-in the innovative real property conveyance practice. Here, the city sought for unforeseeable prospects including a business lab. In the lab, smart city modules meant for mass customization have been developed, which indicates a will for scaling up. However, in this business model approach (Figure 3) the innovation ecosystem risks sustainable competitive advantage with structure tailored for the current development and construction project, which forms the core for the developer-led ecosystem's governance.

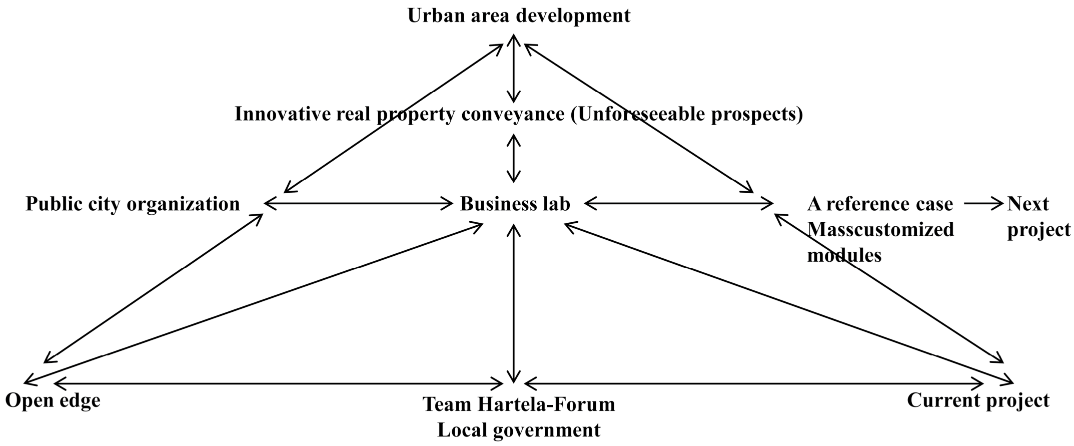

Figure 3: Ecosystemic business model approach in the Karjasilta school area regeneration.

The most future-oriented ecosystemic business model approach (Figure 4) can be found from the Vehkala business and enterprise area. Even though this is an ecosystemic business model approach with open edge, urban area profiling as the core—and mediating artefact—aims at creating a specialized, co-creating ecosystem permanently located in the Vehkala business and enterprise area. There will be a district with diverse stakeholders supporting the selected profile of the area. For its regional scale and scope, the ecosystemic business model approach will possibly be able to scale up to modify the local market. This ecosystemic business model approach will be challenged at the leadership stage, whether it can reach stability and profitability, and finally self-renewal.

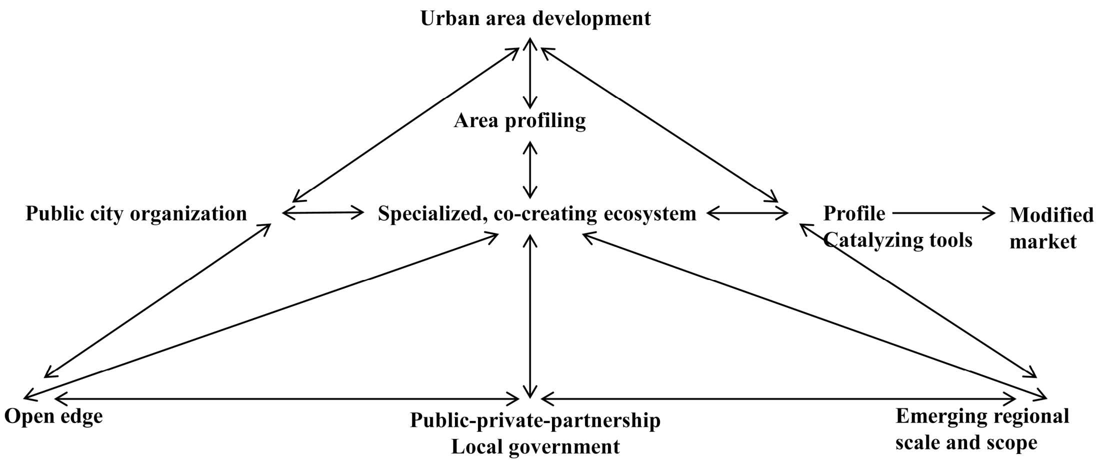

Figure 4: Ecosystemic business model approach in the Vehkala business and enterprise area.

5. Conclusions

We have studied in this article, how business model approach can be applied to analyze new market creation in urban area development. Our contribution is the suggested ecosystemic business model approach, and the analysis on how urban planning and development practices have embraced the ecosystemic business model approach and contributed to new market creation. Hence, this study contributes to business model literature from ecosystem perspective, as well as to the procedural theory of spatial planning utilizing large-scale urban projects as open innovation platforms. We illustrated the applicability of the ecosystemic business model approach through three urban area development cases.

In the ecosystemic business model approach, the city may strive for new market creation by catalyzing ecosystems by offering them an urban area development platform, enabling the innovation ecosystem shift from an evolutionary stage to another, and allowing openness—the ecosystem's natural logic of creating, sharing, delivering, and capturing value. Even though the analyzed ecosystemic business model approaches were with open edge, they had a core facilitated by the city organization. However, our analysis revealed that the nature of this core—a mediating artifact—is decisive in targeting the ecosystems' expansion, leadership, and self-renewal. Here, for instance innovative real property conveyance and area profiling, with more open cores, serve emerging ecosystems better than detailed planning, a normative project.

The ecosystem also needs a clear focus on the opportunities at its birth stage. Possibilities for scaling up need to be similarly considered at the start for the pursuit of new opportunities. We argue that the key for successful exploration and exploitation of opportunities is to have a future-oriented perspective on the ecosystem's life-cycle with a long-term aim. Our analysis shows that all the elements of the business model approach; agency, stakeholders, context, content, structure and governance, need to be continuously reflected during the ecosystem's evolution in order to secure synergy. As the first two cases reveal, the lack of such perspective may result in the cease of the ecosystem's sustainability and risk of its full potential in new market creation. We conclude that the ecosystemic business model approach in urban area development can contribute to new market creation, when there is a clearly defined opportunity and content. This secures the ecosystem's evolutionary path and enables full potential for new market creation.

A Technique for Developing Strategic Differentiation for Small Architectural Firms

John L. Heintz.

Abstract

Since the crash in 2007, the number of small architectural firms has risen dramatically as both recently graduated and recently laid off architects decide to go out on their own. In such a crowded market firms will need to find some way to distinguish themselves from their many competitors. Arguing from the Resource Based Strategy theory the authors assert that to be successful architectural firms must build and promote competences which are both scarce and in demand in order to compete successfully. This should especially be the case in a 'buyers' market'. Architect starting their own firms must provide something more than standard package of architectural services will not be enough to permit new firms to gain clients. A series of case studies was used to compare this theoretical proposition with the experience of recently established architectural firms (+-5 years). The case studies gathered firm histories including the original goals of the principle architect(s), their entrance strategies and marketing approaches, their client list and portfolios of acquired and completed projects. This permitted a comparison to be made between the firm profile the architects originally desired to establish, and the profiles eventually realized. In particular, the perceived selling points which the principle architects believed would provide them with the ability to acquire projects with the services they eventually were able to sell. The case studies supported the assertion that a clear differentiation strategy is one means of successfully launching a firm and gaining a client base.

Keywords: Architectural Firm, Strategy, Differentiation, Competences

1. Introduction

This paper described the results of a preliminary study of the use of the Personal Construct Theory (PCT) and the Repertory Grid Technique (RGT) (Kelly, 1955) to elicit values which characterise a small architectural firm and can be used to guide a strategy of differentiation. The tool has two uses: as a research tool the Repertory Grid is intended as a standardised means of eliciting differentiating values from small firms and establishing a field of values within which small firms typically position themselves. Establishing this field of values would be helpful to principals of small firms in determining their own position, and to researchers in achieving a better understanding of the strategic context in which small architectural firms operate. The second use for the tool is as a consulting or diagnostic tool for individual small firms. The tool is intended not only to elicit characteristic values, but also to contrast the firm with its nearest competitors in terms of these values and thus enable a clearer differentiation of the firm.

2. Small fish in a big market

2.1 The problem facing the many small firms in a very competitive market

The architectural field is characterized by a very large number of very small firms chasing relatively few commissions. Ironically, the crash in 2007 has led to a significant increase in the number of these very small firms. Massive layoffs amounting to as much as 40% of the architectural workforce in countries such as the UK, and the Netherlands, although the impact of the global financial crises (GFC) was to a lesser impact in Australia the number of staff turnover increased considerably moving across practices or contractual amendments – ie. work-week of four days instead of five. In the Netherlands, for example, between layoffs and a pattern of continued newly minted architectural graduates has meant that for many architects the only way to practice has been to freelance or attempt to set up their own firm. This has resulted in a 9% increase in the number of boutique firms and a 47% increase in the number of freelancers between 2007 and 2014 (Consultancy.nl, 2014). All of these new firms fiercely compete with existing and well-established architectural firms for what until very recently has been in most countries a declining amount of architectural work on offer. To be successful in such a hostile market environment one might expect that a firm would need a carefully considered strategy – one in which the firm is carefully positioned in the market between potential clients and their competitors.

2.1.1 The Coxe strategy

What might be considered the standard approach to strategy for architectural firms was developed by the Coxe Group in the 1980s and focuses on conformance to six viable architectural firm types (Coxe, 1987). However, we would like to argue that this approach is no longer adequate to the needs of architectural firms (Heintz, 2012). While the Coxe Groups' fundamental point of knowing who and what a firm is, helps firms to structure themselves well and remains valid, the current situation calls for more. Specifically, the current situation calls for a method for architectural firms to differentiate themselves from their nearest competitor firms, normally firms of the same Coxe type.

The architectural market, especially at the small end, is an unusual market in the sense that there are comparatively many sellers and comparatively few buyers. Clients enjoy a relatively strong position in the architectural market; there are always many architectural firms ready to compete for any commission offered. In terms of the types developed by the Coxe Group, the majority of an architectural firm's competition will be firms of the same type. The vast majority of small firms still offer a "wide range" of design services, claiming competence in all types of building and for all types of clients. These will most commonly be type C Strong Service business-centred-practices (Coxe, 1987). Hence, while the Coxe type strategy may be very helpful in ensuring that a firm is well structured, it is of little use in differentiating a firm from its nearest competitors. For that a firm needs to discover how it can stand out from those most similar to it.

Heintz & Aranda-Mena (2012) concluded in a previous paper (Montreal paper) that more appropriate methods should be used to investigate the topic of business strategies for architectural firms, especially those start-ups or in transition from small to medium or medium to large. Many of the practices would begin with a design agenda or design-oriented, growth and transition would require a business mind-set. Moments of crises emerge when the core value systems might seem compromised by the principals. In other words, to trade the design or artistic values for commercial values, pride in architecture often emerges when a project is 'not compromised' when moving into the Resource Based View (RBV) or similar model. At the conclusion of their earlier paper the authors identified a lack of real-world and empirical evidence on the models of Business for architectural firms and concluding with their paper suggested a more psychological approach to the research in other to better understand the views and values held by a ray of practices suggesting then reading on Personal Construct Psychology and the Repertory Grid Technique (Kelly, 1955).

2.1.2 The need for differentiation

The *Resource Based View* [RBV] of firm strategy may offer us a helpful lens though which to understand strategy in this more competitive environment. The principle conclusion of the RBV was that to be successful a firm had to find a unique resource or competence to which their competitors did not have access (Penrose, 1959; Barney, 2001). This unique potential was then the source of a competitive advantage.

Seen from this point of view, the general problem solving and design competences that form the core of architectural training and of traditional architectural practice are anything but scarce. Signature styles, or at least the ambition to display a signature style, are also relatively common. And to portray a specific 'signature' as a scarce resource seems a bit sycophantic.

2.2 What counts as a unique resource?

If RBV strategy relies on unique resources, what count as a resource for a small architectural firm? And are any of them unique? As architecture does not require a heavy investment in plant or costly materials, the resources in question are the firm's competences to deliver specific services to their clients. However, it is difficult to imagine a truly unique architectural competence, aside, that is from the architect's signature style, which is not relevant to the majority of clients. We therefore argue that strategy for small firms will be a matter of a scarce combination of scarce competences, rather than of truly unique competences. Architectural firms, small or large, must strive to identify one or more scarce competences to which they have access and build their firms around them.

Competition in architecture takes place on a project-by-project basis – in the selection processes of clients. While clients for large projects will often have relatively robust, transparent selection processes based on pre-established criteria, clients for smaller projects, and therefore smaller firms will have more improvised selection processes. For these clients the two most important selection factors will be price and 'click' – the feeling that they can work with this particular architect. Click is a mixt of personality, values and interaction style. This will typically be assessed on the basis of a presentation based on the firm's portfolio and how it proposes to carry out the design of the project. We therefore propose that the relevant competences are:

- Values
- Competencies required to realize values
- Portfolio as evidence of realized values.

The method we propose here will elicit the value system of the principals of firms interviewed. It is at the level of values that a firm can best determine its potential to differentiate itself form its competitors. Once the value system is determined, the firm can then perform an assessment of its competencies and determine which ones to foreground or to invest in developing further. Finally, the firm can determine how to present its portfolio to best exemplify its chosen values.

3. Personal Construct Psychology (PCP)

The overarching theoretical foundation of this paper and approach is that of Personal Construct Psychology (PCP) also known as Personal Construct Theory (PCT) first published by George Kelly in 1955. The theory has a strong psychological foundation but has also been applied in more pragmatic domains. The over all contribution of the paper is to validate RGT as a briefing method for unearthing of tacit knowledge by firm principals. Results overtime are to inform the authors on emerging business strategies applied by architectural firms, clients and designers. For this, the authors are into determining how well RPT - in conjunction with cluster analysis – is able to reveal:

(1) Architects' visions on attributes of practice differentiation and business development strategies.

Psychology aims to predict behaviour. Similar to other psychological theories PCP is funded on a set of assumptions about man and his relation to the world (Kelly 1955). In this way, through the PCP lens the authors draw on respondents experience to plan for their future. PCP only help to expose those plans or predictions and thus the researchers would have a possibility to provide guidance - and the respondent to see and compare their own practice over time.

This study embraces a pragmatic approach towards its validity in which at this point it only seeks to *make-sense* from the respondent view point, thus internally valid. That is, if the grids make sense to those involved in the study the model is internally valid. This is supported by the epistemological framework of Personal Construct Psychology (PCP) (Kelly, 1955). Kelly suggests, that the sorting scenarios proposed to the client are representative of those with which he must deal in structuring his life role. No such thing as general representativeness can be achieved in the same way that there is no general validity of a test. The problems of representativeness in constructs and element where measured in relation to each hypotheses or client under test (Kelly 1955).

PCP offers a framework for understanding human behaviour and decision-making. PCP works on the premise that people spend a lifetime testing personal predictions or hypotheses. In other words, every person is viewed as a scientist who seeks to apply definitions, concepts and constructs (constructs as attributes attached to concepts) to each of his or her actions. By adopting such a view, PCP provides a framework where subjects think and reflect on their decision-making, attitudes, knowledge and as well as actions taken by individuals and collective groups. One of the research techniques to elicit such knowledge and information is the repertory grid technique RGT (Gaines, 1999).

3.1 The Repertory Grid Technique [RGT]

The repertory grid technique falls under the principles of Personal Construct Psychology. The technique has been applied on a wide range of fields spanning from psychology to management. To begin an RGT session on a particular topic the client (or interviewee) and the researcher (in this case software designer) begins with discussions around given scenarios known as *'elements'*. Such elements could also be situations, people, objects or any chosen scenario under investigation and in the case of this paper they may refer to different software applications that planners are asked to consider. As part of such discussions, the technique requires the client to compare elements thus generating a list of *bi-polar* attributes or *constructs.*

RGT requires respondents to compare and contrast a number of elements, objects or scenarios. For instance, the focus of a grid session could be on the assessment of the interface of a number of planning software applications. This will require comparing and contrasting across all ten elements such as software tools - organised in pairs or triads - thus generating *distinctions* also known as *bi-polar constructs*. When the approach is by triads, this comparison takes place by randomly bringing up three scenarios at a time. Then each respondent needs to identify an aspect that is similar to two scenarios and which makes a difference to a third thus generating grids with elements and bi-polar constructs. Grids are generated implying conscious reflections. Grid validation takes place by individual respondents who follow up discussions, thus respondents have the choice to change the grid. A more detailed account of how constructs are elicited will be presented in the next section of this paper.

3.2 Applying RGT to differentiation of architectural firms

In the context of business strategies for design firms, the application of RGT would involve subjects considering subsets of *competing design firms* as *elements* with the purpose of generating a number of constructs and rating them. The first step is to select a number of architectural firms from the environment of the interviewee. Each participant was asked identify 9 architectural firms which exemplified a set of roles and which served in some way as an example to them. Originally, the authors chose a series of roles which were defined in terms of the characteristics of the firms to be named, however during the interviews it emerged that the interviewees were more able to think of relevant firms when triggered to think of firms in terms of their meaning to the interviewee. In all cases the final two firms were the interviewees own practice as it was then, and as the interviewee would ideally see it develop.

Table 1: Original and Emergent Reference Firm Roles

	Original		*Emergent*

1	*Traditional architecture practice*	*1*	*Former Employer*
2	*Alternative architecture practice*	*2*	*Mentor*
3	*Avant-gard practice*	*3*	*Ideal Model (Firms which the subject would like to imitate)*
4	*Small start-up*	*4*	*Negative Model (Firms which the subject would definitely not like to imitate)*
5	*Small established*	*5*	*Competitor*
6	*Design driven practice*	*6*	*Ally*
7	*Process driven practice*	*7*	
8	*My own practice*	*8*	*Subject's own practice*
9	*My ideal practice*	*9*	*Subject's ideal practice*

The way the interviews were structured was by organizing triads, consisting of three of the element architectural firms, and asking the respondent to identify a commonality amongst two practices which makes a difference to the third. For instance, if the triad consisted of elements 1, 4, & 6 (traditional, small start-up, design driven firms). The respondents might then group 1 and 6 together and differentiates them to 4 yielding the construct *Experience*, and the contrast *Lack of negotiation skills*. This means that for the respondents a traditional practice and even a design driven practice are better fit to negotiate with clients. This implies that a small start-up is less prepare with such an important business skill.

The process is repeated with as many practice combinations as felt exhaustive to cover the topic and subtopics of the paper. This could be developed over on-off session or over a number of sessions.

4. Interviews

The study consists of a series of 5 interviews (4 in the Netherlands, and 1 in Switzerland) of principals of small architectural firms using the PCT/RGT technique. The Interviews were conducted according to the protocol described below. Each interview resulted in a completed Repertory Grid comprising of between 7 and 10 constructs consisting of values and their contrasting 'opposite'. These in turn provide a characterisation of each firm individually, and of the strategic context collectively which will be presented in a follow up paper to this one.

4.1 Firms Interviewed

This section reports on emerging constructs on five interviews as a scoping qualitative study.

4.1.1 Frim PN1 A&R10

In going so far as to include the word 'renovation' in the name of the firm the owner-architect signals to potential clients that their problem is not a second choice selection for the firm – not a poor substitute for a new building. By focusing the practice on renovation, the firm has been able to assemble experience in the problems specific to the renovation and repurposing (transformation) of older buildings. The firm supplies advice during the initiative phase, including assistance in obtaining renovation subsidies for listed buildings. The owner-architect started the firm on a part time bases, and have been working fulltime for 3 years by the time of the interview. The firm had 3 contract workers in addition to the principal.

4.1.2 Firm PN2 (Urbmath)

The sole owner-architect started Firm N1 immediately upon graduation from architectural school. Indeed the firm's approach is directly taken from the architect's graduation project – a center for Rotterdam Contemporary Youth Culture. What sets Firm N1 apart from other young architectural firms is the architect's personal interest and facility in what he calls Youth Culture. In essence the architect is hip. He is a figure in the Rotterdam hip-hop scene, and is accepted as a credible speaker for youth culture by the municipality and by private clients. The firm was 3 years old at the time of the interview, and had grown to 5 contract workers.

4.1.3 Firm PN3 (ORGA Architect)

PN3 is specialized in sustainability, specifically "Bio-based Building", and is active in research into bio-based architectural materials as well as design of sustainable buildings. In addition the firm has a strategic partnership with a small contracting firm, also specialised in bio-based building. The firm has received media attention, and the principal has received an award for entrepreneurship and achievement. The firm was 6 years old, and had 4 fulltime employees in addition to the principal.

4.1.4 Firm PN4 (SJO Architecten)

The 2 principals of SJO Architecten took over the firm on the retirement of their previous employers. The succession had been carefully structured by the previous employers, who hoped to leave a legacy and an imprint on the firm. The firm had changed its name less than a year before the interview. The firm had been healthy up to the crisis in 2008, and had continued with reduced staff since then.

4.1.5 Firm PS1 (OOS Architektur)

Firm motto/slogan: **Design is our passion**

PS1 is an architectural firm based in Zurich which was founded in Zurich in 2000 by the four architect-principals. In recent years it has grown into a larger commercial firm with corporate clients operating in Zurich and neighbouring areas. Besides office facilities, other projects also include housing projects and converting old factories into social-housing systems in the townships of Aathal, Flums and Schönau near Zurich. The factory conversions has become one of their trademarks their own office being in an old factory in Zurich's industrial suburb Haltestelle.

"We create space in all scales, and design it comprehensively. Our team is made up of specialists in architecture, interior design, urban planning, spatial development, scenography and branding. They transform the requirements, subjects and values of users and clients into a customized spatial environment. In addition to our wide experience, we continually observe new trends and developments and ensure that the knowledge gained flows into the projects. A trans-disciplinary approach and holistic methods characterize the development process and the results of our work.”

The practice was 13 years old at time of interview and had approximately 20 employees and two principals, both interviewed.

4.2 Interview Results

The method generated both a wide spectrum of constructs, and therefore of values, reflecting the variety of firms interviewed. Yet it was also possible to group the constructs in clear clusters around three themes: Design & Ideology, Process, and Business. The Design cluster was the least surprising. Architects traditionally attempt to distinguish themselves through their portfolio and signature or style. However, we saw some constructs, such as the Flexible-Specific construct that contrasted sharply with the traditional architectural interest in specificity and idiosyncrasy. The Process cluster contained constructs that were both internally focussed and externally focussed.

Table 2: Clustering of constructs, clusters, subclusters and example constructs

Cluster	*Subcluster*	*Construct*	*Contrast*
Design & Ideology	*Design*	*Elegant Design*	*Mediocre Design*
		Flexible, Impersonal	*Specific, Personal*
	Ideology	*Official Culture*	*Subculture*
		Design Driven	*Social Impact Driven*
Process	*Process*	*Joy/Fun*	*Professional/Corporate*
		Openness to share knowledge	*Won’t share knowledge*
Business	*Internationalisation*	*Swiss Market*	*International market*
	Specialisation	*(Social) Housing*	*Divers portfolio*
		Sustainability	*General Services*
	Services	*Architect*	*Architect Developer*
	Size	*Big projects*	*Only small projects*
	Marketing	*Waits for work to come in*	*Creates work*
	Business	*Business as ususal*	*Business innovation*
		Want to make money	*Careless of money*

The process cluster is a combination of current and desirable attributes to the practice - inwards to the firm. Theses align with the practice culture and also technical skills such as ability to share knowledge and problem solving.

The business cluster is outwards to the firm - with constructs such as business growth, national or international expansion, business size, client base and marketing strategies just to mention some.

The overall appraisal is been a positive one in the sense that grid process and results gives instant feedback articulated by the interviewer. In this way, participant and researcher can discuss results and modify them if necessarily. Amongst the graphics for date analyses are: structured repertory grids, cluster analysis, dendograms, principal component analysis and socio maps which are beyond the scope of this paper but previously studied in depth by one of the authors over a PhD investigation (Aranda-Mena, 2003). Grid analytical work will follow up to this paper.

4.3 Feedback on the tool

The authors have asked two of the respondents to provide some comments or feedback on actual Repertory Grid Technique. Here below some of the feedback. In general the interviewees responded positively, e.g. “Extremely Interesting” -- PN4.

4.3.1 Feedback from PN4

“Extremely interesting.”

Thinking about help to the specifics of the firm.

“This is very nice because then you start to think of how you want to position yourself.”

Forced choice is what makes you start thinking.

Each different set requires that you make a switch, either positive or negative.

4.3.2 Feedback from OOS

The Repertory Grid Technique was perceived as good and effective method but it was pointed out that in order to drilldown into more understanding of differentiation across the element organisations more information from the competitors would be required other than the more superficial perception. Follow up *zoom-in* sessions would be required.

Perhaps a follow up session purely focused on internal resources including human resources, skills and assets. It will be then easier to also compare with competitors. This was referred as a *360° degree pan-view.*

Other topics such as organizational maturity were discusses. Especially in relation to architecture which tends to be a “highly-controlled” culture where principal architects tend to keep the knowledge to themselves and run their studios on a top-down approach. Swiss example of Peter Zumthor, Mario Bota came to the discussion as highly personalized practices which must likely will die when their funding members are gone.

A world-view that still prevails in architecture culture is that of the architect at the top of the pyramid above investors and above society. In the view of the interviewees ***design*** is a core business attribute which has to be a must but from there a number of skills and competencies have to be develop.

The triad technique works well however, the perception is that the discussion is too superficial as the tendency is to generate and *outside-view* instead of “drilling-into”.

A recommendation (for the follow up interview) is to have/provide more information (or allow time to research) the particular elements (architecture practices) in order to have a more informed/factual discussion.

The two respondents much liked the triad interviewing technique and are looking forward to follow up discussions and engagement with our research paper/topic of much value to them!

5. Discussion

Past present and future.

Many of the constructs generated are similar to the questions the Coxe group used in their typological approach. On the one hand this suggests that few new values were disclosed. On the other hand it does make it possible to cycle between discussions of typological consistency and points of differentiation within the type.

However, the results do suggest that where the Coxe typologies suggest that few Strong Idea firms would have an interest in profitability, this may no longer be true. Indeed, the firms interviewed, although generally successful, did not fit easily into the Coxe typologies, particularly the distinction between practice-centred-business and business-centred-practice.

Developing tactics, bottom up.

During the interviews a more interviewee centred approach, e.g. the emergent elements, was found to elicit more productive conversation around the constructs. This sets the goals of research and consulting against each other, as mapping the range of strategic values would require using a consistent set of elements and constructs in order to build up a body of data that could be analysed with the statistical tools from the RGT.

The brevity of interviews, and the dependency on perceptions of the element firms, means that the interviews are limited to an exploration of values. The element firms serve as devices with which to prod the interviewees to reveal their values. The results, therefore, are not a complete analysis of capabilities of the interviewee’s and element firms, but rather an analysis of the values by which the interviewee would like to differentiate their firm from the element firms. Further work would be required to determine the degree to which the interviewee’s firm possessed the desired capabilities or needed to invest in developing them.

All of the firms interviewed expressed a clear desire to distinguish themselves from what they saw as the way the previous generation did business. Whether it was in terms of authenticity, design innovation and research, corporatism or business innovation. Interestingly, while there was a clear interest expressed by all the firms interviewed in profitability, most also wanted to contrast themselves from what they perceived as the conservative ‘corporate’ firms which are normally associated with profitability.

Customer orientation. [Actually, the strategy of differentiation of firms implies a similar differentiation of clients. The scarce competences will not be of interest to every client; otherwise they would not be scarce.]

6. Conclusions

On the validity of the current data collected the authors maintain that the paper is of qualitative nature and no further validation other than that of the respondents is required. In other words, internal and not external validity is expected at this point. However, it is envisioned that over a series of interviews eliciting constructs and elements will sum up of statistical analysis with external validity (Wright, 2006). At this point the authors are expecting to provide generic templates to assist industry with various entry points into PCT based mentorship sessions.

Results at this stage indicate wide range of emerging constructs, which have been categorised into a more specific number of clusters. A hierarchy of clusters are discussed such as (1) Design Oriented, (2) Ideology, (3) Process and (4) Business are amongst the most crucial discussion themes.

To conclude, this paper is argumentative in nature and as the abstract and introduction states, it aims to position the Repertory Grid Technique as a method to assist architectural firms with their growth. The RGT has proven to be a flexible, engaging methods that begins from the view-point of the respondents and not from a more traditional prescriptive approach such as the earlier investigated and tested techniques such as the RBV.

One aspect of RGT which could be better addressed in future sessions include ***timing*** control as it is easy to branch into a number of internal and external issues to the practice with some of the interviews taking 90 minutes or in the Zurich case over several sessions. It would be interesting to limit the agenda to more specific topics for discussion with the view to revisit the interviewee and expand from particular points. The other side to timing is that of discussing experiences or aspects to the practice in past, present or even future. The timing in this sense provides a way to compare a point of reference within the same practice as it grows, shrinks or experiences transitions points from stability to crisis and bouncing back (or not) to stability. This aspect of timing can be better managed during the interviews in order to encourage “reflections” and provide a retrospective history to particular clients or firms.

The final argument is that of the utilised terminology via the RGT for eliciting the constructs and thus developing the grids. RGT would provide a number of predefined elements, however the authors found that different respondents react differently to the same set of elements and is some cases better words would suit those same elements – ie. same meaning under different words and in other cases even cultural or language adaptation. This is an interesting development as the interviews took place across three different countries and although in English, the connotations of the elements and in some cases the actual literal translation into Dutch or German would provide a different meaning, in such cases, the element name would be refined to suit the client or respondent and not the interviewer. In this case the authors expect to see overtime a number of similar elements or constructs under different names or labels and possibly moving across different languages too.

Abstract

Projects in the construction industry are accompanied by unique unforeseen threats to overall project goals and risk management (RM) reduces the detrimental effects to the project. However, risk provides a platform for opportunities if properly managed. Contrary to the slow pace of adoption in the construction sector of Singapore, the IT industry possesses a long history of properly managing risk. RM measure are redefined and improved by the IT industry from past projects failures. The demand for productivity gains, skill upgrade and sustainability drives a consistent investment of above S$250 million by the Singapore government in the construction sector. It is therefore imperative to tackle the challenges facing the industry to enhance its long-term competitive edge and business sustainability. Hence, this paper seeks to: (1) to explore and understand the construction and IT industries' acceptance of RM and; (2) to recommend practices that could be adopted by the construction industry from the IT industry in order to increase implementation levels of RM. Attitudinal inclination towards RM was collected via questionnaire from IT and construction companies. The data was analysed using mean score ranking and examined with T-test for statistical significance differences among the different sectors. The results revealed that the barriers reported by the construction industry were significantly different from those experienced by the IT industry. Furthermore, the results established that IT industry practitioners tend to be risk takers who desire training in RM skills while construction industry practitioners tended to be risk avoiders who resisted the changes required to implement RM. Similarly, when compared to the IT industry, the construction industry respondents lack adequate understanding of RM benefits. The study concludes with recommendations for the construction industry to increase its awareness of the benefits of RM and provides recommendations to increase its implementation.

Keywords: Construction Industry, Information Technology, Risk Management, Singapore.

1. Introduction

In the construction industry, identification and analysis choice of risk is opined to improve business risk (Rostami et al., 2015). Failure to adequately envisage unforeseen risk is detrimental to any project. Where RM failure occurs, key stakeholders lay the root causes on implementation rather than on RM core principles (Gendron et al., 2015). The ability to assess and overcome risk provides fertile grounds for project investment growth (Yafai, et al., 2014). Singapore development ideals towards an advanced economy targets superior skills with the construction industry as a key sector. The sustainable growth to provide housing and infrastructure for the growing population requires a long-term strategic outlook. RM is a critical tool for managing projects and failure to manage risks leads to project failure. Construction project involves a large number of players. The Information Technology (IT) and the construction industries came into prominence under the initiatives of the Singapore Government to automate many work functions. IT industry records a long standing history in implementing project management (PM) (Larssen, 2006). Implementation of project and RM arose as a result of the industry's reputation for its many earlier failures. Because so many IT projects have failed, substantial research were conducted to improve their likelihood of success through the implementation of RM. Due to early developments and awareness, the industry has since enjoyed a higher success rate, decreasing overruns on budget and schedules (The Standish Group 1995). RM standards are devoid of basic principles in applying RM in Small and Medium Scale Enterprises (Rostami et al., 2015). Similarly, the anathematised state of RM use in small projects presents a negative trend to the ideals of total RM (Hwang et al., 2014). Oman construction industry places majority risk factors in government category (Yafai, et al., 2014). Companies that hire construction services on a recurring tenure systematically avoid applying RM procedures in projects (Serpella et al., 2014). The construction industry has a very poor reputation for managing risks with projects failure deadlines and cost (Mills, 2001). The construction industry is devoid of a good track record of coping with risks with poor reputations for dealing with risks that produce cost and schedule overruns (Smith et al., 2006; Azhar et al., 2008). In order to distinguish existing deficiencies in the implementation of RM in the construction industry, it would be prudent to perform comparative case studies with the IT industry. This process should stimulate the construction industry to recognize the importance of RM and to improve their capabilities to manage risks, ultimately helping to deliver more successful projects. Therefore, this study seeks to: (1) to identify organizational attitudes towards RM; (2) to recommend RM best practices in the construction industry.

2. Risk Management, Information Technology and Construction Review

2.1 Risk Management

Uncertainties provide a bedrock for discomfort to stakeholders in any project (Olsson, 2007; Serpell et al., 2014). Although inherent in this discomfort lies significant opportunities worth embarking on (Hillson, 2011; Serpell et al., 2014). Risk is defined as the possible occurrence of a detrimental event to a project (Hillson, 2011; Serpell et al., 2014). International Organization for Standardization (2009) defines risk as a combination of the probability of the occurrence of a defined hazard and magnitude of consequences of the occurrence. Project Management Institute (2004) defines risk as an uncertain event or condition that, if it occurs, has a positive or a negative effect on project objective. Most concentration of project managers are directed towards the negative side (Hillson, 2011; Serpell et al., 2014). Hence, identifying, adequate examination and methodological application to risk reduction is key to any project (Tohidi, 2011; Serpell et al., 2014). RM process involves risk planning, identification, assessment, analysis, response, monitoring and recording and management process (ISO, 2009; Serpell et al., 2014). Risk identification and analysis are the most crucial elements in the process of RM (Mills, 2001; Hwang, Chua, 2011; Hwang et al. 2012). Ebrahimnejad et al. (2009) importance of risk identification are: (1) to avert possible events; and (2) relative importance on risks. Lyons and Skitmore (2004) and Hlaing et al. (2008) identified common risk identification techniques. The essence of risk analysis is to quantify the effects of major risks that are identified (Mills 2001). Hayes et al. (1986) stated that project risk analysis is often subjective affecting prospective benefits of RM from being realized. Effective risk analyses require a neutral and unbiased approach, though that is understandably difficult due to the potential for conflicts of interest. Techniques for risk analysis includes direct judgement, expert systems, code optimization, sensitivity analysis, probabilistic analysis, Monte Carlo simulation, kinetic tree analysis, expected monetary value, risk adjusted discount rate, and risk premium (Ahmed and Azhar, 2004; Lyons and Skitmore, 2004; Mills, 2001). RM is viewed from a negative domain rather than a neutral domain from the construction professionals' perspective in Indonesia (Hartono et al., 2014). Mills (2001) summarized that: (1) a cost-benefit assessment; (2) the removal of unnecessary contingency; (3) the clear recognition and acceptance of risk and; (4) realistic cost estimating.

2.2 Information Technology (IT) Industry and Risk Management

The evolving IT spheres provides several platforms for risk assessment. IT businesses provide project solutions that deliver new functionality for existing systems as well as create new systems for processing, storing and manipulating confidential data. To deliver products on time and at minimal cost, players in the industry have to be concerned with systematic invention, production and maintenance. Controlling and managing risks in this industry does not end with the completion of projects. RM to the IT environment is an essential management responsibility rather than a technical function carried out by the IT experts who create, operate and manage the IT system (IT Governance Institute, 2005). The Standish Group (1995) stated that formal managerial processes should be applied to the IT industry because when IT projects fail, it is usually due to the lack of management rather than technical mistakes. This aspect has triggered debates over the importance of RM in the IT industry (Mcmanus 2004). Taylor (2004) and Schwalbe (2009) stated that IT projects are usually linked to business processes and organizational systems that often involve a complex hierarchy of a large number of stakeholders. IT project managers tend to address RM as a standalone process and feed the results into their company integrated project management system (Marks, 2011). Many IT firms use integrated systems in order to balance the operational and economic cost of protective measures. IT professionals are trained and educated in terms of skills, tools, software, and technical and managerial techniques that can be used for RM.

2.3 Construction Industry and Risk Management

The construction industry is characterised by large-scale, complex assembly of components on-site, often requiring significant coordination of project team members (Geddes 1996). Construction firms make business decisions relying more on intuition, personal judgment, and experience than from formal and systematic processes. The deficiency of RM implementation in Singapore construction industry is due to the lack of familiarity with techniques, concepts and methods of RM (Taroun & Yang, 2011). Construction professionals' possess natural inertia to adopt new systems of procedures which are not familiar to them (Enegbuma et al., 2014). Taylor (2004) and Han et al. (2006) proposed the use of intelligent RM system in the industry. Akintoye and MacLeod (1997) regarded cultural issues as one of the major barriers to RM adoption with negative attitudes and mistrust towards risk analysis. Akintoye and MacLeod (1997) summarized the causes as: (1) lack of expertise in the techniques; (2) lack of information and knowledge; (3) time constraints; (4) doubts on applicability; (5) reliance on experience; (6) doubts of its benefits; and (7) lack of client commitment. In risk mapping for cost estimation, ontology approach examines potential risk paths to project perceived future cost overruns for international projects (Yildiz et al., 2014). Knowledge based approach by learning from previous risk experienced from successive projects have been identified as a means to counter future risk (Serpell et al., 2014). Risk sharing between owners and contractors can be modelled by integration of fuzzy logic into systems dynamic modelling structure (Nasirzadeh et al., 2014). RM can be monitored and analysed using a risk evaluation system built on the maturity levels (Serpell et al., 2015). RM technique are not applicable for use in all project situations (Forbes et al., 2008; Serpell et al., 2014). RM and risk identification is better handled through continuous learning process by contractual parties to a project (Perera et al., 2009; Serpell et al., 2014). RM improvements to meet client quality, cost and time needs for small sized projects in Singapore are prominently affected by lack of time, budget and profit margins (Hwang et al., 2014). Lack of managerial skill and underlying knowledge in choice of RM tool presents a challenging factors for SMEs (Rostami et al., 2015). Low level of enterprise RM (ERM) maturity exists among firms in Singapore (Zhao et al., 2014a). Insufficient resources characterised by lack of time, money and people were most critical (Zhao et al., 2014b).

3. Research Methodology

To accomplish the research aim of exploring and understanding the construction and IT industries' acceptance of RM and recommending practices that could be adopted by the construction industry, an extensive literature review was carried out to gain insight into the existing research on RM in both IT and construction sectors. The research instrument for comparison of both the IT and construction sector was developed via a questionnaire (Creswell, 2014). The questionnaires consisted of three sections namely: profile of respondents, RM implementation and suggestions to improve risk implementation. The sampling were randomly carried out for both IT and construction sectors derived from two sources. IT sample respondents were derived from the database of National Computer System (NCS) and Inland Revenue Authority of Singapore (IRAS) while construction was derived from the Contractor registry of Building Construction Authority (BCA). Each respondent was required to be assigned based on adequate knowledge and experience in the RM implementation processes in the firms. The responses were ranked using a five-point Likert scale from 1-Strongly Disagree to 5-Strongly Agree and analysed using mean score approach (Zhao et al., 2014a). The means score results was compared using a two-sample t-test to examine the statistical difference among the two sample respondents.

4. Data Analysis and Discussions

4.1 Information Technology and Construction Industry Demographics

The IT industry responses were 43 completed questionnaires. The work type in Table 1 revealed that PM and project managers made up for 72%. This points to the ability of the IT firms to competently carry out PM which forms the basis for this comparison. The number of employees showed that 93% of the sampled firms possessed over 500 staff strength. The larger the staff strength denotes adequacy in manpower and training in RM within the IT firms. The skill set and manpower is further enhanced by the interaction of the personnel with 70% clientele from both domestic and international. The years of experience in redefining and improving RM techniques is reflected by majority of 28% possessing 5-10 years. The high number of PM certification suggests that continuous professional development is encouraged within this sector.

Table1: Demographics of Respondents

		IT			***Construction***		
			N	***%***		***N***	***%***
Characteristics Company	*Work Type*	*PM*	*31*	*72%*	*PM*	*13*	*40%*
		Development	*5*	*12%*	*Development*	*9*	*28%*
		Design	*7*	*16%*	*Contractor*	*6*	*19%*
					Sub-contractor	*4*	*13%*
	Number of Employees	*350 - 500*	*3*	*7%*	*< 50*	*9*	*28%*
		> 500	*40*	*93%*	*50 - 150*	*19*	*59%*
					151 - 250	*4*	*13%*
	Client Type	*Domestic*	*13*	*30%*	*Domestic*	*29*	*91%*
		International	*0*	*0%*	*International*	*0*	*0%*
		Both	*30*	*70%*	*Both*	*3*	*9%*
Respondent	*Job Title*	*Project Manager*	*31*	*72%*	*Consultant*	*3*	*9%*
		Developer	*5*	*12%*	*Risk Manager*	*4*	*13%*
		Designer	*7*	*16%*	*Project Manager*	*11*	*34%*
					Quantity Surveyor	*7*	*22%*
					Architect	*7*	*22%*
	Years of Experience	*< 5*	*10*	*23%*	*< 5*	*3*	*9%*
		5 - 10	*12*	*28%*	*5 - 10*	*15*	*47%*
		11 - 15	*10*	*23%*	*11 - 15*	*9*	*28%*
		> 15	*11*	*26%*	*> 15*	*5*	*16%*
	PM Certification	*PMI*	*27*	*62%*	*PMI*	*0*	*0%*
		Others	*8*	*19%*	*Others*	*2*	*6%*
		No	*8*	*19%*	*No*	*30*	*94%*

On the contrast, the respondents from the construction industry revealed a 40% involvement in PM. This forms a wide difference of 32% when compared to the IT industry. Other work types were developers, contractors and subcontractors. 60% of the firms were relatively small with staff strength of 50-150. Small companies might be limited in their ability to implement comprehensive RM systems due to the lack of financial capabilities and expertise. A total of 75% of the respondents have experience of between 5-15 years while 10% of them had less than 5 years of experience in the industry. In contrast to the IT industry, 94% of the construction respondents declared that they did not possess any PM-related certification whereas only 19% from IT had no such certification. This may imply that the respondents from the construction industry have not received formal training in management, possibly in preference to enhancing technical skills and knowledge.

4.2 Organizational Attitudes towards Risk Management

Subsequently, the respondents were asked about their companies towards risks that they faced in their business operations, processes and activities. An attempt was then made to assess their firm's attitude towards risks by asking if management could be regarded as risk takers, risk avoiders, or neutral to risk. Table 2 revealed that 67% respondents considered their firms to be risk takers. Those who identified their firms as risk takers were asked about the reason for their selection, most reported that because their organization had established organizational RM policies and processes, their firms were not afraid to take on risky projects. Majority of the IT firms reported that they had been implementing RM for a relatively long span of time (72% for greater than 5 years). Because the practice is well-established, it is likely one of the reasons that the firms were proactive on taking risks.

Table 2: Risk Management in Organisations

Organizational Attitudes Towards Risk Management (RM)		***IT***		***Construction***	
		N	***%***	***N***	***%***
Risk Attitude	*Risk Taker*	*29*	*67%*	*9*	*28%*
	Risk Avoider	*8*	*19%*	*14*	*44%*
	Neutral	*6*	*14%*	*9*	*28%*
Years of RM	*< 1*	*0*	*0%*	*6*	*19%*
	1 - 2	*0*	*0%*	*24*	*75%*
	3 - 5	*12*	*28%*	*1*	*3%*
	> 5	*31*	*72%*	*0*	*0%*
RM Implementation	*Not at all*	*2*	*5%*	*21*	*66%*
	All Projects	*27*	*63%*	*1*	*3%*
	Some Projects	*14*	*33%*	*10*	*31%*
RM Beneficial?	*1 (Strongly Disagree)*	*0*	*0%*	*0*	*0%*
	2 (Disagree)	*6*	*14%*	*1*	*3%*
	3 (Neutral)	*5*	*12%*	*28*	*88%*
	4 (Agree)	*16*	*37%*	*3*	*9%*
	5 (Strongly Agree)	*16*	*37%*	*0*	*0%*
Benefits of RM	*Time Saving*	*10*	*23%*	*14*	*44%*
	Cost Control	*10*	*23%*	*14*	*44%*
	Strategic Planning	*3*	*7%*	*0*	*0%*
	Increase of Stakeholders' Value	*0*	*0%*	*1*	*3%*
	Increase of Understanding of Risk	*7*	*16%*	*0*	*0%*
	Achievement of Project Goals	*0*	*0%*	*1*	*3%*
	Minimal Disruptions	*5*	*12%*	*1*	*3%*
	Utilization of Resources	*8*	*19%*	*1*	*3%*

Furthermore, as shown in Table 2, 63% of the IT firms stated that they implemented RM on all of their projects. Of course, for a firm that considers itself a risk taker, implementation of RM would be a logical “must” on most of their projects. 74% of the respondents choose high ranks, indicating that the implementation of RM was perceived as beneficial to their firms. The survey questionnaire listed possible benefits that can be gained through RM implementation. Most respondents reported that time saving (23%) were the main benefits yielded by RM. Efficient RM allows organizations to develop contingency and mitigation plans that help them to manage potential risks and activate plans to address risks quickly when they occur. The regular review of contingency plans to monitor and control risks allows project managers to better predict cash flow and available budget for work to be completed. RM implementation prevents cost and time overruns and support more efficient utilization of available resources. Implementation of RM can be challenging due to various reasons. On the contract, Table 2 also shows that 28% of the respondents regarded their firms as neutral to risk and 44% reported being risk avoiders. It is noteworthy that respondents from development and contractor firms who encounter uncertainties in projects conform to a passive attitude of risk. However, this result may correspond with the research conducted by Smith et al. (2006), indicating that the lack of RM has persisted in the construction industry even though this industry is bound by a high degree of risk from complicated activities. In fact, 94% of the construction industry respondents reported that they had less than 3 years of experience implementing RM. The degree of implementation of RM is relatively low when compared to the IT industry with a total of 66% reporting that their firms did not implement RM at all on their projects. Although 31% of the firms indicated that they practiced RM on some of their projects, and 3% did so on all their projects, the benefits from RM implementation are apparently not well recognized. The majority, 88% were neutral about its benefits and 3% disagreed that there were benefits. Nonetheless, the survey respondents did indicate that proper implementation of RM may produce better identification and management of risks that affect cost and schedule performance (time saving–44%; better cost control–44%). The inference thus presents a scenario where firms from the construction industry are doubtful about the benefits of RM which invariably hinders implementation.

4.3 Barriers of Risk Management Implementation

Table 3 interestingly shows that more than 90% of the respondents believed that the benefits of RM were neither properly captured nor recognized by their companies (Lack of Belief in Benefits: *M*=4.09; one sample T-test P-value=0.00). On the other hand, none of the other barriers generated were identified as significant obstacles in their firms. The findings suggest that if an IT firm does not implement RM, it is more likely due to the lack of recognition of the benefits of RM rather than limitations of time and budget or resources such as tools and trained project managers and employees. This result may imply that most IT firms have policies, systems, and processes for RM, and their employees have been educated and trained in the area of RM. On the contrast, construction industry respondents believed that insufficient budget was one of the major obstacles hindering implementation of RM in their organizations (*M*=3.94; *P*=0.00). This may not be a surprise as the respondents originated from relatively small to medium-sized companies with limited financial capabilities for investment, development and implementation of RM. Furthermore, 78% of the respondents agreed that untrained staff (*M*=3.63; *P*=0.00) and project managers (*M*=3.56; *P*=0.00), as well as the lack of tools and systems (*M*=3.56; *P*=0.00) were barriers in their companies.

Table 3: Risk Management Barriers

Lack of Tools and Systems	*0%*	*0%*	*100%*	*22%*	*0%*	*0%*	*0%*	*78%*	*0%*	*0%*	*2.00*	*3.56*	***0.00***	***0.00***	***0.00***
PMs Not Trained	*0%*	*0%*	*100%*	*22%*	*0%*	*0%*	*0%*	*78%*	*0%*	*0%*	*2.00*	*3.56*	***0.00***	***0.00***	***0.00***
Staff Not Trained	*0%*	*0%*	*100%*	*16%*	*0%*	*6%*	*0%*	*78%*	*0%*	*0%*	*2.00*	*3.63*	***0.00***	***0.00***	***0.00***
No Culture in the Company	*0%*	*0%*	*100%*	*34%*	*0%*	*25%*	*0%*	*41%*	*0%*	*0%*	*2.00*	*3.06*	***0.00***	*0.69*	***0.00***
Not Much Risk Managed	*3%*	*0%*	*95%*	*13%*	*3%*	*13%*	*0%*	*75%*	*0%*	*0%*	*2.00*	*3.63*	***0.00***	***0.00***	***0.00***

This may imply that RM in Singapore construction industry remains in its infancy and the adaptation of key players to appropriate RM tools and systems is not yet common. It is also possible that insufficient financial support for RM discourages development and implementation of tools and systems, further contributing to the lack of opportunities for training project managers and other project players. This may also explain why the potential benefits from RM are not fully recognized. Considering that the mean scores of the listed barriers are statistically different between the IT and construction industries, it can be concluded that the firms from the construction industry face more barriers to RM than the IT industry. In other words, due to active implementation of RM, IT firms have likely overcome most of the listed obstacles while the firms from the construction industry have not. These results suggest that different strategies for increasing implementation in the two industries are required.

4.4 Improvement of Risk Management Implementation

Organisational culture and applicability of RM techniques are vital towards effective implementation and project success (Akintoye and MacLeod, 1997; Forbes et al., 2008; Serpell et al., 2014). As a result, the respondents were asked to select methods that could improve their current organizational environment towards adapting better RM. As summarized in Table 4, about 90% of the respondents agreed that RM implementation in IT firms can be improved by: (1) educating staff on the importance of RM (M=4.12; P=0.00) (2) conducting training sessions covering the knowledge, skills and tools of RM (M=4.14; P=0.00); and (3) enforcing the use of RM through appropriate measures (M=4.02; P=0.00). This may infer that IT firms have already established processes and systems for RM but they recognize that continuing opportunities for education and training should be given to their employees in order to maximize the positive impact of RM at their firms. As shown in Table 4, the results from the methods for improvement cited by the construction industry were significantly different from IT. These differences are discussed later in more detail. On the contrast, 72% of the respondents in the construction industry agreed that their firms should develop internal systems to improve the degree of RM implementation (M=3.66; P=0.00). This strategy was not recommended by the IT firms. M=2.00; P=0.00 suggests that such systems might already be in place. The mean difference of the responses between the IT and construction industries was found to be statistically significant (two sample T-test P-value=0.000).

Table 4: Risk Management Improvements

Methods for Improvement	***SD***		***D***		***N***		***A***		***SA***		***M***		****One sample T-test***		****Two sample T-test***
	IT	***C***	***IT***	***C***	***IT***	***C***	***IT***	***C***	***IT***	***C***	***IT***	*C*			
	%	***%***	***%***	***%***	***%***	***%***	***%***	***%***	***%***	***%***					
Develop Internal System	*0%*	*0%*	*100%*	*6%*	*0%*	*22%*	*0%*	*72%*	*0%*	*0%*	*2.00*	*3.66*	***0.00***	***0.00***	***0.00***
Educate Staff on the Importance	*0%*	*0%*	*0%*	*31%*	*2%*	*13%*	*84%*	*56%*	*14%*	*0%*	*4.12*	*3.25*	***0.00***	*0.13*	***0.00***
Conduct Training on Knowledge and Skill	*0%*	*0%*	*0%*	*44%*	*0%*	*6%*	*86%*	*50%*	*14%*	*0%*	*4.14*	*3.06*	***0.00***	*0.72*	***0.00***
Invite Relevant Experts	*0%*	*0%*	*98%*	*25%*	*2%*	*0%*	*0%*	*75%*	*0%*	*0%*	*2.02*	*3.50*	***0.00***	***0.00***	***0.00***
Enforce Use of RM	*0%*	*0%*	*0%*	*34%*	*2%*	*28%*	*93%*	*38%*	*5%*	*0%*	*4.02*	*3.03*	***0.00***	*0.84*	***0.00***

Construction firms felt that bringing in relevant experts would be important to encouraging more implementation of RM (*M*=3.50; *P*=0.00) while this method was not one of the top priorities of the IT industry (*M*=2.02; *P*=0.00; two sample T-test *P*=0.00). The results imply that to increase implementation levels in the construction industry, proper internal tools and systems should first be deployed. Experts should be engaged with sufficient financial investment to support the effort. With a proper infrastructure, better implementation of RM can be established and intensive and training can be held to train employees.

5. Conclusions and Recommendations

RM continually plays a pivotal role for effective project delivery. This study examined and compared the status of RM performed by the IT and construction industries. The study observed contrasting differences in the educational level of the respondents where, IT possessed higher levels of training when compared to respondents from construction industry. However, educational training alone does not translate to high level of expertise in RM but relies on the respondents’ ability to apply management skills effectively in any risk assessment situation. This buttresses the need for constant improvement in the practical knowledge on RM by construction sector. The findings also revealed that IT industry respondents took an affirmative stand on the values of their industry in propensity to take more risk and ensure adequate techniques are put in place to mitigate any unforeseen risk that may arise. This ensures higher competitive, productive and financial gains in the long run. This may reflect the flip positive opportunities inherent in risk. In retrospect, IT firms exhibiting the characteristics of risk takers may benefit from more opportunities to generate higher payoff. Caution is warranted here because the assertion is true only when highly productive and effective RM measures are in place such that risks are successfully mitigated or eliminated. IT industry has been implementing RM more and longer than the construction industry. Construction industry respondents took a more conservative standpoint as cautious risk takers. IT and construction firms surveyed for this study agreed that RM is beneficial and may produce better schedule and cost performances, more barriers were reported by the firms from the construction industry. Plausible methods recommended for the construction industry to improve RM implementation were different from the IT industry. The firms from the IT industry reported that they have established systems and tools for RM and thus need to focus more on education and training. The construction firm indicated that proper systems needed to be deployed and used with the engagement of RM experts. It is imperative to educate and train staff on the importance and processes of RM, eventually enhancing the company's capability to mitigate risks and exploit opportunities. Construction firms can achieve long-term success via RM through more investment on a competent RM structure with proper IT solutions and training programs. Governmental and statutory requirements could also increase RM levels. It may be practical to develop a series of certifications focusing on RM and to devise a scheme for giving benefits to companies achieving such certifications. Due to the relatively small sample size, it may not be appropriate for the results of this study to be generalized for broader interpretation of the entire construction and IT industries. Another limitation is that the lack of RM implementation observed in the construction industry might be due partly to the small size of the firms that participated in the survey. It might be especially challenging for small firms to allocate sufficient resources to the development and implementation of rigorous RM.

Changing Construction: Perspectives on Knowledge and Learning

Kim Haugbølle,
Danish Building Research Institute, Aalborg University
khh@sbi.aau.dk

Abstract

The problem of knowledge in construction is not 'just' about knowledge, but about learning and about putting knowledge into action in order to change practices. This paper will use the Danish knowledge system as a case study in order to analyse where and why problems with regard to knowledge occur in construction. This analysis is based on a literature review of seminal studies on knowledge in general and a comprehensive documentary analysis of policy studies on the Danish knowledge system combined with qualitative research interviews of key persons. This paper starts out with a brief exploration of Danish policy studies and initiatives on knowledge and learning in construction. The paper then moves on to outline an analytical framework to understand knowledge and learning within construction. This paper suggests that an analytical framework should: 1) adopt a systemic perspective on construction and refurbishment, 2) highlight the absorptive capacity of firms as a crucial concept for adopting new knowledge, 3) be sensitive to the historicity and path-dependency of the individual construction project, 4) embrace communities of practice as the key framework for learning; and 5) manage the recurrent changes in knowledge types during construction projects, notably from tacit to explicit knowledge and vice versa. Based on this analytical framework, this paper has in broad terms analysed how the various Danish policy studies of the knowledge system have articulated the problem of knowledge in construction, identified how these articulations become controlling of the corresponding solutions, and pointed out some of the shortcomings as a result. With these insights in mind, it is the hope that future studies and public policies will adopt a more reflexive and reflective approach to the problem of knowledge in construction.

Keywords: Knowledge flows, bounded rationality, governance, social shaping, communities of practice

1. Introduction: A sticky problem

Knowledge or rather the lack of knowledge-sharing has frequently been evoked as a core problem with regard to improving the sustainability, performance and productivity of construction. Hence, a range of policy analyses along with development initiatives and research studies have been conducted over the years in Denmark. The policy analyses include for example the use of technological services in construction (Bang, 1997), a survey on learning and knowledge (Alsted Research, 2003), the characteristics of the communication landscape in construction as formulated by the development programme Project House (Christoffersen, 2000) and the repeated call for improved dissemination of building knowledge (see e.g. Carlsen et al., 2005). A number of other policy studies have focused on activities related to research and development in construction. These include among others an analysis by the Danish Building Development Council (abbreviated BUR) on production, use and dissemination of technical building knowledge (Dræbye, 1997) and several mappings of construction-related research and development activities (see e.g. Christoffersen and Bertelsen, 1990; Boligministeriet, 1993; Det Offentlige Forskningsudvalg for Byer og Byggeri (translation: The Public Research Committee on Cities and Construction), 2000; Haugbølle and Clausen, 2002). These have been followed by a number of public action plans like the programme ‘The Future of Construction: From tradition to innovation’ (By- og Boligministeriet & Erhvervsministeriet, 2000), the action plan on research and development activities (Udvalget vedrørende byggeforskning i Danmark (translation: Committee on Construction Research in Denmark), 2002), and a proposal for strengthening research and learning in construction issued jointly by the industry, government and knowledge institutions (Koordinations- og initiativgruppen for viden i byggeriet, 2009).

Along with the long line of policy studies a number of experiments and development activities have been carried out, which have pointed at possible ways to improve the dissemination and sharing of knowledge in particular with regard to the use of new information and communication technologies (ICT). These experiments and development activities include among others the Tele-byg project on the use of virtual communication in long-distance consultancy (Hansen et al., 2002) as well as the MELFO and Melfa projects on the use of handheld devices (PDA or smart phones) to support mobile e-learning for dyslexics. A number of initiatives like the BygSol programme (Christensen, 2008) and Bricklayers in Motion (see e.g. Bertelsen, 2011) have also been targeted at developing vocational training and improving the competences of craftsmen and unskilled labour. The construction-related research on knowledge include among others studies of morality and knowledge production among consulting engineers (Munch, 2005), the cultural organisation in construction and its role in knowledge application (Thuesen, 2006) and the constitution of partnering (Gottlieb, 2010). In recent years, extensive efforts have also been put into developing and applying Building Information Modelling (BIM) among Danish consultants in particular and more lately Virtual Design and Construction (VDC) among some of the major Danish contractors.

Despite all of these efforts, the “problem of knowledge” seems not only to be sticking around, but also to be accentuated by a general shift in most industrialised countries from new construction towards refurbishment activities. Refurbishment entails a different set of challenges compared to new construction, which calls for new strategies, knowledge and development of practices among construction professionals, policy makers and knowledge institutions. Hence, a range of new initiatives are being launched to address these challenges in many countries like the UK Green Deal programme, the Belgian BrusselsRetrofitXL programme and the European roadmap for moving to a low-carbon economy by 2050 (European Commission, 2011).

Denmark is no exception to this general line of development. Thus, two large private foundations recently initiated and funded a think tank to develop a new comprehensive refurbishment strategy for the built environment. The think tank was composed of some 30 members representing all major parties of the built environment. Over the course of a year the think tank held a number of consultations with experts, professionals and policy makers to identify relevant challenges and formulate corresponding initiatives to address these. At the end of 2012, the think tank published its strategy with seven initiatives related among others to improving statistics on refurbishment, accelerating innovation, strengthening education and improving dissemination of knowledge (Tænketank for bygningsrenovering, 2013).

One of the ensuing initiatives encompassed a more substantial analysis of ‘the problem of knowledge’. This chapter will report on the results of this analysis and take a closer look at where and why problems occur with regard to knowledge within construction. It will take as its starting point that the problem of knowledge is not ‘just’ about knowledge, but about learning and about putting knowledge into action in order to transform practices. The chapter will identify different perspectives on knowledge and discuss how these understandings and metaphors of knowledge articulate knowledge differently as a problem and thus becomes controlling of the corresponding solutions.

2. Methodology

2.1 Ontological position

The analytical framework of this paper is developed on the basis of a number of seminal studies on knowledge in general. The ontological position is based on the following assumptions about knowledge in construction and refurbishment, more specifically:

- An analytical framework needs to address five levels to give a comprehensive understanding of the problem of knowledge in construction. These five levels are: 1) construction as a system, 2) firms as key players, 3) projects as the focal point, 4) communities of practice in groups and professions, and 5) individuals as bearers of skills.
- An analytical framework of knowledge in construction needs to be able to include both explicit and tacit knowledge as both forms are strongly prevalent among the different actors of construction.

- An analytical framework needs to acknowledge that knowledge-sharing among project participants and dissemination of knowledge from e.g. development projects takes place through many different means depending on the type of knowledge etc.
- An analytical framework needs to consider knowledge as functional rather than actor-centred, i.e. production, distribution and use of knowledge is not exclusively linked to the different type of actor, but all actors may to a varying degree over time and space act as producers, intermediaries and users of knowledge.
- An analytical framework needs to recognise that the formulation of knowledge problems and possible solutions to these problems of knowledge is largely dictated by how knowledge in construction is perceived and conceptualised.

2.2 Research design

The research design follows a case study design. Flyvbjerg (2006: 230) states that paradigmatic cases *'develop a metaphor or establish a school for the domain that the case concerns.'* Identifying a case as paradigmatic is particular challenging as noted by Flyvbjerg (2006: 232) as paradigmatic cases by their very nature transcends any sort of rule-based criteria. The analysis of the Danish knowledge system on construction and refurbishment may be considered paradigmatic in the sense that it shares a number of characteristics and similarities with other industrialised countries e.g. with regard to the distribution of construction output as new built versus refurbishment, the application of the same European rules of procurement, and the use of a range of similar construction products as in many other countries due to the European internal market. However, there are a number of differences in national building codes, industrial structure etc. that makes it less likely to use the Danish knowledge system as an exemplar for construction knowledge systems in general.

The case also have elements of being a critical case, which makes it possible to draw conclusions or generalisations of the kind that *'if it is valid for this case, it is valid for all (or many) cases'* (Flyvbjerg, 2006: 230). These arguments relate to characteristics of the Danish construction industry like Danish construction professionals being generally considered as highly skilled and knowledgeable, a well-paid workforce with social status, high degree of digital literacy and extensive access to ICT solutions. Hence, if problems of knowledge exist in the Danish construction industry, the same kind of problems – and maybe even in an accentuated form – are likely to be found in other national construction industries.

2.3 Methods and data

The study is based on a documentary analysis combined with qualitative research interviews. The longitudinal documentary analysis is based on a comprehensive selection of written Danish sources covering the most prominent policy studies etc. over a period of over more than two decades. This longitudinal study has been combined with a cross-sectional study of the present situation and challenges through qualitative research interviews with seven key persons representing major actors of the construction industry. These include a representative from educational institutions, information offices, research institutions, contractors, trade unions, wholesalers, and R&D funding offices.

3. The problem of knowledge in construction

3.1 A systemic perspective

Gann and Salter (2000) adopt a systemic perspective on construction, where innovation must be understood in the context of both the technological support infrastructure for producing knowledge and the regulatory and institutional environment. The individual elements of the system are connected to each other through flows of knowledge. Haugbølle et al. (2012) has developed Gann and Salter (2000) systemic perspective to also explicitly include the building users and suggest that links between the individual element can predominantly be understood as business processes between actors in three different types of markets, learning processes and policy processes (see Figure 1).

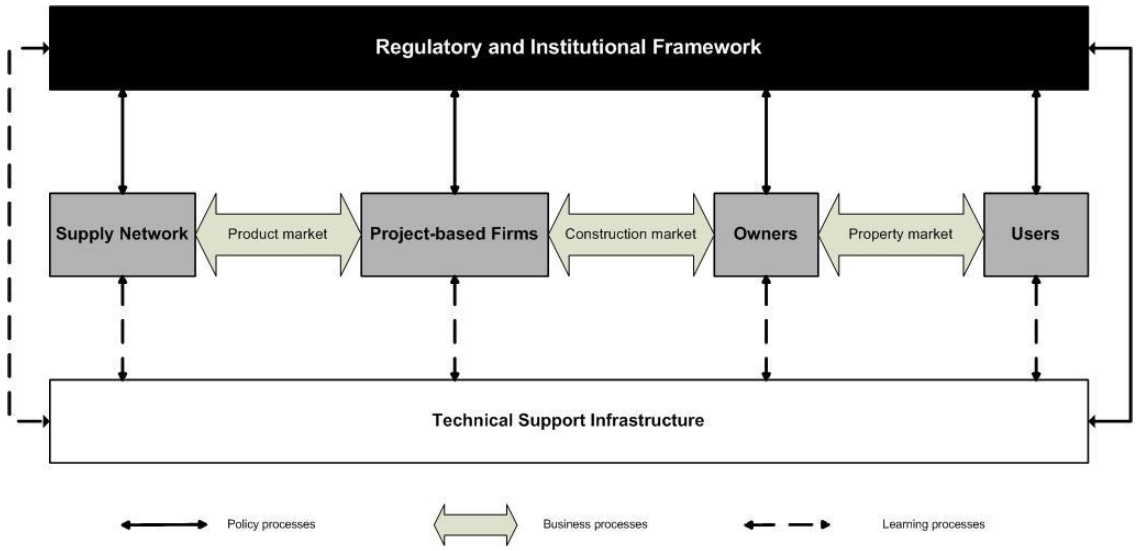

Figure 1: Systemic perspective on construction (Haugbølle et al., 2012: 452)

The majority of policy studies on the problem of knowledge in Danish construction have focused on how new research-based knowledge can be made available for use in the project-based companies of construction. Most of these policy studies criticise in particular the universities and other knowledge institutions for not disseminating new knowledge appropriately to the project-based firms of construction, in particular contractors and consultants. Thus, the preferred solution to the knowledge problem is to improve dissemination from the universities and the like through e.g. mandatory dissemination plans for R&D projects, joint information services e.g. as a sort of digital one-stop-shopping solutions etc.

However, a systemic perspective on the problem of knowledge as mentioned above indicates that it is far too narrow to focus on the dissemination from knowledge institutions. A systemic perspective would rather suggest that the problem of knowledge can be found in four different locations:

- The interaction between the political-institutional apparatus on one side and business as well as users on the other side.
- The interaction between the individual companies and its customers throughout the entire supply chain spanning three separate markets of products, construction and property.
- The interaction between knowledge institutions and each of the business actors – supply network, project-based firms, owner and users of buildings.
- The capabilities and interaction within each of the individual units.

3.2 Firm versus project: Absorptive capacity

Especially the capabilities and interaction within each organisation has often been neglected in Danish policy studies, even though this is central to a firm's ability to adopt new knowledge. A central key concept in this context is 'absorptive capacity'. Cohen & Levinthal (1990: 128) defines this ability to absorb knowledge in the following way:

> *'…the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends is critical to its innovative capabilities. We label this capability a firm's absorptive capacity and suggest that it is largely a function of the firm's level of prior related knowledge.'*

The development of a firm's absorptive capacity depends on both the individual's and the organisation's ability to adopt knowledge, which is both history-dependent and path-dependent. Cohen & Levinthal (1990: 132) further point out that the firm's ability to adopt new knowledge depends on the communicative structures inside and outside the firm, including the nature and distribution of expertise within the organisation:

> *'Absorptive capacity refers not only to the acquisition or assimilation of information by an organization but also to the organization's ability to exploit it. Therefore, an organization's absorptive capacity does not simply depend on the organization's direct interface with the external environment. It also depends on transfers of knowledge across and within subunits that may be quite removed from the original point of entry. Thus, to understand the sources of a firm's absorptive capacity, we focus on the structure of communication between the external environment and the organization, as well as among the subunits of the organization, and also on the character and distribution of expertise within the organization.'*

In project-based industries like construction, the absorptive capacity is not solely linked to the firm as such, but as well to the often many projects being managed by the firm simultaneously and over time. Hence, the interplay between the firm as the basis and the individual projects as well as across projects is crucial for understanding and dealing with the problem of knowledge in construction. In his earlier work with innovation in the project-based organisations of construction, Winch (1998) has suggested the following model for different types of knowledge flows between the project, the firm and the surroundings of both (see Figure 2).

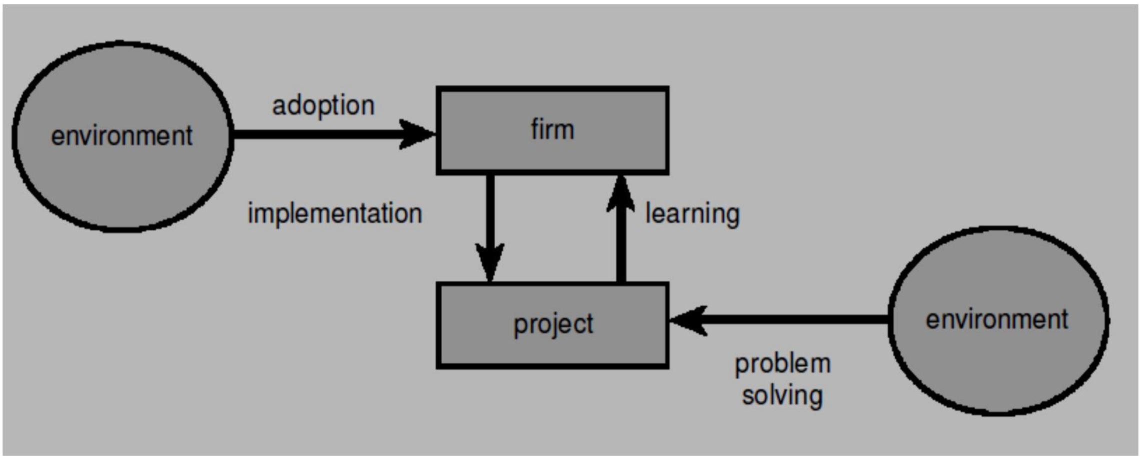

Figure 2: Knowledge flows between project and firm (Winch, 1998: 273)

The model is a reminder that the problem of knowledge must be addressed along at least three dimensions:

- External to the firm – either horizontally in networks with like-minded people for example within the same profession or vertically in networks across disciplines.
- In-between the individual projects and the firm.
- Within the project between the respective project participants, but external to the firms involved in a project.

What the model however fails to acknowledge is the need to address the knowledge flows taking place between different projects either simultaneously in time or consecutively over time.

3.3 No project is an island: Historicity and path dependency

Projects are not only vital for both new construction and refurbishment but the very organising principle of construction firms. The uniqueness of projects is often used as an explanation for why it is difficult to share knowledge and create change in construction. Despite the widely held assumption of projects being both unique and isolated events, projects are not isolated islands as Engwall (2003) points out. Instead projects are embedded in an organisational context and with a historicity marked by previous projects, parallel courses of events and ideas about the post-project future.

Following Engwall (2003), knowledge in projects is not isolated or necessarily unique, but is tied up on experience from previous projects as well as project-independent factors such as general business policies that go beyond the individual project. In this way, previous experience and general policies creates a path dependency that sets the scene for future projects (Figure 3).

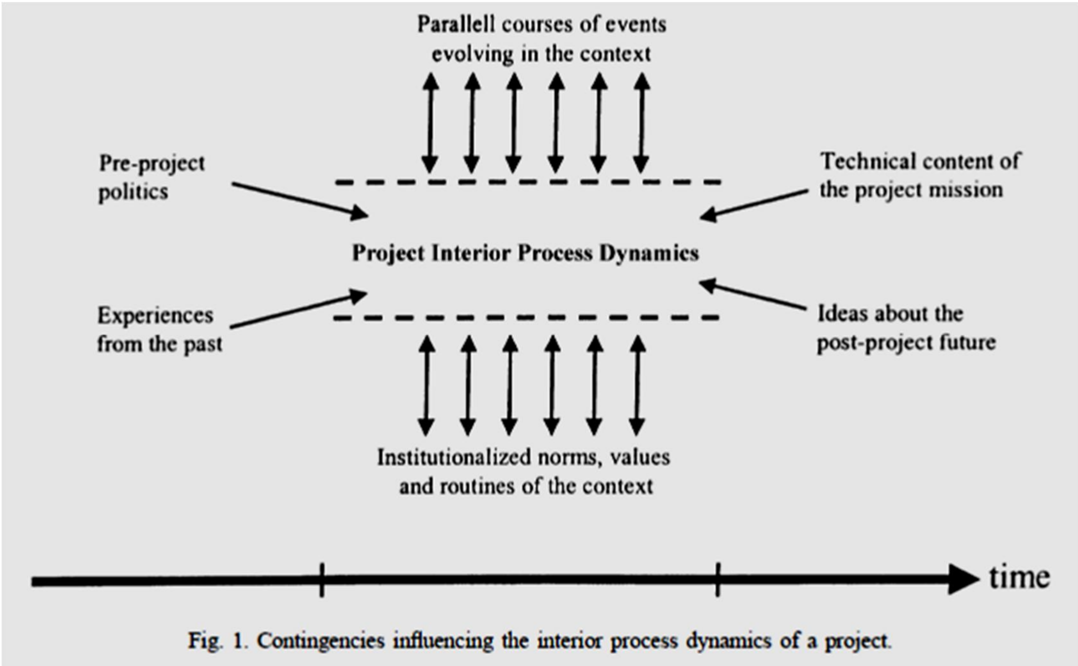

Figure 3: Factors affecting the project's dynamics (Engwall, 2003: 805)

In most Danish policy studies there is a strong rhetoric on the project-based nature of construction and the barriers to knowledge and change created by this very nature. However, a range of possible interventions related to the contingencies influencing the interior process dynamics of a project tend to be ignored. While these contingencies may be overlooked in policy studies, some of the major Danish consulting firms and contractors now attempt to address these in their internal training and course activities on management. But management and learning within and across projects is only side of the knowledge problem in construction. Another side of the problem is related to how trades and professions operate and are organised.

3.4 Learning: Communities of practice

Collaboration, knowledge-sharing and learning across the many trades and professions within construction is notoriously challenging as have been recognised by several (see e.g. Christensen, 2008 and Thuesen, 2007). But these shared communities of practice within trades and professions also hold strong a potential for being a part of the solution to (part of) the problem of knowledge in construction.

Communities of practice have in recent years received considerable attention in the context of organisational development and efforts to understand and improve knowledge and improve learning in organisations. Wenger (1998: 4-5) defines learning as an active participation in the practices of a community and forming of identity in relation to these communities:

'A social theory of learning must therefore integrate the components necessary to characterize social participation as a process of learning and of knowing. These components (…) include the following:

1) Meaning: *a way of talking about our (changing) ability – individually and collectively – to experience our life and the world as meaningful.*

2) Practice: *a way of talking about the shared historical and social resources, frameworks, and perspectives that can sustain mutual engagement in action.*

3) Community: *a way of talking about the social configurations in which our enterprises are defined as worth pursuing and our participation is recognizable as competence.*

4) Identity: *a way of talking about how learning changes who we are and creates personal histories of becoming in the context of our communities.'*

With regard to innovation and change management, the problem of knowledge in Danish construction projects is not only a matter of learning new things, but also to 'unlearn'. The ability to discard knowledge – where appropriate – is also an important aspect of communities of practice, although this is often overlooked.

Knowledge and learning across communities of practice like trades and professions within construction presents challenges because of the very characteristics that are also their strengths, i.e. the internal autonomy of the communities, their informal nature, and not least their differences in prevalence of knowledge types.

3.5 Tacit versus explicit knowledge: Repeated shifts

Knowledge management deals with collecting, developing, distributing and applying knowledge in organisations. One of the most important and seminal work was done by Nonaka and Takeuchi (1995), who studied knowledge and innovation in Japanese companies and developed the so-called SECI model. The SECI model analyses the interaction and transformations between tacit and explicit knowledge. The SECI model points out that both forms of knowledge are important and that the conversion between them is important (see Figure 4).

		TO	
		Tacit knowledge	Explicit knowledge
FROM	Tacit knowledge	Socialization	Externalization
	Explicit knowledge	Internalization	Combination

Figure 4: The SECI model – four types of conversion of knowledge (Adapted after Nonaka & Takeuchi, 1995: 62)

The construction process is typically characterised by the involvement of several firms and trades, which implies numerous and repeated shifts between tacit knowledge and explicit knowledge. The ability to handle these shifts in order to accumulate, disseminate and apply knowledge in practice is probably one of the construction industry's main challenges with regard to knowledge. As pointed out bluntly by Danish practitioners: First, the client must articulate his tacit and more or less explicit knowledge about his needs for a new building. The consultant then turns these into to explicit knowledge in the shape of formal documents such as drawings and specifications. This explicit knowledge is then being adopted and adapted to tacit knowledge, which is the primary knowledge base among the craftsmen in construction companies. Finally, the actual building will be managed by building caretakers based on their mix of explicit and tacit knowledge on caretaking of that particular building, and it will be measured against the more or less tacit knowledge of the end-users of how appropriate the services delivered by the building suits their needs.

4. Conclusions

This paper has provided a brief exploration of an extensive number of Danish policy studies and initiatives on knowledge and learning in construction over the past two decades.

The paper then moved on to outline an analytical framework to understand knowledge and learning within construction. This paper suggests an analytical framework that: 1) adopt a systemic perspective on construction, 2) highlight the absorptive capacity of firms as a crucial concept for adopting new knowledge, 3) is sensitive to the historicity and path-dependency of the individual construction project, 4) embrace communities of practice as the key framework for learning; and 5) manage the recurrent changes in knowledge types, notably from tacit to explicit knowledge and vice versa.

Based on this analytical framework, this paper has in broad terms analysed how the various Danish policy studies of the knowledge system have articulated the problem of knowledge in construction, identified how these articulations become controlling of the corresponding solutions, and pointed out some of the shortcomings as a result. With these insights in mind, it is the hope that future studies and public policies will adopt a more reflexive and reflective approach to the problem of knowledge in construction.

Abstract

In recent years, holding a holistic view of risk management has become the trend in various industries. In this trend, enterprise risk management (ERM) has been viewed as the fundamental paradigm and has attracted the attention from the academics and practitioners worldwide. Implementing ERM in construction firms is inevitably associated with organizational learning. The objectives of this study are to (1) identify the critical hindrances to ERM in Chinese construction firms (CCFs) and (2) analyze them in tandem with theories of organizational learning. To achieve these objectives, a total of 36 hindrances to ERM and 12 hindrances to organizational learning were identified through a literature review, and a questionnaire survey was performed with 119 respondents from 119 CCFs in the global construction market. The results indicated that 20 hindrances were deemed critical, among which "insufficient resources (e.g. time, money, people, etc.)", "lack of a formalized ERM process", and "lack of internal knowledge, skills and expertise" were the top three hindrances. In addition, the critical hindrances to ERM were interpreted from the perspective of organizational learning, and the 12 hindrances to organizational learning were linked to the critical hindrances to ERM. This study presents the theoretical rationale behind the critical hindrances to ERM implementation and contributes to the literature through interpreting ERM implementation from an organizational learning perspective.

Keywords: Risk management, organizational learning, construction firm, hindrances.

1. Introduction

In recent years, enterprise risk management (ERM), as a holistic view of risk management, has attracted the attention from the academics and practitioners worldwide (McGeorge and Zou, 2013). The Committee of Sponsoring Organizations of the Treadway Commission (COSO, 2004, p.2) defines ERM as “a process, effected by an entity’s board of directors, management and other personnel, applied in strategy setting and across the enterprise, designed to identify potential events that may affect the entity, and manage risk to be within its risk appetite, to provide reasonable assurance regarding the achievement of entity objectives.” Because construction businesses are inevitably afflicted with various and complex risks, construction firms have been considered as prime candidates for ERM implementation (Zhao et al., 2013a). Implementing ERM in construction firms can be seen as a gradual organizational change, and Zhao et al. (2014a) interpreted ERM implementation in construction firms from the perspective of organizational change. In addition to organizational change, organizational learning is also necessary for ERM implementation. This is because learning is a medium for change (Alas and Sharifi, 2002), and improves the ability to adapt to change, at both individual and organizational levels (Garvin, 1993, Senge, 1990). Learning and change were not only parallel and simultaneous, but are also interactive processes, as learning has a mediating role in the change process (Lähteenmäki et al., 2001). In the tumultuous environment, learning also helps to reduce uncertainty and thus inevitably reduce resistance to change (Lähteenmäki et al., 2001). Hence, change and learning should not be isolated from each other and ERM implementation cannot be isolated from organizational learning.

In project-based construction firms, most management staff has been familiar with and adopted project risk management (PRM). Thus, it is necessary for the individuals who are accustomed to PRM to learn ERM fundamentals and how to further PRM contributions to ERM. Without this individual learning process, ERM cannot be implemented at all levels across the firm, because individual learning is the basis of organizational learning (Senge, 1990). In addition, the existing learning processes that support PRM can also contribute to ERM implementation, because PRM is an integral part of ERM. The focus on learning from risks is likely to institutionalize risk information and change PRM practices to a corporate-level approach (Dikmen et al., 2008). Furthermore, Smallman (1996) argued that organizational learning, together with data collection and collation as well as forecasting, comprised holistic risk management.

Implementing ERM in construction firms is not easy. Zhao et al. (2014b) reported that most of the Chinese construction firms (CCFs) based in Singapore had low-level ERM implementation. The low-level ERM implementation could be attributed to the influence of various hindrances (Zhao et al., 2015). The objectives of this study are to (1) identify the critical hindrances to ERM in CCFs in the global market; and (2) analyse these hindrances in tandem with theories of organizational learning.

2. Background

2.1 Hindrances to ERM implementation

Previous studies have reported that a number of factors hindered ERM implementation in various industries. Confronted with these hindrances, firms in various industries tend to find it difficult to fully implement ERM and the percentage of firms adopting or implementing ERM was not high. In the construction industry, Zhao et al. (2014b) found that none Singapore-based CCFs had high-level ERM implementation, whilst Liu et al. (2011) indicated that only 14.7% of the leading CCFs in the global market had fully implemented ERM. In this study, hindrances are barriers to initiating ERM and carrying out ERM along the maturity continuum, in all the phases of ERM implementation. In the earlier phase of the larger research project, Zhao et al. (2014a) identified a total of 36 hindrances from previous studies, as shown in Table 1.

Table 1: Hindrances to ERM implementation [Adapted from Zhao et al. (2014a)]

Code	*Hindrances to ERM implementation*	*Code*	*Hindrances to ERM implementation*
H01	*Low data quality*	*H19*	*Perception that ERM interferes with business activities*
H02	*Lack of data*	*H20*	*Inadequate training on ERM*
H03	*Insufficient resources (e.g. time, money, people, etc.)*	*H21*	*Lack of an ERM business case*
H04	*Lack of a formalized ERM process*	*H22*	*Lack of perceived value or benefits of ERM*
H05	*Lack of risk management techniques and tools*	*H23*	*Lack of commitment of the board and senior management*
H06	*Lack of internal knowledge, skills and expertise*	*H24*	*Not perceived as a priority by senior management*
H07	*Lack of qualified personnel to implement ERM*	*H25*	*Lack of board or senior management leadership*
H08	*Lack of a risk management information system (RMIS)*	*H26*	*The movement of the ERM champion from senior management into other areas without a successor*
H09	*Unsupportive organizational structure*	*H27*	*Lack of consensus on benefits of ERM among board members and senior management*
H10	*Unsupportive organizational culture*	*H28*	*Other management priorities*
H11	*Lack of a common risk language*	*H29*	*Lack of a clear ERM implementation plan*
H12	*Lack of risk awareness within the organization*	*H30*	*Inability to coordinate with other departments*
H13	*Confidence in the existing risk management practices*	*H31*	*Lack of a set of metrics for measuring performance of ERM*
H14	*Existence or re-emergence of the silo mentality*	*H32*	*Unclear ownership and responsibility for ERM implementation*

H15	*Lack of shared understanding and approach to risk management across departments*	*H33*	*Organizational turf*
H16	*Lack of understanding relating to effective ERM process*	*H34*	*Employees' reluctance to give up power*
H17	*Perception that ERM adds to bureaucracy*	*H35*	*People' reluctance to share risk information*
H18	*Perception that ERM increases costs and administration*	*H36*	*Recession and business downturn*

2.2 Organizational learning

Organizational learning can be defined as "a continuous testing of experience and its transformation into knowledge available to whole organization and relevant to their mission" (Senge, 1990, p.6). Organizational learning stems from the knowledge acquisition of the individuals within the organization, and progresses with the exchange and integration of this knowledge until collective knowledge is created (Hedberg, 1981, Jerez-Gómez et al., 2005). Although organizational learning has its roots in individual learning (Senge, 1990), it is distinct from adding together the individual learning of the organization's different members (Alas and Sharifi, 2002, Hedberg, 1981).

Sfard (1998) proposed two metaphors of learning: the acquisition and participation metaphors, which are also known as the cognitive-behavioral approach and the sociocultural (or situated) approach, respectively (Ellström, 2010). From the perspective of the acquisition metaphor, the mind is a container of knowledge, and learning is a process of filling the container and implanting knowledge there. Knowledge is viewed as a property or capacity of an individual mind (Paavola et al., 2004). By contrast, the participation metaphor regards learning as a process of participation in cultural practices and shared learning activities. From this perspective, learning cannot be separated from working and other social practices where it is used (Brown and Duguid, 1991). In this view, learning is "situated" in these relations and networks of activities of participation (Paavola et al., 2004). Sfard (1998) argued that both approaches were needed. They are not simply rivals but complement each other. There is also a third approach to organizational learning: the knowledge-creation approach. It is based on the view that the production, transformation, and utilization of knowledge are fundamental for understanding organizational learning (Ellström, 2010).

Table 2: Hindrances to organizational learning

Code	*Hindrances to organizational learning*	*Code*	*Hindrances to organizational learning*
L01	*Lack of leadership commitment and support*	*L07*	*Reluctance to accept knowledge*
L02	*Lack of internal knowledge*	*L08*	*Lack of knowledge absorptive or retentive capacity*
L03	*Lack of organizational commitment*	*L09*	*Lack of channels for dialogue and sharing meaning*
L04	*Lack of psychological safety*	*L10*	*Arduous relationships*
L05	*Lack of motivation*	*L11*	*Downsizing or layoff strategies*

L06	*Reluctance to share knowledge*	*L12*	*Unsupportive organizational culture*

Previous studies have identified several hindrances to organizational learning because individuals have been trained to think and act in conflicting ways (DiBella and Nevis, 1998). As indicated in Table 2, 12 hindrances to organizational learning are identified from previous studies (Argyris, 1995, Atak and Erturgut, 2010, Cohen and Levinthal, 1990, Ellström, 2010, Fisher and White, 2000, García-Morales et al., 2006, Hayes, 2007, Husted and Michailova, 2002, Lipshitz et al., 2002, Pfeffer, 1998, Popper and Lipshitz, 2000, Senge, 1990, Shrivastava, 1983, Szulanski, 1996).

3. Method and Data Presentation

As a systematic method of collecting data based on a sample, the questionnaire survey technique has been widely used to collect professional views in risk management research (Deng et al., 2014, Hwang et al., 2014, Mu et al., 2014, Zhao et al., 2014c). In this study, a questionnaire survey was performed to investigate the hindrances to ERM implementation. The comprehensive literature review supported the development of the questionnaire. In the survey, the respondents were asked to rate the influence of the 36 hindrances on ERM implementation using a five-point scale (1=very insignificant, 2=insignificant, 3=neutral, 4=significant, and 5=very significant).

Table 3: Profile of respondents

Work experience	*N*	*%*	*Designation*	*N*	*%*	*Location*	*N*	*%*
5-10 years	*54*	*45%*	*Senior management*	*35*	*29%*	*China*	*35*	*29%*
11-15 years	*25*	*21%*	*Department management*	*26*	*22%*	*Asia (w/o China)*	*46*	*39%*
16-20 years	*17*	*14%*	*Project management*	*58*	*49%*	*Africa*	*28*	*24%*
21-25 years	*11*	*9%*				*Europe*	*4*	*3%*
Over 25 years	*12*	*10%*				*Latin America*	*6*	*5%*

The population consisted of all the industry practitioners with extensive experience in risk management of CCFs in the global market. As there was no sampling frame in this survey, the sample was a non-probability sample. The non-probability sampling plan can be used to obtain a representative sample (Patton, 2001), and has been recognized as appropriate when the respondents were not randomly selected from the entire population, but were rather selected based on whether they were willing to participate in the study (Liu et al., 2016, Wilkins, 2011). A list of senior and middle management staff of CCFs were obtained and 500 questionnaires were sent out. A total of 119 completed questionnaires were received, representing a response rate of 24%, which was acceptable compared with the norm of 20-30% with most questionnaire surveys in the construction industry (Akintoye, 2000, Hwang et al., 2015). The profile of the respondents is shown in Table 3.

4. Results and Discussion

4.1 Ranking of hindrances to ERM implementation

In this study, the 36 hindrances were ranked based on their influence mean scores, which ranged from 2.82 to 4.29 (see Table 4). The normalized values of the mean scores were calculated to select the critical hindrances. This method was adopted by Xu et al. (2010), who identified the factors with normalized values equal to or greater than 0.50 as critical factors. Thus, the hindrances, which received the mean scores closer to the maximum mean scores, are deemed as critical hindrances. The analysis results indicated that 20 out of the 36 hindrances obtained normalized values above 0.50, implying that these 20 factors were critical hindrances to ERM implementation in CCFs.

"Insufficient resources (e.g. time, money, people, etc.)" (H03) was ranked top, suggesting that ERM implementation in CCFs was not assigned with sufficient time, money and manpower. The majority of time, money and people were invested into project construction, and insufficient resources were allocated for ERM programs, signalling that these firms did not attach adequate importance to ERM.

Table 2: Ranking of hindrances to ERM implementation

Code	*Mean*	*Rank*	*Normalization*	*Code*	*Mean*	*Rank*	*Normalization*	*Code*	*Mean*	*Rank*	*Normalization*
H01	*3.73*	*11*	*0.62*	*H13*	*3.42*	*25*	*0.41*	*H25*	*3.73*	*11*	*0.62*
H02	*3.78*	*9*	*0.65*	*H14*	*3.24*	*28*	*0.29*	*H26*	*3.18*	*30*	*0.25*
H03	*4.29*	*1*	*1.00*	*H15*	*3.54*	*21*	*0.49*	*H27*	*3.33*	*27*	*0.35*
H04	*3.91*	*2*	*0.74*	*H16*	*3.5*	*23*	*0.47*	*H28*	*3.46*	*24*	*0.44*
H05	*3.82*	*8*	*0.68*	*H17*	*2.82*	*36*	*0.00*	*H29*	*3.83*	*7*	*0.69*
H06	*3.9*	*3*	*0.73*	*H18*	*3.61*	*20*	*0.54*	*H30*	*3.23*	*29*	*0.28*
H07	*3.87*	*4*	*0.71*	*H19*	*3.14*	*31*	*0.22*	*H31*	*3.66*	*16*	*0.57*
H08	*3.66*	*15*	*0.57*	*H20*	*3.86*	*5*	*0.71*	*H32*	*3.64*	*18*	*0.56*
H09	*3.64*	*18*	*0.56*	*H21*	*3.51*	*22*	*0.47*	*H33*	*3.01*	*32*	*0.13*
H10	*3.67*	*14*	*0.58*	*H22*	*3.85*	*6*	*0.70*	*H34*	*2.97*	*34*	*0.11*
H11	*3.34*	*26*	*0.36*	*H23*	*3.64*	*18*	*0.56*	*H35*	*2.9*	*35*	*0.05*
H12	*3.67*	*14*	*0.58*	*H24*	*3.71*	*12*	*0.60*	*H36*	*2.98*	*33*	*0.11*
Normalized value = (Mean - Minimum Mean)/(Maximum Mean - Minimum Mean)											

"Lack of a formalized ERM process" (H04) received the second position. This result implied that if there was not a formalized ERM process in a firm, the ERM implementation in this firm would be significantly hindered because such a formalized process can serve as a guide for the staff involved in ERM implementation. The lack of such a formalized process can make staff misunderstand how to implementation ERM.

"Lack of internal knowledge, skills and expertise" (H06) was ranked third. This result suggested that CCFs lacked internal knowledge, skills and expertise relating to ERM, which significantly hindered ERM implementation in these firms. Although ERM was advocated in Chinese firms after the State-owned Assets Supervision and Administration Commission of the State Council of China issued the Guidance to ERM for Central Enterprises in 2006, the CCFs still lacked internal knowledge, skills and expertise relevant to ERM and most of the overseas subsidiaries obtained these resources from their parent companies.

4.2 Interpretation from the organizational learning perspective

Some of the 12 hindrances to organizational learning can be used to interpret the critical hindrances to ERM implementation. Without the senior-level commitment and support, the learning culture would not be created; resources would not be invested into the learning and training programs; the staff would not perceive the learning as being emphasized; and finally, organizational learning mechanisms would not be set up and institutionalized. Thus, the critical hindrances relating to the top management (H23-H25), the organizational culture and structure (H09 and H10), the resource investments (H01-H08, and H31), as well as the training and understanding of ERM (H18, H20 and H22) can be linked to “lack of leadership commitment and support” (L01) in the hindrances to organizational learning.

According to the literature, organizational learning is associated with knowledge acquisition (Huber, 1991, Shrivastava, 1983), participation in the learning process (i.e. situated learning) (Brown and Duguid, 1991), and knowledge creation (Bereiter, 2002, Engeström, 1999, Nonaka, 1991). In the CCFs, ERM implementation involves knowledge acquisition from inside and outside the firm, the participation of the relevant staff in the training programs and risk communication, as well as the creation of knowledge from the ERM practices. Six factors (H01, H02, and H04-H07) significantly hindered ERM implementation because they contributed to the “lack of internal knowledge” (L02) relating to ERM. Specifically, as the data are the predecessor of information and knowledge, the lack of high-quality data can result in the lack of internal knowledge. Also, the lack of a formalized ERM process, relevant techniques and tools represents a low level of knowledge relating to ERM. In addition, the staff qualified to implement ERM are likely to have the relevant knowledge, skills and expertise, and the lack of such staff can therefore led to the lack of internal knowledge.

There should be a channel through which people share their ideas and knowledge. A risk management information system (RMIS) can serve as a platform where the relevant staff can communicate the risk information as well as the lessons learned in ERM implementation (Zhao et al., 2013b), while training programs allow external and internal trainers to share their experience and knowledge relating to ERM with others. Thus, “lack of a RMIS” (H08) and “inadequate training on ERM” (H20) hindered ERM implementation because they represented the lack of channels for sharing knowledge. As setting up such channels needs resource investments and senior-level support, the negative influence of the four hindrances (H03 and H23-H25) can also be interpreted using this hindrance to organizational learning.

Even though there are channels for dialogue and sharing knowledge, the effectiveness of knowledge acquisition depends on the individuals’ ability to absorb and retain the knowledge (Cohen and Levinthal, 1990, Szulanski, 1996). The personnel unqualified to implement ERM may also lack the capacity for absorbing and retaining the knowledge relating to ERM, thus contributing to the lack of internal knowledge, skills and expertise. Therefore, the two hindrances (H06 and H07) can be linked to “lack of knowledge absorptive or retentive capacity” (L08) in the hindrances to organizational learning. In addition, downsizing or layoff strategies are often used when a firm faces a recession or business downturn. These strategies involve the departure or turnover of the staff, who may be experienced and knowledgeable, and would lead to the loss of the experience and knowledge (Fisher and White, 2000, Pfeffer, 1998). Thus, the two hindrances (H06 and H07) can also be linked to “downsizing or layoff strategies” (L11) in the hindrances to learning.

In some cases, the staff would fear that their self-interest would be threatened due to organizational learning, thus leading to the lack of psychological safety. “Perception that ERM increases costs and administration” (H18) is representative of “lack of psychological safety” (L04) because some staff may believe that the additional costs and administration threaten the firm performance, which is associated with the bonus or interest of them. Such a misunderstanding derives from the “lack of perceived value or benefits of ERM” (H22). Thus, the two critical hindrances (H18 and H22) can be linked to “lack of psychological safety” (L04).

Motivation measures are necessary for organizational learning (Szulanski, 1996). As the relevant employees need to spend time, energy and knowledge in ERM implementation, they should be convinced that these resources can pay off. Thus, the metrics to measure ERM performance should be developed and used. The tangible increase in firm performance can motivate the relevant staff to actively participate in the ERM implementation. In turn, the lack of such metrics and perceived benefits of ERM would discourage the staff from contributing to the learning process relating to ERM, thus hindering ERM implementation.

Organizational learning can be hindered by the unsupportive organizational culture, such as the blame culture (Hayes, 2007) and defensive routines (Argyris, 1995). Two critical hindrances (H10 and H12) can be linked to “unsupportive organizational culture” (L12) in the hindrances to organizational learning. As ERM implementation includes learning from the past mistakes, errors, failures and disasters, the unsupportive culture would render these negative issues as taboos and discourage the staff from investigating the root causes of them. Consequently, the employees would remain confident in the existing risk management practices and not believe that it is necessary to implement ERM, which is likely to lead to the underlying assumption that the risks can be dealt with by the current risk management practices. Thus, the staff would not attach adequate importance to the potential risks and lack risk awareness.

5. Conclusions

ERM implementation has been advocated in the construction industry and requires organizational learning in firms. This study attempts to identify the critical hindrances to ERM in CCFs and analyse these hindrances in tandem with theories of organizational learning. To achieve these objectives, a total of 36 hindrances to ERM and 12 hindrances to organizational learning were identified through a literature review, and a questionnaire survey was performed with 119 respondents from 119 CCFs in the global construction market. The results indicated that 20 hindrances were deemed critical, among which “insufficient resources (e.g. time, money, people, etc.)”, “lack of a formalized ERM process”, and “lack of internal knowledge, skills and expertise” were the top three hindrances. In addition, the critical hindrances to ERM were interpreted from the perspective of organizational learning, and the 12 hindrances to organizational learning were linked to the critical hindrances to ERM.

Despite the achievement of the objectives, there are limitations to the conclusions. Firstly, the identification of the hindrances to ERM may not be exhaustive. Additionally, as the survey was performed with the CCFs, one should be cautions when the results are interpreted and generalized in other firms. Nonetheless, the implication of this study is not limited to the CCFs because the theoretical rational behind the critical hindrances can be used to interpret the hindrances in other construction firms. In addition, this study contributes to the literature through interpreting ERM implementation from an organizational learning perspective.

Future studies would investigate the interaction mechanisms among the hindrances to ERM implementation, and identify the influence paths comprised by some of these factors. The theoretical rational behind these mechanisms and paths would be found in organizational learning theories, and a set of best practices, which help the management to handle the influence of these factors and pursue the benefits of ERM, would be proposed based on the interaction mechanisms and influence paths.

Abstract

Given the enormous social and environmental impacts of construction lifecycle, organizations in the construction supply chain realise the need to implement social responsibility (SR) in their construction projects. Different project stakeholders have different understandings towards SR and they display different capabilities of setting forth initiatives, of calling for supports, and of achieving outcomes. This research aims to investigate the stakeholders' interests and power on SR implementation in construction projects and thus discover the invisible gaps between the stakeholders' concerns and influences. A total of 35 SR Issues (SRIs) categorized into seven themes were identified from construction lifecycles perspective. A questionnaire survey was subsequently conducted among the construction practitioners in Hong Kong to investigate the stakeholders' interest and power on these 35 SRIs. Paired t-test and descriptive statistical analysis were adopted to reveal the gaps between stakeholders' interest and power. This study could provide enlightenments to project stakeholders for them to identify the SRIs that they have power on; however, with inadequate commitment to implement. Suggestions can also be made for construction organizations, including main contractor, developer, government, and consultants, to distribute their finite resources optimally to implement SR in construction projects.

Keywords: Social Responsibility, Project stakeholder, Construction project management, Project social performance, Sustainability

1. Introduction

Construction organizations are facing unprecedented pressures and challenges in performing their social responsibility (SR) because of the social and environmental impacts caused by their construction activities (Othman, 2009). According to the report of UNEP-SBCI (2014), the entire lifecycle of buildings consume one-third of the worlds' energy, accounting for 30%–40% of the worlds' greenhouse gas emissions, 40% of the world's resources, and 12% of global water use. Construction in general also has a poor reputation in terms of ethical issues (Ho 2010, Ho 2011, Oladinrin and Ho 2014), being widely regarded as a sector rife with corruption and bribery (Moodley, Smith et al. 2008). In order to improve the notorious reputation of the industry, there is a need for attentions on the implementation of SR practices in construction projects.

SR Issues (SRIs) in construction projects focus on diverse aspects, such as health and safe working conditions, sustainability, environment, community development, and philanthropy. Given the uneven allocation of social resources and public attention, SRIs are attended to in different degrees. Organizations tend to engage in the high-profile SR programs to reinforce their reputational competitiveness on the market (Broomhill 2007). Owing to the Matthew effect, these issues would temporarily become the flavour of the mouth, whereas some important issues may be ignored or may receive inadequate attention. Investigating on the emphasized and the neglected SRIs are highly important in making appropriate SR strategies in the future.

With regard to the various SRIs, different project stakeholders focus on different priorities (Jonker and Nijhof 2006). Stakeholders from public and private sectors should take accountability for the overall project social performance (Shen, Hao et al. 2010). They engage in different ways to initiate, support, enforce, and supervise the implementation of SRIs. Given their different standings and available resources, project stakeholders tend to have their own understanding towards SR and display different abilities to accomplish their initiatives. However, what stakeholders are interested in may not always be what they are most capable of. In addition, SRIs would only be successful if powerful stakeholders utilize their power and exert their influences strategically (Prado-Lorenzo, Gallego-Alvarez et al. 2009). Stakeholders thus need to realize where their power lies so that they can distribute their resources optimally to maximize their overall social performance.

Although SR has been extensively studied, limited attentions have been devoted on the implementation of SR in the context of construction projects (Zeng, Ma et al. 2015). In addition, the stakeholders' interest and power on SRIs has never been compared. In this paper, we tried to answer the following questions. What are the most pressing SRIs in construction industry at present? What SRIs should be prioritized in the future SR policy? Does any gap between stakeholders' interest and power exist? How could stakeholders strategically engage in different SRIs? This study intends to find the answers to these questions through an empirical research conducted among Hong Kong construction practitioners to investigate the current situations of project stakeholders' interest and power.

2. Literature Review

2.1 SR in construction projects

SR was introduced as self-regulatory initiatives for businesses for the benefit of the wider society (Sheehy, 2014), and SR has recently received extensive attention from the academic and industrial communities (Schultz et al., 2013). Whether SR is profit-oriented or society- oriented or whether SR is voluntary or compulsory in nature are not the most crucial problem to be solved; SR could be a continuum between two extremes and consistently shifting along with the changing social requirements (Bhimani and Soonawalla 2005, Pirsch, Gupta et al. 2007). Taking SR as a contemporary moral standard for the proper conduct of business, responding to social problems should also be embedded as one of the purposes in the pluralistic organizational objectives (Enderle 2006).

Construction activities are associated with vast social and environmental problems, including construction wastes, noise pollution, eco-disturbance, severe working conditions, resources exploitation, and corruption and bribe (Moodley, Smith et al. 2008, Barthorpe 2010). Construction projects provide opportunities and potentials to different stakeholders. Many stakeholders (e.g. the companies along the construction supply chain, construction practitioners, end users, and societies, etc.) benefit from construction development while the construction activities exploited substantial natural resources and bring harms to environment and communities. There is a voice that stakeholders alongside enjoy their benefits but also owe similar amount of responsibility. Although SR has become popular among scholars and industrial leaders, few studies have investigated SR in the context of construction industry and is particularly rare in construction project environment (Zeng, Ma et al. 2015). Several studies through archival analysis and interviews that were conducted in some developed countries have shown that some large construction companies have realized the significance of SR and have agreed with the necessity of embracing moral commitments to the society (Petrovic Lazarevic 2008). However, the implementation of SR practices and programs are ineffective and inefficient because of the diverse and fragmented nature of the construction industry (Jones, Comfort et al. 2006). Looking from the perspective of the stakeholders, this research assesses the different concerns and powers stakeholders have on SRIs; thus, this study would facilitate SR implementation in construction projects.

2.2 Stakeholders' interest and power

Construction projects usually involve numerous stakeholders and even hundreds of organizations and individuals that can affect or be affected by these projects, and the stakeholders have different interest and demands throughout the whole project lifecycle (Packendorff 1995, Aaltonen and Kujala 2010). An investigation on the stakeholder' interest on infrastructure projects shows that conflicts and contradictions are inevitable among different stakeholders (Li, et al. 2012). This conclusion also applies on stakeholders' preferences on SR. Lindgreen, et al. (2009) investigated the American organizations and found that these organization place varying emphasis on SR. Likewise, Zeng, et al. (2015) proposed a project SR framework for major infrastructures, demonstrating that project stakeholders should display different spectra of SR in different phases of their projects.

Obviously, not every stakeholder exhibits the same capabilities to attend to SRIs in construction projects. The stakeholders' power has been discussed for decades as an important dimension of stakeholder salience in the three-attribute model of Mitchell, et al. (1997). Some stakeholders with claims or interest may not possess the corresponding power to influence (Mitchell, et al. 1997). By contrast, some powerful stakeholders who exhibit superior ability to initiate some SRIs may not be enthusiastic in delivering these capabilities. Regardless of their intentions and preferences, powerful social actors are supposed to bear the corresponding responsibilities according to the fundamental principle; otherwise, they shall lose their power in return (Davis 1967, Enderle 2006). Therefore, the stakeholders being aware of their power and responsibility is crucial so that they can use these capabilities to influence the implementation of SR agenda in construction projects.

Analysis of the stakeholders' interest and power is an important task in stakeholder management (Polonsky 1996, Polonsky and Scott 2005). However, the analysis was made from the perspective of the focal company, and the result serves as the basis in devising the corresponding stakeholder strategies (Friedman and Mason 2004, Eesley and Lenox 2006). The mechanism by which the stakeholders' interest and power are distributed on different SRIs and whether there are any gaps between stakeholders' interest and power on SRIs exist remain to be elucidated.

3. Methods

To ensure the content validity of the survey, we identified the SRIs through archival analysis and expert screening. First, a pool of 80 SRIs specifically related to construction lifecycle practices were extracted through archival analysis. The sources included academic literature (journal articles published from 1970 to 2015 and were searched in Google scholar using the keywords CSR, sustainability, business ethics, construction, building sector), corporate reports (annual CSR/ sustainability report for the last five years of top construction companies, including Bechtel, The Turner Corp, AECOM, Kiewit Corp, Gammon, and Leighton), CSR standards, guidelines, and initiatives of international organizations (publications from GRI, ISO, Oxfam, UNEP, and WBCSD). Second, we invited 20 experts of project management experts to eliminate the SRIs that they consider unimportant or reduplicative, in order to come up with a shorter list of SRIs to be used in designing a questionnaire. This process was conducted using the Delphi method; after three rounds of anonymous questionnaire, a list containing 35 SRIs was finalized with the under 20% contradiction. The list covered the whole project lifecycle, including the three construction phases, namely, pre-construction, construction, and post-construction stages. In each stage, the SRIs were classified under seven CSR subjects in accordance with the ISO 26000 (SR Guidance). These subjects were 1) organizational government (OG); 2) human rights (HR); 3) labor protection (LP); 4) environment (En); 5) fair operation (FO); 6) customer issues (CI); and 7) community involvement and development (Co). During the screening, the major related stakeholders were also required to be nominated by the experts. A total of seven major contractors were identified, namely, main contractor (MC), developer (DV), end user (EU), government (GV), consultants (CS), NGOs, and district councils. Using these 35 SRIs and 7 related stakeholders, the questionnaire for this study was built in the form of a matrix, with the 35 SRIs as the row titles and the 7 stakeholders as the column titles. In the matrix blanks, the respondents would be asked to evaluate their interest and perceptions of the 7 stakeholders' influence on each SRI using a 5-point scale. The word "influence" was used instead of "power" because of their similarity in daily usage and the negative connotation of the word "power" (Brass and Burkhardt 1993). The questionnaire aims to determine the respondent organizations' subjective interest and to objectively evaluate the 7 main stakeholders' power on the 35 SRIs.

For the pilot study, three versions of the questionnaire (English, Traditional Chinese, and Simplified Chinese) were delivered to small groups of people who use the corresponding language. A formal survey was subsequently conducted on 120 practitioners invited from different stakeholders from the construction industry in HK. Considering the complexity of the questionnaire, the survey was conducted in a paper-based method. Assistance was provided in case the respondents have any queries or confusions. Finally, 89 valid questionnaires were collected (valid response rate 74%). The respondents are categorized mainly into four groups of stakeholder: MC companies (n = 35), DV companies (n = 11), GV departments (n = 6), CS companies (n = 20), and the rest are categorized as others, which include EU, investors, NGOs, sub-contractors (n = 17).

The data on all 35 SRIs were first analyzed as a whole. Considering the disproportion of the sample in this survey, the data was required to be reweighted to reduce the over- or under - representation of the stakeholder groups before calculating the average for the holistic analysis. The average stakeholders' interest and power on the 35 SRIs were compared based on the reweighted data. Second, the entire sample was divided into four subgroups according to stakeholder grouping (MC, DV, GV, and CS). In each subgroup, paired t-test was adopted to test the differences between the stakeholders' interest and power. Paired t-test is frequently used to test the significant difference between two observations in a group of subjects (Hsu and Lachenbruch 2007). Furthermore, to illustrate the details of the interest-power gaps for each stakeholder group, the interest-power profile in seven subjects and the interest-power fluctuations throughout the project lifecycle stages were shown for detailed comparative analysis.

4. Results and Discussion

4.1 Overall gaps between interest and power in all stakeholders

In Figure 1, the stakeholders' average interest is generally higher than the average power, indicating the stakeholders' positive commitments to SR, although the lack of adequate power to launch their initiatives is one of their obstructions. The stakeholders' interest on 35 SRIs reveals that much attention has obviously been devoted on LP issues and some of En issues and CI, whereas limited attention was devoted on OG and Co issues. This result corroborate with that of an investigation on UK construction companies, where health/safety and environmental issues are currently the hotspot SRIs, whereas less concern are devoted on community and governance (Jones, Comfort et al. 2006). The disparities between interest and power vary significantly among the seven subjects of SR. The SRIs on LP, FO, and CI have the significant gaps between higher interest and lower power. The result is reasonable because HK government

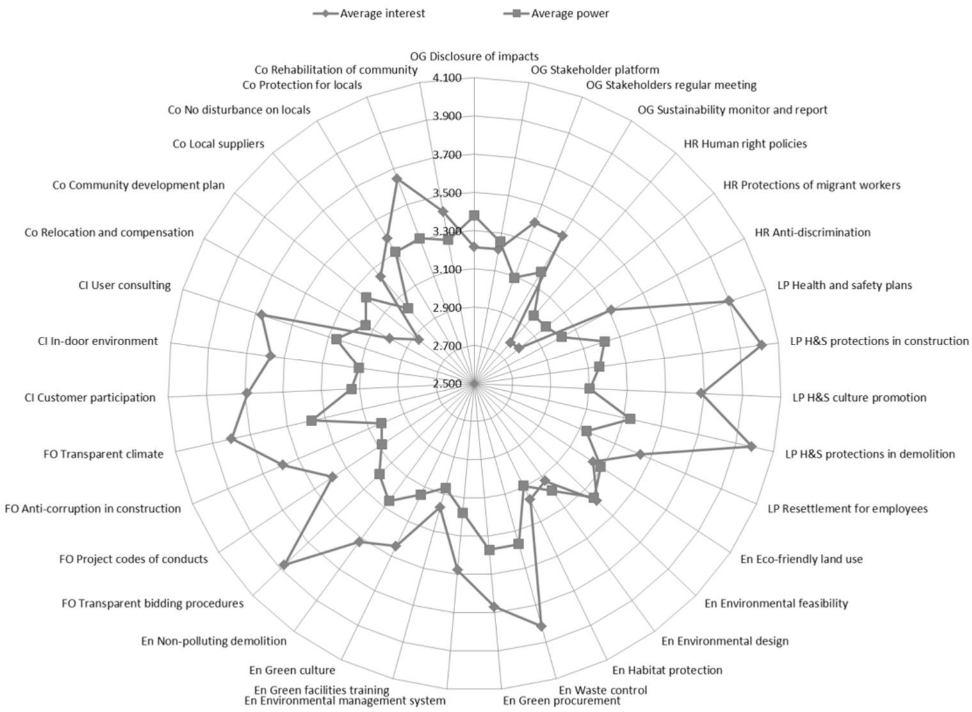

Figure 1: Overall gaps between stakeholders' interest and power

put construction health and safety as the top focus of industrial legislation. Moreover, HK is one of the leading transparent markets in the world (ranked 17th out of 175 countries in corruption perception index in 2014). This finding show that the legislation of local government highly influence the businesses' emphasis on SR. The SRIs that stakeholders' interest is higher than their power (LP, FO, CI, and part of En) are beyond the ability of any single stakeholders and require the communications and collaborations among multiple project parties from public and private sectors (Bendell, Collins et al. 2010, Savage, Bunn et al. 2010). By contrast, stakeholders have more power compared with their interest on HR, and part of OG and Co. More concerns and resources should be invested on these issues because these are within their current capabilities; however, these issues are neglected by stakeholders due to some reasons, such as disclosure of project impacts on the environment or society (OG), HR and protections of migrant workers (HR), and relocations and preparing community development plans (Co).

4.2 Main contractors (MCs)' interest and power on SRIs

The MCs are one of the core project team members, and they take charge of the most essential processes in the project lifecycle. Most SRIs in construction projects will not be successful without the effective engagement of the MCs. The result of the paired t-test on the MC subgroup (Table 1) shows that the mean of MCs' interest is not significantly different from the mean of their power (t = −1.409, p = 0.159). This finding indicates that the MCs' preferences on SRIs and self-perceptions of power are approximately consistent. MCs' power is slightly higher (mean = −0.05934) but not statistically significant. Figure 2 shows that the MCs' power is superior over their concern levels mainly in the dimensions of CI and FO issues. In the project lifecycle, the MCs' interest-power difference is largest in the construction phase than in the undifferentiated beginning and end phases. Moreover, MCs show superior power on LP issues and in the project construction phase. Thus, the occupational health and safety protections issues, especially the on-site protection and safety measures, should be mainly dominated by the MCs. In addition, the SR initiatives of the MCs are more effectively implemented during the construction phase, that is, when they are more powerful to coordinate resources and obtain support from other stakeholders.

Table 1: Paired t-test result of MCs' sub-group

	Paired Differences					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
				Lower	Upper			
MCinterest - MCpower	-.05934	1.27029	.04211	-.14198	.02330	-1.409	909	.159

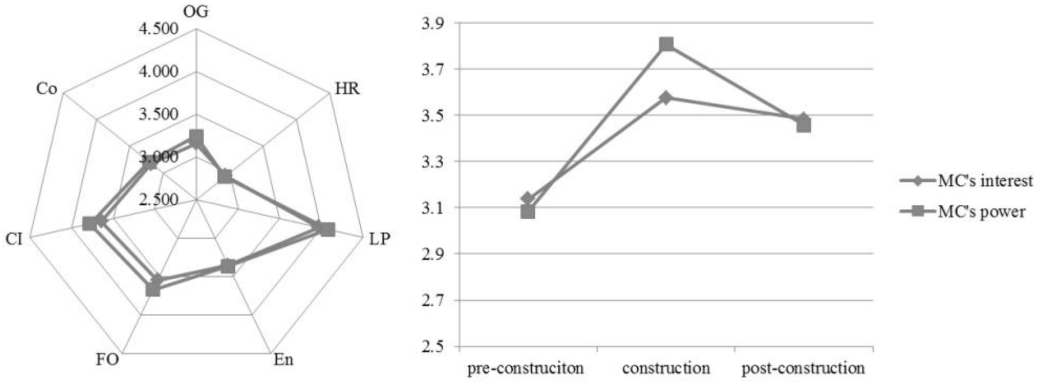

Figure 2: MCs' interest-power in the seven subjects and in the three project lifecycle stages

4.3 Developers (DVs)' interest and power on SRIs

The DVs generally play a powerful role in construction projects because they can directly raise their demands in bidding documents or contracts, as well as the social requirements of the construction outcomes. The paired t-test shows that the DVs' interest and power are significantly different (t = −2.709, p = 0.007) (Table 2), indicating that the mean of DVs' power is significantly higher by 0.14063 than the mean of the DVs' interest. This difference shows that the DVs still exhibit the potential of fulfilling their responsibilities on some issues where they may not be recognized as important. Further comparison of the seven subjects were made and the result (Fig. 3) reveals that the DVs possess more power but devoted less interest in the SRIs on Co. Moreover, Co issues have attracted vast attentions in the SR agenda, especially in mining industry (Jenkins and Yakovleva 2006). The major DV in mining industry have exerted much effort to obtain social license to operate in local communities. However, data has revealed that community issues apparently difficultly attract DVs' attention in the construction industry. On this point, construction DVs should recognize their capabilities in community issues, devote themselves in developing local facilities, care for local residents, and contribute to local employments. In terms of the project lifecycle, DVs' power is highest in the pre-construction stage, exceeding the interest in the same period. By contrast, DVs' power drops to the lowest point in the construction stage and power is considerably lower than the interest. Considering that the DVs' interest continuously rises but the power dramatically decreases after the construction began, DVs should make comprehensive SR plans in project inception and design stage and presents all the plans before construction starts.

Table 2: Paired t-test result of DVs' sub-group

	Paired Differences					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
				Lower	Upper			
DVinterest - DVpower	-.14063	1.01735	.05192	-.24270	-.03855	-2.709	383	.007

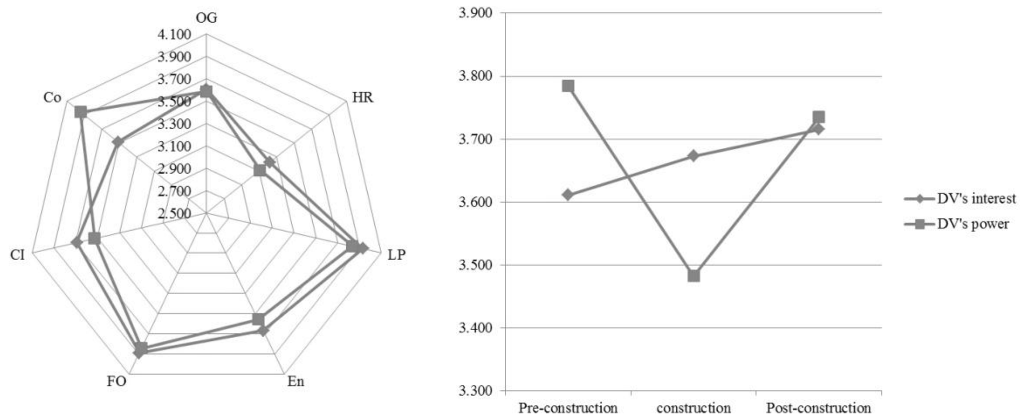

Figure 3: DVs' interest-power in the seven subjects and in the three project lifecycle stages

4.4 Governments (GVs)' interest and power on SRIs

The GV departments set the baseline for the SR of projects; therefore, their power is undoubtedly high. However, whether GVs' interest to set forth to higher level of SR legislation, or encourage SR implementation, is in the same level with their power is questionable. Table 3 demonstrates that there exists a significant difference between the GVs' interest and power ($t = -5.224$, $p = 0.000$). The mean of GVs' power is higher by 0.33333 than the GVs' interest, indicating that in HK, GVs' attentions on SR in construction projects are not considerably sufficient. This phenomenon is possibly caused by the uneven distribution of funds among the different departments, as well as the current strategies of the construction authorities. This lack of attention on SR legislation possibly results in the lagging development of construction market in HK. Among the seven subjects (Fig. 4), the GVs' power-interest gap is most distinctive in the HR dimension, suggesting that the attention the HK GVs' is paying on HR issues are inadequate in view of its social development level. In addition, the government should further endeavor to devise HR policies that are beneficial to the minorities and that eliminate discrimination in construction projects. Similar to DVs, the GVs exhibit the highest power in pre-construction stage, and this power remains considerably high in the whole lifecycle. However, the GVs' interest on SRIs is relatively low and reaches its lowest level in the construction stage.

Table 3 Paired t-test result of GVs' sub-group

	Paired Differences					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
				Lower	Upper			
GVinterest - GVpower	-.33333	.92459	.06380	-.45911	-.20755	-5.224	209	.000

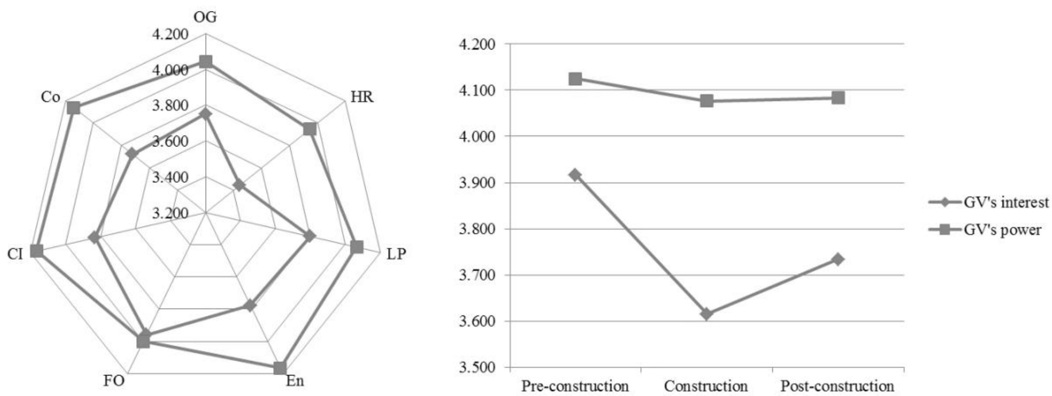

Figure 4: GVs' interest- power in the seven subjects and in the three project lifecycle stages

4.5 Consultants (CSs)' interest and power on SRIs

Significant gap is also detected (Table 4) between the CSs' interest and power (t = 5.044, p = 0.000). However, the opposite pattern of difference is observed; the interest is greater by an average of 0.25215 than the power, implying that the CSs are more proactive and aggressive on SRIs in the construction industry. CSs possess the most advanced knowledge or techniques in improving project social performance and their attitude toward SRIs are relatively positive. However, given that CSs are normally under the command of their clients, implementing their SR plans without the DVs' supports is difficult, although CSs could provide socially responsible alternatives for DVs to decide, such as greener or more resource efficient design, stakeholder communication scheme, and community development plans. This interest over power is observed in all of the seven subjects, especially in the CI and FO dimensions (Fig.5). To effectively achieve the SR goals, CSs must actively align with more powerful stakeholders, such as DVs and MCs, to initiate and implement the SRIs. Figure 5 also shows that the gaps between CSs' interest and power increases along with the progress of the project. This finding implies that it becomes more difficult for CSs to implement their SRIs if they did not bring them up before the construction began.

Table 4 Paired t-test result of CSs' sub-group

	Paired Differences					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
				Lower	Upper			
CSinterest - CSpower	.25215	1.32064	.04999	.15401	.35029	5.044	697	.000

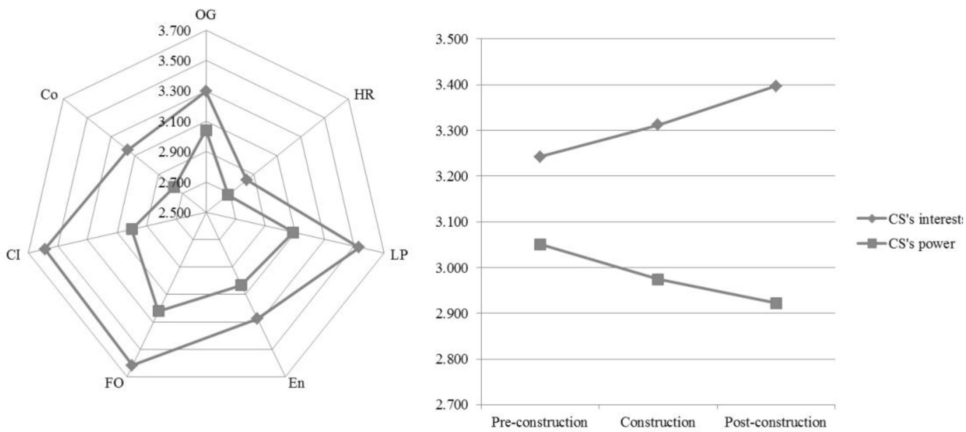

Figure 5: CSs' interest- power in the seven subjects and in the three project lifecycle stages

5. Conclusions

The comparison between stakeholders' interest and power revealed that some SRIs (labor protection, fair operation, customer issues, and environmental issues) are in greatest need of stakeholders' collaborations and joint efforts for their successful implementation. Some issues, including re-allocation and compensation of local residents, development plan for community, and disclosure of the social and environmental impacts of projects, call for more attention from project stakeholders. Main contractors, as key members of project teams, know the SRIs that they have power on. They have power to implement labor protection issues, including employees' health and safety in different project stages. In addition, main contractors should take advantage of their prevalent status in the construction stage to implement their SR initiatives at the right time. Compared with the exclusive power that developers have in presenting SR demands in project scope, developers showed inadequate interests on implementing SRIs. And this lack of interest phenomenon implies that the construction developers have the ability to set forth community development plans and community protection issues but do not have enough motivations to implement them. Moreover, although developers are influential, their status is only superior before construction begins. Government departments should lead the implementation of SRIs in construction projects; however, they have insufficient interest on most SRIs, particularly during construction stage. By contrast, consultants are more disposed on performing SR, even though they lack in power. It suggests that consultants should begin reinforcing their controls on SRIs by aligning with the powerful stakeholders (e.g. governments or developers).

Understanding the stakeholders' interest and power can reveal the implications of the distribution of responsibilities of SRIs in construction projects. Interest implies the stakeholders' intentions and goals on SR, whereas power is the responsibility that they are expected to assume. The result of this study will not only serve as guidance to project managers in engaging powerful stakeholders on SRIs implementation, but also as decision supports for construction organizations to strategically allocate their finite resources on the SRIs that they have superior power on. This investigation has also shed light on the SRIs that are currently neglected by powerful stakeholders; these SRIs call for future concerns and investments. However, the sample size should be increased and balanced among the stakeholder groups to make the result more representative. Considering that this questionnaire survey is devised in the context of HK construction industry only, the results can be hardly utilized in other regions because the results may vary under different social background.

Abstract

The ambition of this conceptual paper is to better understand the fundaments upon which sustainability can be achieved within the context of the construction sector today. The most common methodological approaches to achieving sustainability seem to be based on the presumption that an ever increased refinement of assessment tools of different sorts, – such as LCA, LCC, C/B-analysis, etc. – will eventually provide sufficient for assuring the sustainability of project based ventures. In this paper we argue that the implementation and refinement of such tools cannot be said to secure sustainability of projects given their inherent limitations.

The base premise of the research is that control systems typically function well for promoting organizational or individual behaviour to attain project objectives. They are equally essential in most forecasting and anticipation of events that can lead to undesirable consequences in a project. No control system, however, how detailed and effectively implemented it might be, can foresee every eventuality or unanticipated circumstances. Literature shows that assuring sustainability is highly dependent on proper risk control, predictability, framework conditions, and long term assessments. These are all factors that not easily fall in line with the above mentioned systems. Thus, if sustainability is to be achieved through projects, control systems etc. will not suffice to assure sustainability.

The big question is then what is to replace such control systems. The idea of this paper is to explore the insights from classical virtue ethics – in the tradition from Aristotle – to articulate an alternative path to achieving sustainability than through ever more rigorous control systems. The central notion here is the one of character, most notably the character of the project manager. Projects are realised by project teams under the leadership of a project manager. Enabling the project manager to cope with the eventualities threatening the sustainability of the project thus becomes essential. There is a crucial need for enabling future sustainable project managers to handle this kind of tasks.

Keywords: ethics, sustainability, virtue, education

1. Introduction

This paper outlines an understanding of what the contemporary understanding of sustainability can gain from insights from so-called virtue ethics in the tradition from Aristotle (2009). This is carried out as part of a more general enquiry within the field of the ethics of the Norwegian AEC (Architecture, Engineering and Construction) industry. The ambition is seeing the concept of sustainability as lying in so to say the keel water of that of ethics, the first being a translation of terms to make practical morality operational within the engineering disciplines.

The importance of increasing the awareness among engineering practitioners concerning themes covered both by sustainability and ethics seems crucial to attaining what Mirsky and Schaufelberger (2014) maintain as the most important topic to the future of the AEC industry, notably “honourable, professional practice” (Mirsky and Schaufelberger, 2014). More recently, different industries and trades have witnessed an increasing interest in the field of applied ethics in general and in professional ethics in particular (Christoffersen, 2011). Different professions establish rules and regulations, such as medical doctors, teachers, social workers etc., and the number of publications is ever increasing. The authors of this paper have so far not seen this trend reflected strongly in publications concerning the AEC industry in general, or in actual industry agreements in Norway. Notable exceptions from this general statement include the writings of Bown et al. (2007), Bröchner (2009), Corvellec and Macheridis (2010), Fellows et al. (2004), Hill et al. (2013), Ray et al. (1999)).

Considering that the AEC industry in general and in Norway in particular typically receives attention as an industry of doubtful virtue, 1) where neither the police, the tax authorities nor the professional organisations fully master the challenges posed by professional practice (Andersen et al., 2014); 2) where the inherent complexity in itself opens the opportunity for suspicious dealings (Gunduz and Önder, 2012); 3) where fraudulent business practices undermine the reputation of the industry (Slettebøe et al., 2003); and 4) that lacks a clear vision based on a fortified ethical foundation (Wolstenholme et al., 2009), we find this strange. As Hill et al. (2013) comments, there is probably no simple solution, no “quick fix”, to the challenges of ethical nature that the industry faces. Tackling such challenges necessitates, it seems, both insight and endeavour. The notion of sustainability seems to be one key to addressing such problems within the AEC-industry at large.

The concept of sustainability, however, is multifaceted, and is used in different manners within different contexts. As Gomis et al. (2011, 174) point out, ‘sustainable business’, ‘sustainable technology’, ‘sustainable agriculture’, ‘sustainable economics’, etc. are all buzzwords of the literature today. According to Adams (2006), ‘[a]nalysts agree that one reason for the widespread acceptance of the idea of sustainable development is precisely [its] looseness. It can be used to cover very divergent ideas [...]. The concept is holistic, attractive, elastic but imprecise’ (2006, 3). This differentiated use has in fact, according to Marshall and Toffel, ‘nearly rendered the term sustainability meaningless’ (2005, 673). Those venturing into the literature will in fact find a breath-taking number of different understandings and definitions. In his non-conclusive going-through, Hasna (2010) lists 67 definitions.

Despite the apparent imprecision concerning the comprehension of the notion, a certain general agreement does nonetheless seem to exist. As Adams points out, the 'core of mainstream sustainability thinking has become the idea of three dimensions, environmental, social and economic sustainability' (2006, 2). Sustainability can be analysed with different aspects in mind, but the three dimensions can be used to categorise the identified sustainability factors or elements (Flores et al. 2008). For a discussion of the comprehension of the three pillars, their balancing act, and the different analytic levels according to which it seems necessary to implement them successfully, we refer to Haavaldsen et al. (2014).

It is easy to despair when faced with such seemingly impossible matters of precise knowledge and definition. If turning the question around, however, it takes another colour. If – rather than looking at the definitions, different understandings etc. of the phenomenon – we examine the reason for the term surfacing, the picture alters.

1.1 Sustainability and ethics

When examining the use of the sustainability, there seems to be a strong linkage between the concepts of sustainability and of ethics. A main ambition of this work is to outline what implications this linkage can entail, notably concerning the difference between rules and virtue-based approaches.

Ethics is commonly perceived to be the science that investigates what one ought to do. Moral, on the other hand, is typically considered as the practical mechanisms through which such behaviour is judged. In particular based on the common etymological roots of the two concepts, we in the following consider them as fairly synonymous, basing the exposé on the first of the two.

At a very general level, one main cleavage within the field of ethics can be found between so-called rule-based and virtue-based approaches (we do not here say that all ethical theories fall within a scope that is relevant for this distinction, solely that these occupy a primordial place in the field of ethics). What we here call rule-based covers in fact a variety of theories that are hugely diverse, the most influential today are probably deontology (in the tradition from Kant) and different forms of utilitarianism (such as presented by Mill, 2002). This distinction has been masterfully been described by Anscombe (1997).

What brings together these major intellectual currents is that they proclaim that action ought to be justified and considered ethical or not according to a rule of some sort. For Kant, this rule was formulated in the so-called categorical imperative. For the utilitarist, the idea of the greatest good for the greatest number of people tends to be the rule according to which one is to act in the world.

Virtue-based ethics, on the other hand, takes a different stance to the question of judging what is ethically estimable. Rather than focussing on abstract principles from which rules of conduct can be determined, virtue ethics in the tradition from Aristotle focuses on what it calls the character of the actor. The question haunting fourth century BC Athens – how can one assure that the inhabitants of the republic act in an ethically sound manner – in fact resonates deeply within today's societies in general – and within the professions that form the AEC-industry in particular. This character is typically sought developed using examples, to expose what is ethically good and blameworthy behaviour. To put this in contemporary engineering language, we can say that deductive top-down rules based approaches of the rule-based ethical systems are replaced by an inductive bottom-up approach in virtue-based approaches.

1.2 Rule-based vs. virtue-based understanding of sustainability

If then, we propose that the concept of sustainability ought to be understood as following closely that of ethics, it should follow that the cleavage between rule-based and virtue-based approaches should be as crucial within the context of sustainability as within that of ethics.

To undertake conceptually the implications this insight, however, seem to be rarely treated in the literature, and, to take the consequences of this into actual practice seems even further from the main research agenda, as we perceive it. Some notable exceptions exist; see for instance Helgadóttir (2008) for an example of an analysis inspired by Aristotelianism.

In order to address this general challenge, we address the following research questions:

1.) What are the main challenges to sustainable practice within the Norwegian construction industry today?
2.) What measures can be identified as reasonable to address these challenges?

Questions of this type are inherently difficult to examine from an empirical perspective. They are of a principal nature, meaning that their essence tend to slip from empirical investigations. Therefore, we in the following address these questions in a conceptual manner, illustrated with some general reflection upon general frameworks. The main point is to outline what – from both theoretical and practical perspectives (as understood by the authors of this paper) – can be identified as the main challenges to sustainable practices within the AEC-industry.

2. Methodological approach

The methodological approach constituting the research behind this paper is threefold in nature. First, a literature study was carried out in accordance with the procedures described by Blumberg (2011). A documentation study was conducted in order to provide an overview over the approaches chosen among 25 major actors within the Norwegian AEC-industry, notably an examination of their ethical frameworks. The reason for selecting the large companies was an anticipation of that they want to be in the forefront and show the way for smaller companies. The ten contractors was selected from top of the 2015 top 100-list (based on annual turnover) of the magazine Byggeindustrien (http://www.bygg.no/100-storste). The authors picked the five public owners based on their general knowledge of the Norwegian construction industry. The private owners are more randomly selected, but the selection criteria included visibility in the public debate of social affairs, membership in Grønn byggallianse [Green Building Alliance] and/or have recently developed projects that received BREEAM-NOR certificates for the design phase and/or completion. The engineers were the five most popular on the 2015 career barometer, a result from a survey among approximately 8000 students initiated by a private media house (http://www.karrierestart.no). All the examined companies describe their code of ethics on their web pages, but a few did not publish them there. Finally, we examined the so-called millennium goal of the UN in order to see what this general framework could imply for the understanding of the broad picture.

3. Findings – How actors actually address the challenges?

As Haavaldsen et al. (2014) outline, sustainability can be understood at several analytic levels, and according to several perspectives. In the following, we examine two approaches we perceive to be situated at a strategic level, notably the ethical frameworks of 25 major companies from the industry (national level) and the millennium goals of the UN (international level). These approaches differ in that the overall approach of the ethical frameworks to the subject matter is a relatively hard ruled-based approach; whilst the millennium goals stress a rather fluid approach open to interpretation. As we shall see, challenges of different natures follow each of these two main approaches.

3.1 Codes of conduct interpreted as intended to sanitise the AEC-industry nationally

Most major companies within the Norwegian AEC-industry have ethical guidelines or codes of conduct, the distinction between which is somewhat blurred. What is of interest in this context, is that they all ambition to codify the behavioural stance of members of the company. Ethical codes are adopted by organizations to assist members in understanding the difference between 'right' and 'wrong' and in applying that understanding to their decisions.

On their webpages, the public owners appear as engaged in ethical issues because of their own descriptions of their Code of ethics. According to their own descriptions, their Code of ethics consist of several layers, with for example guidelines for contact with property owners, ethical guidelines for suppliers etc. Despite their engagement, only one public owner has made the Code of ethics available through the webpage. One approach to increase transparency – as public owners should – would be to make the code of ethics easily accessible for all stakeholders. Two of the contractors have not published their Code of ethics at their webpages.

Private owners seem – at least on their webpages – to be concerned with ethics and ethical guidelines. Two private owners that form part of a larger mother organisation with international activities have extensive guidelines that reach for standards above the minimum legal requirements. Two private owners are mainly operating in the Norwegian property market, and their Codes of conduct describe the distinction between legal and illegal, but not the distinction between ethical and unethical. One of the private owners has not established an own Code of conduct, but is planning to do so within short time.

Among the engineers, four have published their Code of ethics on their webpages. The guidelines seem to have general formulations. The fifth one, which has not published their guidelines, describe on their webpage a procedure where their employees have to sign that they have read and understood the meaning of the Code of ethics. A scrutiny of these codes reveals a surprising level of divergence, as table 1 shows.

Table 1: Ethical codes of 10 contractors, 5 public owners, 5 private owners and 5 engineers within the Norwegian AEC-industry

Organisation	Distinction between legal/illegal	Distinction between ethical/unethical	Accessible on web	Number of text pages
Contractor 1	Yes	Yes	Yes	22
Contractor 2	Yes	Yes	Yes	10
Contractor 3	n/a	n/a	No	n/a
Contractor 4	n/a	n/a	No	n/a
Contractor 5	Yes	No	Yes	1,5
Contractor 6	Yes	No	Yes	2
Contractor 7	Yes	No	Yes	9
Contractor 8	Yes	No	Yes	1
Contractor 9	Yes	No	Yes	3
Contractor 10	Yes	Yes	Yes	8
Public owner 1	Yes	Yes	Yes	14
Public owner 2	n/a	n/a	No	n/a
Public owner 3	n/a	n/a	No	n/a
Public owner 4	n/a	n/a	No	n/a
Public owner 5	n/a	n/a	No	n/a
Private owner 1	Yes	Yes	Yes	10
Private owner 2	n/a	n/a	No	n/a
Private owner 3	Yes	No	Yes	2
Private owner 4	Yes	Yes	Yes	3
Private owner 5	Yes	No	Yes	10
Engineer 1	Yes	Yes	Yes	14
Engineer 2	Yes	Yes	Yes	20
Engineer 3	Yes	Yes	Yes	1,5
Engineer 4	n/a	n/a	No	n/a
Engineer 5	Yes	Yes	Yes	9

Most remarkably, their extent varies between one and 22 pages. Secondly, their availability on the net is variable; some are merely not accessible for the general public (without providing any clear explanation for this withdrawal), a fact that renders this analysis problematic. Thirdly, and most importantly, all available codes distinguish clearly between legal and illegal behaviour, condemning the last clearly, whilst the difference between what is ethical and unethical, however, is more blurry.

It is in fact this latter point that is of prime interest to our analysis: All of the examined codes of ethics describe the distinction between what is legal and what is illegal. Among the contractors, only Contractor 1, Contractor 2 and Contractor 10 describe the distinction between what is ethical and what is unethical. Five of the contractors have quite similar codes of ethics, which – roughly – tell their employees to follow the minimum legal requirements. It their employees want to, they can reach for stricter requirements, but that will be their choice.

In our view, this fact point to the weakness in rule-based approaches as observed earlier. There seems in general to be no limit to what you can do, as long as you stay within the limits of the law within these codes of ethics. It thus seems that actors not being aware of the difference between ethical and lawful behaviour has developed a majority of these codes of ethics. On a more general level, this points in fact to the shortcomings of such rule-based frameworks: actors operating within these frameworks can in fact go very far in acting in what can be called an unethical manner, without this action conflicting with the code.

3.2 The 2030 Agenda for Sustainable Development

On the 25th September 2015, world leaders gathered in New York to adopt the 2030 Agenda for Sustainable Development. The Agenda that was agreed upon comprises of 17 new Sustainable Development Goals listed in table 2. The objective was to produce a set of universally applicable strategic goals that balances the three dimensions of sustainability.

The main characteristic of these formulations is how general they are in nature. These are, in fact, policy statements, and it is clearly difficult to implement them directly in projects. Much can be said on the subject of their roundness, giving ample place for interpretation.

Table 2: The Sustainable Development Goals as proposed by the Agenda for Sustainable Development (UN General Assembly, 2015).

Goal 1: End poverty in all its forms everywhere
Goal 2: End hunger, achieve food security and improved nutrition and promote sustainable agriculture
Goal 3: Ensure healthy lives and promote well-being for all at all ages
Goal 4: Ensure inclusive and quality education for all and promote lifelong learning
Goal 5: Achieve gender equality and empower all women and girls
Goal 6: Ensure access to water and sanitation for all
Goal 7: Ensure access to affordable, reliable, sustainable and modern energy for all
Goal 8: Promote inclusive and sustainable economic growth, employment and decent work for all
Goal 9: Build resilient infrastructure, promote sustainable industrialization and foster innovation
Goal 10: Reduce inequality within and among countries
Goal 11: Make cities inclusive, safe, resilient and sustainable
Goal 12: Ensure sustainable consumption and production patterns
Goal 13: Take urgent action to combat climate change and its impacts
Goal 14: Conserve and sustainably use the oceans, seas and marine resources
Goal 15: Sustainably manage forests, combat desertification, halt and reverse land degradation, halt biodiversity loss
Goal 16: Promote just, peaceful and inclusive societies
Goal 17: Revitalize the global partnership for sustainable development

It seems hard to argue against these general formulations. What is of prime importance is their all-encumbering nature. This trait is often criticised in this type of policy documents. The analytic force of such general statements, however, is that they typically leave the actors free to apply the statements to their own context – within the boundaries of their semantic extension. The key element here, however, is the translation from policy statements to sustainable practice, in other words, how to translate the goals that indicate the intended virtue of our generation into practical, achievable project within the AEC-industry.

3.3 Translating the goals into practice

If we first look for the three dimensions of sustainability embedded in the 17 goals in this list, we may find direct or indirect traces of all three. The dimensions are taking on different nature depending on the goal in view. If we look at the first goal, for instance, it is obvious that the goal has a number of social and environmental challenges in addition to the economic dimension.

When planning such projects – that is, interpreting the way from the policy level to actual project realisation – we have found it useful to distinguish between three goal levels where all dimensions of sustainability may be determined from the given (broad) context. This provides a better understanding of the practical issues contributing to the complexity of sustainability.

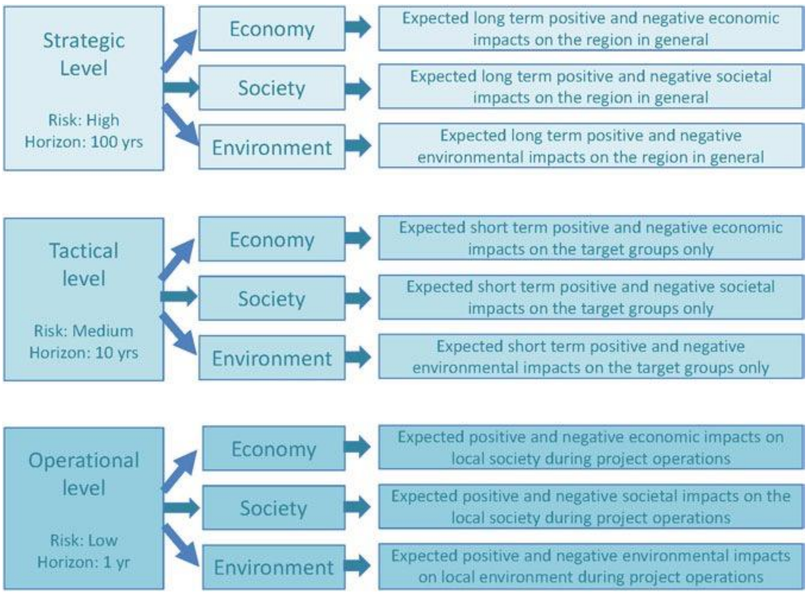

Figure 1. Suggested criteria for assessment of sustainability of projects (Lædre et al., 2015)

The figure outlines the three pillars of sustainability as sorted according to the three analytic levels of strategic, tactical and operational. It also underlines the risk elements pertaining to each of the analytic levels. Lastly, it stresses the differences in temporal horizon typically characterising the different analytic levels. Lædre et al. (2015) go far more into detail.

In other words, it seems useful to evaluate all goal levels of identified project concepts before finally deciding about them. The main reason for this is that the assessment of the three different dimensions of sustainability by addressing economic, social and environmental impacts will certainly vary with the goal level in focus.

4. Discussion and conclusions

The underlying argument in this paper has been to reconsider the recourse to rules as the unique prism through which trying to control activities of an industrial nature with multiple actors. The AEC-industry present a striking case of an industry where such rule-bound optimism stands seems futile – at least in the eyes of the authors of this paper, as the examples cited above clearly indicate. We set out to address what are the main challenges to sustainable practice within the Norwegian construction industry today and what are the corresponding reasonable measures to these challenges. On basis on this, we make the following claims: 1) There seems to be a near universal identified need for a sustainable practice within the industry. This seems to be reflected in the codes of ethics examined. In this paper, we have tried to illustrate how the virtue-based approach can help developing this. 2) The international approach, however, seem to take the virtue-based ethics too far in that their limits are too loose in that the need for translation into engineering practice becomes too complicated. A national strategy for concretising this overreaching might be a way to proceed.

It seems to the authors of this paper that there is a profound need for knowledge-based apprehensions of how to act. Virtue ethics in the tradition from typically recommends the use of examples to enlighten the actors of the correct choice in the specific situation. In order to render this a bit more concrete, we propose the following practical recommendations:

- Expand the understanding of the rules of the profession – and the limits of the rules.
- Expand the understanding temporal aspects of the endeavours you undertake
- Understand the analytical levels of sustainability assessments
- Enable students to learn from examples – people and projects
- All organisations need involve new employees in the ethical foundations of the organisation's practice – not just in ethical codes.

Abstract

Green business models (GBMs) can support green growth because they are based on green value creation and capture with emphasis on clients role. However, GBMs require substantial investment and strong change capabilities. This paper maps organisational changes associated with GBMs transformation. For this purpose, 19 semi-structured interviews are conducted with a heterogeneous sample of academics and managers from the UK construction sector. The interviews then are analysed by a means of thematic analysis with aim to capture any common changes and to form similar patterns of changes which occurred within the sample. Surprisingly, there are a lot of similarities that can be grouped broadly into three major themes: green profile development; structure; and operations. In addition, the change starts from the strategic level (policy) to the operational level but it may be triggered by the people at the operational level. Furthermore, GBMs not only change product/service and process but also catalyse broader systems change of the green value chain. Therefore, construction organisations have to accept that transition to GBMs will bring significant changes to the way they work if these models are to flourish.

Keywords: Change, construction, green business models, UK, and systematic change.

1. Introduction

As sustainability becomes an even more prominent matter of concern for the construction sector, the understanding and enactment of so-called green business models (GBMs) will become more pertinent (Boons & Lüdeke-Freund, 2013; Jing & Jiang, 2013) . Sustainability will lead to fundamental changes in the business world (Esty & Winston, 2009) with the construction businesses being no exception. Naturally, the resulting new business environment brings about enormous opportunities and challenges that can shake the competitive landscape of industries to the core (Boons et al., 2013; Sommer, 2012). *"Thus, hesitant managers should be asking themselves: How do sustainability issues influence the future success of our current business model? And: How can we adapt them to best mitigate the risks and take advantage of* *opportunities arising from sustainability issues?"* (Sommer, 2012 pp.5). GBMs can be a means towards competitive sustainability because they are based on green value proposition creation to customers and capture of profit and reputation. Henriksen et al. (2012) provided a definition for GBMs as follows: *"GBM innovation is when a business changes part(s) of its business model and thereby both captures economic value and reduces the ecological footprint in a life-cycle perspective"*. Therefore, the GBM concept can explain sustainability in terms of creating value and how value is defined (Abuzeinab & Arif, 2013). In addition, the GBM can help organisations to transform their abstract environmental strategies into viable business concepts (Sommer, 2012). Furthermore, concentration on the GBM can help better evaluation of current construction organisations BMs and assess their future suitability regarding sustainability aspects and competitiveness (Mokhlesian & Holmen, 2012; Sommer, 2012). However, it is vital for studies on this field to define GBMs explicitly to reduce the ambiguity around the concept (Abuzeinab et al., 2014).

According to Aho (2013), GBMs have the potential to transform construction organisations. However, this remains relatively unknown and the research is under-developed in this area. The aim of this paper is to investigate organisational changes associated with GBMs transformation in the construction sector. To achieve this aim, it is vital to choose an appropriate research method because little is known about GBMs and organisational change. The remainder of this paper is structured as follows: Section 2 presents the theoretical perspective of this study where sustainability within the construction sector is reviewed briefly followed by a review on sustainability and organisational change in general literature. The review has demonstrated lack of research dealing with organisational change and GBMs in the construction context. The justification of research method is presented in Section 3 where qualitative methods are deemed relevant for this exploratory study. By applying manual thematic analysis, three major organisational changes (themes) are found and discussed in Section 4. Conclusions are presented in Section 5 including limitations and future direction for the topic.

2. Literature review

In the UK, construction is a major sector of the national economy. Rhodes (2014) stated that the construction sector accounts for 6% of the economic output and provides employment for 6.5% of the population. According to Akadiri & Fadiya (2013), several initiatives supporting sustainability of the construction sector have been developed such as regulations, voluntary policies, economic measures and fiscal incentives. Examples of these initiatives include: changes to the Building Regulations; Aggregates Levy; Landfill Tax; and Renewable Grant Schemes. Assessment tools and demonstration projects have been showcased to demonstrate the effort of the government in addressing sustainability issues. Despite these efforts, sustainability in the construction sector is still lagging behind other sectors (Brennan & Cotgrave, 2014). A possible explanation is that the current research has focused on products and services but has ignored the organisations and their changes in responding to sustainability. This study aims to contribute to this gap by identifying major organisational changes associated with GBMs. Organisational change aims to move from the current state to a more desirable one ranging from evolutionary changes to revolutionary ones driven by internal and external factors (Lozano, 2013). Common organisational changes reported in the literature include: strategy, culture, politics, and operations with some overlapping changes (Lozano, 2013).

There are several studies linking sustainability and organisational changes within the general sustainability literature. For example, Lozano (2013) investigated barriers to organisational change related to corporate sustainability by using three case studies. He recommended that organisations need to plan the change to integrate technological and human changes to succeed. In addition, he summarised typical organisational changes associated with corporate sustainability: changes in mental models; the development of future vision for sustainability; management; structure; operations; and proposals of actions to achieve these. Hottenrott et al. (2016) examined the relationship between green technology adoption and organisational change in manufacturing firms. Their research provided new insights into increased productivity resulting from the complementarity effects of new green technologies and adaption of organisational structure. Furthermore, Lozano et al. (2015) advocated the importance of integration of organisational change for sustainability within higher education teaching curriculum. These examples demonstrate the emergence of organisational change for sustainability as a new discipline. However, similar studies and approaches within the construction sector are rare (Albino & Berardi, 2012).

Existing studies investigated sustainability requirements within the construction sector. For example, Akadiri & Fadiya (2013) studied the role of top management commitment, government regulations, and construction stakeholder pressures in determinig envionrmnetal sustainability practices to aid better decision-making for construction sector. Few studies have investigated the role of leadership and top management of construction organisations in driving sustainability (Brennan & Cotgrave, 2014; Opoku et al., 2015). The current study provides a new approach dealing with the organisational changes relevant to GBMs for the construction sector. Although there are studies available linking GBMs and the construction sector, none of these have examined the impact of GBMs on the organisational change. Examples include Aho (2013) who studied sustainable buildings from the BM perspective and Mokhlesian & Holmen (2012) who examined green construction using the BM as an analytical tool.

According to Sommer (2012), GBMs often require substantial investment of capital and other resources and are intertwined with the existing business environment in complex ways. GBMs therefore tend to conflict with conventional business practices and structures. For this reason, many business leaders, including those in construction, overlook the potential benefits of GBMs and fail to question their existing business logic and investment decisions with regard to sustainability issues. Identifying the organisational changes associated with GBMs will increase the uptake of GBMs because construction organisations will be in a better position to prepare for these changes. Albino & Berardi (2012) stated that studies focusing on organisational change relevant to green buildings are required becaue they will lead to a systematic tranistion of the sector towards sustainability. The current study is exploratory in nature owing to lack of similar studies within the construction sector. The next section presents the method used for data collection and analysis.

3. Research method

The aim of this paper is to empirically investigate organisational changes associated with GBMs transformation in the construction sector. Since the topic under investigation is relatively new, a qualitative method is deemed appropriate. The inherent flexibility of qualitative studies and their potential for revealing complexity were particularly relevant to this research, since the topic of investigation was complex in nature (Amaratunga et al., 2002). In addition, qualitative data has often been promoted as the best approach for discovery and exploring a new area (Amaratunga et al., 2002). These features are well aligned with current research aim. Detailed semi-structured interviews were conducted with 19 academics and managers from the UK construction sector. The target sample was purposive sampling to achieve representativeness of main actors of the construction sector value chain. A purposive sampling technique uses participants who are both accessible and willing to participate in the study (Renukappa et al., 2012).The profile of interviewees was chosen according to the following selection criteria:

- Senior/managers in the construction industry
- Relevant experience in sustainability strategies and practices
- A decision maker regarding sustainability issues, for example, being able to initiate and implement future plans
- Ideally, a sustainability manager, expert or officer.

Table 1 presents the details of the interviewees for further information.

Table 1: Interviewee’s details – Total of 19 participants

No	*ID*	*Type of business*	*Job title*	*Years of experience*	*Size of company*
1	*A1*	*University*	*Professor*	*15*	*2500*
2	*A2*	*University*	*Professor*	*15*	*2500*
4	*AR1*	*Architects*	*Architect & director*	*20*	*6*
5	*AR2*	*Architects*	*Associate architect*	*20*	*6*
6	*AR3*	*Architects*	*Associate architect*	*14*	*110*
7	*AR4*	*Architects*	*Associate director architect*	*9*	*12*
3	*CS1*	*Consultancy*	*Freelance consultant*	*36*	*1*
8	*CS2*	*Property and construction consultancy*	*Environmental manager*	*5*	*350*
9	*C1*	*Contractors*	*Director*	*50*	*50*
10	*C2*	*Contractors*	*Sustainability manager*	*17*	*800*

11	*C3*	*Contractors*	*Senior sustainability manager*	*14*	*5000*
12	*C4*	*Contractors*	*Senior sustainability manager*	*12*	*6000*
13	*O1*	*Others – Property development*	*Construction director*	*36*	*16*
14	*O2*	*Others* - *Procurements*	*Sustainability manager*	*8*	*50*
15	*CL1*	*Clients/ Local Authority*	*Capital programme director*	*40*	*10.000*
16	*CL2*	*Clients/ University*	*Associate director operations & facilities*	*36*	*260*
17	*CL3*	*Clients/ University*	*Building surveyor*	*20*	*245*
18	*CL4*	*Clients/Local Authority*	*Operational facilities manager*	*15*	*10.000*
19	*CL5*	*Clients/ University*	*Environmental & sustainability officer*	*10*	*250*

As shown in Table 1 above, all of the interviewees had considerable experience in the construction sector. In particular, they had relevant experience on green issues with some of them having 'environmental' or 'sustainability' within their job titles. The sample has covered major actors of the construction value chain including architects, consultants, contractors, clients, procurement, and property developer.

The analysis is focused on extracting meaning from the interviews which were analysed by means of thematic analysis. The thematic analysis refers to an analytical approach involving examination of discussions to establish meanings and intentions (Patton, 2005). It also refers to qualitative content analysis which has been used in construction research (Harty et al., 2007). The results are presented next and arranged into three subsections representing the major themes emerged from the data analysis.

4. Results and discussions

The Interviewees were asked to report all the changes in their organisations when they implemented green practices or initiatives. The aim was to capture any common changes and to form similar patterns of changes which occurred within the sample. Surprisingly, there were a lot of similarities that can be grouped broadly into three major categories. These categories are: green profile development; structure; and operations as shown in Figure 1.

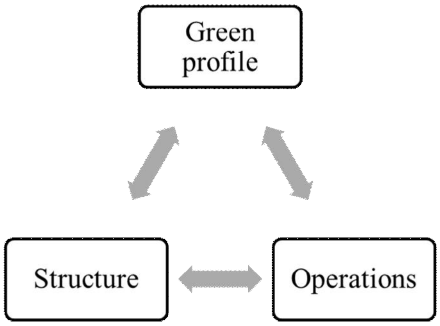

Figure 1: Major organisational changes of GBMs

Figure 1 above presents three major categories of organisational changes as emerged from the data analysis. Each of these major categories of changes is discussed in the subsections below.

4.1 Green profile development

It was evident that a green journey is usually initiated as a reaction to growing risks which can be regulations and uncertainties and it is characterised by discoveries. From the interviewees' answers, green decisions are based on two major reasons. Firstly, a compliance reason coupled with an ethical reason responding to the overwhelming scientific data about climate change and environmental degradation. Secondly, a market reason to seize the green opportunities and demonstrate capabilities in offering green solutions. Alternately, organisations may pursue the green issues for a combination of the above two reasons.

However, market opportunities including clients demand have dominated the interviewees answers as a major reason for offering green solutions. According to AR1 *"there are expectations for business in the marketplace today to have a level of environmental credibility."* This demonstrates the market drivers and the current and future expectations from businesses and organisations leaders. Therefore, it is better to start doing some changes and actions now before it is too late. It was also evident that some organisations within the sample started to deal with green agenda as a source of value creation instead of a legal imperative. These organisations have focused on building green profile starting by relevant training and in-depth knowledge. For example, the architects AR1, AR2, and AR4 have done various training on lower environmental impact buildings design such as offsite construction and code for sustainable home principles. This has some support in the literature. For example, Shiers et al. (2006) developed an environmental profiling system for construction products to aid designers in choosing relevant products. The authors suggested that availability of information and knowledge will encourage the practitioners to build their green capacity and track record. Furthermore, Albino et al. (2009) conducted a study of sustainability driven companies to understand their behaviours. The results showed a high relationship between the development of green products and the existence of environmental strategies. Therefore, it can be suggested that construction organisations need to start with a formulation of green strategies before they can move on to develop their green profile. A well formulated strategy will facilitate a systematic development of green profile to build a green brand and hence attract more revenues from similar projects and services.

Most of the participants suggested that a green profile should include quick wins or quick returns such as lighting upgrades and efficiency measures as well as longer-term, higher risk/higher reward strategies. Although they have agreed that GBMs in essence are long-term investment, they added that a collective approach is needed including policy and financial institution support. It can be suggested that long-term planning for GBMs requires major changes in current practices. The necessary investment to change can be financed by short-term profits or quick wins that will help build the green profile at the same time (Aho, 2013). In addition, the short-term profits can help alleviate the frequently cited barrier of environmental sustainability: cost (Brennan & Cotgrave, 2014). Developing a track record of green capabilities is vital for construction organisations to attract clients and to develop their awareness and appreciation of GBMs. According to Brennan & Cotgrave (2014), clients education and awareness are essential for sustainable construction. However, it is the responsibility of the construction sector to educate clients. We argue that before educating clients, the green profile has to be developed by the organisations to gain credibility. Akadiri et al. (2012) emphasised the role of top management in developing green buildings to build brand equity, innovate, and grow revenues. Consequently, building a green profile will require leadership and champions from top management hierarchy.

4.2 Structure

The results showed that most organisations are not embedding green-oriented resources into pre-existing organisational structure. They are instead adopting new structure and developing new performance indicators.

For example, most of the organisations within the sample established a specialist unit or environmental/ sustainability officer's position to drive the agenda. Some organisations have a large dedicated unit and others have a dedicated individual. This merely depends on the size of the organisation. Not only can there be the specialist unit or individuals, but also some voluntary roles within the staff such as an environmental champion and then it is made part of each individual's job description. The voluntary roles can be seen as empowerment for staff that can promote the green solution and allow them to participate in finding innovative solutions. This view is echoed in other empirical findings in companies in which sustainability practices are contributing to profits and so called "Harvesters." The findings reported lessons learnt such as: Harvesters usually change the organisational structure or adopt new structures and establish the position of sustainability officer (Kiron et al., 2012).

The dedicated environmental/ sustainability units or individuals have a major role to play on green business intelligence. In this role, they focus to identify clients with green agenda to work with and to offer them tailored services. C3 from the contractor group gave an example where they worked with an existing client to offer energy efficiency services. C3 stated that *"as part of* *a facility bid for a local authority we offered them energy investment where we pay the up-front costs and they pay us back from the savings."* This was possible because of the green intelligence staff that had good client knowledge and understood their aspirations and strategic targets.

Additional role of environmental/ sustainability unit or individual is to be able develop and communicate the business case of green practices internally for different departments and externally for clients and supply chain. For example, C3 from the contractor group stated that *"as long as it [referring to new green initiative] works financially you can find away and you can evolve it to client saving them money and saving you money they it is going to have a very good chance of going forward."* Nevertheless, an important issue has been raised by the interviewees that it is not always possible to make the business case in financial terms therefore construction organisations may look at alternative areas such as enhancing the reputation, making a clear statement of commitment to green issues, and social benefits.

The participants described another change in the structure where the operational units or individuals responsible for environmental sustainability have to report at the strategic level. In many cases there will be a strategic board manager responsible for the operational levels. For example, C2 from the contractor group indicated that *"at the moment the sustainability managers reporting to the health and safety director but some more senior appointments will be made so the sustainability managers will be reporting to head of sustainability"* .This strategic backing demonstrates the leadership commitment towards green agenda and empowers the position of environmental/ sustainability units or individuals to have a stronger influence on the organisation. However, CL5 from the client group stated that her current position as environmental and sustainability officer should be diminished over the time as a result of true embedment of environmental objectives within the organisation where this position should be part of everyone job responsibility.

4.3 Operations

The participants explained that the operations have changed significantly across many areas such as collaboration, technology embedment, procurement, and working patterns.

Organisations not only change themselves in response to environmental considerations, but they also become more collaborative inside and outside the organisation boundaries. It was evident within the sample there was a great collaboration and team work across the different organisation units. For example, C3 stated that he works closely with the financial department in developing and identifying green opportunities. Some of these organisations work more closely with their clients and suppliers to develop their green practices compared to their past experience of standard practices. Some of the participants explained their collaboration with certain professional networks that have specialised expertise in environmental issues and their work with the supply chain to ensure that green values are embedded within all activities. A typical comment was, *"If you think that in your company you have everything you need, you are totally* *self-sufficient you need nothing from the outside world then you are mistaken. You have a false view because you start to believe you have the right answers."* Consultant (CS1). Therefore, construction organisations should work more closely with their supply chain to ensure that they adhere to the same principles. Larger organisations may provide support for their supply chain and partners for better results. This vital because of the unique nature of the construction sector where there is a chain of actors involved to deliver products and services (Ballard & Kim, 2007; Kohler, 2008). Albino & Berardi (2012) noted that structure of the construction process is a major barrier to green practices because it is based on temporary arrangements between multiple organisations to deliver a project. Bossink (2007) highlighted the importance of studying the changes of organisational relationships in green practices. Therefore, the findings of this study are a means to overcome this barrier by encouraging collaboration between organisations. Another possible solution is to focus on integrated green projects delivery because it facilitates long-term relationships and shared value delivery.

The operation becomes more reliant on technology because it facilitates work efficiency. For example, the architects within the sample stated their movement to paperless documents. In addition, AR1 and AR2 explained the advantage they have by establishing a strong ICT documentation and automation services. They have a strong knowledge repository to facilitate communication and learning across the organisation. Furthermore, technology has a vital role to play in the changing process such as sensor technology which can help achieving more efficient consumption of energy and water and influencing behaviour to promote low carbon culture and efficient practices. Energy display is also seen as important technology advancement in raising awareness and encouraging lower consumption levels.

Moreover, CL1 and CL4 from local authorities stated that their organisations have changed the way of procurement where they started to procure only from suppliers who match specific criteria to ensure those suppliers are committed to the green agenda. This has some support from the literature where Albino & Berardi (2012) invetsigated relationships between construction organisations in sustainable practices. The results suggested that orgniasations tend to work with others that have green portfolio to show their commitment to sustainability.

Finally, some of the organisations within the sample introduced more flexible working patterns to reduce the travel miles and invested on online facilities to work across geographical regions. For example, CS2 stated that they communicate with their head office through online conferencing and thus reducing the need to travel and lowering their carbon footprint.

The results showed that GBMs can lead to major organisational changes therefore construction organisations should be prepared to accommodate these changes. In addition, it is vital to deal with these changes systemically and to embrace the close relationship between them. This study highlighted the role of supply chain in delivering GBMs and its impact on operational change. Consequently, construction organisations will need to work closely with their supply chain to achieve wider progress towards GBMs.

5. Conclusions

This paper has focused on investigating organisational changes pertinent to GBMs transformation in the UK construction sector. As the subject under investigation is a relatively new, qualitative method is chosen to better understand the subject. 19 semi-structured interviews are conducted with a varied sample representing academia and the sector practitioners. Thematic analysis is then applied to extract the results.

The results showed that organisational changes were grouped into three major themes. Firstly, green profile development where construction organisations start to build and market their green credentials. As the public awareness grows, organisations will find this is a pressing issue to survive in the market. Secondly, organisation structure by establishing a specialist unit or a member of staff to lead green practices and strategies. This position is vital drive the agenda and to make a clear statement of commitment towards GBMs. Finally, a major organisational change rests on the operations practices such as increased levels of collaboration internally and externally, technology embedment to drive efficiency, procurement, and working patterns. Therefore, construction organisations have to accept that moving to GBMs will bring significant changes to the way organisations work. This study contributed to better understanding these changes hence construction organisations can be prepared to address these and channel their resources and capabilities toward the identified areas of change.

Although this study has provided new insights on the relationship between GBMs and organisational changes for the construction sector, it has some limitations. First, GBMs remains fundamentally under-researched topic particularly in the construction context. This has implication on finding comparable construction studies that would have influenced the results of the current research. Second, the research is focused primarily in the UK construction sector and is relied on empirical data from UK only. Therefore, it is difficult to generalise the findings beyond the investigated context. A wider qualitative inquiry as to how GBMs change construction organisations is recommended for future research. Furthermore, the possibility to compare findings of the present paper with organisational changes in other European countries remains desirable.

Performance Based Building by U.S. Architects: An Investigation into Attitudes and Adoption

Abstract

Performance Based Building (PBB) was initially developed alongside sustainability to resolve separate but related issues. Work in the field began with attempts to harmonize design and construction methods and products across national and cultural barriers. Reduction in energy and water consumption, additional added value to the owner and novel, responsive design forms become later goals of PBB efforts. Regulatory, technical, cultural and process-oriented barriers to adoption have been identified within specific disciplines.

There are a number of PBB tools that integrate the full lifecycle of building design and occupation. These tools offer the potential to address many of the causes of the gap between the predicted and actual performance of buildings seeking high levels of sustainability. The mixed-methods research design began with a questionnaire for participant identification and proceeded to in-depth explanatory interviews that explored the barriers and drivers to adoption encountered in daily practice.

Awareness appears to develop slowly, sometimes organically through the firm's interests, but more often via pilot projects and committed pathfinder clients. Opportunity and demand subsequently build. Some firms capitalize on this as a market differentiator while others are pulled along by mandates or more mainstream clients who have recognized the business value. These experiences build basic functional knowledge which, in turn, is developed with the involvement of specialist consultants and software tools into more sophisticated technical knowledge. Levels of sustainability and performance previously seen to be impractical are slowly transformed into standard practice. This process renews itself as committed clients and organizations seek again to demonstrate their values beyond conventional business.

This information can guide the efforts of those seeking to advance the adoption of PBB among U.S. architects. Additional research into the effects of firm culture and the role of committed clients in developing new processes appears warranted.

Keywords: architecture, design, performance, sustainability, values

1. Introduction

The traditional architectural design process begins when the owner hands a complete program of spaces to the architect and ends when the building is ready for the owner to move in. Pre-design and post-occupancy evaluation have emerged more recently as formal services (American Institute of Architects Staff 2013). As the fields of sustainable and high performance design have become mature, a multitude of technical tools and rating systems have emerged to address individual aspects of design. A smaller set of tools and techniques have also been developed seeking to guide the design team in how decisions are made and which goals are pursued.

This research began with the conjecture, based on the author's personal experience, that awareness and adoption of Performance Based Building (PBB) among U.S. architects is low. This research then focused on identifying the barriers and drivers within the specific context of architectural practice and the first-hand experiences of those practitioners. By exploring those experiences, both actual and perceived barriers were identified for further research.

A review of the literature revealed a number of actual and potential barriers, but few explanatory models. Awareness is a barrier that can be measured directly via surveys and questionnaires. However, it is not likely for one to be able to give an insightful answer to the circumstances of his or her own ignorance. The popular Leadership in Energy and Environmental Design (LEED) program served as a proxy for the less well-known concept of PBB. Empirical studies into different delivery systems have centered on project performance during construction (Konchar and Sanvido 1999) but are more recently beginning to investigate how those methods influence operational outcomes (Esmaeili et al 2013). Those relationships are complex and beyond the scope of this research. A two-step mixed-methods approach was able to illustrate the transition of sustainability and building performance from an expression of a small group of clients' values to the design mainstream. The value of these insights lies in their ability to aid the work of those pursuing broader adoption of PBB among U.S. architects.

2. Literature Review

2.1 Conceptual Background

The essentials of contemporary PBB were defined in the 1982 report to the International Council for Building (CIB), "Working with the Performance Concept in Building." The report begins, "The performance approach is, first and foremost, the practice of thinking and working in terms of ends rather than means. It is concerned with what a building or building product is required to do and not with prescribing how it is to be constructed." (Gibson 1982, p. 4) The other key concepts that Gibson (1982) outlines are testing the proposed solution against those requirements and evaluating the final constructed work against the original benchmarks. The CIB continued to develop a research program for PBB through the 1980s and 90s.

This laid the groundwork for a multinational research effort that gave rise to the Performance Based Building Thematic Network that ran from 2001 to 2005 (International Council for Building 2013). That work culminated in a series of final reports intended to establish a consensus for PBB throughout Europe and the United States. Performance standards then become the means by which to judge the productivity of the discourse between supply and demand. Technical applications have developed in step with the advance of technology and computing. The US Department of Energy now lists 411 software applications for measuring and comparing differing aspects of building performance (Building Technologies Office: Building Energy Software Tools Directory 2013).

2.2 Benefits and Barriers

These tools and practices offer an array of potential benefits; increases in Key Performance Indicators (KPIs) with Gross Value Added (Barrett et al 2007), dynamic links between performance parameters and building geometry (Oxman 2008), and even carbon absorbing cities (Geyer & Bucholz 2012). Fowler (2011) and Hammond (2005) point to mandates Federal organizations have enforced as an important determinant of the successful adoption of PBB.

Despite these benefits, many barriers to adoption remain. The lack of acceptance among regulatory bodies was one of the first to be identified (Gross 1996). The increasing technical complexity of the design process limits who can perform more sophisticated performance simulations (Shi and Yang 2013) and the number of simulations that can be performed (Flagler, Haymaker 2007). Outside of large property portfolios managed by a single entity - namely governments and a few large private companies - smaller organizations have not been able to demonstrate the business value that PBB offers successfully (Barrett et al. 2007). Sexton and Barrett (2005) and Panuwatwanich et al. (2009) found that PBB must explicitly address business logic and value in order to find broader acceptance. Seeking to explore the limits of performance across many domains creates fragmentation of the design process. For example, daylighting, facade design and energy performance have become independent consultancies at the same time that the need for the integration of those systems into the whole of the building has become increasingly apparent (Satterfield et al. 2009). Perceived liability, adversarial relationships and the lack of a skilled workforce also constitute cultural barriers (Wright 1996). An organization with a culture that values performance will learn how to express that value to others by integrating the myriad available technical tools. In the case of hierarchically structured federal agencies, that cultural change has been mandated from the top. Without such a mandate, there seems to be no consensus within the reviewed literature regarding the tools or methods that would most effectively address this issue.

2.3 Integration

In contrast to fragmentation of the design process, integration was identified as the primary means by which barriers to PBB can be addressed (Bakens et al. 2005, p. 155):

> *Fixed classification or inflexible separation of the demand and supply sides also do not help. Instead, a programme structure and activities that promote maximum interaction of up- and downstream stakeholders, and of participants in the different phases of building life, should be encouraged to promote integration and remove barriers.*

Lützkendorf et al. (2005, p. 13) created a typology of performance instruments and tools that maps their application across these phases of a building's life. Few of the tools they identified are intended to span all phases of design. All but the ASTM Standards and Design Quality Indicators (DQI) are intended for residential design or are limited in scope by region-specific database information. Similarly, the Soft Landings framework grew from a desire to incorporate user feedback from the end of the design cycle, rather than front-loading technical information before design begins (Way 2004; Bordass, Leaman 2005). Because these systems have the capability to be broadly inclusive of the design process, they are referred to as integrated tools for the purposes of this research.

Highly optimized building performance concepts tend toward complex, multi-dimensional trade-offs that are embedded deeply within the final built solution. This makes identifying the benefits derived from any specific design decision guided by PBB principles particularly challenging. Tools that integrate PBB throughout the design life-cycle offer significant potential benefits. However, their adoption may hinge on the internal dynamics and culture of the organizations seeking to make use of them.

3. Methodology

3.1 Research Design

Given the complexity of the performance-based landscape, is it reasonable to expect the practicing professional to be knowledgeable about the use of these tools? The reviewed literature suggests there has been little formal investigation into the state of knowledge among architects practicing within the U.S. While many barriers and drivers were identified during the literature review, correlations between these variables were not suggested. Without those correlations to explore in a quantitative manner, an alternative method was selected. A two-stage process was developed to first narrow the field and then explore it in greater detail. The first stage was a brief questionnaire only seeking to identify individuals with experience in the systems in question. The second stage was developed as an open-ended and exploratory interview to reveal the specific context of each firm in which the interviewee operates (Weiss 2004). In this mixed-methods approach, the questionnaire is not intended to be a statistically reliable tool. It is used to enhance the qualitative exploration of the interviews. This method aligns with the participant selection variation of the explanatory model for mixed-methods research (Creswell, Plano Clark, 2007).

3.2 Questionnaire

A brief questionnaire was developed to identify individuals with experience in the systems in question. To maximize results, the questionnaire was sent to individuals whose expertise was known to the author or whose qualifications were readily available through published resources, including the United States Green Building Council directory and past members of the AIA national Committee on the Environment. The questionnaire was restricted to three questions: awareness of the subject PBB systems, experience with those systems, and willingness to participate in an in-depth interview. LEED templates and forms were included to ensure a baseline of familiarity with sustainability and building performance. Due to the small sample size relative to the potential total population, statistical analysis of the questionnaire results was limited to internal comparisons.

3.3 Interviews

Interview participants were self-selected through the questionnaire process. After establishing basic facts, the majority of the interview was structured in a biographical arc, beginning with personal history of the subject, working towards present experience, and finally projecting into the future. The method of focusing on a single, specific time is referred to as the Critical Incident Technique, which Chell (2004) asserts is an effective method to elicit more detailed and accurate recollections of past experience. This was also intended to establish a flow that would produce a more active and engaged conversation. This appeared to have been successful as the responses grew longer and more detailed as the interviews progressed.

The analysis of the interviews followed the model outlined by Seidman (2013). Recordings were transcribed and those transcripts were coded for keywords based on the barriers and drivers identified in the literature review. Other keywords emerged as repetitive themes across multiple interviews. The frequency of these keywords was charted and the strongest concepts were grouped together along with any counter-examples.

4. Results and Analysis

4.1 Questionnaire Results

Seventy-two professionals were contacted via e-mail with 20 responding over a period of 48 days. Six of those 20 were aware of one of the subject systems and only two had first-hand experience. All had first-hand experience with the LEED templates.

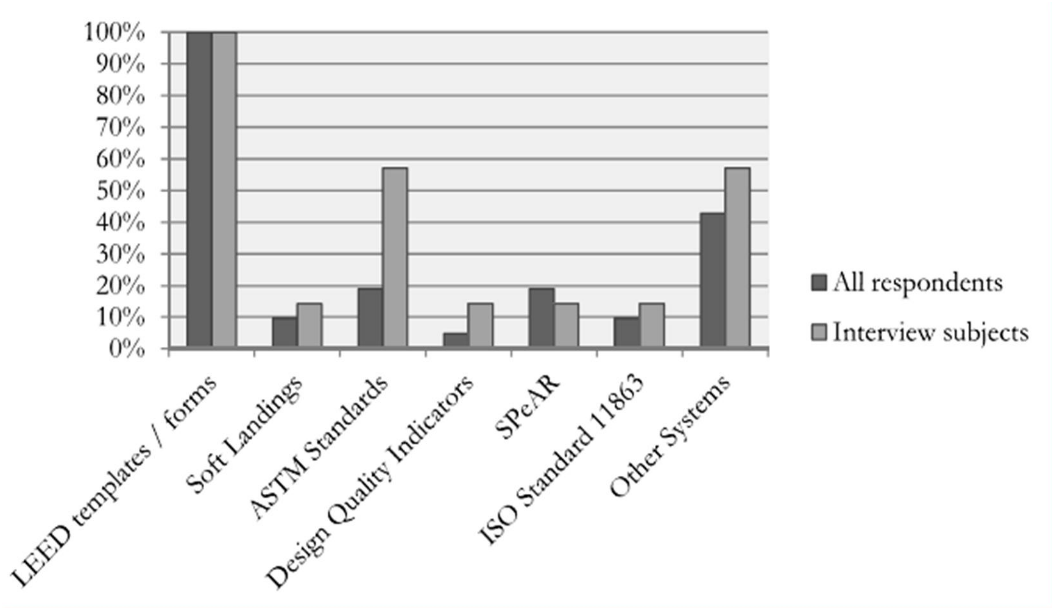

Figure 1: Have you evaluated any of the following systems for use in your practice?

Green Globes and the Living Building Challenge where the two most commonly mentioned of the other systems. Two trends are readily discernable from this data; LEED is ubiquitous among respondents and, while not completely unknown, awareness of the other subject systems is not as pervasive. The interview subject's experience appears to be consistent with the larger group of respondents with the exception of the ASTM Standards.

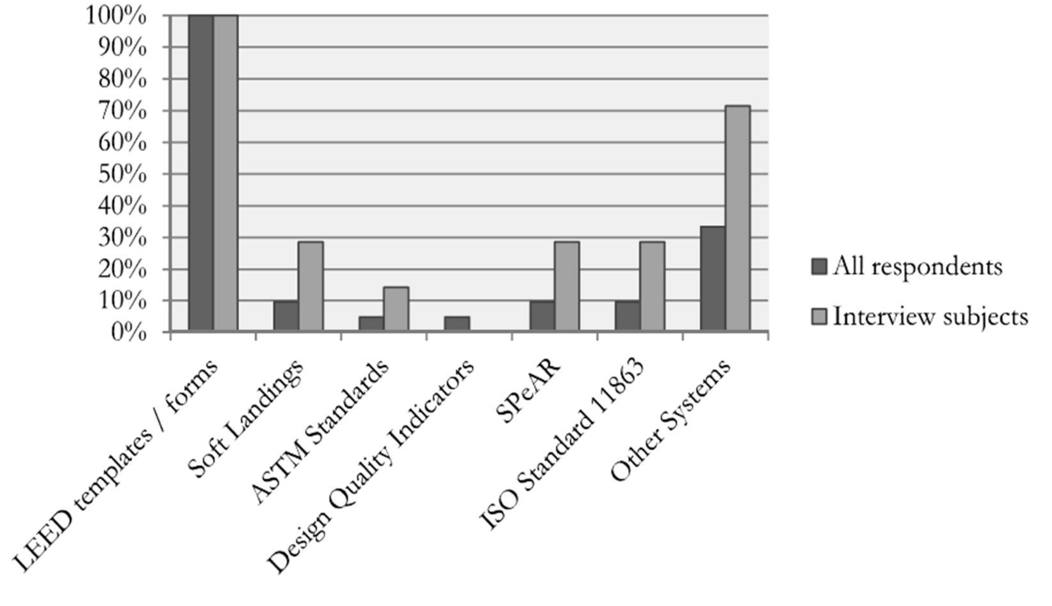

Figure 2: Have you been involved in a project that used one of these systems?

The same two trends were demonstrated by the results for first-hand experience with the low levels of adoption of systems other than LEED being even more pronounced. In this case, it appears that the interview subjects may have slightly more experience with alternate systems than the overall group.

4.2 Interview Results and Analysis

Twelve of the questionnaire respondents elected to provide contact information for the purposes of scheduling interviews. Ultimately, interviews were arranged with seven of those individuals. When asked to reflect upon their earliest experience with PBB, a strong trend emerged. Six of the seven had been involved in the LEED pilot program to varying degrees. For five of those six, a non-profit organization, governmental body or another pathfinder client was mentioned in reference to this initial experience. When asked about barriers to PBB that had been encountered during the course of these initial experiences, financial cost was identified by five of the seven subjects. However, several related concepts were specified: increased design fees, rating system certification fees, actual construction costs, and uncertainty in the bidding process leading to inflated costs. The perception of increased cost was described as having outlasted the reality among some clients. Education of both the design and construction teams was also cited as an early barrier. Responses to the question of what values drove the design team to push through and overcome the barriers that were encountered centered on three ideas: market differentiation, firm values, and client values.

Asking interviewees to identify the benefits the design team had realized from the inclusion of LEED or PBB strategies proved more difficult to frame in a manner that elicited useful feedback. For the four that did address the question directly, one response serves as a succinct summary: *"There are really three prongs of what we received from that [experience]. One was how to do the LEED documentation, but also our reputation as a firm doing sustainable design and our ability to design a building that was at a higher benchmark than what we had done before."*

At this point in the interviews, the focus shifted from present-day experience to speculation regarding the future. Mandates were identified as particularly powerful tools in this regard, especially when tied to funding mechanisms. The specific example of federal and local government adoption of LEED certification was cited by three subjects. A similar state level program, also tied to bond funding for construction costs, was also cited. The business case for performance was also cited: *"…there would have to be a policy or mandate or there would have to be, basically, undeniable quantitative return on investment…"*

The role of building standards or rating systems that reach beyond the conventional also emerged. In particular, the difficulty of achieving the Living Building Challenge was cited as a driver for those organizations seeking to express a qualitative commitment to sustainability that goes beyond what can be evaluated in traditional quantitative terms. It was suggested that this may be intentional on the part of both the clients and the rating organization. One subject questioned the premise of the question and responded:

The path to make anything go on an upswing is instead of making it voluntary, make it compulsory, which then, sort of diminishes the altruistic nature of going after it, which is why Living Building Challenge and various other projects aren't actually interested in having more projects but rather a number of demonstration projects.

This suggests that the creative tension between aggressive rating systems that go beyond the industry's current abilities to measure value and the widespread, tested and proven systems forms a mechanism by which the qualitative values of some organizations are made quantitative and revealed to the broader market.

5. Discussion

5.1 Pathfinders and Mandates

The initial experiences of the interview subjects were defined by pathfinder clients and mandates. The pathfinder client plays a critical role in the adoption of new performance standards by pushing through barriers based on their values rather than waiting for a demonstrable return on investment to justify their efforts. This contradicts Barrett et al.'s (2007, p. 16) assertion that *"…project teams can only really achieve incremental change without this lead [mandates]."* Regulatory obstacles were scarcely mentioned in the interviews, which suggests the concerns voiced by Gross (1996) may have lessened in the intervening years. The role of the pathfinder client appears to shift the need to quantify building performance in business terms identified by Sexton and Barrett (2005) as well as Bakens et al. (2005) from the initial adoption phase to later stages of the process. Adoption of PBB may be better served by including or marketing to those clients rather than focusing on design professionals. This finding parallels the "innovation champions" Brandon (2006) describes as driving technological and design-process adaptations. Pathfinder clients are distinct from innovation champions insofar as Brandon ascribed their efficacy to the force of individual personality and not organizational values. In both cases, however, industry does respond to client demand. This research did not contradict prior findings that mandates are powerful tools for driving the adoption of new systems to the broader market, but it does suggest they follow pathfinder clients in the overall process.

5.2 Process

The emergence of software tools and specialty consultants to serve the architectural profession pre-dates the PBB concept. Four subjects agreed in principle with the concerns and difficulties voiced by Shi and Yang (2013), Reinhart and Fitz (2006), and Crawley et al. (2008). However, the magnitude of these issues and their impact on the final output were both downplayed. It appears that firms have grown comfortable evaluating those tools and consultants and have developed ongoing processes, whether formalized or not, that allow them to adapt to the proliferation of both specialties in the normal course of operations. This incremental approach echoes Yetton et al.'s (1994) findings regarding the initial adoption of CAD technology in the late 1980s and early 1990s.

The same institutional inertia could be a barrier to the adoption of process-oriented tools that do not match the organization's current design methods. This supports Hammond et al.'s (2005) claim that *"...successful implementation of a performance-based approach for Facilities and Constructed Assets is best if embedded in an overall performance-based approach for the whole organization."* However, the lack of awareness of those specific tools appears to have manifested itself in an absence of specific information on this topic within the interviews.

5.3 Feedback

The need to incorporate feedback is growing in recognition of the continued uncertainty of outcomes, otherwise known as the performance gap. Two contributing factors were identified by interview subjects. First, modeling tools are developed and used for documentation and standards compliance, not necessarily for their predictive capabilities. Second, occupant behavior, both at the organizational and individual levels, can be very disruptive to optimizing building performance. Some clients and firms are now actively seeking feedback which may indicate that the adoption of this practice is beginning to grow along a similar arc as LEED. The AIA 2030 Commitment, a single-attribute system comparing predicted and actual energy use intensity, has recently emerged as another example currently adopted by 99 U.S. architecture firms (American Institute of Architects Staff 2013).

5.4 Other Issues

A handful of other issues emerged through the course of the research. It appears that LEED's ubiquity drowns out many other systems. Green Globes may be a viable alternative to LEED but is still far less prevalent. PBB in the U.S. may be dependent on recognition by and incorporation into one of those two systems. Liability is seen as a barrier by some and a driver by others. Performance guarantees and the health impacts of chemicals within building materials were specifically identified. These are significant to the issue of PBB, as they represent potential changes to the professional standard of care for designers that relate directly to specific dimensions of building performance. The findings appear to confirm Wright's (1996) assertions regarding performance, while the topic of chemical health impacts may be a more recent emergence not addressed as thoroughly in the existing literature. International work, where design oversight of contractor activities is prevented by contract or practice, is an area of promise for the PBB concept. Design documents that do not rely on prescriptive methods could help ensure that the final built product meets the intent of the design and needs of the user across significant cultural and technical divides.

6. Conclusions

This research sought to identify barriers and drivers to the adoption of PBB amongst U.S. architects so that those tools may be more commonly brought to bear upon the gap between predicted and actual building performance. The specific context of architectural practice and the first-hand experiences of those practitioners were explored to yield insight into the practical judgement that guides their work. The picture that emerges is of a progressive process that builds over time.

From the data gathered from the interviews, it appears that awareness has developed slowly, sometimes organically through the firm's interests, but more often via pilot projects and committed pathfinder clients. Opportunity and demand subsequently appear to build. Some firms capitalise on this as a market differentiator while others are pulled along by mandates or more mainstream clients who have recognized the potential value in business terms. These experiences build basic functional knowledge which, in turn, is developed with the involvement of specialist consultants and software tools into more sophisticated technical knowledge. Levels of sustainability and performance previously seen to be impractical are slowly transformed into standard practice. This process renews itself as committed clients and organizations seek again to demonstrate their values beyond conventional business. While the sample size of this research cannot be considered broadly generalizable, the coherence of the story told by the interviewees suggests these conclusions represent one thread of experience within the industry.

The implication is that PBB cannot be pursued as an end of its own. PBB is, by definition, focused entirely on what can be measured, demonstrated, and improved. This leaves no space to include the more far reaching and ambitious concepts that capture the imagination of pathfinder client organizations, but have not yet demonstrated a reasonable return on investment. Without that intrinsic driver, those seeking to extend the use of PBB must find another path. Adoption can be most readily furthered by embedding PBB principles as deeply as possible into the rating systems and standards, such as the Living Building Challenge, that do offer this existential demonstration of commitment.

Abstract

The principles of lifecycle costing or whole-life costing has been around for decades, but the implementation of the principles has been modest or even weak despite the obvious advantages of integrating maintenance, operation and management aspects into the design of new buildings and facilities. Several explanations to this apparent paradox have been offered including the absence of robust tools, cost key figures and commonly agreed calculation assumptions along with weak economic incentives, the inherent project focus of designers and contractors etc. In early 2015, the Danish government launched a new package of tools for sustainable construction. The complete package includes a general guideline to sustainability, two specific guidelines on lifecycle costing (LCC) and lifecycle analysis (LCA), a general introduction to the lifecycle of construction and two new tools for doing lifecycle costing (LCCbyg) and lifecycle analysis (LCAbyg). Based on the methodology of structured analysis and agile software development methodology, this paper will review existing tools, discuss (some of) the design choices made and summarise lessons learned from the development of the tool LCCbyg for lifecycle costing. First, this paper will provide a typology of existing tools into three categories with distinct characteristics and associated benefits and drawbacks: 1) Spreadsheets, 2) stand-alone applications, and 3) web services. Second, while the software interface only displays limited unique features and functionalities compared to other available tools, the inherent data model applied in the tool provides a number of unique design choices. These design choices make the tool highly robust to future development; incorporate a fully open standard in XML format for easy exchange with other applications; provide the users with a high degree of adaptability to their specific requirements; and reduce the need for an elaborate classification scheme for cost and building components that would otherwise severely restrict the adaptability of the tool.

Keywords: Sustainable construction, lifecycle costing, agile development, open standard, data model

1. Introduction

The challenge of sustainability has been around for decades. The Brundtland report (1987) introduced sustainability as the balanced development of three pillars: environment, social and economics. Despite progress, there still is a long way to go for governments, businesses, academia and civil society. In 2014, the Danish government (Regeringen, 2014) issued a new building policy with five strategic actions including one action on sustainable construction. This strategic action included a series of initiatives to promote sustainable construction, among others a guidance package. This package was launched in early 2015 and includes a general guideline on sustainable construction (Energistyrelsen and Birgisdóttir, 2015), two guidelines on environmental assessments (LCA) (Birgisdóttir and Nygaard Rasmussen, 2015) and lifecycle costing (LCC) (Haugbølle, 2015), a foundational report on the building's life cycle (Nygaard Rasmussen and Birgisdóttir, 2015) and two tools for environmental assessments (labelled LCAbyg) respectively economic assessments (labelled LCCbyg).

The principles of lifecycle costing or whole-life costing has been around for decades, but the implementation of the principles has been modest or even weak despite the obvious advantages of integrating maintenance, operation and management aspects into the design of new buildings or refurbishments. Several explanations to this apparent paradox have been offered including the absence of robust tools, cost key figures and commonly agreed calculation assumptions along with weak economic incentives (see e.g. Haugbølle, 2015).

Applying the principles of lifecycle costing has for several years been mandatory for both social housing and governmental buildings. While the social housing sector has developed sector-specific tools, the government building agency has effectively neglected its obligations to apply and to disseminate knowledge on lifecycle costing. This negligence was criticized in strong terms by the Danish National Audit Office (Rigsrevisionen, 2014) and the Danish Public Accounts Committee (in Danish, Statsrevisorerne) putting pressure on the building agency to take action on lifecycle costing. Meanwhile due to unfortunate circumstances the building agency had to employ a new CEO, who came from a municipal building agency with a high profile on sustainability and lifecycle costing. Further, three new trends have in recent years actualised a wider use of lifecycle costing in construction (Haugbølle, 2015):

1. New governmental regulation issued in 2013 on quality assurance, public-private partnerships and lifecycle costing in public construction, which requires all public clients (not only governmental) to apply lifecycle costing in projects above certain thresholds.
2. The establishment in 2012 of the German certification scheme DGNB adopted by the Green Building Council Denmark for sustainable buildings and urban areas where economic quality has a very prominent position.
3. The new European procurement directive from 2014 that makes it easier to use total cost of ownership (TCO or lifecycle costing) as an award criterion in competitive tendering rather than just lowest cost.

With these new dynamics in mind, the time seemed ripe to consider how lifecycle costing may be addressed and operationalised. The objectives of this paper are 1) to provide a typology of LCC tools and discuss benefits and drawbacks of different types of tools, and 2) to reflect on the design process of LCCbyg and share lessons learned during the software development process.

2. Methodology

The tool LCCbyg was developed for the Danish Transport and Construction Agency (Trafik- og Byggestyrelsen, 2016) by the Danish Building Research Institute in collaboration with a small software firm. The combined competence of the project team members covered lifecycle costing, data modelling, software architecture and user interface design.

This study is based on a combination of the structured analysis approach and the agile approach for software development. The development has been divided into two main stages: the development of version 1.0 in 2014 and the development of version 2.0 in 2015. Due to conference deadlines for paper submission, this paper primarily addresses the development of the first version. This process can be subdivided into three main phases: Analysis of present situation; formulation of requirements; and development and testing of the tool.

The analysis was carried out using so-called ‘structured analysis’ (Delskov and Lange, 1999). As spreadsheets are effectively the industry standard of performing LCC calculations, it was relevant to analyse the design, inherent data model and calculation procedures of spreadsheets more closely. The methodology was adapted to only include the Data Flow Diagrams, Data Dictionary and Process Descriptions. The second phase covers requirement specification, which the customer writes on the basis of the analysis and own requirements and wishes. In this case, the specification of requirements was developed in parallel with the second half of the analysis as well as the early design stage. The third phase covers the actual design of the application. In addition to structured analysis, this work was in part based on the 12 principles of agile software development (Fowler and Highsmith, 2001). To mention a few of the principles being followed in this project, the project team was a self-organising team with a flat organisational structure based on a recognition of complementary competences among team members; the iterative development process was based on frequent sprints; intensive face-to-face conversation took place through weekly project meetings; changing requirements was welcomed (even late in the process) and adapted regular to changing circumstances through close interaction with a highly knowledgeable reference group and potential users; and the team focused intently at delivering working software as the principal measure of progress.

The approaches of structured analysis and agile development were supported by empirical evidence from a range of sources. The analysis phase provided an overview of existing national and international tools. Based on this overview, the LCC tool for DGNB certification developed by the Danish Building Research Institute was selected for closer scrutiny as this is a very recent example of this development path, the project team had easy access to the coding, and the tool closely follows the approach in similar tools. The purpose of the analysis phase was to explain and document the DGNB system’s use of variables and rules of calculation in order to support the subsequent design phase. The analysis phase also included participation in industry courses on LCC and interviews with and observations of practitioners using LCC tools. During the requirement setting phase extensive dialogue with the funding agency and the reference group was carried out based on e.g. the presentation of mock-ups and draft versions of the tool's reporting schemes. The development and testing phase further extracted empirical evidence through e.g. the use of a structured test protocol by the test persons.

3. Analysis of existing tools

3.1 Existing approaches

A number of different approaches and tools to manage whole-life costing or lifecycle costing already exist both nationally and internationally. Two standards are relevant here: the international ISO15686 series on service life planning (ISO, 2008) and the European EN15643 series on sustainability of construction works (CEN, 2012). Several instructive books and guidelines have also been published over the years. These include among others the very first publication by the Danish national building research institute on economic optimisation of insulation (Becher, 1949), strategic investment and financing (Hedegaard and Hedegaard, 2008), a practical guide to selecting materials from a whole life costing perspective (Caplehorn, 2012), a comprehensive overview of different LCC models and engineering design issues within various business areas of application (Dhillon, 2010) as well as a textbook for engineering students on economic analysis, estimation and management in product development of complex systems (Farr, 2011).

The most widespread type of tools is based on the spreadsheet platform available in most standard software packages for office use (typically Microsoft's Excel spreadsheet). These include among others a low-energy optimisation tool for Danish social housing, the Norwegian government's building agency's tool LCProfit, the LCC tool used in the Danish DGNB certification scheme as well as a range of internal company-specific spreadsheets. Another but less frequent type of tools includes stand-alone applications. These include among others the tool BLCC offered by the US Department of Energy. A third type of applications is web services where calculations are made online using some kind of web browser linking to a server hosted by the service provider or a web hotel. These include among others the mandatory tool for doing LCC calculations in Danish social housing with regard to new buildings and major refurbishments as well as a web service version of the Norwegian LCProfit. A fourth type is apps for tablets and smartphones, but these are currently non-existent.

3.2 Characteristics of different technical solutions

While a spreadsheet solution offers a number of benefits including relatively low development costs, spreadsheets are notoriously fraught with errors. As pointed out by Panko (2008) *"…the issue is how many errors there are, not whether an error exists. And out of 113 investigated spreadsheets 88 % are found with errors."* A web service solution makes it possible to have one common interface, but requires additional resources for optimisation to different browsers as well as extensive management resources. Apps for smartphones and tablets are spreading fast and offer great value for the user "on the move", but are often cumbersome for daily office use. A desk top application is the main platform for the user groups, but desk top application may need to be available for three different operating systems (Windows, OS X and Linux). Linux is used to a very limited degree (around 1 % of the market), while OS X is used to a larger degree (some 8 % of the market). The Windows operating system in its different versions is by far the most widespread operating system, accounting for around 90 % of the market (StatCounter, 2015). Since the operating system OS X has various options for running Windows applications, solutions based on the Windows operating system would potentially cover the vast majority of all desk tops. Table 1 provides an overview of the benefits and drawbacks of each of the four technical platforms for developing LCC calculation tools.

Table 1: Characteristics of technical solutions

Characteristics / *Type*	*Benefits*	*Drawbacks*
Spreadsheet	*Great flexibility* *Wide spread use* *Integrated in office suites*	*Many possible errors (often hidden)*
Web service	*Same interface on all platforms*	*Optimisation to different browsers* *Require fast internet connection* *File handling requires extensive management of servers, security etc.*
Mobile/tablet	*Wide spread and increasing use*	*Cumbersome for extensive office use* *Customised solution required for each mobile platform*
Desk top application	*Mature and open source libraries for XML, PDF and graphs* *Main platform for user groups* *Integrated in work processes, including backup and storage*	*Three operating systems (Windows, OS and Linux)*

3.3 Structured analysis of a spreadsheet tool

An important difference between a software application and a spreadsheet is not the technical difference, but rather that the user is developing calculation solutions. Where the programmer has learned to follow a strict methodology that involves an ongoing focus on troubleshooting, the spreadsheet developer rarely follows any method other than increasingly adding cells. Where a spreadsheet developer sees a variable as a position in a given layer or cell in the spreadsheet, the programmer will see the variable without position. In practice this means that the variables are all unique in their naming, and are available in a variable list. For the programmer the outcome of two interacting variables becomes a new variable, described and reportedly named in the variable list. For the spreadsheet developer an interaction between two positions leads to a third position. In both cases, the calculation will be correct, but in a further development of the application, the programmer would only have to control the variable list. The spreadsheet manager must ensure all rearward positions, which gives a large number of corrections, particularly when multiple columns or rows need to be inserted. References in data, x-refs, are often troublesome because they tend to break.

In order to decipher the logic of the system the starting point was to note the responsibility of data entry and the resulting variables in the DGNB LCC-tool. The tool's calculation views and balances were then reviewed in order to document the use of input variables and to find and explain the resulting calculations (system variables) included in later calculations.

The variables were described in a 'Data Dictionary', and calculation routines were described in 'Processes'. The variables used in the processes were double-checked with the data dictionary, and the processes themselves independently described. Finally, the variables were taken directly from the spreadsheet and listed alphabetically and in conjunction with process variables and data dictionary. Figure 1 shows the result of this analysis as a high level view.

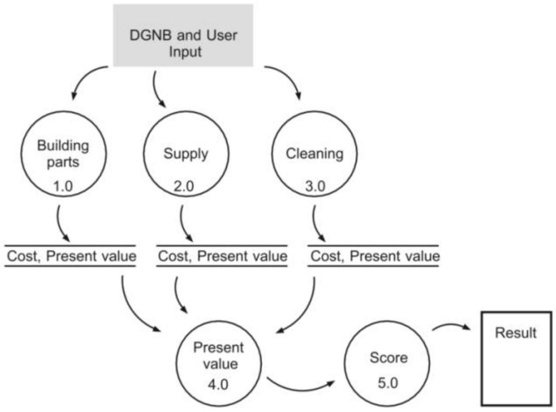

Figure 1: The system's procedural context (High level)

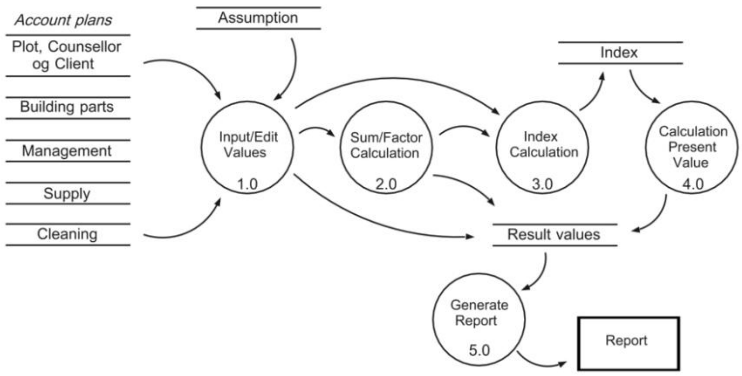
4. Setting requirements

Figure 2 shows the principle of the system where account plans will be completed and customized by the user (Process 1.0), after which the values are used in the subsequent calculations. 'Account plans' contain a number of items the user can select as needed. Interest rates are not implicit in account plans, but located in the register 'Assumptions'. The values entered by the user are stored both in the register 'Result values' and transferred to the calculation processes. The system calculates totals and factors (Process 2.0), which is later used in the calculation of the index values (Process 3.0). Some values are not included in the calculation of factors and sums, and used directly in the index calculation. The purchase will not be calculated as index or present values, and therefore saved directly in the register 'Result values'. The index values are saved for each year of the chosen calculation period. On this basis the present values are calculated (Process 4.0). All input, used standard values, and the calculated present value are placed in the register 'Result values', which forms the basis for generating a ‘Report’ (Process 5.0). Process 1.0 and 5.0 are ‘semi-manual’ while Process 2.0, 3.0 and 4.0 are automated.

Figure 2: Outline of the system



Each of the predefined building parts has been associated with values for ‘Lifetime’, ‘Maintenance rates’ and ‘Replacement rates’. The values are taken from a report on lifetimes by SBi (Aagaard et al., 2013) and supplemented with maintenance rates and replacement rates from the price calculation database V&S Prisdata and the Green Building Council Denmark (2014). Lifetime is indicated as number of years the building component is functional and does not need replacement. When the estimated lifetime of a building component expires, the building component is replaced. Maintenance of the building components is specified as a percentage of the purchase price (the construction of the physical building components). Maintenance is calculated for each year of the calculation period, so the value represents an annual maintenance cost. Replacement is also a percentage of the purchase price of the building components, but appears only in the calculations of the year in which the lifetime expires.

The account plan for ‘Building parts’ calculates acquisition cost of the building, maintenance of the building components and replacement at end of life (Figure 3).

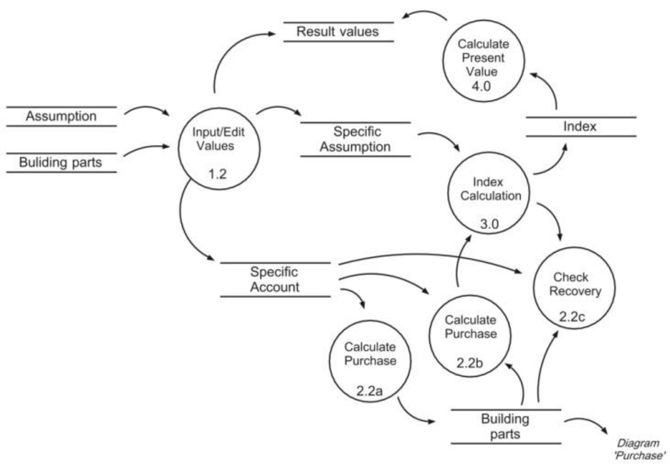


Figure 3: Calculation of building parts

For each year during the calculation period an indexed value and a present value is calculated. The input and editing made by the user in Process 1.2 is used in the calculations and saved simultaneously in the ‘Result values’. The register called ‘Acquisition of building parts’ is also used in ‘Acquisitions’. The account ‘Building parts’ contains parts classified under SfB group 1-6 (Byggecentrum, 2012).

5. Converting requirements to a solution

5.1 XML as data format

Data – and specifically data related to building structures with a long life – must be stored in a manner that allows data to be retrieved over time independent of specific tools, software, operating systems and hardware. The unique properties of the XML format makes it ideal for storing hierarchical data directly in a data tree, thus avoiding the need for the often troublesome references. It also allows adding and deleting posts where needed and belong in the logical structure. Consequently, the system store and exchange data in XML, as it makes it possible to store data in clearly defined structures without sacrificing flexibility. Storing data in a human readable format also allows data files to work outside the tool and it allows project file authors to create new project types by hand and merge outside data by using existing XML tools.

In naming the XML elements, tags and attributes are exclusively in English to avoid future problems with external XML tools. All tags and attributes are written in lowercase. Although it is possible to achieve a slightly higher human readability by using letter casings such as Camel-Case, the benefits are outweighed by the many trivial errors that can arise later when trying to figure out the correct casing for an element or attribute. The choice also allows the software code to define software objects as Camel-cased and XML elements as all lowercase, making it easier to identify what is referred to when working on the code base.

Many automatic XML-to-code generators will default to serialising data into elements rather than attributes. In order to preserve human readability, and make the XML correspond to the logic behind, it was chosen to handcraft the XML/Data Object conversion. This allows for values to be stored as attributes inside the relevant tags and reserve element creation for bearers of the hierarchical information. Making this distinction is helpful for deciding how the XML structure should look like when adding and refactoring the data format.

5.2 Development platform

In order to contain, edit and standardise the use of the aforementioned XML file, the project team chose to write a software program. In order to do that, an execution platform and one or more programming languages must be selected. A number of considerations were taken into account including use on the web, multi-platform compatibility, mobile and desktop use, industry standards, prevalence of programming languages, and availability of free, open source third-party extensions. As a consequence the application was created in C# as a Windows Presentation Foundation (WPF) application.

5.3 Graphical User Interface (GUI)

The general approach has been to design the application as a series of steps represented by tabs in the project pages. These are bound to the underlying software objects that are updated directly and with a minimum of filtering. An update of a value in the GUI triggers a complete recalculation of all results in the model. This allows showing in real time the effect of a specific change in value on the calculation. The cost data breakdown structure holds the account plan elements. These are shown in two tabs: one for editing structure and setting key values, and one for entering the main body of user values. The overall calculative results are shown in a tab labelled ‘Conclusion’. The application can deliver output in three different forms: 1) a PDF document for circulation to decision-makers, 2) an XML file for others to continue working with, and 3) a spreadsheet.

5.4 Software structure

The software started its life as a relatively “thin” wrapper around the XML file, the idea being that calculations and formulas where held in accompanying XSLT style-sheets, and XSLT transformations made the calculations. The idea was that formulas and calculations could be shared as XSLT files allowing for future expansion and flexibility. The software lived through quite a few iterations in this form. In the end it proved too slow to execute and too cumbersome to maintain. Thus, it was decided to rewrite the core of the program using a more “classic” approach. The XML file is now serialised and de-serialised from/to software objects, each XML element getting a corresponding code class with the necessary fields and members. The rewrite resulted in a core that can now update its results in real time.

The model that was finally settled on was in part a result of the initial analysis of the existing spreadsheet solutions, and in part a result of realizations that took place while implementing the model and features. A great deal of work went into modularising parts of the calculation and the different functionalities. By standardising the calculation at the lowest possible level, calculations at higher up levels avoid having to deal with ‘if/then’ scenarios, where the source of the data has to be accounted for. The exclusion of references makes it easy to edit the structures without having to synchronize with an external reference. External references are not entirely excluded as the format has a ‘code’ attribute meant to identify the account plan row in another context such as SfB or similar.

The reporting feature is based around the idea of a clear separation of data and presentation as it is known in HTML and CSS. It has been important to limit the intertwining of presentation data, and data needed for the presentation, so where presentation data is necessary in the project file, it has been moved to separate elements. Table 2 shows the elements that both the XML file and the internal software model shares.

Table 2: Description of the system elements

Elements	***Description***
accountplans	*Account plans are structured in main-groups, sub-groups and rows.*
basevalues	*Each row comes with the possibility to store key values obtained from real life use, used as a common starting point of the calculation.*
costdatabreakdown	*This element holds the account plans.*
inputvalues	*The input-values store the specific user data. There is one set of input-values per row per version.*
periods	*The general prerequisites are stored inside periods, the main one being "period-of-analysis". Future periods can exist next to the main "period-of-analysis".*
project	*A collection of the elements below.*
projectcollection	*A collection of projects. Typically describing the same building(s) in different development stages.*
projectcollectioninformation	*Metadata and comments, some of which are output to the report.*
projectinformation	*Metadata and comments, some of which are used in the report function.*
results	*Results are stored inside their relevant parent element.*
resultgroups	*A list of and labels for the common way calculations are posted.*
viewdefinitions	*A list of selectable views including their names and accompanying texts. The views are the parts that make up the PDF report.*
versions	*Calculation and value sets. The names and description of alternatives are listed here.*
versionresults	*The common calculation results are stored here. Because the results at this level are standardised into specific result groups, it is possible to compare results from projects structured differently structured.*

The calculation flow starts at the account plan <row> level and follows a bubble-up method:

1. Resolve the origin of values, and pick the correct set for the row + version calculation. Different account plans will have different value sets. As an example an "acquisition" account plan, will only have a "unit-price" value, while a "maintain-renew-and-restore" plan will have the values "amount", "unit-price", "lifetime", "maintenance" and "restore" values to calculate from. It is at this level that prerequisites and inflation rates are applied.
2. Calculate the acquisition cost (if relevant), and the indexed values, throughout the calculation period. Repeat this for each selected version.
3. While there are differences on the row level, results can now be treated uniformly from here on up. Sub-group results are simply sums of the underlying rows, main-group results sum up the sub-groups, and on the account plan level, main-groups are summed up as the top level of results of the plans.
4. The account plan results are then summed up and posted in the categories as described in the result groups.

Although the application has at the outset adopted the SfB classification scheme, the application is fully open to other classification schemes. Rather than waiting for a national committee to form consensus on a new national classification scheme for building parts, a choice was made to store data in an editable structure that can be customized at run time by the user. Consequently, the data files has been flagged in order to mark elements as 'locked', and the GUI edit features are turned off accordingly.

6. Conclusion

The principles of lifecycle costing or whole-life costing has been around for decades, but the implementation of the principles has been modest or even weak despite the obvious advantages of integrating maintenance, operation and management aspect into the design of new buildings and facilities. Based on the methodology of structured analysis and agile software development methodology, this paper reviewed existing tools and discussed (some of) the design choices and summarised lessons learned from the development of LCCbyg – a new tool for lifecycle costing launched in its first version by the Danish government in early 2015.

First, this paper provided a typology of existing tools into three categories with distinct characteristics and associated benefits and drawbacks: 1) Spreadsheets, 2) stand-alone applications, and 3) web services. A fourth type – apps for mobile platforms – is not yet relevant as a calculation tool.

Second, while the software interface only displays limited unique features and functionalities compared to other available tools, the data model inherent in the tool provides a number of unique design choices. These design choices make the tool highly robust to future development; incorporate a fully open standard in XML format for easy exchange with other applications; provide the users with a high degree of adaptability to their specific requirements; and reduce the need for an elaborate classification scheme for cost and building components that would otherwise severely restrict the adaptability of the tool.

Business Model Innovations for Low or Zero Carbon Building: An Analysis of Empirical Research from 1996 to 2015

Xiaojing Zhao,
Department of Civil Engineering, The University of Hong Kong
(email: xjzhao@hku.hk)
Wei Pan,
Department of Civil Engineering, The University of Hong Kong
(email: wpan@hku.hk)

Abstract

The low or zero carbon building (LZCB) approach has been promoted in many countries, however, the claimed environmental, social and economic benefits from utilizing this approach are often impaired or unrealized. Traditional organizational business models face challenges in the delivery of LZCBs, and require re-thinking in order to create and sustain competitiveness and economic value. However, there is a deficiency of previous research into the commercial viability of LZCB from the perspective of business model. The aim of this paper is thus to develop a conceptual model of business model innovation for LZCB, and to identify archetypes of business model innovations for LZCB and their general development trend over the study period. The research was carried out through a meta-analysis of the literature of business model and LZCB. Evidence was collected and examined from 98 empirical studies of business strategies and processes for LZCB and industrial or corporate reports on LZCB published during the period 1996 - 2015. Through analysing the collected qualitative data using Nvivo 10 and HistCite^{TM}, the paper develops a conceptual framework of business model innovation for LZCB, which compasses three core components: value proposition, value delivery and creation, and value capture. Business model innovations are explored from these three core components respectively to describe common patterns and mechanisms of business model innovations for LZCB. The evolution of business model is tracked based on the qualitative analysis of LZCB projects of industry players over a twenty-year period (1996-2015). The results show that organizations generally adopt three interrelated innovative approaches to promoting LZCB, namely, reconfiguration of value proposition for customers, reconstruction of delivery mode and stakeholder network, and innovation of revenue generation logic. The archetypes of business model innovation and business model evolution path support the successful delivery of LZCBs. The findings contribute to a systematic understanding of the relationships between business model and LZCB.

Keywords: Business Model, Low Carbon Building, Zero Carbon Building, Innovation, Data Mining

1. Introduction

The term ‘business model’ has gained substantial attention in literature and industry since the emergence of e-business and the so-called new economy boomed. Recent management and business literature has widely used this term as an effective management tool for companies’ value creation and company performance (Osterwalder, Pigneur et al. 2005, Bocken, Short et al. 2014). Broadly speaking, two types of uses of this concept are identified. On the one hand, the concept articulates a series of activities between different ‘building blocks’ to produce a proposition that can generate value for customers. Business model is closely related to a company’s competitive advantage and expresses the business logic of a specific company through designing business products, services and activities (Rasmussen 2007, APEC 2009). One the other hand, the business model construct has been utilized in the facilitation of technologies or innovations (e.g. Chesbrough and Rosenbloom 2002, Zott, Amit et al. 2010). An appropriate business model can increase the market attractiveness of a technology and transform certain attributes of innovation into sources of the economic value creation (Bohnsack, Pinkse et al. 2014). In this view, “progressive refinements” to business model (Demil and Lecocq 2010) i.e. business model innovations are required to adapt to the external environment and/or to create a competitive advantage.

The construction industry, nevertheless, is a sector where the concept of business model seems to be far underdeveloped. Discussions of business model in the construction industry are mostly embedded in the literature of competitive advantage, strategic management, and innovation. The building industry holds the promise to reduce carbon emissions and improve energy efficiency due to the enormous energy consumption the industry accounts for. According to IEA (2014), building blocks consume 32% of the total energy use worldwide. The carbon emissions of buildings are predicted to reach 42.4 billion tonnes in 2035 due to the continuous increase of buildings and the growing expectation of building services by occupants (USEIA 2014). A wide range of technological innovations, such as energy efficient technologies, renewable technologies, and microgeneration technologies, can be potentially used as a part of the solution for achieving low or zero carbon targets. Despite the conceptualisation of technical rationality, low or zero carbon buildings (LZCBs) still face challenges in penetrating mainstream building markets. The problems faced by business practitioners include that LZCBs challenge prevailing construction practices (Johnson and Suskewicz 2009), the lack of customer preferences and market attractiveness (ZCH 2010), and the requirement for new knowledge, experience and managerial expertise associated with LZCB (Pless, Scheib et al. 2014). It has been argued that, firms need different business models to address these problems and come up with new sources to generate economic value in addition to their contribution to environmental sustainability (Chesbrough 2007). However, the emerging ‘LZCB sector’ is still in search of viable business models. Various business models are being simultaneously experimented, trial-and-error learned within and across early adopters (Sosna, Trevinyo-Rodríguez et al. 2010, Teece 2010).

Compared to the widely reported benefits and up-take barriers of LZCBs, there is quite limited understanding of the building companies’ business models for the uptake of LZCBs. Firms’ processes of business model innovation and evolution is still vague. This paper thus aims to address these knowledge gaps by exploring the general development trend of literature in the fields of business model and innovation, the conceptual framework of business model innovation and its main constituents, main archetypes of business model innovation for LZCBs, and the evolution roadmap of business model evolution for LZCBs. The paper develops a structured approach to extracting and creating value from LZCBs by innovative business models. The research on which this paper reports was carried out through a meta-analysis of scholarly publications and LZCB project reports of key industry actors in the field of business model.

2. Methodology

This section describes the methodological approach which systematically locates and analyses the research related to business model in the field of LZCBs, from both academic journal publications and reports and magazines of industry and key project players. As shown in Figure 1, the research on business model not only explored and identified research thematic objects with classical approach, but also processed and structured the thematic objects and bibliographic data with text mining techniques. The two approaches are interrelated and mutually enforced with continuous feedback loops.

At Stage One, four criteria were applied in the literature survey to determine the research scope and time framework. To retrieve the bibliographic data, first, the term ‘business model’ is included in the title of the paper. In view of massive articles on the subject of business strategy and business management, the search eliminates papers that only make an incidental references to business model. Second, to ensure the quality of the data, scholarly peer reviewed articles were retrieved from the Web of knowledge database, while proceedings, book reviews, commentaries, reports, and working papers were excluded. Third, since the research focus is LZCBs, the research areas were limited to “business economics”, “engineering”, “operations research management science”, “energy fuels”, “environmental sciences ecology” and “construction building technology”. The journals that have no concern on the construction sector were eliminated from the search results. Fourth, since the nature of the research is primarily empirical, the paper searched for and extracted business cases for LZCB projects, covering trade magazines and corporate/project reports, which provides detailed descriptions of LZCB projects and associated business models, and offers insights into perceptions and business strategies towards LZCBs. The search period starts from year 1996 when the number of LZCBs increased at a clear growth rate (see Pan and Ning 2014).

To conduct meta-analysis of the data retrieved at Stage 1, a two-phase approach was applied in the following 3 stages. At the first phase (Stage 1 and 2), the bibliographic data from Web of Knowledge was analysed with HistCite^{TM} software to give an overview of the research field over the study period. The abstracts and author keywords were further analysed to extract the most frequent terms and phases. The results indicate the main themes and components of business model innovation, which provide a comprehensive basis for the development of the conceptual model of business model innovation.

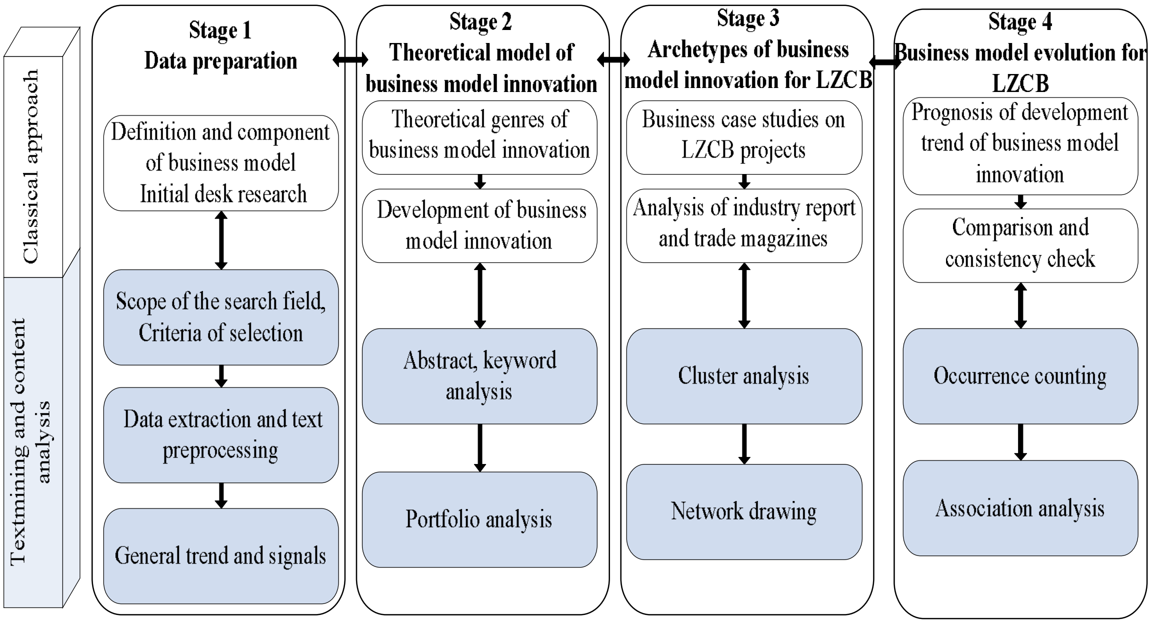

Figure 1. A meta-analysis-based process model adopted in the paper

At the second phase (Stage 3 and 4), qualitative data analysis software Nvivo 10 was used to organize and analyze data of empirical studies from academic articles and trade periodical/reports. First, the information that connects to the main components of business model innovation was labelled and structured according to the conceptual model. The objective of this step is to derive the archetypes of business model innovation in the context of LZCBs. Second, the occurrence number of business model innovations at the core themes of business model innovation will be counted and statistical analysed to give an overview of the development trend of the identified archetypes of business model innovations. Business models of large firms and small and medium enterprises (SMEs) that have delivered LZCBs were traced over the timeline in order to generate the roadmap of business model evolution regarding LZCB development. The contingent events were also identified, the effects of which were examined by exploring the explanatory power of the events on the LZCB market evolution in chronological order.

3. Findings

The main findings of the study are presented in this section, which are centered on the general trend of business model, the conceptual model of business model innovation based on the dominant themes emerged from bibliometric analysis, and the archetypes of business model innovation for LZCB and their evolution.

3.1 Profile of research on business model and LZCB

Before exploring the theoretical framework and archetypes of business model innovation for LZCBs, the paper detects the origins and particularly the surge of the business model documents. The paper searched the titles of scholar articles in the Web of Knowledge database for the word string "business model". The number of the search results is shown in Figure 2.

According to the search criteria and screening process, the search results include 483 articles published in 299 journals in the field of business model in total from 1996 to 2015. The query suggests that the term "business model" rose to prominence until the middle of 1990s in the construction sector, though it appeared in an academic article in 1957 (Bellman, Clark et al. 1957). A general growth trend can be observed in the publications on the topic of business model.

In the field of LZCB, the paper identified 639 papers that featured "low OR zero carbon OR carbon neutral* OR sustainab*" and "building OR home OR hous* OR project" in their titles. There is a significant trend of growth of the number of academic articles during year 1986 and 2005. Most of the articles that reported the environmental aspect only focused on the element of carbon emissions or energy consumption. The contribution of LZCBs on the environmental aspect was consistently the main theme of the majority of the articles.

In the field of intersections between business model and LZCB, however, a limited number of articles can be obtained from the database. After the screening process, a total of 98 articles were retrieved from the database, which were validated to be concerned with the business models of LZCB. The results of this step illuminate the knowledge gap on business model for LZCB, and generate the first inputs for generating a conceptual framework of business model innovation.

3.2 A conceptual framework of business model innovation

The components and process of business model innovation have been emphasized and widely studied in the recent decade. In the business and management discipline, the literature in this stream examines the innovations of business model from two perspectives: activity-based approach and value chain-based approach. The activity-based approach characterizes the innovations of business model as a system of interdependent activities reacting to environmental changes. Afuah (2004) described a business model as the set of activities a firm performs, the way the company performs them and complemented assets supported these activities. Zott and Amit (2010) defined the term 'business model' as an activity system supported by the focal firm and its partners. Artto, Wikström et al. (2008) analyzed business models of project-based firms, and identified the impacts of services on business model innovation from the project delivery process.

The other stream of research conceptualises business model innovation as a flow of value chain. Osterwalder and Pigneur (2010) described a business model as "the rationale of how an organization creates, delivers, and captures value". Lenssen, Bocken et al. (2013) developed a value mapping tool for sustainable business model, and examined the business model innovation by mapping the value captured, missed, destroyed and opportunities of sustainability. Demil and Lecocq (2010) developed a RCOV framework of business model (resources & components, value proposition, organization) and viewed business model evolution as fine-tuning process involving changes both within and between its main components.

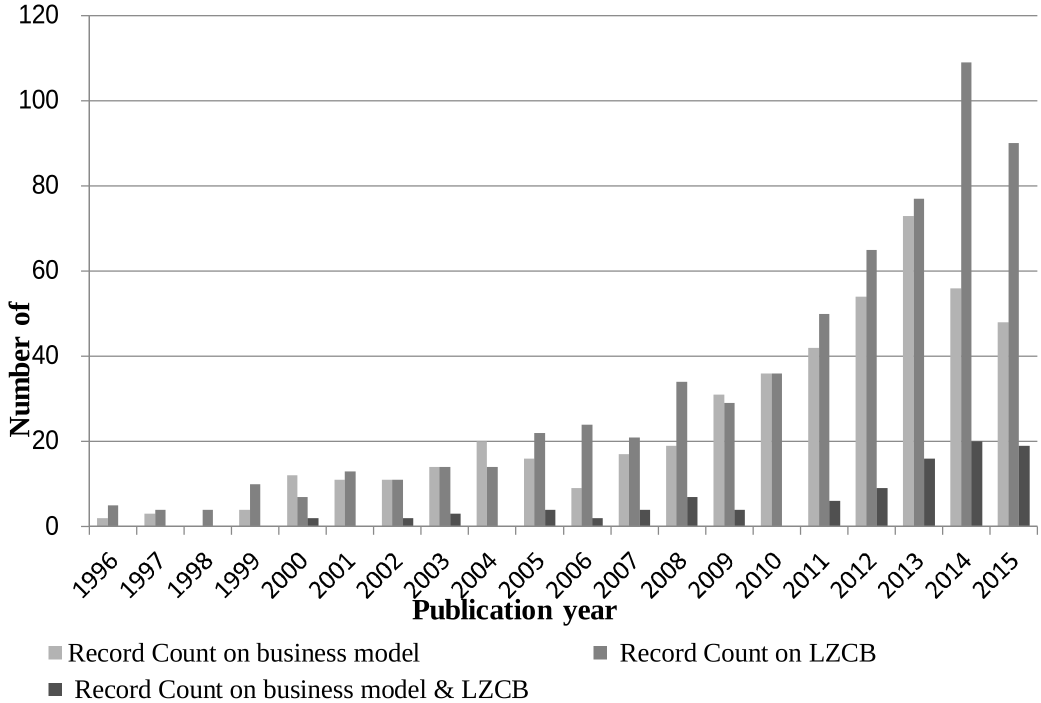

Figure 2. Recent development of research in the field of business model and LZCB over the timeline

While the two dominants logics of business model innovation have been established in the management discipline, the novel part of this section is to verify the theoretical assumption in the field of LZCBs through text mining of abstract phases and keywords in the bibliographic data derived at Step 1, and to identify recent themes/components of business model innovation for LZCBs. Figure 3 shows a word cloud map and a frequency table of the top 50 terms.

Figure 3 and Table 1 show the key areas of business research on LZCBs. Topic related words (sustainable, building, business, model, innovation, project, green, etc.) and stopwords (using, based, provide, study, paper) were removed since they are general and display no content.

Figure 3. Word clouds of top frequent terms from 1996 to 2015

Table 1. *Frequency table of top 32 terms in abstracts and keywords*

Terms	*Frequency*	*Terms*	*Frequency*	*Terms*	*Frequency*
develops	*194*	*production*	*61*	*operation*	*49*
design	*115*	*service*	*59*	*household*	*49*
environmentally	*93*	*cost*	*56*	*urban*	*49*
managing	*71*	*systems*	*55*	*construction*	*48*
industry	*66*	*economic*	*55*	*city*	*47*
value	*64*	*social*	*54*	*markets*	*45*
technology	*62*	*efficiency*	*53*	*environments*	*44*
policy	*62*	*governments*	*53*	*organizations*	*44*
pricing	*62*	*process*	*52*	*engineering*	*39*
performance	*57*	*plans*	*49*		

The terms "household", "market", "value", "performance", "service", and "environmental" closely relate to products/ services that are provided to the customer/occupants sector, i.e. 'value proposition'. Terms such as "plans", "develop", "design", "manage", "construction", "organization", "engineering", and "process" describe the delivery process of LZCB projects, and organizations and stakeholders that are involved in the value delivery process. This category of terms can be attributed to "value delivery and creation". 'Value capture' is another element that was emphasized in Table 1. "Pricing", "cost", "economic", "urban", "government", and "market" portray the structure of cost and revenue, which include building scales, pricing and financing strategies, government incentives, and any additional incomes. Combining the analytical results above, the paper structured the conceptual model of business model innovation for LZCB as three interrelated components: value proposition, value delivery and creation, and value capture, as shown in Figure 4.

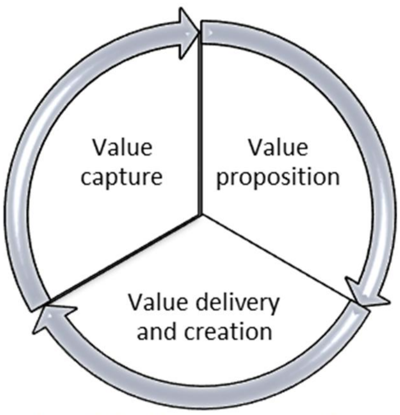

Figure 4. Conceptual model of business model innovation for LZCB

3.3 Business model innovations for LZCB: archetypes and evolution

Firms' experiences and related complemented resources and networks in empirical studies were examined in this section. Based on the developed conceptual model mentioned above, archetypes of business model innovations have been identified from the three main components respectively. The archetypes in the category of 'value proposition' (LZCBs and related services provided to target customers) can be distinguished from variations in building types/purposes, scales and contents of product/service. For the 'value delivery and creation', this paper tracked changes in the modes of LZCB development and delivery, and associated stakeholder networks. The activities in the value creation process depend upon the range of value proposition, may cover the land acquisition, design, preconstruction, construction, operation, demolishment and recycling phases. With regard to the 'value capture', this paper explores how LZCBs were brought to the market, how firms compensate cost from the revenues schemes, and whether there were financing reimbursements and government incentives supporting LZCBs. The archetypes in the three categories are summarized in Figure 5.

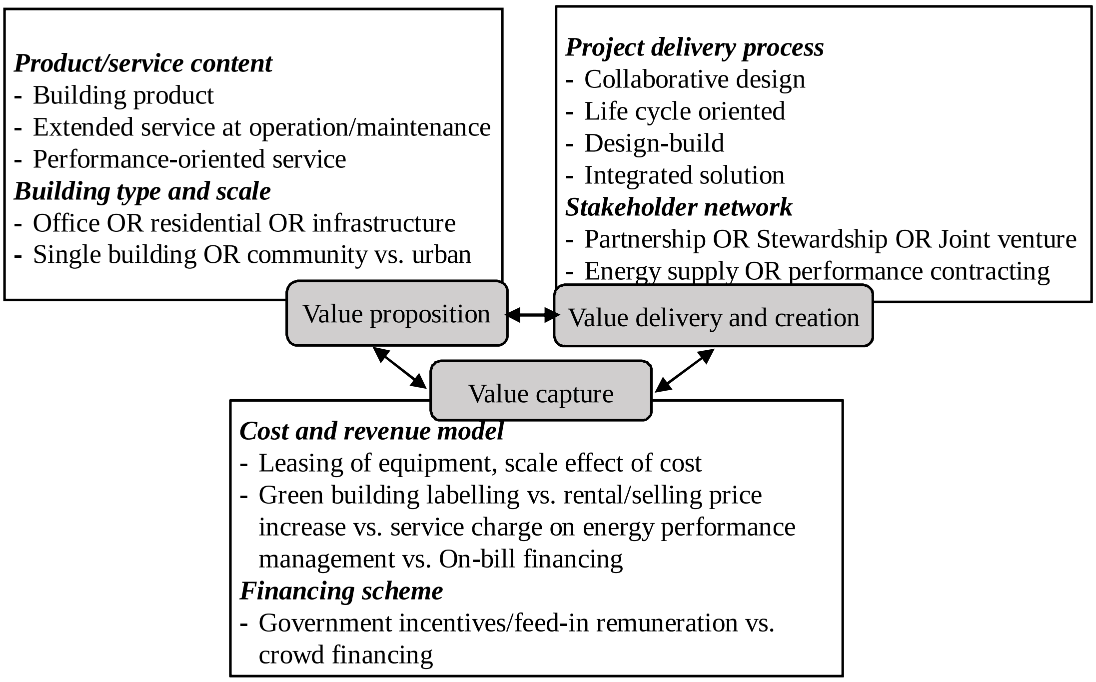

Figure 5. Main archetypes of business model innovation for LZCB

Value proposed to building owners and occupants locates at the centre of a business model structure. Evidence from studies proved a range of -0.4%-12.5% higher building cost for LZCB compared to conventional code-compliant buildings (WGBC, 2013). To prove the LZCB assets value to customer and improve customer acceptance is therefore the foremost issue for developers. Depends on the building type and purpose, higher sale prices/lease rates, lower life cycle cost, and improved indoor air quality and resulted improved productivity have been demonstrated in various resources. In addition, supported by product service system theory, companies have extended their value proposition from building itself to a combination of building products and services in operation and maintenance stage. In this way, developers have shifted customers' focus from building ownership to use-based functionality. Measured by the building scale addressed, the majority (63%; 75) of the identified articles targeted their research object to a single building, and some (17 and 21 respectively) examined community scale LZCB and urban scale LZCB. The identified research by building type was mainly contributed by the articles examining residential buildings (38%; 45) and the commercial buildings (35%; 41), with marginal contribution from those studying multipurpose buildings (7%; 9). Among the studies addressing the product or service provided to end-users, aside from the vast majority of research addressing LZCB itself, one half (50%; 59) examined the extended service provided to customers in a building's life cycle process. This result reveals the significance of customer-oriented service after commission, which is consistent with the emphasis of the group of articles regarding users' concerns on building performance (47%; 56).

To successfully deliver LZCBs in the value creation process, companies should make full use of available resources and capabilities within project delivery processes and stakeholder networks. Key strategies in the delivery process identified from the dataset include: collaborative design, integrated solution, proactive contracting, value recycle from 'waste', and design-build mode etc. Since most building stakeholders' knowledge on LZCB is minimal at current stage. To design functionally low or zero carbon, the collaborative inputs of all specialists are proved to be successful in multiple projects. Opinions are sought from clients, designers, architects, community and end-users to optimize design solution for best performance. In addition, proactive contracting such as design-build mode has been adopted in LZCBs project to maximize contractors' inputs and improve the project time performance. Correspondingly, firm actively expand its stakeholder network through partnership, stewardship and Joint Venture. To proactively engage with stakeholders and keep a stable long-term relationship, companies have managed to improve the cost efficiency, and maximised its positive societal and environmental impacts.

By project delivery process, the largest group of the business model articles for LZCB focused on the examination of design stage (52%; 61), followed by the group mentioning the construction stage (38%; 45), and operation and maintenance stage (24%; 61), while very few examined business models of LZCB from the supply chain and project planning stage. The collaborative design and integrated solution are emphasized in the articles examining design stage and delivery mode, the number of which reach about two fifth (52) of articles. Moreover, the life cycle oriented solution is another salient point in the literature, almost one third of the articles were concerned with the lifecycle impact of LZCB and life cycle oriented design.

Innovative financing and revenue schemes help create LZCB case if these innovations help to overcome the relatively higher upfront cost. Aside from loans and government incentives for low or zero carbon, new schemes have been employed, such as equipment leasing, crowd financing, pay-per-use, ESCO model, and green building benchmarking. Over one third (44; 37%) of the articles addressed the governments' role in the delivery of LZCB, which includes government incentives, feed-in tariff schemes, and remuneration. While a relatively small number of articles have reported the use of utility manager (17) (such as ESCO) in the operation stage and the green building labelling (11) as innovative revenue models.

From qualitative analysis of LZCB practices of key industry players over the timeline, firms generally take their existing business model for conventional building projects as a starting point to incremental adjust and refine, in order to bring LZCBs in their business domains. Due to variations of firms' scales, history backgrounds and complemented assets, firms have different abilities to tap into LZCB business and react to change initiatives at external environment. Incumbents and entrepreneurial firms adopt different. Relying on the economies of scale and well-developed partnership network, large established firms have ability to experiment LZCB projects with multiple business models simultaneously, fine-tune and select the standard business model for LZCB in future. The future target of these firms is to achieve production scales with LZCB and optimize cost efficiency.

Compared to large incumbents, small and medium-sized enterprises (SMEs) in the building sector are less constrained by their dominant business model. The novelty is their main value proposition for customers. However, due to the relatively vulnerable customer base and assets, they are more susceptible to external incentives and contingent events. Generally, SMEs are most likely to test a single business model at one time. In the value delivery process, SMEs are more agile to cooperate with outside partners, and make use of their expertise and knowledge. For the value generation logic, SMEs have to explore innovative ways to fund the projects. Aside from loans and capital investment, green building certification, on-bill financing, and government incentives such as feed-in remuneration schemes and have been applied in the financing and revenue strategies.

4. Conclusions

This paper has examined the literature of LZCB and business model and industrial practices of LZCB during the period 1996-2015 through a structured meta-analysis. One conclusion of this paper is that a significant knowledge gap has been identified between the fields of business model and of LZCB with regard to their general development. This knowledge gap is evidenced by the remarkable difference in the quantity of relevant publications. Although there has been a general growing research interest in both the fields of business model and LZCB separately, research that integrates the two is limited. Another conclusion of the paper is that from the analysis of the key terms used in abstracts and keywords, three thematic focuses have emerged, i.e. value proposition, value delivery process, and value capture. These themes together form a conceptual framework of business model innovation for LZCB. A further conclusion of the paper is that through the analysis of the detailed contents and empirical data, archetypes of business model innovation have been explored from the three emerged core components. Two different paths that large firms and SMEs have adopted to evolve their business models for LZCB have then been identified over the timeline.

The findings of this paper illuminate effective mechanisms that firms can adopt to promote LZCB and help detect the future trend of LZCB development. Future research should explore the interdisciplinary field of business model innovation for LZCB, which has been identified as a knowledge gap. It should help to track the trajectory of business model innovations and examine their relevant impact on the delivery of LZCBs.

Real Estate and Construction Management, KTH, Royal Institute of Technology
vahenurm@kth.se

Abstract

Building information modelling (BIM) is believed to improve the information management flow through the whole life cycle of the building. In current practice, benefits of BIM are generally used at the design and construction phases. Despite the progress of BIM technologies and practices, product data management (PDM) is neither well known nor common in the industry. There is a need for product libraries that are software neutral including standardised data content and structure, in order to provide consistent and unbroken flows of information through the whole life-cycle of buildings. Examples from other industries (e.g. mechanical engineering) could encourage the development of product libraries. The product libraries that exist today for construction projects are primarily software specific and directed to various user groups and cause interoperability issues when used over time and between actors. Enhanced and standardised libraries would potentially increase sustainability in the construction. This paper presents the current state of BIM product libraries for the construction industry (in BIM mature countries) in the context of information format (proprietary or open), content (generic or manufacturer specific), structure (level of granularity for geometry and information), provider (software vendor, commercial, or in-house), and usage (project phase, contract type). Finally a proposed framework with through life support is presented based on existing open international standards, life cycle phases and the high level building classification framework standard ISO 12006-2.

Keywords: BIM, Product Library, Level of Detail, Level of Information, Life cycle support

1. Introduction

There is a growing interest in developing product libraries internationally. The actors are national bodies, manufacturers and specialist companies who see a potential in the market, but do not address the issue of production and distribution of product information for the emerging open BIM software systems. The main developments of library objects, called BIM objects in this paper, are addressing proprietary formats supporting only one or few software systems. This increases the cost of populating product libraries as multiple formats must be supported and also increases the difficulties maintaining them over different platforms and over time (Duddy et al., 2013). Different contract types use generic and manufacturer specific BIM objects differently over the life cycle of the construction projects – and possibly also during operation and maintenance, see Figure 1, which illustrates when generic and manufacturer objects are generally used in different delivery methods during the project life cycle (Vahenurm, 2014).

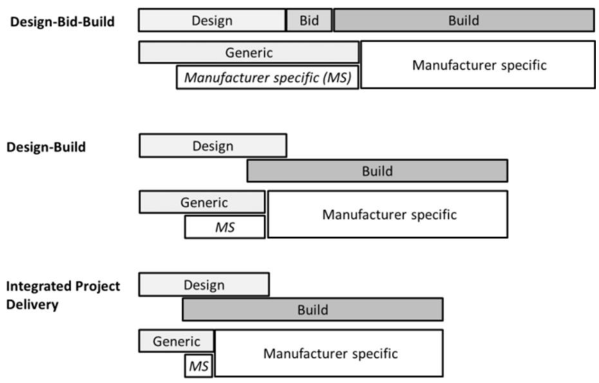

Figure 1: Project delivery types and use of Generic and Manufacturer specific BIM objects (Vahenurm, 2014)

There are several different types of product libraries with BIM objects available and suitable for different phases of the construction projects, depending on the level of specialisation of geometry and information linked to the objects in the library. Some typical examples are:

· CAD/BIM libraries	coming with the design software – generic BIM objects
· Product type libraries	compiled by different associations – standard components in industry segments, e.g. ducts
· Manufacturer's libraries	manufacturer specific products
· Project libraries	project specific, selected for the project
· Company libraries	in-house preferred, selected from old projects

These libraries have very different structures, content and formats and they have also limited support for different levels of detail and information. There is lack of open BIM product information in well-structured and rich information content libraries supporting the whole life cycle of products and buildings.

1.1 Background

Several studies have been carried out regarding product libraries with the focus on accessibility to product information from manufacturers and beneficial ways of interacting with product information (Amor et al., 2004). One of the criterions for comparison of content in the different libraries is the level of definition (LOD) as defined by the American Institute of Architects. For building products, this can be summarised as LOD 200 indicating the approximate size and position of a product or construction type through increasing levels of detail to LOD 400, which is a fully detailed definition of the product/construction type to be installed. LOD 500 is reserved for a verified on-site installation. (Duddy, et al., 2013). The problem is that there are very different interpretations and definitions for these concepts, as well as how and when to use them during the construction process. Amor et al. (2004) state that the following issues are remaining barriers to the uptake and development of online product libraries: ***Products' data representation, Extraction of data from manufacturers, Business models for online catalogues, Contextual impact of project requirements, Mapping between representations, Support for preferences, Life-cycle support.*** Until these barriers are overcome we can expect our access to powerful online identification and incorporation of manufactured product information to be severely constrained (Amor et al., 2004).

1.2 Purpose and Method

This study is focusing on presenting the current state of BIM product libraries supporting the construction industry and the barriers for a wider uptake. The context is information format (proprietary or open), content (generic or manufacturer specific), structure (level of granularity for geometry and information), provider (software vendor, commercial, or in-house), and usage (project phase, contract type).

The research question is: How can a framework for through life support of BIM objects, based on existing open international standards, life cycle phases and a high level building classification framework standard, be a solution to overcome barriers to the uptake and development of online product libraries?

Method: The study was carried out as a review of literature in journals and conferences on BIM product libraries. Also implementations of BIM product libraries in Europe and Australia were reviewed and analysed, as being in the forefront. Planning, implementation and operation of product libraries were in focus. The study started in June 2014. The findings were used as requirements for an object model framework for through life support of BIM objects. They were compared with the life-cycle support for open BIM at the BIM Collaboration platform and experiments carried out at KTH, Royal Institute of Technology (Tarandi, 2015).

2. Definition of used concepts

Product library – "a storage were information about products can be found and accessed." (Stangeland, 2013). As no formal definition exists, this can be a starting point. The content of a Product Library should be products corresponding to BIM objects in the BIM models used in the construction processes. The products have geometry, which can be parametric, and they can have properties with units and values. The classification of objects and properties is vital, and is preferably defined by a dictionary, like buildingSMART data dictionary (bSI, 2015). Today no common guidelines or open standards for BIM object libraries are implemented and used (Palos et al., 2014).

BIM objects - The product objects in a BIM, Building Information Model, are also called BIM objects and they have a geometric representation of physical products and can be high-level assemblies at various levels of detail, including specific products (Eastman, et al., 2011). The granularity of the BIM objects should be matched with the International framework for Construction classification ISO 12006-2:2014 (2014) to fit industry practice for bill of quantities and construction planning.

3. Development of product libraries

Paper catalogues including descriptions, parameters and illustrations were substituted with electronic online product libraries (Amor, Jain & Augenbroe, 2004) when information technology solutions improved. Today, several providers have started to offer online BIM orientated product libraries which include BIM objects with different levels of geometry and information. Some examples are NBS National BIM Library, BIMcomponents, BIMobject, and SmartBIM. More BIM libraries are presented in Table 2. The product libraries that exist today are primarily software specific and directed to various user groups (Palos et al., 2014 p. 59).

There are several ways how to categorise Product Libraries. Succar (2009) states that interchange can occur in three main ways; proprietary (e.g. Revit file – RVT), open-proprietary (e.g. DWF and many XML schemas), and non-proprietary which is open (e.g. IFC and CIS/2). This paper categorises Product Libraries by the following:

1. **Content** – Products (objects) can be (Stangeland, 2013):
   a. Generic
   b. Manufacturer specific
2. **Content's format**
   a. Libraries containing PDF sheets and/or 2D drawings in e.g. PDF, DWG formats
   b. Proprietary Product Libraries – 2D & 3D CAD and BIM software specific formats like DWG, RVT etc. Here also the open – proprietary formats ca be included
   c. Non-proprietary Open Standard Product Libraries – e.g. IFC, bSDD formats
   d. Multiplatform Product Libraries – Proprietary and open formats mixed
3. **Provider**
   a. Software vendors
   b. Associations (e.g. ventilation product manufacturers)
   c. Commercial providers – manufacturers, suppliers, wholesalers
   d. Private AEC companies – have created in-house Product Libraries

The Manufacturer specific products can be designed and produced in alternative ways, and this influence when they have to be ordered and when they can be delivered to the construction site. MTO (made-to-order) components are usually produced as needed due to the short shelf-life and high inventory costs. ETO (engineered-to-order) elements involve more specific design, while the suppliers of MTS (made-to-stock) and MTO components are rarely involved in installation phase as the components are designed for general use. Generally the elements available on BIM platforms are generic and do not describe specific manufacturer's components and do not include product specific information. Product type from a manufacturing and supply chain point of view is also influencing the accessibility of the product information. They are ETO, followed by MTO, and then ATO (assembled-to-order), finally MTS products, as shown in Table 1

(Zeng et al., 2015). It is based on CODP (Customer Order Decoupling Point) classification thinking.

Table 1: Types of product, according to CODP, after Zeng et al. (2015)

CODP	Product Example	Lead Time	Stock
ETO	Power distribution equipment, Preassembled rebar components	long	no
MTO	cast-in-place concrete, prefabricated panels	long/short	no
ATO	doors, windows	short	yes
MTS	consumables such as bricks, bolts	short	yes

Several countries, including UK and Australia, have set requirements or recommended to adopt BIM in the public projects. This has initiated another form of product libraries supported by national institutions. One example of Open standard libraries is IFC Product Libraries that are supported by product information from templates and bSDD (Stangeland, 2013). Table 2 below is an overview of proprietary and multiplatform Product Libraries. Work by Eastman et al. (2011) has been updated.

Table 2: Overview of Proprietary and Multiplatform Product Libraries

4. Standards

Standardisation is especially important for product libraries, as there often is a change of actors when going from design to supplier specific products in the BIM (Berlo et al., 2015). Palos et al., (2014) state that there is a great need for a product library standard in the construction industry. The purpose of the standard is to determine what products should be contained in the libraries, what properties are required and how libraries are supported by different classification systems (Palos, et al., 2014). Also Nummelin et al. (2011) state that enhanced and standardised libraries would potentially increase sustainability in the construction industry. Three important standards/groups of standards for BIM product libraries are described in the following paragraphs.

4.1 ISO 12006-2

Internationally, the ISO 12006-2:2014 (ISO, 2014) standard is a framework for classification for organising the information about construction works. It defines the granularity of building elements, work results and products to fit the manufacturers' products and their classifications.

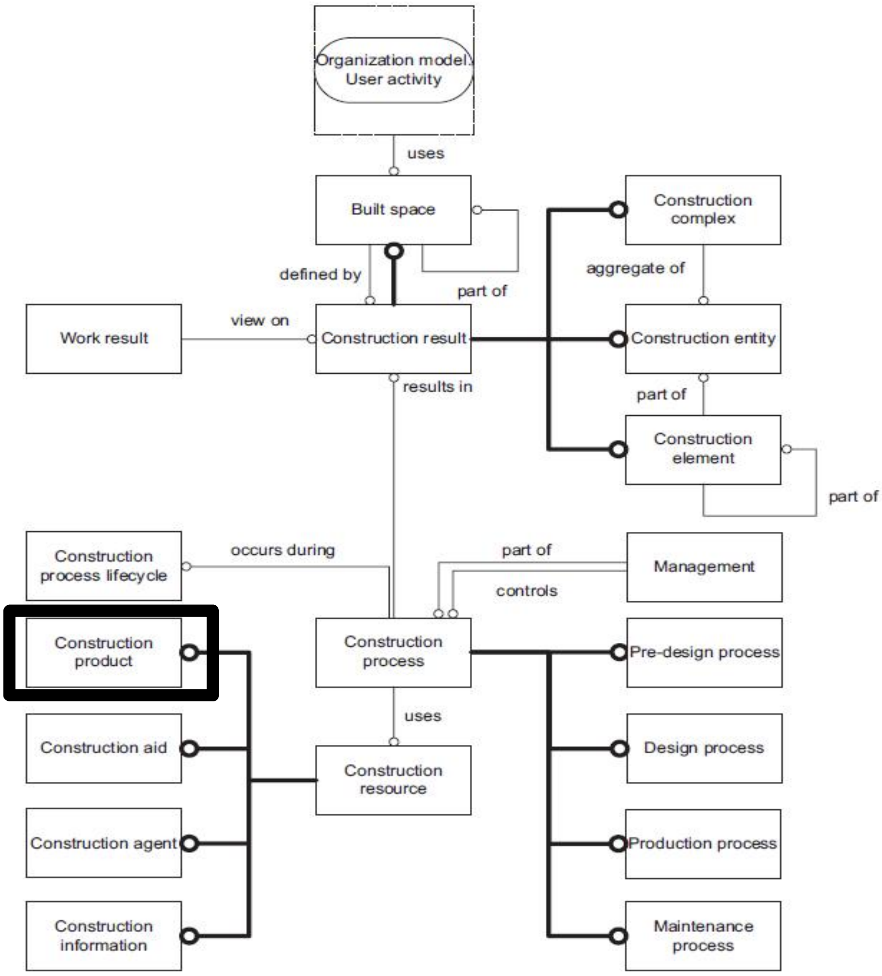

Figure 2: ISO 12006-2:2014 (ISO, 2014) Construction product in relation to Construction resource

The standard is for “Organisation of information about construction works and is implemented in many national classification systems” (ISO, 2014). The Construction product entity is a Construction resource with a relation to the Construction result, which can be a Construction complex (e.g. airport), entity (building) or element (window). In Figure 2 the Construction product is highlighted.

4.2 buildingSMART International open standards

buildingSMART International (bSI) is a worldwide standardisation organisation driving the transformation of the built environment through creation and adoption of open, international standards (bSI, 2015). IFC is a building product data model for building planning, design, construction and management (Eastman, et al., 2011). In addition to IFC and bSDD (IFD), buildingSMART has three other basic methodology standards, Information Delivery Manual (IDM), BIM Collaboration Format (BCF) and Model View Definitions (MVD).

ISO 12006-3:2007 (2007) “Building construction – Organisation of information about construction works – Part 3: Framework for object-oriented information” is known as buildingSMART Data Dictionary (bSDD) and describes the meaning of information that is exchanged.

4.3 PLCS, Product LifeCycle Support

The business objects in PLCS, ISO 10303-239 (ISO, 2012) cover the whole life cycle for products, with the goal to support the maintenance, influence the design, development and production for maintainability and finally influence the requirement improvements for the coming projects.

5. Levels of development, detail and information

While the concept of LOD is gaining popularity as more projects are required to be delivered in BIM, the definition of what LOD levels mean and how they should be used is getting more interest. Moreover, there are different meanings of LOD. This can stand for Level of Development and Level of Detail. One possible view is that Level of Development is better to represent the LOD as it can be thought as a combination of geometry (detail) and non-geometric content (information), while Level of Detail mainly represents the geometry. The need to properly define the concept of LOD is stated by Berlo et al. (2015). Today the industry participants are still asking for different LOD models and everyone has their own idea what the LOD model is. It is not clear what kind of information should be available in a model on a particular level.

“Level of Development is the degree to which the element’s geometry and attached information has been thought through – the degree to which project team members may rely on the information when using the model” (BIMForum, 2013). Berlo et al. (2015) described the Dutch National BIM Levels of Development and the 7 levels of development as having only limited adoption by the industry. In a new research (Berlo & Bomhof, 2014) the result show that the Levels of Development were used, but the names of the phases they represented could not be agreed upon. In the collaboration between multiple partners it should be required to know exactly what the model can be used for, what data in the model is definite, and what confidence level is appropriate for the model? Level of Development (LOD) is a measure how seriously the information presented by the BIM object can be taken (McPhee, 2013). It is not a measure of the amount or accuracy of graphical information, rather the level on trust of the data that can be assigned to a BIM model. It should be clear what information to have in the model to perform a specific task (Berlo et al., 2015).

Level of Detail is a measure of the amount of information provided (quantity). Level of Development cannot exist without Level of Detail. In reality the Level of Detail might be the highest at the beginning of the project while the Level of Development is the lowest. This is in the stage where the design is being sold to the client and the stake-holders. In documentation phase one usually wants to keep Level of Detail low while Level of Development is high (McPhee, 2013).

Level of Information: UK standard PAS 1192-2 (BSI, 2013) “Specification for information management for the capital/delivery phase of construction projects using building information modelling” (BSI, 2013) specifies the requirements for achieving building information modelling (BIM) Level 2, according to UK BIM implementation. PAS 1192-2 defines two components to the level of definition:

- Levels of model detail (LOD), which relates to the graphical content of models.
- Levels of model information (LOI), which relates to the non-graphical content of models.

In this definition the LOI (information) is developed in parallel with the LOD (detail).

6. Life-cycle model

From a life-cycle perspective it is important to have an unbroken information flow. The different phases of the life-cycle for a construction project and the construction itself need to be represented by several unique objects over time. The designed physical element, fulfilling requirements through its function, the product realising the technical solution and finally the product as realized with its serial number (not for all products). This is studied and realized in the BIM Collaboration Hub at KTH (Tarandi, 2011). This requires interoperability through open standards and effective product data management. The presented Plans of Work in Figure 3 are only to be seen as examples of the life cycle stages. Many development projects are ongoing in UK now, and several examples are taken from these like the “resolving of objects at different levels” by Gelder (2012). The following references have been used for the diagram in Figure 3: RIBA Plan of Work 2007 (RIBA, 2008), RIBA Plan of Work 2013 (RIBA, 2013), A report for the Government Construction Client Group (BIM Industry Working Group, 2011) for the Data

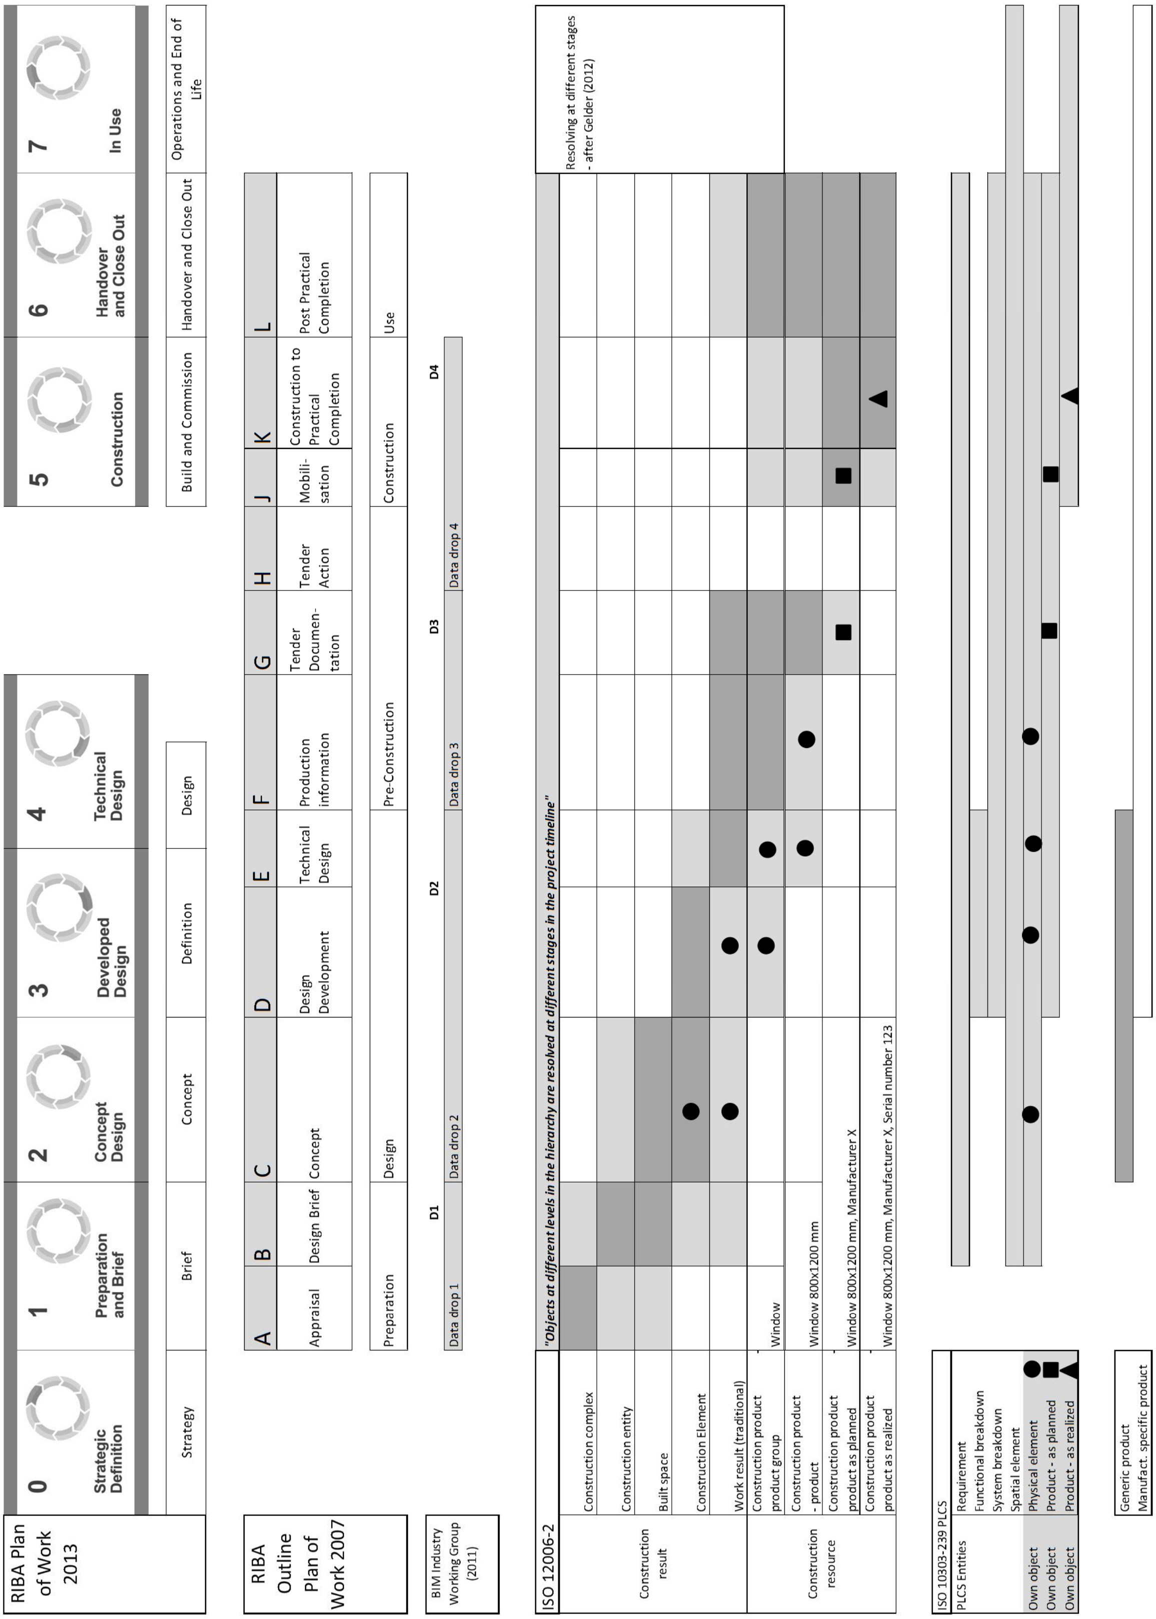

Figure 3: Life cycle framework based on through life support for BIM objects over all the project phases

drops, ISO12006-2 (ISO, 2014), and PLCS ISO 10303-239 (ISO, 2012) for the physical elements, products – as planned and products as realized.

The shaded fields are illustrating the plausible process phases where the different elements in the construction complex from the building (Construction entity) down to the Construction product – as realised - fit. Gelder (2012) explains it as "Objects at different levels in the hierarchy are resolved at different stages in the project timeline". Darker grey means more plausible than the lighter grey. At the bottom the PLCS entities, based on the studies of implementing them in the BIM Collaboration Hub (Tarandi, 2015), are outlined over time to present where BIM objects for different life cycle phases can be managed. The point in time when they – physical element, product and product as realized – are created and used vary depending on contract and project type.

7. Discussion

In the study, the state of and requirements on BIM product libraries for the construction industry gave the answer, there are many alternative developments without open formats being implemented in a consequent way. The granularity standard is fundamental for linking BIM objects from Product libraries to a life cycle supporting BIM model. Many different library types without common metrics for classification of products and properties. Most of the barriers presented by Amor et al. (2004) are still there. Some of them like ***Life-cycle support, Mapping between representations,*** and ***Products' data representation*** can be managed with the life-cycle framework presented in paragraph 6.

Level of Development – geometric and non-geometric information are equally important (Berlo & Bomhof, 2014), but no agreements have been made on international level on how to combine Level of Development and Level of Detail. The information content of the BIM objects which should capture information for different life-cycle phases matching Level of Development both with regards to geometry and properties supporting analysis, simulation and visualisation is not there. The following questions are still open:

- How is transition between different levels of development for BIM object realised?
- What information exists in current libraries?
- How is information delivered to the libraries?

Also these barriers can be eliminated by the life-cycle framework as all these states and definitions can find a place based on granularity, context and life-cycle phase in the framework. The physical element in the design, the product as planned and finally the product as realized on site.

8. Conclusions

The industry should have a clear understanding of what the model should be used for, what data in the model is definite and what confidence level it has in order to have more efficient collaboration between the industry actors. The Level of Development can be seen as the degree to which project team members may rely on the information when using the model. In Level of Development the geometry and non-geometric information are equally important. To make this operative in industry there is, still is, a need for continuing the work on coming to international agreements on how to structure these concepts and also very important – to link it to the life-cycle of the projects. The proposed framework with through life support based on existing open international standards, life cycle phases and the high level building classification framework standard ISO 12006-2 can be one way of managing the BIM objects over the projects, even before the issue of Levels of D has been resolved. The life cycle platform presented is capable to support the unbroken information flow over all the life-cycle phases!

wuzezhou88@gmail.com

Abstract

Nowadays, there is an increasing demand for sustainability in construction industry. As significant efforts have been made on reducing operating energy, the share of embodied energy is increasing from the lifecycle perspective. In order to reduce carbon footprint caused by embodied energy, stakeholders should make more optimized material purchase schemes in the design stage. An environmental product declaration (EPD) provides environmental data of a particular product, thus it can serve as an effective tool to assist decision-makers in selecting environmentally friendly products. The aim of this paper is illustrating how EPDs can be used to assist stakeholders in designing buildings with low-carbon footprint. In addition, the concept of carbon footprint index (CFI) is introduced in this paper. CFI can be used as a threshold in a green building rating system for evaluating the cradle to gate embodied energy of a building. A two-story office building with concrete frame structure is used to illustrate the application of EPD in selection of concrete products. The results show that selection of concrete with low carbon footprint can reduce the CFI by 68%.

Keywords: carbon footprint, environmental product declaration, concrete, cradle to gate

1. Introduction

Construction industry is one of the largest consumers of natural materials. According to the Worldwatch Institute, buildings consume three billion tons of raw materials annually, accounting for 40% of the global consumption (Roodman and Lenssen, 1995). In the United States, the situation is even more severe, the Environmental Protection Agency (EPA) reported that the raw material consumption from construction activities contributes to 60% of the national demand (EPA, 2012). Meanwhile, the proportion of energy use in construction industry is higher than other sectors. According to the National Trust for Historic Preservation (NTHP), the energy used in buildings is about 41% of U.S. primary energy consumption, while the industrial and transportation sectors represent 30% and 29%, respectively (NTHP, 2012).

Echoed with the large resources and energy consumption, construction industry imposes serious impacts to the environment due to unwanted discharging, such as waste, greenhouse gas, etc. In the United States, it is estimated that the amount of waste generated from construction related activities reached 170 million metric tons in 2003, which is equal to 1.45 kilogram per capita per day (EPA, 2009). The large amount of construction waste may cause pollution to air, water, soil, and thus further affect human health (Wu et al., 2013). Greenhouse gas (GHG), which is also a main emission of building operations, is regarded as a significant cause of global warming (Buchanan and Honey, 1994). In 2002, the GHG emission from construction industry in the United States is estimated as 131 million tons CO_2 equivalents. Fuel consumption of on- and off-road construction equipment and electricity used for providing power are regarded as the two main emitters (EPA, 2008). From the above presented figures, it can be seen that construction industry is a significant consumer of resources and energy, and produces a substantial amount of wastes and carbon emissions. Thus, there is an urgent necessity to develop strategies to promote sustainability in construction industry by using less natural resources and energy while producing less waste and carbon footprint (Zhang et al., 2014).

In the lifecycle of a building, the consumed energy can be divided into three main categories according to its usage, namely embodied energy, operating energy, and building transportation energy (NTHP, 2012). Building transportation energy refers to the energy used to transport individuals or materials to and from a building, while operating energy is utilized to make building related facilities work. It has been investigated that operating energy is the most significant component among the three categories, accounting for 80-90% of the lifecycle consumption (Liu et al., 2012). So far, building designers have been focusing on the reduction of operating energy in the design stage. However, as technologies have improved energy efficiency of buildings, the proportion of operating energy is decreasing (Islam et al., 2014). As a result, the share of embodied energy is increasing and its reduction is gradually becoming an important aspect in decreasing building energy consumption. Embodied energy is defined as the energy that consumed to construct a building, involving the processes of extraction, processing, manufacture and delivery (Venkatarama Reddy and Jagadish, 2003). A stage that significantly affects the embodied energy of a building is design stage (Shrivastava and Chini, 2012). Therefore, in order to reduce greenhouse gas emissions caused by embodied energy, stakeholders should focus mainly on material selection in the design stage.

Environmental product declaration (EPD) can serve as a useful tool to assist the decision-makers in selecting environmentally friendly materials in the design stage. An EPD is a standardized, third-party verified document that communicates a product's environmental data, which obtained from lifecycle assessment, in accordance with the international standard ISO 14025 (Type III Environmental Declarations) (NRMCA, 2014b). By providing detailed information about the environmental impacts of a product, EPDs can give designers the information they need to minimize embodied carbon footprint of a building. EPD has been implied in other fields for reducing environmental impacts. For instance, Fet et al. (2009) has utilized EPD to provide stakeholders the environmental performance of furniture. However, the application of EPD for selecting environmentally friendly and economically efficient construction materials is not widespread.

The aim of this paper is to illustrate the application of EPD in reducing buildings' embodied carbon footprint at the design stage. A carbon footprint index (CFI) is introduced to facilitate the design determination. The focus in this study is concrete product selection because it is a main material in construction industry and its production process involves an intensive energy demand and CO2 emission. The rest of this paper is organized as follows. Section two gives a general literature review of current studies on carbon footprint reduction in construction and concrete. This is followed by introducing the research method used in this study. Results and discussions are subsequently presented, and conclusions are given at the end of the paper.

2. Literature Review

2.1 Carbon footprint reduction in construction industry

Construction industry contributes significantly to carbon footprint due to the large demand of natural resources and energy. Metz et al. (2007) claimed that the CO_2 generated from construction industry increased at an average rate of 2.7% from 1999 to 2004. To have an insightful understanding of greenhouse gas (GHG) contribution of construction industry, many studies have been conducted to quantify the emissions at both industrial and project levels. At the industrial level, an input-output life cycle assessment, which is based on the whole industrial chain, has been widely implemented (Acquaye and Duffy, 2010). At the project level, a process-based life cycle assessment method is very popular (Wu et al., 2012). In addition to the quantity, the sources of GHG emissions were also investigated. It is found that manufacture and transportation of construction materials, on-site electricity use, and disposal of waste are the main activities that produce GHG emissions during construction process (Hong et al., 2014). Moreover, a number of methodological tools have been developed for investigating carbon emissions in construction projects, such as carbon footprint estimation tool (Melanta et al., 2012), management information system (Barandica et al., 2013), and virtual prototyping technology (Wong et al., 2013).

In addition to the quantification methodologies, a series of technologies have been introduced to reduce carbon footprint in construction industry. For example, Hidalgo et al. (2008) compared a solar absorption system with a conventional vapor-compression machine from the aspects of system performance, economic feasibility, energy saving and environmental impact reduction. The outcome of their comparison supported the utilization of the solar absorption system. In the aspect of heating and cooling, Hacker et al. (2008) conducted a case study and found that the inclusion of thermal mass can reduce building's lifecycle carbon emission by decreasing operational heating and cooling energy. Recently, Zhang et al. (2014) introduced a PV-LED lighting system which produces solar photovoltaic energy in the underground garage to substitute the traditional system. The results proved that the new system can bring benefits in economic effectiveness and CO_2 reduction. A number of green technologies have been introduced to mitigate environmental impact. Johnston et al. (2005) claimed that current available technologies can reduce CO_2 to a large extent by strategic shifts in both energy supply and demand sides. However, most of these technologies focus on reduction of carbon footprint due to operation of the facilities. Researchers from both academia and practice appealed that particular focus should be given to the design stage of facilities (Kim et al., 2013; Zhu et al., 2013).

2.2 Carbon footprint reduction for concrete

Concrete is one of the main materials with high environmental impact in construction industry. It has been widely used in the process of making foundations, structures, infrastructures (e.g., roads, bridges, and dams), etc. (NRMCA, 2008). The consumption of concrete is huge in many countries. For instance, there are approximately 5,500 ready mixed concrete plants in the US, and the value of ready mixed concrete trades is around $30 billion (NRMCA, 2013). Based on the Portland cement sales, it is estimated that the production of ready-mixed concrete in the US is about one billion metric tons per year (EPA, 2013). In China, the concrete consumption is tremendous as well. It is reported that the amount of concrete production in 2007 was two billion cubic meters with an average annual growth rate of larger than 10% (Li et al., 2007).

Concrete is composed mainly of water, aggregate, admixtures, and Portland cement. The proportion of Portland cement in concrete is about 7% to 15% depending on the performance requirements of concrete (NRMCA, 2008). Although concrete has a lower total energy intensity than other generally used construction materials, cement production is a highly energy-intensive process and entails potentially significant air and water pollution (Chini, 2009). In addition, the natural aggregates have finite resources and concern over environmental issues oppose the production of sand and gravel by dredging huge cavities in traditional landscape. Furthermore, the demolition of old concrete pavement and structures produce large quantities of waste that in most cases are landfilled. It has been reported that concrete waste occupied one third of the total wasted materials in the landfills of the US (Zhang, 2012).

Currently, as the concept of sustainable construction has motivated innovative companies, researchers, and industrial coalitions to be more environmentally responsible, potential solutions have been suggested to reduce the carbon footprint produced by concrete. Some highlights of the prevailing technologies and approaches are listed as follows.

- Use of supplementary cementitious materials. The traditional technologies for manufacturing concrete have required unnecessary quantities of cement, thus consuming less cement in production of concrete is the first step for reducing energy consumption and GHG emissions. One solution to achieve this goal is using supplementary cementitious materials (SCMs). SCMs are industrial byproducts which are usually end up in landfills, however, they can be used to substitute a portion of cement in concrete production, such as fly ash, blast furnace slag and silica fume (NRMCA, 2008). The appropriate use of SCMs in concrete production can consume less energy and emit less GHG. In addition, a blend of 50% or more granulated blast furnace slag or fly ash can increase the durability of concrete products compared with using pure Portland cement (Mehta, 2001).

- Use of recycled concrete aggregates. So far, the natural resources of the earth have been exploited to a point where the availability of gravel is scarce in some places. Furthermore, disposal problems have risen because of excessive volume of construction and demolition waste generation (Wu et al., 2014). As a result, there is a need to curtail the production of concrete waste. A possible solution is recycling wasted concrete by crushing it into acceptable sizes and removing impurities such as rebar, PVC pipes, etc. Numerous studies have been conducted utilizing recycled concrete waste to substitute natural raw materials (Chini et al., 2001).

- Design innovation of concrete products. The design of concrete products has been improved continuously, such as design of flat slabs and voided slabs. The recent flat slabs were designed without drops and column capitals, which can withstand greater slab loadings and allow thinner slabs in the design (BCA, 2012). In addition, the deletion of beams allows lower floor-to-floor heights, which contributes significantly in concrete reduction. Especially in cases where there is no requirement for a deep suspended ceiling, flat slab construction can minimize floor-to-floor heights (BCA, 2012). Voided slabs are a form of structural slab system in which voids are introduced to reduce concrete usage, and in turn reduce the dead load of the structural slab (BCA, 2012). This design contributes not only to concrete reduction because of the voids, but also to the reduction in size of the supporting columns and foundation.

- Reuse and deconstruction. The best way to preserve the embodied energy of a concrete structure is adaptive reuse. Adaptive reuse is defined as “to leave the basic structure and fabric of the building intact, and change its use” (Langston et al., 2008). Buildings that employ concrete frame structural systems are well suited for adaptive reuse. Deconstruction or disassembly of the structure can be utilized to divert the maximum amount of the structural components from the waste stream (Chini, 2005). It is regarded that the top priority is placed on the direct reuse of the component in new structures (Chini and Bruening, 2003). This approach has been successfully applied in several countries (CCANZ, 2007).

Through the literature review, it can be found that the concrete industry has been dedicated to reducing the carbon footprint of concrete products. However, the current practice is mainly focusing on the manufacture and recycling of concrete, no attempt has been conducted on reducing carbon footprint in the concrete product selection process. Therefore, this paper is attempting to introduce a tool for reducing carbon footprint by optimized concrete product selection.

2.3 Environmental product declaration for concrete products

To facilitate concrete product selection, EPD is utilized in this study. As introduced in the introduction section, an EPD can provide quantifiable data about the potential environmental impacts of a particular product. The typical procedure for creating an EPD is as follows. Firstly, identify product category rules for describing how to implement life cycle assessment on a particular product. Then, perform the life cycle assessment according to the outlined rules. Finally, input the derived life cycle assessment data into an EPD format and create an EPD for the particular product. Usually, an EPD includes the information about manufacturer, use of the product, and environmental data. Before its publication, a verification must be derived from a third party.

The implementation of EPD has been encouraged in green building rating systems. For example, in the most updated version of Leadership in Energy & Environmental Design (i.e., LEED v4), points can be awarded if a project uses more than 20 products having their EPDs (NRMCA, 2015). As concrete has a wide application in manufacturing construction products (e.g., columns, beams, walls), it is regarded that concrete products with corresponding EPDs can contribute significantly to satisfying this requirement.

In order to help concrete manufacturers meet the new requirements, the National Ready Mixed Concrete Association (NRMCA) of the United States has operated an EPD program for guiding them to develop draft EPDs and conducting corresponding verification. The concrete EPDs verified under this program are all listed on the official website and free for download. An industrial wide EPD which indicates the average environmental characteristics of 48 ready mixed concrete products is provided as well.

3. Methodology

To illustrate the application of EPD in building construction, two scenarios are proposed in this study. The first scenario is designed to explain how to use EPD to make material selection from the environmental perspective. In this scenario, an office building with concrete frame structure is used as an example. This is a two-story building with twenty square reinforced concrete columns (300 mm × 300 mm) located in the grids (4.3 m × 6.1 m). Three concrete slabs which are 100 mm thick are used as floors. The sectional and plan views of this building are presented in Figures 1 and 2.

The second scenario is proposed to introduce the concept of carbon footprint index (CFI) which can be used as an indicator for facilitating carbon footprint reduction at design stage. In this paper, the CFI is defined as the amount of carbon emissions due to the use of concrete to cast a square meter of construction floor area. The calculation scope involves structural and non-structural concrete elements in superstructure, regardless of concrete used in external works and sub-structural works such as basements and foundations. The formula for calculating CFI is shown in Eq. 1.

$$CFI = CV \times CFE / TA \qquad \text{Eq. 1}$$

where CFI ($kgCO_2e/m^2$) is the carbon footprint index, CV is the concrete volume (m^3) that used in building the superstructure, CFE refers to the carbon footprint emission ($kgCO_2e$) in one cubic meter of selected concrete material, TA represents the total floor area (m^2) of the superstructure.

The different values of CFI indicates various levels of carbon footprint. More specifically, the material with a higher CFI produces more carbon footprint than the material with a lower CFI. In the determination process of material selection, the material with the lower CFI is preferred from the perspective of environmental protection. This concept can be introduced into green building rating system (e.g., LEED) to provide thresholds for different categories of buildings.

4. Results and discussions

4.1 EPD application for selecting environmental materials

In terms of the first scenario, the basic information of the office building is shown in Table 1. From Table 1, it can be seen that the concrete strength is various in different floors. Based on the NRMCA member industry-wide EPD for ready mixed concrete (NRMCA, 2014a), the potential concrete products for satisfying different strength requirements and their carbon footprint are abstracted and presented in Table 2.

Table 1 Basic information of the office building

Item	*Floor area (m^2)*	*Concrete volume (m^3)*	*Required concrete strength (MPa)*
Floor 1	*391.9*	*39.19*	*21*
Floor 2	*409.3*	*40.93*	*34.5*
Floor 3	*385.4*	*38.54*	*34.5*
Columns		*14.81*	*28*
Total	*1186.6*	*133.47*	

Table 2 Carbon footprint of potential concrete products

Strength (MPa)	*Range (psi)*	*Potential products*	*Carbon footprint ($kgCO_2e/m^3$)*
21	*3001-4000*	***4000-00-FA/SL***	***416.1***
		4000-20-FA	*357.1*
		4000-40-FA	*291.6*
		4000-30-SL	*316.6*
		4000-50-SL	***250.4***
28	*4001-5000*	***5000-00-FA/SL***	***509.1***
		5000-20-FA	*435.6*
		5000-40-FA	*353.9*
		5000-30-SL	*385.1*
		5000-50-SL	***302.4***
34.5	*5001-6000*	***6000-00-FA/SL***	***536.1***
		6000-20-FA	*458.5*
		6000-40-FA	*372.1*
		6000-30-SL	*405.1*
		6000-50-SL	***317.8***

Note: the name of concrete product is given according to the following rules: the first section of the product name indicates the range of compressive strength in psi, the second section declares the percentage range of supplementary cementitious materials (SCM) used to manufacture the concrete products, and the third section stands for the components of the SCM (FA is short for fly ash, while SL represents slag).

From Table 2, it can be seen that the most environmental-friendly concrete products for different strength levels are 4000-50-SL, 5000-50-SL, and 6000-50-SL. On the contrary, using 4000-00-FA/SL, 5000-00-FA/SL, and 6000-00-FA/SL produces the most carbon footprint.

Tables 3 and 4 show the total carbon dioxide produced using the mix designs without cementitious materials (66,451 $kgCO_2e$) and mixes with 50% slag (39,547 $kgCO_2e$), respectively. Based on the results, it can be found that various schemes of concrete product selection can make a significant difference on carbon emission. While the selected case is just a regular office building with only three floors, the difference can be more significant if it is a high-rise building.

Table 3 Total global warming potential using mix designs without cementitious materials

Member	*Floor Area*	*Material Volume*	*Mix Design*	*Concrete Strength*	*GWP*	*Total GWP*
	m2	*m3*		*MPa*	*Kg Co2e per m3*	*Co2 Eq. Kg*
Floor 1	*391.9*	*39.19*	*4000-00-FA/SL*	*21*	*416.1*	*16,307*
Floor 2	*409.3*	*40.93*	*6000-00-FA/SL*	*34.5*	*536.1*	*21,943*

Carbon Footprint Index Kg Co2e/m2						*49.4*

GWP = Global Warming Potential

4.2 EPD application as an indicator for carbon footprint

Equation 1 was used to calculate the carbon footprint index of the building for each case. Tables 3 and 4 show that the carbon footprint index decreased from 82.9 to 49.4 Kg Co2e/m2 when the mix designs without any cementitious materials were replaced by those with 50% slag. Ground granulated blast-furnace slag is a byproduct of steel production and much cheaper than Portland cement. It is highly cementitious in nature, ground to cement fineness, and hydrates like Portland cement. Substitution of ground granulated blast furnace slag for up to 70 percent of the Portland cement in a mix has been used. In addition, Portland cement blends containing 50% or more granulated blast furnace slag can yield much more durable concrete products than the pure Portland cement.

The introduction of CFI can assist designers to measure and benchmark the carbon footprint of building during the design stage to arrive at an optimal design early in the design and construction process. The CFI can also be used as a measure of environmental impact of buildings in building rating systems.

The carbon footprint analysis in an EPD can facilitate manufacturers to understand more about the effects of their products to the environment, while the CFI can assist construction stakeholders in improving the carbon footprint reduction.

5. Conclusion

The construction industry produces a significant amount of carbon footprint. As energy efficiency of buildings has improved, the proportion of embodied carbon footprint with respect to operational energy is increasing. An EPD of a concrete product can tell the customers how much carbon footprint can be generated from the manufacture of this product, thus provide convenient and useful information on materials selection with the aim of reducing embodied carbon footprint. The research findings in this paper reveal that different schemes of materials selection can make significant difference in carbon footprint reduction. Furthermore, the concept of CFI is introduced in this paper, which can be used at the design stage to arrive at an optimal design as well as in a green building rating system for evaluating the carbon footprint reduction performance of a building.

The paper contributes to illustrating the applications of EPD on carbon footprint reduction in construction industry. Further research can be addressed to integrating building information modeling (BIM) with EPD to simulate the effectiveness of different materials selection schemes, establishing CFI thresholds of different materials for green building evaluation.

Abstract

This conceptual paper provides a desk-top study of secondary sources to outline a robust program of research to increase the market penetration of high quality green buildings produced in advanced manufacturing facilities. The environmental benefits of such buildings are investigated, a theoretical approach to understanding the drivers of best practice is outlined and a field work-method is proposed to understand the dynamic capabilities that support leading manufacturers. An extended sociotechnical systems view of the firm is developed to guide a program of international case studies. This paper makes a theoretical contribution to the understanding of firm performance in an important empirical setting. Future research by the author will involve execution of the described research program. A limitation of the paper is that the effectiveness of the proposed theory and methods is yet to be tested empirically.

Keywords: Sustainability, buildings, off-site, socio-technical systems, Australia

1. Introduction

There is an urgent need to improve the environmental sustainability and the whole-of-life cost of buildings by increasing the market penetration of green buildings produced in advanced manufacturing facilities. This requires new management theory to understand the latent variables underpinning successful facilities internationally. The building sector represents an urgent environmental problem because of its poor performance in energy, carbon, materials, water and waste. It is the single largest contributor to CO_2 emissions among industry sectors (UNEP, 2014) and produces more greenhouse gases than the transport sector (World Business Council for Sustainable Development, 2009). These significant environmental problems can be efficiently and effectively addressed through a shift to advanced manufacture of buildings and their parts, such as modules, bathroom pods and structural insulated panels.

Advanced manufacture results in a higher quality and more sustainable asset compared to buildings constructed on-site through manual processes (Johnsson and Meiling, 2009, Poon et al., 2003, Monahan and Powell, 2011). However, Australian efforts to develop such an industry, although promising, are hampered by a number of obstacles. These include social stigma, sector resistance to radical innovation and lack of design flexibility (Steinhardt et al., 2014). In Australia, it is estimated that less than 5% of new buildings are produced using advanced manufacturing, while in leading countries, such as Japan, the comparable rate is 15% (Steinhardt et al., 2013a). Although these figures indicate that market penetration is currently low, there is overwhelming evidence that such approaches are the direction of the future (CEDA, 2014). This is because of the strong business drivers for green buildings (WGBC, 2013) and the potential for advanced manufacturing to deliver sustainability benefits (Kibert, 2012).

The Australian manufactured building industry has some competitive advantages, but is relatively undeveloped in a global sense (Steinhardt et al., 2013b). The current paper provides a desk-top study of secondary sources to outline a robust program of research to increase the market penetration of such buildings in Australia. The proposed study aims to benchmark current best practice globally, framed by an integrated conceptual framework. This framework is essential to uncovering the latent drivers of excellence in this field. The proposed study addresses the research question ‘How can factory production of buildings be optimised?’

2. Literature Review

The study will address the: conceptual problem of modernizing the STS view of the firm; the empirical problem of reducing the impact of building engineering and operation on climate change; the management problem of the best way to improve building quality; and the policy problem of encouraging efficient building production and expanding export markets.

The focus of this study is residential buildings, like houses and apartments. The vast majority of such buildings in Australia and elsewhere are constructed manually on-site. A small percentage are produced in a factory and transported to site. The factories might produce whole buildings or their parts. Most of these factories are not employing advanced manufacturing techniques;

however this is the approach that leads to the most significant environmental benefits (Noguchi, 2011). The definition of advanced manufacture adopted here follows that of the Committee for Economic Development of Australia (CEDA). CEDA recently produced an Industry Plan that distinguishes between traditional assembly-line manufacturing based on low-cost, high-volume production and advanced manufacturing which is 'about variability, complexity and extensive customisation with high value-add' (CEDA, 2014). Advanced manufacturing directly addresses many of the obstacles to increased market penetration of green buildings by providing (1) flexible and sophisticated designs; and (2) detailed monitoring of whole-of-life outcomes (Noguchi, 2011).

Advanced manufacture of buildings also offers significant efficiency improvements to substantially lift the productivity of construction processes (Kibert, 2012, Manley, 2008), potentially doubling efficiency compared to on-site production (Eastman and Sacks, 2008). The technologies supporting these gains include advanced numerical controlled machinery, robotic assembly, building information models and enterprise resource planning systems. Improved productivity is urgently needed, given that previous attempts to improve the performance of the construction industry have had very limited success (Productivity Commission, 2014). Efficiency improvements are in part reaped through a higher quality product that eliminates re-work (Manley and Miller, 2014, Blismas and Wakefield, 2009). Yet the adoption of advanced manufacture in the building sector has been slower than expected (Middleton, 2014). Recent research suggests that this may be due to inappropriate firm-level management strategies (Brege et al., 2014). The current study builds on those findings by developing a systems approach and employing international comparisons that enable the identification of best practice.

UNEP (2014;16) reports that the building sector is an urgent environmental problem: (1) 30% of energy end-use world-wide takes place within buildings; (2) 10% of the global energy supply is consumed during the manufacture of building materials; (3) 30-40% of CO_2 emissions are generated during the use phase of buildings; (4) 40-50% of the total flow of raw materials globally is used in the manufacture of building products and components; (5) 12% of global water use takes place in buildings; and (6) 40% of solid waste streams in developed countries comes from building engineering and demolition. These issues must be addressed immediately if the ravages of climate change are to be minimised.

Leading international studies show that the average cost premium for a zero-carbon building is 12.5% (WGBC, 2013), yet neither the World Green Building Council, nor the United Nations Environment Program assess how this cost premium might be reduced by extending the use of advanced manufacturing technologies in a factory setting to produce buildings and their parts. For the first time, the current study will compare the cost profiles and environmental outcomes of leading green building manufacturers internationally. By doing so, it will improve the performance of Australian building manufacturers, thus reducing the environmental problems outlined above.

There are persuasive statistics demonstrating the gains to be made if more buildings were produced through advanced manufacture. For example, a recent UK study compared the performance of manufactured homes with those that were constructed on-site. The figures demonstrated a 34% reduction in embodied carbon (Monahan and Powell, 2011). The proposed study will improve (1) the success of climate change mitigation strategies; (2) Australia's standing in the international community; and (3) the international competitiveness of Australia's manufacturers of buildings and their parts.

As a traditional industry, lacking the glamour of research-intensive industries, the building and construction industry has received limited attention from innovation analysts (Gann, 2000, Kibert, 2012). The study addresses this urgent empirical gap by focussing on a significant innovation (advanced manufacturing) that can reduce the environmental impact of buildings and improve efficiency. This empirical gap has occurred because of an acute shortage of rigorous research in this area. Climate change responses are currently focused on high profile polluters such as the coal or transport sectors, yet the building sector is the biggest polluter amongst all industry sectors (UNEP, 2014). The proposed study directly addresses this important issue.

The proposed study addresses the efficiency and effectiveness of the built environment, where the human population lives and where 95% are employed (Newton et al., 2009). This is achieved by encouraging a shift in market preferences away from 'stick-built' buildings constructed on-site, towards the advanced manufacture of buildings and their parts. Advanced manufacture has the twin benefits of improved environmental and productivity outcomes. Although the focus of this study is on environmental outcomes, productivity is also improved through the ability to (1) utilise advanced manufacturing technologies, (2) work through rain, storms and heatwaves, and (3) recycle waste materials more efficiently. Historical data comparing buildings produced on-site, with buildings produced in advanced manufacturing factories, shows higher labour productivity and faster growth in the factory sector. For example, data on curtain wall production in the U.S. between 1992 and 2002 showed a 32% growth in labour productivity in the factory sector, while the comparable figure for on-site production was 8% (Eastman and Sacks, 2008). Data from another study shows that producing a bathroom pod in an advanced manufacturing facility takes one tenth the time of traditional on-site bathroom construction (Singerman, 2013).

The proposed study is likely to reduce the financial burden placed on owners and taxpayers arising from paying too much for buildings. Cost savings will have significant ramifications for Australian society as a whole given that the building and construction industry contributes 8% of GDP and is the 3rd largest industry division across 19 ANSZIC divisions (ABS, 2014). The industry produces the built environment and thus has a significant impact on living standards, the production of other goods and services, and trade. Yet, it is known as a 'serial productivity under-performer' (PWC, 2013). The scale and ubiquity of the industry means that productivity improvements will have much larger multiplier effects compared to nearly all other Australian industries.

3. Conceptual Framework: Validation of Techniques

Conceptually, the problem at the centre of this study can be framed as inadequate diffusion of a radical innovation (advanced building manufacture) given its potential benefits compared to established methods. CI Manley is a global expert in innovation systems and has an intimate knowledge of the evolution of systems approaches to the study of innovation (Manley, 2002, Rose and Manley, 2014). Leading approaches include technological regimes (Nelson and Winter, 1977), technological systems (Carlsson and Stankiewicz, 1991), systems of innovation (Edquist, 1997) and STS (Trist and Bamforth, 1951, Cooper and Foster, 1971). The STS view is selected for development here as it is the most promising for addressing the urgent environmental problems at hand. This is because the STS view explicitly combines the linear end-points of 'technological fix' on one hand, and 'behavioural change' on the other, in framing approaches to sustainability transition problems (Geels, 2012). A STS is a multi-level concept that describes a work system that is typically described as having four components that need to be balanced to maximise performance: (1) goals, (2) actors, (3) technology and (4) structure (Leavitt, 1964). At firm-level, an STS is described here as follows:

1) Goals: work is assigned to actors to achieve the goals of the firm
2) Actors: employees with different beliefs undertake tasks to achieve goals
3) Technology: physical tools are employed by the firm to help actors achieve goals
4) Structure: work is designed to help the actors and technology achieve goals

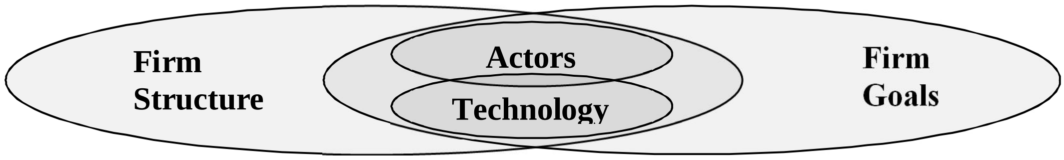

Figure 1: Integrated STS concepts

Figure 1 shows the interconnectedness of STS components. STS theory is more than 60 years old and has been used ubiquitously over the years, yet it is increasingly criticised for being outdated (Eason, 2008), and too focused on information systems (Davis et al., 2014). Key authors are calling for renewal to extend the conceptual basis of the theory and to apply it to new fields (Eason, 2008, Davis et al., 2014). The current study addresses these gaps, building on the integrated concepts encapsulated in Figure 1 by providing theoretical depth and currency for each of them. It challenges the currently limited approaches to understanding STS by developing a highly structured and detailed theory suitable for application to the built environment, based on related management theory, which itself borrows from social psychology theory. The new theory will aid in the understanding of the dynamic capabilities that underpin firm performance (Zollo and Winter, 2002). The application of renewed STS theory to the built environment responds to calls from academics in that field for theoretical approaches that combine technological and social dimensions of change (Schweber and Harty, 2010). The outcome is valid and reliable advice for firms to help them extend market share, based on detailed prescriptions driven by strengthened and streamlined theory.

A taxonomy of dynamic capabilities will be provided by combining the STS literature (Trist and Bamforth, 1951, Cooper and Foster, 1971) with more nuanced management theory, such as planned behaviour (Ajzen et al., 2011), organisational ambidexterity (Patel et al., 2013) and user-producer interaction (Lundvall and Vinding, 2004). While the STS view provides a very useful organising principle for understanding dynamic capabilities and firm performance, its integration with more nuanced approaches, focused on each of the four individual system components, will provide the depth required to direct real-world change. In this way, the learning routines that underpin dynamic capabilities can be better understood and the operational relevance of the STS view will be vastly improved. The new theory developed by this study makes a significant contribution to the emergent field of sustainability transitions that has developed over the past 10-15 years. A recent summary of this field emphasises the critical need for more comparative studies, as will be undertaken here (Markard et al., 2012).

4. Approach and Methodology

The epistemological approach adopted is 'realism' giving rise to modified objectivist findings, through case studies (Healy and Perry, 2000). A deductive approach is proposed, driven by research questions within a rigorous qualitative framework. Based on existing conceptual approaches, an integrated theory is developed to guide the case studies. The proposed study is forecast to take 3 years to complete, as detailed below.

4.1 Stage 1: Theoretical Development: 3 months

Objective: Modernize and improve the operational relevance of the STS view by developing measurable items drawn from related theory for each of the four components.

Method: Development will be based on the procedure pioneered by CI Manley in earlier research funded by the Australian Research Council (LP110200110) (Chen and Manley, 2014). A robust and structured literature search will be undertaken, using directed content analysis (Krippendorff, 2004). CI Manley has extensive experience with this method, leading to many significant journal publications. She will supervise the process of sourcing, classifying and interrogating potentially useful theories, with an RA doing the routine sourcing and classification work, and a Post-doc examining the potential to add value to the predictive power of the initial model. The management literature on topics relevant to the four system components will be reviewed, focussing on highly-cited contributions in leading journals. A two-stage process will be employed, commencing with *general* management literature to establish broad principles and concluding with *engineering* management literature to provide relevant contextualisation. The integrity of the final integrated result will be supported by feedback from a panel of international experts on management theory and firm capabilities sourced from CI Manley's extensive networks.

Contribution: An integrated theory of STS that better facilitates empirical work in the current context.

4.2 Stage 2: Case Study Logistics: 3 months

Objective: To identify and secure interviewee firms and managers for the 15 cases; and establish the flight, accommodation and interview schedules in each of the five countries sampled.

Method: Three leading firms in each of five countries will be studied, including Australia, resulting in 15 cases. The data obtained will cover the four components of the new STS theory. This data will describe the drivers of firm performance. CI Manley's experience suggests that three firms are sufficient to get a good sample of best practice in each country. Each firm will be a leading advanced manufacturer of green buildings, selected on the basis of advice from our foreign collaborators regarding the firms with the largest market share. The foreign countries themselves were selected because they are considered to be progressive in this area, based on earlier pilot research by CI Manley in late 2014 (Steinhardt et al., 2013b). Using contacts established by CI Manley during that study, the schedules will be developed using phone and email communications. This work will be driven by CI Manley, overseen by the Post-doc and actioned by the RA. CI Manley will secure participation; the Post-doc will establish schedules and the RA will make bookings.

Contribution: A register of 15 leading firms globally in the advanced manufacture of buildings.

4.3 Stage 3: Case Study Performance: 12 months

Objective: To efficiently and effectively conduct the case studies to help grow the Australian green building industry.

Method: Case studies are recommended for analysis of messy empirical contexts (Eisenhardt and Graebnew, 2007). This means contexts that are (1) significantly multidimensional, giving rise to a large number of variables; (2) marked by interactive relationships with unclear cause and effect; (3) impacted by situational factors in the surrounding environment; and (4) being examined from a systems' perspective. These conditions apply to the current research, justifying the use of case studies.

Two senior managers from each manufacturing firm will be personally interviewed for one hour by two researchers at the same time; CI Manley and the Post-doc. This dual approach allows for cross-referencing of information provided by the two managers and cross referencing of observations across the two researchers. Personal interview enables unobtrusive observation, augmenting word responses, particularly in relation to non-verbal cues from interviewees, technological infrastructure and factory lay-out. Company reports will also be collected and consulted, including performance audits, employee opinion surveys, training materials and operation manuals. Pilot study manufacturers have indicated a willingness to share such material. The RA will be responsible for transcribing the interview recordings and pulling salient material from company reports. Triangulation across two managers, two senior researchers and three data sources assures robust findings. CI Manley's extensive interview experience suggests that one hour is sufficient time to reach data saturation point, after which no new material is likely to emerge. Academic and industry partners in each foreign country have been secured to help with the case studies.

Many of the case study firms have already been identified and secured including Broad Sustainable Building (China), Sekisui House (Japan), Baufritz (Germany) and BoKlok

(Ikea/Skanska in Sweden). The interviews will be semi-structured involving two phases. In the first phase, the interviewee will be given a short questionnaire to complete, taking about 15 minutes, based on the four system components. In the second phase, open-ended questions about each component will be discussed with the interviewee.

Contribution: 15 'demonstration' case studies, each describing success factors in advanced manufacture of green buildings, driven by integrated theory.

4.4 Stage 4: Cross Case Analysis: 3 months

Objective: To understand the role of context in the different countries and to isolate common success factors.

Method: Directed content analysis will again be employed to review the 30 interview transcripts and associated company documents and researcher notes, with the RA organising and reviewing these research materials to maximise their accessibility. The identification of key variables and initial coding categories will be driven by the novel STS theory developed earlier in the study. NVivo, a qualitative data analysis software package, will provide a rigorous system to assist with coding. The coding will focus on identifying themes within the theory components and will be undertaken independently by CI Manley and the Post-doc, then cross-referenced to produce the final result. This triangulation process will support the validity and reliability of findings. Care will be taken to ensure that coding categories are mutually exclusive, limited in number and clearly aligned with theory components.

Contribution: The first evaluation of pathways to environmental excellence in advanced manufacture of green buildings internationally.

4.5 Stage 5: Theory Refinement: 3 months

Objective: To improve the value of the theory developed in Stage 1

Method: The explanatory power of the theory is reviewed by reflecting on its usefulness in the field. Did some items seem irrelevant? Were new items indicated? Through such analysis, contemporary empirical findings can improve the current state of theory. Analysis will again be undertaken independently by CI Manley and the Post-doc, then cross-checked to produce an interim result, which will be further cross-checked with an expert panel to improve validity and reliability. The final model will be particularly relevant to the study of advanced manufacturers, which is a very valuable research output as these manufacturers are currently being targeted by the Australian government for development through an Industry Growth Centre. During this stage, the RA will be working on industry magazine articles.

Contribution: A refined and contextualised management theory dedicated to an industry sector that is of strategic significance to Australia's future industry growth.

4.6 Stage 6: Knowledge Diffusion Program: 12 months

Objective: To provide advice to industry for improving market penetration of advanced manufactured green buildings and extend the academic knowledge base.

Method: Industry publications will provide research results, together with a set of normative guidelines for firms on how to achieve environmental excellence in their advanced manufacture of buildings. Such guidelines will be validated through feedback from an expert panel of industry practitioners. A Capstone Symposium will also be held for industry stakeholders in the three largest capital cities; Sydney, Melbourne and Brisbane; to share knowledge and map future pathways to greater market penetration. The RA will play a major role in framing industry publications and liaising with industry associations to validate guidelines and ensure appropriate distribution, as well as providing logistical support to the Post-doc, who will organise the Symposia under the direction of CI Manley. This industry phase of the knowledge diffusion program will consume six months. The academic publications will focus on the theoretical and empirical work, and target leading management journals, as well as refereed conferences. The Post-doc will generate the first-drafts of many of these articles. CI Manley will draft some articles herself and provide heavy revision for the others. Initial submission of articles will consume six months. See ‘Communication of Results’.

Contribution: Validated industry guidelines, industry publications, Capstone Symposia, conference papers and journal articles.

5. Conclusions

This conceptual paper was based on a desk-top study of secondary sources to justify and design a proposed program of research. The contributions of the paper comprise (1) an assessment of the environmental benefits of manufactured green buildings, (2) a theoretical approach to understanding the latent drivers of best practice and (3) a field work-method to understand the dynamic capabilities that support leading manufacturers.

The extended sociotechnical systems view of the firm developed here is both useful for the proposed study and has more general applicability as a more nuanced approach to assessing the capability of firms and the strength of their socio-technical systems. The current paper makes a theoretical contribution to the understanding of firm performance in an important empirical setting. Future research by the author will involve execution of the proposed study. A limitation of the paper is that the effectiveness of the proposed theory and methods is yet to be tested empirically.

Abstract

Construction Materials Stewardship can be thought of as the range of activities that go into the products and materials used in the infrastructure construction and maintenance process with respect to how they impact society. In particular, Materials Stewardship examines both the material manufacturing process and the raw materials used in addition to the deconstruction or demolition process and the disposal of the waste products. The Construction Materials Stewardship focuses on closing the material loop between the demolition process and the materials manufacturing process or product reuse. By reusing or recycling construction waste products, the quantity of raw materials required for future construction can be reduced in addition to diverting waste away from landfills. The Construction Materials Stewardship mission is interested in (1) drastically reducing the extraction and consumption of new non-renewable construction materials, (2) replacing non-renewable materials with renewable ones whenever possible, (3) achieving equilibrium in the demand and supply of renewable materials, and (4) ultimately restoring the renewable resource base. With this framework in mind, the research is intended to carry out these tasks in ways to maximize positive financial, social and environmental and ecological sustainability effects, impacts and outcomes.

This paper discusses the conceptual framework for the Research Roadmap of The CIB W115 and will address the issues related to construction materials stewardship, their interrelation, and the characteristics of the most relevant systems, processes and technologies.

Keywords: Construction, Materials, Waste, Reuse, Design

1. Introduction

Construction Materials Stewardship can be thought of as the range of activities that go into the products and materials used in the infrastructure construction and maintenance process with respect to how they impact society. In particular, Materials Stewardship examines both the material manufacturing process and the raw materials used in addition to the deconstruction or demolition process and the disposal of the waste products. The Construction Materials Stewardship focuses on closing the material loop between the demolition process and the materials manufacturing process or product reuse. By reusing or recycling construction waste products, the quantity of raw materials required for future construction can be reduced in addition to diverting waste away from landfills.

During the construction process, a significant amount of waste can be generated based on the materials selected due to excess supplies, errors in material selection, or damaged products. Material Stewardship is interested in measures that can be taken to reduce these waste streams and improve the sustainability of the facility based upon product selection. An initial aspect of these studies looks at how existing construction materials can be used more efficiently to reduce waste on the construction site and improve performance. A few examples of this type of improvement can be seen in using techniques such as Lean construction to prefabricate assemblies (Nahmens, 2012) and BIM to evaluate material locations (Wong, 2015). In addition, further research is necessary to look at new technologies that can be applied to material production that would result in improved environmental performance. The design of new products has seen tremendous advancements in technologies that improve the life cycle of the individual materials as well as reduce the pollution emissions of the building. An example of this type of improvement is implementation of nanotechnology in concrete that improves durability and facilitates cleaning of the surfaces (Ortiz et.al, 2009). Additionally, the application of sustainable construction materials in which reused or recycled products are incorporated to create an eco-material with an improved life cycle performance can be significant (Nie and Zuo, 2003). By evaluating the individual construction materials from a sustainable stand point, can result in modifications that can improve the life cycle properties of the materials, increase the useful life of the products, and recognize reductions in waste along with other environmental and economic benefits.

The waste stream generated from the life cycle of infrastructure including building, maintaining, and end of life disposal is often referred to as Construction & Demolition (C&D) waste. Due to the large volume of materials, such as concrete, steel, glass, and masonry, most countries track their recycling rate separately. In the European Union, it is estimated that 850 million tons per year or about 30% of the total waste stream is attributed to C&D waste (Fischer and Werge, 2009). This percentage of the waste stream is consistent with other developed countries in the world as reported in previous W115 publications.

Over time, a building's ownership and/or functionality can transition quite often. If the facility does not have the flexibility to adapt to the new needs, the building may be demolished or left vacant. Either case would not provide the most sustainable use of the facility. By extending the useful life of the facility by planning for the adaptability of new users and occupiers would provide significant economic and environmental benefits. When a building can be initially designed with adaptability in mind, the space and materials would be considered relative to their life cycle and the flexibility that is needed to maximize the building's lifetime while minimizing disturbance to the integrity of the structure. In addition, by designing for adaptive reuse the building owners can more readily adjust the facility at lower costs to account for new technologies. From an environmental perspective, any design for adaptive reuse will demonstrate significant savings in both demolition material being landfilled in addition to the purchase of new structural materials (Saleh & Chini, 2009). Despite the lack of initial designs for building adaptability, a concentrated effort should be made for adjusting existing buildings that have exceeded their current functionality to be altered to permit reuse. The added effort to convert the facility to an adaptable structure will vary depending on the design; but should be considered as a viable option to demolition or the construction of a new facility.

The Construction Materials Stewardship mission is interested in (1) drastically reducing the extraction and consumption of new non-renewable construction materials, (2) replacing non-renewable materials with renewable ones whenever possible, (3) achieving equilibrium in the demand and supply of renewable materials, and (4) ultimately restoring the renewable resource base. With this framework in mind, the research is intended to carry out these tasks in ways to maximize positive financial, social and environmental and ecological sustainability effects, impacts and outcomes.

2. Background

The percentage of Construction and Demolition (C&D) waste that is recycled varies tremendously from country to country. Although a few countries have indicated recycle rates as high as 90%, most countries have less than 50% recycling rates, with several as low as 10%. Recognizing the importance of recycling C&D waste, some national legislative bodies have implemented regulations to encourage more recycling efforts. One of the most stringent new requirements is the EU Waste Framework Directive (European Parliament and Council, 2008) which has established a strategy to handle waste, including a minimum of 70% of C&D waste reuse, recycling, or material recovery by the year 2020 (Hiete, et al, 2012).

C&D waste is generated at four intervals during the life cycle of the facility or structure. First, the site will often require some form of preparation prior to commencing any construction activities. The initial demolition could involve clear and grubbing for an undeveloped site, infrastructure removal for a previously occupied site, or a combination of these methods. Second, during the construction process, excess materials are often discarded as waste. Factors that affect this waste stream include impacts of selected materials and methods, poor workmanship, uneconomical design, and improper material handling. Third, during the operating phase of the building, any renovations or repairs will generate waste from the removal of old material and excess from the new product. Finally, during the building demolition process, all the demolished building materials are often disposed of as waste. Despite attempts to require the recycling of materials during demolition, it is often uneconomical, time consuming, or impractical to sort the waste for efficient recycling. Ideally, if the building is designed for deconstruction at the end of the life cycle, many of the challenges regarding the sorting of the waste to an acceptable quality for reuse or recycling can be dramatically improved.

The following is a summary of the major drivers that can influence designers to design for deconstruction in the initial design process (Hobbs & Adams, 2012):

- **Environmental driver:**
    - Reducing the extraction of new materials;
    - Diverting waste away from landfills
- **Socio-economic driver:**
    - Employment: Jobs may be lost in primary manufacturing, but some will be created in the refurbishment of equipment and in the processing of reclaimed materials;
    - Social benefits: Benefits from reduced loss of land due to materials extraction and landfill sites
- **Political driver:**
    - Government policy on sustainability (minimization of waste, maximization of recycled and reclaimed materials)
- **Risk management:**
    - Legislation, health and safety, fiscal measures encouraging minimization of primary materials extraction and waste generation;
    - Reclassification of materials and waste
- **Economic driver:**
    - Design for deconstruction increases the flexible use and adaptation of property at a minimal future cost;
    - Reducing the whole-life environmental impact of a project and diverting waste away from landfills
- **Ethical Responsibility:**
    - There is a moral responsibility to protect the natural environment and ensure social equality when selecting products for construction.
    - Product selection and waste handling can play a significant role in the ecological and social impacts of a business.

3. Issues

Despite the numerous advantages, the barriers to designing for deconstruction often make it difficult for architects to incorporate material recovery procedures into the initial building design. The following are some of the challenges faced to design for deconstruction (Hobbs & Adams, 2012):

- **Lack of legislation:**
    - At present there are no legal requirements in any country for clients or contractors to consider deconstruction at the design stage or require that waste materials from construction or demolition be sorted for recycling.
- **Human barrier:**

    - Habits: It is easier for people to carry on what they have been doing;
    - Mindset: People tend to prefer new materials to second hand ones.
- **Additional design cost:**
    - Additional time is often required for architects and engineers to include the added features to make the building deconstructable.
- **Procurement and contractual responsibilities:**
    - The design agents may be hesitant to specify products that are not normally used by contractors since they may become liable for the quality of the installation due to their proprietary control of the contractor's choice of products.
    - Likewise, contractors may be hesitant to select products that are not normally recognized by the design agents since they could become liable for any variations from the standard specifications.
- **Technical barrier:**
    - Jointing systems, for example between pre-cast concrete beams, are usually stronger than the actual beam and are very difficult to deconstruct.
- **Economic barrier:**
    - Cost of individual units (tiles, paving slabs etc.) is usually low, so it is more cost effective to buy new ones.
- **Dimensional barrier:**
    - Structural units (beams, columns, etc.) are normally for one-off custom elements with unique dimensions.
- **Physical barriers:**
    - Pre- and post-tensioned beam/ floors, jointing systems, natural ageing of concrete, reinforcement corrosion, presence of coatings.
- **Contamination and aesthetics of components issues:**
    - Contamination with pollutants (petrol, grease, grime)
- **Perception and education:**
    - Perception that composite and strongly bonded elements are more durable and stronger structurally. In reality, a well-designed building that incorporates design for deconstruction elements should pose no increased risk of structural failure.
- **Problem of storage and double-handling of materials:**
    - Transportation between sites and locations can increase reuse costs.
- **Lack of markets for reusable elements or components:**
    - The reusable parts are perceived as being more inferior to newly constructed elements or components in terms of performance and quality.
- **Lack of design codes/ standards/ guidelines:**
    - Without consistent codes that include deconstruction, it is difficult to provide specifications that can be met by a large variety of contractors.
- **Lack of expertise:**
    - To carry out deconstruction and/or supervise the deconstruction process.
- **Lack of project references:**
    - Without good examples to follow that demonstrate the effectiveness of design for deconstruction, it may be difficult for both design agents and contractors to have a reference project to emulate.

An essential element in the evaluation of construction products to reduce waste and minimize the depletion of natural resources is the initial selection of the appropriate materials. In some cases, existing products can be modified or used in alternative methods and thereby improve their performance while minimizing their ecological effect. Additionally, new products should be evaluated to ensure that their manufacture, use, and disposal will not result in further environmental impacts. Life Cycle Analysis tools are one method that can be used to assist in performing these evaluations. By examining the full life cycle of a product it is possible to determine the environmental, social, and economic impact that is expected from the processing, operation, and end of life or recycling. This method of analysis can prove useful in determining which materials are considered sustainable. Construction Materials Stewardship is concerned with the developing methods, strategies, and initiatives to promote the use of more sustainable products.

Churn rate has been used to measure how often a business or building changes its operation. When the old tenant vacates the facility, there can often be a complete demolition of the interior and the installation of new finishes and furnishings. A significant tool in the minimization of material waste is the design for a facility to readily transform and adapt to new tenants and operational requirements. A critical aspect in the success of these transformations is the initial design of the building to facilitate the easy turn over. Additionally, the appropriate materials need to be selected that are durable and can withstand the periodic displacement. By planning in advance to design the building for the eventual churn, significant amounts of construction waste can be reduced.

As communities transition, often there are buildings that outlive their original design and become vacant or abandoned. In many cases, the site will be completely demolished prior to subsequent facilities being constructed. This building demolition results in a tremendous amount of material being landfilled that otherwise could have been reused. The renovation or adaptable reuse of the existing structure would provide a significant improvement from complete demolition and additionally minimize the amount of raw materials needed for new construction. However, changing the functional classification of a building may introduce new regulatory conditions and perhaps require zoning consent (Langstom, 2008). Again, the early planning for the potential adaptable reuse can have significant impacts on the economic, ecological, and social aspects of a building.

4. Stakeholders

With regards to the construction industry, there are two groups of major stakeholders: Internal and external stakeholders (figure 1). The internal stakeholders refers to the groups that have a direct impact on the construction process, while the external stakeholders have more of an impact on the internal stakeholders than they do on the actual infrastructure construction. The internal stakeholders include project owner, clients, project leader, and core team members such as designers, contractors, suppliers, and subcontractors. The external stakeholders include regulators (both local and national), public community groups, financiers, the media, end users, and special interest groups (Chinyio & Olomolaiye, 2010).

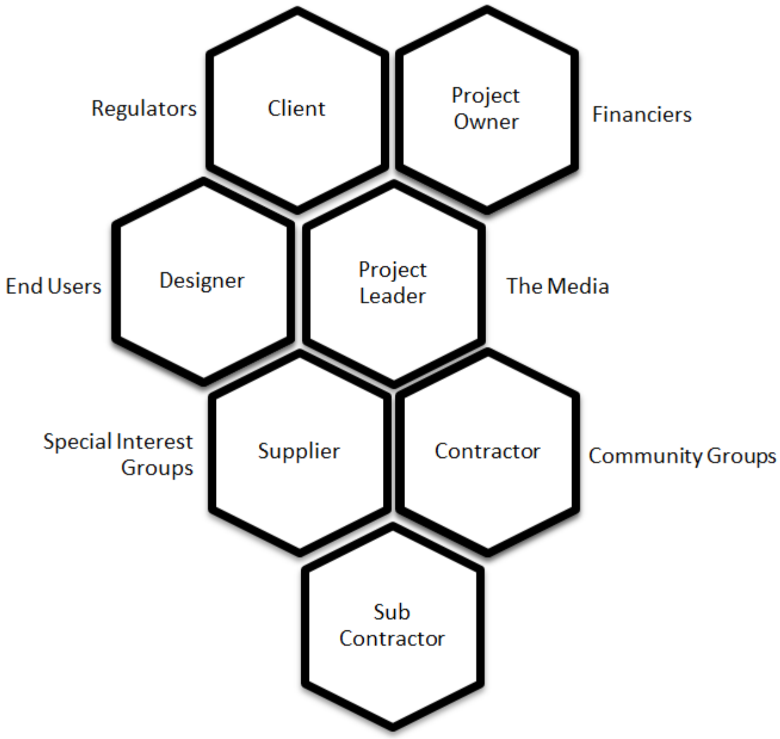

Figure 1: Internal and External Stakeholders

With regards to Construction Materials Stewardship, the following list describes the influences provided by the stakeholders and the perceived barriers for recycling or reuse:

- **Project Owner:**
  - As the primary group or individual responsible for the project, the owner sets the tone and establishes the priorities for the entire construction process. However, the owner may argue that designing for deconstruction or requiring more source sorting recycling programs will increase the cost of the project and not be economically feasible. If only a small portion of the owners are implementing these programs, it may be difficult to sell or lease the more expensive property unless the clients demonstrate a greater need for these requirements or the designers/contractors can perform the material recovery at the same cost.
- **Client:**
  - The group that will lease the spaces or purchase the property. In some cases, the clients may also be the project owners. The group may argue against the materials stewardship principles since they do not want to incur the added costs. Unless, there is government regulations that require that they operate from an environmentally responsible facility they will not have an even playing field from their competition and the added costs for materials stewardship will add an unnecessary expense.
- **Project Leader:**
  - Depending on the contractual situation, the project leader is often the individual responsible for coordinating design and construction efforts with the owner. With regards to materials stewardship, the project leader recognizes the need

for added costs from the design and construction team and thus passes these costs along to the owner. However, if the owner does not desire to pay for these added services, then the project leader normally will not require these services.

- **Designer:**
  - The design team is normally comprised of the architects and engineers responsible for developing the drawings and specifications for the project. They often feel that the limitations of including design for deconstruction are from two other groups. First, is that the material suppliers do not provide enough material options using recycled material that is of equivalent quality to virgin products. Second, the owner may not be interested in paying the added cost to enhance the drawings to the level needed for a structurally sound design that can be readily deconstructed at the end of life. Thirdly they may not want to bear additional responsibilities or risks for being the first movers to adopt design for deconstruction concepts in view of the current lack of project references, design codes/ standards/ guidelines.
- **Contractor:**
  - The contractor is responsible for the physical assembly of the infrastructure in accordance with the design and specifications provided by the architect/engineer. The limitations regarding infusing materials stewardship principles into the construction are directly limited by the design, the regulatory environment, and the market for recycled products. In other words, unless the construction specifications specifically require the recycling operations, the regulating authorities have policies for mandatory recycling, or there is a financially viable market for recycled products, the contractor does not have a strong incentive for capturing the material waste. Another common issue is that obtaining a higher grade of recycled product can be very labor intensive or delays the project; thereby further increasing the construction costs.
- **Suppliers:**
  - The suppliers include all of the material manufacturers that provide the products necessary for the construction. This group has often argued that developing new products using recycled materials can be costly and often there is not an adequate consumer market to justify the expense. Additionally, when the quality of the recycled material is inadequate, it is more difficult to develop better quality products that would be comparable to virgin materials.
- **Subcontractors:**
  - Many of the basic trades that demolish or install the building materials are conducted by subcontractors. The common barrier for subcontractors is due to the uncertainty in performance of new products from recycled material. If the quality is inadequate, the project may require substantial rework and incur significant additional costs.
- **Regulators (both local and national):**
  - This group includes the legislative bodies and government officials that establish the codes and standards along with the tax laws that are applicable for the region. Although it has been demonstrated in many countries how effective legislation can make a significant difference in implementing materials stewardship principles, there is often resistance from industry on excessive legislation in a free market society. Additionally, many of the laws that would

implement the environmentally friendly programs may require higher revenues to administer the policies and this may be politically challenging to acquire.

- **Public Community Groups:**
  - These groups refer to the locally organized citizens organizations that have jurisdiction over the area of the construction project. They can provide a very positive impact on the materials stewardship of the project by specifying that certain demolition and recycling practices be implemented within the community. However, if they see the recycling and reuse practices as unnecessary expenses, then they may also have a negative impact by not encouraging the materials stewardship practices.
- **Financiers:**
  - This group includes the various funding sources that provide the revenue for the project. When sustainable practices can demonstrate a financial benefit for the project, then they are interested in encouraging implementation of the materials stewardship policies. However, if the financial institution is not concerned with the environmental principles then they may not be interested in the extra costs that may be involved in recycling or reuse operations.
- **The Media:**
  - This group includes the various news and public information agencies for a community. In some instances if the owner feels that the media's positive publicity on the material stewardship principles of the project will assist the marketing of the project, there is a greater likeliness that recycling or reuse operations will be implemented. However, depending on the media service, if there is an impression that the materials stewardship principles are adding excessive costs to the project, then it may have a negative impact on publicity.
- **End Users:**
  - The final users of the constructed project are often referred to as the end users. Their impact on material stewardship is often through their willingness to shop or use the appropriate infrastructure. If the recycling or reuse operations created added cost for the users beyond competitive service, it may cause a loss of end users and similarly a decline in revenues for the owner.
- **Special Interest Groups:**
  - Organizations that are interested in promoting various causes and agendas can be referred to as special interest groups. Depending on the environmental preferences of the group, they can have a very positive impact on influencing the implementation of material stewardship principles. Although, there are likewise other groups that are more concerned with fiscal responsibility and reducing costs that may be just as likely to have a negative impact on recycling or reuse practices.

5. Conclusions

The expertise needed to solve these issues includes researchers and policy makers that can collaborate with the stakeholders. The mission of Construction Materials Stewardship is to provide the framework for this collaboration by encouraging the additional research that practitioners need to implement the changes. By working with the policy makers, schemes can be developed to encourage adoption of the procedures that will close the loop of the infrastructure's material life cycle.

Abstract

Starting from the 1960s, concrete structures have become prevalent in Finnish construction. This is a result mainly from urbanization and domestic housing policy in Finland which triggered the production of prefabricated concrete buildings. Because of the huge volume of this building stock, its renovation is also challenging in terms of resources. Approximately 11–40 % of the repair costs of prefabricated concrete facades result from corrosion-induced damage.

A subjective methodology is required to compare different repair options technically as well as economically including instant and life cycle costs. Essential information on the durability properties of single buildings and their repair possibilities is gathered in condition assessments but to estimate the residual service life of a concrete structure or to provide strategies for a large number of buildings it is necessary to utilize predictive models. At present, a methodology to assess the residual service life of existing buildings in practice is not available. The propagation of corrosion on concrete facades in Finnish environmental conditions was studied by a series of field and laboratory studies conducted on twelve residential concrete buildings located in different parts of southern Finland. In addition, corrosion rates in concrete facades were evaluated by long term field measurements on concrete facades under natural conditions. The experimental results were contrasted to statistical information on 947 case buildings. This information was used in determining critical parameters in service life modelling.

In the rising trend of renovation in the construction sector, this research will provide information on when to initiate repairs and in what extent. Thereby, the results will enable deciding the order of importance of renovation projects and change from reactive to proactive maintenance. Future applications could include the establishing of alliance type contracts between building owners and renovation specialists covering the long time span upkeep of a large building stock.

Keywords: Concrete facades, service life, modelling, renovation strategies

1. Introduction

Corrosion of reinforcement affects concrete structures basically either by cracking of concrete cover caused by corrosion products or by reduction of effective steel cross-section. The functionality of reinforcement (structural/non-structural) and the corrosion mechanism are decisive for which effect is dominating service life. However, cracking is typically the first sign of corrosion damage visible to the structure's surface. Corrosion is responsible for approximately 11–40 % of the repair costs of prefabricated concrete facades in Finland depending on the surface finishing, and along with insufficient frost resistance, carbonation induced corrosion is the most significant degradation mechanism of concrete buildings in Finnish environment. The damage caused by the both mechanisms accounts for € 3.5 billion in repair need and is increasing. It alone makes 1.8 % of the 2013 GDP of Finland. This is an issue that cannot be solved instantly, but requires a rehabilitation plan over several years.

Private and public buildings built of concrete make up 34 % of the whole building stock in Finland, of which almost 40 % is now 30-50 years old. The majority of the existing concrete facades in Finland have been built in time when service life design practice was not yet established (compared to a common service life requirement today of 50 years). The reinforcement service life is in Finnish guidelines (by50 2012) defined as only corrosion initiation. This means that the target service life should be achieved by carbonation resistance alone. This strategy withholds additional safety since no damage at all has happened yet at the chosen end of service life. In addition in new construction carbonation can be fairly easily accounted for by engineering concrete composition and reinforcement cover depths accordingly. Concerning existing buildings a problem is formed since these properties are already fixed. Also, the initiation phase is in many cases already passed. This makes the assessment of the residual service life of these structures problematic in two ways: (i) the residual service life is, by the definition, zero even though no damage at all has happened, (ii) there is no methods available to evaluate the residual service life.

This research entity focuses on the service life design and maintenance strategies of existing concrete facades in Finland. Service life extension is gained by defining the end of service life in a new way and reliably modelling the corrosion propagation phase. It is a practical issue since many of these concrete buildings have poor quality and ongoing degradation due to freeze-thaw and corrosion. The residual service life of these facades cannot be estimated by carbonation resistance since this phase has already passed. The motivation is to find a way to compare renovation projects and to manage the ever growing renovation needs. The aim is to be able to combine a carbonation model and an active corrosion phase model to form a larger picture of the service life of these structures.

2. Background

2.1 Renovation strategy for concrete facades

Renovation strategy of a built asset is tied to the business/maintenance strategy, financial situation and future prospects of the owner. The renovation project should begin with a project planning phase where the owner sets the requirements (technical, visual, etc.) and the budget for the project. In particular, the owner should define the target service life for the renovation.

The options available for renovation projects can be divided into (SFS-EN 1504-9):

a) do nothing & monitor
b) re-analyse & downgrade in function
c) prevent & reduce further degradation
d) repair & protect
e) replace with new
f) demolish.

The first two options can be used in delaying and budgeting for a larger project in the future. If utilized, these options require comprehensive survey/investigation of the condition of the structure (Lahdensivu et al. 2013). The optimal renovation on the point of view of economy and sustainable use of resources would include options c (prevent & reduce further degradation) and d (repair & protect). In practice, it is however far too common for the owner to only focus on repairing visual damage without analysing properly the need for protective/preventive measures. Cases showing high degree of degradation or obsolescent facilities or technical systems may have to be replaced.

Another way of classifying the repair options is (by41 2007):

a) do nothing
b) preserving renovation
c) altering renovation
d) renewing of the whole structure
e) special methods.

The repair options are followed by the choice of (a set of) renovation principles. The renovation of concrete structures in general can follow several main principles (SFS-EN 1504-9) shown in Table 1. The selection of the renovation principle is often guided by technical, financial, valuation and social aspects.

Table 1:Renovation principles in SFS-EN 1504-9.

Repair principle
1. Protection against ingress
2. Moisture control
3. Concrete restoration
4. Structural strengthening
5. Increasing physical resistance
6. Resistance to chemicals
7. Preserving/restoring passivity
8. Increasing resistivity
9. Cathodic control
10. Cathodic protection
11. Control of anodic areas

2.2 Reinforcement corrosion modelling

A widely accepted description of the corrosion process of steel in concrete withholds the phases of initiation and propagation (Tuutti 1982). The both phases can be analysed as separate entities or combined to form a holistic view of the structure's lifetime for the service life design purposes. The assessment of the residual service life of corroding concrete reinforcement requires detailed information on the corrosion mechanism, initiation, corrosion rate and conditions which are regarded as the end of service life. The diameter and cover depth of the corroding reinforcement as well as the type of products (rust) formed in the corrosion process have been found to have significant impact on the formation of corrosion cracking. These factors are critical in modelling of the residual service life of structures in active corrosion state.

Carbonation of concrete cover is behind the corrosion phenomenon in many outdoor concrete structures, such as facades and balconies. Carbonation of concrete is a chemical reaction between the alkaline hydrates of concrete and carbon dioxide gas, both of which are dissolved in concrete pore water. Because carbonation is mainly controlled by the diffusion of carbon dioxide within concrete, it is commonly modelled using the square root of time relationship, derived from Fick's diffusion law.

Many models have been proposed for depicting carbonation, all of which make use of the square root of time relationship (Parrott 1987). However, empirical measurements have indicated it to overestimate carbonation especially in cases where the concrete is exposed to rain (Tuutti 1982, Huopainen 1997). Therefore, the square root equation should be regarded as an upper limit for carbonation in such cases. The carbonation coefficient k is used to adjust the model to describe the carbonation of different concretes in different environments. (Tuutti 1982).

Another approach has been to incorporate the effect of different environments by modifying the exponent of time (Parrott, 1987). A number of studies e.g. (Thiery et al. 2007, Hyvert et al. 2010) have been concentrated on the reaction kinetics of carbonation by utilizing physical models. The square root equation has also been improved to distinguish between the influences of different individual internal and external factors affecting carbonation (Neves et al. 2012), and to isolate the influences of specific factors (fib 2006) opposed to the one parameter in Eq. (1). A statistical analysis of a carbonation coefficient based on field measurements has been recently presented in Portugal (Monteiro et al. 2012) and in Finland (Lahdensivu 2012).

The main difference between the carbonation model proposed in fib model code (fib 2006) and the one and two parameter models by Tuutti (1982) and Neves et al. (2012) is the requirement for a specific accelerated carbonation test performed in a laboratory environment to determine the carbonation resistance parameter. The latter models, on the other hand, are applicable in practice based on natural carbonation measurements conducted on site.

Corrosion propagation can be modelled by (i) empirical, (ii) numerical or (iii) analytical approaches. (Otieno et al. 2011) Empirical models are sub-divided into three types i.e.: expert Delphic oracle models, fuzzy logic models and models based on electrical resistivity and/or oxygen diffusion resistance of concrete. Empirical models are based on experimentally achieved relationship between corrosion and controlling parameters (e.g. DuraCrete 2000). Three different approaches can be used to develop numerical models: finite element method (FEM), boundary element method (BEM) and resistor networks and transmission line method. Numerical models rely on computational solving of larger entities by dividing them into small elements connected to each other by boundary conditions (FEM, BEM) (e.g. Gulikers and Raupach 2006). Analytical models apply usually thick-walled cylinder approach. Division into cracked inner cylinder and an uncracked outer have also been developed. Analytical models are based on the closed-form solving of mathematical equations derived from the geometry of the problem such as concrete cracking (e.g. Goltermann 1994).

A traditional way of modelling corrosion propagation is by the corrosion rate modified by the diameter of reinforcement and the concrete cover. (Siemes et al. 1985) The corrosion rate itself is related to the wetness and temperature of the structure and is modelled e.g. by the potential electrolytical resistivity of concrete (DuraCrete 2000). A way of finding information on the corrosion propagation phase by statistically calculating backwards the age and initiation time on existing concrete structures subjected to condition assessments has been proposed by Köliö et al. (2014).

3. Research material and methods

The propagation of corrosion on concrete facades in Finnish environmental conditions was studied by a series of field and laboratory studies conducted on twelve residential concrete buildings located in different parts of southern Finland. The studies were conducted in tandem with the normal condition assessment inspections for these buildings. In addition, the extent to which the corrosion rates in concrete facades are affected by the outdoor environment was analysed using long-term (25 months) field measurements from concrete facades under natural weather conditions. These experimental results were compared with statistical information on 947 buildings.

The condition assessment database was used in studying statistically the realized service life of concrete facades in regard of visual damage caused by reinforcement corrosion (Köliö et al. 2014). The age at which visual corrosion damage is generally observed in concrete facades was studied using visual damage ratings given in condition assessments. This damage rating was used together with the age of buildings to study the time it takes for corrosion damage to propagate.

The type and critical amount of corrosion products were studied by electron microscopy and X-ray diffractometry on concrete and reinforcement samples from existing concrete facades on visually damaged locations. This information was utilized in creating a service life limit for concrete facade panels in regard of visual corrosion damage occurrence. Corrosion rate was determined as a combined effect of weather parameters on already carbonated concrete structures exposed to natural outdoor environment. A long term corrosion rate measurement data was combined with weather data from the location of the measurements from the same time period.

These in-depth studies were used to model the probable extension in residual service life given by the active corrosion phase for existing concrete facades. The modelling approach counts among the empirical models with statistical experimental data.

Ways of utilizing the knowledge on the corrosion propagation phase in the renovation strategy were analysed based on acknowledged renovation intervention options or principles (SFS-EN 1504-9; by41 2007). The possible benefits from the propagation phase were analysed in regard of timing, budgeting and prioritizing of renovation projects.

4. Results and discussion

4.1 Reinforcement corrosion modelling

This chapter discusses the service life of concrete facades in Nordic climate including the initiation of corrosion and corrosion propagation until visual corrosion cracking occurs. The discussion is based on studies described in chapter three.

During initiation phase the concrete cover is carbonated as a barrier and finally reaching the steel initiating the actual corrosion process. Until this point, no actual damage has occurred at all. In the propagation phase, as the corrosion proceeds it will eventually induce visual damage to the concrete structure’s surface as cracks or spalls. The rate of this process depends on many things, such as cover depth, diameter of the reinforcing steel as well as temperature and the availability of moisture. A statistical distribution over time was produced for the formation of visual damage after consecutive initiation and propagation phases on concrete facade and balcony structures (Fig. 1). Because the information about the age of the building is linked to the time of condition assessment these examinations do not take into account the fact that visual cracks or damage have, in fact, emerged some time before the assessment date. This time before the condition assessment is in this study unknown. Thus, the visual damage is likely to be formed even earlier than the results indicate, and the results of this study should be treated accordingly.

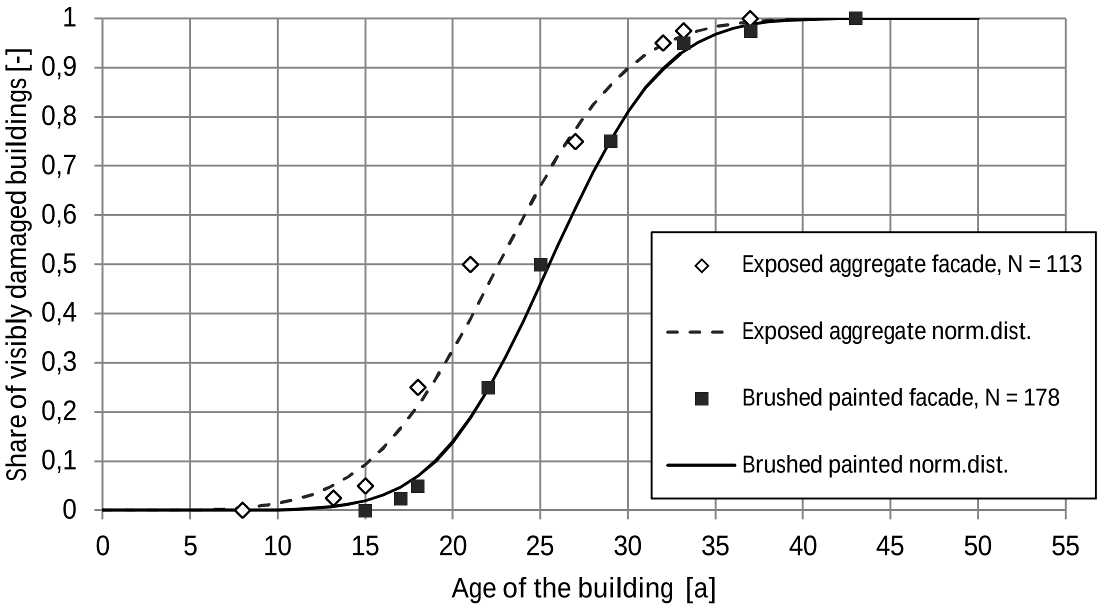

Figure 1: Statistical model for the evolution of corrosion damage after consecutive initiation and propagation phases based on condition assessment data.

The first visual damage had occurred after 15 years from construction in brushed and painted concrete facades and after 8 years in exposed aggregate facades. By median, visual corrosion damage has formed on concrete facades after 21 to 25 years from construction (exposed aggregate and brushed painted respectively). The propagation phase was estimated by extracting from the total age (Fig. 1) a known initiation phase based on carbonation depth measurement data. According to the calculation, the length of the propagation phase is 0.6–1.4 years when adopting a commonly used 5 % safety level. It relates to corrosion of reinforcement with extremely small cover depth or in very capillary concrete. However, this safety level may be too strict compared to empirical knowledge. On average, the length of the propagation phase has been 6–10 years depending on the type of structure.

Concrete structures studied by characterization methods (SEM, EDS, XRD) were on average 38.8 years old. The average time under active corrosion was for the cracked locations 26.0 years. It should also be noted that for all of the samples corrosion has been initiated quite fast (by average 12.6 years) which indicates that both concrete resistance against carbonation has been poor and the environmental conditions favourable to carbonation (somewhere between exposure classes XC3 and XC4). Corrosion products associated with carbonation initiated corrosion on the studied concrete facade panels were mostly hydroxide type of rusts with a unit volume of roughly 3 times the volume of iron. Taking the determined relative volume of the rust layer into account the required corrosion penetration to initiate visually observable cracks in the studied facade panels was by average 67.5 µm (total range of 22.2–119.1 µm) with a corresponding rust thickness of 202.5 µm.

Measured corrosion current densities show high scatter but are in general rather high (Fig. 2). The wind-driven rain amounts on the structures have during the monitoring period been 47 % higher inland than in the coastal region. Inherently, the corrosion rates have been 11–18 % higher inland than in the coastal region. This observation stresses the importance of the micro climate around the building along with the geographical location in regard of degradation rate. Current densities measured as a reference from the bottom surface of a balcony slab (sheltered from rain) were very low. In a regression analysis between corrosion rate and weather parameters all seasons showed high correlation between wind-driven rain and corrosion rate.

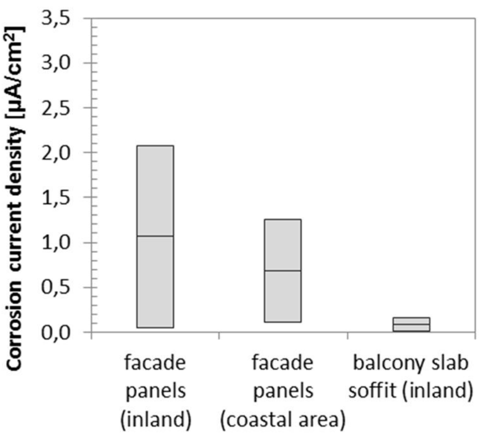

Figure 2: Monthly averaged corrosion current densities recorded in field measurements in inland and in coastal area of Finland.

Corrosion rates during the lifetime of the concrete structures at inland and coastal area locations were estimated using the model with a record of 30-year weather data from 1979–2009. The weather data was available for coastal site from Helsinki-Vantaa airport (distance to site 15 km) and for inland site from Jokioinen observatory (distance to site 79 km). On a long time scale the corrosion rate on concrete facades were relatively steady at the both locations.

The overall average level was 1.2 µA/cm^2 at inland and 1.7 µA/cm^2 at coastal area site. These corrosion rates correspond to a steel loss of 14.6 µm/year and 19.6 µm/year, respectively, derived from the Faraday's law. These corrosion levels can be considered high (Andrade & Alonso 2001) in carbonation initiated outdoor concrete structures. Based on the modelled corrosion rate and the measured critical corrosion penetration, the length of the propagation phase is estimated to be approximately 1.5–8 years in inland and 1–6 years in the coastal area in south facing facades.

4.2 Active corrosion phase in renovation strategy

The studies presented in this paper aim to enhance the knowledge on the corrosion propagation phase in reinforced concrete facades as a part of their service life. The research project confirmed that the propagation phase can provide a considerable extension to the service life of concrete facade panels in Nordic climate. This extension can be from ten to even 30 years. However, it varies considerably due to material, structure and environmental factors.

Table 2: The relationship of initiation and propagation phases in concrete facade panels (average in brackets)

structure surface	share of the initiation phase in the total service life, average in parenthesis (%)	share of the propagation phase in the total service life (%)
brushed painted concrete facade	85–98 (88)	2–15 (12)
exposed aggregate concrete surface	91–99 (94)	1–9 (6)

It appears, from Table 2, that the potential for extending a structure's service life with the propagation phase is in some cases considerable (by average 6–12 %). Although, majority of the service life of concrete is accounted for already in the initiation phase. Therefore, when assessing the total service life of a building, it is critical to ensure the structures have the required resilience to carbonation in terms of concrete composition, concrete quality and cover depths. If the properties of the initiation phase are already fixed (as is the case in existing structures) it seems clear that accurate information about the propagation phase will have to be utilized to extend a structure's service life.

The ability to model or forecast corrosion rates on concrete facades will enhance the capability of realtors to react on upcoming repair needs. This kind of model would be able to predict the residual service life of a certain structure, but it could also be used in creating renovation strategies for a larger building stock by revealing the order of importance or the urgency of single renovation projects. The knowledge on active corrosion phase will enhance the capability of the owner to utilize the delaying options with more confidence. Especially this knowledge will help in pointing out the cases where these options are applicable and where they are not (Table 3). It also illustrates clearly the influence of the delaying of renovation, which will in eventually render lighter repair options not applicable due to increasing degradation.

The occurrence of visual damage is a natural way of judging the service life of these structures since all of the renovation and maintenance decisions are made based on investigations usually commissioned based on these visual signs. This, however, means that lighter remedial actions are not anymore available and repair & protect options have to be considered to some extent. In order to be able to utilize only protective options, the service life should not include propagation phase. The intervention should in this case be taken directly in the end of the initiation phase.

Corrosion induced damage occurred on the studied structures commonly on the lap splicing locations of rebars, in the edges and window openings of the panels and in locations with pronounced moisture load due to poorly functioning flashings and rain water runoff control. If the ratio of concrete cover to reinforcement diameter was small (below 1.5) corrosion related damage had emerged as spalling. If the ratio was well over 1.5 the damage more probably emerged as cracking. Careful design of the above mentioned details will allow longer propagation phases to be taken into account in service life.

Table 3:Renovation options contrasted to different renovation strategies.

Repair option	Early intervention (up to initiation)	Early intervention (up to first visual damage)	Need-based-repair (intrusive)	Maximized service life
a) do nothing & monitor	Available	Available	Not available	Not available
b) re-analyse & downgrade in function	Downgrade not required	Downgrade not required	Available	Not available
c) prevent & reduce further degradation	Available	Available	Not available	Not available
d) repair & protect	Available	Available	Available	Not available
e) replace with new	Not reasonable	Available	Available	Available
f) demolish	Not reasonable	Not reasonable	Available	Available

The available repair options (Table 3) illustrate the importance of early intervention. At this point the available options are many and they are in general fairly light. A need-based renovation strategy already requires some level of intrusive repair. A strategy aiming at maximizing the available service life of the existing structure will lead to heavy renovation, replace or demolition eventually. A conventional limit for the early intervention strategy is the initiation of corrosion. However, it is visualized that this strategy is not compromised even when the service life is extended to the propagation phase. Same set of renovation options will be available until the occurrence of damage as cracking or spalling. This information can be utilized in planning of the renovation of structures, where the initiation phase has already passed. Modelling the length of the propagation phase will allow a time-span of up to 8–10 years for planning and budgeting of the renovation work without compromising the choice of strategy.

5. Conclusions

Renovation strategy of a built asset is tied to the business/maintenance strategy, financial situation and future prospects of the owner. The options and principles available for the renovation of concrete facades are many. However, all of them have specific uses and preferable conditions where they perform best. It should be acknowledged that the decisions of the owner in the timing of the repairs greatly affect which renovation options and principles are applicable. Protective renovation options usually perform best when applied in the initiation phase of degradation whereas delaying intervention will force the use of repair/renew options.

The knowledge on active corrosion phase will enhance the capability of the owner to utilize the delaying options with more confidence. Such a tool could be used also in moving towards a predictive upkeep of realty and the confidence of making long term contracts between realty owners, renovation engineers and contractors.

The research project confirmed that the active corrosion phase can provide a considerable extension to the service life of concrete facade panels in Nordic climate. This extension can be from ten to even 30 years. However, a probable extension is 8–10 years in high environmental stresses. This time period may well provide the necessary latitude for the renovation budget and planning.

Abstract

In building operational phase, facility management problems such as the deferral of critical repair, replacement or renovation of building structure or equipment are often observed in Taiwan due to inadequate annual maintenance funding. Building owners and facility managers are in great need of a method or tool to predict the maintenance costs over the life spans of their facilities in order to allocate adequate maintenance funding to sustain their facilities. To solve this problem, this study adopts and integrates existing technologies such as building information modeling (BIM), facility management system (ArchiBus○,R), and local construction and maintenance cost database (PCCES) to establish the Building Life Cycle Maintenance Cost Prediction method (BLCMCP) to predict annual maintenance costs over building life span based on a set of predefined maintenance plans. It is proposed that (1) BIM software such as REVIT is used to create all the components (each with a CSI's MasterFormat code) of each building subsystem of a building, from which a 'component list' of a building subsystem with quantity takeoff can be generated; (2) Facility management system such as ArchiBus○,R is used to specify the schedules of various maintenance tasks (inspection, repair, renovation, or replacement) for each component of a building subsystem over building life span such as 30 years; (3) local construction and maintenance cost database such as PCCES in Taiwan is used to provide updated construction and maintenance cost data (labor and material costs) for each component of a building sub-system. The annual maintenance cost of a component of a building subsystem in a particular year can be estimated by retrieving the maintenance tasks scheduled from the ArchiBus○,R as well as the unit cost data of each maintenance task from the PCCES according to its MasterFormat code. The 'elevator' subsystem of the Taiwan Building Technology Center (TBTC) building located on the NTUST university campus is used as a case to demonstrate how the established BLCMCP method can be used to estimate the annual maintenance costs of this subsystem and its components over a 25-year life span.

Keywords: MasterFormat code, maintenance schedule, construction and maintenance cost database

1. Introduction

1.1 The Problems

The structure and various building control equipment of a building have their design service lives, and they are expected to degrade or breakdown sometime during the building life span. Facility management plays an important role in operating and maintaining building components and keeping them in reliable conditions. Nevertheless, facility management problems such as the deferral of critical repair, replacement or renovation of building structure or equipment are often observed due to inadequate annual maintenance funding. Building owners and facility managers are in great need of a method or tool to predict the maintenance costs over the life spans of their facilities in early operational phase in order to allocate adequate maintenance funding to sustain their facilities.

1.2 Potential Technologies as the Solution

To solve this problem, this research argues that existing potential technologies such as building information modeling (BIM), facility management systems, and local maintenance cost database can be adopted and integrated to establish a building life cycle maintenance cost prediction tool.

Building Information Modeling (BIM) has recently attained widespread attention in the architectural, engineering and construction (AEC) industry worldwide. Many researches have been dedicated to demonstrate the applications of BIM's responsive quantity takeoff capability in cost estimation in building design and construction phases (Eastman et al., 2008; Meadati and Nelabhotla, 2011; Lu et al., 2016; Popov et al., 2006; Smith, 2014). This study argues that the same capability is potentially applicable to maintenance cost prediction during operational phase as well by producing quantity takeoff for those building elements to be maintained.

Facility management systems or computerized maintenance management system have been used to plan and manage maintenance tasks during building operational phase. To predict building life cycle maintenance cost in early operational phase, it's critical that cost estimations are based on a set of pre-planned maintenance tasks to be conducted on various building subsystems and their components over a certain life span, which can be effectively assisted and scheduled by facility management systems.

To further estimate the cost of each maintenance task, it is necessary to acquire the unit costs of the labor, material, or equipment involved in that task. Local construction and maintenance cost databases, such as RS Means cost data (Plotner, 2013), have been established in many regions or countries, and can provide cost data required for maintenance cost estimation purpose.

1.3 Research objectives

This research intends to develop a building life cycle maintenance cost prediction method to be used in early operational phase. To be more specific, the objectives of this research are:

1. To establish a Building Life Cycle Maintenance Cost Prediction method (BLCMCP) that integrates BIM, ArchiBus®, facility management system and a local construction cost database (PCCES) to predict the annual maintenance costs of a building over its life span given a set of maintenance plans specified in early operational phase;
2. To demonstrate how the developed BLCMCP framework can be applied in the Taiwan Building Technology Center (TBTC) Building on NTUST university campus to predict the life cycle maintenance costs of its elevator subsystem.

2. Literature review

Compared to the construction cost estimation methods devised for new building construction, relatively few researches have been dedicated to developing effective building life cycle cost estimation methods. In their book *Life Cycle Costing for Facilities*, Dell'Isola and Kirk (2003) not only present the methods for economic analysis (ROI, etc.) and life cycle cost analysis (NPV, etc.), but also suggest a framework for estimating life cycle costs, in which decomposing a whole building into several levels of hierarchical elements and adopting MASTERFORMAT or UNITFORMAT that link to cost databanks appear to be the key concepts. Stanford (2010) proposes effective building maintenance as a way to protect capital assets. He not only addresses the importance of budgeting for various types of maintenance taking place during building life span, but also presents budgeting methods adopting the ideas of decomposing a building into four levels of elements as well as remaining design service life for maintenance cost estimation. Kim et al. (2010) employed similar decomposition structure to develop a life cycle cost estimate system for structures of light rail transit infrastructure. The notions underlying the life cycle cost estimation methods proposed above are to decompose a building into several levels of components and then to estimate the life cycle costs for all components individually, which represent great amount of work if done manually.

BIM seems a reasonable technique to be adopted for life cycle cost estimation, considering its capabilities in structuring building components and automatic quantity takeoff. In fact, numerous studies have proposed the 5D concept and applied BIM in building cost estimation to be used during design and construction phase (Cheung et al., 2012; Lu et al., 2016; Popov et al., 2010; Smith, 2014). In these applications, BIM involves more than just 3D modeling and is also commonly defined in further dimensions such as 4D (time) and 5D (cost). 4D links information and data in the 3D object model with project programming and scheduling data and facilitates the simulation analysis of construction activities. 5D integrates all of this information with cost data such as quantities, schedules and prices.

Literature review conducted by this study reveals that little research has been done in applying BIM in predicting long term building life cycle costs. Whyte and Scott (2010) employed statistics and probability, fuzzy set logic, artificial neural networks and objected orientated analysis to develop a life-cycle-cost system in order to assist design decisions, which require advanced techniques to implement. This study argues that the 5D BIM concept, although mainly applied in new building construction cost estimation, linking the 3D BIM model, quantities, schedules, and prices is still a feasible approach to be explored in life cycle cost prediction.

3. The Building Life Cycle Maintenance Cost Prediction (BLCMCP) Methodology

3.1 BIM Model and the MasterFormat Code

This study proposes that building information modeling (BIM) technology be used to organize a building in the following ways for the purpose of life cycle maintenance cost prediction:

1. Each building is decomposed into ten building subsystems: structure, enclosure, interior, HVAC, electrical, telecommunication, fire safety, water/plumbing, conveying, and landscape sub-systems (Table 1).
2. Each building subsystem is decomposed into two levels of elements. A subsystem is first categorized into several major 'assemblies' (level one element), which is then further decomposed into several 'components' (level two element). BIM software such as REVIT can then be used to establish the BIM models for all the 'components' of each subsystem (Table 1). For each 'component' of a subsystem, the maintenance schedules or frequencies of various types of maintenance task can be further specified by facility management software.
3. For each component of a building subsystem, a CSI's MasterFormat code is assigned (Table 1). The MasterFormat code of a component is an unique number or 'key' used to link to and retrieve its maintenance cost data stored in a local maintenance cost database.

Once the BIM models of all subsystems of a building is established, the 'bill of quantity' of all components of ten subsystems can be generated automatically. The 'quantity' of each component is an important parameter for estimating its long term maintenance cost.

3.2 Facility Management System for Long Term Maintenance Tasks Planning

Over the life span of a building, various maintenance tasks (planned or unplanned) are often conducted on individual subsystems and their components to sustain their performance and achieve their service lives. To predict the long term maintenance costs of a building, it is imperative to plan ahead (in early operational phase) for the planned maintenance tasks to be conducted on each component of each subsystem at different time during a certain building life span. The planned maintenance tasks typically conducted are preventive maintenance (inspection/ testing, repair) as well as planned renovation and replacement (Stanford, 2010). The labor (man-hour) and material (or equipment) involved in a particular maintenance task on a component can be assessed, based on which the maintenance cost can be further estimated.

Given the decomposition-structure of a building described in the previous section (3.1), this study suggests that facility management systems (such as ArchiBus®) be used to plan and specify the frequencies (or the schedules) of each type of planned maintenance task (inspection, repair, renovation, and replacement) to be conducted annually for each component of a subsystem over building life span such as 30 years (Frequency columns in Table 1).

3.3 Local Construction Cost Database for Providing Updated Maintenance Cost Data

The unit cost data of the labor and material (or equipment) involved in a particular maintenance task performed on a particular component of a subsystem are required for the estimation of this maintenance cost. In many regions or countries, local building related cost data (in hardcopy or online) have been investigated and updated periodically. For example, the Gordian Group Inc. offers RS Means facilities maintenance cost data in the US, which are organized by using the Construction Specifications Institute's MasterFormat (Plotner, 2013). In Taiwan, the Public Construction Cost Estimation System (PCCES) is a cost estimation system developed by the government to be used by the contractors to prepare the construction cost estimation of a building project. The PCCES contains an updated construction and maintenance cost database (labor, material and equipment unit cost data) for various components of building subsystems which are given with individual MasterFormat codes.

This study suggest that the unit cost data of labor and material (or equipment) involved in four types of maintenance tasks (inspection, repair, renovation, replacement) performed on components of all subsystems be retrieved from the local construction or maintenance cost database in order to further estimate the maintenance cost of all subsystems year by year over a certain building life span (labor cost and material unit cost columns in Table 1).

3.4 Building Life Cycle Maintenance Cost Estimation Model

3.4.1 Total Building Life Cycle Maintenance Cost

To predict the total building life cycle maintenance cost over a certain life span of a building, this study proposes that the total costs of planned maintenance conducted on all ten subsystems and their components are estimated year by year, as indicated in Eq-1.

$$BLCMC_n = \sum_{i=1}^{n}(STRUCTURE_i + ENCLOSURE_i + INTERIOR_i + HVAC_i + POWER_i + TELECOM_i + FIRE_i + PLUMB_i + CONVEY_i + LANDSCAPE_i) \quad \text{(Eq-1)}$$

where:

$BLCMC_n$ = total long term maintenance cost over a n-year building life span
$STRUCUTRE_i$ = total maintenance cost of structure subsystem in year-i
$ENCLOSURE_i$ = total maintenance cost of enclosure subsystem in year-i
$INTERIOR_i$ = total maintenance cost of interior subsystem in year-i
HVACi = total maintenance cost of HVAC subsystem in year-i
$POWER_i$ = total maintenance cost of power/electrical subsystem in year-i
$TELECOM_i$ = total maintenance cost of telecommunication subsystem in year-i
$FIRE_i$ = total maintenance cost of fire safety subsystem in year-i
$PLUMB_i$ = total maintenance cost of plumbing subsystem in year-i
$CONVEY_i$ = total maintenance cost of conveying subsystem in year-i
$LANDSCAPE_i$ = total maintenance cost of landscape subsystem in year-i

3.4.2 Annual Maintenance Cost of a Subsystem and its Components

To predict the annual total maintenance cost of a subsystem and its components in a particular year, this study proposes that the total costs of four major types of planned maintenance (inspection, repair, renovation and replacement) conducted on the subsystem and its components in that year are estimated. For example, to predict the total annual maintenance cost of HVAC subsystem in year-i ($HVAC_i$), the total costs of inspection, repair, renovation and replacement tasks conducted on all HVAC components in year-i can be estimated individually and added up, as indicated in Eq-2.

$$HVAC_i = H\text{-}inspect_i + H\text{-}repair_i + H\text{-}renovate_i + H\text{-}replace_i \qquad \text{(Eq-2)}$$

where:

$HVAC_i$ = total cost of four types of maintenance on all HVAC components in year-i
$H\text{-}inspect_i$ = total cost of all <u>inspection</u> tasks conducted on all HVAC components in year-i
$H\text{-}repair_i$ = total cost of all <u>repair</u> tasks conducted on all HVAC components in year-i
$H\text{-}renovate_i$ = total cost of all <u>renovation</u> tasks conducted on all HVAC components in year-i
$H\text{-}replace_i$ = total cost of all <u>replacement</u> tasks conducted on all HVAC components in year-i

3.4.3 Annual Maintenance Cost of a Particular Component of a Subsystem

To predict the annual total cost of four types of planned maintenance tasks conducted on a particular component of a subsystem in a particular year, this study proposes that the monthly costs of each type of planned maintenance conducted on that component in that year are estimated and added up, as shown in Eq-3.

$$HVAC_{k\text{-}i} = \sum_{j=1}^{12}(H_k\text{-}inspect_{i\text{-}j}) + \sum_{j=1}^{12}(H_k\text{-}repair_i) + \sum_{j=1}^{12}(H_k\text{-}renovate_i) + \sum_{j=1}^{12}(H_k\text{-}replace_i) \qquad \text{(Eq-3)}$$

where:

j ranges from 1 to 12, representing 12 months;
k represents the k^{th} component of the HVAC subsystem.

To further estimate the annual 'inspection' cost conducted on the k^{th} component of HVAC subsystem ($H_k\text{-}inspect_{i\text{-}j}$), the frequency of inspection and the labor and material required in year-i planned earlier can be retrieved from the FM system, and then the labor and material unit costs can be retrieved from local construction cost database, whose multiplications yield the monthly inspection costs and thus annual inspection cost. Similarly, annual 'repair', 'renovation' and 'replacement' costs for the k^{th} component of HVAC subsystem can be estimated.

By adding up the annual total maintenance costs of all components of HVAC subsystem in year-i, $HVAC_i$ can be estimated. Similarly, the annual total maintenance costs of all other sub-systems can be estimated. Likewise, the annual total maintenance cost of a ‘whole building’ can be estimated year by year, and finally the total building life cycle maintenance cost.

4. Demonstration Case

4.1 The Subject - TBTC

The Taiwan Building Technology Center (TBTC) building is a relatively new but small building (in operation since 2011.1) located on the NTUST university campus (Figure 1). TBTC is a steel structure with a curved facade assembled from triangular punched aluminium panels, and a seven-story facility (plus B1) with a total floor area of 1,400m^2. It's mainly a research building with functional uses of research lab, conference room, and office. Its 'elevator' subsystem is used as a case to demonstrate how the established BLCMCP method can be used to estimate the annual maintenance costs of this subsystem and its components over a 25-year life span.

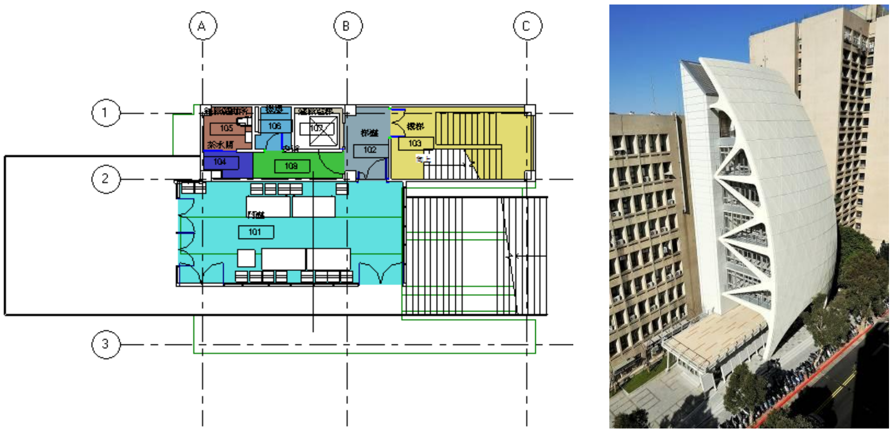

Figure 1: First floor plan and exterior view of TBTC.

4.2 The BIM Model of TBTC

Autodesk's REVIT® was used to build the BIM model for TBTC (Figure 2). BIM models were built for each of the ten subsystems with two levels of elements according to the decomposition structure specified in Section 3.1. Each component of a particular subsystem is given a MasterFormat code. The exemplary 'elevator' subsystem consists of four assemblies (machine, car, control and hoistway) and 18 components (Figure 2, Table 2).

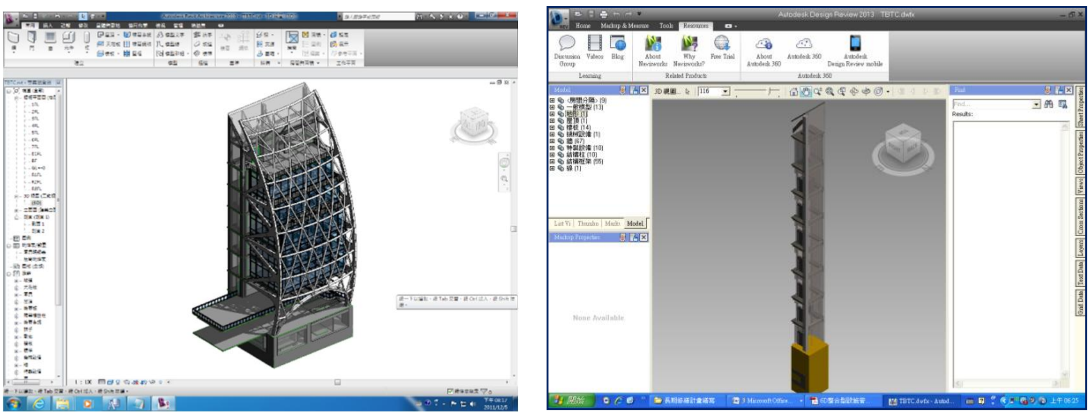

Figure 2: The established BIM models of a certain floor and the elevator subsystem of TBTC.

4.3 ArchiBus○,R for Maintenance Planning

Facility management software ArchiBus○,R was used to establish the maintenance plans of all the components of the ten subsystems of TBTC over a 25-year life span. In the case of TBTC's elevator subsystem, the schedules or frequencies of four types of maintenance tasks to be conducted on each of the 18 components were planned year by year. Table 2 shows conceptually the maintenance schedules of all 18 components planned for 2026 (to be 16 years old). It's noteworthy that five components are scheduled to be replaced in January, 2026 (Ds in Jan. column in Table 2). Besides, the labor and material required for each type of maintenance tasks are specified by ArchiBus○,R, as indicated by the MD and Mat. columns in Table 3.

Table 1: The maintenance schedules of all components of elevator subsystem planned for 2026.

Note: A = inspection; B = repair; C = renovation; D = replacement.

4.4 PCCES: The Maintenance Cost Database

The Public Construction Cost Estimation System (PCCES) is a local construction cost estimation system and construction cost database in Taiwan. For each component of all ten subsystems of TBTC, the labor and material unit cost data for each type of maintenance task were retrieved from PCCES according to the MasterFormat code of the component. Table 3 shows conceptually the labor and material unit cost data for each type of maintenance task retrieved from PCCES for all 18 components of the elevator subsystem.

4.5 The Building Life Cycle Maintenance Cost Prediction for TBTC

For the elevator subsystem of TBTC, the annual total cost of each type of maintenance tasks conducted on a certain component (say 'inspection') were calculated as: $CONVEY_{k-15}$ = quantity * $INSPECT_{freq}$ * ($INSPECT_{labor}$ * $INSPECT_{lab\text{-}unit\ cost}$ + $INSPECT_{material}$* $INSPECT_{mat\text{-}unit\ cost}$). Three other types of maintenance tasks conducted on this component were calculated similarly. Table 4 shows the monthly maintenance costs for all components of the elevator subsystem in 2026 (inflation rate not considered in this study for simplicity reason). In most of the months in 2026, periodical inspection and repair are to be conducted, resulting in 1441~2936 NTD monthly maintenance costs; whereas five components are scheduled to be replaced in January, resulting in 238,224 NTD replacement cost. The annual total maintenance cost for elevator subsystem in 2026 is estimated to be 263,574 NTD. Figure 3 exhibits the annual and accumulated maintenance costs of TBTC's elevator subsystem over its 25-year building life span. Most of annual maintenance costs of the elevator subsystem range from 20,000~30,000 NTD and the accumulated maintenance cost over 25 years is estimated to be 1,362,415 NTD.

Similarly, the annual total maintenance costs of nine other subsystems of TBTC over 25-year life span can be estimated and added up to generate the building life cycle maintenance cost at the whole building level for TBTC.

Table 2: The labor and material required for each type of maintenance task are specified by ArchiBus and their unit cost data retrieved from PCCES for all elevator subsystem components.

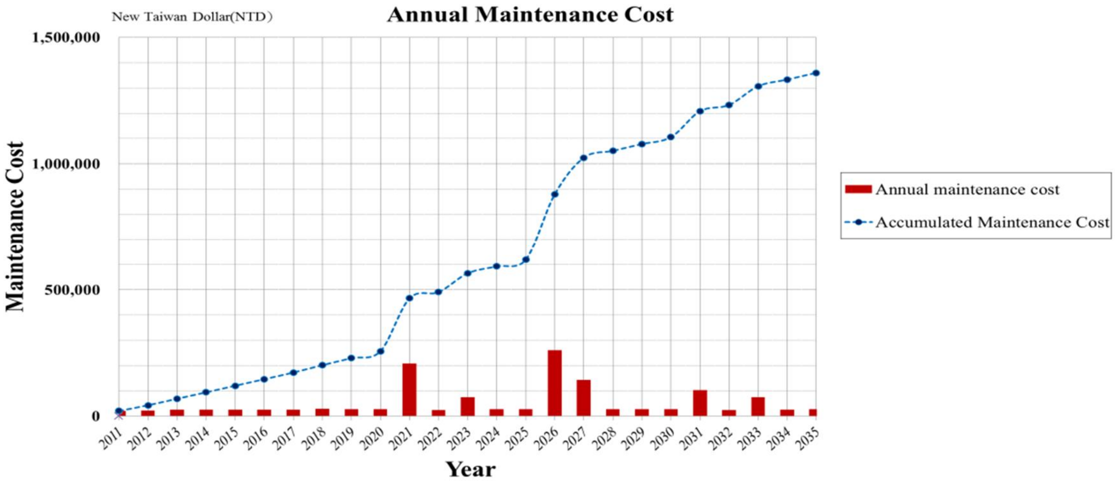

Figure 3: Annual and accumulated maintenance costs of TBTC's elevator subsystem over its 25-year building life span.

5. Conclusions

Building owners and facility managers need a method or tool to predict the maintenance costs over the life spans of their facilities in early operational phase to allocate adequate maintenance funding to sustain their facilities. Responding to this need, this study adopts and integrates existing technologies such as building information modeling (BIM), facility management system (ArchiBus○,R), and local construction and maintenance cost database (PCCES) to establish the Building Life Cycle Maintenance Cost Prediction method (BLCMCP) to predict annual maintenance costs over building life span according to a set of maintenance plans specified in early operational phase. The 'elevator' subsystem of the Taiwan Building Technology Center (TBTC) building located on the NTUST university campus is used as a case to demonstrate how the established BLCMCP method can be used to estimate the annual maintenance costs of this subsystem and its components over a 25-year life span.

This research focuses more on elaborating the concepts and the framework of the developed Building Life Cycle Maintenance Cost Prediction method (BLCMCP). The life cycle maintenance cost estimation for the exemplary elevator subsystem of TBTC was done manually in Excel. Further research effort is required to make the BLCMCP a working tool in predicting building life cycle costs. For example, building utility cost and custodial cost should be included as the major items of life cycle costs as well as the prediction methods should be researched. In addition, inflation rate should be considered when making long term cost estimations. Finally, software engineering effort is required to provide a functional system architecture, database, and user interface that integrate BIM model, FM system, and local construction and maintenance cost database so that life cycle cost estimation can be performed automatically.

Abstract

The emergence of BIM in the construction industry has come with promises of improving efficiency in project delivery and asset management. BIM concerns the digitization of the building project by depending on information technology capabilities already achieved in various professional domains associated with different stages of the building life cycle. While the utilisation of BIM in the various professional domains and project stages is increasing, research suggests that the building operation and management stage is being left behind. Exploring BIM applications that encompass the building operation are therefore important to improve efficiency during use and coordination with other stages in the project life cycle. As such a framework for utilizing feedback loops on building energy consumption to inform and improve design and facility management in a BIM environment is proposed. In this paper, the authors present the prototype from the implementation of the framework which is interfaced with a BIM-enabled tool. The paper concludes that the framework is useful in contributing to bridging existing gaps between the design, construction and operation phases of a building's life-cycle.

Keywords: BIM, data acquisition, facility management, energy consumption

1. Introduction

A considerable amount of research has been conducted on digitizing the various aspects of a typical building project since the advent of building information modelling (BIM). Most of these efforts leverage on the BIM/computer-aided capabilities already achieved in the various professional domains associated with the different stages of the building life cycle. The overall aim is to provide consistent digital information that can be reused by stakeholders throughout the building life cycle (Eastman et al., 2008; Arayici et al., 2012). It is predicted that BIM will help to drastically reduce errors, fast-track project delivery time and save implementation costs, as well as assisting with asset management. Benefits in the latter sphere can only be accrued if feedback loops can be established so that the information in a BIM is used to inform future design of similar buildings and facilities management. This paper illustrates how such feedback loops can be established by incorporating building management system (BMS) data into BIM to inform the designer and the facility manager.

Section 2 provides a background on the role of data acquisition in facility management integration with BIM .The challenges associated with the utilization of acquired data from building management system are presented in Section 3. The proposed framework is discussed in Section 4 before presenting a test-case of the prototype from the framework implementation in Section 5. Section 6 concludes the paper.

1.1 Research Problem

The existing multi-disciplinary nature of the construction industry offers advantages entrenched in the division of labour. However, it presents challenges such as the lack of interoperability between IT tools used by different professionals resulting in barriers to seamless information exchange. One aspect that is common in these different domains is design specifications, where materials are specified for production/construction according to anticipated performance mainly based on laboratory tests in order to meet the relevant standards. In this context, the design stage offers the best opportunity to influence cost and sustainability through design specification (Ding, 2008; Kohler and Moffatt, 2003). However, professional domains have not sufficiently explored even this clear opportunity (Wang et al., 2013; Oti and Tizani, 2015). Concerning the area of facility management (FM), BIM deficiencies are partly due to the fact that projects are being delivered with little or no considerations for FM integration unless a Client specifically requires this to be done. FM is particularly peculiar as it covers the building operation stage when the performances of all facilities in the building are tested against the building as designed. In addition, the efficient management and integration of resources in the form of people, places, processes and technology are panaceas to ensuring optimum functionality of the built environment. Thus, the facility manager is confronted with location of the property/project, type of facility vis-à-vis users, quantity of workspace and associated requirements, quality and performance of workspace, and the impacts of content layout and space allocation on work performance (Tay and Ooi, 2001). The advent of BIM promises to greatly lighten up the seeming complexities inherent in the tasks assigned to the facility manager as well as other professionals. Despite this potential, the results from a recent survey (Becerik-Gerber et al., 2011) in the USA suggests that the operation and management stage appears to be the least explored, compared to design and construction, in adopting BIM applications to execute requisite project tasks. By implication, the process of leveraging on BIM to close up the feedback loop of learning from best practice examples inherent in the project life cycle stages is equally at the lowest ebb. As the scope of

BIM application gradually expands, there is therefore the need to learn from performance histories of projects via feedback loops to the appropriate stages in the project life cycle.

1.2 Research methodology

Review of literature has been carried out to establish research gaps and further employed to ascertain appropriate methodologies for achieving the aim of this research. The review covered aspects relating the modelling of building energy consumption histories from building energy management systems and areas such as BIM enabling systems, building design and construction and facility management. This helped in identifying research gaps associated with modelling building performance feedback to BIM and possible process options for such communication. The Rapid Application Development (RAD) information modelling approach (Maner, 1997) was used to develop and implement a framework for utilizing performance histories in BIM and facility management. The RAD methodology employs cycles of re-specify, re-design and re-evaluate on the prototype system from its conception to when it achieves a high degree of fidelity and completeness. The prototyping process is therefore characterized by increased speed of development and experiences of series of births rather than deadlines. It informed the implementation of the prototype which entailed the interfacing of a BIM-enabled tool with object oriented representation of information in a contemporary computer programming language.

2. Data acquisition in FM and integration with BIM

There exist potential areas for BIM application in facility management where feedback can be useful. Some areas already identified by Becerik-Gerber et al (2011) include locating building components, facilitating real-time data access, visualization and marketing, considering ease of maintenance, creating and updating digital assets, space management, planning and feasibility studies for noncapital construction, emergency management, controlling and monitoring energy, and personnel training and development. While the modalities of BIM implementation may differ in all these areas, what will perhaps be common to all is the process of harnessing feedback from the model to inform and improve asset performance. This process will require more than just engaging the facility manager in the design stage as suggested in Wang et al (2013). It will require careful planning, mapping and integration of the facility management operations into the BIM approach, including the operations data acquisition, analysis and management strategy. This research stems from this premise. Its aim is to present a framework focused on the integration of energy performance data as an option in BIM implementation.

Energy consumption in the building operation stage is higher than other life cycle stages (Clarke et al., 2008). Obviously, one of the reasons behind such high energy consumption is the cumulative consumption over the long building life-cycle, usually in decades. It is therefore important that efforts are directed towards keeping energy consumption at a very low level during the operation of the building. This requires active participation of facilities management personnel in decision making regarding regular building operation and maintenance tasks. As such facility management personnel need to be better informed about the performance of building systems. A means for enhancing informed decision making and effective management of facilities is through context sensing and data capture from applications or entities in the building (Taneja et al., 2010). Context sensing operations may cover the monitoring of information on the environmental state, behaviour and situation of an application or a device (Dey, 2001).

The use of building energy consumption data to improve the design and operation of buildings is an active area of research. This process has been commonly called building energy management system (BEMS) or simply building management system (BMS). It is concerned with the active control of energy-dependent systems in the operation phase of the building (Doukas et al., 2007). The technological advances in BIM offer opportunities to integrate BMS data. This area needs to be fully explored. The existing gaps in linking BMS data to BIM has been noted for contributing to the inconsistencies in graphical energy data generated from manual input of repetitive energy management system data (Becerik-Gerber et al., 2011). It is therefore necessary to integrate data acquisition systems into BIM to facilitate real-time monitoring and automated control of building facilities.

2.1 Approaches to the integration of BMS data to BIM

A key goal of this paper is to facilitate the understanding of how BMS data can be analysed to inform design iterations taking advantage of technological trends of using BIM. This encompasses identifying how to provide feedback loops from the building in-use to successive design iterations of proposed building projects. The integration of facility management with BIM that particularly relates to the aim of this paper has two basic approaches to linking BMS data to BIM. The approaches include (1) BIM – Energy Analysis Tool – BMS link and (2) BIM – Energy Consumption Viewer Plugin link.

- **BIM – Energy Analysis Tool – BMS Link**

In this approach (Figure 1), it is envisaged that BMS data can be sent to Energy Analysis tools to carry out requisite analysis before feeding the outputs to building models in a BIM-enabled tool. This approach can take advantage of database management systems, open file formats and common data environments. The linking of DAT to Onuma Planning Systems (Ozturk et al., 2012) falls into this approach. It is also possible to have the Energy Analysis Tool in a single module with BIM tool or integrated with BMS data collection. For example Autodesk Project Dasher, as a visualization tool, can overlay BMS data on 3D BIM for the monitoring of historical and real-time analysis of building performance data (Attar et al., 2010; Khan and Hornbæk, 2011). In a BIM environment, meaningful visualisation of energy consumption profiles becomes possible which can aid the quick understanding of non-experts including occupants and so may influence their behaviours.

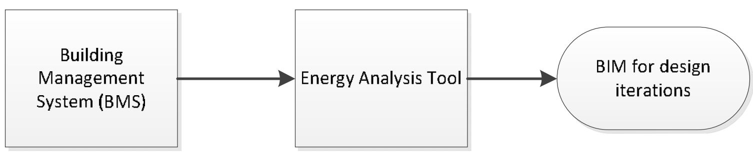

Figure 1: BIM - Energy Analysis Tool Link

- **BIM – Energy Consumption Viewer Plugin Link**

Here, a BIM tool is bolted with an external application such as Energy Consumption Plugin to enable the viewing of energy consumption profiles of buildings (Figure 2). A plugin is an external application which can be continuously improved in sophistication through computer programming. Refined BMS data is uploaded into the plugin linked to a BIM-enabled tool through associated application programming interface (API). Depending on the sophistication of the plugin, aspects of consumption data analysis could also be carried in the plugin environment. The result is addition of a new external tool to the BIM environment that can be called up for the visual presentation of historical energy performance to ease understanding of non-experts such as building occupants. For our research, this approach offers us a flexible way to input refined BMS data into the prototype system for display in a BIM environment that is beneficial to standardized building designs.

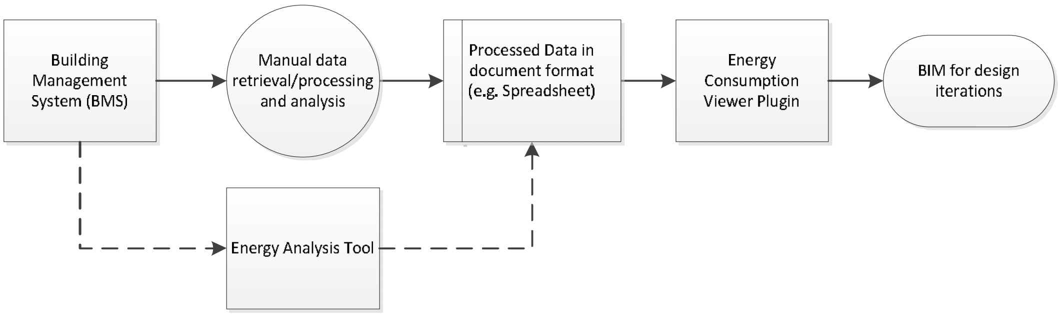

Figure 2: BIM - Energy Viewer Plugin Link

3. Challenges in the use of BMS data

The technological advances made in the development of building data acquisition systems are well acknowledged (Taneja et al., 2010; Becerik-Gerber et al., 2011; Ozturk et al., 2012). However, there have been challenges in utilizing such data to meaningfully inform and improve subsequent project design and delivery. The Big Data syndrome is also associated with the streaming of data from such acquisition systems (Olsson et al., 2015). More often than not, data collected from acquisition systems grow very large in size and is too unstructured to put to immediate beneficial use without some form of structuring and analysis. Thus, the technological advances in BIM offer opportunities to overcome a number of these challenges by integrating BMS data and learning from energy performance data as feedback to various building life cycle stages.

One obvious objective of measuring building energy consumption such as through BMS is to ascertain how the building performs in use. It also helps in determining what the user needs to pay for the services provided. Besides the collective responsibility to reduce environmental pollution, “the polluter pays” approach (Owen, 2006; Bürger et al., 2008) has been a major driver compelling energy consumers to explore avenues to reduce their quotas of pollution arising from energy use. The monitoring and acquisition of energy consumption over a period provide opportunities for strategising various means to achieving reductions in costs that accrue from energy bills. This is especially important as energy is used for a wide range of activity categories including air conditioning and heating, heating and pumping of water, lighting, powering of ICT, and the plethora of personal electronic devices etc. Ascertaining the various proportions of consumption attributed to these categories could be beneficial. BIM-BMS linkage may prove useful for the facility manager in achieving desired energy consumption reductions. Such linkage will provide opportunity for harnessing feedback from the model to inform and improve asset performance and vice versa. It will entail careful planning, mapping and integration of the facility management operations into the BIM approach. This includes the use of BMS to improve the design and operation of buildings concerned with the active control of energy-dependent systems (Doukas et al., 2007). Research suggest that the existing gaps in linking BMS data to BIM are contributory to the inconsistencies in graphical energy data generated from manual data input of repetitive energy management systems (Becerik-Gerber et al., 2011).

4. Proposed framework for utilizing data from BMS in BIM

Figure 3 summarises the overall research context. It shows the proposed schematic framework of the BIM implementation process to improve building design. As illustrated in the figure, existing drawings, textual information and specification are reproduced as BIM generic systems which can be combined with various site models. These combinations can then be further tailored as site – specific building information models for building construction and operation purposes. These processes produce progressive as-designed BIM, as-built BIM and the live BIM which are used for actual building construction operations and the building operation. They also serve as channels to supply feedback information as a learning process to Model Preparation stage for the development of the generic building design model. Also highlighted in Figure 3 is the aspect of BIM - BMS data interaction for which the BIM - Energy Viewer Plugin Link proposed. This achieves the requirement of users (designers) being able to graphically visualize and compare energy consumption histories of completed buildings in BIM environments. Also such system should allow appreciable degree of flexibility in configuring the input of data from BMS. Lastly, the linkage system should leverage on automating the process of entering BMS data into the system.

5. Case illustration of framework implementation

The framework of data acquisition utilization in BIM is implemented using a prototype as a demonstration of proof concept. The technicality involved in developing the prototype is briefly explained in this section including a scenario of using the prototype in a real- life project.

5.1 Description of prototype for data acquisition utilization in BIM

The approach adopted in developing the prototype for data acquisition utilization in BIM is the BIM – Energy Consumption Viewer Plugin Link. The BIM platform used in developing the prototype for data acquisition utilization is Revit 2014. The prototype can be configured to work in Revit 2015 or new versions to come. The implementation of the prototype system was carried out in C# using .NET and linked to the BIM enabled software (Revit 2015). The prototype plugin can be accessed via the external tools link in Revit 2014 IDE. It functions as an extension of plugin application of the earlier research work on the sustainability appraisal of structural steel framed building (Oti and Tizani, 2015).

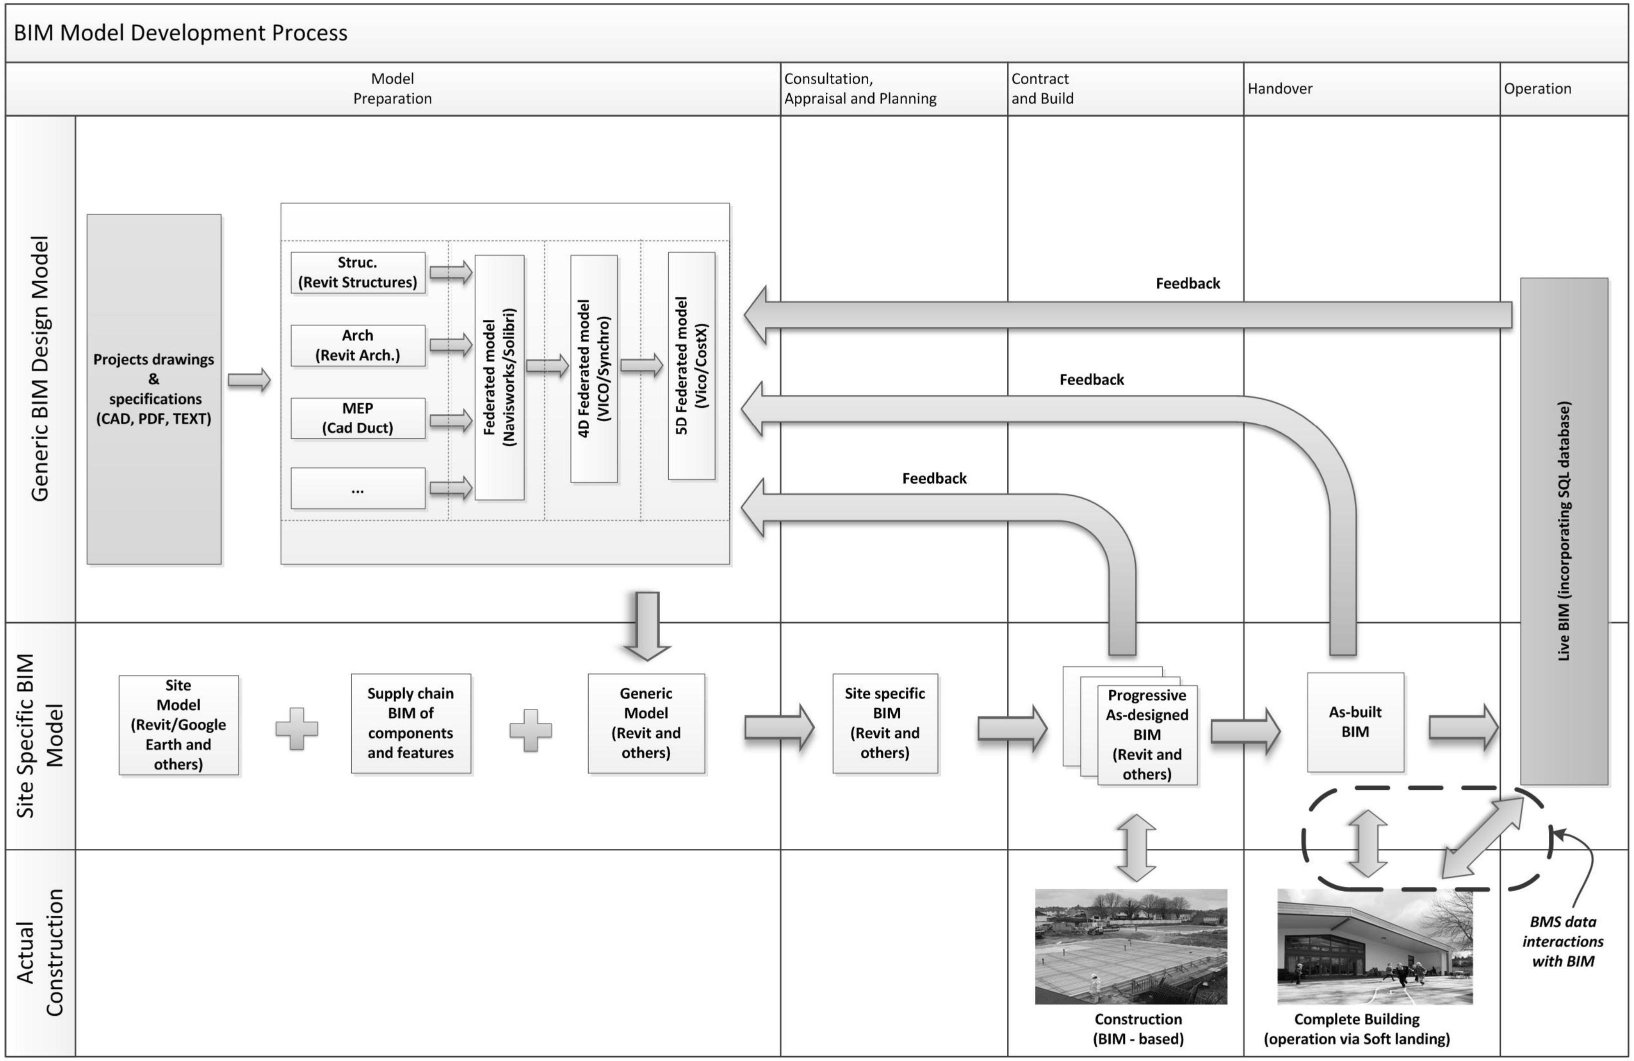

Figure 3: Framework for using BIM to improve the project delivery process

The prototype has been developed through the iterative testing of system components following the RAD approach. It leverages on the characteristic increased speed of development and progressive system refinement to achieve early usability. The flowchart illustrating the actions and processes captured in the prototype system is given by Figure 4. The programme is called through the Energy Use History option of the sustainability Estimation Programme from a BIM enabled environment. On the selection of the project (by name) to examine, the type of information to further explore can then be specified. This offers the option of comparing Design benchmarks and Actual Consumption records or examining various energy consumption categories. These information records are extracted by the system from spreadsheets saved in the various project names and containing pre-defined data. The consumption categories can be examined for a single project or a combination of projects. The intention of such combination is to compare and contrast trends of the same consumption categories of different projects. The system then displays corresponding output charts; from this point, reports can be produced. The user can switch back and forth different projects and consumption categories or quit the programme.

The prototype accesses design data and processed BMS (energy consumption) data saved in MS Excel file formats and expresses abstracted information on energy consumption in terms of ‘Design’ and ‘Actual’ for buildings. These values are compared at various levels of granularity to investigate wastes and encourage the use of appropriate measures to reduce consumption levels and save costs. At the moment, the input data into the plugin need to be provided in Excel file format which requires manual processing of the BMS data. However, there is a possibility that this function of processing BMS data and saving in Excel Format can be done by an appropriate Energy Analysis Tools if available.

5.2 Test case of using the prototype

Three projects have been used to illustrate the testing of the prototype. The data from one (Oakfield Project) of the projects have been obtained from a collaborative research project platform on low impact school procurement. The data from the other two projects were generated as a variant of the Oakfield project in order to demonstrate the operation of the prototype. The Oakfield Project is a primary school building in the UK completed and opened for use in October 2012 with a data acquisition system in place and running. Energy consumption levels have been collected and processed in spreadsheets serving as ready input for the prototype. The relevant information were extracted from the spreadsheet and recorded in formats for easy abstraction by the prototype. Since the prototype can be called in a BIM-enabled environment, the operation history of consumption levels and design benchmarks of buildings can be compared.

Figures 5 and 6 show alternative chart views of the design and actual energy consumption figures of the Oakfield project from November 2012 to February 2014. Similar charts can be obtained for the other listed projects. Thus, project information need to be entered in prescribed Excel format and loaded into the prototype to appear in the list of Project and Analysis listBox. The advantage of these charts to designers is that they will help to provide opportunity for quick review of design and performance benchmarks for more critical examination and analysis where required. For example, the designers' attention may be drawn to the Heating, Hot water and ICT sub-consumption category for further investigation if the respective charts reveal some unexpected outputs. The plug-in neither extracts data from nor feeds data/information to BIM objects but serves as a visualisation tool for historiacal building energy performance as a starting point. Further, the prototype can compare information on energy costs for design and actual consumption of projects. This can be done for any of the listed projects and also compared on project basis. These charts and the underlying data can be viewed and printed for hard copy recording.

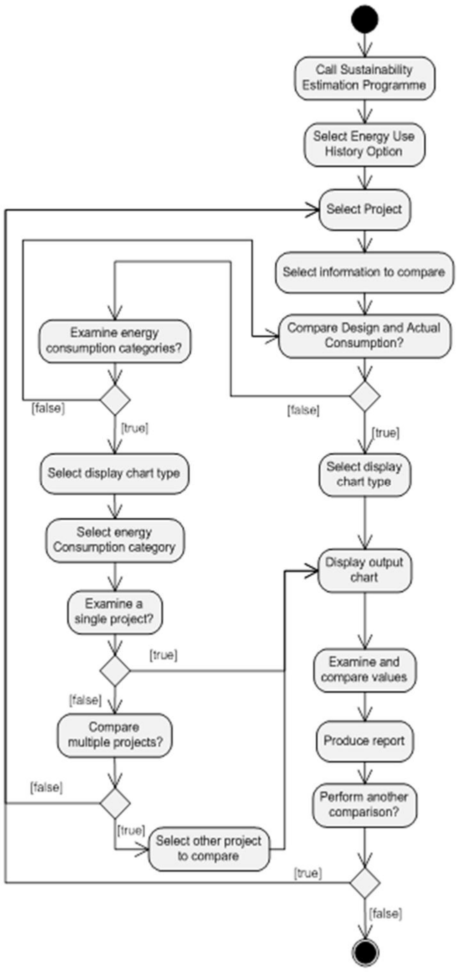

Figure 4: Prototype implementation flowchart

6. Conclusion

One aspect of concern in the emerging BIM applications is how to influence overall project costs and improve sustainable construction practices right from the planning and design stages. This requires the integration of existing work stages and processes into BIM. The incorporation of FM issues into BIM have seen the least patronage even though it is one of the key stages where all the outputs of the concerted efforts of planning, design and construction of the building is put to test by use. There is the existing gap of how outcomes from such tests are fed back to the planning, design and construction processes to contribute to improving the overall project delivery.

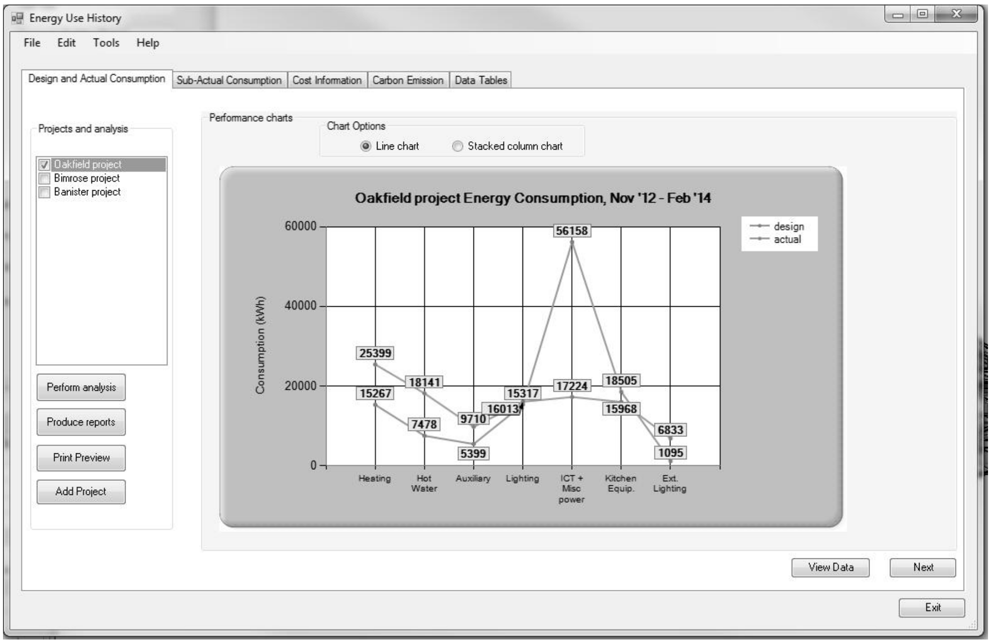

Figure 5: Comparison of Oakfield project design and actual (line chart)

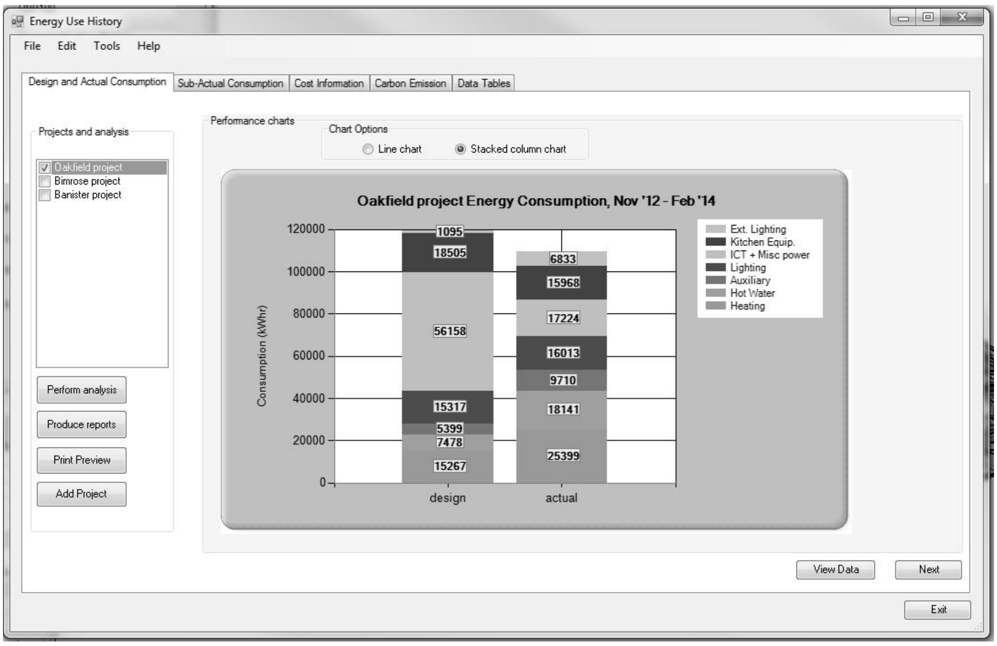

Figure 6: Oakfield project design and actual stacked column comparison

We therefore proposed a BIM-BMS data linkage plugin as feedback to enable designers learn from building energy performance histories. Thus, current energy analysis and design tools utilize conceptual design information such as volumetric and spatial data. These tools are lacking in achieving the aim of establishing requisite feedback of performance histories to BIM. Thus, it is difficult to input raw or refined BMS data in these tools for the purposes of analysis and linking such data back to a building information model. The reason are that (i) large volume of data will usually be involved, (ii) the process of entering data into such tools lack flexibility and (iii) facility management tools do not carry out energy design and analysis at the early project phases but have the capability of capturing and reporting data generated in the field or during building operation. In this paper we detailed the approach to meeting the requirement of utilizing sensing and automated data acquisition technologies (BMS data) in building information models (BIM). Also, we identified available approaches for integrating BMS data to BIM and described the adopted approach of using plugins. The work described a framework that utilizes feedback loops on building energy consumption to inform and improve design and facility management to explore adequate building digitization. The demonstrated approach including the process flow chart and information representations utilized in this work are useful in bridging existing gaps of harnessing historical data from the building operation phase to assist in building information modelling and design.

Abstract

The integrated design (ID) process has received numerous endorsements across many disciplines as an effective way to design and build more sustainably. Countless reports, papers, journal articles and lectures have demonstrated the many benefits inherent to the ID process; however, rarely do these accolades provide concrete numbers. Energy modeling is becoming common practice, especially for buildings seeking green certifications or improved performance. However, energy modeling is often done too late in the process, after nearly all design decisions have been made. As a result, the process of modeling after design negates the possible benefits and does little to improve the energy performance of the building. Energy modeling professionals have the capacity to provide concrete predicted energy use numbers throughout the design process that can lead to informed design decisions.

This research outlines how to effectively utilize the ID process in order to build a more sustainable building. Additionally, it looks at the role of live energy modeling during the ID process and identifies the benefits of providing design teams with predicated energy use information early in the design process.

The purpose of this research is to identify the benefits of interactive live energy modeling during the ID process over the use of energy modeling simply to show code compliance. The research consists of a comparative analysis using case studies, data analysis and expert interviews with energy modeling professionals. This research demonstrates how the use of live energy modeling within the context of an ID charrette can reduce the predicted energy use of new schools.

Keywords: Integrated Design, Live Energy Modeling, Energy Conservation Measures, ID Charrette, Case Study

1. Introduction

In his book *Sustainable Energy – Without the Hot Air* author David MacKay outlines the need for 'numbers, not adjectives' when it comes to our conversations about energy efficiency. He writes,

> *"In public debates, people just say 'Nuclear is a money pit' or 'we have a* huge *amount of wave and wind.' The trouble with this sort of language is that it's not sufficient to know that something is huge: we need to know how the one 'huge' compares with another 'huge,' namely our huge energy consumption. To make this comparison, we need numbers, not adjectives* (MacKay 2009, p.3).

We often look for the 'silver bullet' or 'low hanging fruit' that will dramatically improve the energy performance of our buildings. But in order for us to come up with effective solutions, we need numbers on which to base our decisions and not mere adjectives. Energy modeling is one tool that provides designers with numbers to demonstrate building performance though it can be utilized in many different ways.

The purpose of this research is to identify the benefits of interactive live energy modeling during the integrated design (ID) process, over the use of energy modeling simply to show code compliance. The research consists of a comparative analysis using case studies, data analysis and expert interviews with energy modeling professionals. The quantitative methods include case studies and data analysis, while the qualitative methods include expert interviews with energy modeling professionals. This research demonstrates how the use of live energy modeling within the context of an ID charrette can reduce the predicted energy use of new schools.

Additionally, this research establishes a road map for future design teams looking to effectively design and build more sustainable K-12 schools. This research focuses on schools in particular because they are often owner-occupied and directly concerned with operating costs. By focusing on schools that have utilized energy modeling during the early design stages, specifically during ID charrettes, and comparing the predicted energy use results and various modeling inputs with schools that did not participate in charrettes, this research will show the tangible benefits of live energy modeling.

2. Integrated Design and Live Energy Modeling

In order to gain a better understanding of the relationship between integrated design and live energy modeling, below an overview of the ID process is outlined along with how it benefits the design process.

2.1 Overview of the Integrative Design Process

The design and construction industry has long struggled with being efficient, collaborative and cost effective (Latham1997; Gallaher et al. 2004). These drawbacks have made it challenging to produce high performance buildings that meet the needs of the occupants and the environment. Over the years, a number of approaches have been developed to address these drawbacks such as "Building Information Modeling" or "Integrated Project Delivery," yet these approaches still lack the holistic methods inherent in an ID process (Owen et al. 2010).

In 2001, the British Columbia Green Building Roundtable, comprised of public sector and non-profit organizations in the province of British Columbia, Canada, came together to develop a "Roadmap for the Integrated Design Process." This roundtable led to a number of publications and reports designed to advance green building principles and practices across the sector. One of the early roundtable reports established a working definition of the ID Process, which is described as:

> *[a] method for realizing high performance buildings that contribute to sustainable communities. It is a collaborative process that focuses on the design, construction, operation and occupancy of a building over its complete life-cycle. The ID Process is designed to allow the client and other stakeholders to develop and realize clearly defined and challenging functional, environmental and economic goals and objectives. The ID Process requires a multi-disciplinary design team that includes or acquires the skills required to address all design issues following the objectives. The ID Process proceeds from whole building system strategies, working through increasing levels of specificity, to realize more optimally integrated solutions (BC Green Building Roundtable, 2007).*
>
> Excerpt from "The Integrated Design Process: Report on a National Workshop" held in Toronto in October, 2001.

We are still designing buildings the way we have for decades, but the ID process offers a more sustainable building by design as evident from the definition above. In order to have a clearer understanding of what the ID process is, it is important to recognize how it differs from conventional design. Table 1 outlines the primary difference between a conventional design process and an integrated design process. The simplest way to understand the difference is to think of conventional design as ***linear*** and integrated design as ***iterative***.

Table 1: Integrated Design Process vs. Conventional Design Process

Integrated Design Process	**Conventional Design Process**
Inclusive	Involves team members only when necessary
Front-Loaded	Less time and energy early on
Decisions made by team	More decisions made by fewer people
Iterative	Linear
Whole-system Thinking	Systems considered in isolation
Allows for full optimization	Constrained optimization
Seeks synergies	Few opportunity for synergies
Full life-cycle costing	Emphasis on up-front costs
Process continues post-occupancy	Process ends with construction completion

There is nothing exceptionally revolutionary about the ID process, rather it benefits from a holistic and principled approach that can lead to a better built building. By combining a set of attitudes, principles and strategies, the ID process can result in more sustainable buildings (BC Green Building Roundtable 2007). These attitudes and principles set the tone for the project and allow for the creation of measurable goals.

3. Types of Modeling Processes

For this research, two types of modeling processes were identified and formalized based on the first author's professional experience and familiarity in Canadian K-12 energy modeling requirements. These modeling processes are *compliance modeling* and *integrated design*. Together they form the energy modeling processes that establish a framework for the selection and analysis of case studies. In mapping out the two processes, key factors contributing to the design processes and energy performance outcomes emerged and allowed for comparisons and conclusions to be drawn.

3.1 Compliance Modeling Process

The first process identified is a *compliance modeling* process. For the purpose of this research, the compliance modeling process is defined as: energy modeling completed using Issued for Construction (IFC) drawings and specifications with the modeling team having had no input during the design stages of the

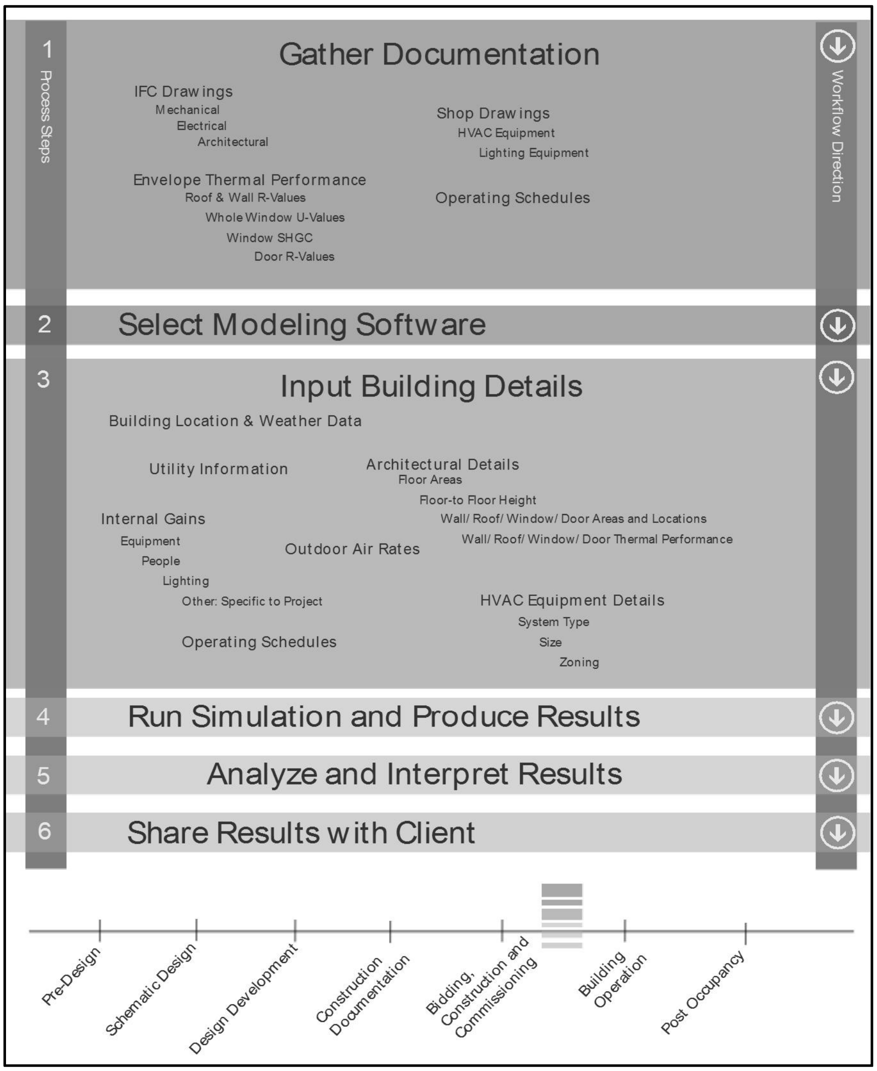

Figure 1: Compliance Modeling Process

project. During the compliance modeling process, an energy model that includes predicated energy use and energy cost numbers is produced; the results are often used to indicate if the building complies with specific requirements such as building code, LEED, or other industry standards. The steps of the process are visually represented in Figure 1 below.

3.2 ID Charrette Modeling Process

The second process was modeled using an *integrated design (ID) charrette modeling* process. For the purpose of this research, an ID charrette modeling process is defined as: energy modeling that takes place live during an ID charrette where design team members are present and are provided with energy use results based on the discussion and suggestions made during the actual charrette. During an ID charrette modeling process, an energy model that includes predicated energy use and a number of discussed Energy Conservation Measures (ECMs) is produced; the results are often used to indicate if the building achieves established energy performance goals. The steps of the process are listed below and a visual representation can be found in Figure 2.

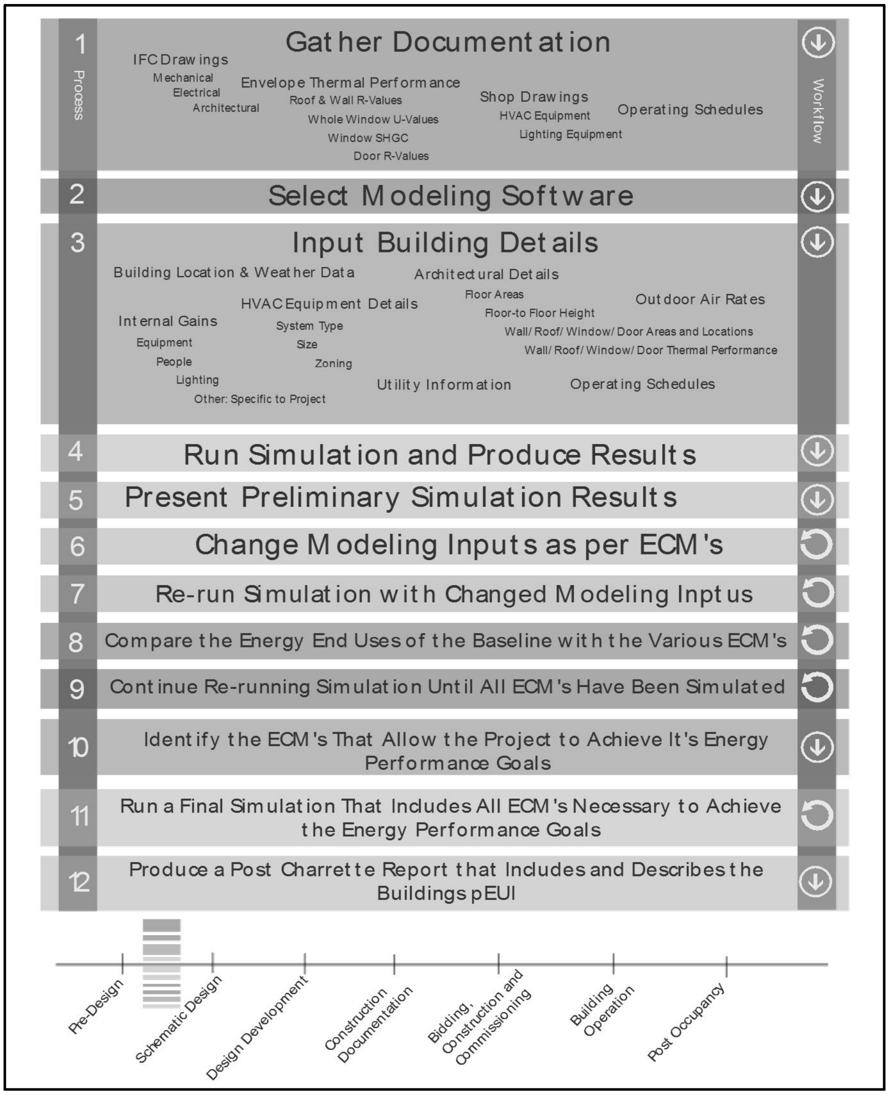

Figure 2: ID Charrette Modeling Process

4. Case Studies Analysis

Buildings utilizing the ID process should use energy simulation early and often. This provides the design team with the necessary information and adequate time to make informed energy related design decisions. The purpose of this research is to demonstrate how the use of live energy modeling can lead to predicted energy savings in new K-12 schools. As such, the following six case studies were analyzed in order to identify the different variables that lead to improved energy performance. All six schools are located in Eastern Ontario, Canada and are publically funded. All Ontario publically funded schools are subject to the same funding formula used to determine the schools operating budget and construction budgets for new builds. Since all six schools are proposed new builds, they are subject to the same funding formula, which in turn means no school within the data set has a budgetary advantage. Schools A1, A2 and A3 serve as the compliance modeling data set, while schools B1, B2 and B3 serve as the ID Charrette modeling data set. The model inputs and energy performance results can be seen in Table 2.

4.1 Case Study Results

Drawing causation conclusions based on an analysis of the case study results is very difficult. The modeling results (energy end use and performance) for each school are the result of a single simulation, as isolating the impact of a single variable (model input) is nearly impossible because there is no point of reference. However, comparing the modeling results of each school helps identify trends, which are further explained through the expert interviews. A more accurate picture emerges only when the quantitative data (modeling inputs) is examined next to the qualitative data (interview findings).

The analysis of the case studies revealed that the ID charrette modeling schools use 58% less energy than the compliance modeling schools, on average. Additionally, the ID charrette schools have an average Predicted Energy Use Intensity (pEUI) that is 11.1 ekWh/ft2/yr less than compliance modeled schools. A deeper analysis of the modeling inputs helps identify what impacts these predicted energy savings, but it does not tell the whole story. No individual variable or modeling input alone can be linked to the significant reduction in predicted energy use, however, averaging each input and comparing them between the two data sets tells a different story.

In nearly every case, the average input variables for the ID charrette modeling schools are better than the compliance modeling schools; however, in a few cases the reverse is true. Focusing only on the averages for each input is deceiving since the averages are not generalized; it is important to drill down on some of the outliers in order to better understand how these two data sets compare. For example, the compliance modeling schools average glazing U-value is 0.36 verses 0.38 for the ID charrette schools; the poorer glazing performance for the ID charrette modeling schools is directly due to the fact that school B1 has a U-value of 0.44 and pushes the average down to 0.38. Looking a bit closer at all the inputs for school B1 shows that the design is not particularly high performing. The primary energy savings measure for school B1 is its outside air rate of 0.16 cfm/ft^2, which is significantly less then all of the other schools. School B1 has a much lower outside air rate partially because it was a discussion topic during the ID charrette and the design team was able to test assumptions and develop a design that specifically addressed the schools needs. Comparing the average values for each input is important, however, understanding the differences and strengths of the two modeling processes is equally important.

5. Expert Interviews

The primary goal of the interviews was to identify how live modeling is done in practice and link the benefits of this process with possible energy savings. Interview participants were selected based on their level of experience with live energy modeling within the context of ID charrettes. Five interviews were completed with professional energy modelers from across Canada. Two of the interviewees were from Ottawa, Ontario (in Eastern Ontario), two from the greater Toronto, Ontario area, and one from Vancouver, British Columbia. Additionally, two of the interviewees had direct experience with the models for the three ID charrette modeling case studies. Despite there being countless professional energy modelers around the world, the selected experts represent a group of modelers who have spearheaded the use of live modeling for the purpose of identifying energy savings within a Canadian context. Each interview participant was asked the same series of questions especially designed to get a better understanding of the live energy modeling process.

The interviews were broken down into four main sections in order to outline the process of live energy modeling. The first section focused on background experience and knowledge; this series of questions was used to collect information about the knowledge areas needed to be successful at energy modeling as a profession. The second section focused on charrette preparation; this series of questions addressed the groundwork leading up to a live energy modeling session within an ID charrette. The third section looked charrette activity; these questions focused on what the live modeling expert was doing during the actual charrette. The fourth section focused on post-charrette activity and lessons learned; these questions addressed what the modeling experts did after the charrette and how the knowledge acquired during the charrette works its way back into the practice.

5.1 Background Experience and Knowledge

The first series of interview questions focused on the background experience of the interview participants and identified the necessary knowledge areas to effectively run live modeling within an ID charrette. Each interviewee was a professional modeler or energy efficiency expert that had between 4 to 30 years' experience. In addition, they collectively have administered more than 200 ID charrettes that incorporated live energy modeling with projects dating back more than 10 years. It is clear that the interviewees are highly experienced professionals working to find innovative ways to use energy modeling to improve performance.

Each participant was asked the question: 'What skills or knowledge areas do you believe to be essential to successfully run a live energy modeling session?', and several themes emerged. First, some key areas of understanding were identified that included thermodynamics, building science, and relevant energy codes. It was also identified that modelers should be familiar with current state-or-the-art building technologies and be highly experience with the selected software used in the charrette.

Finally, interviewees were asked what software they use and what about that software makes it ideal for live modeling. The most common software was eQuest, which uses the DOE 2.2 engine, while another group of charrettes utilized DOE 2.1e. It was indicated that these software programs were used primarily because of their ability to complete simulations quickly, but also because they are well-supported and fairly simple to use. During a live energy modeling session, simulation run time is critical since the entire discussion hinges on the speed at which results can be produced. Although being able to produce simulation results quickly does not directly impact the performance of the building, it allows the ID charrette to run more smoothly, which in turn improves the quality of the charrette.

5.2 Charrette Preparation

Like most complete processes, a key element of a smooth charrette is preparation. Each interviewee was asked what information do they required for charrette preparation, as well as how much time do they spend preparing and what assumptions are made at the onset. There was little variation about what information is required in preparation. Generally, every modeling expert required a complete set of preliminary mechanical, electrical and architectural drawings as well as a complete set of preliminary shop drawings or specifications. Or as one modeler said, "any information available concerning the building program, design information (which varies depending on how advanced the design is), and intended use of the facility," is requested for preparations.

A lot of information is still missing when the team begins preparing for an early stages ID charrette. To get a better understanding of what information is still missing at this stage, the modelers were asked 'What assumptions need to be made in order to move the project forward while remaining accurate?' Because projects can vary so dramatically, no consistent list of assumption beyond using standard ASHRAE 90.1 defaults whenever information is missing was identified through the interview process.

Finally, the amount of preparation time varied between 20-60 hours within the 2-week period leading up to the charrette. Several modelers identified that part of the preparation included either scripting or pre-running a number of generic ECMs in order to make the actual live modeling sessions run smoother. There is a lot of pressure on the modeler during the actual live modeling session, so good preparation is key.

5.3 Charrette Activity

By the time the actual charrette is underway, the modeler's role is fairly focused. When asked what they do during the actual charrette, each modeler described a fairly similar process. It begins with participating in the team discussion with a greater emphasis on listening; this way they are fully aware of the charrette goals and innovative ideas being discussed. They also each described how, working in tandem with the charrette facilitator, they start to run each ECM discussed by the team while the facilitator keeps the conversation focused and moving. As they begin to get results, the modelers provide the energy use changes of each discussed ECM to the group so that the process can continue forward. At times, certain ECMs require additional input from the team; this is where other experts can support the modeler. Several modelers described scenarios where fenestration experts or envelope experts were able to provide more accurate thermal performance numbers rather than relying on software defaults for example. As a result, more team members were involved and the charrette model calculations were more accurate while also offering an opportunity for collective learning.

Several of the modelers described charrette processes that involved cost consultants. In the first section of this research, the importance of including a cost consultant was addressed. It was identified that the financial information that cost consultants are able to provide leads to greater buy-in from the team members and also connects the energy performance goals with the project budget. Although there is clear value in ID charrettes as a whole, it is important that cost consultants are always involved.

Finally, each modeler identified the need for taking notes on the various ECMs discussed. This aided in the development of the report after the charrette and ensured the spirit of the conversation was incorporated into the model as well as the report. Additionally, each modeler described a charrette process that involved multiple team members, this generally included a facilitator and note taker in addition to the dedicated modeler.

5.4 Post Charrette Activity and Lessons Learned

The lessons learned and post charrette activities part of the interviews provided the most insight in the process, as each of the modeler had a lot to share. There was a wide range of lessons learned, yet there was still quite a bit of consistency between responses. Every modeler identified that live modeling sessions are stressful and that good preparation is key. Because live modeling requires expert knowledge of the modeling software and engineering principles, it was identified that experienced modelers should always be involved. However, several modelers identified that live modeling sessions is a great way for a less experienced modelers to learn. Actively participating in the charrette process is a great way for inexperienced modelers get a better understanding of how to successfully run an ID charrette with live modeling.

Another lesson learned was the need to run the ID charrette as early in the process as possible; a best practice identified earlier in the ID charrette process section. A charrette runs smoother earlier in the process for several reasons, as identified in the interviews. First, during an early charrette fewer decisions have been solidified and the design team members are more willing to consider changes. In turn this leads to more innovation and willingness to participate from all of those attending the charrette since there is less need to defend certain decisions.

Keeping the model as simple as possible was another lesson learned. As one practitioner put it, ‘we should aim to make our models accurate rather than precise.’ The more complicated the model is, the longer the simulation run times will take; when performing energy simulation live, speed is almost as important as accuracy. For example, a recent project the first author was working on required collaboration with the mechanical designer to provide deeper analysis. The project was still in the schematic design phase, however, the model received from the design team already had every room defined, all 346 rooms. As a result the model took roughly 1 hour to simulate on a fairly robust computer. In an ID charrette, this run time would ruin the entire process. Had the model been created with larger thermal blocks rather than every room, the simulation time would have been much quicker. Keeping a model simple and selecting software capable of quick simulations is key to a successful charrette.

5.5 Key Interview Findings

Running a live modeling session is not an easy task, however, if done correctly it can yield superior energy performance and improve the design process and outcomes. The expert interviews led to a number of key findings that allow for a successful live modeling session. The key findings are:

- Schedule the modeling session as early in the design process as possible.
- Ensure that all of the necessary documentation has been collected in order to prepare. This includes a complete set of preliminary mechanical, electrical and architectural drawings as well as a complete set of preliminary shop drawings or specifications.
- State assumptions and ask design team to confirm inputs and ensure assumptions are correct.
- Allow for enough preparation time, somewhere between 20-60 hours. During that time, try to run likely ECM's so that the modeling session runs smoother allowing for certain trends to be identified early.
- Select software capable of running simulations quickly.
- Do not over complicate the model.
- Take lots of notes.
- Ensure a cost consultant is present.
- Invite other experts to the session, i.e. fenestration, building envelope, landscape, lighting, etc.
- Have a dedicated session facilitator, someone other than the modeler, so that things continue to move forward.

6. Conclusion

An improved process almost always leads to an improved outcome, and as this research indicates the same is true for the ID charrette modeling process over the compliance modeling process. ID charrette modeling schools have significantly less predicted energy use than compliance modeling schools, as indicated by a 58% predicted energy use reduction. This research clearly indicates that participating in live energy modeling during the ID process can lead to significant predicted energy use reduction for new K-12 schools in Ontario, Canada. Live energy modeling provides design teams with concrete number necessary to make informed design decisions and allows for participation in the process by all design team members. It should be noted that this research is limited in its generalizability due to a small sample size of six schools located in Eastern Ontario.

An area for further research is the variation of predicted energy use versus actual energy use. Based on the findings, concluding that live modeling during an ID charrette results in a better performing occupied building is inaccurate. Predicted energy use is based on simulation results and actual energy use is based on metered data and it is important that distinction be made when interpreting the results of this study. Additional research needs to be completed in order to state the effect of live modeling during ID charrettes on actual energy use. Are larger sample size across a verity of geographic locations would allow the research to be more generalizable. Once all of the schools in this study are fully constructed and occupied, an analysis of the actual metered energy use of each school could be analyzed in order for additional conclusions to be made.

Investment Value of Long-Term Building Adaptability

Jussi Vimpari,
Department of Built Environment, School of Engineering, Aalto University
(email: jussi.vimpari@aalto.fi)

Abstract

Physical adaptability of buildings has a major role in creating competitiveness for property investors as well as creating a sustainable built environment. Current real estate investment analysis methods do not value investments into long-term adaptability because the discounting effect gives less weight to cash flows further in the future. This paper attempts to apply a newly developed investment theory for justifying the investor value of long-term adaptability. The theory, which combines of real options valuation, investment analysis and building component lifecycle design, proposes that physical asset characteristics can create valuable real options (i.e. building adaptability) for the real estate investor. This paper applies this theory into a real life property development case and evaluates the value of real options for the investor. The results try to explain in economic terms why investors should invest into long-term adaptability. The study found that the value of real options ranges from 0,0 % to 221,4 % compared to the initial investment cost of the building component. The extra investment costs for creating these real options ranges from 0,0 % to 5,0 %. The real option values exceed the costs in most of the cases. As can be seen from the results, it is important to recognize valuable options from the ones that do not provide value in the long-term. More research and discussion regarding the practical usability of the results is needed, as the topic is quite complex.

Keywords: Building adaptability, real options, investment analysis, technical lifecycle, economical lifecycle

1. Introduction

Average lease lengths have decreased rapidly and in major markets are now under 5 years (IPD, 2014; Titman and Twite, 2013). The shortened interval for lease break points requires more active management from the property owner. Since tenant requirements are changing rapidly, the buildings have to be adaptable into different scenarios of best use in the future. Physical adaptability of buildings has a major role in creating competitiveness for property investors as well as creating a sustainable built environment. However, current real estate investment analysis methods do not value investments into long-term adaptability.

Real estate investment analysis is mainly done with discounted cash flow (DCF) valuation method (KTI and IPD, 2012; Shapiro, Mackmin and Sams, 2013) where predicted net rental cash flows are discounted to the present value. The discount rate effect gives less weight to cash flows further in the future. Many authors, such as Hayes and Garvin (1982) and Myers (1984), have noted that the use of DCF results in short sighted decision-making because short-term cash flows can make up the best part of the investment value. In the property sector, this short sightedness is especially problematic as buildings are constructed for lifecycles of 50+ years and initial design plays a key role on how the buildings can be used in different market conditions.

Many of the opportunities in active real estate management are constrained by the physical asset characteristics (PACs) of real estate investments, which are in turn determined in design processes. Vimpari and Junnila (2015) define PACs as *"the limitations and opportunities that the physical attributes of buildings impose on assets' economically best use... In other words, PACs express the extent in which the real estate manager has to operate during the lifecycle of a building investment."* They also noted *"it appears that PACs do not have a large role in property analysis as they are mainly assessed through their negative effect on rent and on capital expenditures that is not as a source of value creation, per se."* Vimpari and Junnila (2015) developed a theory for valuing building lifecycle investments that can justify the investor value of long-term adaptability. The theory, which combines of real options valuation, investment analysis and building component lifecycle design, proposes that PACs can create valuable real options for the real estate investor. Real options are originally defined as *"opportunities to purchase real assets on possibly favourable terms"* (Myers, 1977). In the context of this paper, real options enable that the PACs can adapt into new use when the best use of the building requires it, in economically favourable terms.

This paper applies this theory into a real life investment case and evaluates the value of real options for the investor. The results try to explain in economical terms why investors should invest into long-term adaptability. The study found that the value of real options ranges from 0,0 % to 221,4 % and the extra investments into adaptability ranges from marginal to a maximum of 5,0 %. This paper aims to discuss the reliability and practical usability of the numerical findings.

The paper is organized as follows. The next section describes the relationship between economical and technical lifecycle as well as presents the Vimpari and Junnila (2015) framework. The following section presents an applied case study of the framework. Then discussion and conclusions are provided.

2. Aligning economical and technical lifecycles of buildings

Arge (2005) found that short-term owners, such as developers, invest less into long-term adaptability because the extra investment may be hard to justify in the transactions. On the contrary, long-term owners, such as owner-occupiers, invested more into adaptability. This is an interesting observation because construction literature argues that the cost of adding adaptability into PACs is only marginal. Slaughter (2001) analysed 48 commercial renovation projects and found that interaction between building systems (i.e. structure, enclosure, services and interior finish)*"strongly influenced the building's adaptability, and that the structural and exterior enclosure systems, as well as the services and interior finish, should be designed with respect to anticipated changes."* The study found out that different design strategies that increase the adaptability often requires only, on average, 2 % extra investments into initial construction costs.

These small extra investments can have an important impact on the building's economical lifecycle. To understand the economical value of adaptability, the connection between the market demand of project (economical lifecycle) and the actual lifecycle of the building components (technical lifecycle) needs to be examined. In principle, sustainable use of built environment resources would expect that both the economical and technical lifecycles are as close as possible. Often this is not the case because the economical lifecycle changes faster than the technical lifecycle, which results into inefficient occupancy rates or premature demolition.

The importance of aligning economical and technical lifecycles is explained through technical lifecycle measurement. A building component (i.e. PAC) has an expected technical lifecycle based on the design requirements for the project. Building components can be divided into two categories, fixed and movable, with an expected average technical lifecycle. The fixed category includes components, such as heating (technical lifecycle of 40 years), ventilation (40), sewage and water (40), air conditioning (40), electricity (50), structures (200), windows (35), façade (40), roof (40), balconies (40) and fixed devices and systems (40). The movable category includes components, such as surfaces of walls (12), roofs and floors (12), fittings (40), partitioning walls and doors (40). These lifecycles are used as a basis for building design as well as for calculating the future renovation costs.

However, since the economical lifecycle of the first best use can be much shorter, the technical lifecycle cannot be exploited fully if there is no adaptability, i.e. investments into technical value is lost because the PAC cannot adapt into the new economical demand. This effect of this is more dramatical in the building components that have longer lifecycles, such as HVAC, electricity and building structures. The lost or gained value with adaptability is pointed out numerically in the Vimpari and Junnila (2015) framework presented in Figure 1. The NPVs in the framework *"represent the amount that is lost or gained due to the length of the lifecycle that is, if the lifecycle lasts only* n_{min} *years,* NPV_{min} *is lost because the PAC has to be replaced* n_{stan}-n_{min} *years earlier compared to the standard lifecycle. On the other hand, if the lifecycle lasts* n_{max} *years,* NPV_{max} *is gained for the opposite reasons. Therefore, if the PAC reinvestment has to be made early, the X cannot be invested elsewhere with the hurdle rate and it is lost because the PAC does not produce any profits, per se. The higher the hurdle rate, the higher the amount lost/gained and vice versa."*

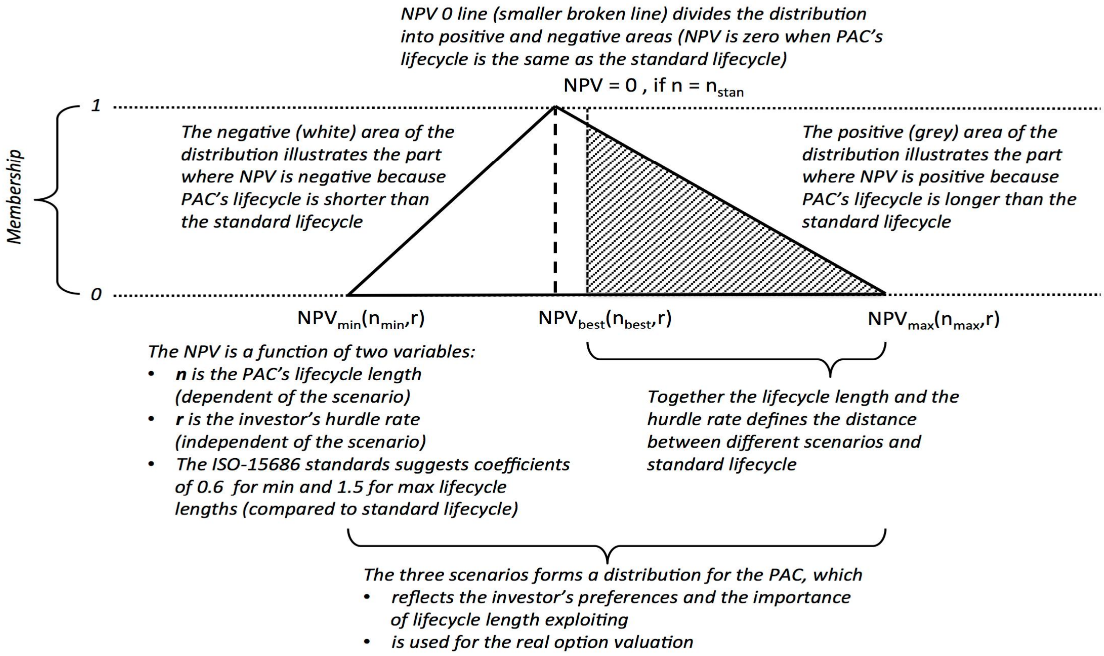

Figure 1: Conceptual framework for valuing lifecycle investments (Vimpari and Junnila, 2015)

The framework is used to form a single distribution of the PAC's lifecycle. A distribution is used because the technical lifecycle defines the limits for the economical lifecycle, i.e. at best the economical lifecycle has the same distribution as technical lifecycle. At worst, a short economical lifecycle transforms the distribution in a way that the positive area has a much smaller proportion (this is illustrated in Figure 2) because there is no adaptability. The framework uses a triangular distribution because it is much easier to use in practice, as there is often limited information to form a probability distribution in property context. The framework suggests that the ISO-15686 standards can be used to define the minimum and maximum lifecycle lengths to form the triangular distribution. The standards suggest that a coefficient of 0.6 can be used for the minimum lifecycle and the 1.5 for the maximum lifecycle, compared to the standard expected lifecycle. For example, a façade has a standard expected lifecycle of 40 years, but the coefficients suggest that the range for the lifecycle is from a minimum of 24 years to a maximum of 60 years. In practice, wear and tear, different conditions, etc. can have an effect on the length of the lifecycle.

The technical lifecycle distribution (which gives the upper boundaries for the economical lifecycle) is rather straightforward to measure, but defining the economic lifecycle is not as straightforward. However, it is more important because it dictates how efficiently the technical lifecycle can be exploited. The economical lifecycle distribution is affected by uncertainty in space demand during the technical lifecycle. Figure 2 presents the relationship of time and demand uncertainty.

Figure 2: Relationship of time and demand uncertainty

The figure presents what kind of uncertainty can incur to the property owner during the technical lifecycle of the building. The longer the expected same use of the building, the smaller the amount of uncertainty is during the technical lifecycle. For example, a very long lease agreement reduces the uncertainty dramatically and thus reduces the need for adaptability investments, from the property owner's perspective.

If the PACs cannot adapt to the uncertainties, the economic lifecycles for the PACs will be shorter than the technical lifecycles. The value of adaptability comes from the fact that the economic lifecycle is aligned with the technical lifecycles. Therefore, to value adaptability we need to define the technical lifecycle and economical lifecycle. If these are not aligned, we need to identify real options (adaptability investments) for aligning the lifecycles. Then the options are valuated with the framework and the values are compared to the cost of the extra investments. This is attempted in the following case study.

3. Case Study

AINOA is a 4-story shopping centre development in Tapiola, Espoo, Finland. It is part of a larger urban development project that transforms the old centre of Tapiola into new use. A lot of older buildings from the 1970's and 80's are demolished, as they cannot be used anymore. Additionally, a new metro line will connect the area to the metro grid of Helsinki Metropolitan Area (HMA). The shopping centre will be ready in 2017.

The investor in AINOA is LähiTapiola that is one of the largest institutional investors in Finland. LähiTapiola plans to own the centre for a long holding period and thus can be considered as an owner who is interested in the long-term lifecycle performance of the building. Even though the building has better construction quality than average and is in a great location, there is uncertainty regarding the economical lifecycles of rentable space within the centre. The main tenant is renting majority of the premises. In addition to the main tenant, there are a few large and several smaller retail spaces in each floor. While the main tenant is a very reputable tenant, the owner cannot expect that it will occupy the premises indefinitely.

In order to value the adaptability strategies for different PACs, technical and economical lifecycles are defined. Let us assume that the best-guess estimate for the building's technical lifecycle is 40 years (in Finland, the average life of shopping centres before demolition has been 39 years according to Huuhka and Lahdensivu, 2014). Based on the ISO standards, the minimum technical lifecycle would be 24 years and maximum 60 years. The minimum lifecycle can feel very short but the triangular distribution gives only a very small weight to it - see Vimpari and Junnila (2015) for more details. For the economical lifecycles, let as use the following lengths presented in Table 1.

Table 1: Economical lifecycle distributions

Tenant	Min	Best	Max
Main tenant	10	25	60
Large tenants	5	10	60

The economic uncertainty can have the largest effect to the main tenant and the larger tenants. The smaller retail spaces are so small that it is unnecessary to include them into the analysis. The table presents the economic lifecycles for the tenant categories. The maximum lifecycles are based on the maximum technical lifecycles, i.e. in the most optimistic scenario the economic demand is in line with technical lifecycle. The minimum lifecycles are based on hypothetical first lease agreements (the owner does not want to disclose the real lengths). The best-guess lifecycles are the most likely scenario for how long the tenant will remain in the building. Figure 3 illustrates the economical distributions the large and main tenants with and without adaptability.

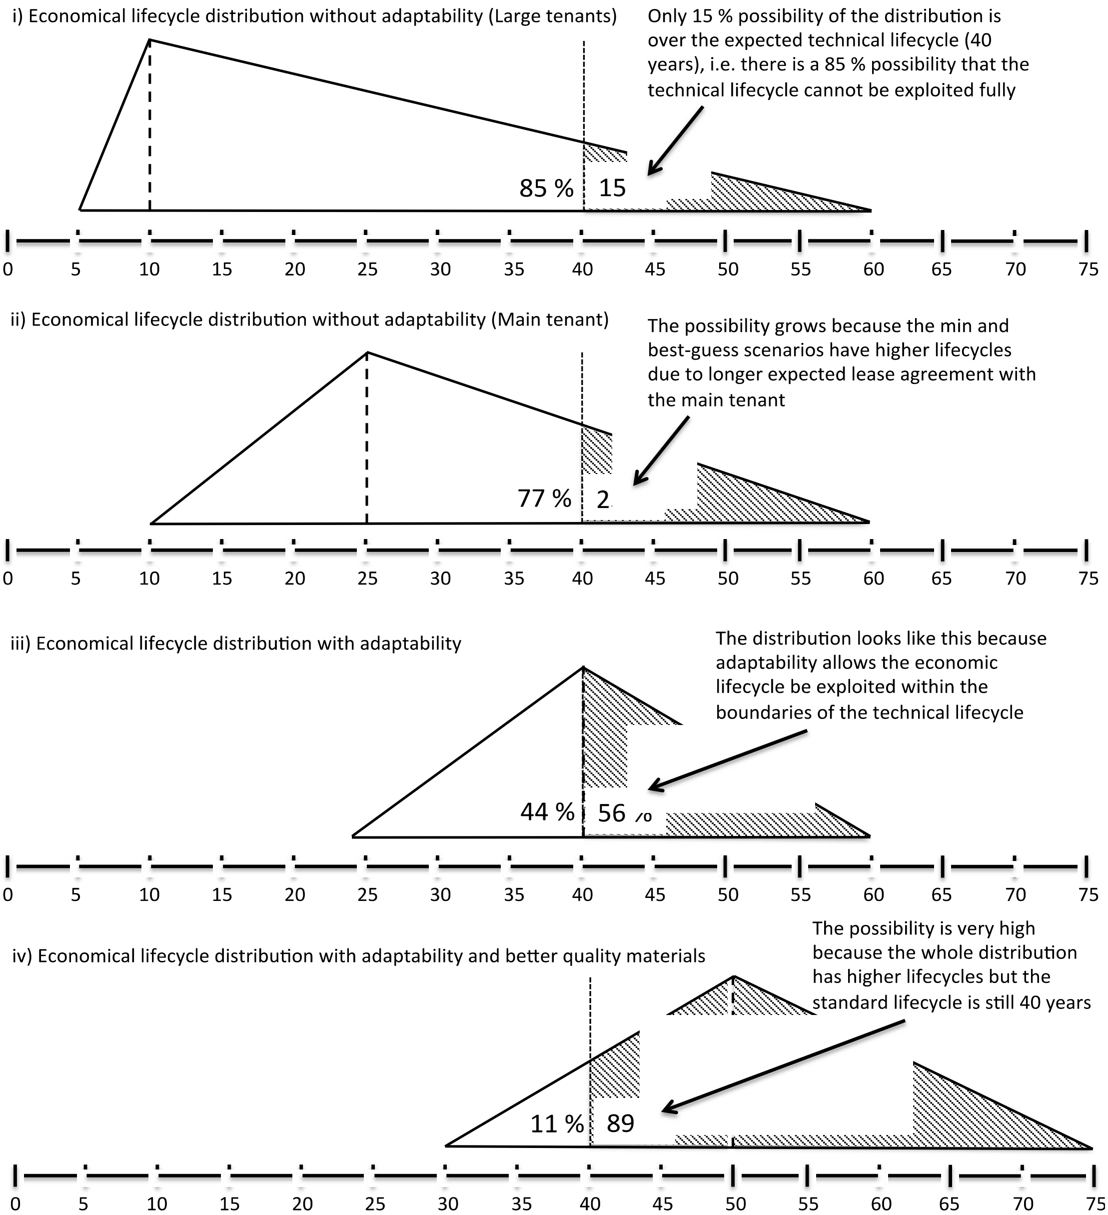

Figure 3: Economical distributions with or without adaptability

The figure presents four different economical lifecycle distributions. The first two illustrate how uncertainty affects the economic distribution and the chance of exploiting the whole technical lifecycle. The third distribution illustrates how adaptability changes the possibility of exploiting the lifecycle. The fourth adds the effect of better materials into the distribution, i.e. better materials raises the expected technical lifecycle for the PAC, which reduces the possibility that the PAC has to be replaced early.

The grey area in the distributions represents the proportion of the area that exceeds the average expected lifecycle of 40 years. This is the area where extra optional value is created when the lifecycle lasts longer than expected. The option value, is calculated from the grey area, see Vimpari and Junnila (2015) for details. The option value increases as the proportion of the positive area increases because the expected lifecycle for the technical lifecycle is higher. This means that more clever design with potential extra investments is needed to increase the adaptability. In essence, if the main tenant would leave and the space would have to be divided into much smaller areas, it would not be possible efficiently without the real options. Without the adaptabilities the areas would have to be divided inefficiently which could results into loss in rentable space, etc.

Using the formulas in the Vimpari and Junnila (2015) framework, the real option values for the distributions are as follows: i) 0,2 %, ii) 0,5 %, iii) 3,3 % and iv) 18,3 %. These numbers are the value of adaptability compared to the initial investment. For example, in distribution iv), a maximum of 18,3 % can be invested into adaptability and better materials.

To find out what kind of adaptability is needed to change the distributions, the building design solutions had to be assessed. Different designers (Electricity, Architecture/Structure and HVAC) were interviewed in order to find out what kind of adaptability has been constructed into the building. The following real options were identified. In the parenthesis is presented the best-guess technical lifecycle based on common expectations in Finland - the min and max lifecycles for the option valuation are estimated using the ISO-coefficients as the framework suggests.

- Electricity:
  - E1: Higher capacity for the main electricity connection (50 years)
  - E2: Higher capacity in the cabling (50 years)
  - E3: Higher capacity for the main electricity unit (25 years)
- Architecture/Structure:
  - A1: Openings for escalators/staircases in middle floors (100 years)
  - A2: Storey heights allow all types of use (100 years)

A3: Distance between pillars very long (100 years)

A4: Façade not load-bearing and allows for window openings (100 years)

· HVAC:

H1: Higher capacity in the ventilation units (25 years)

H2: Ventilation ducts allow higher airflows (40 years)

H3: Higher capacity for district cooling can be installed easily (40 years)

These real options changes the i) and ii) distributions to iii) and iv) distributions. The extra costs and option values are presented in Table 2. In the option valuation is assumed that the standard lifecycle is 40 years. Therefore, the option value is based on the area that is over 40 years. The area weighted option value is the value of adaptability. The further over 40 years the area is, the higher the option value.

Table 2: Option values and extra investment costs

Real option	Extra investment costs	Option value	Option value (better materials)
E1	Max 5,0 %	18,1 %	46,2 %
E2	Max 5,0 %	18,1 %	46,2 %
E3	Max 5,0 %	0,0 %	0,0 %
A1	Marginal	180,1 %	221,4 %
A2	Max 5,0 %	180,1 %	221,4 %
A3	Max 5,0 %	180,1 %	221,4 %
A4	Marginal	3,3 %	13,7 %
H1	1,3 – 1,7 %	0,0 %	0,0 %
H2	1,3 – 1,7 %	3,3 %	13,7 %
H3	1,3 – 1,7 %	3,3 %	13,7 %

The results in Table 2 suggest that the option values are higher than the extra investments costs in all cases except E3 and H1. This means that the extra investments are worth the investments because the potential upside from the options is higher. Raw estimates were used for the extra investments because the designers had not systematically identified and calculated the extra investment costs. In the better materials is assumed that they increase the best-guess lifecycle by 20 %. This chosen to demonstrate how the value of adaptability increases because of better materials chosen.

The extra investments in Electricity allow using the same cabling and main electricity unit with higher loads that is if the space efficiency increases or tenants with higher electricity requirements occupies the premises. The electricity designer had a raw estimate that these investments have a maximum extra investment cost of 5,0 %.

The extra investments in Architecture/Structure allow using the same structures if the layouts have to be converted into new use. Additionally, the structures can be used in different type of use as the storey heights are higher and facades allows for windows openings. Based on a raw estimate, the extra investments costs ranges from marginal to maximum of 5,0 %. The option values are very high because the technical lifecycles of building structures are very long.

The extra investments in HVAC allow using the same ventilation units and ducts if the space efficiency increases or a tenant with higher cooling requirements occupies the premises the same component can be used. The designer had a raw estimate that these extra investments are only 1,3 % to 1,7 %.

4. Discussion

When interpreting the results, it should be remembered that the numbers are best approximations based on the expected lifecycles. Nevertheless, the magnitudes of the results seem somewhat intuitive, as the value of adaptability should correlate with the length of the lifecycle. For example, the very high option values for the building structures seems logical if they allow using the same structures for different types of uses over a lifespan of 100 years. Naturally, when talking about lifespan lengths of this magnitude it raises questions about how relevant it is to prepare for a period that far in the future. However, if the extra investments into a very small part (e.g. pillars and ceiling height) of the total building investment ranges from a marginal to a maximum of 5,0 % of extra costs, and as a results it raises the possibility that the whole structures can be used much more efficiently, the investments is likely worth it. The option value tries to approximate the monetary value of the extra investment, even though they are merely an approximate. The option value of e.g. 180,1% would suggest that this is the maximum amount that could be invested into adaptability – intuitively it does not make any sense. On the other hand, as the extra investments point out, the real costs are very small. It should be acknowledged that some of these options could be added later but it would result into much higher investments costs as well as longer periods of vacancy during the construction activities. This is why the author thinks that the value of these options should be looked from the lifecycle perspective rather than the rental perspective.

If we look at the results of E3 and H1 where the option values are zero. The results does not make sense because it suggest that the main electricity unit and the HVAC unit does not need any adaptability because their expected lifecycles are only 25 which is shorter than 40 years that was chosen for the standard lifecycle in the valuation. The results would make sense if there would be no economical uncertainty during the 25 years but there is as the lease agreements can have a minimum length of only few years.

The challenge with the framework seems to be on how to choose correct the standard (n_{stan}) lifecycle length for different PACs and for the whole building. Actually, the results would suggest that the property owner should take an active role of choosing the expected lifecycle from the business perspective, rather than basing it on the technical quality (lifecycle) of the product. Then the value (grey area) that exceeds this expected business lifecycle would be optional and the property owner would seek for design solutions that maximize this optional value. Thus, the property owner would have to take a stand on the actual business lifecycle of product (with technical implication) rather than take them as a given from the developer, which is the case at the moment. This would result into better alignment of the economical and technical lifecycles.

5. Conclusions

This paper attempted to use the Vimpari and Junnila (2015) framework in practice by applying it into a real life investment case. The study founds that the value of real options ranges from 0,0 % to 221,4 % compared to the initial investment cost of the building component. The extra investment costs for creating these real options ranges from 0,0 % to 5,0 %. The real option values exceed the costs in most of the cases. As can be seen from the results, it is important to recognize valuable options from the ones that do not provide value in the long-term. More research and discussion regarding the practical usability of the results is needed, as the topic is quite complex. The value of the options depends on what kind of lifecycles is inputted into the framework. Defining these lifecycles is somewhat confusing because both economical and technical lifecycles have to be considered.

Abstract

This paper aims to pinpoint the global megatrends related to urban water management, and to make recommendations for urgently needed institutional innovations. This paper and the subsequent analyses are based on the literature study. Almost 700 million people lack access to safe drinking water, 2.4 billion lack access to improved sanitation services, and 600,000 children under five die every year as a result of lack of access to improved water services. While these estimates identify the extent of the problem, the number of people threatened by poor management of constructed systems is much greater.

The world's population is increasingly urban, and cities cannot be sustainable without ensuring reliable access to improved water services. Urban settlements are the main source of point-source pollution. In many fast-growing cities in developing countries, wastewater infrastructure is non-existent, inadequate or obsolete. Water storage, treatment and distribution systems are poorly maintained, and water losses due to leakage and theft, often exceed 40-60% of the total water distribution. Water infrastructure is rapidly aging and facing massive rehabilitation. By 2016 the capital expenditure on water infrastructure is estimated to increase 1.5 times from USD 90 billion in 2010 to USD 131 billion. It's estimated that the urban infrastructure of the world's cities over the next 20 years will require USD 41 trillion, including USD 22.6 trillion on water and sanitation.

To achieve the Sustainable Development Goal 6 *"Ensure access to water and sanitation for all"* by 2030, specific enabling conditions will be required. Therefore, the typology and concepts of the green economy, along with the principles, approaches and processes of the Integrated Urban Water Management, and the institutional innovations should be considered and applied.

Keywords: Integrated Urban Water Management, the green economy, institutional eco-innovations, efficiency improvements, strategic asset management

1. Introduction

Water is arguably more fundamental than any other resource – to life itself, supporting a huge array of ecosystem services – and to every economy and society. Water contributes directly and indirectly to virtually all other ecosystem services but the area of water supply and sanitation also comprises an economic sector in itself. Water supply and sanitation can thus be considered as a driver with its own dynamics of pricing, infrastructure and governance (UNEP 2012, 15-16, 19).

According to the United States Environmental Protection Agency (EPA), the sustainable water infrastructure (the collection and distribution systems, treatment plants and other infrastructure that collects, treats and delivers water-related services) and the sustainable water sector systems (all aspects of effective operations and maintenance practices of the utilities and systems that provide water-related services) are necessary to safeguard the sustainable environmental and economic development of all the communities (Figure 1, EPA 2012).

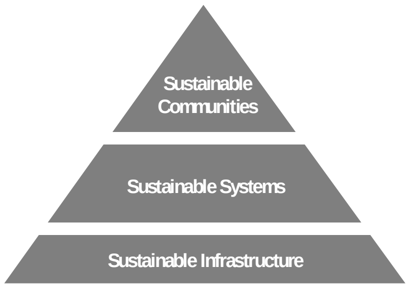

Figure 1: Sustainable communities are based on sustainable drinking water, wastewater and stormwater infrastructure and on sustainable systems' operations and maintenance (EPA 2012).

In 2015, however, 663 million people still lack improved drinking water sources and 2.4 billion people still lack improved sanitation facilities (UNICEF and World Health Organization 2015, 4-5). Deaths from water-related diseases are inadequately monitored and reported. A wide range of estimates is available in the literature, ranging from 2 million to 12 million deaths per year. The best estimates analysed by Gleick (2002, 4) appear to fall between 2 and 5 million deaths per year.

While these estimates identify the order-of-magnitude of the problem, the numbers of people threatened by poor management of constructed systems is much greater (Biswas 2013). Billions lack access to safe water that is reliably and continuously delivered in sufficient quantities (WHO 2014, iv). Of critical importance is the fact that access to an "improved" water source does not necessarily mean access to "safe" water fit for human consumption. As a result, for example, half of Africa's hospital beds are filled with people suffering from a water-related disease (OECD 2012b cited by OECD 2013a, 38-40).

A UN-Water Global Analysis and Assessment of Sanitation and Drinking-Water (GLAAS) 2014 Report provides a global update on the policy frameworks, institutional arrangements, human resource base, and international and national finance streams in support of sanitation and drinking-water. Ten key findings emerge from the GLAAS 2014 Report as follows (WHO 2014, ix-xi):

1. Governments show strong support for universal access to drinking water and sanitation.
2. Political aspirations, nonetheless, are impeded by weak capacity at country level to set targets, formulate plans, undertake implementation and conduct meaningful reviews.
3. Critical gaps in monitoring impede decision-making and progress for the poorest.
4. Neglect for WASH (water, sanitation and hygiene) in schools and in healthcare facilities undermines country's capacity to prevent and respond to disease outbreaks.
5. National financing for WASH is insufficient.
6. International aid for WASH has increased and regional targeting has improved.
7. Lack of human resources constrains the sector.
8. Sanitation in rural areas: high needs, yet low expenditures.
9. Weak monitoring of the critical 'H' factor – hygiene promotion.
10. Efforts are being made to reach the poor, but few at scale.

A UNESCO report states that a shortage of engineers in developing countries is hampering development. For example, to meet the target of the Millennium Development Goal (MDG) to safe drinking water and basic sanitation, the report gives an estimate that some 2.5 million new engineers and technicians would be needed in sub-Saharan Africa alone (Marjoram 2010, 3).

According to the United Nations Department for Economic and Social Affairs 3.9 billion people, or 54% of the global population, lived in cities in 2014, and by 2050, two-thirds of the global population will be living in cities (UNDESA 2014, 2). Major growth will take place in developing countries, particularly in urban areas that already have an aging, inadequate or even non-existent sewage infrastructure, unable to keep up with rising populations. It is estimated that the urban infrastructure of the world's cities over the next 20 years will require USD 41 trillion for investments in urban infrastructure, including USD 22.6 trillion on water and sanitation (UNEP 2011a, 44).

The increase in the number of people without access to water and sanitation in urban areas is directly related to the rapid growth of slum populations in the developing world and the inability (or unwillingness) of local and national governments to provide adequate water and sanitation facilities in these communities (UN-Water 2015, 3). Globally, more than 80% of wastewater resulting from human activities is discharged into rivers or seas without any pollution removal (UN 2015). The financial, environmental and social costs are projected to increase dramatically unless wastewater management receives urgent attention. Under-dimensioned and aging wastewater infrastructure is already overwhelmed, and with the predicted population increases and changes in the climate the situation is only going to get worse. Without better infrastructure and management, several millions of people will continue to die each year and there will be further losses in biodiversity and ecosystem resilience, undermining prosperity and efforts towards a more sustainable future (Corcoran, Nellemann, Baker, Bos, Osborn and Savelli 2010, 9-11).

Water storage, treatment and distribution systems are often poorly maintained. Moreover, in many countries of the developing world, water losses due to technical leakage and water theft often exceed 40-60% of the total water distribution (UN-Water 2012b, 4-5). Underpricing of water has contributed to the situation across Africa, where on average 35% of water supply infrastructure assets needs rehabilitation (Foster and Briceño-Garmendia 2009, 73). In the OECD countries the water services infrastructure is also aging and decaying, and needs rehabilitation or replacement. The estimated investment gap and the state of water infrastructure in some OECD countries and in sub-Saharan Africa (SSA) are shown in Table 1.

Table 1: Estimated investment gap of water services (water and sanitation) infrastructure in some OECD countries and in sub-Saharan Africa (compiled by the authors in 2014-16).

Country/ Region	*Population*	*State of water services infrastructure (scale)*	*Estimated current funding gap (EUR)*	*Estimated funding gap per population (EUR/hd)*
Canada[1]	*35,182,000*[a]	*Good (Very good-very poor)*	*34,755,000,000*[**]	*988*

The study question is ultimately, how the access to the water services can be increased and how the functioning of the built systems and facilities can be sustained through their planned lifetime. Therefore, in the following chapters we briefly introduce the typology and concepts of the green economy, along with the principles of the Integrated Urban Water Management and the institutional eco-innovations, which are – based on our findings – the keys in solving the above problems.

2. Integrated Urban Water Management

Integrated Urban Water Management (IUWM) is nested within the broader notion of Integrated Water Resources Management (IWRM). Given that cities are significant elements of their catchments, IUWM needs to be linked to IWRM plans and management processes in the broader basin context to allow the alignment of the urban water sector with others beyond the urban boundaries (Bahri 2011, 3). IUWM principles are the following (GWP 2013, 2-3): Encompass alternative water sources; Match water quality with water use; Integrate water storage, distribution, treatment, recycling, and disposal; Protect, conserve and exploit water resources at their source; Account for non-urban users; Recognise and seek to align formal and informal institutions and practices; Recognise relationships among water, land use, and energy; Pursue efficiency, equity and sustainability; and Encourage participation by all stakeholders.

It is essential that we develop a framework for green growth and water security that incorporates the integrated approach and addresses water within wider socio-economic goals (GWP 2012, 13). Figure 2 illustrates the coordinating structure that will ensure communication between departments, levels of government, local communities, and stakeholders (GWP 2013, 3, modified from Tucci 2010).

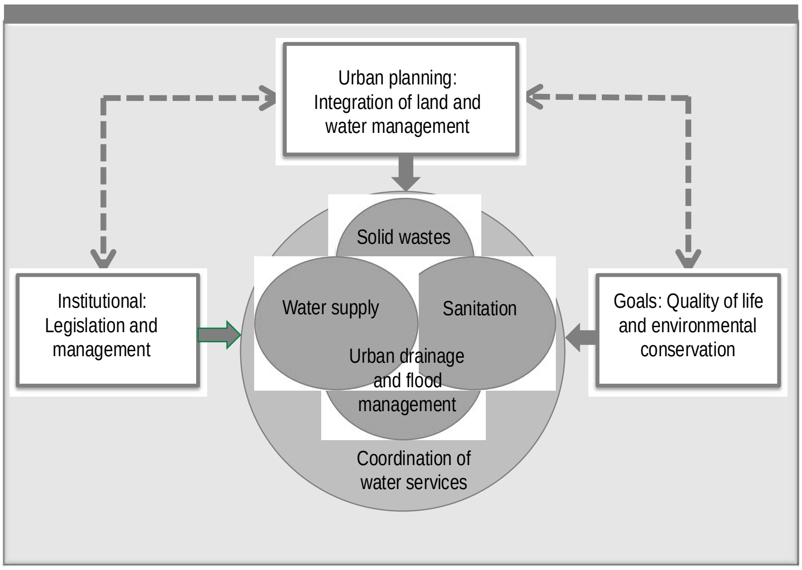

Figure 2: Integrated Urban Water Management (GWP 2013).

Urban planners can help governments overcome fragmented public policy and decision-making by linking planning with other policy sectors like infrastructure, and adopting collaborative approaches that involve all stakeholders in determining priorities, actions, and responsibilities (Figure 3, GWP 2013, 3, modified from Tucci 2010).

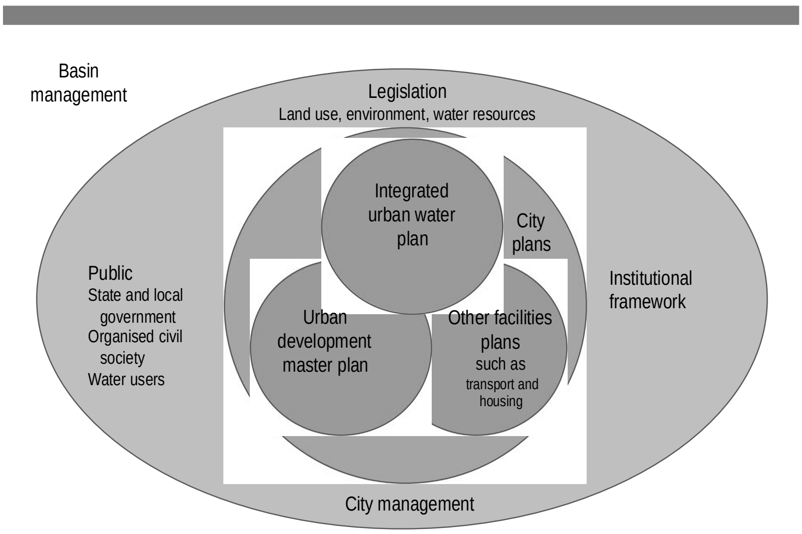

Figure 3: Institutional framework for municipal land and water planning (GWP 2013).

3. The green economy and water

The United Nations Conference on Sustainable Development (UNCSD) took place in 2012. The aim was to define pathways to a safer, more equitable, cleaner, greener and more prosperous world for all, in particular with the help of one important tool available in the context of sustainable development and poverty eradication—*the green economy*. The outcome document "*The Future We Want*" recognized that water is at the core of sustainable development as it is closely linked to a number of key global challenges. In particular, the report underlined the critical importance of water and sanitation within the three dimensions of sustainable development (United Nations 2012, 32).

According to Rotmans, the green economy is not only dealing with the new technological solutions, but it also requires sustainable ways of living, new institutions, and cultural changes (Rotmans 2012, cited by Hatakka 2013, 5). The concept of a green economy is not a replacement for that of sustainable development, but rather a way of conceiving the contribution of economic activities to sustainable development. If sustainable development is the "what," a green economy is the "how." (Federation of Canadian Municipalities 2011, 10).

There is, however, no internationally agreed definition or universal principles for green economy, and interrelated but different terminology and concepts have emerged over recent years. Allen and Clouth (2012, 63-64) gave several definitions developed by different organizations for the green growth and the green economy. Based on the review of emerging literature using a green economy policy typology, policies that were proposed in most of the publications included public investment in infrastructure (such as sustainable energy, water, transport and waste) as well as public investment in innovation (through measures such as funding for R&D and deployment) (Allen 2012, 40).

Water is fundamental to the green economy because it is interwoven with so many sustainable development issues, such as health, food security, and poverty. In developing countries, access to water and sanitation services is a fundamental precondition for poverty reduction and economic progress (UN-Water 2012a, 5). According to the UN-Water Decade Programme on Advocacy and Communication (2011b, 33-34):

1. Achieving a green economy is not possible without ensuring everyone has access to basic water and sanitation services.
2. Transitioning to a green economy in water requires a shift from current practice. Some key tools to promote the necessary change and support the transition: i) economic instruments; ii) green jobs; iii) cost recovery and financing; iv) investments in biodiversity; v) technology; and vi) water planning.
3. Creating incentives for improving efficiency is appropriate where basic water and sanitation services are already being provided.
4. There is an important role for social dialogue and for communities in the provision of water services. Community initiatives are vital in places where government action does not reach.
5. The transition to a green economy requires mobilising more funds, but also requires increasing efficiencies to make better use of the limited financial resources available.
6. Investing in the improvement of biodiversity is critical for sustaining or restoring the water-

related services provided by ecosystems.

7. Governments need to facilitate innovation and adoption of greener water provision and water use technologies, contributing to job creation and structural transformation towards greener economies.
8. Water planning is a powerful social tool for identifying the best way to use water resources to meet the competing needs of different users.

Direct benefits to society can be expected to flow from increased investment in the water supply and sanitation sector, including investment in the conservation of ecosystems critical for water. Research shows that by investing in green sectors, including the water sector, more jobs and greater prosperity can be created. Arguably, these opportunities are strongest in areas where people still do not have access to clean water and adequate sanitation services. Early investment in the provision of these services appears to be a precondition for progress. Once made, the rate of progress will be faster and more sustainable, thus making transition to a green economy possible. The costs of achieving a transition will be much less if the increased investment is accompanied by improvements in governance arrangements, the reform of water policies and the development of partnerships with the private sector. The opportunity to improve governance arrangements is one of the biggest opportunities to speed transition to a greener economy (UNEP 2011b, 146).

The World Water Council (2011) proposed three strategic directions, twelve priorities for action, and three conditions for success as the means to achieve progress in three strategic directions. They constitute strong enabling factors in addressing all the priorities for action (Figure 4).

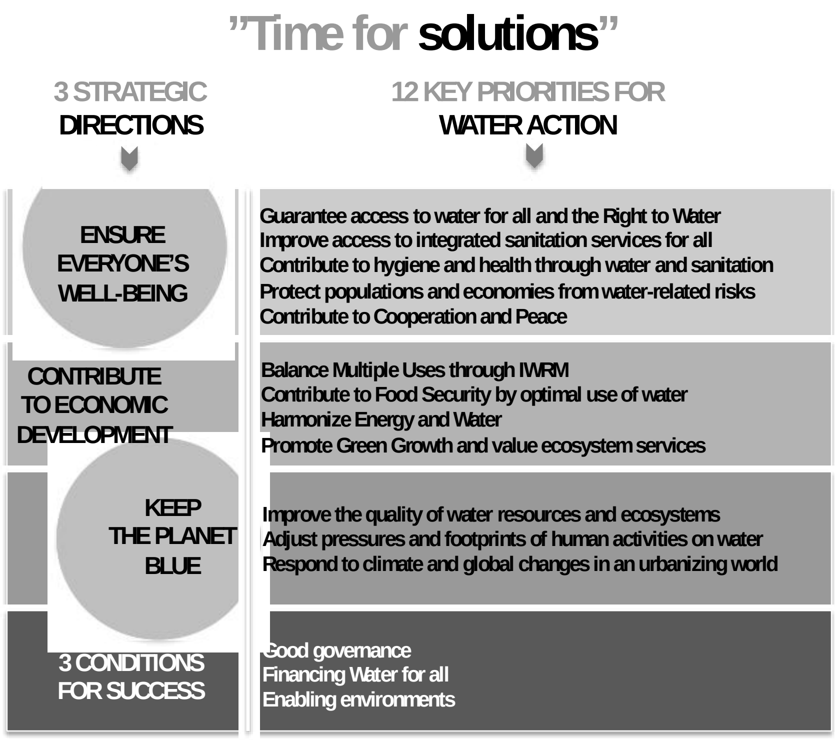

Figure 4: Three strategic directions, twelve priorities for water action and three conditions for success (World Water Council 2011).

Focusing on effectively managing assets to sustain services can be as important as focusing on new infrastructure (World Health Organization 2012, 3). The results of the abovementioned GLAAS 2014 Report show that to improve access and reduce inequalities beyond 2015, much needs to be done to effectively implement and monitor WASH policies at national level, including to (WHO 2014, ix):

- Secure, absorb and target sustained international and national financing;
- Renew focus on health facilities as a priority; to strengthen action in the crucial area of hygiene promotion;
- Support the operation and maintenance of existing infrastructure and services;
- Expand efforts in neglected rural areas where the need for improved services is greatest.

4. Institutional eco-innovations

The most popular definitions of an institution have at their core *social factors that influence, to some extent, human behaviour* (Davis 2009, 3). According to North (1991, 97) institutions are the humanly devised constraints that structure political, economic and social interaction. They consist of both informal constraints (sanctions, taboos, customs, traditions, and self-imposed codes of conduct), and formal rules (constitutions, laws, property rights). Kemper (1996) pointed out that in colloquial language the expression institution also applies to organizations. For more clarity, she used the term of *institutional arrangement*, which indicates the structural nature of institutions. According to her, institutional arrangements and actors, i.e. individuals, agencies and organizations, compose *the institutional framework*.

OECD (2011b, 1-2) notes that *innovation* will play a key role in implementing strategies for green growth. In the Oslo Manual, eco-innovation is defined as “the creation or implementation of new, or significantly improved, products (goods and services), processes, marketing methods, organizational structures and institutional arrangements which – with or without intent – lead to environmental improvements compared to relevant alternatives”. Figure 5 presents an overview of eco-innovation and its typology (OECD and Eurostat 2005, 46, cited by OECD 2009, 13):

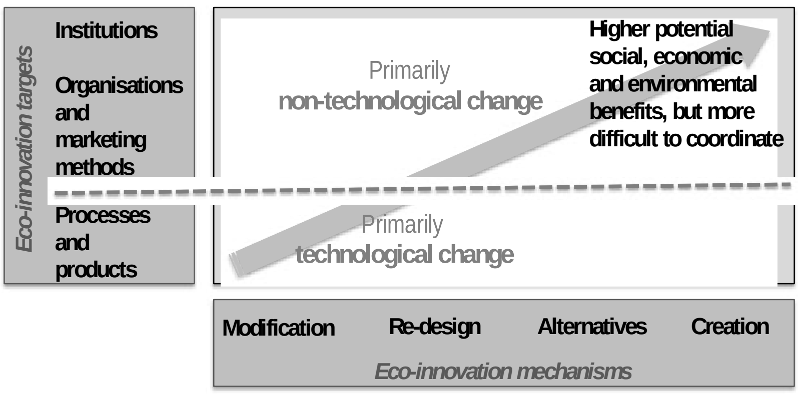

Figure 5: The typology of eco-innovation (OECD and Eurostat, 2005, modified by Hukka in 2015).

In this definition, institutional innovations such as changes in values, beliefs, knowledge, norms, and administrative acts are included, along with changes in management, organization, laws and governance systems that reduce environmental impacts. Innovation, therefore, is not simply about technological solutions (‘techno-fix’ approach). Rather, innovation is a process that has three different forms with different outcomes: 1) Technological innovations providing specific techniques for managing/processing materials and energy; 2) Institutional innovations for managing on a society-wide basis – or even globally – incentives, transaction costs, rents, benefit distribution, dispersal, contractual obligations, precautions, and individual obligations; and 3) Relational innovations for managing cooperation, social cohesion, solidarity, social learning and benefit sharing (UNEP 2011a, 36).

5. Conclusions

We conclude that to make a coherent transition to the green economy and to meet emerging needs of the poorest citizens, the Sustainable Development Goal 6 *“Ensure access to water and sanitation for all”* by 2030 must be achieved. Therefore, there is an urgent need to create enabling institutional framework for urban water services provision and production – in addition to the exploitation of technological innovations. First of all, the reformed institutional framework should ensure that there are more funds available for building new urban water infrastructure to extend access to services as well as more funds for rehabilitation and replacement of existing deteriorated infrastructure.

Secondly, the framework should have a strong focus on improving resilience, performance and maintenance of built infrastructure through effective strategic asset management processes, supported by proper enforcement structures, and on upgrading pricing of services and cost recovery practices. The framework should, therefore, also include improvements in governance arrangements, reforms of water policies, and development of viable cooperation between public and private sectors. Thirdly, the critical role of engineering in addressing water-related global challenges must be recognized more widely, and human resources development should be addressed accordingly.

We also recommend that in formulation of a new institutional framework, the typology and concepts of the green economy, along with principles, approaches and processes of Integrated Urban Water Management, and institutional innovations such as changes in values, beliefs, knowledge, norms, administrative acts, changes in management, organization, laws and systems of good governance should be carefully considered and adopted to build up universal coverage and resilience of urban water and sanitation services.

Delivering Value with BIM: A Framework for Built Environment Practitioners

Adriana X Sanchez,
Sustainable Built Environment National Research Centre, Curtin University
(a.sanchez@sbenrc.com.au)
Sherif Mohamed,
School of Engineering, Griffith University
Keith Hampson,
Sustainable Built Environment National Research Centre, Curtin University

Abstract

The built environment industry worldwide is facing significant external pressures such as increased competition, higher owner expectations, rapidly changing technology and skill shortages. Building Information Modelling (BIM) has been identified as a socio-technical system that can be used to improve team communication throughout the project life-cycle, produce better outcomes, reduce rework, lower risk, provide better predictability of outcomes and improve operation and maintenance of an asset, among other benefits. Within this context, proactively establishing quality improvement cycles based on standardised work processes and corresponding measures of effectiveness will ensure better project outcomes. These outcomes can be driven by continuously improving systems and active monitoring. This paper introduces a methodology for developing a whole-of-life asset management strategy for delivering value with BIM across the life-cycle of built assets. It also presents a framework to assess progress towards value-driven goals.

Keywords: BIM, value, whole-of-life, asset management, strategy

1. Introduction

The built environment industry has been facing significant external pressures worldwide such as increased competition, higher owner expectations, rapidly changing technology and skill shortages (Hampson, et al., 2014). Building Information Modelling (BIM) is "a digital process that encompasses all aspects, disciplines and systems of built assets within a single virtual model" (Sanchez, et al., 2015). It has been identified as a socio-technical system "that can be used to improve team communication throughout the project life-cycle, produce better outcomes, reduce rework, lower risk, provide better predictability of outcomes and improve operation and maintenance of an asset" (Sanchez, et al., 2014). There is a growing body of anecdotal evidence about benefits that can be achieved by implementing BIM (Gilligan & Kunz, 2007) and some firms are measuring some benefits (McGraw Hill Construction, 2014b; McGraw Hill Construction, 2014a). However, unclear business value and return on investment (ROI) are often identified as barriers for adoption (Barlish & Sullivan, 2012).

Identifying, monitoring and managing benefits throughout the life-cycle of a project or asset have been highlighted as a way to help achieve success during implementation of new technologies (Yates, et al., 2009). "By defining how each benefit will be measured and then providing evidence for the expected level of improvement that will result from the changes, rigorous and realistic business case and financial argument for the investment can be developed" (Ward, et al., 2007). Capturing and disseminating information to ensure intelligent decision making can also help reduce risk and deal with the large number of variables characteristic of construction projects (Roper & McLin, 2005).

Within this context, proactively establishing quality improvement cycles based on standardised work processes and corresponding measures of effectiveness can help ensure better project outcomes. Metrics play a critical role in driving this process (CURT, 2005). There is a great deal of literature on BIM adoption and benefits for specific applications, stakeholders and life-cycle phases (Bryde, et al., 2013; Arayici, et al., 2011; Migilinskas, et al., 2013; Eadie, et al., 2013; Azhar & Brown, 2009; Kasprzak & Dubler, 2012; Teichholz, 2013). However, there is a lack of comprehensive studies that focus on mapping and measuring the benefits of implementing BIM across the whole-of-life of built assets (Sanchez & Hampson, 2016). This paper introduces the research done to develop a framework to assess the actual benefits of implementing BIM throughout asset planning, delivery and management applicable to both buildings and infrastructure.

2. Methodology

This research was developed in Australia in consultation with national and international organisations encompassing client, designer, surveyor, contractor and facilities management organisations as well as industry organisation that represent thousands of individual organisations across the supply chain. The research aimed to:

(i) Define indicators to measure tangible and intangible benefits of BIM across a project's life-cycle in infrastructure and buildings; and
(ii) Pilot test a whole-of-life BIM value realisation framework on leading infrastructure and building case studies.

The research was informed by a thematic analysis of an extensive literature review covering over 400 academic and industry references. The framework was tested through expert consultation and three exemplar case studies in Australia that featured the use of BIM during design, construction and asset management. The expert consultation included 31 industry, government and research experts from across the supply chain with 10-30 years of experience in the field and roles related to BIM implementation and uptake at the organisational level.

It was important that the framework could be easily applied to both infrastructure assets and buildings. The research team studied a number of different approaches available to develop a strategy for measuring the value of information technology in construction. It was also consistently reviewed by a group of industry and academic experts from infrastructure and buildings, and at different levels of the supply chain. An introduction to the framework was also presented at the Australasian Regional Conference organised by the International Roads Federation (IRF) and Roads Australia in May 2015. This was done to obtain feedback from a wider audience and address common concerns of BIM guidelines being often directed only to buildings and architectural design. This research builds on Love, et al. (2014) who proposed the use of Benefit Realisation Management (BRM) by asset owners. However, the present work provides a different adaptation of the BRM method and extends it to be applicable to all built environment stakeholders across infrastructure and buildings. It was also modified to include the value of unplanned and flow-on benefits as later defined, as well as used to develop a step-by-step guide and an online interactive tool.

3. BIM Value Realisation Framework

The value of BIM is realised through its benefits for different stakeholders. Benefits arise because information technology systems such as BIM enable people to carry out tasks more efficiently and effectively. They do this by allowing and shaping new ways of working through the re-design of intra- and inter-organisational processes or facilitating new work practices (Peppard, et al., 2007). The Benefits Realisation Management (BRM) approach was originally developed in the 1980s and 1990s. This method offered a way of understanding the return on investment from information technologies and systems, and overcoming the limitations of traditional investment appraisal techniques. This aspect of project management has received increasing attention in the past few years (Breese, 2012). These practices have been shown to be associated to the creation of value (Martins Serra & Kunc, 2015) and been applied to a number of sectors and stakeholder groups (Bradley, 2010; Peppard, et al., 2007). However, tailoring this framework for specific organisations and sectors is an essential step towards optimising its value (NSW Government, 2014b). Love, et al. (2014) proposed the use of BRM and resource-based view (RBV) "to provide asset owners with the capability to realize its benefits". Although building on Love et al's idea, this research provides an alternative adaptation of the methodology to serve a larger audience and projects at different life-cycle phases. It was also used to develop a detailed step-by-step guide and online interactive tool to provide guidance for built environment practitioners on how to operationalise the overarching framework.

The framework (Figure 1) largely follows the traditional BRM structure and principles but acknowledges that value is realised not only through specifically identified end-benefits but also through unintended benefits. This has been addressed by including “flow-on” benefits. These are benefits that can be obtained once the end-benefit is achieved. While not being specific project goals with targets and associated milestones, they are included to account for the full value delivered by implementing BIM. The monitoring processes suggests the inclusion of other considerations such as project context and unexpected situations which may hinder the achievement of specific benefits. It additionally acknowledges the role of team and organisational capabilities in attaining value from implementing BIM. This broader view may enable more complete future benchmarks and better understanding of project-to-project different levels of implementation success. Finally, it proposes that enablers have associated risk which should be taken into consideration as they may bring “disbenefits”, these are non-value-adding outcomes which are counterproductive to the implementation goals.

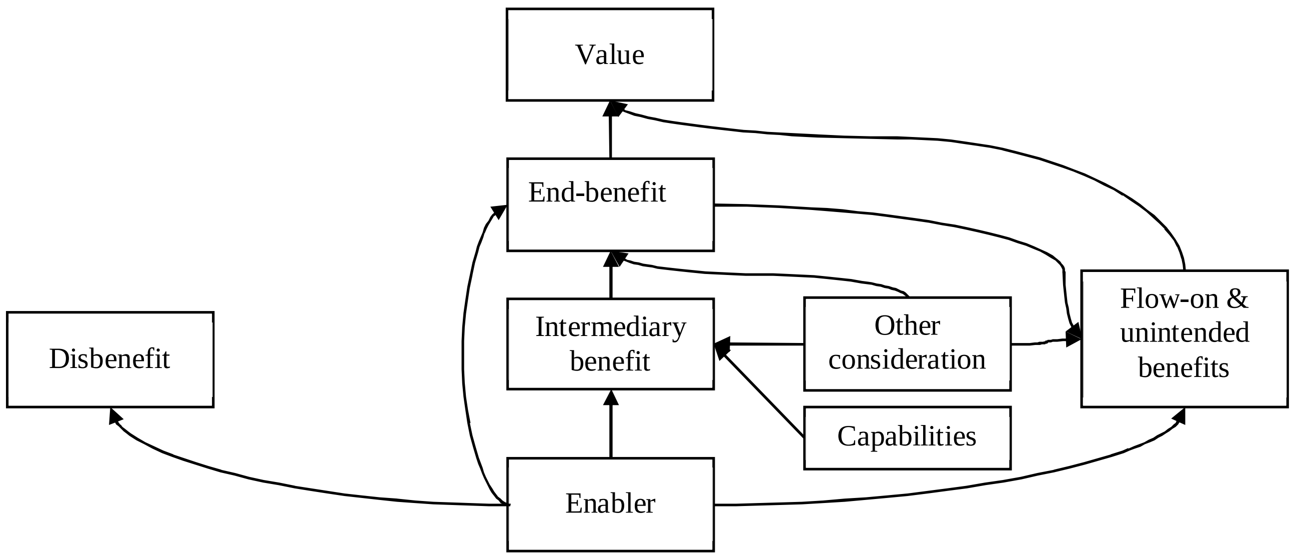

Figure 1: Framework principles

The BIM value realisation framework can be applied at any phase of the life-cycle of an asset and is meant to complement BIM implementation guidelines. The MacLeamy Curve (AIA, 2007) however applies to this process as well. This means that, as shown in Figure 2, the earlier changes and processes required to implement BIM are introduced, the larger impact they are likely to have on the outcomes of the project and realising its full value.

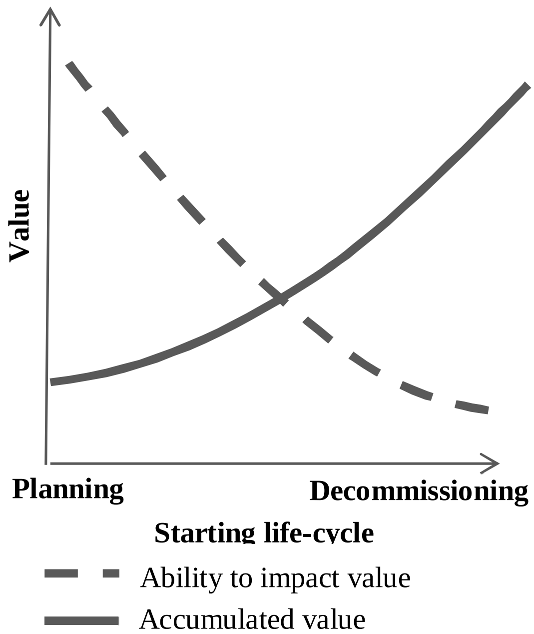

Figure 2: Value/life-cycle relationship

There is no single BIM software that covers all functionalities and processes. The value to each stakeholder is therefore delivered by identifying the specific benefits they aim to gain by implementing BIM-related tools and processes. This allows teams to have a clear understanding of the overall goals, select the path to these goals based on performance-driven objectives and establish a strategy to monitor their progress towards these goals. Thus, another key aspect of the framework is that it focuses on specific benefits driving the BIM implementation strategy and proposes specific asset and project management processes where this can be embedded.

3.1 Step-by-step Guide Summary

The detailed methodology and dictionaries were published in the book: *Delivering Value with BIM: A Whole-of-life Approach* (Sanchez, et al., 2016a). This section presents a brief summary of the main proposed steps.

Step 1 - Define end-benefits: end-benefits are the ultimate objectives. They are the value the team wants to have realised from implementing BIM – such as lower cost, improved safety and gaining competitive advantage. These are defined in a workshop environment with key stakeholders that include project manager, asset manager, designers, end-users and other relevant stakeholders. Including asset managers and end-users can help ensure a whole-of-life insight.

Step 2 - Define intermediary and flow-on benefits: these are the *story* behind each end-benefit and defined in the same workshop environment as the previous step. Intermediary benefits are those *expected* to occur between the implementation of early changes and the realisation of the end-benefits. Flow-on benefits are those that may be derived from achieving the end-benefit. There may also be unintended benefits arising from implementing specific enablers which may be identified at later stages.

Step 3 - Define enablers: enablers are processes and tools related to BIM uses and implementation. They help achieve the first intermediary benefit in the chain. A risk is associated to each enabler, and other considerations such as new skills requirements and cost need to be included in the assessment.

Step 4 - Assign metrics, targets and incentives: metrics provide the means to justifying investments made, comparing and ranking benefits, providing targets for success and benchmarking and monitoring progress towards goals. Assigning metrics to benefits is the basic requirement to provide effective accountability. Choosing as many metrics as possible related to the identified benefits may provide better insight into the success of the implementation strategy. Targets should be assigned to each metric and, if appropriate, financial incentives for exceeding targets.

Step 5 - Embed metrics and targets into progress report documentation and processes: this ensures accountability and provides a rich source of information based on which the group can make decisions and introduce changes in a timely manner in order to correct situations that may be hindering the achievement of the goals established in previous steps. Metrics, targets and incentives should be embedded in the project documentation including the regular progress report as well as the BIM model itself as appropriate. These should also include processes to record context information that may be used to understand different levels of success across different projects.

Step 6 - Workshop follow-up / feasibility and approval: this step is a reality check to evaluate what specific software solutions can be used as enablers to achieve the selected benefits most effectively. The associated cost, for example, will largely depend on the capabilities of the project team and previous experience with specific software packages as well as licences already purchased.

Step 7 - Progress review and correction initiatives: benefits require active monitoring and advancement towards targets related to benefits should be reported on and reviewed during project progress meetings.

Step 8 - Ongoing active learning: benefits are dynamic and will change as technology develops. Therefore, benefits, enablers and metrics dictionaries should be developed and regularly reviewed and updated.

Next steps: following the value realisation strategy, there are a number of considerations that will have to be addressed such as standards, protocols, BIM management roles, risk apportioning, skill development plans and system requirements. This methodology is proposed to be complementary to technical implementation guidelines and standards.

3.2 Dictionaries

BIM is not a single software package that teams can just buy and implement in isolation. It is a new way of working that commonly includes the use of a number of tools, processes and software solutions. One of the exemplar case studies carried out for this research project was based on the design and construction of the Perth Children's Hospital in Australia. This study identified 20 different BIM-related tools and processes that were associated with 26 different benefits (Sanchez, et al., 2015). The second case study was based on the design of the New Generation Rollingstock Maintenance Centre also in Australia and identified 17 tools and processes associated with 25 benefits (Utiome, et al., 2015). This can be overwhelming, especially for new users. To address this issue, the research team carried out an extensive literature review to develop a set of dictionaries.

The *Benefits Dictionary* includes 31 profiles of benefits that are currently achievable from implementing BIM. Benefit identification is a critical process in the BRM methodology “used to create a detailed plan of how those benefits are to be realised throughout the life-cycle of implementation and use of the new technology, process or system” (Sanchez, et al., 2016b). Benefits are defined as improvement on the status quo; as opposed to enablers which are those tools and processes used to achieve a benefit. This distinction is important because in many academic and industry publications enablers are often cited as benefits themselves. Clash detection is for example often mentioned as a benefit of using BIM. This however makes more difficult identifying appropriate metrics that can be used to monitor progress and create industry benchmarks. In this example clash detection is a tool/process; an element that cannot be measured in specific terms but just is or is not in use. The real benefit of clash detection is an improvement in the efficiency of the process of detecting clashes, brought by higher levels of automation and better communication and coordination; this in turn leads to fewer errors and lower cost. All of these are benefits that can be measured in different ways and specific levels can be targeted as success criteria.

Each profile provides a general description of each benefit and provides information about some interpretations that are specific to particular life-cycle phases. They also include a list of enablers that can help realise and maximise the value of BIM at different life-cycle phases, benefits that can flow-on from achieving the profiled benefit, main benefiting stakeholders, metrics that can be used to monitor the benefit and examples of projects where they have been achieved. The list was created based on a thematic analysis of the literature with input from the three exemplar case studies. It includes benefits at different scales that could be considered intermediary or end-benefits depending on the strategy chosen. This was done aiming to cater for progressive and incremental implementation strategies that may focus on different benefits at each step. This may be especially relevant to small and medium sized enterprises (SMEs) and cautious client organisations with limited resources.

The *Enablers Dictionary* contains information about 51 enablers grouped under two overarching categories and 28 sub-categories. The categories were developed using the Pennsylvania State University “BIM Execution Plan” (Penn State, 2011) as a starting point and further developing it based on input from industry experts. The two overarching categories are:

(i) Intrinsic/core: These are enablers that were considered to form the basis of BIM and maximise benefits from its use across different life-cycle phases. These included processes that were not standard practice in many countries yet but were considered an intrinsic part of BIM implementation strategies that aim to maximise its value for all stakeholders. Examples include “design authoring and data-rich accurate models”, “early and effective stakeholder engagement” and “object libraries”.

(ii) In Use: These are enablers which are either commonly used nowadays and/or that, although having had limited use in common practices, either are already growing in use or have the potential to do so in the near future and provide significant benefits. Examples include "3D laser scanning", "automated clash detection", "design reviews", "GIS-BIM" and "digital fabrication".

The *Metrics Dictionary* aims to provide a practical way of avoiding wasted efforts often seen in recording and tracking metrics which are being tracked elsewhere. The dictionary includes a comprehensive set of 43 metrics that were found to be practical and offer a set from which each project can select those that are most appropriate to their goals and needs. These metrics are mostly based on literature but also include indicators proposed by the authors based on professional experience, experts consulted and the three exemplar case studies. Metrics were categorised in four groups:

(i) People - serve to monitor benefits achieved through changes in behavioural patterns or that directly affect staff. Examples include "safety", "meetings", "stakeholder involvement" and "labour intensity".

(ii) Processes - monitor benefits achieved through changes to general process improvement and generally aim to measure the efficiency of these processes. Examples include "time predictability", "schedule conformance", "cost of change", and "latency".

(iii) Procurement - monitor benefits achieved during or through procurement and asset management processes. Examples include "cost per unit", "quality", "program capacity" and "globalisation".

(iv) Sustainability and future proofing - monitor benefits achieved in terms of better environmental sustainability outcomes and improved emergency management. Examples include "resource use and management", "carbon emissions and footprint", "emergency latency" and "emergency plan and response effectiveness".

It should be noted that, although case study participants highlighted sustainability as one of the drivers to implement BIM, the research team found it particularly difficult to find literature about metrics that could be included in this category. This is proposed as a potential gap in the literature for future research.

A complete list of benefits, enablers and metrics can be found online on BIM Value (see section 3.3) or in Sanchez et al. (2016a).

3.3 BIM Value

The experts consulted to test the practicality to the framework suggested that one of the main barriers to adoption is fast and easy access to information about benefits, enablers and metrics. This led to the research team translating the dictionaries into an open access online interactive tool to step through the first four levels of the framework. This tool, BIM Value (http://bimvaluetool.natspec.org/), provides a tailored information delivery system. It guides the user through six steps where they select the stakeholder group and life-cycle phases they are interested in and the tool provides a set of benefits that apply to those two parameters. The user can then select those benefits they are interested in and the tool provides a new list of enablers and metrics which apply to the selected stakeholder group, life-cycle phase and benefits. In the final step, it produces a report with a summary of descriptions of the different benefits, enablers and metrics selected that also includes examples and references to follow upon. The tool also offers the possibility of accessing the dictionaries directly and provides links to other sites with BIM-related videos and guidelines. In its first week and with close to no publicity, the tool had over 240 new users trying it out, mainly from the UK and Australia. Four months later, the tool has had over 4,000 views with a return rate in March 2016 of 49.3%. This is suggested to be a reflection of the industry's interest in accessing information about tangible and measurable benefits from implementing BIM.

3.4 Research Limitations

The methodology presented here, although based on an arguably proven approach such as BRM and submitted to a thorough review process with industry and academic experts has had a limited validation process. The framework was partially validated by the Sydney Opera House which was transitioning into a BIM-based asset management system. Feedback from this effort and the previously outlined consultation was used to finalise the framework into its present form. However, although originally planned, a more comprehensive validation process was not possible due to time and resources constrains. The research team will continue to work towards the validation of the complete process in the near future.

3.5 Future Research

Future research will aim to continue to develop and improve the BIM Value tool through new modules in order to increase its value to the industry. One of such modules is for example expected to form the basis for a world-first BIM benefits benchmarking system (BIM Value Benchmark). This new effort will also seek to understand how meta-data created from using the tool can be used to most benefit the industry.

4. Conclusions

This publication has introduced a methodology to identify and monitor benefits that will serve to realise and deliver value with BIM across the life-cycle of an asset to different stakeholders. This research was based on an extensive literature review, expert consultation and three exemplar case studies. An important aspect of the research was to collaborate with industry and government organisations across the supply chain to receive feedback on the practicality and completeness of the outcomes. This collaborative effort aimed to ensure that the outcomes of the research were most relevant to different industry stakeholder groups as well as complementary to outputs of other organisations active in this space. Outcomes of this research are expected to help achieve more informed value-driven assessment and continual improvement of the implementation of BIM across assets and life-cycle phases.

Combining BIM and Lean Construction: Towards Enhanced Collaborative Working?

Ketil Bråthen,
Fafo & Norwegian University of Science and Technology
(email: keb@fafo.no)

Abstract

In this paper, the influence on collaborative working by using BIM and two Lean Construction inspired tools in a real-life design process is scrutinized. Statsbygg, as the building commissioner, expected that requiring the use of BIM, as well as the two Lean Construction principles; co-location and a takt-time planning would enhance the collaborative working among the design team. The case study is based on qualitative data which stems from semi-structured interviews, observational as well as document studies. The findings indicate that the combination of BIM and co-location helped to improve the collaborative working including fostered faster communication, and contributed to a good social climate in the design team. However, the data also suggest that not all parts of Statsbygg's contractual "BIM and Lean Construction package" were equally successful in practice. The takt-time planning tool was not used at all by the design team. An explanation for this disparity in successfulness is partly due to that BIM and co-location got more attention from Statsbygg compared to the takt-time planning tool in the implementation process. Moreover, the design team had experiences with BIM and co-location from an earlier project, and thus found it easier to make use of elements that were familiar. Based on the analysis, it is concluded that the combination of BIM and co-location have a potential to impact positively on collaborative working in the design phase by linking actors together both technological and organizational. However, such an outcome requires a careful planning and implementation process.

Keywords: BIM, building process, case study, collaboration, lean construction

1. Introduction

The architectural, engineering, and construction (AEC) industry creates complex and unique buildings. Construction work is organized as projects; temporary coalitions between two or more organizations (Jones and Lichtenstein 2005). Construction projects consist of teams from different companies who work together to realize the project's goals. These industry specific characteristics are of great importance for how the industry operates. As pointed out by numerous researchers, the construction industry suffers from several unfortunate conditions that affect the industry unfavourably. Some have characterized the relationships in construction as "loose couplings" (Dubois and Gadde 2002). This notion refers to temporary coalitions of companies and individuals that come together to complete a project, and then disband. An important feature is the fragmented nature of the industry. Consequently, potent collaboration between actors from different companies throughout the constructions process is required. Still, prior experience recognizes that this is really difficult to achieve. However, in the last decade we have seen promising technology in terms of building information modelling (BIM). With the use of BIM, a network of interdependent actors can collaborate to develop and utilize a 3D object of the planned building (Taylor and Bernstein 2009). Ideally, BIM technology should create a tight technological coupling among the actors who share models (Dossic and Neff 2010). The starting point of this paper is how potentially tight technological couplings work out in an industry known for its fragmented nature.

In this paper, an explorative case study from Statsbygg is investigated. Statsbygg provides guidance in the purchase and leasing of premises and, in respect of new buildings, act as building commissioner on behalf of the Norwegian government. This case deals with the detailed design phase of a refurbishment of a university building where Statsbygg acted as building commissioner. The case study is about Statsbygg's request of using BIM, and some Lean Construction principles including co-location of the design team as well as a takt-time planning system. Statsbygg's expectation was that this combination would enhance collaborative work among the actors in the design team. By collaborative work I refer to the joint working of various actors or different organizations to effectively accomplish a project (Xue et al. 2010). However, one cannot simply assume that improved collaborative working is automatically achieved. Previous case studies have shown that implementation and use of BIM and Lean Construction are affected by the interplay between the triangle of technology, people and process. To succeed, mutual adaptations regarded to the three elements are required by the involved actors (cf. Moum 2008). Thus, the following research question will be examined: How was the collaborative work among the design team in the case studied affected by the request of using BIM and Lean Construction?

2. Conceptual framework: Lean Construction and BIM

Taiichi Ohno is the person usually credited for having launched the Toyota Production System (TPS), which can be seen as a precursor to what is here referred to as Lean Construction. Lean thinking is generally based on the following five principles: 1. the value associated with the product as specified by the customer. 2. The value stream, identifying the value stream for each product and to avoid waste. 3. Flow, to create a value flow without interruption. 4. Pull, to let customer needs guide the production process. 5. Continuous improvement, creating a continuous improvement throughout the process (Womack and Jones 1996). Lean Construction is inspired by TPS, and emerged as a concept in the early 1990s. Lean Construction is based on an assumption that Lean manufacturing principles cannot be transferred directly to the construction industry. The construction industry is characterized by more variety and uncertainty about production compared to the manufacturing industry. Koskela (2000) proposed the use of the Transformation-Flow-Value (TVF) theory where production was conceptualized in three ways: 1. As a transformation of inputs to outputs. 2. As a flow, in addition to transformation there is waiting, inspection and moving stages 3. As value; where production is seen as means for the fulfilment of the customer needs. The conventional conceptualization of production within construction industry has been based on the transformation concept only. This implies that production management in this conceptualization is all about dividing the total transformation into tasks which is sought to be handled as efficiently as possible. Koskela (2000) claims that all three conceptualization are necessary and they should be used simultaneously. The TVF theory led to the birth of Lean Construction. The aim of Lean Construction is thus *"… to design production systems to minimize waste of materials, time, and effort in order to generate the maximum possible amount of value"* (Koskela et al. 2002, p. 211). It is significant to stress that the term Lean Construction may refer to the use of Lean in the entire construction process and not only the construction phase. However, in this paper Lean Construction is used to denote the use of Lean principles and tools in the design phase (cf. Emmit et al. 2004).

The acronym BIM can be used to refer to a product building information model, a structured dataset describing a building, or an activity building information modelling - the act of creating a building information model (Moum 2008). In this paper, BIM is a term referring to three-dimensional computer-aided and product-oriented design technologies and processes in the AEC-industry. With the use of BIM, a network of interdependent actors can collaborate to develop a model of the planned construction works (Taylor and Bernstein 2009). A frequent scenario is that the designers merge their discipline-specific models to a multidisciplinary model, and by using applications for visualization and collision controls get a better cross-disciplinary understanding of each other's requirements, detecting conflicts, errors and omissions across disciplines (Moum 2008).[1] It has been argued that the construction industry may be facing a new paradigm triggered by BIM (Azhar 2011). This paradigm shift is partly expected to change the traditional discipline's practices towards more integrated processes. It is also expected that BIM can result in a seamless flow of information across different actors and disciplines in the construction process. This implies that it is not only a change in technology itself, but that the change also affects procedures, tasks, roles, etc. Consequently, the new paradigm can be seen as organizational as well as technological. One of the most striking arguments for implementing BIM is that it has the potential to improve the collaboration among the actors involved in the construction process. To

1 In this scenario, BIM is not used to its full potential. See this link for a discussion of different BIM maturity levels: https://www.thenbs.com/knowledge/bim-levels-explained

accomplishing these promised improvements, the project team needs to adapt and work together in an integrated unit.

2.1 BIM, Lean Construction and collaborative working

Lean Construction and BIM are not dependent on each other. This means that Lean Construction can be adopted without BIM and BIM can be adopted without Lean Construction. However, evidence of interactions between Lean Construction and BIM has been identified. In a paper, Sacks et al. (2010) discuss interactions of Lean Construction and BIM. Based on a comprehensive analysis they find that Lean Construction and BIM have several overlaps. Consequently, the authors claim that: *"… the breadth and depth of interconnections between them [Lean and BIM] implies that any company or project on a lean journey should seriously consider using BIM for enhancing the lean outcomes. Conversely, any company or project implementing BIM should ensure that their adoption/change process is contributing to the fullest extent possible to making their processes leaner"* (Sacks et al. 2010, p. 979). Based on this conclusion, I assume that the potential for improvement of a construction process are enhanced when BIM and Lean Construction are integrated. As the discussion above shows, basic premises for both BIM and Lean Construction are about improving collaboration by different actors in the construction process. This was also present in Statsbygg's thinking in the project. Statsbygg assumed that BIM and Lean Construction positively affect each other and that the combination of the two would strengthen the collaborative work in the design phase. The relationship between BIM, Lean Construction and their impact on collaborative working as it is perceived in this paper, is illustrated in figure 1. In the following, figure 1 will be briefly explained. The introduction of BIM and Lean Construction in a project may have impact on collaborative work in all parts of the construction process. In addition, using BIM and Lean Construction can affect and influence different processes on several levels. Following Moum (2008), three levels can be identified: 1. the micro-level which focus on individual processes. 2. The meso-level covers processes and mechanisms within a group, for instance the design team. 3. The macro-level covers mechanisms on the overall project level. There has been increasing recognition in research that collaborative working is one of the most important and critical success factors for construction projects (Xue et al. 2010). In this paper, collaborative working constitutes the "dependent variable", while BIM and Lean Construction are the two "independent variables". This paper studies the impact of BIM and Lean Construction on collaborative working delimited to the *design phase*. This is no coincidence; a fundamental pillar of a successful construction project is a good design process (Moum 2008). Thus, I concentrate on BIM and Lean Construction's impact on collaborative working among the design team. This implies that processes primarily on the *meso-level* will be in the spotlight (highlighted in figure 1).

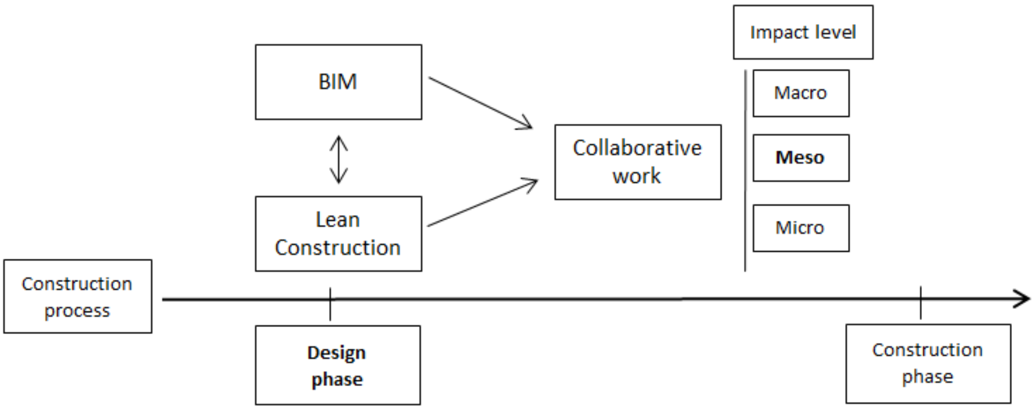

Figure 1. BIM, Lean Construction and collaborative work.

3. Methods

According to Yin (2003), a case study consists of an in-depth inquiry into a specific and complex phenomenon, set within its real-world context. Case studies are seen as appropriate to answer "how" and "why" questions and allow for the investigation of many variables consequently generating in-depth knowledge (Yin 2003). In this paper the impact of using BIM and Lean Construction on collaborative working in a real-life construction project is studied. Consequently, an in-depth case study seems necessary. The case study in this paper is based on qualitative data which are generated from semi-structured interviews with leaders and "hands on" project participants; this includes both people from Statsbygg and the design team. The purpose of the interviews was to get informants' own assessments of the project and how the use of BIM and Lean Construction affected different aspects of collaborative work. In the interviews, I asked questions about how co-location influenced collaboration across organizational boundaries, how BIM was used across disciplines as well as what takt-time planning meant for planning processes. All interviews were done in Norwegian. Consequently, the quotes used in this paper are translated from Norwegian to English by the author. All in all, it was conducted eleven semi-structured interviews. As a part of the data collection I have also observed five design meetings. About 10 persons attended each of these meetings. In this part of the study I chose a non-participant strategy (Yin 2003). Such a strategy implies that I was not a part of the activity taking place at the meetings, but simply visible observers. In addition, documents have been used as a supplement to other data types generated through interviews and observation. The documents are mainly project-specific documentation from Statsbygg. This includes contracts and tender documents, written information about the building, as well as more general information such as Statsbygg's current BIM manual.

4. The case: Urbygningen

Statsbygg is one of the industry partners in an ongoing Norwegian research project called SamBIM (Collaboration with BIM as a catalyst) financed by the Norwegian research council. This research project is based on a joint effort of Norwegian industry and research partners. In this project several actors from the construction industry wants to try out and develop BIM-driven processes and collaborative models that boost value creation in the SamBIM partners, in the building projects, and in the AEC-industry.

The case study in the paper deals with the detailed design phase of a refurbishment of a university building named *Urbygningen* at the Norwegian University of Life Sciences (NMBU) located outside Oslo. This building project is one of Statsbygg's contributions to the portfolio of case studies in the SamBIM project. The detailed design phase lasted from April 2013 to august 2014. The buildings gross floor area is 8.190 m2 and the budget for refurbishments is 307.5 million NOK. The rehabilitation of Urbygningen has been a long-drawn process. The preliminary design was completed in 2009. Then, the project was abandoned for several years while waiting for the necessary government funding. In January 2013, Statsbygg received an assignment from the

Norwegian Ministry of Education and Research to start up the process for rehabilitating the building Urbygningen at NMBU. In March 2013, Statsbygg put the project out to tender. The task was about hiring a design team for carry out the detailed design phase. Because of the connection to SamBIM, the building project's ambitions were raised compared to a more “normal” Statsbygg project according to some of the informants from Statsbygg. In the contract documents it was also emphasized that the project should be executed as what is referred to as a “Lean project”. One of the tender documents had a distinct focus on collaborative working, BIM and Lean Construction. This document was titled “Collaboration memo” and describes how Statsbygg envisioned BIM and Lean Construction in this project. In the document we can read the following: *“… Lean construction should be used in this project, both during the detailed design phase and construction phase. Lean is introduced in the project together with BIM and logistics planning. Lean is about creating flow between individual actors, disciplines, phases and tasks in a construction project allowing holistic process. An important factor succeeding with Lean is that everyone in the project participates and is willing to take part of the process”* (Statsbygg 2013). Altogether, Statsbygg anticipated that the use of BIM and Lean Constriction should lead to a project with more collaborative working among the actors in the design team thus leading to better design phase (Statsbygg 2013).

4.1 Implementation: How was the design phase carried out?

Based on a competitive tendering, a design team was selected. The chosen design team was a constellation of five Norwegian consultant companies. This group started their work in the spring of 2013. In the very beginning of the design phase the whole design team attended a training course where they were given a brief introduction to the main ideas of Lean Construction and takt-time planning principles. According to my informants the takt-time planning principles were neither used nor particularly mentioned throughout the design phase. This lack of use was by my informants related to the fact that the design team itself did not have any experience with such principles. In addition it was emphasized that the planning principles was not further requested by Statsbygg during the design phase. In other words, it was mainly the design team’s responsibility to determine the organizing of their work, albeit based on Statsbygg's contractual specifications. It was in particular the use of BIM and co-location of the design team in a so-called big room which got most attention and became the fundamental work principles. This kind of working implied in this project that the design team should be co-located in a common office two days a week. This form of working is inspired by Lean Construction and some principles taken from so-called Virtual Design and Construction (VDC) (Chachere et al. 2009). There exists several touch and overlaps between Lean Construction and VDC. An important shared feature is the focus on activities that bring value to the project and minimize waste activities. When working co-located, all relevant actors are gathered in a big room where they work simultaneously using technology such as BIM. In this construction project, the big room was furnished with desks, one interactive whiteboard as well as an old fashioned screen and projector. In addition, adjoining offices were made ready for separate meetings, phone calls etc. They also had a fairly large room where everyone had a permanent work station. Statsbygg and the design team agreed upon a weekly schedule. The schedule meant that the main disciplines should be present two days each week together with representatives from Statsbygg. Representatives from the end-user would also be present when needed. The intentions with this form of working were to strengthening collaborative working, including the interdisciplinary collaboration as well as reducing waiting time.

5. Findings

In my interviews, I was concerned about getting deeper insight into how the use of BIM and Lean Construction affected the relationship and collaborative working among the actors in the design phase. These are processes which primarily are located at the meso-level as discussed in the paper's conceptual framework (figure 1).

All actors interviewed were familiar with BIM from earlier projects. Most of them had worked on several BIM-enabled projects. When asked about BIM and collaboration, almost all informants told that BIM had led to a better understanding and knowledge of the other designers' work and had brought valuable opportunities for interdisciplinary control. Below is a quote that demonstrates what a number of informants told in the interviews:

"BIM is a significant improvement. It is easier to work together when we have a common model. I can see what's have been done by others. I can also see how other designers have planned and how I must relate to their work" (Designer).

In the quote above, aspects related to the interdisciplinary work are highlighted as favorable by using BIM. Nevertheless it was especially the combination of BIM and co-location in a big room my informants emphasized as particularly useful. All informants' from the design team had earlier experience from projects where co-location and BIM were used in combination. This experience was by several pointed out as something valuable because the team knew about the working methods and what that entailed. In addition, the design team was familiar with each other from a Statsbygg project some months in advance, were the combination of BIM and co-location was tested. Some informants claimed that this familiarity gave the project a flying start because the team did not have to "go up a completely new path". Below follows a quote from an informant who underlined the significance of being familiar the "new" way of working form prior projects:

"This [the co-location of the design team] was not completely new to me. I have been working on another project with Statsbygg where we were co-located two days each week biweekly. Several persons from the design team [in this project] were also involved in that project" (Designer).

5.1 More and better inter-organizational collaboration

Several of my informants upheld that the combination of BIM and the co-located type of working had facilitated the group working together as a unitary team. This was partly explained by pointing out that it was much easier to approach designers from other disciplines and companies when the team was co-located and the intention was that they should work together. Some informants pointed out that this kind of working contributed to erase the organizational boundaries between the different companies. The two following quotes illustrate some of what is discussed in this section; in addition they show that the informant's claim that they behave differently towards people they get to know better:

"… it is about that we get a different relationship, a better relationship, with the other persons in the project when are co-located and working together compared to the 'usual projects'. This is my experience at least" (Designer).

"I think maybe I behave a little differently towards the other people in the project [when co-located]. I mean, differently towards the people I do not usually work together with in my company" (Designer).

The next quote illustrates the dynamics that may occur when the design team is co-located. The informant points out that designers who initially was not a part of a discussion easily can join in and contribute to the interdisciplinary development of the project:

"I think it is very positive to be co-located… If I have a problem I need to discuss with another discipline. Traditionally, I would make a phone call. However, when we are co-located and talk together often also other consultants are drawn into the discussion make important contributions. This would not happen if just the two of us talked about this on the phone" (Designer).

Some of my informants also claimed that working co-located with BIM had a positive impact on what they referred to as the team spirit. Because of the co-location the actors spent quite some time together socializing; working, held meetings and had lunch breaks twice a week. In my interviews, the social aspects were a recurring theme. Two informants put it like this:

"We have spent much time together, it's nice and I think that it has helped us to create a good social atmosphere in the group" (Designer).

"Co-location has a positive effect on faster communication. In addition it can also prevent conflicts, and create a better atmosphere [in the design team]" (Designer).

5.2 Faster communication and shorter waiting periods

Several informants were particularly concerned about being co-located, which they perceived as leading to short lines of communication and better opportunities to make decisions quickly; "*decisions can be made right away on the spot"*, as one designer said. Especially the combination BIM and co-location opened for faster ways of communication. Using BIM co-located made it feasible to go quickly into the model together, to watch and discuss different scenarios. Some informants argued that such a combination meant that they could make clarifications and quick decisions, as compared with traditional projects that could take several days if the communication took place on telephone or email. This may imply that the design phase in full can be completed faster with this way of working. In the interviews, the informants told a great deal about faster communication and reduced waiting time. Below is a quote that summarizes an essential part of what I was told in the interviews:

"The greatest profit in my view is that we have access to everyone who know something about the project in less than a minute - often it takes only 10 seconds [to contact other members of the design team]. This makes things very efficient. In that sense, other projects can learn a lot" (Designer).

5.3 A challenging aspect: "professional loneliness"

Even though a number of positive sides of working co-located with BIM for the collaborative working were mentioned, some more difficult aspects came up in the interviews. Several informants told that being away from the workplace and then from their own professional environment could be challenging. This is due to the lack of co-workers or others with more or less the same educational background for discussing professional issues. Such an aspect can be denoted to as a kind of professional loneliness. One informant told about the professional loneliness in this way:

"You lose some of the contact with others in your profession. In my previous project, the whole group was co-located, it was better. It was an advantage. In this project I feel a bit 'lonely'. At my workplace I have a lot of colleagues to discuss with" (Designer).

Most of the processes discussed in this paper are group processes at the meso-level. However, professional loneliness primary concerns individual design team members at the micro-level (cf. figure 1).

6. Discussion

Prior research has pointed out that collaboration problems in construction processes are partly caused by industry characteristics. The industry is project based, meaning that construction projects most often consist of participants from several different companies working together for a limited time span (Jones and Lichtenstein 2005). The central question in this paper is then if the combination of BIM and Lean Construction can help to remedy this problem and thus lead to enhanced collaborative working among the design team?

My data suggest that this to some extent occurred. In particular, it turned out that the combination of BIM and co-location of the design team generated quite good results on the collaborative working. This is in accordance with the framework presented in section 2.1. Hence, the findings point to that BIM and Lean Construction influence each other positively in enhancing collaborative working. First and foremost, virtually all my informants were very satisfied with the use of BIM. Several informants told that BIM makes it easier to collaborate across disciplines and companies. The informants highlighted the opportunity to work on a common model, carry out clash controls, and the visualization possibilities as especially useful and important for strengthening the collaborative working. In addition, almost all informants stressed that the use of BIM in combination with co-location of the design team fostered fruitful climate of collaboration. Several informants also stated that communication is going faster under such conditions; the co-located team can quickly find good solutions while using BIM technology to visualize complex problems and potential solutions. These kind of situations opened up for making decisions “on the spot”, which was particularly advantageous. In addition, quite a few told some more about social aspects; when working closely together each week the member of the design team becomes more familiar with each other and that could result in a greater level of understanding for others professional perspectives. In other words, my findings point toward that such an approach helped to improve the inter-organizational and interdisciplinary collaboration, fostered faster communication and made improvements in waiting time, as well as it contributed to build understanding among the involved actors. As a whole, this contributed to enhance the collaborative working among the actors in the design team. Despite many positive experiences, some informants also expressed that co-location could lead to a form of professional loneliness. This happened as a result of missing colleagues with more or less the same competence to discuss professional issues when co-located.

However, the data also reveals that not all parts of Statsbygg’s contractual “BIM and Lean Construction-package” were successful in practice. This relates especially to the intended use of a Lean Construction inspired takt-time planning concept. In the findings I described that the building commissioner Statsbygg specified some specifications. However it was largely the responsibility of the design team itself to take care of the implementation. The empirical presentation and discussion in previous sections has shown that the informants consider that they succeed quite well with implementing BIM and working co-located, but not with takt-time planning. According to the informants from the design team, the lack of using the takt-time planning system could partly to be explained by fact that it was not further requested by Statsbygg during the design phase. In addition, the design team did not have any experience with such a system. The lack of demand combined with limited experience made it easy for the design team to take the presumably easiest path; they chose what they had done some months ago, namely BIM and co-location. This is not necessarily a bad choice. It implies that the design team applied a model they knew worked quite well and that they could further improve in this project. A drawback is that such a decision easily can lead to a kind of lock-in situation where old certainties are exploited rather than searching and exploring for new and perhaps more superior ways of working (March 1994). Because of the design team’s lack of experience, it would probably be favorable if Statsbygg as an actor with a lot of resources to a larger extent had been helping to facilitate the implementation process in this case. This can be seen in connection with another SamBIM case project where Statsbygg played a much more active role in the implementation process. In that project Statsbygg was a driving force in the implementation of BIM and various Lean Construction tools in the design phase. At the same time Statsbygg emphasized to involve the design team in decisions about BIM and Lean Construction (Bråthen and Moum 2015). Bråthen and Moum (2015) claim that Statsbygg’s active role combined with the involvement probably was essential for the successful implementation. As the analysis points out, BIM and co-location had a quite good effect on the collaborative work in the case studied. However, this positive effect could possibly be even better if the takt-time planning system had been adopted together with BIM and co-location as initially planned by Statsbygg. Earlier research such as

Sacks et al. (2010) emphasize that great advantages can be realized when several processes and tools are combined.

7. Conclusion

The various processes and tools that Statsbygg planned to test out in this construction project turned out quite differently in practice. The disparity in successfulness is probably partly due to that different elements being emphasized in varying degrees by Statsbygg in the implementation process. Put differently, elements which are given little or no attention in the implementation process are less likely to lead to good results. Due to no knowledge within the design team combined with little attention from Statsbygg in terms of takt-time planning, there was not created a necessary ownership and a common vision for the use of this planning system in the project. These shortcomings were probably significant for the less successful result of the takt-time planning system compared to the combination of BIM and co-location. This argument may also have a more practical implication for actors like Statsbygg who wants to take an active role in the development of the construction industry. To succeed with new working methods, the actual implementation and development process "on the ground" is just as important as formulating well considered and innovative contract specifications.

Despite this, it is important to be aware of the limitations of this case study. There are certainly some factors in this pilot case which distinguishes it from "the usual construction project". One factor is related to the fact that the design team knew each other quite well and had worked co-located with BIM in another Statsbygg project some months earlier. This "earlier experience factor" may have led to better results than usual since the constellation already knew each other and had partly adapted work principles. In addition, the findings in this paper are limited to a single case study. Further research from other contexts is thus needed to draw firm conclusions which could be applied to the construction industry at large. Despite the abovementioned limitations, it appears that BIM and co-location have a potential to impact positively on the collaborative work in the design phase of construction projects by linking actors closer together both technological and organizational. For that reason, the previously proposed conceptual framework finds support in the empirical evidence. Indeed, such a successful outcome requires a careful planning and implementation process.

Angelo Luigi Camillo Ciribini,
University of Brescia
(angelo.ciribini@unibs.it)

Abstract

The aim of this paper is to investigate different approaches adopted to define the content of a Building Information Model (BIM). In order to improve the effectiveness of the Built Asset during the whole life-cycle, the Construction Industry is moving towards a digital eco-system. Thus, the implementation of Data-Driven Projects based on Building Information Modeling is wide-spread and becomes more and more a mandatory requirement. The Building Information Modeling methodology is based on an Information Model that contains the updated and amended information related to the project, starting from Briefing and Conceptual Design. So to achieve a performing process, it is essential to provide any needed information at the right time. For this reason, several concepts related to the definition of data sets belonging to BIM, such as 'Level of Development' and 'Level of Detail', have been established. The main focus of this study is to provide an overview on this topic and to investigate possible different approaches. The study is based on both literature review and interviews. The findings indicate that there is not a univocal approach suitable to manage this issue, and numerous definitions and acronyms have been defined in different Countries, especially in US and in UK. However, it is possible to compare them and to find similarities. The findings can be used to gain an in-depth understanding on this topic, especially for experts who work with BIM in various Countries.

Keywords: Building Information Model, Level of Development, Level of Detail, Level of Definition, Level of Information.

1. Introduction

In order to achieve whole life-cycle effectiveness, the Construction Industry is moving towards a digital eco-system. The implementation of Data-Driven Projects based on Building Information Modeling is spreading and becoming more and more a mandatory requirement. Indeed, several Countries such as the UK, Germany, Spain and France are actively mandating governmental strategies, seeking to promote a Smart Construction Industry. The Building Information Modeling methodology is based on a Building Information Model (BIM) that virtually represents the design and project, and contains updated information (Eastman et al., 2011). In order to attain any expected outcomes, it is essential to provide needed information at the right time to the right person. For this reason, several concepts related to the definition of data within the BIM have been developed. Different data are needed for different purposes; thus, from the early beginnings it is important to clearly define the authorized uses and responsibilities. Authors themselves realized that nowadays there is not a clear understanding of these concepts and the literature does not provide enough findings. Thus, the focus of this paper is to provide an overview on this topic and to investigate possible approaches as well as similarities. Finally, a possible future scenario concerning the data management is discussed.

2. Methodology

First, in order to obtain information on the data management within Information Modeling, a literature review has been performed. The concept and application of this topic is still relatively new, thus, there are limited scientific existing studies. The literature review therefore does not include only academic publications, such as journal papers and books, but it incorporates also guidelines, specifications, protocols, standards and reports published by governments and other regulatory bodies, blogs and articles published in respected online newspapers. Different types of databases have been analysed: both scientific (e.g. *ScienceDirect*®) and non-scientific (e.g. *BuildingSMART*®) available online. The same keywords ('Building Information Modeling' and 'Building Information Model' associated to 'Level of Detail', Level of Development', 'LOD') have been used to find references. Sixty-two documents have been analysed, but only part of them were useful for the research work and are included in the reference list. Later, semi-structured interviews were carried out with five public agencies that delivered publish standards (in UK and US) as well as with their consultants. The interviewees were selected based on their role (e.g. BIM Managers) and experience in this topic to better understand how documents and tools, related the management of data within a BIM, are implemented as well as possible benefits and challenges. The interviews were conducted in person and they were recorded. Afterwards, in order to analyse data, responses were transcribed into statements where evidence was convergent.

3. An Overview on the Progression of Data-Driven Projects

This paragraph is based on literature review and it presents the principal initiatives to support information production and exchange within a BIM. At the end of the paragraph, Table 1 summarizes such initiatives and compares different definitions, acronyms and classifications.

3.1 The origin of 'LOD': from Information Levels to Level of Detail

Denmark has been one of the first Countries to define a classification for information within BIM (van Berlo et al., 2014). The *3D Working Method 2006* introduces seven (0-6) *Information Levels* to set the content of discipline models at a given time in the design process. The Information Level is a '*stage of information content and/or quantity*' and it is related to '*individual discipline models and building elements and/or geometrically limited building sections*' (BIPS, 2007). The seven levels describe a rising degree of detailing and correspond to the traditional construction phases, but they can be customized to allocate roles based on the nature of tasks (BIPS, 2007). The document suggests to use a table in order to clarify Information Levels for each phase and working practices (BIPS, 2007). Moreover, for each Information Level the document shows *Graphical representation*, *Alphanumeric representation*, *Objective*, *Parties/responsibilities*, *Content*, *Use*, *Degree of detailing* and *Classification* to be used (BIPS, 2007). It is possible to affirm that the Information Level is related to geometrical as well as non-geometrical data that different parties can rely on. This concept has been incorporated in the Australian CRC document in 2009, but Information Levels are associated with *Model Development phases* (0-6) and *Object data levels* linked to Level of Detail (A-E). The Level of Detail refers to '*detailed geometry and with additional or different information attached to the objects*' (CRC, 2009).

In 2004 the software company Vico Software started to work on a standard apt to facilitate the management of information within a BIM (Bedrick, 2008; Vico Software, 2015). Indeed, Vico developed the Model Progression Specification (MPS) defined as '*a language that owners, designers, and builders can use to define every element and task in the building construction process. It serves as a coordination point for information about the building, what is being modeled, and to what level of detail it is being modeled, estimated, and scheduled. It provides the efficient framework for the project stakeholders – a written checklist that matures from a very schematic level of detail to a high level of detail in terms of 3D geometry, cost, and time*' (Vico Software, 2015). Vico created a standard to manage BIM in an effective way, introducing the MPS concept as well as the 'Level of Detail'. The Level of Detail plays an important role within the MPS and is defined as '*the specificity required for a particular element at a particular stage of the project*' (Vico Software, 2015). Moreover, the '*level of detail for a BIM model must correspond to the needs of the modeler, the project engineer, and the estimators and schedulers. LOD identifies how much information is known about a model element at a given time. This "information richness" grows as the project comes closer to breaking ground*' (Vico Software, 2015). Thus, for Vico the 'Level of Detail' concept is associated to the reliability of information in a particular period of time and it also refers to a quantitative aspect that progressively increases. The acronym 'LOD' for the first time is used for 'Level of Detail'.

The company Webcor Builders teamed with Vico to further develop this concept, and later they brought it to the technology subcommittee of the American Institute of Architects (AIA) California Council's Integrated Project Delivery (IPD) Task Force (Bedrick, 2008; Vico Software, 2015). In 2008 Bedrick defined the Level of Detail as '*descriptions of the steps through which a BIM element can logically progress from the lowest level of conceptual approximation to the highest level of representational precision. It was determined that five levels, from* *conceptual through as-built, were sufficient to define the progression. However, to allow for future intermediate levels we named the levels 100 through 500. In essence, the levels are as follows: 100. Conceptual; 200. Approximate geometry; 300. Precise geometry; 400. Fabrication; 500. As-built*'. The definition is linked to a '*BIM element*' and not to the entire model. Bedrick (2008) also provided a definition of each level in a table and he reported some '*Authorized uses*' of the BIM. The Level of Detail can be used in two different ways: (1) to define phase outcomes and (2) to assign modeling tasks (Bedrick, 2008). In the first case, the Level of Detail of various elements must be defined because even if elements progress from one level to the next one, they can have different rates at the design develops (Bedrick, 2008). This concept is very important because it moves from the concept of scale in traditional design process where all elements are represented in a homogeneous way. Thus, it is clear that the requirement of a BIM at e.g. LOD 200 no longer makes sense. The second use, instead, deals with the ownership of the geometrical representation of elements (Bedrick, 2008). Indeed, the *Model Component Author (MCA)* is introduced as *'responsible for creating the 3-dimensional representation of the component, but not necessarily for other discipline-specific information linked to it'* (Bedrick, 2008). In this case, a separation between the geometrical representation of a component (3D geometry) and any data associated with it is clear. Thus, the MPS can track only who is in charge of the geometry creation and not who is responsible for the information, which usually is the most important part of a BIM.

3.2 The introduction of Level of Development

Later, the work performed by the AIA California Council's IPD Task Force was adopted by the AIA National Documents Committee to be developed (Bedrick, 2008). In 2008 the concept was incorporated in the *E202™–2008. Building Information Modeling Protocol Exhibit*[1] (AIA, 2008). The AIA evolved the notion into 'Level of Development' (Bedrick, 2013a). The AIA (2008) document does not contain any references to the Level of Detail and the acronym 'LOD' stands for Level of Development. The *E202™–2008* defines the protocols, expected LOD and Authorized Uses of the BIM for a specific project. Moreover, thanks to a Model Element Table, specific responsibility (Model Element Author/MEA) is assigned for the development of each Model Element to a defined LOD at each project phase (AIA, 2008). The Level of Development is defined as '*the level of completeness to which a Model Element is developed*' (AIA, 2008). The *E202™–2008* defines five progressively detailed levels (100, 200, 300, 400 and 500). Each subsequent LOD builds on the previous one and includes all previous characteristics (AIA, 2008). Moreover, for each level it gives a definition of the *Model Content Requirements* and it explains the *Authorized Uses* that can be customized (AIA, 2008). The LOD refers to the reliance on Model Elements; so, even if they could include more data than required, any user may rely only on the accuracy and completeness of the stated LOD (AIA, 2008). In the AIA (2008) document the MEA is responsible for both geometrical and non-graphical aspects of the Model Element and from LOD 200 to 500 also non-geometric data can be attached.

[1]Definitions from AIA Documents have been reproduced with permission of The American Institute of Architects, 1735 New York Avenue, NW Washington, DC 20006.

After the publication of *E202™–2008*, Vico continued to develop the MPS releasing version 2.0 in 2010 included 'Aspects' and 'Classes' concepts (Vico Software, 2015; Trimble Navigation, 2013). For each 'Classes' a *Target Level of Detail* can be defined (000, 050, 100, 200, 300, 400, 450, 500, 550, 600) (Vico Software, 2015). However, a clear definition of each Target Level of Detail is not available. In 2011 the latest version MPS 3.0 introduced different types of generic building elements called 'Primitives' (Vico Software, 2015; Trimble Navigation, 2013). Trimble Navigation (2013) developed a guide for each 'Primitives' showing Model 'Classes' with written requirements (mostly geometrical) and images. The guide (Trimble Navigation, 2013) does not provide any reference to suggested Level of Detail for each Model 'Classes'. The main focus of Vico is on 5D; for this reason the structure of MPS mainly supports effective cost and schedule evaluations rather than the overall process.

3.3 The use of LOD in several Guidelines and the introduction of 'Model Granularity' and 'Grade' definitions

In 2010, the Department of Veterans Affairs (2010) published 'The VA BIM Guide' that includes a spreadsheet, 'Object Element Matrix', to define BIM objects, properties, and attributes for each Level of Development (LoD). Both acronyms 'LoD' and 'LOD' are used and definitions of Level of Development are based on the *E202™–2008* (Department of VA, 2010). Later, the NATSPEC published the National BIM Guide (2011) including the *NATSPEC BIM Object/Element Matrix* based on the Department of Veterans Affairs matrix. In addition, the NYC DDC (2012) introduces the *Model Level of Development (LOD)* concept as '*level of detail to which a Model is developed and its minimum requirements. The Level of Development is accumulative and should progress from LOD 100 at Conceptual Design through LOD 400 at completion of Construction*'. However, it also '*describes through five categories, the completeness of elements in a Building Information Model. Completeness will range from geometric detail to element information*' (NYC DDC, 2012). There are some inconsistent aspects between the two definitions because the first refers to the '*Model*', while the second to '*elements*' of the BIM. In the appendix, there are Object requirements tables to set LOD from 100 to 400, however, the guideline presents also LOD 500; for this reason, Table 1 contains a (?). The DDC Level of Development has been developed in alignment with the *E202™–2008* and it introduces the *Model Granularity* concept as the '*representation of geometry needed to support specific BIM use*' (NYC DDC, 2012). It is associated to the '*level of detail needed*' that can '*vary by object and by model, and the BIM itself may not represent the exact design intent of real live elements*' (NYC DDC, 2012). Another US institution, the Pennsylvania State University (2012), has adopted the *E202™–2008* Level of Development standard for their projects, but it expanded the LOD 500 category (510, 520, 530, 540, 550) to more adequately meet their needs for operation and maintenance phases. Table 1 contains a start (*) under LOD 500 to remind that this level has been further developed.

In 2012, the US Army Corps of Engineers (USACE) released the BIM Minimum Modeling Matrix (M3), a spreadsheet for modeling requirements. It contains three levels of Development (LOD) from 100 to 300 (USACE, 2012) based on *E202™–2008*. Moreover, the *Element Grade (GRADE)* is added to the LOD concept because '*within each Level of Development, there is the potential to represent information in various formats. In practice, it has been proven that there* *are certain elements for which there is a greater benefit in providing 3-dimensional representation, while in others drafting or representation in the form of narratives is sufficient for a particular deliverable'* (USACE, 2012). The M3 contains two columns to specify the Grade (A, B, C, '+'); there is not a column for the MEA, but a *Primary Discipline* can be set.

In the UK, the AEC (UK) Initiative released for the first time a BIM Protocol in 2009 and in 2012, published version 2.1. It introduces the *Model Development Methodology* concept that is related to the Level of Detail, also called *Grade* (AEC (UK), 2012). Even if the protocol recognizes that the '*graphical appearance is completely independent to the metadata included in the object*', there is only a classification for geometrical aspects (*G0-G3*) (AEC (UK), 2012). This concept has been included in the first version of the AEC (CAN) BIM Protocol (2012) together with new acronyms ('LOD^{ev}' for Level of Development and 'LOD^{et}' for Level of Detail). However, the last version (2014) includes only the Level of Development (LOD) concept that is related to both Model Elements and Model.

In Netherland, even if the concept of Level of Development has been used, there has been a lot of confusion on the real meaning (van Berlo et al., 2014). Thus, seven *Information Levels* (0-6) have been created following the Danish standard (BIPS, 2007) together with a matrix, a practical guide and a project template (van Berlo et al., 2014). The practical guide contains the purposed use of *Information Levels* supported by pictures and use case examples (van Berlo et al., 2014). The project template is used as a spreadsheet that holds a demarcation of the project and for each section; responsibilities, status of that model, classification system and minimal Information Level can be defined (van Berlo et al., 2014). In this case, the Information Level could be assigned to the model or part of it, and not only to Model Elements.

3.4 The new version of AIA documents and the BIMForum LOD Specification

In 2013, the AIA published three new documents related to the management of a BIM that should be incorporated into an agreement between parties and used in conjunction: *E203™–2013*, *G201™–2013* and *G202™–2013*. In addition, the AIA published the *Guide, Instructions and Commentary to the 2013 AIA Digital Practice Documents*. According to the *E203™–2013*, the Level of Development (LOD) describes '*the minimum dimensional, spatial, quantitative, qualitative and, other data included in a Model Element to support Authorized Uses associated with such LOD*'. Indeed, the Level of Development of a given Model Element informs project participants about '*how developed the information is expected to be, and the extent to which that information can be relied upon, at a particular point in time in the development of the Model*' (AIA, 2013d). Thus, the main focus of the LOD concept is still related to the reliability of data within the BIM. The new document (AIA, 2013c) defines content of model elements as '*minimum*' and not '*specific*' requirements, as reported in the previous version (AIA, 2008). There are still five levels, however, instead of '*Model Content Requirements*' (AIA, 2008) the new version (AIA, 2013c) uses '*Model Element Content Requirements*'. Starting from LOD 200, each definition (AIA, 2013a) is divided in two parts: graphical and non-graphic representation. The definition is discussed for each LOD; instead, a general statement is used to define non-graphical information (AIA, 2013c). The structure of the Model Element Table (AIA, 2013c) is similar to the one already included in the previous document (AIA, 2008) with the exception of note sections that are added for each project milestone (AIA, 2013c). Moreover, the MEA is no longer seen as a modeler (AIA, 2008), but as a responsible party for the management and coordination of the development of elements (AIA, 2013a). For the first time, the *AIA Guide* (2013d) clearly explains the difference between Level of Detail and Level of Development making a comparison between the traditional approach and the BIM-based one, where there could be elements with high Level of Detail but very low Level of Development. The definitions of LOD in the AIA document (2013c) are a point of reference for other Countries such as France (Le Moniteur, 2014).

In 2011 a new group in the US, called BIMForum, started to work on a LOD Specification (BIMForum, 2013). In 2013, the *Level of Development Specification* was published including AIA's basic LOD definitions (2013c) for each building system and graphical examples of most of them (BIMForum, 2013). Definitions included in the *LOD Specification* (2013) were developed to address '*model element geometry*', taking into account three of the most common uses: quantity take-off, 3D coordination and 3D control and planning. The working group believed that by taking this approach, the interpretations would be complete enough to support other uses (BIMForum, 2013). Also in this case, the acronym LOD means Level of Development. The Specification should be used in conjunction with a project BIM Execution Plan, providing a '*means of defining models for specific information exchanges, milestones in a design work plan, and deliverables for specific functions*' (BIMForum, 2013). Also this document (BIMForum, 2013) provides a clear explanation on the difference between Level of Detail and Level of Development; the first can be considered as '*input to the element*', while the latter as '*reliable output*' (BIMForum, 2013). There are two main differences related to the LOD definitions between the Specification (BIMForum, 2013) and the *G202™–2013*. The first deals with the introduction of LOD 350 to enable coordination between disciplines (BIMForum, 2013). Only the *Guide* (AIA, 2013d) contains a reference to this new LOD (AIA, 20013, p. 60), even if it is not included in the *AIA Document G202™–2013*. The second difference is related to LOD 500 that has not been further defined and illustrated by the BIMForum working group (BIMForum, 2013). In 2014, a new version of the Specification was published adding new graphic illustrations in compliance with common building codes and at the end of October 2015 a new version was released with relevant updates (BIMForum, 2015). Indeed, for the first time non-graphical attributes were added and the Specification was divided in two parts: (1) Part A and (2) Part B (BIMForum, 2015). Part A, *Element Geometry*, basically defines required geometry and it is an extension of the previous version with a new appendix (BIMForum, 2015). Moreover, an interpretation of LOD definitions has been added for LOD 100, 200, 300, 350 and 400 (BIMForum, 2015). Part B, *Associated Attribute Information*, instead, is a Model Development Specification (MDS) spreadsheet that defines required attributes (numeric and/or textual) (BIMForum, 2015). Part B contains a Model Element Table where LOD, MEA and Notes can be defined for milestones (BIMForum, 2015). Moreover, there are Attributes Tables divided in three parts: attribute description, LOD profile and project-specific milestone (BIMForum, 2015). More attention should be paid while using this spreadsheet in order to create univocal information, because there is not an automatic correlation between the Model Element Table and Attributes Tables (e.g. to create consistent project-specific milestone). BIMForum Specifications have been a point of reference for contractual documents (e.g. ConsensusDocs©301 (2015)) as well as several guidelines and protocols (e.g. Massport (2015) and Canada (AEC (CAN), 2014)). The NATSPEC (2013) published a BIM Paper on the use of BIM and LOD to promote the adoption of the BIM Object Element Matrix for non-geometrical data and LOD Specification (BIMForum, 2013) for appropriated geometry. This document should be updated to include parametric requirements of the latest BIMForum Specification (2015). In addition, the document (NATSPEC, 2013) refers to the use of 'Grade' developed by USACE (2012).

3.5 The UK introduces new definitions and acronyms

In the UK new definitions and acronyms have been set. Indeed, the *PAS 1192-2:2013* does not include the Level of Development but it defines the Level of Definition as '*collective term used for and including "level of model detail" and the "level of information detail"*'. The Level of Model Detail (LOD) is '*the description of graphical content of models at each of the stages*' and the Level of Model Information (LOI) is '*the description of non-graphical content of models at each of the stages*' (BSI, 2013). *PAS 1192-2:2013* defines seven levels of model detail and information (1-7). Moreover, Figure 20 contains example pictures for each level and other information such as permitted uses, output and parametric information (BSI, 2013). The CIC BIM protocol (2013) introduces the Model Production and Delivery Table (MPDT), a key document that '*both allocates responsibility for preparation of the Models and identifies the Level of Detail ("LOD") that Models need to meet at the project stages or data drops stated in the table*'. However, there is no any reference to the LOI. In February 2014, the Technology Strategy Board decided to develop a free-to use digital BIM tool and since October 2015, the final version of the 'NBS BIM Toolkit' has been available. Its aim is to integrate the classification system with the Digital Plan of Work to control the presence of required data at each phase. Indeed, for each stage (0-7) of the RIBA Plan of Work, the Employer's Information Requirements (EIRs) can be defined including the Level of Definition of each element. Thanks to this tool, at each stage of each project, it is possible to define details, roles, tasks and deliverables. In addition, for each deliverable a LOD, a LOI and a responsible entity should be set. The tool changed the definitions from 'Level of Model Detail' to 'Level of Detail' and from 'Level of Model Information' to 'Level of Information' but the same acronyms are used. Finally, the tool can verify a BIM against defined requirements. This tool is the first example of a digital platform for the definition of data within a BIM, taking into account the entire life-cycle of built assets. Recently, the new version of the AEC (UK) was released (2015) including definitions from the *PAS 1192-2:2013*. The protocol contains a new classification of *Component Grade* to be conformed to the Level of Detail (1-6) (AEC (UK), 2015). The acronym LOD has been added and 'Grade' is used as synonym for Level of Detail. Finally, the CPIC (2013) document requires a *Responsibility matrix for information production* to define 'who models what (the BIM Author) and to what Level of Detail (LOD)' for specific *Model Authoring* and *Model Analysis*; together with a *Task Information Delivery Plan* (TIDP) and a *Master Information Delivery Plan* (MIDP).

Table 1: Comparison of different classifications related to the management of data in the BIM

Source	Name	Authorship	Definition	Level						
Denmark: BIPS	3D Working method	Parties/ Responsibility	Information Level	0	1	2	3	4	5	6
Australia: CRC	Object data levels	Responsibility	Level of Detail	-	*A*	*B*	*C*	-	*D*	*E*
Vico Software	Model Progression Specification	-	Target Level of Detail/ Level of Detail	-	*100*	*200*	*300*	-	*400*	*500*
US: Department of VA	BIM Object/Element Matrix	Model Element Author	Level of Development (LoD/LOD)	-	100	200	300	-	400	500
Australia: NATSPEC	NATSPEC BIM Object/Element Matrix (BOEM)	Model Element Author (MEA)	Level of Development (LOD)	-	100	200	300	-	400	500
US: NYC DDC	Object Requirements	-	-Model Level of Development/ Level of Development (LOD) -Model Granularity	-	100	200	300	-	400	500 (?)
US: Pennsylvania State University	BIM Information Exchange – Level of Detail Matrix	Model Element Author (MEA)	Level of Development (LOD)	-	100	200	300	-	400	*500* *
US: US Army Corps of Engineers	USACE BIM Minimum Modeling Matrix (M3)	-	-Level of Development (LOD) -(Element Grade/Grade (A, B, C, +))	-	100	200	300	-	-	-
Netherland	Matrix and Project Template	Aspect-model	Information Level	0	1	2	3	4	5	6
US: AIA *E203™–2013*	Model Element Table	Model Element Author (MEA)	Level of Development (LOD)	-	100	200	300	-	400	500
France: Le Monieur	-	-	Level of Development (LOD)	-	100	200	300	-	400	500
US: BIMForum 2015	LOD 2015 Element Attributes Tables	Model Element Author (MEA)	-Level of Development (LOD) -Level of Detail -Element Geometry -Associated Attribute Information	-	100	200	300	350	400	500
Canada: AEC (CAN) 2014	Information exchange worksheet or modelling matrix	Responsibility	Level of Development (LOD)	-	100	200	300	350	400	500
UK: PAS 1192-2:2013	-	-	-Level of model Definition -Level of model Detail (LOD) -Level of model Information (LOI)	1	2	3	4	5	6	7
UK: CIC	Model Production and Delivery Table (MPDT)	Model Originator	Level of Detail (LOD)	1	2	3	4	5	6	7
UK: NBS BIM Toolkit	NBS BIM Toolkit	Responsibility	-Level of Detail (LOD) -Level of Information (LOI)	1	2	3	4	5	6	7
UK: AEC (UK) 2015	-	-	-(Level of Definition) -(Level of Information (LOI)) -Grade/Level of Detail (LOD)	1	2	3	4	5	6	-

Finally, it is important to take into account that CityGML (2015) has developed five Levels of Detail (LOD 0-4) to define geometrical details and semantic precision (Tolmer et al., 2014) to link BIM with Geographic Information System (GIS) data (Kang and Hong, 2015).

4. Discussion and Future scenarios: from static assembly to dynamic entities

Nowadays, there is still confusion on how to manage the content of a BIM and definitions are differently interpreted. This lack of consistent understanding could be due to the presence of different definitions and acronyms in the industry that have changed during the years, vary from different Countries and, sometime, are inconsistent. For example, the 'Level of Detail' was originally associated to the reliability of both geometrical and non-geometrical data (BIPS, 2007), but recently it deals more with the level of geometrical attributes (e.g. BIM Forum, 2015; AIA, 2013c; BSI, 2013). The same acronym 'LOD' is used for both Level of Detail (e.g. BSI, 2013) and Level of Development (e.g. BIM Forum, 2015); similar concepts are differently called (such as 'Level of Information' (AEC (UK), 2015) and 'Associate Attribute Information' (BIM Forum, 2015)); and the Level of Development is associated both to elements (e.g. BIM Forum, 2015; AIA, 2013c) and the entire model (e.g. NYC DDC, 2012; Massport, 2015).

Usually, space programming and BIM authoring follow an elemental approach mirrored in the EIRs and BIM Execution Plans. However, thanks to the BIM Toolkit, the progressive maturity of the assemblies might be decoupled. The LOD Specification allows managing the different speed on the elemental basis, whilst the NBS BIM Toolkit makes it affordable on a sub-elemental degree, because LOD and LOI could be split and data might be misaligned. Such an assumption has to be felt as disruptive, because it implies that different players could concurrently manage shareable and accountable data upon the same element or assembly according to different progressions. Thus, in spite of pursuing the traditional BIM uses, the linear progression of the design stages is clearly hampered, because the original space programs could be troubled by the architectural digital sketches as far as general construction is concerned. For this reason, Drobnik and Riegas (2015) suggest to introduce a Level of Development (LOD) 0 as well as a negative one (e.g. LOD -100) due to the complexity of the iterative design process. Meanwhile, heterogeneous elements have to be handled within a Common Data Environment (BSI, 2013) or rather, within a digital eco-system merging hardware and software on the internet of buildings, infrastructures, grids and things. Unfortunately, such a stressing elemental perspective, where the design teams are asked for anticipating the progressions and are stimulated for optioneering the solutions, is additionally burdened by the behavioral and interactive design. The simulated users' and passengers' behaviors, as well as the simulated flows and motions, engender some spatial syntaxes and options which could be, on a real time basis, interactively checked and validated by means of immersive environments (CAVEs or portable devices). Indeed, dealing with game engines, more and more, the BIM will have to take into account not only *discrete* Level of Detail, but also *continuous* LOD (CLOD) (DigitalRune, 2013). Moreover, the validation plays a key rule for the success of Data-Driven Projects and Model Checking should be used to control the content of the BIM as discussed also by Hopper (2015). Today, the control of different Levels (e.g. of Detail, Information and Development) is still difficult and the NBS BIM Toolkit tries to fill this gap. However, more effort is needed to validate the information flow related not only to EIRs, but also to the Facility Management data. In addition, the pre-occupancy management requires the involvement of potential users within the early design stages, because more and more an intelligent clientship deals with a ‘to be’ servitized and sensored built asset. Therefore, a question is arising, stemming from the aforementioned remarks: could such a design process be consistent with the traditional elemental approach centered more on static (objectual) assembly rather than on dynamic (motional) entities?

5. Conclusions

This study indicates that there is not a univocal approach to define and manage the content of a BIM and several definitions and acronyms have been defined in different Countries, especially in US and UK. However, it is possible to compare them and find similarities. Results can be used to get an in-depth understanding on this topic, especially for experts who work with BIM in several Countries. Finally, the authors believe that in the future Model Checking should be included in the process and more flexibility is needed moving from static assembly to dynamic entities.

The Perceived Business Value of BIM: Results from an International Survey

Susanna Vass
Real Estate and Construction Management, KTH Royal Institute of Technology
susanna.vass@abe.kth.se

Abstract

Building Information Modelling (BIM) has emerged as an IT-based solution towards the construction industry's challenges. The expectations on BIM are high in both research and industry and there has been an increasing interest in evaluating the benefits and business values of BIM. Many of the reported benefits and business values in research have been the same or very similar. This suggests that there might exist certain categories of benefits of BIM and that the benefits also might interrelate with each other. However, weather this is the case has not been explored in previous research. The purpose of this study is to explore how the business value of BIM is perceived by exploring what categories of benefits of BIM there are and how these benefits interrelate with each other. Results from a large international survey on the perceived business value of BIM are analyzed. The findings show that there are two categories of benefits of BIM. The first is project progress related and relates to managing and minimizing project managerial issues. The second is project outcome related and relates to increasing efficiency and optimization. The interrelation of the benefits is also shown by which category of benefits they contribute to and by their relative importance in these categories. The findings have both theoretical and practical implications.

Keywords: Business value, BIM, project management, survey, factor analysis

1. Introduction

The construction industry is an important player in economies and societies throughout the world and significantly contributes to GDP and employment (e.g. Ortiz et al 2009). Is also an industry characterized by challenges in terms of low productivity (e.g. Teicholz et al 2001), slow adoption of new information technologies (e.g. Brandon et al 2005), low innovation (e.g. Styhre 2011) and negative impact on the environment (e.g. Ortiz et al 2009). Building Information Modelling (BIM) has by many proponents been suggested as an IT-based solution towards the industry's challenges (e.g. Succar 2009, Rezgui et al 2009, Crotty 2013). BIM has been described as "a set of interacting policies, processes and technologies generating a methodology to manage the essential building design and project data in digital format throughout the buildings life cycle" (Succar 2009). The high expectations on BIM can also be reflected in that there are currently many governmental BIM initiatives promoting the use and implementation of BIM (e.g. UK Cabinet Office 2011, Trafikanalys 2015).

In order to understand if the implementation of BIM meets the high expectations, the effects of the BIM implementation must be evaluated. Firms implementing BIM have also stated that a major challenge towards their adoption of BIM has been that that they themselves have not had sufficient time to evaluate the business value of BIM and experience a lack knowledge about the business value of BIM ((McGraw-Hill 2009, 2010) FMI and CMAA 2007). There has been much research aimed at evaluating and measuring the benefits and business values of BIM (Table 1). Many of the studies have come to similar conclusions about the effects of BIM and have tended to repeat the same benefits and business values of BIM (Table 1). Many of the benefits and business values are also similar to each other (Table 1) and are likely to interrelate in ways that previous research have not yet investigated. For example, a commonly reported benefit of BIM is cost reductions, which is likely to be impacted by and interrelate with other commonly reported benefits of BIM, such as earlier completion times or fewer errors. The similarity and repetitiveness of the many benefits and business values of BIM reported in previous research suggest that there might be certain categories of benefits of BIM and certain interrelations between the benefits. This issue that has however not been investigated in previous research. The purpose of this study is to explore how the business value of BIM is perceived by exploring what categories of benefits of BIM there are and how these benefits interrelate with each other. This is accomplished by analysing the results from a large international survey on the perceived business value of BIM through factor analysis.

2. Rationale for investing in BIM

An underlying assumption behind a firm's choice to make an investment, such as investing in new IT, can be described by the theory of the firm and transaction cost theory (Coase 1937). Firms decide to make an investment when the investment provides a return that that is greater than its initial investment costs (Coase 1937). The theory of the firm and transaction cost theory are based on the assumption of rationality in organizational decision making. Firms are assumed to make rational choices based on complete and perfect information and to make investments that maximize the profit of the investment. However, firms actually make decisions in uncertain and changing environments where the firms are left with an uncertainty and unpredictability about the future, where they do not have complete access to all the available information and where the information is often incomplete and imperfect (Coase 1937, Simon 1959, Simon 1991). These conditions limit the extent to which firms can make rational decisions and inhibit the seeking of maximization (Simon 1959, Simon 1991). The individuals of the firm also suffer from bounded rationality meaning that they are bounded and limited in their cognitive ability to analyse and process all the available information, to discern which of the incomplete and imperfect information that is of relevance for the decision making process and to make rational decision in complex and uncertain situations. These conditions results in that firms often decide to make an investment given that the investment yields a satisfying return rather than a maximizing one (Simon 1959, Simon 1991). Firms are described as being content with making decision that satisfy rather than maximize a target return. Thus, the decision-maker is a satisfier and one seeking a satisfactory solution rather than the optimal one (Simon 1959, Simon 1991).

The argument and rationale for making decisions to invest can be applied to construction firm's decisions to invest in BIM. Drawing on the theories in Coase (1937) and Simon (1959, 1991), firms make decisions to invest in BIM given that the investment in BIM yields a return that is satisfying enough. In order to evaluate weather the investment in BIM yields a satisfying return, the investment in BIM has to be evaluated and measured and the benefits and business values of BIM assessed. Research also shows that particularly in the constriction industry, managers often need to prove that the investment in new IT, and in particular BIM, will yield a certain return or satisfy a certain target before they receive the funds to invest in new systems and processes (e.g. Becerik-Gerber and Rice 2010, Marsh and Flanagan 2000). Therefore, the benefits and business values of BIM need to be evaluated.

3. Benefits and business values of BIM

There have been numerous studies that have attempted to evaluate and measure the benefits and business values of BIM (Table 1). The benefits of BIM have been studied from both qualitative and quantitative research approaches and by both researchers and industry actors (Table 2). A total of 23 peer-reviewed journal papers and 9 industry reports were analyzed in order to map the benefits and business values of BIM.

There were a total of 38 different benefits and business values of BIM identified in the literature review. The most common benefits of BIM in research include reduced errors, rework and changes (e.g. Becerik-Gerber and Rice 2010, Barlish and Sullivan 2012), faster completion times (e.g. Dawood and Sickka 2008, Hartmann and Fischer 2008), cost savings (e.g. Kam et al 2013, Suermann and Issa 2009, Haymaker and Fischer 2001), improved information management (e.g. Grilo and Jardim-Gonclaves 2010, Mäki and Kerosuo 2015), more accurate design (e.g. Demian and Walters 2014, Gilligan and Kunz 2007) and improved collaboration and collaboration among different disciplines and actors (e.g. Demain and Walters 2014, Zuppa et al 2009).

Table 1: Benefits and business values of BIM in research and industry reports

Benefits of BIM	*Frequency*	*Benefits of BIM*	*Frequency*
Less errors, rework & changes	*21*	*Fewer RFI*	*8*
More accurate design	*20*	*Less conflicts and disputes*	*8*
Improved information management	*18*	*Risk management*	*7*
Faster completion times	*17*	*Marketing new clients*	*6*
Reduced costs	*17*	*Improved simulations*	*6*
Higher quality	*16*	*Better decision*	*5*
Improved collaboration	*15*	*Client satisfaction*	*5*
Improved coordination	*13*	*Stakeholder engagement*	*5*
Improved communication	*13*	*Increased ROI*	*4*
More design alternatives	*11*	*More engaged staff*	*4*
Better estimations	*11*	*Improved team work*	*3*
Clash detections	*11*	*Reduces waste*	*3*
Improved life cycle management	*10*	*Code compliance*	*3*
Increased productivity	*10*	*Increased profitability*	*2*
Improved scheduling	*10*	*Creativity*	*2*
Increased safety	*9*	*Employment satisfaction*	*2*
On-site efficiencies	*9*	*Less administration costs*	*1*
Competitive advantage	*9*	*Faster bid preparation*	*1*
Higher efficiency	*8*	*Innovation*	*1*

4. Method

In order to explore what different categories of benefits of BIM there are and how these benefits interrelate with each other, the results from a large international web-based survey on the perceived benefits of BIM is analyzed through factor analysis. The survey was created based on a literature

[1] In Conference Proceedings

review of the benefits and business values of BIM in previous research (Table 1) and on in-depth semi structured interviews with nine experienced BIM representatives in the Swedish AEC industry from clients/owners, contractors and consultants about the perceived business values of BIM. The BIM representatives were selected by purposive sampling based on their experience of BIM, their current position, and their engagement in BIM communities.

The survey consisted of three parts. This paper addresses the second part of the survey where the respondents were asked questions about what benefits they had perceived from implementing BIM in a specific ongoing BIM project of their choice. Based on the literature review and interview study, 15 benefits of BIM were included in the survey (Table 3). The respondents were to assess to what extent they had perceived each of these 15 benefits of BIM as beneficial to their specific BIM project on a seven point Likert scale, where 1 equaled no perceived benefit and where 7 equaled a large perceievd benefit (see Table 3). The survey was addressed to and administrated to a group of BIM users in the AEC industry that were perceived to be knowledgeable and experienced in working with BIM - the members of the worldwide buildingSMART network (http://www.buildingsmart.org). The survey was administrated to the target respondents in three steps. In a first step, the target respondents were contacted via each buildingSMART regions contact person listed on the buildingSMART website. The contact person was asked to distribute the link to the web-based survey to their members in their respective chapters. One potential bias of contacting representatives of an organization to distribute the survey to their members is that the response rates are typically lower of this procedure when compared to distributing the survey directly the population of individuals of that organization (Baruch 1999). Therefore, in a second step, the individual members of the selected 12 buildingSMART chapters were contacted directly via email. In a third step, the members of the selected 12 chapters were also contacted via groups on LinkedIn.

The purpose of factor analysis is to reduce larger sets of data and variables into a smaller set of variables in order to identify if there are certain types or categories in which thee variables tend to group in (Kim and Mueller 1978, Stevens 2012, Thompson 2004). Factor analysis is suitable when there are many variables in a dataset and when these variables are suspected to group in certain types or categories (Kim and Mueller, 1978) (such as there are in the respondent's answers to the 15 benefits showed in Table 3). In factor analysis, the aim is to find the linear combination of the variables that achieves the maximum amount of variance. A first factor (category) is given by the linear combination of the original variables that accounts for the maximum possible variance. A second factor (category) then captures the information that was not captured by the first factor and is also uncorrelated with the first factor (Kim and Mueller 1978, Stevens 2012, Thompson 2004). Only those factors (categories) are retained that fulfill the Kaiser criterion. The Kaiser criterion stipulates that only those factors (categories) that have an eigenvalue > 1 can explain the variance and are thus retained as factors (Stevens 2012). Those components with eigenvalue less than 1 contribute little to explaining the variance and are thus not retained. The factors retained then represent different types or categories of the variables analyzed. The factor loading of each variable indicates which variables that belong to which factor (category). The variables that are retained in one factor are uncorrelated with the variables retained in another factor (Stevens 2012). In the next section, the results of the factor analysis and the interpretation of the results are presented.

5. Results

Of a total of 988 respondents contacted to answer the survey 234 responded, corresponding to a response rate of 23,7%. For web and email based surveys, response rates usually range around 20%-30% (Kaplowitz et al 2004, Baruch and Holtom 2008). In Table 3, the respondent's answers to the question about what benefits they had perceived from working with BIM on a seven point Likert scale are presented.

Table 3: The responses in the survey regarding the perceived benefits BIM

The perceived business value of BIM							
What benefits do you/did you expect from using BIM in the specific project?	*(1= no benefit, 7= very large benefit)*						
	1	*2*	*3*	*4*	*5*	*6*	*7*
Increased worksite safety	*22*	*21*	*23*	*37*	*41*	*22*	*20*
Improved coordination	*1*	*0*	*2*	*7*	*29*	*45*	*102*
Increased client satisfaction	*2*	*2*	*10*	*24*	*38*	*56*	*54*
Higher profits	*9*	*11*	*16*	*42*	*47*	*33*	*28*
Lower overall costs	*6*	*7*	*15*	*37*	*42*	*42*	*37*
Earlier completion times	*2*	*10*	*15*	*32*	*55*	*43*	*29*
Improved energy performance	*15*	*14*	*21*	*42*	*35*	*31*	*28*
Less modifications (e,g, errors, rework, changes)	*1*	*4*	*5*	*11*	*36*	*54*	*75*
Improved communication (e,g, fewer RFI)	*2*	*1*	*8*	*17*	*33*	*51*	*74*
Improved understanding of project purpose	*7*	*2*	*9*	*12*	*37*	*54*	*65*
Increased productivity	*2*	*2*	*10*	*25*	*51*	*47*	*49*
Higher quality of final product/service	*3*	*3*	*2*	*12*	*45*	*55*	*66*
New business (e,g, new clients/services)	*14*	*13*	*19*	*31*	*41*	*33*	*35*
Reduced conflicts	*2*	*4*	*3*	*18*	*44*	*55*	*60*
More accurate estimations (e,g, quantity take-offs)	*3*	*6*	*4*	*27*	*38*	*52*	*56*
Total number of responses	*92*	*102*	*165*	*378*	*617*	*679*	*785*

Factor analysis was performed on the 15 benefits in order to examine whether there were existed certain types or categories of benefits of BIM and to examine how the benefits interrelate with each other. The results from the factor analysis are shown in Table 4. Two factors, i.e. two categories of benefits of BIM, emerged (with eigenvalues >1). The first factor (first category of benefit of BIM) seemed to be more significant as it had an eigenvalue of 6.86 (compared to the eigenvalue of 1.14 of the second factor). The factor loadings in Table 4 show which variables (which of the 15 perceived benefits of BIM) that belong to each of the two factors (two categories). The larger the factor loading, the more relevant the variable is in explaining the factor (category). The benefits of the first category are uncorrelated with the benefits of the second category, and vice versa.

Table 4: Results from the factor analysis on the 15 perceived benefits of BIM

Factor analysis on the perceived benefits of working with BIM	*Eigenvalue Factor 1 6.86*	*Eigenvalue Factor 2 1.14*
	Factor loadings for Factor 1	*Factor loadings for Factor2*
Increased worksite safety	*0.31*	*0.49*
Improved coordination	*0.74*	*0.17*
Increased client satisfaction	*0.55*	*0.43*
Higher profits	*0.20*	*0.83*
Lower overall costs	*0.19*	*0.78*
Earlier completion times	*0.36*	*0.69*
Improved energy performance	*0.31*	*0.58*
Less modifications (e.g. errors, rework, changes)	*0.77*	*0.21*
Improved communication (e.g. fewer RFI)	*0.73*	*0.31*
Improved understanding of project purpose	*0.53*	*0.33*
Increased productivity	*0.50*	*0.62*
Higher quality of final product/service	*0.67*	*0.33*
New business (e.g. new clients/services)	*0.28*	*0.52*
Reduced conflicts	*0.73*	*0.25*
More accurate estimations (e.g. quantity take-offs)	*0.54*	*0.34*

From Table 4, the first factor (the first category of benefits of BIM) consists of the following benefits of BIM (in relative order):

1. Less modifications - fewer errors, rework, changes (largest factor loading 0.77)

2. Improved coordination (largest factor loading: 0.74)

3. Reduced conflicts (largest factor loading: 0.73)

4. Improved communication (largest factor loading: 0.73)

5. Higher quality of final product (largest factor loading: 0.67)

6. Increased client satisfaction (largest factor loading: 0.55)

7. More accurate estimations (largest factor loading: 0.54)

8. Improved understanding of project purpose (largest factor loading: 0.53)

From Table 4, the second factor (the second category of benefits of BIM) consists of the following benefits of BIM (in relative order):

1. Higher profits (largest factor loading: 0.83)

2. Lower overall costs (largest factor loading: 0.78)

3. Earlier completion times (largest factor loading: 0.69)

4. Increased productivity (largest factor loading: 0.62)

5. Improved energy performance (largest factor loading: 0.58)

6. New business - eg new clients (largest factor loading: 0.52)

7. Increased worksite safety (largest factor loading: 0.49)

The benefits in the first category of benefits of BIM seem to be related to managing and minimizing project managerial issues (i.e. project progress related). The benefits in the second category of benefits of BIM seem to be related to efficiency and optimization (i.e. project outcome related).

The factor analysis shows the relative importance of the benefits. In the first category of benefits of BIM that were project progress related (i.e. related to managing and minimizing project managerial issues), the benefit of less modifications (such as fewer errors, rework and changes) had the highest factor loading and was the most significant benefit in explaining the category. Then followed, in relative order, improved coordination, reduced conflicts, improve communication, higher quality of final product, increased client satisfaction, improved understanding of project purpose and more accurate estimations. In the second category of benefits of BIM that were project outcome related (i.e. related to efficiency and optimization), the benefit of higher profits had the highest factor loading and was the most significant benefit in explaining the category. Then followed, in relative order, lower overall costs, earlier completion times, increased productivity, improve energy performance, new business, and increased worksite safety.

6. Discussion

In the outset of this paper, it was argued that previous research has come to repeat the same benefits of BIM and/or very similar benefits of BIM. Many of these benefits were also claimed to likely interrelate with each other in ways that the previous have not explained. This study aimed to contribute to this gap. The theoretical contribution of the findings is an increased understanding of the different categories and types of benefits BIM and increased knowledge about the dimensions, variations and nuances of these benefits. Although the 15 benefits of BIM examined in this paper are not entirely new by themselves (se literature review of the benefits of BIM), the novelty of the findings lie in showing the perceptions among BIM users worldwide of the different types of benefits of BIM and the relative importance of these benefits. The novelty also lies in showing to what type of project management activities that these benefits contribute to. For example, BIM was found to contribute to both project progress related activities and project outcome related activities. The findings also contribute with increased understanding about where the impact of BIM seems to be largest. The impact of BIM was larger on the project progress related benefits (related to managing and minimizing project managerial issues), such as improved coordination and fewer conflicts, as indicated by the larger factor loading of 6.86. The findings thus have practical implications as well and contribute with increased knowledge about how BIM can be applied in the daily management of projects in order to create business value.

The main impact of BIM on project progress related activities (and not on project outcome related activities) contribute with a contrast to previous research on the benefits and business value of BIM. In reports, project outcome related effects, such as increased return on investment and other economic effects, were identified as the main contributors to the business value of BIM (e.g. McGraw-Hill 2009, 2010 and FMI and CMAA 2007). In research, the efficiency and optimization related benefits of BIM are often promoted (e.g Kam et al 2013, Barlish and Sullivan 2012, Suermann and Issa 2009, Manning and Messner 2008). However, the findings in this study showed that the project outcome related effects of BIM (e.g. higher profits, lower costs, earlier completion times and other economic effects), almost did not qualify as a category of benefits of BIM in the factor analysis. With an eigenvalue of only 1.14, it almost did not qualify according to the Kaiser criterion that implied an eigenvalue>1. Thus, for practitioners and policy makers investing or planning to invest in BIM, this study suggest that the major business value of BIM lies in the daily project managerial activities in improving project management such as improving coordination and communication among all project actors, reducing conflicts and disputes and minimizing the errors make by the partied involved in projects.

There are also limitations to this study. For example, targeting the members of the buildingSMART network in the survey implies that their responses are more likely to be biased and reflect a more optimistic view of BIM as opposed to a more neutral view of BIM. In analyzing the results, the author was aware of this sampling bias, yet there is a need for future studies that explore how the business value of BIM is perceived among different kinds of users of BIM who have both positive and neutral views of BIM and who are both experienced and less experienced in BIM. Suggestions for future research also include examining how to implement BIM in order to achieve the two categories of benefits of BIM. Future research could also examine how various project and profession specific factors positively or negatively contribute to how the benefits of BIM are perceived.

7. Conclusions

The expectations on BIM are high. There has been many studies examining the benefits and business values of BIM and many of the benefits and business values found have been the same or very similar. From a large international survey on the perceived business value of BIM, two types of categories of benefits of BIM were discovered. The most important category of benefits of BIM was project progress related and evolved around managing and minimizing project managerial issues. The findings had both theoretical and practical implications. They made a contrast to previous studies on the benefits and business values of BIM and showed where the impact of BIM on the day to day management of project was largest.

Abstract

Although Building Information Models (BIM) are declared as singular and correct expressions of buildings, these still are merely representations of designs and complete buildings. The digital model is not the building and is not the design. The digital model does allow visualisations of the buildings allowing stakeholders a new perception of the building through its 3D representation with the ability to choose viewpoints and to travel dynamically, but virtually, through the represented building. This paper explores what is perceived by clients and users in building information models using phenomenology. It emphasises the differences in perception and explores the meaning of this for design and construction. The work has involved interviews and experimental studies with users using models in different forms including static 3D, walk-throughs, 2D and room data sheets. The results show that different people view models with a difference in focus, intent and expectation. This makes models not have a singular and correct expression which means that the engagement with stakeholders still needs to be worked on and actively managed during design and construction. Digital tools then are not finished expressions but examples to be worked with dynamically and used to demonstrate differences proactively to help work on these different perceptions so that a higher performing building can be produced. The future of BIM to deliver value for both the client and users then lies in its ability to provide soft informated representations.

Keywords: Building-use, users, performance, perceptions, representations

1. Introduction

The application of digital technologies is developing rapidly and is now being adopted by the Architecture, Engineering and Construction (AEC) industry. In AEC, Building Information Modelling (BIM) is considered to be the new improvement solution for the construction industry as it allows the transition to better communication of information so that it can be shared and exchanged between different stakeholders (Drettakis *et al*., 2007). Bullinger *et al*., (2010) have pointed out that although the existence of such technology has supported the integration of multi-stakeholders, the involvement of the end-user has so far been limited; this is considered to be a major issue in current approaches. This is due to the promotion of BIM, more as a vehicle to drive productivity and efficiency for the construction industry, rather than to increase value in its outputs (Miettinen and Paavola, 2014). This is hiding the client and user perspectives on BIM and not utilising its potential for radical improvement.

The paper is part of a larger research study on enhancing building performance in buildings during design using BIM. The focus of this paper is on the way clients and users perceive their buildings in design and how BIM might be used to allow user input. The key point is the way that BIM represents the building to help this process. The issue of representations in building design is not new but the development of digital representations is explored. This presents theory of how BIM is perceived in a more phenomenological manner where it is the subjective experience that is crucial. This paper uses data from interviews with client teams and interviews and experimental studies with users. The latter, used BIM models in different forms including static 3D, walk-throughs, 2D plans and room data sheets. The results are explored both comparing the positions of client team and users and emphasising the user perceptions of BIM and their particular needs. The conclusion identifies how BIM needs to be modified to handle soft information to enable a more user involved design as well as greater understanding of user needs by the client team.

2. Literature Review

2.1 Design and Users

There has been a growing movement to make design more performance orientated (Kolarevic and Malkawi, 2005). This concept is embedded in Vitruvius's 1st century BC requirements for buildings of commodity, firmness and delight as well as the more detailed and quantitative design quality indicator (CIC 2003). The ratio 1:5:200 (1 = construction cost; 5 = maintenance and building operating costs; 200 = business operating costs) (Evans *et al*., 1998) focuses attention on the fact that the business operation of a building, costs several orders of magnitude more than its design and construction costs. Even though this ratio is challenged (Hughes *et al*., 2004), the idea that buildings should be designed to assist the work of the business is crucial. However, there is a gap between the expectations of design and how a building actually performs (Bordass et al., 2001). Jensen *et al*. (2011) and Sanoff, (2000), argue that involving users in the design and operation of the built environment taps into their knowledge and preferences and so creates spaces that work more effectively. Vischer's (2008) built environment theory identifies building use and user as critical design determinants of buildings. Sanoff (2000) has pointed out the difficulty of delivering this experience, due to, for example, the gap between the demands from the users and the design provided by the architects. Forty (2000) claims that building space appears to be a homogeneous concept, partly because architects consider space via representations (abstract space) rather than experiencing space by living it (lived space). However, Hensel et al. (2009) argue that bridging the gap between lived and abstract space requires another level of complexity, which is stopping any change from current practice. The solution to greater building performance requires user involvement and the handling of the complexity of technically undertaking this and including it in the process (Barratt and Stanley 1999). The sophistication and integration provided by BIM offers the opportunity to address this problem explicitly but this has only currently been researched in a limited manner.

2.2 BIM, Design and Users

Building Information Modelling provides a repository in a centralised data location for a full design model integrating structural, architectural, mechanical, electrical and plumbing (Kensek 2014). Its use in design has developed rapidly as a tool for composition, testing and construction delivery with full national government support. There is a complexity associated with the technical side of BIM within its software and hardware that limits the size of the model and their ability to represent all the information explicitly, and this remains a problem within the AEC industry (Johansson *et al*., 2015). This creates a challenge for the development of BIM for it to be useful for design rather than just as a repository for the end design (Whyte 2013). There has been little consideration of challenges associated with user involvement during the design stage (Kunz and Fischer, 2009). Kim *et al*. (2015) have reviewed user involvement during both pre and post construction showing how simulation tools can be employed by architects to understand the relationships between users and spaces. They concluded, however, that one of the current challenges is 'formalising' this involvement process, and there was a need for further inquiry into virtual design and construction tools. Khemlani (2008) reported that 3D and 4D simulation (e.g. Navisworks) have enhanced users' understanding of the design allowing a third person view to support users' in obtaining a sense of scale, but this navigation is relatively simplistic. There are some recent attempts to involve end-users and facility management; e.g, Lee and Ha (2013) have proposed a BIM-based tool for residential buildings to meet different customer needs which would allow them to be involved in decision-making. It was found that collaboration using the tool helped to meet customer needs for the optimum use of space. Shen et al. (2012) proposed a user activity simulation and evaluation method (UASEM) that aimed to enhance the user's visual experience of the built environment, but did not explore whether such simulations have an impact on improving design solutions. Oerter *et al*. (2014) pointed out that the use of avatars within the BIM environment can support by providing feedback to the users' and clients. None of these studies acknowledged the problems of perception of BIM environments.

2.3 Digital Representations and Users

The shift to a digital world in construction involves the creation and use of digital representations. According to Allen (2009), 'representations' are an entire intellectual and social construct that allows the imagination to construct new fragments of reality. Representations are the interface between the data and individuals as the representation conveys meaningfulness in a form to enable the data to become information. Thus, the design process requires a study of representations suitable for users to be integrated into the design process. Many theories of knowledge-use see mental activity working on representations thus it is possible to see representations as reality (Zhang and Norman, 1994) and for computing to work as this representation as reality. This has been opposed most vociferously by philosophers such as Dreyfus and Dreyfus (1986) who argue that thinking can occur without mental representations and Lorino *et al*., (2011) suggest that external representations have a communicative role in the activity itself. According to Hatfield (2003), the visual experience aims to represent a visual space in relation to the physical space. In the study of visual space, it is often assumed that the observer has an internal representation of surrounding physical space where he/she attempts to measure properties of the visual space to establish how well various properties of physical space are preserved in the mapping to visual space (Loomis *et al*., 1992). Ishii (2006) argues that people have an active interface with digital information with two components: control and representation. These can also be described as input and output where controls refer to what input users provide to manipulate information, while representations refer to what is perceived with the human senses.

There is a growing body of work on the phenomenology of digital environments. Turk (2001) explored how the product models in BIM are not as conceptually robust and material as they are presented and discussed. Meaningful work requires engagement with people with virtual worlds which has been reviewed by Farr et al (2012) who call for the greater use of the concept of embodiment to support user interaction.

3. Research Methodology

This research reported here sought to gain a richer understanding of users' and client's perceptions of BIM with a view to using it to improve user involvement in design. Given this problem of alternative perspectives, the research question was set to determine how BIM might help this situation during the design phase. This study adopted a critical realist position (Mingers 2000) and used qualitative methods. The study investigated three case study building projects at different times of their design, construction and operation phases all of which had used digital design. Two of the buildings were university teaching blocks and the third was a local authority office. Data were collected using semi-structured interviews with the client design teams and users and an experiment where 2D and 3D representations of the buildings were shown to users who at the same time answered questions in a questionnaire. Overall, the study involved four participants representing the client side, and nine participants representing the building users side.

It was recognised that the building users' perspective is best conceived phenomenologically. A phenomenological position focuses on the subjective experience of individuals thus is concerned with being, consciousness, and awareness (Seamon 2007). As such individuals experience a context, i.e. the building or work on a building, modified by their own beliefs about themselves and their well-being. Users' perceptions are created from the interaction of this 'being' with the physical and social environment provided by the building. In Christopher Alexander's terms this requires a wholeness of conception of a building (Seamon 2007). The study was phenomenological in that it asked questions into the thinking and feelings of the respondents. In particular, it asked questions about their lived experience which composed their perceptions. The phenomena in this research where firstly the way the design team and users saw buildings and secondly the way they interacted with the representations of the buildings as generated by BIM models. In the first phase, the study asked open ended questions about the nature of building performance in the buildings they engaged with for their work. It did this without defining performance in order to stimulate a subjective response. These responses were analysed in a form of discourse analysis to draw out the phenomenological perceptions. In the second phase, the study aimed to gain insights into the respondent's engagement with BIM. The case study was delivered using BIM, and thus the client was already familiar with the outputs of BIM whereas the users had to be briefed on what BIM was in order to gather meaningful data. A questionnaire was used to collect data from a group of users as they were shown 2D representations and 3D walkthroughs. However, the questions were again open-ended to allow the subjective impression to be captured. Different types of spaces within the building where shown and the participants had to write down what their perceptions were of the represented spaces. The data were analysed to explore how users could assist client teams during design.

4. Results and Findings

<u>Different Perspectives of Performance</u>

The first set of data was gathered during interviews with both the client team members and users about the buildings they were engaged with for their work. The data showed a number of characteristics that separated the building client team and the building users. Firstly the users' requirement for performance is concerned with how they could act in a space.

'I want an environment that allows me to perform a certain task or daily job comfortably' (PS u1, 2013)

"Building performance is gauged by how comfortable an environment is, so it provides the right temperature, access to fresh air and the right level of lighting" (WS u1, 2014)

"In terms of community space, it is any space that can take you completely out of work, so you can sit, relax, allow to do work, but most important that it makes you feel like offline" (WS u2, 2014)

The users' expressions do contain functional aspects like temperature, fresh air and lighting but these are actually subjective characteristics. However, they do refer to a way of being in the building environment that involves performance supported by an environment that is beyond their aware attention. The notion of 'right' is here self-defining giving it a very subjective character. This is emphasised more when users express problems of the space.

"Some problems we have now, some facilities don't fit within their spaces, and we don't necessarily have the right furniture" (PS u3, 2013)

"the furniture within the open spaces is too big, and some of the sockets do not sit down properly" (PS u3, 2013)

"It is important to consider the positioning of some facilities such as projectors, one of the major concerns I have now, is whether our current spaces provide the right environment to work or lecture within" (PS u3, 2013)

"I think as a team we don't really have enough space to perhaps store some of the things that we need, so when you work, you want things, you want the things around that you would normally need, so you want them to be accessible and to hand, but it becomes hard when things are pile up because you haven't got enough space" (WS u2, 2104)

This draws out how users see things particularly which get in their way and so come to their attention. This is both as an individual experience but also a social experience e.g. the need for a team to have things at hand to perform their task.

The building client team performs a role as well as using experience, both of which centre on the delivery of buildings.

"For XXXX building, we tend to drive specification to a need, so what we are really controlling over, not necessarily the legislative side, but more a specification side, so when you walk into room, you still feel like a university building" (PS c2, 2013)

'the space is defined by four sides with single or multiple accesses and designed to perform a particular function' (PS c3, 2013)

"For such a modern educational building, we had to ensure the balance between aesthetics, robustness and durability, thermal comfort, appropriate levels of natural and artificial light, energy usage, flexibility to suit changing uses, acoustic performance, capital budget and on-going maintenance costs, brand identity for the university," (PS c4, 2013)

"From my perspective, building performance is related to maintenance, energy and operation, and also all the systems within the building, so it's about maintaining all the level of understanding" (PS c1, 2013)

"I think that performance is about saving money, so what we are looking for is a cost effective building, value for money, deliver what we want for the occupants, and try and reduce as many issues as possible" (WS c1, 2014)

Clearly, this is much more technical view than the users' where problems exist in relation to what is deliverable and controllable against a functional brief and view of building operations.

BIM and Design

The second set of data gathered from the client team and users considered how BIM could help them see performance in design. The users' results are responses to 2D and 3D images. Although users are not proficient with building representations, these representations did provide the users with information. Firstly, in response to the static 2D images which were building plans:

Hard to get a real feel of size/ Doesn't show the scale (CS, u1, 2D, 2014)

Good for seeing layout of furniture/ Can't tell how many people will fit in room (CS u2, 2D 2014)

Certainly, the users did not feel that they could appreciate any spatial quality from the 2D representations. However, the 3D and dynamic images were also challenging:

Doesn't show colour/it might change feel if [colour] shown/ 3D gives better visualisation, but you can't visualise how much space your computer will take up (CS u4, 3D, 2014)

I hate revolving doors /Spaces don't look comfortable/ Desks look small – need to see what it looks like with the PC on it./ Cannot tell the space, ventilation, light (CS u2, 3D, 2014)

Probably stuffy, Small, Shared space / Unsure have ability to open windows /Room access is difficult to tell whether it is scan or lock or other (CS u1, 3D, 2014)

Users need details that are not important for the delivery model. The users were inclined to be upset by what they could not see. These details are needed as an experiential scaffolding to understand how the spaces can be used and how easily this is. The users did not trust the 3D representations; they thought they might be used to make it look attractive by using reduced size furniture or hide problems. This goes back to the organisational context within which the new building was being designed.

Turning to the client team, they saw 3D helping them with their role:

"The representations provided information on the areas within the building, and allowed me to gauge it against the brief" (CS, c1, 2014)

"The visualisation has provided accurate briefing on predicted space use by occupants" (CS, c2, 2014)

However, as these were experienced members of the client team, they did understand the inadequacies of BIM for delivering subjective performance information and how the users (or even non expert clients) were disappointed with the BIM representations; e.g.

"Spatially, it's quite restricted what you can do beyond an appreciation for the space itself, so one thing is that BIM in its current iteration lacks is that visual connectivity to the building itself so it gives you an understanding of the form and shape but not necessarily how it actually physically looks. So when people look at the model, they actually look quite disappointed expecting much more of a 3D representation of what's physically out there not just the shape and form." (CS, c2, 2014)

This was interesting as the client team promoted BIM strongly but from experience they also saw its current limitations for other than technical delivery.

5. Discussion

5.1 Users and Clients

The case study data explicitly shows that users and client teams perceive the buildings in different ways. The client team's perceptions are driven by their experience and need for building delivery producing a requirement to control and be explicit through measurement about aspects that they have specified. The users' perceptions are driven by their experience of working in buildings producing a need for comfort and ease of action. In a sense the two perspectives are connected but the users' perspective is describing a function in relation to their task. The client team has a more abstract view, not concerned with user tasks, but around measurable functions; but this abstraction can hide many problems of user tasks. This was shown by the client *(PS c2, 2013)* when demanding that certain specifications were delivered but these were not there for the occupants' needs. It is argued that the differences between the views of the client and users are not currently explored during design. Indeed, the client teams seemed somewhat reluctant to engage users, other than departmental managers, as they provided too complex or unspecifiable requirements, plus users gave often contradictory and unrealistic requirements which could be contrary to the client team's delivery objectives. The case studies also showed that clients have a corporate perspective on buildings as being expensive and their strategy is to cut this cost and make building-use more efficient; often referred to as space rationalisation. This was conducted purely at a space cost vs space area per activity level. Most often space per activity was set as a standard for that activity throughout the building even making savings by explicitly reducing this standard globally by say 10%. Client design teams do not investigate the business performance of space and how this might enhance work or how their designs might impede work. The idea that such decision-making might cost money from ineffective business operations was not in any way acknowledged. The users' perspective (e.g. *(PS u1 2013)* and *(WB u2 2014)*), had a focus upon the use of spaces in terms of how they operated as facilities and whether they provided comfort; thus, performance for users is much more from their individual perspective and not from some general or standardised basis.

5.2 Perceptions on digital representations

Not surprisingly given their drivers for buildings, the client team and users also perceived the digital representations (2D and 3D) presented to them differently. Looking at the client's side *(e.g. CS c1, 2014)* their perception of the representations is directly associated with the brief they had formed at the design stage. Some of the representations supported the quantitative aspects, such as area and occupancy level. Others were used as a reference to aid them in visualising aspects within the 3D representations such as furniture type, access to services (e.g. electricity sockets) and lighting (e.g. *CS c2, 2014*); which do support predicting how the space is can be utilised by the occupants. However, the client team use the visualisations and the completeness of the model to satisfy them about the successful delivery of the building.

The case was different from the users' perspective, as each representation triggered a number of concerns. They struggled to use the representations to experience the spaces. According to Oliva *et al*. (2010: 108) "we often acquire information about our surroundings by moving our head and eyes, getting at each instant a different snapshot or view of the world". The users try to use both their past experience as well as the representations to make sense of what they saw. Their concerns related to both operational and usability aspects but also the inadequacy of getting a feeling for the space. For instance, the user *(CS u1, 3D, 2014)* had concerns about space accessibility and whether windows could be opened. We argue that the gap between client and users is phenomenological where the client's concern focuses on the tangible aspects of the built environment whilst the users engage with intangibles that directly influence their experience.

5.3 New Interactions with BIM

The inquiry then into whether BIM can support the use of user experience in design is problematic. In this study a pragmatic approach was adopted to see what could be seen from the BIM models. Whilst acknowledging that virtual environments have been used as a collaborative design tools (e.g. Iorio *et al*., 2011), which allow information exchanging and sharing; these do not acknowledge the differing information requirements from the client's and users' perspectives. The current immersive virtual environments, which allow a sense of presence (e.g. Heydarian et al 2015), do not recognise how such environments can support the users' input into the design. The visualisation tends to focus on objects (e.g. Heydarian et al 2015) as this is easily provided by a virtual world that people experience in games. The difficulty of distinguishing a gaming virtual world and an understanding of the experience of a real physical world then becomes critical. The IT world is obsessed by creating an apparent simulated reality even when this is not possible. The evolution of virtual reality applications has focused on the interface provided to visualise objects rather than what information is needed to design user productive space.

Current visualisation does not allow people to feel a space merely showing a connection of detail. This detail is all that is necessary for computer games where the gaming aspect, e.g. the action hero killing elves, is set within a context. In the building design world, it is the context and our engagement with it that is the critical aspect not the detailed representation of the objects. In fact, it may be that, because perception is phenomenological, simple representations that are engaged with interactively and dynamically, may be more successful. Such a change in outlook for digital representations requires a change in aspect and intent. The intent has to be about inducing feeling and experience and the aspect has to be more holistic. The idea that the interaction is metaphorical rather than simulated reality (Dade-Robertson 2012) and the phenomenological aspects (Murray 2000) needs to be explored in greater detail. Future interaction with BIM would require further constructive approaches where lived experience is informing the digital experience, which potentially can support producing more informative representations. This needs to be undertaken within a metaphorical informating environment involving a social situation, an interactive process and a dynamic enquiry.

6. Conclusions

Given that there is much evidence that buildings do not meet user needs (Bordass et al, 2001) methods are required to address this. The advent of BIM provides the opportunity to engage users more in design and so to deliver buildings that perform better. This paper has adopted a phenomenological position on the use of BIM. Using a study of client team and user views of BIM, it established that they have different needs and different perceptions of building performance and BIM. For the client the performance is described by functional and quantitative aspects that can be controlled for building delivery. However, for the user, the performance is experiential and so is not containable by functional terms or aesthetic considerations. This phenomenological aspect has not been acknowledged and certainly does not feature in the current BIM debate. There is an assumption in BIM promotion that visual representations are all that is required to accommodate experience where this paper demonstrated that this is not the case. Although gaming worlds are experiential they have not been created for this application and engage people at a superficial level.

The evidence suggests that it is not virtual realism that is needed as regards experiential engagement; it is a user interactive process with a range of information that can elicit experiential understanding. Some of this may be quantitative or visualisations but other representations and interactive enquiry are needed. The paper suggests that BIM needs to support much softer information and this will be more metaphorical, interactive and developmental placed within a social situation of design. This also means that it is not possible to automate such activities and work is needed on the processes of design not just the product. The future of BIM then to deliver value for both the client and users lies in its ability to provide soft informated representations.

Abstract

Building information modelling (BIM), which involves the use of computer-generated n-dimensional (n-D) models to manage and integrate information in different phases of a building's life cycle, has rapidly evolved over the past decade. Yet there is still limited use of BIM in the Hong Kong construction industry, especially in building services engineering (BSE) which covers various disciplines such as electrical, air-conditioning, fire services, and plumbing and drainage. In order to explore how to achieve wider adoption of BIM in BSE, a study was commenced. Through an extensive search and review of relevant literature in the initial stage of the study, benefits of and barriers to implementation of BIM in building projects were identified. With reference to the characteristics of design, construction, operation and maintenance works, analyses were made to ascertain the applicability of the benefits and barriers in different building lifecycle phases. The findings will be used for designing a questionnaire for a focus group meeting that will be conducted in the next stage. Reported in this article include the outcomes of the above works and the tasks ahead.

Keywords: Barriers, benefits, building information modelling, building services engineering, construction industry

1. Introduction

In the 21st century, advanced information technology (IT) has rapidly changed the work processes of almost every industry. In the construction industry, one of the most significant IT developments has been the proliferation of the Building Information Modelling (BIM) technology. BIM is an IT-enabled approach that involves development and use of computer-generated n-dimensional (n-D) models to manage and integrate the essential building design with project data in different phases of a building's life cycle.

Recently, the global construction industry has entered a new era where adoption of state-of-the-art BIM has begun. More and more governments and public authorities have even set up a scheduled roadmap for full adoption of BIM. Though the Hong Kong government, for example, has decided to promote BIM implementation, there are only a few BIM-enabled construction projects. Whilst the Hong Kong Housing Authority has intended to implement BIM in all public housing projects from tendering stage in 2015, whether and when the best potential of BIM could be realized are yet to be seen.

Although the topic of BIM has been widely studied, very few studies are focused on the use of BIM in building services engineering (BSE), which covers various disciplines such as electrical, air-conditioning, fire services, and plumbing and drainage. As such, a study was commenced to explore how to achieve wider adoption of BIM in BSE.

2. Literature Review

2.1 BIM and Buildings

The concept of BIM has been in existence for a long time (Xiao and Noble, 2014). The first notion of virtual buildings came about in the 1970's (Eastman et al., 2011) and it did not came to the forefront of thinking until the term 'Building Information Modelling' was used as the title of a white paper by Autodesk in 2003, where the acronym "BIM" was also introduced. However, to define BIM is problematic as no single definition of BIM seems to exist. According to NIBS (2007), BIM is considered as "*a digital representation of physical and functional characteristics of a facility creating a shared knowledge resource for information about it forming a reliable basis for decisions during its life cycle, from its earliest conception to demolition*". Gu and London (2010) had the same idea. They considered that BIM is an IT approach that enables the management of digital building information in different project phases in the Architecture, Engineering, Construction and Operation (AECO) industry.

BIM can be defined with more inclusive definition. Eastman et al., (2011) defines BIM as "*a verb or adjective phrase to describe tools, processes, and technologies that are facilitated by digital machine-readable documentation about a building, its performance, its planning, its construction, and later its operation*". It is important to note that BIM is far more than a simple transition of 2D objects to n-D modelling offered by software vendors but manages graphical components and attributes of building information, allowing computer-aided generation of drawings and reports, design evaluation, project scheduling clash detection and resource organization from project design till building operation (Chan, 2014; Smith and Tardiff, 2009). BIM applications connect all parties such as architects, contractors, surveyors and owners to work together on a common information system (Eastman et al., 2011). This allows all parties to share information with each other and increase the confidence and consistency among them.

Today, BIM has been used in different stages of construction projects - from conceptual design phase to operation and maintenance phase. Many BIM studies have been conducted by academics, professional groups and software vendors (Autodesk, 2010; Bryde et al., 2013; Lu et al., 2014; McGraw Hill, 2014; Popov et al., 2010; Zhang et al., 2013). One group of these studies documents the use of BIM on specific successful project cases so as to demonstrate where BIM should be applied in building projects (Bryde et al., 2013; Hanna et al., 2014). A number of other studies, focussing on the software development of visualization and coordination at design stage, simulate improvements in future construction work for avoiding redundant work or demolitions caused by design changes or errors (Popov et al., 2010; Lu et al., 2014).

2.2 BIM and Building Services Engineering

Building services engineers are mainly responsible for design, installation, operation and maintenance of mechanical, electrical and plumbing systems required for the safe, comfortable and environmentally friendly use of buildings. Nevertheless, the BSE sector is considered to be one of the riskiest sector in the construction industry because it is a follow-up trade - its involvement in a project's construction sequence hinges on other critical trades, such as architecture and structural engineering (Hanna et al., 2013).

The rising interest of BIM in the BSE sector can be seen by referring to the potential benefits it can bring to the consultants and contractors for controlling change, increase in productivity and better coordination during the design and construction of buildings. Studies found that 10-30% conflicts can be resolved by using BIM prior to the construction stage (Eastman et al., 2011). Additionally, an approximate 2% cost saving and 3% time saving were attributed to the use of BIM (Korman et al., 2008).

The existing research on the use of BIM in the BSE sector is limited. Previous studies concentrated on the coordination practices and they tried to find out, for instance, which software was popular (Hanna et al., 2014; Korman et al., 2008; Yung et al., 2014). On the other side, some studies provided insight into the use and value of BIM. Simonian et al. (2009) found that the electrical contractors are able to expand their services with BIM implementation. The adoption of BIM could also enhance the delivery and value of the contractor's expertise; streamline workflow; improve communication with clients, consultants and contractors; broaden the services they offer to clients; and increase the revenue per employee.

A number of reports and papers have also been published to provide insight into the use of BIM and recommend improvements to BIM practices in the mechanical and electrical construction industries (Azhar and Cochran, 2009; Azhar et al., 2008). Whilst such research found that the advent of BIM in the industries can contribute to significant cost and time savings and quality improvements, several barriers to BIM adoption were also identified, including the lack of BIM knowledge and technological experience, software compatibility issues and high initial investment costs.

Hanna and his colleagues highlighted the state of BIM practice in the US and Canadian mechanical and electrical industries (Boktor et al., 2014; Hanna et al., 2013; 2014). The study results indicated that there was a significant increase in the use of BIM in electrical contracting when compared to the previous results obtained in 2008 and 2009. It was found that the use of BIM in the electrical construction industry has helped productivity and profitability; however, electrical contractors are still struggling to overcome the challenges of BIM implementation (Hanna et al., 2014).

The above parts show that the existing literature of BIM focused mainly on the benefits, barriers and implementation framework of BIM in the construction industry in general. Potential benefits and barriers which are specific to BIM implementation in the BSE sector are not entirely clear. Therefore, as reported in the following, a review of the relevant literature was made to identify the applicable benefits and barriers in relation to the use of BIM for BSE.

3. Benefits of Implementation of BIM for BSE

After an extensive literature review, it was found that a significant volume of studies agree that BIM adoption can bring along multiple benefits to the AECO industry. These benefits, as listed in Table 1, are applicable to the BSE sector.

Table 1: Benefits of Implementation of BIM for BSE

Benefits	*Justification*
(a) Better cost management	· *BIM can be used to check for structural, architectural and building services clashes so as to reduce the cost spent on rework and requirement changes (Bryde et al., 2013; Construction Industry Council, 2014).*
(b) Better time management	· *By using the integrated BIM model to visualize, explore and analyze the impact of changes, the project stakeholders can have better monitoring to the change in scope and progress of the whole project (Construction Industry Council, 2014; Guo et al., 2014; Hanna et al., 2013; Hanna et al., 2014; McGraw Hill Construction, 2014)*
(c) *Better quality control*	· *As a project moves into the construction phase, the depth of information contained within the n-D BIM model improves the contractor's ability to understand the design details and resolve problems (Bryde et al., 2013).*
(d) *Better risk management*	· *BIM increases the surety of investment and decision-making by improving visualization with respect to clarity, confidence and risk management (Bryde et al., 2013; Construction Industry Council, 2014).*
(e) *Better safety management*	· *BIM assists with the development of a method statement and enhances the understanding of construction safety issues that may arise (Construction Industry Council, 2014; McGraw Hill Construction, 2014).*
(f) *Better security*	· *BIM can assist the owners to better plan for security control during construction through early identification of the adequacy of relevant*

Benefits	*Justification*
	equipment provided in the construction site (Construction Industry Council, 2014).
(g) *Better project management*	· *BIM systems having model production enables the construction sequence to be simulated prior to construction, which also facilitates activity programming for project management (Bryde et al., 2013; Construction Industry Council, 2014; Hanna et al., 2013; Hanna et al., 2014).*
(h) *Better decision making*	· *Visual representations of BIM can help to enhance project stakeholders to understand the design details, resolve problems and aid decision-making (Construction Industry Council, 2014).*
(i) *Better visualization of design and construction process*	· *BIM shows what different options look like, not only upon completion but before and during the works. Its visualization capacity can help project participants to better understand the design and construction process (Boktor et al., 2014; Chan, 2014; Guo et al., 2014; Hanna et al., 2013; Hanna et al., 2014).*
(j) *Better design and drawing*	· *Using BIM in the design phase can help to ensure consistency among a project's many plans and drawings and monitor changes easily throughout the design process (Chan, 2014; Construction Industry Council, 2014; Hanna et al., 2013; Hanna et al., 2014).*
(k) *Better assembly of data and information*	· *With consistent and standardized exchange of information, BIM can reduce the information lost during handover from designer to contractor (British Standards Institution, 2010; Construction Industry Council, 2014).*
(l) *Improved quantity take off and tendering*	· *When BIM is correctly aligned with the method of measurements, the programme can generate the necessary quantity of materials for measurement purpose (Boktor et al., 2014; British Standards Institution, 2010).*
(m) *Improved construction workflow and method*	· *BIM provides previews of the site planning and construction works, which facilitates the enhancement of construction sequence and method (Construction Industry Council, 2014; McGraw Hill Construction, 2014).*
(n) *Improved interdisciplinary communication, coordination and engagement*	· *BIM enables significant improvements in inter-disciplinary coordination and communication through the use of consistent and standardized information (Construction Industry Council, 2014; McGraw Hill Construction, 2014).*
(o) *Enhanced the value of different discipline*	· *BIM help the professionals to execute labour intensive work (e.g. CAD drafting, quantity measurement), thereby freeing professionals to focus on value-added work and activities (Construction Industry Council, 2014).*
(p) *Better lifecycle asset management and performance*	· *An accurate BIM model captures the requirements, design, construction and operational information etc. facilities management of the building. Through more detailed asset and life cycle planning, lifecycle costs are better understood and performance is more predictable (BIM Task Group, 2013; Boktor et al., 2014; Construction Industry Council, 2014).*
(q) *Earlier occupancy*	· *By utilizing BIM, the efficiency of construction can be improved and hence earlier use of the building can be achieved (ASHARE, 2009; Construction Industry Council, 2014).*
(r) *Improved environmental performance and promote sustainability*	· *The full 3D energy consumption analysis can be performed by the BIM model and simulation programme with a short lead time (ASHARE, 2009; BIM Task Group, 2013; British Standards Institution, 2010; Construction Industry Council, 2014).*
(s) *Improved productivity and*	· *As a clearer link between design decisions and cost implications are developed through BIM adoption, clients are able to attain better*

Benefits		*Justification*	
	business outcomes		*productivity and business outcomes for the company (Construction Industry Council, 2014; McGraw Hill Construction, 2014).*
(t)	*Better customer service*	·	*By improving communication and understanding of the clients' needs for the project at the at the planning and design stage, BIM can help the construction professionals and contractors to provide better service to the client (Construction Industry Council, 2014).*
(u)	*Improved stakeholder and public engagement*	·	*BIM improves a project team's ability to present the specifics of a design and their intentions to stakeholders and the public. Proposals can be better understood by the public through accurate visualizations (Chan, 2014; Construction Industry Council, 2014).*
(v)	*Provision of a forward thinking platform*	·	*BIM "pre-builds" a project, allowing problems to be addressed as and when found throughout the design process (Construction Industry Council, 2014).*

With the above-identified potential benefits, it is considered that BIM implementation can provide a number of major benefits to the BS engineers in managing the time, cost and quality of a construction project from the design till the operation and maintenance stage (Table 2). With BIM, BSE data and information are more easily shared, value-added and integrated into the architect design model at any point in time. BS engineers do not have to wait until the completion of architectural design concept to proceed with their work. Digital BSE product data can assist BS engineers in providing more accurate cost estimation and management in the design and construction stage, with lifecycle costs more predictable in the subsequent operation and maintenance stage. Quick and versatile simulation functions of BIM software also help to achieve better production quality of BSE.

In addition, BIM can provide benefits in the design stage - facilitating aesthetic considerations, design decision, system function and performance and quality control by the BS engineers. With BIM, BS engineers are able to detect any clash between building services and building structure, which means mistakes are identified before work commences on site. The BIM visualization can also help the BS engineers to quickly analyse and compare several design alternatives, conducive to quality control in later stages.

Other than its benefits to the design stage, BIM application is also beneficial to the construction, and operation and maintenance stages for it can enhance sequencing and installation consideration, accessibility, sustainability, occupancy, safety requirements, data assembly, interdisciplinary cooperation and engagement for the BSE sector. Using BIM enables clash detection and hence early resolution of conflicts in the design stage. Thus, the schedule of BSE activities can be accurately prepared. When BSE coordination work starts, different professionals in the BSE team can rely on BIM models when they need specific information, instead of searching information from different engineers in the traditional manner. Safety analysis can also be conducted by using simulation tools to check for safety and health issues in the planning of BSE works.

Table 2: Benefits of Implementation of BIM for BSE in different building lifecycle phases

Benefits	*Design*	*Construction*	*Operation and Maintenance*
(a) *Better cost management*	*X*	*X*	*X*
(b) *Better time management*	*X*	*X*	*X*
(c) *Better quality control*	*X*	*X*	*X*
(d) *Better risk management*	*X*	*X*	*X*
(e) *Better safety management*		*X*	*X*
(f) *Better security**	*X*	*X*	*X*
(g) *Better project management*	*X*	*X*	*X*
(h) *Better decision making*	*X*	*X*	
(i) *Better visualization of design and construction process*	*X*	*X*	
(j) *Better design and drawing*	*X*		
(k) *Better assembly of data and information*	*X*	*X*	
(l) *Improve quantity take-off and tendering***	*X*	*X*	
(m) *Improve construction workflow and method*		*X*	
(n) *Improvements in interdisciplinary communication, coordination and engagement*	*X*	*X*	*X*
(o) *Enhanced the value of different disciplines*	*X*	*X*	*X*
(p) *Better lifecycle asset management and performance*			*X*
(q) *Earlier occupancy*		*X*	*X*
(r) *Improved environmental performance and promote sustainability*		*X*	*X*
(s) *Improved productivity and business outcomes*	*X*	*X*	*X*
(t) *Better customer service*	*X*	*X*	*X*
(u) *Improve stakeholder and public engagement*	*X*	*X*	*X*
(v) *Creation of a forward thinking platform*	*X*	*X*	

*The benefit of better security is controversial (CIBSE, 2015). ** Whether quantity take-off is involved in the design or construction stage depends on the procurement method.

4. Barriers to Implementation of BIM for BSE

Although many benefits can be gained by the implementation of BIM, the pace of its adoption for BSE is much slower than anticipated. This may be because BSE companies and practitioners are struggling to overcome the barriers to BIM implementation. Such challenges are summarized in Table 3.

Table 3: Barriers to Implementation of BIM for BSE

Barriers	*Justification*
(a) *IT infrastructure and software related problem*	· *There is lack of a common standard and protocol for data interoperability and data management of which BIM models cannot be efficiently shared between different disciplines (BIM Task Group, 2013; Construction Industry Council, 2014; RICS, 2011).*
(b) *Project participants related issues*	· *Project participants may not appreciate the value of collaboration among different parties working on the same project throughout its duration (Boktor et al., 2014; Construction Industry Council, 2014; RICS, 2011).*
(c) *Lack of client demand*	· *Adopting BIM incurs the client to pay more professional fees to the design professionals. Private clients will demand BIM in their project design and construction when they realized the benefits of BIM (Chan, 2014; RICS, 2011).*
(d) *Lack of training or education*	· *Although there is a wide range of BIM short courses offering in the market, the quality of these BIM courses varies considerably as no clear BIM guidelines are available for institutions to follow (RICS, 2011).*
(e) *Lack of studies to quantify the value of BIM*	· *There is a lack of local studies to quantify the exact local benefits and value of BIM, which also affects the industry to adopt BIM (Burcin and Kensek, 2010).*
(f) *Lack of government support*	· *Government support is strongly related to the ambitious of BIM implementation in the construction industry (Chan, 2011; RICS, 2011).*
(g) *Lack of legal standards or specification to cope with BIM adoption*	· *There is a lack of relevant contract terms and legal standards that reflect the changes in data ownership, confidential information, risk allocation, and procurement practices that will be affected by the adoption of BIM (BIM Task Group, 2013; Chan, 2014; Construction Industry Council, 2014; RICS, 2011).*
(h) *Lack of new or amended form of contract*	· *Prior to BIM adoption, there is a need to review existing contract provisions as to ensure the responsibilities and risks among contracting parties can be properly reflected (Chan, 2014; Construction Industry Council, 2014; RICS, 2011).*
(i) *Widespread of mistakes and errors produced*	· *BIM's integrated concept blurs the accuracy and control of data entered into the model of which an error will be propagated among stakeholders if a mistake is produced (Chan, 2014).*
(j) *Timing issues*	· *Most construction projects have a tight design schedule and intensive construction period in terms of return on investment philosophy. However, design consultants cannot avoid the uncertainty of design changes according to clients' requests. This not only increases the difficulties for design consultants to reduce time on project documentation, but may also contribute to delay in construction phase. The delay in construction may also impede the BIM utilities (BIM Task Group, 2013).*
(k) *Investment and costing issues*	· *Investment of BIM is strongly related to high level management commitments as adopting BIM incurs initial investment costs related to management and administrative processes, including staff time, hardware, software and training (Azhar and Cochran, 2009; Construction Industry Council, 2014; Hanna et al.,2013; Hanna et al., 2014).*
(l) *Too new and complicated for use*	· *Adopting BIM is difficult for certain amount of design professionals as they are educated and trained in the conventional 2D CAD environment and do not know much about BIM (Azhar and Cochran, 2009; Chan, 2014).*
(m) *No opportunity to use*	· *In the construction industry, due to the tight design schedule and intensive construction period, design and construction companies normally will not consider the adoption of BIM in the project until it is required by the clients or owners. Thus, without the requirement of the client, there is no opportunity for BIM to be used by the construction professionals (Azhar and Cochran, 2009).*

The barriers to implementation of BIM for BSE can be categorized into different categories (Lai and Yik, 2006): knowledge, finance, motivation, information and timing (Table 4). The knowledge category refers to the limiting factors related to lack of familiarity and understanding of the relevant software and contractual requirements for BIM adoption. When moving to adopt BIM, new requirements are needed to ensure effective interoperability and information exchange. However, the traditional training for BS engineers may not facilitate them to readily pick up new BIM technology and requirements. The absence of standard BIM contract documents in protecting the BSE information also prevents BS engineers from adopting BIM in the construction project. The financial category is about money-related limiting factors and the motivation category is about lack of support from different parties. The BSE sector consists of many small companies which have trouble to afford high initial investment to purchase the needed BIM software. With insufficient number of case studies showing the potential financial benefit of BIM, the BSE sector does not show much interest in investing towards the change in technology. The information category refers to the supporting cases and technology limiting factors. Timing issues affect the opportunity of using BIM in the BSE sector.

Table 4: Categories of Barriers to Implementation of BIM for BSE

Barriers	*Knowledge*	*Financial*	*Motivation*	*Information*	*Time*
(a) IT infrastructure and software related problem	*X*	*X*		*X*	
(b) Project participants related issues	*X*		*X*	*X*	*X*

5. Conclusion and Future Work

Although it has been widely believed that BIM is an advanced technology that improves the performance and productivity of building projects, there has been a relatively slow uptake of BIM in the Hong Kong construction industry, especially in the BSE sector. This paper has identified the possible benefits and barriers for implementing BIM in BSE. It is clear from the above findings that BIM can help to enhance productivity, profitability and project performance in terms of time, cost and quality in various building lifecycle phases. On the other hand, BIM is still in an evolving process and there are many barriers to its implementation.

The findings provide a solid basis for designing a questionnaire for use in a focus group meeting to be held in the next stage. In order to obtain as many useful findings as possible from a focus group discussion, careful selection of the group members who are experienced and representative in the field is necessary (Berg, 2009; Fern, 2001; Hesse-Biber and Leavy, 2004). The meeting, during which opinions of BSE related experts will be solicited, will validate the applicability of the above benefits and barriers to BSE.

Abstract

The deployment of Building Information Modelling (BIM) on construction sites has been slower than many anticipated and has lagged behind BIM adoption by design teams. The greater social and organisational complexities surrounding the on-site construction process suggest that BIM implementation faces multiple challenges. However, today's information technologies also offer opportunities for improvements in overcoming some of the barriers to construction process integration and efficiency.

The socio-technical environment has changed considerably over the past five years - smartphone use has become ubiquitous, tablet computers have become familiar and widespread as have wireless technologies, cloud computing, social media, and mobile data. Thus the current context for BIM implementation is quite different in terms of hardware, software, users and their expertise and expectations to what it was in 2010. In contrast, the research publication cycle is relatively slower and much of our accumulated knowledge and understanding of the construction site context vis-a-vis BIM as represented in the academic literature dates back to an earlier time.

This paper reports a survey of Estonian construction managers' opinions regarding BIM use on site obtained through semi-structured interviews. The survey found that BIM use on Estonian construction sites has been largely experimental to date and that most construction managers have little or no experience of it. Clear steps towards BIM implementation are not generally apparent and individual needs and priorities for BIM differ markedly. It is recommended that specific, problem-based interventions would contribute to BIM adoption.

Keywords: BIM, construction innovation, construction sites, Estonia, site managers

1. Introduction

The adoption of IT on construction sites has historically been slower than expected and the implementation of Building Information Modelling or Building Information Management (BIM) on sites remains limited with information exchange on most sites still in 2D and often paper-based (Davies and Harty, 2013; Dib *et al.* 2013; Cao *et al.* 2015). While initial efforts to develop BIM tools concentrated more on design and pre-construction planning (Sacks *et al.* 2010), an increasingly wide range of applications to support the construction phase has since become available (Ding *et al.* 2015; Karan and Irizarry, 2015; Matthews *et al.* 2015). Although BIM use is reported to be widespread in the design phase (McGraw Hill Construction, 2010), it is yet to become standard practice even in countries which are relatively advanced in BIM adoption terms (NBS, 2013). Merschbrock and Figueres-Munoz (2015) noted that current BIM practice in design still relies on local 'work-arounds' to overcome obstacles in implementation. Given the greater diversity of firms and personnel engaged in the construction phase, it is unsurprising that the application of BIM tools in support of construction management has been problematic (Hartmann *et al.* 2012).

In terms of enabling the adoption of BIM on sites, recent research has questioned the effectiveness of top-down impositions of BIM technology and new ways of working to accommodate the new technology (Hartmann *et al.* 2012). In addition, Davies and Harty (2013) draw attention to the dichotomy between firm- and project-level innovations in the adoption of BIM on sites. Miettinen and Paavola (2014) note the importance of the social and human conditions for the implementation of new technology.

Despite Estonia's relatively well-developed IT sector (in terms of e-government, cyber security, widespread use of digital signatures, etc.) and the considerable movement and interaction of construction personnel (particularly subcontractors) between Estonia and Scandinavia in what is increasingly a regional construction market, BIM adoption on Estonian construction sites appears to be lagging well behind that in the Scandinavian countries. In the World Economic Forum's Global Information Technology Report 2014, Estonia ranked overall 21st in the world but this hides a far more complicated picture. It ranked relatively higher in terms of government usage (12th) than individual usage (17th) with business usage being ranked lower (28th). The lowest ranking it received was in terms of the affordability of IT (61st) (WEF, 2014). Although government has actively and successfully promoted IT development in some areas this has not been the case with regard to construction and, to date, there has not been a coordinated effort by government to impose or promote the use of BIM in public construction projects.

This paper describes an initial investigation to gain a clearer understanding of the current state of BIM adoption on Estonian construction sites and an appreciation of the current attitudes and opinions of construction managers in relation to BIM. It is intended to provide a basis for further research efforts aimed at enabling BIM adoption in the construction process. Section 2 of this paper describes the research methodology adopted for this initial study. The results of the investigation are presented in Section 3, and these are further analysed and discussed in Section 4. Conclusions including recommendations for further research follow in Section 5.

2. Research methodology

The lack of progress to date with BIM adoption on Estonian construction sites and the intention to design future research studies aimed at enabling BIM use on sites suggested the need for an initial study to gain a better understanding of the current situation regarding BIM adoption on sites. To ensure as rich an understanding of the context as possible while attempting to limit the imposition of the researchers' own notions of the situation but still allowing for comparison between responses, a qualitative approach of semi-structured interviews was adopted for the study. The construction managers responsible for construction site operations were considered the most appropriate and convenient stakeholders to interview since they were directly affected by the adoption of BIM, were central to any BIM implementation initiative and had an overview of all the issues involved.

The interview questions were divided into three main groups:

1. IT use on construction sites currently and in the future – the current situation, what and who determines IT use, expectations, needs, barriers/challenges;
2. Modes of communication and collaboration between the on-site management and the various other parties to enable the construction process;
3. BIM – what the term means to each interviewee, their experience with BIM to date and the steps being taken towards adopting it on sites.

Particular attention was paid to ensuring that different personal definitions of BIM would not limit the scope of the information obtained from respondents yet, at the same time, it was intended to discover what these personal definitions of BIM were. For this reason, the term BIM was avoided until the end of the interview and the earlier questions referred to all 'IT solutions' and all forms of 'communication and collaboration'.

From the research of Davies and Harty (2013), it was acknowledged that the firm versus project dichotomy may have an important bearing on BIM adoption on sites and, therefore, both Site Managers and Project Managers (who are less site-focused) were included as interviewees. The sample of interviewees selected comprised one Project Manager and one Site Manager from each of six firms – three of the largest general contractors in Estonia (with annual turnovers approaching or exceeding 1 billion euros) and three medium-sized construction firms. This arrangement allowed for the possibility of drawing comparisons of both Project Managers versus Site Managers as well as large versus medium firms. Small construction firms were considered to be outside the scope of this study as their working arrangements and the issues they faced with regard to BIM would not be typical to general contractors.

The interviews were carried out individually by 3 different researchers according to a common set of open-ended questions which corresponded to the 3 main question groups in the list above. All the interviews were conducted in Estonian language. The interviews were audio recorded and the audio recording was later transcribed. The content of each of the transcripts was then analysed.

3. Results

Eleven interviews were conducted during July and August 2015. The interviewees comprised one Site Manager and one Project Manager from each of five construction firms but only one Site Manager from a sixth construction firm.

Table 1: Summary of prevalent responses from the interviewees

Higher Level Categories	*Nodes most referenced by interviewees*	*Number of Interviewees*
Current IT use on construction sites	*E-mail*	*11*
	Project server	*6*
	AutoCAD (in 2D)	*6*
	Dropbox	*6*
Project specificity of IT use	*IT use depends on project complexity*	*5*
	IT use doesn't depend on the project	*5*
Current needs for additional IT	*Clash detection*	*4*
	Avoiding mistakes	*3*
Which party determines IT use?	*Client*	*9*
	Main contractor	*6*
Current barriers / problems / challenges	*Knowledge of subcontractors' personnel*	*7*
	Hardware constraints	*3*
Positive trends / reducing barriers	*None - problems will remain the same*	*3*
Expected current and future benefits from IT use	*More accurate information*	*5*
	Improved time planning	*5*
	Better visualization	*5*
Modes of communication / collaboration	*[Responses are shown separately in Table 2]*	
What does the term 'BIM' mean to interviewees (in the construction context)	*3D model*	*6*
	Coordination through the building lifecycle	*4*
Interviewee's experience with BIM	*Little or no experience*	*7*
	Some, limited experience	*3*
Expectations for BIM in the future	*More complete information*	*3*
Steps currently being taken by firms towards BIM adoption	*Training of personnel*	*2*
	Setting up new systems and standards	*2*
	Hiring new (BIM) personnel/experts	*2*
	Non-specific (small) steps	*2*

An initial system of classification for analysing the contents of the interview transcripts was set up on the basis of the interview questions. This classification system comprised 12 higher level categories (refer to Table 1 above). Under each of these higher level categories, an initial set of 'nodes' was generated based on the anticipated responses to the questions. The transcripts were then analysed and evidence in support of each node was identified and referenced to the appropriate node. Additional nodes were added as necessary to accommodate the full range of responses given by the interviewees. In this way a refined list of nodes was generated and all interview responses within the complete set of transcripts were represented in terms of their references mapped to this list of nodes. Table 1 (above) summarises the nodes which were referenced by the highest numbers of interviewees under each higher level category with the exception of the higher level category: 'Modes of communication and collaboration' which is separately summarised in Table 2 (below).

Table 2: Current modes of communication and collaboration on construction sites

Communication / collaboration modes	*Proportion of interviewees referencing these responses*				
Between:	*On-site and off-site managers (contractor)*	*Within the on-site team (contractor)*	*Contractor and designers*	*Contractor and sub-contractors*	*Contractor and client*
Face-to face (informal)	*91%*	*82%*	*18%*	*73%*	*9%*
Regular meetings	*36%*	*36%*	*18%*	*55%*	*82%*
Telephone	*64%*	*45%*	*73%*	*64%*	*36%*
E-mail	*73%*	*73%*	*100%*	*73%*	*55%*
Online collaboration	*0%*	*0%*	*9%*	*0%*	*0%*
Shared file server	*9%*	*18%*	*0%*	*0%*	*0%*

4. Further analysis and discussion of results

In addition to the compilation of the total number of interviewees referencing each identified response node and the total number of references from the transcripts associated with each node, the results were further analysed in terms of whether the responses from Project Managers differed substantially from those of Site Managers and also whether the responses from interviewees from the larger construction firms were substantially different to those from medium-sized firms. The findings from these analyses are reported below according to each of the 12 higher level categories listed in Table 1 above.

4.1 Current use of IT on Estonian construction sites

As shown in Table 1, the use of e-mail was, unsurprisingly, reported by all respondents. The importance of e-mail to Site Managers and Project Managers is difficult to overstate as, in their words: *"e-mails are automatically archived and are equivalent to signed documents in law"* and because *"e-mails leave a mark of the conversation"*.

Just over half of the interviewees reported use of 2D AutoCAD, and file sharing systems (either a project server or Dropbox) while 4 out of 11 referred to the use of 3D models and only 2 interviewees mentioned the use of software for viewing these (both referring to Tekla BIMsight).

The use of project servers was reported by 6 of the interviewees. All 6 of these were from large construction firms and this was the main reported difference in IT use between large and medium-sized firms. A second difference between large and medium-sized firms appeared to be greater use of 3D (virtual building) models by the larger firms (reported by 50% of large firm interviewees) compared to their use being reported by only 1 of the 5 interviewees from medium-sized firms.

A slight difference between the Site Managers' and Project Managers' reported IT use seemed to reflect a more technical, hands-on role of the Site Managers in that more Site Managers reported the use of AutoCAD, 3D models and Tekla BIMsight than did Project Managers.

4.2 Project specificity of IT

Interviewees' opinions differed markedly on whether project characteristics affected IT use (Table 1). The view that IT use is not dependent on the project was held by similar proportions of Project Managers (40%) as Site Managers (50%) as well as large firm representatives (50%) and medium-sized firm representatives (40%). For those interviewees who suggested that IT use was indeed project specific, project *complexity* was the most commonly cited project characteristic determining IT use but project *budget*, project *size* and project *manager* were also mentioned as determinants. In the words of one Project Manager: *"the budget determines everything"*.

4.3 Current needs for additional IT solutions

As shown in Table 1, the most popular suggestions for current needs which could be satisfied through IT solutions were clash detection and avoiding mistakes. Both of these suggestions were supported more by the medium-sized firm representatives (60% and 60% respectively) than by their large firm counterparts (17% and 0%). Two interviewees from large firms who reported that 3D models were in use did not indicate clash detection as a current need. However, it is unclear from the data whether this was because clash detection was already being used or that they didn't consider it a current priority or neither of these and it simply wasn't mentioned during the interview.

Both clash detection and avoiding mistakes as well as other suggestions appeared to reflect the Project Manager / Site Manager role differentiation to some extent in that Site Managers tended to offer more specific and technical suggestions (clash detection, combined 3D model and time schedule, documentation of changes, easier and faster quantity take-offs, visualization tool, construction model) whereas Project Managers offered more general suggestions (project bank, single system for communication and file sharing).

4.4 Which party (client, designers, contractor) determines IT use

The majority of interviewees (82%) considered that the client determines what IT solutions are used on construction sites. This was a view held equally by Project Managers and Site Managers and by large and medium-sized firm representatives. From the interview context, it is clear that the interviewees were referring here to the use of new and innovative IT solutions such as those associated with BIM rather than to standard, ubiquitous IT applications such as e-mail. The notion that the client should require BIM in order for it to be used suggests an assumption that BIM use would be a burden on the contractor rather than an opportunity for efficiency gains. These sentiments were variously echoed in the interviews: *"I haven't heard of someone asking for BIM to be used [on site]"; "the client doesn't know what BIM is and therefore doesn't ask for it"; "there are projects, where the private client is quite sophisticated and price isn't the only important thing anymore"; "the [BIM] software, to be honest, slowed down the work".*

However, this was not the only perspective nor a necessarily exclusive one, as 55% of interviewees also indicated that the contractors themselves determined IT use on sites.

Only two interviewees suggested a role for the designers in determining IT use on sites. But the role of designers appears complex - whereas one interviewee noted that the designers have helped to encourage BIM use on site: *"the 3D constructive model was probably made out of the good will of the designer"* another implied that their actions might be impeding progress in this area: *"as a rule, many designers use BIM but then they convert their models to AutoCAD and changes can't be made. The 3D model isn't sent to us."*

4.5 Current barriers / problems / challenges for IT use

Although the actual question avoided using the term 'BIM' and so referred to the adoption of any new IT solutions, it appears to have been generally understood by the interviewees that it referred to barriers to the adoption of BIM-related innovations.

The problem most widely cited by interviewees (64%) was the knowledge and capabilities of subcontractors' personnel: *"The men themselves must be able to use it."; "On site, it largely depends on the subcontractors who actually do the work... I would waste a lot of my time making it clear to them."*; "*A lot of subcontractors have not yet reached to the level of [proficiently using] AutoCAD"*; *"The biggest barrier are the project managers of subcontractors, who do not see the big picture".*

This challenge was referred to by similarly high proportions of Project Managers and Site Managers, and by representatives of both large and medium-sized firms. It was the single most highly referenced response node in the entire analysis with interviewees making a total of 23 references to this issue.

'Hardware constraints' was the second most cited challenge (by 3 interviewees) with knowledge / capabilities of main contractors' personnel (*"but also we ourselves are unable to* *use these models, so it is difficult to order things which we don't know nor can we check"*), software constraints, financial constraints and a perceived older generation resistance to new technology each being referenced by two interviewees. In addition, the following further barriers were identified (by only 1 interviewee in each case): creates additional work, clients' (un)willingness to pay for them, the current education system, time constraints, no single standard / protocol for IT/BIM use, insufficient support from IT personnel, details in BIM model differ from the real world, insufficient information in the BIM models, not cost effective on small projects.

4.6 Positive trends that are serving to reduce barriers to IT use

The most cited response was pessimistic – that there are none and problems will remain (3 interviewees) - as one put it: *"There will always be problems, as people are involved"*. Less cited but more positive suggestions included increased interest in BIM and improved computer literacy (both cited by 2 interviewees) and experience (cited by 1). *"When people get experienced and use gets more effective and quicker, then [BIM] certainly will get used"*.

No direct mention was made of improved and more available software or of new and improved hardware being positive trends.

4.7 Expectations of current and future benefits from IT use

A considerable list of potential benefits was suggested by the interviewees, these can be summarised as being the expected consequences of more accurate and complete information being available quicker and in a format which makes it easier to understand and, particularly, to visualize. As shown in Table 1, the three most highly cited of these benefits were more accurate information, improved time planning and visualization (each cited by 5 interviewees). A difference in the number of Project Managers (1 in each case) and Site Managers (4 in each case) citing these can be observed and this is likely to once again reflect the greater engagement that the site managers appear to have with the technical details of the projects. In most cases of expectations put forward, Site Managers make up the majority of or are the only interviewees who referenced them. The notable exception to this was the response: 'more efficient communication' which was cited by 2 Project Managers and no Site Managers.

4.8 Current modes of communication / collaboration between the different parties on- and off-site

In analysing the reported modes of communication and collaboration, it is convenient to consider three groups (refer to Table 2 above): those engaged in the works (the contractor's team and the subcontractors/suppliers), the designers, and the client. From the results obtained, it appears that communications between Project Managers / Site Managers and each of these groups are distinct.

Between Project Managers / Site Managers and those engaged in the works, the primary mode of interaction is informal, face-to-face meetings (presumably on the site) – *"People tend to meet face-to-face very regularly"*. This form of communication was particularly dominant among Site Managers – all of whom reported such informal meetings with the contractor's off-site personnel, with the on-site team and with the subcontractors and suppliers. The next most important modes of communication among this group were e-mail and then telephone.

Between the interviewees and designers, the primary mode of communication is e-mail (100% of interviewees) and then telephone (73% of interviewees). The automatic archiving and the accountability associated with e-mail noted in subsection 4.1 above are undoubtedly important here and one interviewee gave insight into why telephone communication remains a popular alternative: *"a phone call ensures a response"*.

Communications between Project Managers / Site Managers and the client are mainly within regular scheduled meetings (82% of interviewees) with e-mail (55%) and telephone (36%) also having some significance.

The modes of communication differ somewhat between Project Managers and Site Managers and this appears to relate to their separate roles. Project Managers (100%) reporting higher telephone use than Site Managers (50%) in communicating with designers. Conversely, Site Managers (83%) reported higher telephone use than Project Managers (40%) in communicating with subcontractors and suppliers.

Notably, there was only one reference to collaboration with designers. This took the form of online, asynchronous collaboration. There were no reports of online collaboration in real time or any formal collaboration through colocation (Big Room, knot-working, or similar).

4.9 What the term 'BIM' means to the interviewees

As anticipated, the term BIM carried different meanings for the interviewees and some of them acknowledged this: *"Everyone thinks that they understand BIM the same way, but in reality it is not the case"*. A slight majority (6 interviewees) noted the 3D model component and 4 interviewees' responses reflected the notion of 'coordination through the building lifecycle'. Beyond these were a further 12 suggestions offered by only one or two interviewees as follows: collaborative design, joint management of the construction process, communication platform/tool, 4D model (3D model with integrated time schedule), information for operation and maintenance, information model for construction, overview of work done and work to do, notifies what needs ordering and when, visualization tool, all information in a single model of the building, platform to manage time and cost.

4.10 The degree of experience that interviewees have had with BIM

Of the 11 interviewees, 3 described themselves as having some limited experience with BIM while 7 professed to have little or no BIM experience. One interviewee did not provide an answer to this question. The experience with BIM was slightly greater amongst Site Managers than Project Managers and representatives of large firms rather than medium-sized firms.

4.11 Expectations for BIM in the future

The responses elicited from the interviewees in terms of expectations from BIM in the future was somewhat similar to those given for their expectations of current and future benefits from IT use described in subsection 4.7 above. Once again, the responses related to expectations of more complete, more accurate information being available earlier and Site Managers provided the majority of these responses.

4.12 Steps that the interviewees' firms were reported to be taking to implement BIM

Very little common ground is evident in terms of the reported steps being taken by the interviewees' firms towards BIM implementation. Although 4 reported types of actions being taken (training of personnel, setting up new systems and standards, hiring new (BIM) personnel/experts and non-specific (small) steps) were each referenced by 2 interviewees, it is only in the case of the last of these (non-specific (small) steps) that the 2 interviewees were representatives of the same firm and, since this action is 'non-specific' it is more likely a function of a coding decision than precise agreement between the two interviewees.

Among the responses provided by single interviewees (research and development activities, keeping aware of BIM developments, creating 3D models, self-development activities by individuals, no steps are currently being taken) the two last ones equate to nothing being done at the firm level. The overall impression, therefore, is of a few, minor initiatives and, generally, that the interviewees are aware of very little being done towards the implementation of BIM within their firms.

5. Conclusions

The depiction of IT use and communications on Estonian construction sites gained from the interviews indicates that BIM use appears to have been primarily experimental to date. The Project Managers and Site Managers interviewed had some awareness and knowledge of BIM but little actual experience of it and clear, common steps towards BIM adoption by their firms were not apparent. There seemed to be a widely held view that BIM adoption on sites should be imposed and paid for by the client rather than evolving from internal needs and innovation.

Thus, it appears that BIM adoption has yet to convince the majority of Estonian project and site managers that it is cost and time effective – as one put it: *"It seems that paper on the wall is still the best solution at the moment."* However, benefits are expected from BIM in the future and there are undeniable changes including improved computer literacy, hardware and software that are enabling BIM adoption. The interviews also revealed the intense pressure felt by contractors' middle management to get on with the present job and this may be dissuading them from investing their time and effort for potential but uncertain efficiency gains in the future. *"If money and time weren't issues, I would of course make a model."*

It therefore suggests that interventions to promote BIM adoption on sites should focus on demonstrating clear efficiency gains and value for money without requiring major time and money investment. This initial research indicated numerous challenges including subcontractors' knowledge and capabilities, the considerable diversity between individual needs, views and expectations from BIM and relative satisfaction with existing, non-BIM methods. However, there was also some common ground in the form of the specific needs and current expectations for the future of BIM that were identified in the interviews. This provides an initial list of possibly fruitful areas for intervention including: clash detection, mistake avoidance, better planning, the improved accuracy and timeliness, more appropriate formatting and easier visualization of information.

The complexities implied by the revealed role, knowledge and capability differences among construction site stakeholders, as well as the current ways of working and the reasons why these are found to be advantageous suggest that a thorough examination of a specific construction site process would have to precede any BIM intervention design if it were to have any possibility for success. It is therefore recommended that further research would take the findings of this initial study into account in order to identify specific 'candidate' processes for BIM improvement interventions. These processes should then be studied in detail and on a specific site from the perspectives and with the collaboration of all the stakeholders involved in them. Experimental BIM interventions could then be collaboratively designed together with performance measurement indicators relevant to all the stakeholders prior to their deployment and subsequent evaluation. This suggests an action research approach would be appropriate in the first case to identify specific, problem-based interventions before more general BIM adoption recommendations could be made.

Acknowledgement

This research was supported by the Collaborative Action towards Disaster Resilience Education (CADRE) project funded with support from the European Commission. Organising the Implementation of BIM: A Study of a Large Swedish Client Organisation

Hannes Lindblad,
Real Estate and Construction Management, KTH Royal Institute of Technology
Hannes.Lindblad@abe.kth.se

Abstract

Building information modelling (BIM) is currently much discussed in the construction industry. It has been brought forward as a way to address the problems with slow increase in productivity perceived in the industry. To support and drive the industrywide implementation of BIM, many large public client organisations are currently in the process of implementing BIM. The purpose of this paper is to explore how a large client organization organises their BIM implementation. In order to reach this objective a case study of the BIM implementation process at the largest public infrastructure client in Sweden has been conducted. This case study is supplemented with interviews with the management of the implementation project together with interviews with project managers in pilot projects implementing BIM. Based on the results of this study, it has been found that the BIM implementation is mainly focused on the technical requirements to support the shift from traditional drawings, to object oriented information. How this shift towards object oriented information will influence changes to work practices is however not defined within this implementation project.

Keywords: BIM, building information modelling, implementation, causal structure

1. Introduction

Today, Building Information Modelling (BIM) is frequently brought forward as a way to address many problems in the construction industry. For many years the industry has been described as fragmented with problems of low increase in productivity (Egan, 1998 and NIST, 2004). In research, BIM is described as being able to provide several potential benefits as shown in studied pilot projects (e.g. Eastman et al., 2011). At the same time, the implementation of BIM within the industry has been very tentative and there is a view that BIM has not yet shown its promised benefits (Gustavsson et al., 2012; Jung & Joo, 2011, Fox, 2014).

The role of government and public actors in this implementation process has been discussed in BIM related research. This role has been described as a driving force towards BIM in many countries and as being critical for successful implementation (Wong et al., 2010, Wong et al., 2011). There is also a view that the industry has to be convinced of the importance of BIM adoption in order to drive implementation. Khosrowshahi and Arayici (2012) argue that there is a need for researchers in the field to intervene in order to reach higher levels of BIM maturity. Furthermore they present a roadmap for BIM implementation in the UK construction industry to address the disinterest currently found in parts of the industry (Khosrowshahi & Arayici, 2012). In many countries there are and have been BIM initiatives by the government. Several large public client organisations are starting to demand the use of BIM in order to drive development. In the UK for example, there is currently a demanding that all public contracts awarded from 2014 and onwards contain requirements that all project participants will work collaborative through the use of BIM (CabinetOffice, 2011:14). In Sweden several BIM related initiatives are being conducted, many public client organisations are defining their requests for BIM use in projects (BIM i Staten, 2014). In parallel with this process the Swedish Transport Administration, the largest Swedish client for infrastructure projects, is initiating their implementation of BIM. With the expressed goal of increasing productivity both in their organisation and the industry as a whole, they are aiming to implement BIM in all of their projects.

This argued importance of BIM connected with public actor's central role as driver for change highlights the relevance of studying this implementation process. The purpose of this study is to explore how the Swedish Transport Administration organises their implementation of BIM. With the objective of analysing how BIM is expected to influence organisational change, both internally as a client organisation and how other actors are expected to be influenced, this article studies the BIM initiative and the implementation process by this client actor.

2. Method

In order to explore how the BIM implementation process is organised within this public client organisation a case study of the 'BIM initiation project' at the Swedish Transport Administration has been made. This qualitative case study has focused on analysis of documents produced as a result of this project. Furthermore it has been supplemented with 4 semi-structured interviews with the management of the project together with 4 semi structured interviews with BIM responsible persons in the pilot projects most influential to the 'BIM initiation project'. The results from this case study has been analysed based on a literature review studying BIM implementation initiatives in other countries. This literature review has gone beyond the BIM field and studied research on the implementation of other IS/IT and how such implementation generates increase in productivity.

2.1 Delimitations

This study is limited to the analysis of the first stages of the BIM implementation process by a large Swedish infrastructure client. The studied process contains the initial implementation project by this actor which was later continued with two more simultaneous projects in different branches of the organisation. How the implementation process actually influences change is not part of this study. Rather this study focuses on how the BIM implementation is organised, the successfulness of this process will be analysed in later studies. That is to say, this paper does not analyse any actual increase in productivity, but rather focus on what steps this organisation took in order to implement BIM.

3. Literature review

BIM is described by many as a paradigm shift in the construction industry (Azhar, 2011). Several substantial benefits have been shown. In order to take advantage of the numerous potential benefits there are many barriers to BIM adoption that has to be bridged (e.g. Eastman et al. 2011), and implementation of BIM is described as a major managerial task (Khosrowshahi & Arayici, 2012). Not only technical solutions are required, rather, there is a need for corresponding changes in work practices and skill sets of the project participants to be made (Froese, 2010). In addition to these changes, substantial changes in business practices and rearrangements of contractual agreements are needed (Mihindu & Arayici, 2008; Succar, 2010; Tylor, 2007). The BIM concept is also unprecise; it can be implemented and used in many different ways, on many different levels. Each of these levels of BIM-use presents different possibilities combined with various challenges in order to achieve successful implementation (Succar, 2009). To achieve BIM implementation at higher maturity levels there is a need for proper implementation at the organisational level together with its integration at the industry level (Khosrowshahi & Arayici, 2012). It is also suggested that the greatest gains can be found at these higher levels of BIM maturity (Khosrowshahi & Arayici, 2012).

3.1 The role of public actors

Client organisation has been argued to be the actor who benefits the most from BIM implementation (Eadie et al., 2013). It is also the actor, together with the main contractor, who is in power to demand compulsory BIM use (Linderoth, 2010). The adoption of BIM is also perceived as slow within the construction industry (Gu, 2010, Smith 2014). An unwillingness to adopt BIM has been observed, firms are satisfied with continuing using traditional CAD (Khosrowshahi & Arayici, 2012). Together, this has open for suggestions that public client organisations and governments should intervene and support BIM use. A study by Wong et al.

(2011) stated that “the role of the government is critical in the implementation of BIM in any country”. It is also argued that government mandates demanding BIM in their projects is effective in driving implementation (Smith 2014). These types of initiatives are taking place in many different countries, where the different governments are involved with setting up BIM policies (Wong et al. 2010).

Several papers discuss how BIM implementation rates can be increased in the construction industry. Wong et al. (2011) presents six steps for BIM implementation by the government. The initial step is the need for a specific BIM policy, establishing BIM as something that should be implemented and used in all new projects. Further these steps focus supporting BIM-use by external actors, such as contractors and consultants, thereby enabling inter-organisational use of BIM (Wong et al. 2011). One major issue is interoperability between different software and formats, governments have been shown to be able drive the development towards more open standards to increase interoperability (Porwal & Hewage, 2013). Khosrowshahi and Arayici (2012) state that education and awareness about BIM is critical to address resistance to change. Further they state, as BIM implementation is often supplemented with process improvement, a need for support services for actors implementing BIM processes in their organisation.

3.2 Information technology and increased productivity

The main reason for the BIM interest is the expected increase in productivity. Such an influence on productivity has been shown in several case studies (e.g. Azhar, S. 2011; Eastman et al. 2011). The actor who is expected to acquire the greatest benefits is the client (Eadie et al., 2013; Olofsson et al., 2008), and this has been brought forward as one more argument for letting the client organisations drive the BIM implementation. However, the extent of the benefits following BIM implementation is discussed and has been questioned (Gustavsson et al., 2012; Jung & Joo, 2011; Fox, 2014).

The link between implementation of new information and communication technology (ICT) and increased productivity has been described in many different contexts. How investments in ICT influence the productivity of an organisation has been described as the “productivity paradox”, where these investments generate little or no increases in productivity (Brynjolfsson, 1993). This paradoxical connection has been suggested to stem from several different reasons for example, difficulties to measure influences of ICT and mismanagement of implementation and use of new systems (Brynjolfsson, 1993). In later studies Brynjolfsson and Hitt (1998) problematizes the concept of the “productivity paradox”. They argue that the use of ICT does not increase productivity by itself; rather, it is an essential part of a wider context of organisational changes which in turn influences productivity positively. A major part in the value of ICT is its ability to enable further investments in the organisational layout adapting business processes and work practices to the new possibilities (Brynjolfsson & Hitt, 2000). There can be found similarities between the earlier ambiguities in the link between ICT and productivity and the interest for BIM in the construction industry of today. Many potential benefits with BIM implementation have been presented and several studies presenting case-studies indicating positive outcomes of BIM-use in projects (Eastman et al., 2011). However there is still ambiguity in how this BIM use influences the productivity of the industry. The implementation and use of BIM is currently tentative within the industry and its promised benefits have not yet been shown (Gustavsson et al., 2012; Jung, & Joo, 2011). It has been argued that there is currently hype around the concept of BIM, further that this hype can lead to suboptimal decisions throughout implementation projects (Fox, 2014).

3.3 Casual structure – information technology and organisational change

The connection between information technology and organisational change has been of interest for many decades. Markus and Robey (1988) describe how there are several different theories describing the link between information technology and organisational change, but these theories are argued to have problems with reliable generalisations regarding this relationship. Further their study describes the causal structure of these theories as composing of three dimensions: Casual agency, logical structure and level of analysis.

Casual Agency:	Logical Structure:	Level of Analysis:
· Technological Imperative · Organisational Imperative · Emergant perspective	· Variance Theory · Process Theory	· Macro · Micro

Figure 1: Dimensions of Causal Structure (Markus and Robey, 1988)

Causal agency – describes the assumptions about the causal agent and the direction of influence of this agent. The 'technological imperative' views technology as the causal agent which determines the behaviours of individuals in the organisation. The 'organisational imperative' views the human individuals within the organisation as agents of change. The 'emergent perspective' finds causality in complex interactions between technology and human actors within the organisation.

Logical structure – describes the relationship between elements identified as precursors and those identified as outcomes. 'Variance theory' views specific precursors as essential and sufficient to achieve outcomes. 'Process theory' however, assumes that the precursors necessary to achieve certain outcomes, but insufficient to cause them.

Level of analysis – describes the level at which theories describes the impact of information technology, and is generally either: individuals, organisations or society.

Depending on the casual agency of how information technology is predicted to generate change different strategies of how to manage the change in an organisation follow. With the ‘technological imperative’ implementers focus on the choice of information technology and its technical requirements. When the correct technology is in place and working organisational change is expected to follow. Following the ‘organisational imperative’ focus tend to be on the allocation of resources and improving implementation strategies while the results of the implementation is perceived to stem from the behaviour of managers and system designers. The ‘emergent perspective’ finds predictions of implementation impossible and to support changes extensive participation of the analysis, design and implementation by the people involved can be advised. (Markus and Robey, 1988)

4. Results

The Swedish Transport Administration is the public actor responsible for long term construction, operation and maintenance of roads and railways in Sweden. The organisation is also designated to, in its role as client, to work towards increasing productivity both for its own investments and also in the branch on the construction industry related to infrastructure (SFS 2010:185). The interest for BIM by the Swedish Transport Administration was initially brought forth in a strategy document by the Swedish government emphasising the possibilities with the use of ICT. This document was presented in late 2011 and presented the government’s aim to establish Sweden at the forefront in regards to taking advantage of the possibilities with digitalization. In a Swedish government official report in 2012, these ambitions were concretized in regard to the infrastructure sector (SOU 2012:39). This report explored ways of increasing productivity and innovation in this sector. Building information modelling takes up a large part of this report and it is expressed that BIM has large potential to increase performance for the Swedish Transport Administration. In 2013 the Swedish Transport Administration initiated a project to begin structured implementation of BIM in their organization, the ‘BIM initiation project’. According to the project specification, this project is an answer to the guidelines given by the Swedish government and to increase productivity and innovation both for the client organisation but also for the industry as a whole. At the time, BIM was explored and used by an unstructured network of projects managers at the Swedish Transport Administration. The initiatives were driven by interested project managers and not coordinated by the mother organisation. The ‘BIM initiation project’ was the first coordinated step towards BIM by this actor.

4.1 The BIM initiation project

According to the project specification the ‘BIM initiation project’ was initiated 2013, with the following goals:

- All new projects in the ‘investment’ department uses BIM to some extent from 2015 and onwards. These projects make an active choice concerning BIM based on predefined levels.

- Make the work processes more efficient and thereby saving approximately 150M SEK to the end of 2015

- Make the Swedish Transport administration a client with an obvious demand for BIM both in design and construction.

The project aimed to address the possibilities and suggestions presented in the governmental official report, but also the organizations ongoing assignment to lead innovation within the infrastructure industry. The project was scheduled to end in 2015 and at that time introduce BIM-supported work practices in all projects initiated thereafter. According to the ‘strategy for BIM implementation’ presented by The Swedish Transport Administration within the ‘BIM implementation project’, BIM is described as: “the use of information models in a continuous flow through the main processes connected with a constructed facility”. Further it is expressed that the information produced in these processes could be used for multiple purposes, for example: clash control, analysis of different design alternatives, cost calculations and time scheduling. Combined, these benefits are expected to result in a more efficient work process. The BIM concept is described as being related to three different aspects: *Product* – The planned and constructed project, *Organisation* – The actors, planning constructing and maintaining the facility and *Process* – The work process which the organisation follows in their work.

4.2 Pilot projects

Within the ’BIM initiation project’ there were planned a total of 28 pilot projects. These projects were of varying size and complexity and were supposed to reconnect to the BIM initiation project and transfer knowledge of experiences of how BIM had been used in these pilot projects. According to interviews with several of the project managers in some of these projects, there are large differences in how BIM was used. The extent by these pilot projects influenced the ‘BIM initiation project’ also varies a lot. These pilot projects can be divided into three different groups:

- Projects using BIM extensively. These projects began their BIM use before the ‘BIM initiation project’ was started. Generally large projects with large interest for BIM within the project organization.
- Projects using BIM to some extent following the BIM initiation project.
- Projects not using BIM at all.

Among these projects the first category has been the most influential in regard to impacting the results of the BIM initiation project. In this category there are mainly two very large projects that distinguish themselves. According to the technical manager in one of these projects, much of the material presented by the ‘BIM initiation project’ was based entirely on documents produced in this project.

4.3 Results from the BIM implementation project

At its finish the ‘BIM initiation project’ resulted in a total of 32 documents, these documents contained changes to guidance documents and templates for e.g. meeting agendas. Most of these documents manly changed the templates to include ‘BIM’ and ‘models’ rather than ‘drawings’.

In addition to these documents there are three documents describing the use of BIM within the organization. All these documents went through a referral process within the organisation before they were reworked, resolved and incorporated in the project process by this actor.

General guidelines for BIM in projects – This document seeks to manage and support the use of BIM in new projects and ensure that BIM satisfies the goals presented in earlier visions. Within this document, changing roles and responsibilities following BIM implementation is described. The project manager in every project will be responsible for: (1) assuring that BIM will be used in a current extent to ensure efficient information management (2) ensure that the project organization reserves education regarding BIM and (3) to define BIM in relation to the specific project. This document also describes a ‘base level of BIM’ that should be fulfilled in all construction projects. There are however room to increase this level and use BIM at a larger extent in projects where it is deemed suitable.

Tutorial document for BIM-use in projects – This document is supposed to provide guidance for the actor responsible for BIM-use in the project (BIM-coordinator for example). It provides recommendations and descriptions of BIM and how it can be used in relation to process, organization and product. The document supports BIM-users and is supposed to be used as a compliment to other guiding documents.

Requirements on object oriented information – This document defines how information should be generated and managed to ensure use of object-oriented information in projects in a life cycle perspective. The document contains demands on technical aspects of the generation of object-oriented information and is supposed to be used in procurement processes. These are demands that should be used both in-house but also in contracts with external contractors. The document defines the file formats for exchange of model based information between actors to be DWG (AutoCAD) or DGN (MircroStation). Information should be classified according to BSAB 96 (Swedish standard).

Among the documents presented by the ‘BIM initiation project’ there is a focus on the technical aspects. How models should be produced and shared and what types of file-formats that can be used are well described. The documents regarding this information is categorised as requirements. On the other hand, the work practices when using these models are described more vaguely, with large degrees of freedom for the project managers in the actual construction projects. These documents are categorised as general guidelines or tutorial documents.

4.4 ‘Base level’ of BIM

The ‘base level’ of BIM defined by the ‘BIM initiation project’ is supposed to be used in all projects. As the description of the BIM concept, this ‘base level’ of BIM relates to both: *Product*, *Organisation* and *Process.* This level of BIM is defined in a list of 17 points supposed to be fulfilled in all projects. This level of BIM emphasises on enabling the shift towards an object-oriented work-practice, the use of models to ensure the quality of information. The ‘base level’ of BIM is presented as changing the current practice of presenting project related information in drawings, lists and descriptions into an object-oriented practice. Information should be stored in one or multiple models instead of the traditional alternatives. The details of this lowest level of BIM is affected both by the technical limitations such as problems with interoperability as well as organisational preconditions both internally and externally where lack of experience with the new work-practices is argued to hinder the implementation. The Swedish Transport Administration describes BIM as a structured way of managing information of good quality related to a constructed facility. With BIM this will give an unbroken information flow throughout the whole lifecycle of the constructed facility. This holistic perspective is said to bring conditions to minimise costs and time in: planning, design, construction and maintenance of the facility.

According to the BIM-coordinator in one of the most influential pilot-projects this base level of BIM implementation is a compromise between what is possible to achieve in the industry with the current level of BIM experience and possible benefits with BIM use. This level is further presented as an enabler for actors, wanting to use the collaborative aspects of BIM. By demanding models as a client, models can be available for exchange between contractors and consultants, supporting BIM oriented work practices by these actors.

5. Analysis

Prior research argues that the main role of public client organisations is to demand BIM use in their projects, thereby forcing other actors in the construction industry to adopt BIM if they want to continue to work for these clients. The BIM initiative in Sweden very closely resembles what other studies have found governments and public clients are doing in other countries. In order to increase productivity and innovation the Swedish Transport Administration is promoting the use of BIM. Similar to for example the UK, the Swedish Transport Administration is developing demands stating that project related information should be delivered in object oriented formats, de-facto demanding BIM-use. There is a view within the 'BIM initiation project' that, by following these requirements contractors and consultants are enabled to work collaboratively with the new possibilities that BIM enables. As in some BIM related research the 'BIM initiation project' assumes that such BIM requirements will result in higher BIM use in the industry. However, as studies by Brynjolfsson and Hitt, (2000) have concluded, in order to achieve the full potential of new IS/IT solutions there are a need for organisational change. It has been described that changes to work practices, enabled by new technology, is generating the sought after increases in productivity, rather than the technology itself. These conclusions are in line with research on BIM implementation describing the guidelines for high level BIM implementation. For example, Khosrowshahi and Arayici (2012) described the need for an effective implementation strategy as BIM requires substantial changes to how construction business is conducted.

As described by Markus and Robey (1988) there are many different theories describing the relationship between implementation of new technology and organisational change. Depending on the causal structure of the theory chosen, different focus will be taken and different results are expected. The 'BIM initiation project' by the Swedish Transport Administration is described as a structured first step towards implementing BIM in all new projects initiated by the organization from 2015 and onwards. The main deliverable from this project is the documents with proposed changes to how projects should be conducted. These documents mainly focus on the technical preconditions needed in order to use BIM. The technical requirements for how ‘object based models’ should be produced and managed. This information is described in detail within the requirement document, defining formats etc. The requirement document (Requirements on object oriented information) is supposed to be referred in the tender templates used in all newly started projects. Thereby, this document influences how information is managed in projects. A ‘basic BIM’ level, which should be used in all projects, is defined. This ‘basic level’ mainly focuses on a shift from drawings to models in order to support object oriented work practices. However, how these models should influence changes to work practices in projects using BIM is not focused upon. Instead the responsibility for these changes is delegated to each responsible project manager in the respective projects.

The results from the ‘BIM initiation project’ are based extensively on input from the pilot projects connected to this BIM implementation project. These projects differ widely in extent of BIM use. Most of the smaller projects on the list do not use BIM at all or at a very limited extent. The two large projects used BIM even before the ‘BIM initiation project’ started and it is mainly experiences from these projects that have influenced the referral material produced in the ‘BIM initiation project’. The individuals responsible for BIM in these projects have an extensive insight and knowledge in how BIM is and can be used as well as how it can influence work practices. This is however not defined and stored in the documents presented by the ‘BIM initiation project’. The importance of training in relation to BIM implementation presented by e.g. Khosrowshahi and Arayici (2012) is not addressed in this implementation project.

6. Conclusions

With the opinion that governments and public actors should drive BIM implementation it becomes relevant to study how these actors organise the implementation processes. Based on the study of the ‘BIM initiation project’ by the Swedish Transport Administration, it can be argued that this actor organises their BIM implementation based on the ‘technological imperative’. The technology is viewed as a causal agent for organisational change; in this case the use of object oriented models is expected to act as a driving force towards change in work practices. Following this view of BIM, the focus in this implementation process has been on ensuring the right preconditions for enabling a shift towards using object oriented models to store and manage information. The use of a ‘basic BIM level’ which should be used in all projects is expected to act as driving force for changing work practices. The project manager in infrastructure projects is given the role of change agent, responsible for ensuring the use of BIM within their projects. The ‘technological imperative’ view of BIM implementation addresses some of the barriers described in research in regards to the slow implementation of BIM. For example the issue of BIM training is not as well discussed in this stage of the BIM implementation by this actor. By demanding models as deliverables in construction projects there will have to be a shift towards producing models. However, this view does not address many other barriers in relation to BIM implementation. In order to evaluate which ‘causal structure' is most suitable in relation to BIM implementation, further research should study the results BIM implementation initiatives and relate them to the implementing actor's view of BIM in terms of causal structure.

Abstract

Building Information Modelling (BIM) has been hailed as an artefact of collaboration, where all project participants are able to create, modify and implement design/construction configurations within the same virtual environment codified by International Foundation Classes (IFC). To facilitate communication between human participants during project development, the BIM Collaboration Format (BCF) was developed, enabling users of BIM applications to communicate issues and refer those to specific objects. A single BCF entity holds a textual description of the issue, a status, links to a BIM IFC model and objects, a picture of the issue, and a camera orientation. Therefore, BCF poses a rich repository of complex fuzzy semantic knowledge concerning design risks, such as change requests and rework proposals, in a readily accessible format based in the XML schema. This research investigates how data in BCF files can be extracted, and processed using a linear algebra method known as singular value decomposition (SVD). SVD is extensively used, along with dimensionality reduction, for pattern recognition applications and has been shown to infer semantic correlations amidst a variety of different unstructured data (e.g. texts, images, signals etc.), comparable to that of human cognitive associations. Consequently, a dynamic knowledge-base is established of past BCF cases, whereby designers can flexibly query and systematically retrieve most relevant past issues and related objects, given any known current parameter – reminiscent of how a human may recall past experiences upon inquiry or design review. This paper introduces the BCF structure, describes the machine learning steps taken to extract and process BCF data, and presents the conceptual framework of a queryable knowledge-discovery system. This allows for relevant past issues to be recalled and the knowledge integrated in future designs as problem- and change-prediction. It is of particular pertinence for users of BIM, in sight of the ever-growing masses of BCF data generated from project to project.

Keywords: BIM collaboration format, singular value decomposition, latent semantic analysis, change management, knowledge management.

1. Introduction

Design changes are very common in the building industry, where dynamic feedback, due to iterative cycles, are ubiquitous (Lyneis, Cooper, & Els, 2001). Change is a major cause of delay, disruption, and disputes (Motawa, Anumba, Lee, & Peña-Mora, 2007). Furthermore, it is hard to predict changes in construction projects, given the uniqueness of each project and the limited resources (Hanna, Camlic, Peterson, & Lee, 2004). There is thus an obvious need to better manage change, as well as to garner competence to predict and avoid unnecessary changes early during the design stage. The one-off nature of construction projects have often been used to justify unpredictable changes, however, even in such contexts many repetitive issues occur from project to project. Many of such potential change issues could well have been anticipated in advance and thus avoided given the tacit knowledge of experienced designers, and close collaboration between different design parties.

In the advent and increasing adoption of Building Information Modelling (BIM), the design reviews and change issue prediction are often done in the BIM environment. BIM is used to produce building models of different aspects of the building: architecture, structures, plumbing, heating, air-conditioning, and so on (Eastman, Teicholz, Sacks, & Liston, 2011). Therefore during the design, multiple interrelated models are produced in individual design tasks by different disciplines/parties. This creates great a challenge for the management of change across different models, in sight of change prompts and requests for information (RFIs) from both designers and contractors on site.

In recent years, the introduction of the BIM Collaboration Format (BCF) into the BIM ecosystem has enabled an additional layer of semantically rich communication between different project participants. It introduces a workflow communication capability connected to models based in the International Foundation Classes (IFC). The idea is to separate the "communication" aspects from the actual model. In particular, it was envisioned to enable the conveyance of RFIs, proposals, change prompts, or other queries/requests related to the model, collectively referred to as *issues*. It was also to allow such issues to be exchanged in collaborative work without the need to transfer the whole BIM-model as bulk data, as in the past. The BCF is an Open BIM standard format developed by BIM companies Solibri and Tekla in 2010 as "bcfXML v1", and later "bcfXML v2" became released in October 2014 and adopted by BuildingSMART (BuildingSmart, n.d.).

The BCF presents a repository of semantically rich issues of change-related knowledge. Alluding to knowledge management concepts of Nonaka & Takeuchi (1995), the BCF presents a codified form of, otherwise tacit, knowledge, which can then be *internalized* by the designers to be applied in value creating work, as part of the knowledge management lifecycle. However, *internalizing* these issues as human practitioners currently requires much time and effort as it occurs organically through the acquisition of experience dealing with such change cases from project to project. In order to aid this process, this study proposes the mining/extraction of textual natural language descriptions in BCF issues and process the dataset using the machine learning textual processing technique known as latent semantic analysis (LSA). LSA is based on a linear algebra operation called singular value decomposition (SVD) and has been shown to infer conceptual links amid natural language texts comparable to human semantic intuition (Landauer, McNamara, Dennis, & Kintsch, 2007) and similar techniques have been used in a variety of other pattern recognition problems (Deerwester, Dumais, Furnas, Landauer, & Harshman, 1990). This allows the matching of texts on semantic/conceptual level rather than explicit string matching used in word search-functions, where semantic relationships between texts are not involved. This ability of LSA is cardinal in managing and retrieving possible future change cases, where different building elements may be related to each other through different types of issues qualified by a variety of parameters. Consequently, this enables change cases to be automatically captured and stored in such a way that future designers are able to effectively query the system for past similar and/or related issues. This helps to enhance the designers' capacity to learn or *internalize* historical change-related knowledge and thus improves future design decisions in avoiding change.

In the Section 2 we cover some preliminaries regarding the background and mathematical basis of the latent semantic analysis method. Section 3 describes the methodology applied in our particular case, the nature of the textual *issue* descriptors extracted from the BCF of a specific project, and the pre-processing steps taken before the analysis. We then discuss the results in Section 4 with reference to other potential developments. Section 5 concludes by drawing up a brief summary and reiterating the value of our proposal in the BIM-based design change management context.

2. Theoretical preliminaries of LSA and SVD

Latent semantic analysis (LSA) is a techniques for creating vector-based representations of texts, which are claimed to capture their semantic content. The primary function of LSA is to compute the similarity of text pairs by comparing their vector representations, and has been shown to closely match human capabilities on a variety of tasks. It extends the vector-based approach by using Singular Value Decomposition (SVD) to reconfigure the data.

2.1 Pre-processing

LSA starts with a text quantification method based on what is known as Vector Space Model (VSM) (Salton, Wong, & Yang, 1975), where a corpus of d documents using a vocabulary of t terms is used to compile a t x d matrix **A**, containing the number of times each term appears in each document (term frequencies). Some trivial terms such as "the", "of", etc. (the stopwords) are excluded, and some others are consolidated, because they share a common stem (Porter, 1980) or some other lexical quality. The frequency counts in **A** typically undergo some transformation (term weighting) known as TF-IDF that penalizes common terms and promotes rare ones. After weighting, the term frequencies are also normalized so that the sum of squared weighted term occurrences within each document is equal to one (Salton, 1989). Subsequently, **A** is subjected to Singular Value Decomposition (SVD).

2.2 Singular Value Decomposition

Matrix **A** of dimensions *t* x *d* is decomposed into the product of three other component matrices **U** (*t* x *t*), **S** (*t* x *d*) and $\mathbf{V}^{\mathbf{T}}$ (*d* x *d*), that is, $\mathbf{A} = \mathbf{USV}^{\mathbf{T}}$. **U** columns consist of the *term* eigenvectors, and **V** columns are the *document* eigenvectors, and **S** is a diagonal matrix of singular values (i.e. square roots of common eigenvalues between terms and documents). In other words, matrix **U** describes the original **A** row entities as vectors of derived orthogonal factor values, matrix **V** describes the original **A** column entities in the same way, and the middle **S** matrix is a singular diagonal matrix containing scaling values in descending order along the diagonal of the matrix. When the three component matrices are multiplied the original **A** matrix can be reconstructed. The **U** and **V** matrices are thus regarded as all the constituent patterns that determine the original matrix **A**. The columns in **U** and **V** are orthonormal vectors that describe these patterns and are arranged in descending order of significance.

2.3 Dimensionality reduction

Dimensionality reduction is carried out in order to remove noise (small irrelevant patterns) inherent in natural language. This step is done by removing column vectors from **U** and **V** starting from the least significant, and retaining the most significant vectors. This corresponds also to the same number of diagonal singular values retained in the **S** matrix. The reconstruction of the truncated/reduced component matrices produces another matrix (essentially an approximation of matrix **A**), which exhibits latent semantic relationship between words and documents not evident in the original matrix **A**. The number of dimensions to keep is a difficult question as it depends on how much of the original variance is desired to be kept without loss of relevant data. In linguistic terms, it is difficult to interpret intuitively. However, many case-specific guidelines are given within different contexts. A very common technique is to plot the square of singular values of the **S** matrix against the number of dimensions (Sidorova, Evangelopoulos, Valacich, & Ramakrishnan, 2008). One may choose the number of dimensions corresponding to where the singular values decrease substantially (elbow of the graph) indicating the point where the patterns become insignificant. Generally, the more noise is removed (dimensions reduced), the clearer will the semantic relationships be revealed in the reconstructed approximate matrix.

2.4 Cosine similarity

The reduced **U** and **V** row vectors represent the semantic space of the words and documents. Thus a similarity function can be used to measure semantic correlations between term-term, document-document, and term-document relationships. The cosine similarity function tends to work well empirically (Landauer et al., 2007) and is widely used for vector matching in many applications. Cosine similarity is denoted by the cosine of the angle between two vectors (suppose vectors *a* and *b*) and can be calculated by dividing the dot product of *a* and *b* by the product of their magnitudes, that is, $a \,.\, b \,/\, (\, \|a\| \, \|b\| \,)$.

3. Methodology

Broadly, this study involves the automatic extraction of natural language information from BCF issues and processing it using latent semantic analysis. This is used to demonstrate how higher level semantics and linked data may be inferred automatically from existing data or documentation embodying some level of professional knowledge. The semantics inferred can then be fed back to the workflow to augment the knowledge of practitioners for future work. The BIM data acquired for this study is from a large renovation project of a heritage complex in downtown Helsinki, and the BCF issues thus reflect the nature of changes accordingly - predominantly related to mechanical, electrical, and plumbing (MEP) services. The steps of this study are covered in the subsections below.

3.1 Extract issues from XML schema of BCF

As described in Paasiala et al. (2015) a BIM Collaboration Format v2.0 formatted bcfzip file contains a folder for each issue. The issues correspond to proposals and change requests in BIM-data-models (BuildingSmart, n.d.). Each folder contains a markup.bcf file that embodies textual information about the issue, a viewpoint.bcfv file that specifies the related elements, the viewpoint, and the camera angle, and snapshot.png pictures describes the issue.

Only markup.bcf files contain human written sentences. In that XML file, although title and description tags can contain clauses, in practice, only comment tags had any content. A small program was written in the Java programming language to extract the comments from the files. The full source code of the program is available in (Oraskari, 2015). When extracting the bcfzip file, the program follows the first steps that was presented in (BIMServer, 2015). However, instead of marshalling the XML documents into Java objects, we parse the files using a JDOM XML parser (Hunter & Lear, 2015). The XML document tree of the markup.bcf is traversed recursively. Whenever there is a comment tag in the graph, the content is copied. A total of 71 passages of text from BCF issues were extracted as natural language descriptions for each issue logged by human project participants.

3.2 Textual parsing and term-document matrix

The extracted text passages (documents) are then parsed into words. The words are filtered in order to remove stopwords – such as “the”, “a”, “an”, “is”, “in” etc. – that supposedly do not contribute to the semantic value of each document. A standard “stoplist” is used for the English language. The words then undergo morphological stemming, where the words with different morphological conjugations would be reduced to the root of the word. For instance, “ventilate”, “ventilating”, “ventilated” etc, would be reduced to be the same stem or root of the words. As an example, the document “Office area: Electric duct location? Radiators hot water piping penetrates electric duct” are parsed into the following terms: “are”, “duct”, “electr”, “hot”, “locat”, “office”, “penetr”, “pipe”, “radiat”, “water”. The resulting words are now considered the terms in the term-document matrix (t x d), consisting of the occurrences of term t in document d.

The term-document matrix is transformed through TF-IDF (term-frequency, inverse document frequency) weighting to enhance the discrimination between documents, by discounting the weight of very common terms and promoting the weight of less occurring terms (Salton, 1989). The term-document matrix's raw occurrence values are replaced by the product, $\boldsymbol{w_{td} = tf_{td} * idf_t}$, where $\boldsymbol{tf_{td}}$ is the normalized term occurrence in each document *d*; and $\boldsymbol{idf_t = \log(N/df_t)}$, where **N** is the total number of documents in the collection, and $\boldsymbol{df_t}$ is the number of documents that contains term *t*. After TF-IDF weighting, the document vectors are normalized to remove the advantage that longer documents have over the short documents. Cosine normalization is an effective normalization technique and is computed, by dividing the TF-IDF weights by the Euclidean length of the respective document vector (Salton, 1989).

3.3 SVD, dimensionality reduction, cosine similarity, and query

The term-document matrix (*t* x *d*) undergoes singular value decomposition to yield the **U**, **S** and **V** matrices. Effectively, the terms and documents are vectorised and transformed or mapped to the same vector-space through dimensionality reduction. To choose how many dimensions to retain, the squares of the diagonal values of the singular **S** matrix are plotted against the number of dimensions (the number of singular values to retain) as shown in Figure 1. The number of dimensions to retain is chosen to be 13, after which the graph starts to flatten out, indicating that the patterns before dimension 13 contributes most to the variance of the original matrix **A**. Singular values after dimension 13 is therefore assumed to constitute "noise".

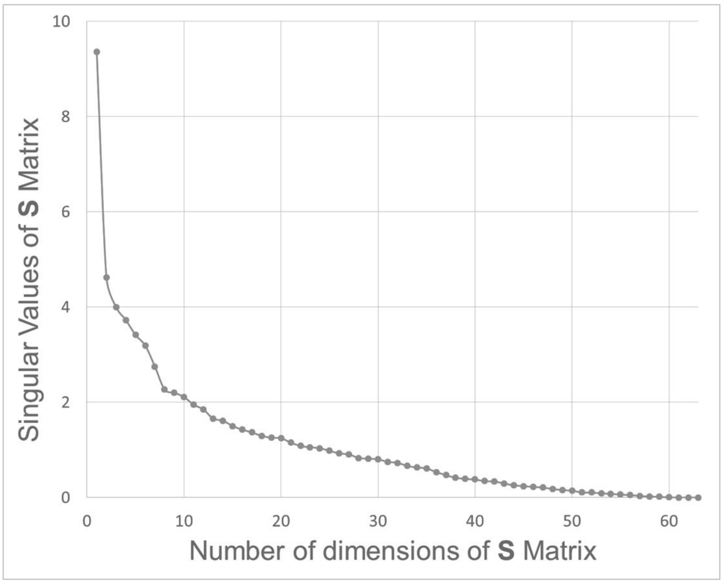

Figure 1: Plot of squares of singular values against the number of dimensions

3.4 Cosine similarity and query

The terms and documents can now be represented as vectors of 13 dimensions, as the rows of the reduced **U** and **V** matrices respectively. The similarity between any two vectors can thus be computed (through cosine similarity as earlier explained). If the two vectors are identical, the cosine similarity is 1 since the angle between them is 0°. Vectors that are totally uncorrelated has a cosine similarity of 0 (angle 90°), while cosine similarity of -1 implies that the two vectors are total opposites (angle 180°) or inversely proportional intuitively. The cosine similarity between vectors of the reduced **U** and **V** matrices equates to semantic similarity between them. Since this process is automated, it allows the system to calculate similarities upon query and recommend similar terms or documents from the database. The query is achieved by creating a pseudo-document consisting of a set of terms as query input. This pseudo-document can be represented as an explicit vector (q) of term occurrences, which can be mapped to the semantic space. The semantic query vector (q_s) can be obtained, through a simple algebraic manipulation following $\mathbf{A}=\mathbf{USV}^{\mathbf{T}}$, to be $q_s = q^{\mathrm{T}}\mathbf{US}^{-1}$. Cosine similarity can then be applied to gauge the similarity between the query vector q_s and all the other semantic term and document vectors represented by the dimensionality reduced rows of **U** and **V** matrices.

4. Discussions

In principle, the cosine similarity values between term and document vectors depends on the degree of correlations between the row and column spaces of the original **A** matrix, in particular, how co-occurrence of terms within the same documents indicates some level of relationships between these terms. The fundamental concept of semantic inference in human text is that similar/related terms would have much higher co-occurrence within documents than unrelated terms. For instance, considering the hypothetical corpora consisting of all of human literature, it is understandable that the terms "pear" and "apple" would have a much higher chance of occurring together in the same sentence, than "pear" and, for instance, "radiochemistry", to name an arbitrary example. The semantic meaning of certain terms, and their potentially numerous metaphorical or ambiguous nuances in natural language, can be qualified by other terms that occur together with it. In the same way, a semantic space can be established for domain knowledge, such as design change issues in this case, and co-relationships between the constituents of these issues can be automatically inferred, even to reveal non-apparent associations. To demonstrate the logic, some results of the analysis are shown with more specific detailed discussions covering the interpretation of the output of the proposed data extraction and latent semantic method on change issue management, integrated in BIM.

4.1 Interpretation of query and matching

Queries can be made to the system by inputting any number of terms. Some arbitrary query and results are shown in Figure 2. One- and two-term queries are shown and the top 10 semantically related documents (issues) are tabulated. One can very quickly use simple data visualizations to gain an overview of the nature of the spectrum of issues with relation to specific concepts. For instance, issues related to "corridor" are high in similarity though not as spread out as say "window", which seems to have one very similar issue, while the rest are spread out. Issues related to "electric cable" and "ventilation ducts" do not have as high semantic similarities as others, implying that even though the issues related to both concepts are widespread, they are not very specific. "Ablution area" has quite a few issues that are very semantically relevant, but not as widespread as the others. Such a table gives a strategic view about the how common certain issues occur with respect to specific concepts queried by the user, as well as how much semantic similarity there is between the issues and the queried concepts. This poses a suggestive function for the user to gauge the likelihood that certain change issues may arise in a new project given certain parameters as concepts to query the historical knowledge.

"Electric cable"		"Ventilation ducts"		"Ablution area"		"Windows"		"Corridor"	
Issue24	0.664	Issue54	0.747	Issue57	0.909	Issue53	0.851	Issue1	0.857
Issue62	0.618	Issue33	0.697	Issue68	0.902	Issue50	0.657	Issue27	0.805
Issue63	0.588	Issue11	0.683	Issue67	0.775	Issue44	0.617	Issue28	0.777
Issue38	0.544	Issue65	0.643	Issue60	0.767	Issue54	0.591	Issue7	0.682

Issue2	0.318	Issue38	0.480	Issue19	0.195	Issue70	0.320	Issue59	0.275

Figure 2: Top 10 semantically related document/issues with respect to specific concept queries

"Electric cable"		
Issue24	0.664	Technical area: Electric cable tray through ventilation duct
Issue62	0.618	Technical area: Electrical box through ventilation pipe and ventilation pipe through cable tray
Issue63	0.588	Technical area: Cable tray through sewage pipe
Issue38	0.544	Business area: Electric cable tray through ventilation duct
Issue39	0.538	Business area: Electric cable tray location
Issue8	0.532	Technical area: Electric cable tray penetrates inside ventilation pipes
Issue57	0.424	Ablution area: Electric cable tray underneath the ceiling
Issue32	0.400	Sewage drain through electric cable tray?
Issue20	0.334	Corridor area: Electric cable tray through the hot water pipe
Issue2	0.318	Office area: Electric duct location? Radiators hot water piping penetrates electric duct

"Windows"		
Issue53	0.851	Window and ceiling height? Architect model space object is missing
Issue50	0.657	Social area: ventilation duct door and water drain are at the same point. Floor is missing.
Issue44	0.617	Lobby area: ventilation piping in the same place as the front surface of the ceiling
Issue54	0.591	Ventilation duct and ventilation terminal clashes with electric duct and cooling pipes. Space object is missing
Issue30	0.575	Display area: Radiators in front of windows and door
Issue14	0.540	Stairwell: modelled staircase elevations dimensions?
Issue11	0.493	Drainage pipe penetrates ventilation ducts.
Issue65	0.446	Utility area: Cooling coil penetrates ventilation duct and electric cable tray
Issue67	0.431	Stairwell: ventilation duct is underneath the ceiling and goes through the building structure
Issue70	0.320	Technical area: Cooling pipe and electric cable tray penetrate the ventilation duct

Figure 3: Full issues semantically similar to queries: "electric cable" and "windows"

Figure 3 tabulates more detail about the "electric cable" and "windows" queries for further interpretation. For "electric cable" the top 10 semantically similar issues all contain some form of the terms "electric" or "cable", but it doesn't necessarily need to be the case, as the system uses "concept matching" rather than "string matching". Nevertheless, it is of course expected that issues explicitly containing the query terms would have high semantic similarity. A few explanations need to be given for how the issues are ranked for "electric cable". One sees that cases to do with clashes with ventilation related elements seem to be placed higher than other issues related to electric cables. This is due to the terms being weighted differently. "Ventilation" related terms appear many times in the corpus, so much so that the weight of those terms have been reduced as they are deemed non-unique (through TF-IDF and normalization). Therefore the contribution of "ventilation" to the semantic value of the issue is low, thus leaving the semantic weights of the electric cable to be prominent in that specific issue. A bit lower down (Issue57, 32, and 20 for instance) all contain "electric cable", but because of the contributing semantic weight of the other related elements, the share of the weight of "electric cable" is reduced with respect to the issue. Therefore, as one can see, the method is able to cater for different semantic weights of terms and aggregation of terms to match whole issues to a concept, and not merely wherever a term appears within an issue. This is the property of LSA that allows latent semantic traits of passages of texts to be identified and mapped to other passages of text, as concepts denoted by the aggregation of semantic vectors.

The results for "windows" (Figure 3) can be interpreted in a similar way. However, one sees that only Issue53 contain "window" and is expectedly semantically significant, while the rest is somehow related even though "window" doesn't occur explicitly. Issue 50 for instance is matched, because Issue53 (where "window" is evident) also is related to some object being "missing", while Issue50 has similar (i.e. floor is "missing"). This co-occurrence of concepts has created a link between "window" and some problem related to "missing" objects or information. Issue44 is linked probably due to the relation to "ceiling" which also occurs in Issue53. LSA has the ability to take into account the complex second order relationships of concepts, in fact, all latent relationships identified are based on aggregates of multiple orders of semantic associations across all the issues in the corpus.

Of course, it is also possible for the system to return the most semantically related terms rather than issues as shown above. However, in this particular exercise, the terms by themselves (being out of context) are difficult to infer meaning. It is therefore more meaningful for this particular renovation orientated context to retrieve the issues. Other cases, for instance, colloquial discourse within large corpora of literature, term retrievals usually reveal synonymy – multiple terms describing similar concepts.

"in the conference area, the hot water pipe is below the ceiling"		
Issue20	0.734	Corridor area: Electric cable tray through the hot water pipe
Issue7	0.677	Corridor area: Hot water pipes penetrates through the electric cable tray.
Issue41	0.567	Office area: Lighting rail clashes with ventilation terminal. Electric cable tray clashes with ventilation pipe and hot water pipe.
Issue42	0.474	Office area: Electric duct and radiator clash
Issue59	0.465	Corridor: Level and the stair in the same place? Cable tray and water pipe clash

Figure 4: Example of a natural language query

Due to the limited length of the paper, more detailed discussions and interpretations will be reserved. However, it is worth mentioning that given the nature of how query vectors are established, the queries can be indeed done in natural language. An example in Figure 4 shows the most semantically related issues returned given the arbitrary natural language query. Such queries will be much more accurate and valuable when the training corpus is big. In our case, we only have 71 issues (for one change review cycle) consisting of 78 terms. If, for instance, the BCF knowledge regarding change management is extracted from 10 projects, each having just 100 change issues, 1000 issues could be processed and vectorised semantically in the database, and used as suggestive knowledge augmentation for future engineers' decisions. The benefit is that the system can handle datasets of change cases that are ever growing from project to project and the latent semantic structure of the data also updates accordingly. This is comparable to how a human engineer may accumulate experience over time through experience, and apply the lessons learnt to new decisions and predictions to avoid problems.

Currently, with only 71 issues, consisting of 78 terms (4430 characters, thus supposedly 4.3 kB of data), it is remarkable how intuitive semantic relationships between terms and documents can be inferred through the proposed semantic system. This is noteworthy in sight of the association of machine learning techniques with “big data”, where large datasets (in the order of Gigabytes) apparently needs to be mined to train algorithms. Our proposed technique demonstrates effective results even given small sets of data, available in all segments of the construction context.

4.2 Extended BIM possibilities

It is useful to enrich the textual comments used in this study with some further explicit contextual information. They can be added in the sentences in the form of “keywords” or even include ontological entities from IFC schema. The sample sentences would contain not only more information, but also it would allow the learning algorithm to use the information that is available in the BIM models.

The BCF specification makes it possible to obtain a list of identifiers of entities that are related to a BCF issue. In principle, those identifiers can be used to fetch information from the relevant BIM models. This can be done either manually using a BIM tool or using a program to automate the task. In practice, the relevant identifiers are listed in the viewpoint.bcfv files, the corresponding entities can be marked visible or selected using tags. The viewpoint.bcfv files further specify a camera view inside a BIM model. That makes it possible to use standard 3D graphics processing to calculate which parts of the model are visible for the camera. For example, ray tracing (Glassner, 1989) can be used. The parts could be used to infer the affected BIM entities. They could, in turn, be used to enrich the issue descriptions, so as to allow these BIM entities to be included in the latent semantic analysis.

Additionally, if we had a series of changes in the model that has taken place after the BCF is time stamped, and possibly before the next BCF prompt, the series can automatically convey information of the actual changes that were imposed upon the BIM model, following the requests in the previous BCF issues. In principle, BIM tools could keep track of changes in the model, which is possible if the BIM tool can be changed. Otherwise, a more generic way is to export the model versions into IFC/RDF representation (Pauwels & van Deursen, 2012) and use algorithms presented in Oraskari and Törmä (2015) to provide change sets of added and removed RDF triples. The triples include identifiers of entities in the model and they have location in the graph. It makes it possible to deduce the affected entities in the BIM model and the triples express the changes made. The change description could be used as a context for a BCF issue comment. In other words, these change events identified can be attached to the change requests in BCF issues, therefore establishing the possibility for the semantic retrieval of not only change requests, but as well as the change actions taken in response. For instance, the natural language query in Figure 4 may be used to retrieve similar past issues, and if the past issues also include the following change events, it poses a suggestive function to respond to future change requests/prompts, be it in BCF or otherwise. This is especially useful for a novice engineer who may query possible change risks, and the system adds an additional layer to suggest the possible actions to be taken in response to the risk, thus catering both for the prediction (change avoidance), as well as mitigation (change cost alleviation) functions.

5. Conclusions

Design change management poses a huge challenge in any civil engineering project. This study sets out to investigate how to better manage design changes in a BIM integrated environment, in sight of the growing adoption of BIM in typical workflows. In particular, this study demonstrates how data from existing BCF files in the BIM environment can be extracted and semantic inferences made to predict future changes given natural language queries by the user. Natural language is particularly interesting as it is able to capture specifics, as well as fuzzy semantic dimensions, required to describe complex change prompts and issues. The proposed method uses data extraction techniques to obtain textual data from BCF issues, processes the texts via latent semantic analysis and establishes a semantic knowledge repository, which can be flexibly queried by future users. The types of semantic inference is shown and discussions are made on how retrieval results can be interpreted to illustrate the reasoning of the technique. This semantic knowledge repository, in the form of vectorised terms and issues, is to some extent an analogy for how human tacit experience in change prediction and mitigation can be captured and presented in an intuitive manner, that is also both scalable in size and flexible for multiple domains. The computational technique thus simplifies the complexity of knowledge/information modelling, by harnessing the properties of linear algebra decomposition, thus enabling an inductive logic to be applied to complex, unstructured data. It is remarkable that with as little as 4.43kB of training data in this exercise, intuitive semantic associations can be inferred and thus used for matching intuitive concepts, otherwise tacit in expert reasoning. On a fundamental level, the simplicity and effectiveness of the prototype democratizes artificial intelligence for construction contexts, and shows the possibilities beyond natural language texts to include specific BIM or IFC entities, made possible by innovations in linked-data and ontology-related research. Ultimately, the effectiveness of the system can be enhanced given more data over time, which also caters for the adaptability of the system by considering the shifting trends of the industry or domain with respect to how design changes are managed.

Construction Supply Chain Coordination Leveraging 4D BIM and GIS Integration

Abstract

Construction supply chain management (CSCM) is challenging and information demanding due to the fragmentation of project participants and one-of-a-kind nature of construction projects. Construction supply chain coordination is the core issue to improve the performance of CSCM. Coordination of construction supply chains requires tracking of construction activities, an integrated platform, and certain coordination mechanisms. Some researchers have suggested the use of building information modeling (BIM) to monitor construction activities and manage construction supply chains. However, since material warehousing and delivery are mostly performed outside construction sites, a single BIM model is not sufficient to coordinate the entire construction supply chains over a wide region. In this research, an integrated framework was developed based on 4D BIM and geographic information sciences (GIS) for coordination of construction supply chains between the construction site and other project related locations, such as supplier sites and material consolidation centers. The integrated platform was used to solve three critical problems in CSCM, namely selection of supplier sites, number of deliveries, and the location-allocation of consolidation centers for multiple sites using information from BIM and GIS. The framework will be demonstrated using scenario examples in San Francisco.

Keywords: Construction supply chain management, Building information modeling, GIS, Coordination mechanism, Lean construction

1. Introduction

The construction supply chain is a converging supply chain directing all materials to the construction site where objects are assembled from incoming materials. Moreover, the construction supply chain is a temporary supply chain producing one-off construction projects. As a result, the construction supply chain is typified by instability, fragmentation, and especially by the separation between the design and construction of built objects. A closer look at the construction industry shows that a considerable amount of waste produced is rooted in poor management of the material supply chain (e.g. delivery services, inventory, communications). Therefore, since the end of the 1980s, the construction industry has seen the launch of a number of CSCM initiatives.

While there is abundant literature on the design, application and evaluation of construction supply chains, the effective use of geographic data in CSCM has not been fully explored. Jadid and Idrees (2013) argued that traditional SCM had no effective mechanism for locating the nearest suppliers for particular materials. Li et al. (2003) pointed out that location-related information plays an essential role in all kinds of business activities, including an E-commerce system for construction activities. GIS is potentially applicable in construction supply chain management to manage spatial information, and provides an ideal solution to manage costs of transportation and market analysis in the overall E-commercial activities. Irizarry et al. (2013) revealed that the traditional way of managing the supply chain with a focus on the site activities (e.g. to reduce costs or the duration of site activities) or on the supply chain itself (e.g. to reduce logistics costs, lead time and inventory) are not adequate anymore and the processing of information for any other section of the supply network using a BIM and GIS integration framework should be clearly studied.

In this research, three problems are identified as only solvable when considering geographic data in the CSCM system. The first problem is the selection of supplier, when the supplier with the lowest cost may not be the nearest supplier. The second problem is to determine the number of deliveries, as there is an adverse relationship between the number of deliveries and inventory cost. Increasing the number of material deliveries will decrease the need for onsite inventory, but it will increase the fees for delivery. The third problem is the location allocation problems for consolidation centers (CC) for construction material for multiple sites. an integrated framework was developed based on four-dimensional BIM (4D BIM) and GIS for the coordination of construction supply chains between the construction site and other project-related locations, such as supplier sites and material consolidation centers. 4D BIM provides schedule information for pull-based CSCM and material demand information, while GIS provides related geospatial data such as delivery distance estimation, material tracking and consolidation center information. The objective of the integrated framework is to minimize costs in construction supply chains by generating optimized solutions for selecting supplier sites, determining the number of deliveries and allocating consolidation centers. Information from 4D BIM is used to determine the construction activities and their material demands. A bidding and requisition module is developed based on GIS to allow suppliers to bid for material orders. Based on the actual travel distances from the supplier sites to the construction sites, the integrated framework calculates the delivery fees that are used to optimize three solutions, namely the supplier selection, the number of deliveries and the allocation of consolidation centers.

2. Literature Review

The study of supplier selection is an important part of SCM research. The information in 4D BIM can be used to determine the products and quantities to be ordered. There are extensive studies on supplier selection and inventory lot sizing. Kasilingam and Lee (1996) examined the development of a chance-constrained integer programming formulation to address the vendor selection problem and the determination of order quantities to be placed. However, in their model, the unit cost of each item already includes the transportation cost and does not change according to delivery distance. Jayaraman et al. (1999) presented a mixed integer programming formulation of the supplier selection problem. The model could help an organization choose an optimal set of suppliers, taking into account quality requirements, restrictions in storage and production capacity, and production lead time. However, this study did not consider the delivery fees of products while it is estimated that transportation costs account for 10-20% of construction costs (Shakantu et al., 2003). In this regard, the locations of suppliers and construction sites and transportation distances should be retrieved. Thus, a GIS should be introduced in the CSCM process to support the wide range of network/spatial analysis used in the supply chain coordination process.

The setting up and allocation of consolidation centers are seldom studied in CSCM. Kasim (2008) reported the setting up of consolidation centers in an airport terminal and airfield modification project. The implementation of the consolidation center ensured that the correct construction materials were efficiently delivered to the correct construction site at the required time. In this method all materials are transported to the consolidation center before distribution to the construction site, in order to avoid the congestion of materials at the site loading area. The implementation of the consolidation center also solves the problem of lack of storage space at the construction site. However, to our knowledge there is no more literature concerning the design and allocation of consolidation centers in the construction industry. In the area of SCM for the manufacturing industry, there is a rich body of literature focusing on the design and operations of consolidation centers. Song et al. (2008) developed coordination mechanisms for shipments while considering the product release times at the source locations, the latest arrival times at the destinations, the routes and options used for the transportation, the storage cost at the consolidation center, and the consolidation policies (as early as possible or as late as possible). The objective of the study was to minimize the sum of the transportation cost and the storage cost through optimizing shipment coordination. While there are a lot of studies on the coordination mechanisms in consolidation centers, the allocation of consolidation centers has not been studied. Specifically, we will show that consolidation centers are cost-effective when onsite inventory is limited. Thus the problem remaining is that given project information and supply chain network, how is it possible to determine the location of consolidation centers so that the cost for inventory and delivery is minimized. In this regard, the project information can be retrieved from BIM, and the allocation problem can be solved using network analysis functions in GIS.

3. Construction Supply Chain Management Problems

3.1 Supplier selection and finding the optimal number of deliveries

By introducing GIS in the problem setting, we added one more constraint to the CSCM problem, which is delivery distance from different suppliers to construction sites. With this new setting, we first formulate the CSCM problem in mathematical form and then discuss solutions to the problem.

Some notations used in the problem formulation (capital letter plus subscript) are introduced here:

Construction Sites: CS [CS_a,CS_b,CS_c]

Activities in construction retrieved from BIM: A[A_{ai},A_{aj},A_{ak}]

Starting time of activity A_{ai}: ST[ST_{ai},ST_{aj},ST_{ak}]

End time of activity A_{ai}: ET[ET_{ai},ET_{aj},ET_{ak}]

Task duration retrieved from BIM: D[D_{ai}, D_{aj}, D_{ak}]

$$D_{ai}= ET_{ai} - ST_{ai} \tag{1}$$

Quantity of required material used in each task: Q[Q_{ail}, Q_{aim}, Q_{ain}]

Supplier Sites SS[SS_l,SS_m,SS_n]

Onsite inventory for each material I [I_l,I_m,I_n]

We assume that all the materials are delivered right on time in the ordered amount, so in a case where only one order is needed, the normal ordering time will be related to the lead time of material delivery. For each construction activity, at the beginning of material purchasing, based on information from BIM (material demand and scheduling information) and GIS (geolocations, true travel distances), we want to find an arrangement of ordering of material that aims to:

Find the supplier site SS_l for activity A_{ai} (as ordering cost OC (Irizarry et al., 2013), material price and delivery cost may vary according to supply and the location of suppliers)

Compute the optimal number of orders N for each activity A_{ai} considering inventory cost, delivery cost and ordering cost

Following the principle of Just-In-Time, the ordering cost can be calculated as:

$$OC = OCR \times Q_{ail} \tag{2}$$

where OC is Ordering Cost, and OCR is ordering cost rate proportional to the quantity of material ordered.

The delivery cost can be calculated as:

$$DC_N = \begin{cases} N \times DD_{al} \times DFT_l \\ DD_{al} \times DFT_l \end{cases} \tag{3}$$

where N is the number of deliveries, $N >= Q_{al} / CP_l$, CP_l is the capacity of one delivery (i.e. number of material l that can be delivered each time)

The material cost can be calculated as:

$$MC = Q_{ail} \times P_{Sl} \tag{4}$$

In an ideal case, the onsite inventory is reloaded when the inventory level hits zero. In this case, the inventory cost can be calculated as:

$$IC_N = \begin{cases} \dfrac{QD_{ai}}{2N} \times ICR \\ \dfrac{I_{ai} D_{ai}}{2} \times ICR \end{cases} \tag{5}$$

Where ICR is the inventory cost rate, proportional to the inventory level.

So the problem of selecting supplier site and finding the optimal number of deliveries becomes finding S and N to:

$$Min(OC + DC + MC + IC_N) \tag{6}$$

Subject to constraints of onsite inventory and the delivery capacity of suppliers.

$$Q_{ail} / \mathrm{N} \le \mathrm{I}_\mathrm{l} \tag{7}$$

$$Q_{ail} / \mathrm{N} \le DC_\mathrm{l} \tag{8}$$

Since only a finite number of potential suppliers and finite discrete number of orders are considered in the solution, to find the solution for (6), a Monte-Carlo simulation is used to find the value of S and N.

3.2 Allocation of consolidation centers using BIM-GIS integration

Kasim (2008) investigated two construction projects involving the use of consolidation centers. It is revealed in this study that the implementation of consolidation solved the problem of a lack of storage space at the construction site, provided a solution for improvement of site security and safety, reduced congestion from construction traffic within the airport perimeter, improved delivery reliability, and there was an associated environmental benefit, improved workforce efficiency, and reduced materials losses. However, Kasim (2008) did not provide details as to why consolidation centers should be set up and how to allocate them. In this study, we first show how consolidation centers can reduce the cost of inventory and delivery, and solve the allocation problem of consolidation centers using GIS.

In Equation (6), since Ordering Cost and Material Cost are fixed for a given amount of material, the flexible part of costs related to geolocations of facilities are:

$$LoationSensitiveCost = DC + IC_N \tag{9}$$

which can be further elaborated as:

$$LoationSensitiveCost = N \times DD_{al} \times DFT_l + \frac{QD_{ai}}{2N} \times ICR \tag{10}$$

In a congested site (when *I* is small), we assume:

$$I_{ail} = Q_{ail} / \mathrm{N} \tag{11}$$

Then:

$$LoationSensitiveCost = \frac{Q_{ail}}{I_{ail}} \times DD_{al} \times DFT_l + \frac{I_{ail} D_{ai}}{2} \times ICR \tag{12}$$

The tipping point where cost is at minimum is:

$$I_{ail}' = \sqrt[4]{\frac{8 \times Q_{ail} \times DD_{al} \times DFT_l}{D_{ai} \times ICR}} \tag{13}$$

This equation reveals the relationship between inventory space and project conditions. I_{ail}' can be seen as a critical inventory value. If onsite inventory $I_{ail} < I_{ail}'$, the total cost will increase rapidly. In a construction market where *DFT* is small, this critical value I_{ail}' is small as well. This implies that if contractors can find suppliers nearby, the inventory level on construction sites could be smaller. However, if some suppliers for some materials are far away, then I_{ail}' is large, which implies that site inventory must be large as well; otherwise cost will increase dramatically. Therefore, the setting up of consolidation centers is essential.

Finding the optimal location for a consolidation center is challenging, as this problem is affected by the location of construction sites, supplier sites and the traffic network itself. Assume that we set up a consolidation center Z, with distance to site *a* as D_{Za}, to supplier *S* as D_{ZS} (distance as actual travel distance calculated from GIS). The capacity of inventory of Z for material *l* is I_{Zl}.

It is reasonable to assume that:

$$I_{Zl} > I_{ail} \tag{14}$$

With a buffer zone, the total cost of delivery and inventory can be calculated as:

$$\begin{aligned} TotalCost &= \left(\frac{Q_{ail}}{I_{ail}} \times DD_{al} \times DFT_l + \frac{I_{ail} D_{ai}}{2} \times ICR\right) \\ &+ \left(\frac{Q_{ail}}{I_{Zl}} \times DD_{Zl} \times DFT_l + \frac{I_{Zl} D_{ai}}{2} \times ICR\right) + ZC \end{aligned} \tag{15}$$

where ZC is the cost to set up the consolidation center.

Denote

$$F_{aiZ} = \frac{Q_{ail}}{I_{ail}} \times DFT_l \tag{16}$$

$$F_{SiZ} = \frac{Q_{ail}}{I_{Zl}} \times DFT_l \tag{17}$$

$$F_Z = \frac{I_{ail} D_{ai}}{2} \times ICR + \frac{I_{Zl} D_{ai}}{2} \times ICR + ZC \tag{18}$$

Then

$$TotalCost = F_{aZ} \times DD_{al} + F_{SZ} \times DD_{Zl} + F_Z \tag{19}$$

Since F_Z is fixed, F_{aZ} and F_{SZ} are cost ratios proportional to the distance between a consolidation center and site and supplier. F_{aZ} and F_{SZ} are only affected by project parameters. Consider a consolidation center serving different construction projects. For a project, the total cost ratio factor is:

$$F_a = \sum_{i=1}^{m} F_{aiZ} \tag{20}$$

where *m* is the total number of activities

For multiple projects, the total cost for setting up a consolidation center is:

$$TotalCost = \sum_{a=1}^{n} F_{aZ} \times DD_{al} + \sum_{S=1}^{k} F_{SZ} \times DD_{Zl} + F_{Z} \tag{21}$$

So the problem of finding an optimized location for a consolidation center becomes:

$$\min\left(\sum_{a=1}^{n} F_{aZ} \times DD_{al} + \sum_{S=1}^{k} F_{SZ} \times DD_{Zl} + F_{ZZ}\right) \tag{22}$$

We can use Equation (21) to evaluate different candidate locations for setting up consolidation centers. Or, if certain areas are considered for consolidation centers, we can turn it into a discrete simulation problem using point sampling in the given area. Later we use a case study to show the work flow for finding the optimal location of consolidation centers.

4. Framework Development and Validation

4.1 Framework Description

The construction supply chain management process requires massive data input as well as reliable analytical functions to provide management decision-making. Therefore, a CSCM framework should at least have three layers: the data retrieval and storage layer, the analysis layer, and management interface. The use of 4D BIM and GIS provides opportunities to minimize the manual efforts for data input, and all data can be stored in the geodatabases in GIS with customized analytical functions. A comprehensive 4D BIM model stores the full range of information about activities with associated material demand and duration. In the proposed BIM-GIS integration CSCM framework, a detailed quantity takeoff of the construction project is executed at the early stage of procurements from BIM, and GIS is used to support the wide range of analysis functions to provide decision-making in the CSCM process. The data from BIM are exported to databases linked to GIS, which will be used for analysis. The manually input data are mostly related to the quotations for material from multiple suppliers and changes in current project plans. It is possible that some of the construction activities, for example scaffolding, are not present in the 4D BIM. In this case, manual inputs of such activities along with their material demand and time duration are needed. In the proposed CSCM framework, the data storage, analysis and decision-making are performed in a GIS system. GIS has the capacity to store massive amounts of data and the ability to access fundamental analysis tools such as route finding for delivery cost analysis.

The architecture of the proposed CSCM framework is shown in Figure 1. The data input layer consists of data sources (BIM, GIS and user input) and data retrieval functions. The retrieved data are used by various analysis functions such as cost analysis and network analysis to support solutions of CSCM problems.

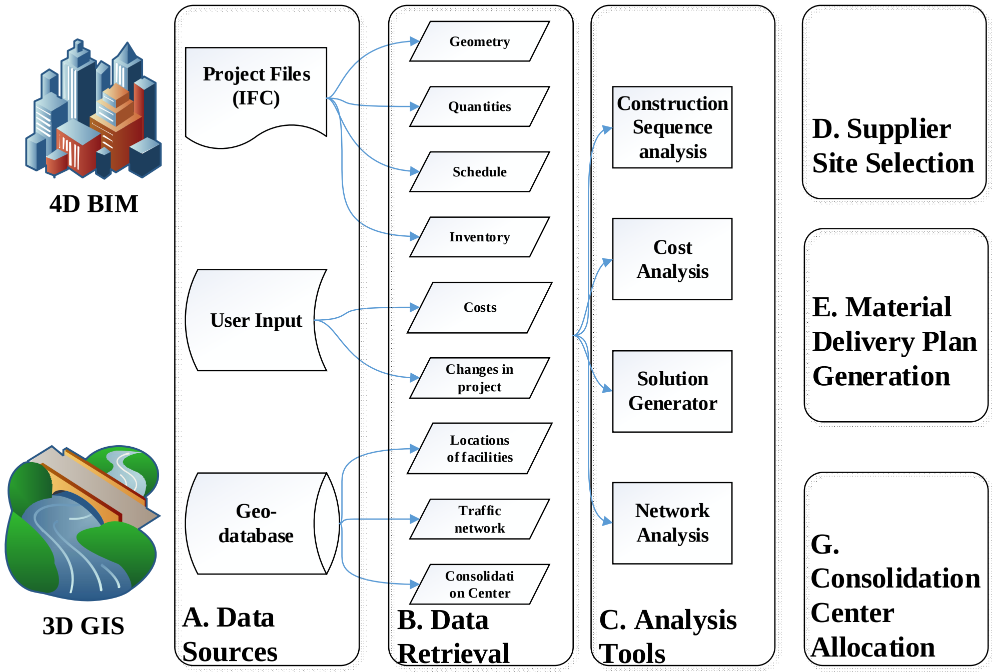

Figure 1 Framework Overview

4.2 Validation of Framework

In order to demonstrate the BIM-GIS integration CSCM framework, we use the road network data in San Francisco, USA as a base map. A five-storey building construction project is used to demonstrate the problem of the selection of suppliers and number of deliveries. Specifically, we show that the delivery fees and inventory fees are critical in calculating the total cost incurred in the supply chain. Selection of material supplier cannot only rely on the unit prices or nearest delivery distances. We use another supply network with five construction sites and 15 suppliers to demonstrate the location-allocation problem of setting up consolidation centers.

We first validate the effeteness of BIM and GIS integration in supplier selection and number of order optimization, In the design phase, a 3D model of the building was created using BIM software Autodesk Revit. The schedule information was added to the BIM later by linking to project databases using Navisworks. The generated 4D model was exported to IFC format, which was then parsed by our developed parser. All the relevant information for CSCM was finally exported to data tables in the GIS system, which is based on ArcGIS.

We used the material Brick (230 mm) in Level 1: Interior wall construction to demonstrate the material selection process. The potential suppliers that are willing to supply this material and their location along with the location of the construction site is shown in **Figure 2**. The GIS network analysis function allows route finding with the shortest distance, which is used for delivery fee estimation. The route finding results are also shown in **Figure 2**. The manual input function is used to enter the information of different potential suppliers. The delivery distances are obtained from the network work analysis to represent the actual delivery distance. The cost analysis function in the framework computes the delivery cost and onsite inventory cost for every potential supplier considering different numbers of deliveries. In order to find the suppler with the lowest cost, the total costs were analyzed. The results are shown in Figure 3.

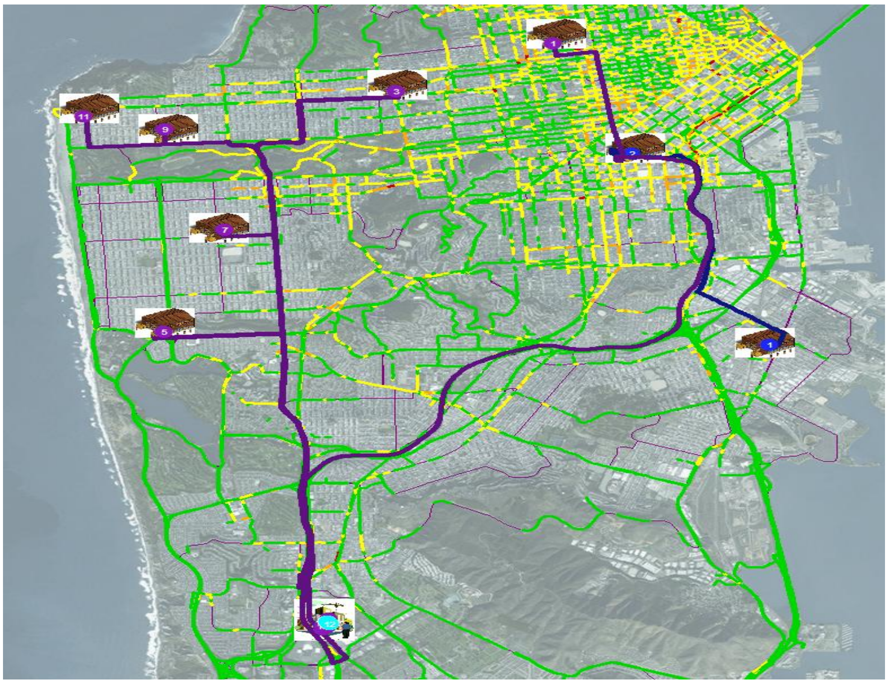

Figure 2 The route finding to calculate delivery fees

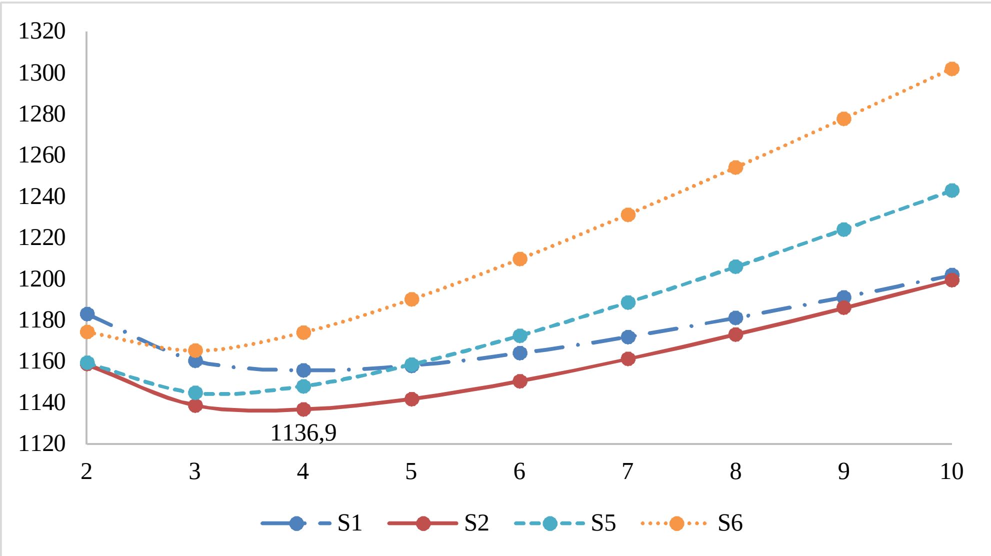

Figure 3 Total cost analysis for different suppliers and different number of deliveries

The second case study considers a supply chain network consisting of five construction sites and 15 suppliers in different locations supplying different material. The road network data in San Francisco are used here to calculate delivery costs. The first step of the consolidation allocation problem is to determine the cost ratio F_{aZ} and F_{sZ} using Equations (16) and (17) with data from these five projects.. With the calculation of F_{aZ} and F_{SZ} from project data, the allocation problem of consolidation centers has been transformed to a location-allocation problem in GIS. The process of consolidation center allocation starts from generating unified distributed sample points on the base map. Here we set the resolution of sample points to 100 meters. After acquiring the sample points, the cost for each sample point is calculated using Equation (21). After calculation of each sample point, it is possible to generate a cost map which represents the cost of setting up a consolidation center in a given location, as shown in *Figure 4*. The location with the lowest cost after setting up the consolidation center is shown by a star symbol. *Figure 4* also provides guidelines for project managers to find an optimal location for setting up consolidation centers. It is noticeable that near the optimal location in *Figure 4*, there is a zone with a consolidation center cost. The reason is that in this area the traffic network becomes less dense, and the transportation cost will increase dramatically in this area. This is more evidence that GIS network analysis should be used in calculating delivery costs.

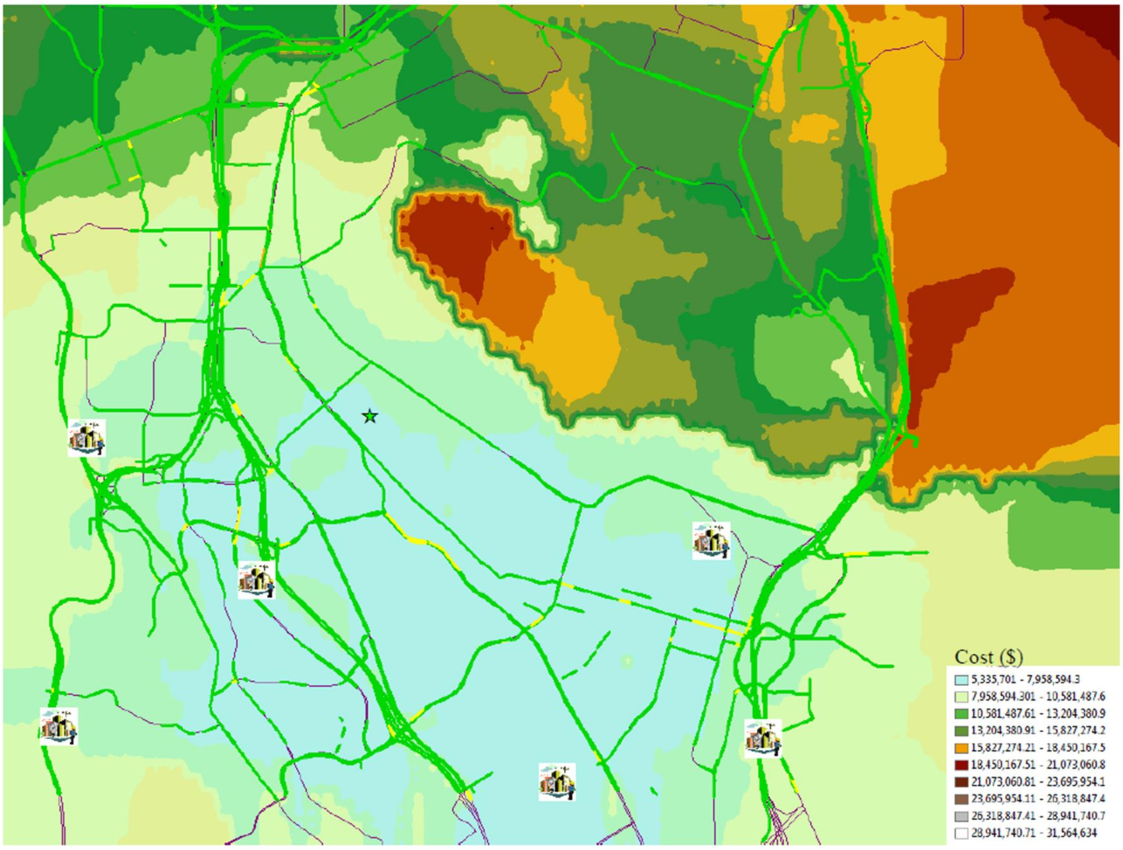

Figure 4 Finding an optimal consolidation center location

5. Conclusion

By using data from BIM and GIS, we formulate the three problems in mathematical form and provide solutions to these problems. Specifically, we make the following contributions to these three problems: firstly, we prove that selection of suppliers should not only consider factors such as delivery distance or unit price solely. Secondly, we should understand that the number of material deliveries has impacts on the total invoice cost of the supply chain, and we provide a Monte-Carlo Simulation solution to this problem. Thirdly, we prove the necessity of setting up of consolidation centers given the congested sites and long delivery distances using mathematical modelling. And finally, we provide a solution to the location-allocation problem of the setting up of consolidation centers. It is noticeable that all the contributions could not be made without the data inputs and analysis functions in BIM and GIS.

Abstract

The successful implementation of new technologies plays a major role in the economic growth of the country. Building Information Modelling (BIM) is considered to be one of the most recent technologies introduced within the Architecture, Engineering and Construction (AEC) industry. However people who are involved in BIM based construction projects are struggling to achieve their project outcomes due to not having enough knowledge and skills to work with this new technology. The main aim of the paper is to explore how knowledge can be distributed among the project participants to acquire the appropriate knowledge and skills during the implementation of new technologies. Connectivism theory has been adopted in this study to understand the distribution of knowledge and the learning process in the BIM construction projects. Following that, data was obtained through conducting the interviews with the professionals who have used BIM in their construction projects. The collected data focused on the knowledge acquisition in the implementation of BIM technology. In addition the learning process within BIM construction projects was also looked in terms of achieving the knowledge and appropriate skills which is essential to support the various stakeholders to efficiently use BIM technology.

Keywords: Building information Modelling (BIM), Connectivism, Construction, Learning, Skills, Knowledge.

1. Introduction

Productivity in a country influences in determining the competitiveness for the businesses and wages for people at work (UKCES, 2015). According to HM Treasury (1988) productivity is ‘a fundamental yardstick of economic performance’ however the UK significantly lags the best performing OECD countries due to poor productivity records (Allen, 2015). The construction industry has been one of the main engines of UK economic growth nevertheless still UK’s productivity gap is driven back due to skills challenges faced in the construction industry. One of the reasons for the construction industry to face these skills challenges is due to its resistance to adopt new technologies. However, the purpose of introducing these new technologies is to improve productivity (UKCES, 2015) which also leads to alter and create quicker ways to deliver goods and services (Corney, 1997), high performance work practices (Bresnahan *et al*, 2002) and economic well-being (Hansushek and Woessmann, 2008). The studies in construction industry highlight the skills challenges as a major barrier in improving productivity (UKCES, 2015). Supporting this construction skills report (CITB, 2004) suggests that employer's skills requirements need to be taken into consideration to enhance efficiency of the construction projects to cope up with continuous changes in construction industry. Even though skills challenges have been highlighted in many construction studies lack of knowledge is the key factor that leads to these skills issues in the construction. Therefore distribution of knowledge is important within the project participants to acquire the appropriate skills to achieve the project outcomes. Therefore the aim of the study is to explore how knowledge can be distributed to acquire the appropriate skills during the implementation of new technologies within the construction industry.

2. Literature Review

2.1 Importance of skills and knowledge in construction industry

Acquiring appropriate skills encourages economic performance (O'mahoney and de Boer, 2002), innovation and flexibility (Leiponen, 2005). Moreover it helps to determine individual's employability to productivity (HM Treasury, 2006) and business profitability (Bosworth, 2013). This has been highlighted in Sami's (2008) study where he claimed more attention is needed to reskill, multi-skill or upskill professionals in construction industry to successfully achieve project targets. However, skills must be grounded and the meaning might differ according to its reference to context (Spencer, 1990) as shown below.

Table 1: A summary of the skills definition

Author/s	*Year*	*Definition*
Becker	*1964*	*Capabilities of workers that they acquire outside the work place and the job on and the capabilities have meaning only when they translate into productivity and job rewards, such as earning.*
Mangham and Silver	*1986*	*Dexterity and knowledge of the workforce.*
Wood	*1988*	*Expertise that describes the quality of overt behaviour in a particular job.*
Odusami	*2002*	*Ability to perform the task well or better than average. Skills can also be described as the ability to translate knowledge into action.*
Boyatzis et al	*2002*	*Emotional intelligence which includes both self-awareness of one's emotional reaction to specific events, situations and unexpected circumstances and the coping strategies that may be developed to handle those feelings and concomitant reactions effectively.*
HM Treasury	*2006*	*Capabilities and expertise in a particular occupation or activity.*

These definitions state that skills are centred on various different factors such as capabilities, people, physical and practical activities. However, Odusami's (2002) definition is adopted in this study which states that skills are not only about completing the task better than average but also translating the knowledge into action. The UK Commission's Employer Skills Survey 2013 (UKCESS 2013) and CITB (2015) have discussed about the skill deficiencies and highlighted the need for people with appropriate skills and knowledge. Moreover these studies show that knowledge should be developed along the process to acquire the appropriate skills to complete the task. Therefore to resolve this current situation there is a need for people who are capable, agile and able to respond to the challenges presented by new technologies.

2.1.1 Skills gaps, Skills shortages and Latent Skills shortages

Current skills challenges within the construction industry are mainly due to skill gaps, skills shortage and latent skills shortages. Skills gap happens due to employees in workplace not having appropriate skills to achieve the organisation's objectives (Campbell *et al*., 2001). On the other hand skills shortages also occur when there is shortage of skilled people in labour market to fill in the vacancies (Barnes and Hogarth, 2001).Campbell *et al* (2001) argued that there are more skills gaps in construction industry and Bloom *et al* (2004) believed skills shortage plays a significant role towards the economic growth. Apart from this, latent skills shortage is also an issue, which is a situation where establishment fall short of what might be considered good or best practice. This might be the reflection of low skills or poor business performance, even though there is no report of recruited problem or skills gap (Hogarth, 2001). Generally this occurs when the organisation starts to manage a project with existing skills without being aware of necessary skills. Chan and Cooper (2006) claimed that this situation is more frequent in construction industry because construction practitioners often do not know what skills they need to produce to achieve their project outcomes. Therefore skills challenges are problematic to move towards the digital world. Building Information Modelling (BIM) is a recent technological development introduced within the AEC industry to integrate processes throughout the entire project lifecycle (Aouad and Arayici, 2010). Moreover BIM also helps to drive a step-change to increase the productivity of the construction process, tangible quality improvement in the end product and associated reduction in true cost (O'Rourke, 2015). Recently the UK government has mandated to use BIM in public sector projects since 2016 (Cabinet Office, 2011) therefore construction companies have slowly started to adopt BIM in their construction projects.

2.2 Building Information Modelling (BIM)

There are many ways of looking at BIM as shown in below in Table-2; this study has adopted the National BIM Standard (2014) definition that looks from a knowledge point of view. Here BIM is about unlocking knowledge and insight, creating the platform for more efficient and sustainable solutions through sharing the information. While the information is shared through BIM, knowledge needs to be distributed among the project participants for the decision making to achieve the project targets. Therefore this paper is looking at how knowledge is shared and distributed among the project participants using BIM in construction projects. Furthermore Connectivism theory has been adopted in this paper to study the knowledge distribution and learning process to achieve the project outcomes.

Table 2: A summary of the BIM definition

Author/s	*Year*	*Definition*
Autodesk	*2007*	*A building design and documentation methodology characterized by the creation and use of coordinated, internally consistent computable information about a building project in design and construction.*
Eastman et al	*2008*	*A computer aided modelling technology for managing and generating building information, with the related processes of producing, communicating, and analysing building information models.*
Vanlande et al	*2008*	*The process of generating, storing, managing, exchanging, and sharing building information in interoperable and usable way.*
McGraw Hill	*2009*	*The process of creating and using digital models for design, construction and or operations of projects.*
Nisbet and Dinesen	*2010*	*A digital model of a building in which information about a project is stored. It can be 3D, 4D (integrating time) or even 5D (including cost) – right up to 'nD' (a term that covers any other information).*
National BIM Standard (NBIMS)	*2014*	*A digital representation of physical and functional characteristics of a facility and a shared knowledge resource for information about a facility forming a reliable basis for decisions during its life-cycle; defined as existing from earliest conception to demolition.*

The impact of technology on humanity continues to grow in greater prominence which allows entering into a new form of 'knowledge society'. Moreover Bloom *et al* (2004) claimed that even though new technologies are out there, significant amount of knowledge and skills are not there to work with those new technologies. Therefore, there is a need for a suitable learning theory to increase human cognitive functioning to cope with this changing society. Connectivism is a theory introduced by Siemens and Downes (2009) for the digital world.

2.3 Connectivisim

Connectivism is an application of network premises that define both knowledge and process of learning. In this, knowledge is defined as a particular pattern of relationship whereas learning is defined as the creation of new connections and patterns along with the ability to maneuver around existing networks/ patterns. Moreover Connectivism focuses on the presence of technology as a part of cognition and knowledge. Previously philosophers and theorist had different views of learning where they failed to address the learning that occurs outside the individual and to discuss the learning process that happens among the group of people or organisation. According to Sieman (2004) Connectivism is an intriguing development where learning happens with the knowledge and perception gained through the additional personal network. Even though it is impossible to experience everything, there is an opportunity to develop the knowledge through sharing and collaboration. In this digitalised world there is a necessity for further knowledge to understand the amount of the data available to complete specific tasks. Therefore Connectivism which is an actionable knowledge can be considered as a learning theory, where understanding of where to find the knowledge is more important instead of answering how and what the knowledge incorporates. According to Siemens (2005) and Downes (2005) Connectivisim theory is appropriate to handle this digital world where its main principle is linking ideas and connecting people and information sources. However opposing this Duke *et al* (2013) state that in comparison to existing learning theories there is an overlap of ideas and therefore this cannot be accepted as new learning theory.

Learning process in Connectivism is not entirely focused on the control of the individual and more focused on connecting the specialised information sets and enable people to learn more than their current status of knowing. In this process information flow is a key factor where new information will be continuously acquired. In Connectivism, the starting point for learning occurs when knowledge is actuated through the process of learners and then connecting and feeding information into learning community. This begins with an individual and the personal knowledge is included of a network which feed into organisations and institutions, which in turn feed back into the network, and then continue to provide learning to individual. This cycle of knowledge development allows the leaners to be up to date in their field through the connections they have formed. Therefore the fundamental idea of this is about 'Distribution of knowledge'. This means a property of one entity must lead to or become a property of another entity in order for them to be connected; the knowledge that results from such connections is referred as connective knowledge.

The Diagram-1 generated by García (2008) shows the Connectivist view of learning as a network creation process that impacts the way learning is designed and developed. Diagram-1 emphasis the central principle of Connectivism which is the creations with usual nodes (element connected to any vertices, elements, or entities) supports and strengthens existing large effort activities. The integration of learning, knowledge and understanding through the personal extension of a personal network is the key of Connectivism.

Diagram 1: Connectivism: Process of creating network (García, 2008)

Supporting the Connectivism theory several studies have highlighted the importance of the knowledge to successfully complete the tasks. Hutchins (1993) in his study emphasised that knowledge is necessary and it should be distributed among the team to carry out a certain task. Moreover Lave (1988) suggested that relationships between human thoughts, human action and the environment is so tightly interwoven that the mind cannot be studied independently of the culturally organised settings within which people function. On the other hand Nonaka and Takeuchi (1995) believe that the knowledge is created and expanded through social interaction between tacit knowledge and explicit knowledge. Therefore these previous studies have highlighted the important to view the knowledge as composed of connections and network entities to encourage the interaction within these complex systems. This will then lead to the acquisition of appropriate skills to complete a task in an efficient way. From this discussion it is clear that initially knowledge needs to be acquired to gain the appropriate skills to work with the new technologies to achieve the project outcomes. However in this study the knowledge acquisition and learning process is viewed through Connectivism which is appropriate to tackle the rapid technological changes.

3. Methodology

The purpose of this research is to explore how knowledge can be distributed to acquire the appropriate skills when new technologies are introduced to achieve the project outcomes. The situations were analysed through interacting with BIM professionals by asking about their experience and their beliefs. Therefore, qualitative research is adopted as a method best suited to explore the new area. Qualitative research is ‘‘Multi-method in focus, involving an interpretive, naturalistic approach to its subject matter’’ (Denzin and Lincoln, 1994). Moreover this method explores and understands the meaning where individuals or groups ascribe to a social or human problem (Creswell, 2008). The purpose of this qualitative method study is to understand how construction project participants gain their knowledge and acquire skills during technology change within the construction industry.

Data for qualitative study analysis is collected through conducting 10 semi structured interviews with BIM professionals working in the UK construction industry. Firstly BIM professional’s personal opinion about BIM and their BIM experiences were collected. Secondly gaps within BIM learning and their causes were discussed. Finally their learning experience to work with BIM and recommendations for future BIM professionals were discussed. These interviews were conducted to understand the significant of skills challenges and to explore the skills issues in BIM construction projects. Moreover this is also to understand how project participants within the construction projects learn and acquire the appropriate skills to work with the new technologies. During these interviews professionals engaged with BIM construction projects shared their experience and individual perception about the skills related issues faced in BIM construction projects. Two pilot studies were conducted with the construction professionals working with BIM before conducting the interviews. This has assisted to refine some of the questions with appropriate wordings and made the questions clear to the interviewees. This semi structured interviews were conducted across the UK, open-ended questions were employed to get a wider view of the situation and interpretation was done along the way. The data collected through the semi structured interviews explained how knowledge is distributed among the project participants which have then led to the skills acquisition to work with the new technologies introduced in the construction industry.

4. Discussion

The data collected from the interviews clearly show that the way of gaining knowledge has been changed from old days. In the beginning knowledge acquisition is more focused on individual and their influences on the organisation or community. This is supported through one of the interviewee saying ‘‘learning the new software in BIM with the multidisciplinary team helped us to know the difficulties the other employees face’’. Moreover another interview stated that ‘‘Learning process with other project team members provide us a wider knowledge of the new software’’. Therefore it is evident that currently knowledge is not about focusing on the individual but also gaining the knowledge outside the primary knowledge.

As discussed in the literature, skills challenges can be viewed from the point of skills gap, skills shortage and latent skills shortages. BIM professionals indicated that they had to face several skills gaps such as detailing elements in BIM applications and using software , lack of understanding about family creation and detailed understanding, lack of knowledge about in putting the data into the objects and extracting it, process and standard gaps and lack of engineering. This is due to lack of knowledge within the internal workforce. On the other hand latent shortage is also a problem where skills gaps are unrecognised because project organisations have simply coped operationally without the necessary knowledge and skills. In BIM projects latent skills shortages are derived from lack of defined project process, lack of understanding of role and responsibilities and frequent change of software to work with BIM. In addition this happens more often in BIM construction projects due to lack of communications between the project team members. In other words the problems faced by the project team members are rarely discussed among them and in most situations doesn’t not get reported to the top management. This clearly shows that skills gap, skills shortages and latent skills shortages are significant constraints to achieve the project outcomes. Interviewees believe that adopting a new way of gaining knowledge which will then invest in skills acquisition could produce a radical shift in employees’ perception of working which can lead to achieve the project outcomes quickly.

From the interview results a similar situation is observed in BIM construction projects. In BIM construction projects individuals gained their fundamental knowledge through different learning methods such as degree programs/ education, self-learning, basic software training, attending meeting, conference and workshops. However most of them expressed that they were reluctant to use BIM due to lack of understanding of fundamental aspects of BIM enabled technologies. This involved in understanding what BIM is and some of the benefits associated with it. Therefore interviewees suggested that old learning theories that focused only on the individuals needs to be replaced to tackle the new digital world.

After the individuals have gained the fundamental knowledge BIM models were used to share the information among the project participants. In this situation knowledge needs to be distributed among the project participants to complete the necessary tasks through decision making. Therefore after connecting the information resources and people within the BIM construction projects the property of one entity leads to become a property of another entity in order for them to connect and finally connected knowledge will be generated. This will allow all the project participants involved in the project to gain the knowledge and also to understand the current situation of the project. The connections and knowledge gained allow individuals to work effectively and help to avoid mistakes during the projects. While an individual keeps repeating this process again in different BIM projects he/she is expected to become a skilled person with ability to deal with BIM issues in any project setting. However it is important to notice that every project is unique and has its own BIM related skills challenges. Therefore as interviewees suggested more training, engaging with other BIM projects, following BIM courses, getting constant feedbacks about software from the newsletters, understanding the standards and setting out the project goals in the beginning of the project needs to done to achieve better project outcomes.

Therefore this current situation in the construction industry has confirmed that new technology such as BIM has created a new culture and it has reshaped the way of learning. In early days learning theories were only concerned of individual learning whereas currently learning as a function is not under control of learner therefore learning needs to be redesign as two-way process (García, 2008). Actuate known knowledge at the point of application is vital in a learning theory. When the knowledge is needed and not known; it is important to have the ability to plug in the sources to meet the requirements. Connectivism theory is suitable to adapt these circumstances and these interview results highlight the importance of distribution of knowledge within the construction team during the implementation of new technology. Diagram-2 explains the learning ecology in BIM construction projects. Understanding this learning process helps to improve the knowledge as well as makes the individual as a skilled person.

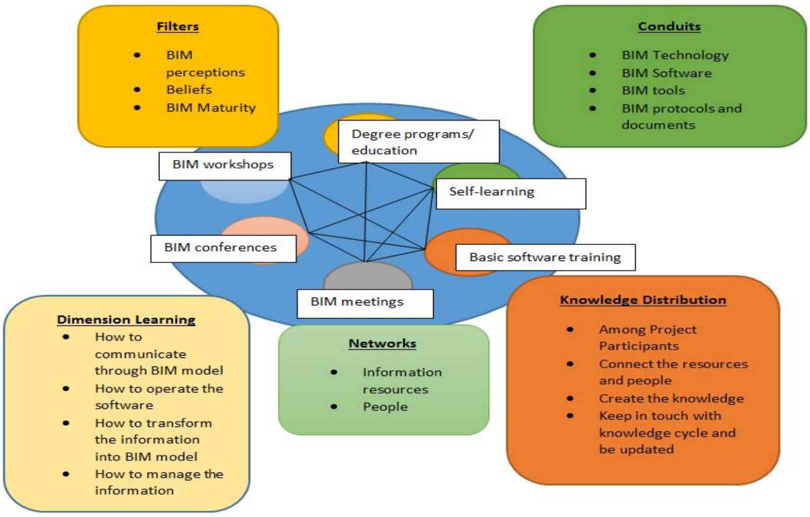

Diagram 2: Knowledge acquisition and learning process in BIM Construction projects

5. Conclusions

The construction industry has been one of the main engines of UK economic growth. Therefore several new technologies are introduced to improve productivity. BIM is one of the recently introduced technologies in the UK construction industry however it is not fully utilised due to the skills challenges. Therefore it is ever more important to focus on knowledge and skills acquisition during the technological change. The study conducted with BIM professionals working in the UK construction industry articulate that a new way of learning and knowledge acquisition needs to be introduced among the project participants to gain the appropriate skills to work with new technologies. Connectivism theory has been identified as a suitable approach to develop knowledge among project participants during the implementation of new technologies. The main principle of this theory is to distribute the knowledge through forming the connections between nodes. Therefore in this situation the knowledge acquired will be both individual learning and the learning outside the primary knowledge. This would help the project participants to achieve the project outcomes efficiently. Since a project participant keeps on accessing back to the knowledge cycle he/ she not only becomes a skilled person but also knows about the up-to date situation of their field. Therefore Connectivism theory is beneficial to understand the use of new technology and to improve the distribution of knowledge among project participants.

Abstract

The paper is a literature review on Big Data in project management of construction projects. The literature shows practical examples of use and potential use of Big Data in construction management research. Big Data has become common as a business term in most businesses. However there is little published management scholarship that tackles the challenges of using Big Data, or even that explores the opportunities for new theories and practices that Big Data might bring about. There is a need for further discussion of the possible implications Big Data can have for construction management research.

The construction process can be studied in a number of dimensions. We structure documented and potential use of Big Data related to construction projects in the time perspective of a typical construction project, from concept preparation and brief, through design and construction to use.

We have identified studies describing Big Data applications and theory. Thematically they fall into three broad categories: 1) New construction equipment; generating, sharing and storing data about use. 2) Data from internal IT systems; such as planning, procurement and Building Information Modelling (BIM) can be utilised. Lastly, 3) people generate an increasing flow of information, which can be useful if handled with care. In combination this addresses the life-cycle from concept to decommissioning. We find that the construction phase appear to have received most attention from researches. We also find that several studies are applicable to more than one phase of a construction project. We find a potential for increased use of Big Data methods and applications within construction. While some data and applications have been analysed in isolation previously, there is a potential to combine different types of data.

Keywords: Big Data, Construction management, Construction projects.

1. Introduction

Big Data has become common as a business term in many industries, like manufacturing, transportation, retail, finance and IT. However, according to George et al. (2014), there is little published literature in management scholarship that deals with the challenges of using big data or even explores the opportunities for new theories and practices that Big Data might bring about. Olsson et al. (2015) discuss how Big Data can be applied in project evaluation and in project management research. But there is a need for further discussion of the possible implications Big Data can have for construction management research.

1.1 More quantitative data available

On a worldwide basis, the total amount of digital data created and replicated each year is expected to increase exponentially up to 2020 (Tien, 2013). This is also the case for data that can be applied in construction projects and management. The principles used in Big Data can also be applied on smaller quantitative data sets. This include data stored in company internal IT-systems.

The definition of Big Data is shifting as software tools become more powerful. Big Data was first defined as data sets whose sizes are too large for commonly used software tools to capture, manage and process within a tolerable elapsed time (Manyika et al., 2011; Tien, 2013; Waller & Fawcett, 2013). However, other definitions will probably be needed, as Big Data is becoming a part of commonly used software tools. The uniqueness of Big Data is the volume, velocity and variety, the three V's (Courtney, 2012; Russom, 2011). The volume refers to the size of data sets, containing a few terabytes to many petabytes. But it is the variety and velocity of the generated data that makes the data sets so big. Variety refers to the variety of sources. In addition, the data are measured and captured in more detail, such a location, time and metadata, giving both structured and unstructured data sets (Russom, 2011; Waller & Fawcett, 2013). The velocity of data refers to the speed at which the data is generated, from being recorded, updated or measured monthly and weekly to more frequent updates such as daily, hourly or continuously (Courtney, 2012). The access to real time or almost real time information makes it possible for a company to be much more agile than its competitors (McAfee & Brynjolfsson, 2012).

Courtney (2012) mentions veracity and value when describing Big Data. Veracity refers to a quality of the data sets, while value is reference to the goal from using the data sets. Veracity is a description of how the measures are reliable, referring to the accuracy and the quality of the generated data. Value refers to turning the Big Data-sets into value for the business. Size does not need to be the only defining part of Big Data, and data can be discussed along more than the mentioned three dimensions. George et al. (2014) points out that there are discussions among practitioners that "big" is no longer the defining parameter, but rather "smart", including a fine-grained nature of the data. The data available to companies are often unstructured (Davenport et al., 2012). The sources of digital data can include retail transactions, security cameras, internally registered data in the organisation, time-stamps, GPS-tracking, sensor-data from instrumented machinery and metavalues of documents.

The main reason to carry out data analysis is to derive information from data, knowledge from information, and wisdom from knowledge (Tien, 2013). And this is the purpose of Big Data. Big Data can give new information and knowledge for decision-making. For instance, Big Data can be used to make more precise predictions, and it follows that better predictions yields better decisions (Jagadish, 2015). McAfee and Brynjolfsson (2012) found that the more companies characterized themselves as data-driven, the better they performed on objective measures of financial and operational results. More and more business activity is digitized, and new sources of information are available (McAfee & Brynjolfsson, 2012). This also applies to the construction industry.

1.2 Use of new quantitative data in construction management

Technology has always been a part of construction management, both in research and practice, but there are new technological demands. This means that new data can support the trend towards an intelligent built environment, covering the whole lifecycle of facilities. Big Data has a potential to generate new insights into the costs, designs and processes of construction management. The aim is to develop tools and approaches for intelligent, efficient and sustainable construction management. Such strategies need to be sufficiently flexible to meet requirements resulting from changes in user-demands, technology and other framework conditions, while at the same time increase efficiency. It is a potential to integrate areas such as Computer Aided Facility Management (CAFM), Building Information Modelling (BIM), and Integrated Building Control and Monitoring Systems (BCMS). Such knowledge can later be utilized in decision making support, innovation of technical systems and in the education and training of project managers.

Monitoring activity across a large, complex construction site is particularly difficult because there are so many moving parts, and because the jobs being performed change frequently. In contrast to production industry, most construction sites are also temporary by nature, often challenging the investment in production infrastructure. Several reports document (including Egan, 1998; Lo et al., 2006; Durdyev & Mbachu, 2011) that construction lags behind other industries such as manufacturing in terms of productivity, and blamed the situation on problems with planning, coordination, and communication.

Modern construction equipment also generates data through usage. Producers of equipment such as trains have for some time utilised equipment life-cycle management data, which are generated in large scales through the period of production, operation, and maintenance. There is broad recognition of value of data and information obtained through analysing it. This type of data is also possible to generate from construction equipment. The exponential growth in this type of data means that new measures are needed for data management, analysis and accessibility. MIT Technology Review (2015) reports on the use of drones to monitor construction progress. Once per day, drones automatically patrol the work site, collecting video footage. The footage is then converted into a three-dimensional picture of the site, which is fed into software that compares it to computerized architectural plans as well as the construction work plan showing when each element should be finished. The software can show managers how the project is progressing, and can automatically highlight parts that may be falling behind schedule.

A discussion has emerged about use of Big Data and performance measurement for micro management and continuous monitoring of employees. Using drones to monitor activity continually can be controversial. Such controversies have occurred related to monitoring of employees in other sectors. As reported by the New York Times (2015), the company Amazon monitor employees in warehouses using sophisticated electronic systems to ensure they are packing enough boxes every hour. In a similar way, the Amazon also uses a self-reinforcing set of management, data and psychological tools to spur its tens of thousands of white-collar employees to do more and more.

1.3 Purpose and research questions

There is a need for broader discussions of Big Data in society and its implications for management research in general, including construction and project management. George et al. (2014) points out that even though "Big Data" has become commonplace as a business term, there is little published management scholarship that tackles the challenges of using such tools, or that explores the opportunities for new theories and practices that Big Data might bring about. The purpose of this paper is to investigate different use and potential use of Big Data in construction management research. The construction process can be studied in a number of dimensions. We structure documented and potential use of Big Data related to construction project along a time axis of a typical construction project, from concept preparation and brief, through design and construction to use.

Our research questions addressed in this paper are:

- Which applications of Big Data in construction project management have been published in recent years, based on the defined literature search criteria?
- Which time phases of a construction project are recent Big Data research relevant to?

2. Method

We review previous research and structure the papers based on the time perspective of a typical project. Several approaches were used to identify relevant literature. Searches in the Norwegian library database (Bibsys) were conducted, covering both books and academic journals. Searches were made using several search engines on the Internet, such as Emerald, Science Direct, Wiley Online Library, and Google Scholar. During the database searches, both titles and keywords were examined. In the searches in Google Scholar the entire texts are searched, consequently providing more search results of both relevant and irrelevant papers. Exclusion keywords were provided in the search, to exclude papers from non-relevant research fields. The collected material was subsequently examined in more detail. The main keywords used in the search were «big data», «construction project/industry», and (construction/project) management. Relevant literature was also found in the journal for automation in construction, as this is relevant technology and data source even though the papers do not use the phrase "big data".

Searches were also made with capital projects and engineering projects as search keywords, but with limited additional search results. Exclusion keywords used were psychology, ecology, biology, constructionism, health, and network construction. The overview of search keywords, databases and number of results is given in Table 1.

In the search results, there are several papers that are not available or do not deal with construction industry. Most of these were excluded by the excluding keywords. However, several papers are within the areas of software development, data management, construction of data centre facilities, Big Data project etc. but are not directly related to the construction industry. The papers where excluded by the search keywords, based on headings, abstracts, or a quick search for construction, management, and Big Data within the main text. Exclusion criteria were used to exclude studies that are not relevant to answer the research questions. Only papers that give a clear contribution or are of clear relevance to Big Data in construction projects or management are of interest. The papers are limited to 2014 and 2015, and Table 1 show that most research contribution has been published these last couple of years.

*Table 1: Overview of search keywords, databases and results. (*Year 2005-2015, **Year 2011-2015, ***Year 2014-2015)*

The literature that we found to be relevant to our research questions, where structured into the time perspective of a typical construction project inspired by the phases in the RIBA (The Royal Institute of British Architects) model. The RIBA Plan of Work is the definite UK model for the building design and construction process (RIBA Plan of Work 2013). The RIBA model has served as an inspiration to a recently presented Norwegian phase model for construction (bygg.no, 2015). The Norwegian model uses a time frame similar to the RIBA model, but highlights the perspectives of owner, user, supplier and society. The Norwegian model has the following phases: Strategic definition; Concept development; Concept design; Detailed design; Construction; Handover; Use and facility management and finally, Disposal. The selected literature is categorised based on this life cycle perspective. In addition to the time perspective, we found need for adding a second dimension, and discuss a number of alternatives.

3. Literature

As mentioned in the previous section, the construction phases that we structured the literature based on, are; Strategic definition; Concept development; Concept design; Detailed design; Construction; Handover; Use and facility management; and Disposal. The result of the structuring of the literature that we found to be relevant is given in Table 1.

A significant portion of Big Data is geospatial data, generated from sources such as mobile devices and RFID sensors. Geospatial Big Data gives both opportunities and challenges, as discussed by Lee and Kang (2015). Related to the construction industry, location aware data can give useful information into urban planning, by providing information in the early project phases on how people use public spaces and infrastructure.

Caron (2015) focus on the importance of an early engagement of stakeholders to improve the forecasting/planning process and manage the project. Engagement of stakeholders from the stage of the project life cycle, in which they may be involved in or be impacted by the project, can significantly increase the available amount of both explicit and tacit knowledge. Managing stakeholders is critical in large construction projects, and in infrastructure major projects this is especially difficult due to the diversity of stakeholders and interests. A study by Bakht et al. (2014) evaluate stakeholders' impact on infrastructure megaprojects through analysis of Big Data captured from online social media.

During the project phases, from early preparation to handover and the liability period, a project produces a lot of documents. Kähkönen et al. (2015) study content and characteristics of current practice of Electronic data/document management systems (EDMS) in building construction projects. This includes project cost, number of files and file accessing actions (open, view, download). They looked at 15 building development projects, which used the same data system.

According to Naderpajouh et al. (2015), effective frameworks to facilitate data-driven decision-making are noticeably lacking in the construction industry. They developed a hierarchical definition for health of the construction industry that was used to propose a framework to benchmark, interpret and analyse data associated with the status of the health of the industry. The dimensions of the framework include; positive financial performance; stability and resilience to shocks, pleasant working atmosphere, applying the best expertise, science, and technology in the production process, and producing high quality products.

Collection of new data and analytical approaches has potential to develop new insights in project management maturity, as examined by Williams et al. (2014). In particular two Big Data analytical techniques is highlighted to have potential to develop understanding of maturity in organisations. These are social network analysis and text analysis. The study by Whyte (2015) analysed change management practices in three separate organizations, including a large construction project, who all deliver complex projects, rely on digital technologies to manage large data-sets, and use configuration management to establish and maintain integrity. The organisations use for instance configuration management in the concept, product identification and definition stages, and as control at the "as-built" stage before handover. The authors conclude that the unstructured, uncontrolled nature of Big Data presents challenges to complex projects that deliver assets. Martínez-Rojas et al. (2015) demonstrate that suitable data handling facilitates and improves the decision-making process and helps to carry out successful project management. They analysed what the main information and communication technologies are, and reviewed the proposals that exist in the literature that focused on the management of information and knowledge from a general point of view in the field of project management.

Barista (2014) presents some early successful applications of data-driven design and planning applications, and how Building Teams can benefit from this. For instance, designers can capture and analyse data from key building performance metrics, such as energy use intensity, to optimize early prototypes. Based on feedback data from building occupants, firms can evaluate design concepts against the real world, and help the building team to understand how people interact with spaces. Redmond et al. (2015) studied how social network analysis and energy usage analyses can be a source to create integrated models for green building design. The main objective was to highlight green building technologies, while at the same time engaging end-users and harnessing their collective knowledge in building design. Several papers also treat opportunities and challenges in combining BIM and Big Data (e.g. Chen et al., 2015).

Several of the papers cover the construction phase. Akhavian et al. (2015) investigate the prospect of using built-in smartphone sensors as data collection and transmission nodes in order to detect detailed construction equipment activities. The method demonstrated a perfect success in recognizing the engine off, idle, and busy states of construction equipment. The work by Teizer (2015) outlines early results for vision-based sensing technology for tracking of temporary assets on infrastructure construction sites. Research and practical industry applications demonstrate promising work towards automated visual recording and progressing of temporary construction resources. Guo et al. (2015) show that Big Data can be used for behaviour observation in China metro construction. The suggested framework was verified in an example to be able to analyse semantic information contained in images effectively, extract worker's unsafe behaviour knowledge automatically.

Automation is a field in construction that uses new data sources and technologies. Machine-to-machine (M2M) installed on construction machines could be used to recommend overhauls to end users at the optimum timing according to Vanzulli et al. (2014). To track the progress of earthwork processes at underground construction sites, Bügler et al. (2014) suggests a novel method that combines two technologies based on computer vision, photogrammetry and video analysis. Combining these data sources allows exact measurement of the productivity of the machinery and determining site-specific performance factors. The construction quality of the material roller-compacted concrete, used in construction of storehouse surfaces, is affected by factors such as the roller compaction, concrete temperature and construction climate. Liu et al. (2015) proposes a real-time construction quality monitoring method, to provide the construction operations on site with timely collection and comprehensive analysis of construction data from the construction process. Wang et al. (2015) presents a method for automatic object recognition and rapid 3D surface modelling, including point cloud data collected from a construction jobsite. Yang et al. (2015) reviews state-of-the-art vision-based construction performance monitoring methods. According to Skibniewski et al. (2015), the construction and operation of infrastructure systems have opportunities for improvement through research on robotics and automation. Automated equipment could cut waste, improve job safety and the overall quality of construction projects. Performance monitoring can be made more effective with tools that better characterize the extent to which construction plan are being followed and the extent to which workers and equipment are being fully utilized.

Lu et al. (2015) study the performance of construction waste management for the construction categories building, civil engineering, demolition, foundation, and maintenance and renovation. The study develops a set of key performance indicators (KPIs)/waste generation rates using an available Big Data set on construction waste management in Hong Kong. Demolition was found to be the most wasteful works that generate both non-inert and inert construction waste.

There have been published several examples of evaluation of buildings in use, using quantitative methods based on Big Data approaches. The study by Hong et al. (2015) reviews the state-of-the-art in the major phases for a building's dynamic energy performance, focusing on the operation and maintenance phase. Ioannidis (2015) presents Big Data and visual analytics techniques for comparing building performance under different scenarios and design. Data that provide useful information is energy consumption, building geometry, and space occupancy. Isikdag (2015) provides a method for facilitating the geographic information system (GIS) based fusion of information residing in digital building "Models" and information acquired from the city objects. The virtual BIM sensors in the proposed design pattern will provide geometric and semantic information together with information related to the state of the building elements, and the information can be used to represent the building within a GIS environment, and city monitoring/management.

4. Concluding discussion

Our first research question was related to which applications of Big Data in construction project management that have been published in recent years, based on the defined literature search criteria. We have identified studies describing Big Data applications and theory. Thematically they fall into three broad categories: 1) New construction equipment; generating, sharing and storing data about use. 2) Data from internal IT systems; such as planning, procurement and BIM can be utilised. Lastly, 3) people generate an increasing flow of information, which can be useful if handled with care. In combination this addresses the life-cycle from concept to decommissioning. We find that Big Data have been used in energy management. Data from internal IT systems, such as planning, procurement and BIM can be utilised. People generate an information flow, which can be useful but also treated with care to safeguard personal integrity. Heating, ventilation, and air conditioning (HVAC) and electricity management systems generate large volumes of data that can be applied for life-cycle management of the equipment, but also for describing the use of the building. None of the capabilities described in this study are entirely novel in inception nor unique to the construction industry, producers of major equipment such as train rolling stock have for some time utilised equipment life-cycle management data, which are generated in large scales through the period of production, operation, and maintenance.

Other categorisations of Big Data could have been applied. One alternative is to use a hierarchy of increasing aggregation; raw sensor data, databases of sensor data, reports from such systems, and different forms of presentations and reports based on input from several systems. Other alternative dimensions include different stakeholders involved in the project, type of data sources or different types of use of the data.

Our second research question was which time phases of a construction project that recent Big Data research is relevant to. The literature is presented based on a project phase perspective. We find that the construction phase appear to have received most attention from researches. We also find that several studies are applicable to more than one phase of a construction project.

We find a potential for increased use of Big Data methods and applications within construction. Typically, the power of data integration is hard to demonstrate in limited and small pilots, but requires critical mass before providing return. Big Data can be used to make more precise predictions, which can lead to better decisions. While data and applications related to different engineering disciplines, such as energy, have been analysed in isolation previously, there is a potential to combine different types of data. This creates opportunities, but also challenges related to personal privacy. Big Data appear to have a potential to generate new insights into the costs, designs and processes in project management. The aim is to develop tools and approaches for intelligent, efficient and sustainable construction project management. This research addressed Big Data. It is not necessarily the “big” part of Big Data that is key in construction applications. A possible development is that concepts from Big Data are applied on smaller datasets. Focus will then be on new data, or expanded use of existing data.

Abstract

The purpose of this paper is to explore the impact of an Integrated Public Procurement Approach on the main contractor's attitude and to investigate how Building Information Modelling (BIM) can support emerging needs. Innovative Procurement Approaches that promote collaboration and sharing of risks among counter parties are spreading in the Public Construction Sector. However, there is still limited knowledge on what types of changes are required when these procurement models are applied. The research is based on a case study involving active participation. The Procurement Approach used is Leasing Costruendo, where a financial institution gives the money to the contractor to build public project and, only at the end of the construction phase, public administration pays the financial institution. The design team and the main contractor should work together to develop the project. Moreover, for a fixed period the main contractor carries out the facility management on an agreed bid price. The findings indicate the main contractor had to change work practices and processes and the implementation of BIM was very useful to manage emerging needs. The Procurement Approach forced the main contractor to collaborate with the designers and the suppliers, paying more attention to the quality of the building as well as to the schedule. The main contractor had to control design and construction phases in order to minimise future costs related to the facility management. Moreover, tight deadlines were respected to get money by the financial institution. Thus, higher quality public buildings have been delivered to the society. Results can be used to understand implication of an Integrated Public Procurement Approach and the role of BIM in helping the main contractor.

Keywords: Integrated Public Procurement Approach, Building Information Modelling, Leasing Costruendo, Public Construction Sector

1. Introduction

Recently, the Construction Industry has been asked to introduce some changes due to the economic crisis. Moreover, the construction activity has been reduced in the last years especially in European Countries such as Italy. This situation generates problems not only for construction companies, but also for public clients. On one hand, there are fewer projects for construction companies and, on the other hand, public clients have fewer possibilities to invest on public services and finance construction works for the community. In order to mitigate this trend, new procurement methods have been developed such as Public-Private Partnership (PPP) (Osei-Kyei and Chan, 2015). Osei-Kyei and Chan (2015) have identified the principal critical success factors of PPP in several Countries as appropriate risk allocation and sharing, strong private consortium, political support, community/public support and transparent procurement. *Leasing Costruendo* falls into the PPP category. One of the major innovation in *Leasing Costruendo* deals with the involvement of financial institutions, such as banks, to realise buildings and infrastructures. Meantime, these innovative procurement methods introduce new requirements and responsibilities for the parties involved in the process (Love et al., 2015), especially for the main contractor. Thus, new approaches are required to deal with new challenges in procurement (Love et al., 2015). However, there is still limited knowledge on what types of changes are required when these procurement models are applied. The proposed paper explores the impact of the *Leasing Costruendo* procurement method on the involvement of main contractors in design processes and how Building Information Modelling (BIM) can support emerging needs.

2. Methodology

The research approach is based on a single case study where an Integrated Public Procurement approach (*Leasing Costruendo)* has been used together with Building Information Modelling (BIM). An Italian case study has been selected to investigate main contractor's perspective. The author's team actively participated in the case study and followed the progression of the projects taking part into meetings and supporting the introduction of BIM in the workflow.

The use of a BIM methodology was not included in the tender documentation. However, the main contractor decided to implement it in order to better manage risks associated to this procurement method. The main contractor selected a design firm and a financial institution to bid together for a public tender. The object of the tender concerned the construction and the twenty-year maintenance of two new pre-primary schools (four-class and eight-class), an auditorium and a food service building. After the awarding of the tender, the main contractor, a small-to-medium enterprise (SME), started to concern on risks related to the contractual agreement with the financial institution (a bank) as well as on problems due to the maintenance activity. The main contractor, in fact, did not have any previous experience on facility management tasks. For that reason, it agreed to embrace an innovative approach that could have helped them to take into account the entire life-cycle of assets. Some years before the awarding of the tender, the main contractor attended training courses related to BIM benefits for construction companies. Even if it did not have any direct past experience on BIM projects, the construction company decided to contact the authors' team to implement a BIM-based process. The first aim of the main contractor dealt with the realisation of a Building Information Model through which to effectively support facility management activities. After some meetings, the chair decided to involve the authors' team in the design process, that was still ongoing at the detailed design phase, in order to create a parametric model from the traditional 2D drawings. Thanks to the Building Information Model, several clashes and omissions were identified in advance and the entire process was optimised.

Research results are based on a single case study, for this reason, they cannot be generalised to the entire construction sector. In addition, the authors' team was actively involved in the decision-making process: weekly meetings were arranged in order to present and discuss critical issues with designers, main contractor and sub-contractors. The authors are aware of weaknesses of being involved in the process due to the contractual agreement with the construction company. However, this approach allowed the authors to better understand the construction company's 'way of thinking'. An active participation in the process was crucial to understand the main contractor's needs and to study the constant evolution of the project from design to construction.

3. BIM and Procurement

3.1 Overview on building procurement systems

The construction sector has a long experience in using traditional procurement methods such as Design-Bid-Build (DBB), Design-Build (DB), and Construction Management (CM) (Lahdenperä, 2008). Starting from 1990s a growing interest in Public-Private Partnership (PPP) has emerged, especially after 2007-2008 global financial crises (Osei-Kyei and Chan, 2015). Public institutions seek to use private sector's knowledge and capital to minimize their deficit and, in the same time, maximise taxpayers with value for money (Osei-Kyei and Chan, 2015). In addition, in order to reduce risks and costs associated to procurement, new procedures are spreading in the AEC industry as discussed by Bolpagni (2013). Some of them are Cost Led Procurement (CLP), Integrated Project Insurance (IPI), Two Stage Open Book, Integrated Project Delivery (IPD) and Project Alliancing (PA) (Bolpagni, 2013).

Within the UK Construction Strategy (Cabinet Office, 2012), three innovative procurement methods CLP, IPI and Two Stage Open Book, have been developed in 2011. The new procurement models are based on early contractor involvement, independent assurance and higher levels of integration and transparency (Cabinet Office, 2012). The client plays a crucial role as driver in order to promote innovation, identify waste, secure knowledge transfer and corresponding growth opportunities (Cabinet Office, 2012). Integrated Project Delivery (IPD) and Project Alliancing, also called Alliance Contracting (Petäjäniemi and Lahdenperä, 2012), are relational project delivery arrangements where all the stakeholders are committed to a mutual objective and are involved from the very beginning of the project (Halttula et al., 2015).. It is important to underline that, even if it is possible to achieve IPD without BIM, its adoption is essential to efficiently achieve the collaboration required for IPD (AIA, 2007; Eastman et al., 2011).

3.2 Role of BIM in building procurement systems

Despite significant differences on the management of these innovative procurement procedures, all of them encourage the early involvement of counterparties and a collaborative behaviour, trying to move from an 'everyone against everyone' approach to 'we are all in the same boat' (Ciribini et. al., 2015). This is the reason why Building Information Modelling can be used to achieve these goals, as it allows cooperation and transparency (Eastman et al., 2011; Bolpagni, 2013, Halttula et. al., 2015).

Building Information Modelling can be implemented in several procurement methods, from traditional to innovative ones (Bolpagni, 2013). However, when BIM is used in traditional procurement methods full potential cannot be expressed (Salmon, 2012). According to Dave et al. (2013) traditional procurement routes and forms, such as DBB, can be the 'biggest hindrance to a proper Lean/BIM implementation (or even individual Lean or BIM implementation)'. Actually, the maximisation of value and the minimisation of waste is difficult when the contractual structure inhibits coordination, stifles collaboration and innovation, but incentives individual goals at the expense of others (Mathews and Howell, 2005). A partnering approach, as supported by the new form of contracts (*e.g.* ConsensusDOCS, 2015), can support principles required for Lean/BIM implementation such as collaboration and integration (Dave et al., 2013). Relational contracts enable commercial relationships between the parties that not only stimulate 'mutual trust, but also facilitate the sharing of knowledge and information to generate innovation and value' for the parties involved (Colledge, 2005). The approach is generally 'people oriented' and, thanks to it, time, cost and quality risks are managed collectively focusing on the achievement of wider, shared values or purposes such as a successful outcome for a client (Colledge, 2005). Moreover, relational contracts often provide team-based incentives or reward mechanisms, placing value on successful outcomes, rather than in cost or individual performance (Colledge, 2005). Thus, relational contracts can better support co-location of teams, early contractor involvement, joint development of design and other such crucial requirements, rather than traditional contracting methods (Dave et al., 2013).

There are already contractual forms suitable for a BIM environment (McAdam, 2011). In the UK there is a long experience of collaborative procurement and currently Government is fostering it (McAdam, 2011). NEC3, PPC2000 and JCT Constructing Excellence promote working in a 'spirit of trust and co-operation' (McAdam, 2011). Thus, even if they have not been developed on purpose of BIM, they can be appropriate for use as part of a successful BIM process (McAdam, 2011). On the other hand, Document E202 and ConsensusDOCS 301 have been set in the US to be incorporated in a BIM project (McAdam, 2011).

Relational contracting principles are more difficult to be applied in the public sector rather than in the private one due to several limitations such as legal constraints, cultural clashes and lack of skills (Ke et al., 2011). Thus, more attention is needed dealing with public sector in order to achieve successful results.

Nowadays, there is not an Italian governmental strategy to guide the growing implementation of information-based technologies. Thus, several Italian public calls for tender have required the use of BIM ‘tools’ without a proper change in the working process. The Legislative Decree on public work is currently being updated to include the European Directive (European Parliament, 2014). For the first time the European Directive stated that ‘for public works contracts and design competitive bids, Member States may require the use of specific electronic tools, such as of building information electronic modelling tools or similar’ (European Parliament, 2014). Thus, also the European Directive explicitly refers to the use of BIM ‘tools’ instead of a BIM-based methodology. The Italian legislator is carefully dealing with this topic to avoid the use of BIM just as a technological change.

4. Case Study

4.1 Introduction of *Leasing Costruendo*

The leasing is a financial method mainly used in the private sector. Recently, it has been used also in the public sector. It mainly involved three parties: a public administration (*e.g.* a town council), a financial institution (*e.g.* a bank) and a construction company. During the tender phase the financial institution and the construction company bid together in order to award the project. After the awarding, the public administration periodically sends the money to the financial institution and the bank gives it to the main contractor in order to build the asset (Figure 1). The construction company must respect the schedule in order to be paid by the leasing company during the construction phase. After the construction phase, the construction company is in charge of the maintenance for an agreed period (Figure 2). That is one of the reasons why the construction company has to provide a high quality building to reduce future maintenance works and organise all the information in an efficient way in order to easily access them if needed.
When the agreed maintenance period ends (in the proposed case study it lasts twenty years), the construction company has to give back the property to the public administration (Figure 3)

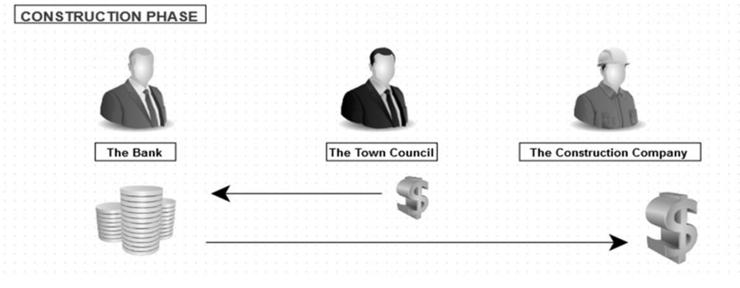

Figure 1: Leasing Costruendo - Phase 1

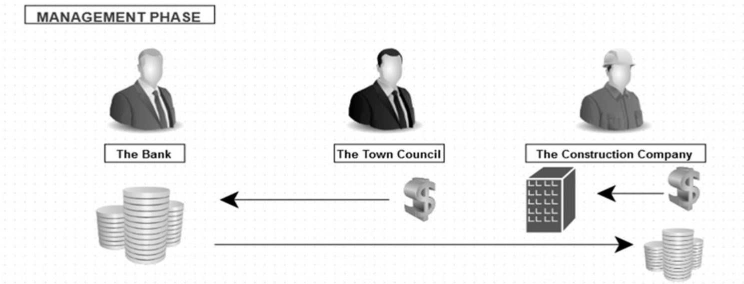

Figure 2: Leasing Costruendo - Phase 2

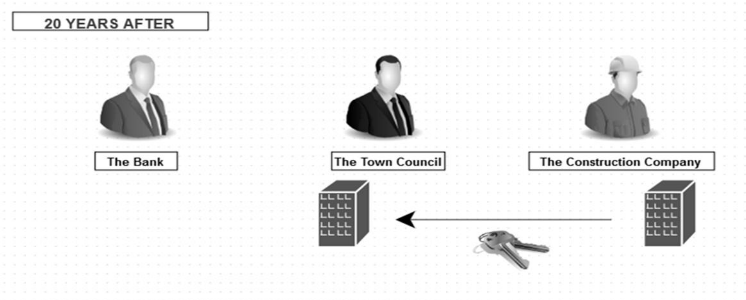

Figure 3: Leasing Costruendo - Phase 3

In the presented case study, the public administration developed the first phases of the design process and it asked bidders to present a detailed design. After the awarding phase, the public administration was in charge of monitoring the construction phase. In this procurement method the financial institution assumes all the financial risks related to the investment. On the other hand, the construction company assumes all the non-financial risks related to the construction and maintenance of assets, such as supply management and maintenance costs. *Leasing Costruendo* is a beneficial financial method for the public administration, because it can promote the realisation of high quality buildings and payments can be divided in several quotes. Moreover, usually the schedule is respected because the financial institution can receive payments only on the base of previously defined construction percentage progress. During an economic crisis as the current one, with a large number of Italian public administrations not having financial capabilities to promote new projects, the use of *Leasing Costruendo* is growing.

Leasing Costruendo could be considered as an innovative procurement method that forces the parties involved to collaborate in order to reduce risks. The main contractor, in fact, has to establish integrated and collaborative workflows with designers, subcontractors and the public client in order to define efficient solutions. *Leasing Costruendo* falls into the PPP category of procurement. A BIM approach could be beneficial to support a collaborative and a life-cycle approach as also discussed by Love et al. (2015).

4.2 Description of the project

The proposed case study is related to the construction and the twenty-year maintenance of two new pre-primary schools (four-class and eight-class), an auditorium and a food service building.

The public client divided the tender in two parcels with a different delivery deadline. The first parcel includes three buildings, two new constructions (four-class pre-primary school and food service building) and the renovation of an existing auditorium. This first parcel had to be completed in a time span of 240 consecutive days. The construction activities within the second parcel could start only once the first parcel had been completed, in accordance with some constraints such as the start of the new academic year and the necessary time to move the educational activities from the existing school to the new one. The second parcel includes the new construction of an eight-class pre-primary school. Because of this schedule, the main contractor had to carefully organise its construction activities in order to avoid penalties and delays on the starting date scheduled for the second parcel. A lack of production, in fact, would have led a payment postponement according to the construction percentage progress and, at the same time, resources that could not be relocated on other construction sites.

The four-class pre-primary school is a one-floor new construction building and it has an area of 1200 m^2. The structure is composed of a reinforced concrete foundation (thickness 40 cm), supporting precast wooden vertical structures. In accordance with architectural and structural designs, the MEP systems are collocated within the ventilated under-floor cavity; ducts and pipes are supposed to climb only in specific points. The construction company needed a detailed planning of the sewerage and ventilation systems installed in the ventilated under-floor cavity to be coordinated with the design of the precast vertical structures in order to optimise coordination and construction sequences on site.

The first parcel also contains an auditorium, an existing building of 1000 m^2 built in the nineties with a precast concrete structure. This building needed to be renovated with new architectural and MEP systems parts, including the ventilation and electrical ones. A critical issue was the coordination between architectural design and ventilation systems. In the first parcel there is also a food service building, a new construction of 1250 m^2 to be built next to an existing one. The structure is in cast-in-place reinforced concrete. MEP systems are mainly installed above suspended false ceilings. Finally, in the second parcel there is the eight-class pre-primary school. It is a two-floor new construction building with an area of approximately 2900 m^2. The structure is entirely in cast-in-place reinforced concrete and MEP systems are allocated above suspended false ceilings.

4.3 The BIM implementation

In the proposed case study, the bid was related not only to the construction phase, but also to the maintenance one and the construction company had to include costs related to both phases in the offer. Moreover, the tender selection criteria was the lowest-price one, a very common criteria in Italian public procurements. The evaluation of construction costs was a well-known activity for the main contractor; on the other hand, it was not familiar with facility management activities. For the first time, it had to consider a twenty-year maintenance project, taking into account facility management issues. Moreover, usually traditional practises do not effectively integrate different phases, such as the design, construction, operation and maintenance ones, leading lack of knowledge and inefficiencies (Eastman et al., 2011). In the proposed case study, the required integration of design, construction and maintenance phases was a new challenge for the SME. For that reason, the main contractor thought that Building Information Modelling could have been a valuable support. Therefore, the principal needs of the construction company were related to a constructability review of the designed buildings, optimising the construction phase, and to the definition of optimal solutions for an efficient facility management in order to reduce possible future costs.

A small group of Civil and Building Engineers with competences in Information Modelling and Management (IMM) was organised in order to coordinate a BIM-based approach between designers, the main contractor and the subcontractors. Unfortunately, the use of a BIM approach started only in the final phase of the design process, between the technical design phase and the construction one. At first, in order to set up a successful process, it was necessary to answer to the following questions:

- According to the defined BIM uses of constructability review and facility management, what is the Level of Development (LOD) (AIA, 2013) required for the informative content of the Building Information Model? Which kind of geometric accuracy is needed?
  For example, it was decided that a high degree of geometric accuracy was essential in order to avoid intersections and to identify and correct any problems that, otherwise, might have arisen during the installation of MEP systems (COBIM, Series 6, 2012). Moreover, the Building Information Model was managed in order to visualise construction sequences and support the installation phase, as suggested by Rischmoller et al. (2001). Facility management parameters were embedded in BIM objects according to the Construction Operations Building Information Exchange (COBie) standard (Eastman et al, 2011) and the contractor's requirements. A shared calendar between the main contractor and the suppliers was also organised in order to remind maintenance scheduled dates by means of an automatic alert e-mail system.
- Which would be the best procedure in order to exchange information among the stakeholders involved?
  An iterative process of Model Checking allowed the main contractor to effectively implement the BIM methodology for improving the construction phase (AGC, 2010). Model checking was used to detect clashes and validate coordination and collaboration

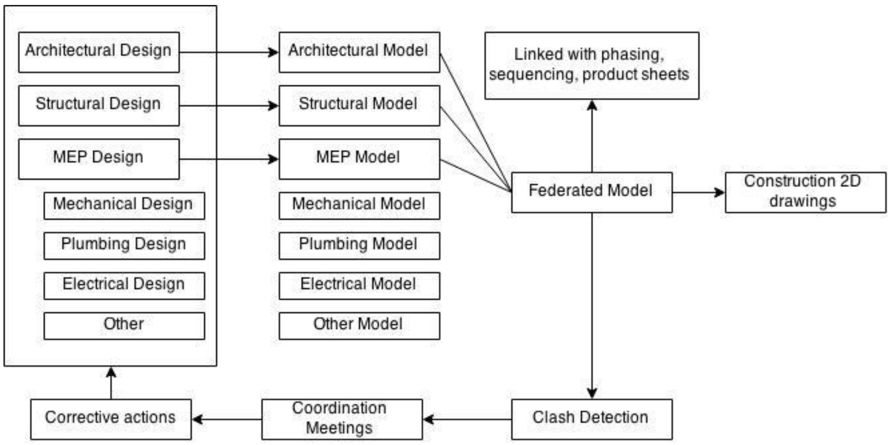

Figure 4 Ongoing discipline and multi-discipline clash detection to support the decision-making process and the constructability review (Caratozzolo et al., 2015)

between designers, main contractor and subcontractors (COBIM, Series 13, 2012). This approach allowed the optimisation of the design phase according to constructability and maintenance needs. Building Information Models of each discipline were produced based on traditional 2D designs and merged into a federated model. Clash detection results were exported in clear and effective coordination reports and documentation to be used during interdisciplinary meetings between designers, main contractor and subcontractors. After that, corrective actions were taken and the optimisation process started again (Figure 4).

5. Results and Discussion

The iterative and collaborative validation process, was essential for construction and the maintenance phases. It was strictly connected to a high level of coordination and responsibility for all the actors involved, from designers to suppliers. Subcontractors actively participated to all the coordination meetings during the constructability review process and they had the opportunity to clearly visualise what would have been realised on site. Moreover, subcontractors had an active role in the decision-making process integrating their knowledge to designers' and main contractor's. An example of the coordination achieved is related to the construction of the pre-primary school 'four-class': here the position of the ventilation vertical ducts influenced the design of the precast wooden walls. The subcontractor of the wooden structure had the opportunity to exactly know where MEP systems would have been located and their actual dimensions, so it was decided to optimise the design and the installation process by customising the precast wooden panels.

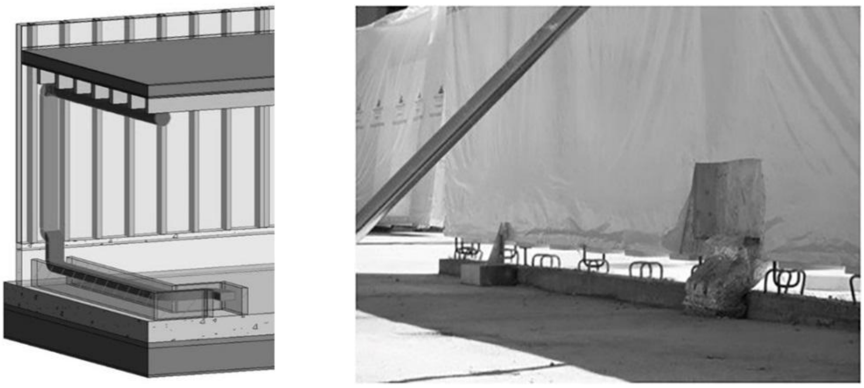

Figure 5 Customised precast wooden walls based on the BIM Model (Caratozzolo et al., 2015)

A special area to host the climbing vertical ducts within wooden panels was added (Figure 5). In this way, the energy efficiency of the wooden panels was controlled. Indeed, on site some climbing ducts in the wooden panels could have modified the dimension of the insulation layer and the final energy efficiency of the system. Moreover, MEP geometric accuracy was such that the installation of MEP components could have been conducted based on the Building Information Model. From the beginning, in fact, the main contractor understood the potentialities of this BIM-based approach, and it decided to use the Building Information Model as the unique source of data to review the project and extract shop drawings. In this way, a high level of coordination was guaranteed and the merged model was the reference point that everyone had strictly to follow. This approach allowed subcontractors to work at the same time on different tasks, reducing construction time and costs. This result was very important to respect schedule deadlines with the bank required in *Leasing Costruendo*. Moreover, the improved collaboration between parties favoured trust in the decision-making process.

This approach is still not common in Italy, especially for SME, which traditionally use 2D drawings. The Italian law does not require the use of BIM procedures and Building Information Models are rarely considered effective due to lack of skills and trust in new approaches. *Leasing Costruendo* is an innovative procurement method and contractors are still not used to integrate design, construction and facility management phases. Finally, they are not used to work with a financial institution and respect deadline to receive the money.

6. Conclusions and Future Works

Leasing Costruendo is a quite new procurement method that creates emerging needs for construction companies such as a project life-cycle approach and respect of the schedule. In this procurement method, contractors have to deal with facility management issues that usually are not part of their business (Love et al., 2015). Moreover, even if the construction site of the proposed case study did not have large dimensions, realisation times were tightened and the different types of buildings required different skills, construction procedures and maintenance solutions to be defined. In order to meet these new needs, the implementation of the BIM methodology was crucial.

In this case study the effectiveness of the BIM implementation was limited because it was implemented in a traditional design process and required by the main contractor. More benefits would have been reached if the public owner had asked for such an integrated process since the beginning, including Employer's Information Requirements (EIRs) (BSI, 2013) in the tender documentation. The public client has to be an intelligent driver, anticipating and solving possible issues during the entire project life-cycle. Moreover, clients need to work within a single source of digital information, defined as Common Data Environment (CDE) (BSI, 2013), with the entire supply chain in order to manage a fully effective BIM process. With regard to the use of BIM, in fact, general issues depend on the level of collaboration within the project team since the early beginning. The public client has to learn how to effectively formalise the EIRs to outline issues and then collaboratively work with the entire supply chain. Thus, it is important to explore several possible solutions, taking into account issues of constructability and facility management from the design phase. In this way, clients become co-author of the process.

Moreover, information modelling is based on the management of an integrated knowledge; but today traditional procurement methods tend to put the various parties one against each other (Eastman et al., 2011; Bolpagni, 2013). For this reason, the implementation of the BIM methodology is an opportunity to improve procurement processes, promoting the digitalisation of the entire supply chain. Integration Project Delivery (IPD) and other collaborative procurement methods such as *Leasing Costruendo* allow the early involvement of contractors in the design process increasing benefits of using BIM.

Finally, the implementation of the information-based technologies needs to be consistent with an effective BIM-oriented strategy. If the awareness on the change of the entire process is not fully developed, the tendency is to use new tools of information modelling and management only to emulate traditional processes and to provide traditional documentation. This practice, however, leads to data fragmentation, invalidating the potential innovative aspect of the Information Management and Modelling (IMM) methodology. In Italy a government BIM mandate seems to be necessary for an effective implementation of new digitalised practises and integrated methodology, together with the development of standards and guidelines to support all the parties involved in the process according to their specific needs.

Abstract

The paper shows the client's attitude towards the quasi-automation of the procurement processes in the backdrop of a digital environment in some European countries. The construction industry is increasingly competing on new bases, implementing a digital approach. The client plays a key role in defining digital requirements and controlling the entire supply chain in the very early phases. Indeed, first, an 'intelligent' digital built environment needs an 'intelligent' driver. In this scenario, clients should set digital requirements able to control the compliance of offers in a quasi-automated way during tendering and awarding stages. However, the current implementation and understanding on this new attitude is not very clear and there is a gap in literature. For this reason, a deductive approach based on an online questionnaire delivered to a sample of leading European clients has been used to investigate the state of the art. Results indicate that a large number of clients use digital tools to set digital requirements and include digital deliverables in the contract (such as Building Information Models). However, the adoption of e-Procurement platforms and the evaluation of the entire supply chain during the tendering and awarding stages are still limited. Moreover, most of the clients perceive that the quasi-automation of the procurement process can generate benefits and favour risk mitigation for banks and insurances. The results can be used to get a better understanding of the current situation and to define fields where a digital approach can be further implemented.

Keywords: Procurement Process, Digitalization, Tendering, Quasi-Automation, Building Information Modelling

1. Introduction

Several European Countries, such as the UK, Germany, France and Spain are actively working on the digitalisation of the construction sector implementing Building Information Modelling (BIM). By now, there is not an univocal definition of BIM; Eastman et al. (2011) define it as '*a verb or adjective phrase to describe tools, processes, and technologies that are facilitated by digital machine-readable documentation about a building, its performance, its planning, its construction, and later its operation*'. It is important to underline that BIM is not just a technology change, but also a process change focused on a life-cycle approach (Eastman et al., 2011). Moreover, it promotes a high level of collaboration among project participants (Eastman et al., 2011). In the last year, several reports have been published on the impact of BIM (e.g. Dodge Data & Analytics, 2015). Even if there are still limitations on its full implementation, BIM can improve the overall process (Bolpagni, 2013). For this reason, the European Parliament (2014) incorporated it in the new Directive on public procurement and several European Countries have decided to include it in their construction strategies.

In 2011 the UK Cabinet Office published a Government Construction Strategy followed by an Industry Strategy for 2025 (HM Government, 2013), a report on the digital future of the Built Environment 2050 (Philp and Thompson, 2014) and the *Digital Built Britain* initiative (HM Government, 2015). The Government will require level 2 of BIM on its projects by 2016 and it is working to promote an industry that is 'efficient and technologically advanced' (HM Government, 2013). Moreover, in 2015, the German Federal Ministry of Transport and Digital Infrastructure declared the creation of a Digital Building Platform and it announced an initiative for the digitalisation of the construction industry. Indeed, BIM will be applied to all new projects from 2020 onwards. In addition, the French Ministry of Territorial Equality and Housing is promoting the modernisation and innovation within the construction sector and a BIM Task Group has been established in 2015. Moreover, in the same year, the Spanish Ministry of Public Works has established a national BIM strategy and it is working to include BIM as a mandatory requirement on public projects. In addition, Scandinavian Countries, such as Finland and Norway, have developed national BIM Guidelines to support the use of BIM in public works.

These initiatives demonstrate that the Construction Industry is increasingly competing on new principles, implementing a digital approach. More and more the client plays a key role in defining digital requirements and controlling the entire supply chain in order to achieve an effective process. Indeed, first, an 'Intelligent' built environment needs an 'Intelligent' driver. However, the current implementation and understanding on this new attitude is not very clear and few published data is available in literature. Thus, the aim of the paper is to show the client's attitude towards the quasi-automation of the procurement processes in the backdrop of a digital environment in some European Countries. Nowadays, it is not possible to fully automate the procurement process, especially the creation of digital requirements and the evaluation of offers (e.g. due to the presence of subjective requirements that cannot be translated into machine-readable rules) (Ciribini et al., 2015). Thus, expression 'quasi-automation' is used in the paper.

1.1 Overview of the digitalisation of the Procurement process

The digitalisation of the procurement process is not a new concept and in literature there are several publications on the use of e-Procurement and e-Business indicating the state of art, benefits and barriers both in the public and private sectors (Chaffey, 2009; Eadie et al., 2010; Ronchi et al., 2010; Costa et al., 2013). As showed by Eadie et al. (2010) the principal drivers deal with reduction of costs and time together with improvement of quality. On the other hand, the principal barriers are related to cultural, infrastructure, security, legal and compatibility limitations (Eadie et al., 2010).

In the public sector, the European Commission has promoted several initiatives. In 2010 the European Commission delivered a document to define objectives of the European Digital Agenda. The principal aim is to promote 'sustainable economic and social benefits from a digital single market based on fast and ultra fast internet and interoperable applications'. One of the key elements deals with the digitalisation of public services for citizen and business (e-Government) (European Commission, 2010a). In the same year, several documents have been published such as the 'The European eGovernment Action Plan 2011-2015. Harnessing ICT to promote smart, sustainable & innovative Government' (2010b). Today the EU is working on a new e-Government Action Plan 2016-2020 to complete the Digital Single Market (European Commission, 2015b). Moreover, the Green paper on expanding the use of e-Procurement in the EU (European Commission, 2010c) explained the importance of e-Procurement, the current state of art, challenges and actions to be taken. The principal challenges deal with the overcoming inertia and fears on the part of contracting authorities and suppliers, lack of standards, absence of means to facilitate mutual recognition of national electronic solutions, onerous technical requirements and the management of multi-speed transition to e-Procurement (European Commission, 2010c). The last topic has been clearly described also in the IDC report (2013). The new Directive on public procurement (European Parliament, 2014) makes the use of e-Procurement progressively mandatory and by October 2018 Member States are required to use e-Submission. Despite several initiatives to promote e-Procurement in EU, such as the PEPPOL project, there are still several barriers (2012, 2015).

It is important to underline that usually e-Procurement is associated with the use of electronic processes to procure supplies and services (European Commission, 2010c). Instead, e-Procurement is often used to procure works due to its greater complexity (Bolpagni, 2013).

As previously discussed, Building Information Modelling is more and more becoming a key element of the digitalisation of the construction sector. However, there is not a large number of e-Procurement platforms able to manage a BIM-based process. In Portugal, several research activities have been developed to integrate BIM within e-Procurement platforms during the PLAGE project (Jardim-Goncalves and Grilo 2010a, 2010b; Grilo and Jardim-Goncalves 2011, 2013; Costa and Grilo, 2015). However, a functional platform is not yet available. Moreover, Costa and Grilo' s approach (2015) is focused on e-tendering using a Building Information Model to purchase a specific product for a building, but it does not discuss procurement processes where a Building Information Model is not yet available in tendering.

Some platforms (e.g. Viewpoint For Projects™, Asite™, Aconex© and Conject©) are emerging in the market in order to manage a collaborative BIM-based process and some procurement tools are available. For example, Viewpoint For Projects™ allows setting an invitation to tender attaching a Building Information Model. However, effective data analytics tools are not available and e-Procurement platforms cannot fully take advance from a BIM-based approach.

2. Methodology

A deductive approach based on an online questionnaire has been used. The empirical data was gathered via an online SurveyMonkey® questionnaire. SurveyMonkey® is an online survey programme that allows the user to create and manage the survey from a web-interface. A sample of leading European clients has been chosen to investigate the state of the art on the digitalisation of the procurement process. Three European Countries, the UK, Finland and Germany, have been selected. The clients were chosen for their active participation in national working groups for the innovation of the AEC sector. In the paper, they are both defined as 'clients' or 'European clients' due to their belonging to Countries where European directives on Procurement are adopted, especially for the public sector. Initially, 46 clients were selected and each of them was contacted by email, telephone or direct contact. A presentation was sent to all contacts by email to get an introduction of the research topic and to better explain the purpose of the survey. Moreover, the same email included a web link to access the online survey.

The survey was a structured questionnaire where questions were listed in a pre-arranged order and all questions required answers. The survey contained 19 questions: 14 closed-ended and 5 open. The survey was divided in three parts: a) general questions to investigate the type of clients b) questions related to the management of tendering and c) questions related to the use of a digital procurement process. The survey covered the following main topics:

- use of information requirements
- evaluation of the entire supply chain in tendering
- digital requirement in tendering
- use of e-Procurement platforms
- benefits and limitation of a quasi-automated procurement process

The online questionnaire has been accessible for three weeks starting from January 2015 and responses were received from 14 contacts, all of them were full completed. First, results were analysed using SurveyMonkey®. The tool provides an automatic visualisation of results in graphics as well as in tables. Later, data were exported in Excel in order to create different graphs. In addition, the free tool Wordle™ was used to create world clouds to analyse results coming from open questions. Finally, results were shared among interviewees and a workshop was organised to present findings. It is important to underline that the number of received responses is very limited; thus, findings cannot be generalised to the entire construction industry. Moreover, interviewees were selected from groups that are actively engaged in digitalisation processes of their respective countries. Therefore, findings are especially addressed to the leading edge of the industry.

3. Survey Findings

The paragraph reports findings of the survey divided in three consecutive sections: general questions, management of tendering and the use of a digital procurement process. Later, results will be discussed in paragraph four.

3.1 General questions

The first part of the survey investigates client's general information to better understand if they work in the public or private sector and which is their type of business.

The interviewees are mainly public clients (64,29%) followed by developer private clients. Most of them are involved in infrastructure works (42,86%), some only in vertical assets (35,71%) and only few have a mixed portfolio (21,43%). As clients, most of them usually buy capital projects (64,29%) and only few both capital and operational expenditure (35,71%).

3.2 Management of tendering

The second part of the survey explores if clients usually provide information requirements in tendering. In the UK, such requirements have been defined as Employers Information Requirements (EIRs) (The British Standards Institution, 2013). EIRs are pre-tender documentation '*setting out the information to be delivered, and the standards and processes to be adopted by the supplier as part of the project delivery process*' (The British Standards Institution, 2013). The use of client's information requirements in an early phase of the process, forces clients to reason about their needs and provide more information to bidders. The survey investigates also if clients have standard organisational and asset requirements. In addition, other questions explore how clients usually evaluate the supply chain, especially on BIM capabilities. Indeed, BIM is more and more mandatory in tendering, but in literature there are not standard evaluation criteria and it is not clear if and how clients evaluate this requirement.

Most of interviewees (78,57%) affirmed that they determine and issue client's information requirements as part of the tender process. Most of interviewees do not have standard set of organisational and asset requirements (42,86%), others develop them uniquely for each project (35,71%) and only few have such requirements (21,43%). Moreover, the survey reveals that most of the interviews evaluate only the tier 1 design team and main contractor (78,57%) on BIM capabilities. On the other hand, only few (21,43%) evaluate the tier 1 plus their proposed supply chain. In addition, interviewees were asked to express how they usually assess capabilities of the supply chain ticking all options that applied. A large number of clients use BIM pre-qualification questionnaires (92,86%) followed by pre-contract BIM Execution Plans (BEP) (64,29%), interviews (42,86%) and capabilities assessments tools (35,71%). Finally, most of clients use standard criteria to measure capabilities of the supply chain (50,00%), others apply tailored project specific criteria (35,71%) and only few do not measure them (14,29%).

3.3 The use of a digital procurement process

The third part of the survey shows client's feedback on the adoption of a digital approach for the procurement process. Questions examine client's use of digital deliverables as well as electronic procurement (e-Procurement) platforms. Moreover, interviewees express their opinion on the main benefits, risks and cultural barriers related to the implementation of a quasi-automated procurement process, especially in tendering and awarding phases. The survey also investigates potentialities of gamification in procurement. It is a quite new concept and it deals with the paradigm of anticipation. For example, during the tender phase a gamified approach could force the main contractor to simulate its relations with perspective suppliers in front of a specific situation. Finally, interviewees were asked to evaluate clients' and supply chain's current level of competence on the digitalisation of the procurement process.

Most of clients (50,00%) usually include digital deliverables such as 3D parametric domain models plus federated models as part of the contract. Other clients ask also for non-graphical data exchanges such as Construction Operations Building Information Exchange (COBie) (35,71%) and only few do not include any digital deliverables (14,29%). Moreover, the survey reveals that still a large number of clients do not use e-Procurement Platforms as part of their business process (57,14%). Most of interviewees (85,71%) perceive benefits from the quasi-automation of the procurement process and a large number (71,43%) believe that a quasi-automated approach can favour risk mitigation for banks and insurances through the validation process. In addition, interviewees were asked to express how ready are clients in their Country to deploy a computer-readable bidding process through an open question. Most of them said that by now clients are not ready and they are only at the starting point. Furthermore, most of clients answered that they will be ready to automatically generate client's information requirements from a digital brief within one year.

The survey shows that the main risks related to the quasi-automation of the bidding process are the loss of control, poor client's requirements, poor supply chain's skills, technology limitations, the structure of the public sector procurement itself and poor briefing culture change. As previously said, the gamification applied in the procurement process is a quite new concept. Most of clients think that the gamification could not help the awarding stage of a contract. Others believe that it will add costs for clients or interviewees do not have a precise opinion on this topic. On the other hand, other clients think it will be helpful to better understand the scenarios and to promote a dynamic intelligent evaluation of offers. Thus, it will support a more transparent process. Moreover, results on supply chain's readiness for a quasi-automated procurement process are included in Table 1. Tier 1 project managers and technical adviser and main contractors are mainly self-confident; designers, tier 2 specialist sub-contractors and tier 3 product manufacturers, instead, are mainly beginners in managing a quasi-automated process. On the other hand, most of interviewees believe that tier 1 facility managers have less experience.

Table 1: Supply Chain's readiness for a Quasi-Automated Process

Tier / *Evaluation scale*	*No experience*	*Beginner*	*Self-confident*	*Expert*
Tier 1 Project Managers and Technical Advisers	14.29%	14.29%	57.14%	14.29%
Tier 1 Designers	35.71%	50.00%	14.29%	0.00%
Tier 1 Main Contractors	0.00%	21.43%	57.14%	21.43%
Tier 1 Facilities Managers	42.86%	42.86%	14.29%	0.00%
Tier 2 Specialist Sub-Contractors	21.43%	57.14%	21.43%	0.00%
Tier 3 Product Manufacturers	7.14%	57.14%	28.57%	7.14%

Finally, clients were asked which cultural barriers need to be overcome to move towards an automated bidding and awarding process using computer-readable data through an open question. Most of clients believe that trust is the biggest barrier followed by collaboration, inertia to change, security, confidence in data, quality assurance of information, share of risks and rewards and understand of benefits of such approach.

4. Discussion

This paragraph presents the principal implications of findings, taking into account the limited number of responses received.

The survey shows that only few interviewees have a standard set of organisational and asset requirement as well as standard benchmarks to evaluate offers. Such a trend could slow down the potentialities of a quasi-automated procurement process because, without clear standards, clients would have to spend more time in creating digital requirements and evaluation criteria. Moreover, it will be more difficult to compare results of different projects in order to create updated benchmarks. Thus, in order to promote an effective digital process, clients should establish clear standards.

In a digital procurement process, client's information requirements play an important role. Indeed, they can promote more transparent offers because bidders have a better comprehension of client's needs (The British Standards Institution, 2013). On the other hand, thanks to them, clients can speed the evaluation of offers checking the compliance between bids and initial requirements in a quasi-automated way. The UK has been the first Country to develop a digital tool, the NBS BIM toolkit, to set and manage digital client's information requirements (EIRs). Such requirements should be included in each UK public tender by 2016. The research findings reveal that several interviewees understand the importance of client's information requirements and include them as part of the tender process. However, most of interviewees are not ready to manage a computer-readable bidding process using clients' information requirements; even if they are working on this direction to be ready within one year. The results mirror the situation in Countries, such as the UK, when this practice will soon be mandatory. Different results could be identified in other European Countries without similar compulsory requirements. In addition, it is interesting to notice that interviewees believe that project managers, technical advisers and main contractors are self-confident in managing a quasi-automated procurement process. On the other hand, designers, tiers 2 and 3 should improve their skills, together with facility managers who received the lowest score. For this reason, an appropriate training and support should be provided to improve the overall process.

Recently, the use of Building Information Modelling has been increased and it is used in several phases of the overall process (Dodge Data & Analytics, 2015). Thus, more and more it has been used as selection criteria in tendering, especially in complex projects. Indeed, clients have to evaluate BIM capabilities in order to select tenders able to manage a BIM-based contract. Still a small number of interviewees evaluate the tier 1 players (design team and main contractor) together with their perspective supply chain. Such results could be due to the complexity in defining members of the supply chain in the very early phase of the process. However, the evaluation of the entire supply chain in tendering could be beneficial to better understand if all parties are capable to manage a collaborative BIM-based process. For this reason, the survey includes a question related to the use of gamification. Even if the gamification applied to tendering and awarding phases is a quite new concept, some clients believe that it could create a dynamic intelligent evaluation of offers. Indeed, the involvement of key players of the perspective supply chain in tendering could improve the reliability of bids, moving from evaluation of written promises to the evaluation of real capabilities. For example, a simulated and gamified approach could support the assessment of the supply chain's attitudes towards working in a collaborative environment. Such approach is being used in innovative procurement methods, such as Integrated Project Delivery (IPD) and Project Alliancing (PA), where, before the awarding phase, clients organise workshops and interviews with a selected number of bidders to assess their capabilities, attitudes and behaviours. After the awarding phase, contracts should ensure that the selected team will remain the same in order to take advance of the gamified approach.

Moreover, a large number of interviewees do not use e-Procurement platforms as part of their business process, even if the European Commission is strongly encouraging them as previously discussed in paragraph 1.1. This result confirms results of other published studies and could be linked to presence of several barriers (Chaffey, 2009; Eadie et al., 2010; Ronchi et al., 2010; Costa et al., 2013) and to the absence of mandatory requirements at national level (IDC, 2013).

It is interesting to notice that a large number of interviewees see benefits from the automation of the procurement process such as risk mitigation for banks and insurance companies. Thus, the digitalisation of the procurement process could be beneficial to better monitor, track and check data reducing possible claims and associated risks, as also discussed by Chaffey (2009). However, in order to reach this goal, an electronic platform is needed.

Finally, interviewees highlighted some risks related to technology limitations as well as others due to the structure of the current procurement process. There are still legal issues related to the implementation of BIM in the procurement process (Eadie et al, 2015) and it is difficult to change people's attitude. Such risks can be correlated to cultural barriers needed to be overcome, such as the lack of collaboration and trust among parties. For this reason, a change in the management of procurement process is needed, introducing innovative procurement processes that favour a collaborative approach (Bolpagni, 2013). Results are in line with cultural and legal barriers against the implementation of e-Business and e-Procurement identified in literature, as discussed in paragraph 1.1.

5. Conclusions and Future Works

The paper shows the attitude towards the quasi-automation of the procurement processes in the backdrop of a digital environment of a limited number of European Clients that are actively engaged in digitalisation processes of their respective Countries. Results indicate that a large number of interviewees use digital tools to set digital requirements and include digital deliverables in the contract (such as Building Information Models). However, the adoption of e-Procurement platforms and the evaluation of the entire supply chain during tendering and awarding stages are still limited. Moreover, today not all members of the supply chain are ready to manage a quasi-automated procurement process. On the other hand, most of interviewees perceive that such approach can generate benefits and favour risk mitigation for banks and insurances. The results can be used to get a better understanding of the current situation and to define fields where a digital approach can be further implemented, such as the integration between e-Procurement and BIM, as well as the definition of client’s standard set of organisational and asset requirements. However, due to the low response rate, results cannot be generalised to the entire construction industry, but only for the leading edge of the industry.

For this reason, in the future, the same survey could be submitted to other European Countries to get more data, especially from Countries with a specific governmental digital construction strategy. Moreover, it could be useful to interview the same group after one year and compare results to monitor client’s attitude.

Abstract

New approaches to prefabricated steel framing are proving popular in both first world and third world countries. A container can be packed with a steel section fabricator and all materials required to construct the steel framing for a range of client specified building designs. Such a container can be delivered to a building site in even the most extreme and isolated locations to enable a building to be erected. However, especially in third world environments with a poorly trained workforce, it is possible to assemble the framing incorrectly (e.g., back to front sections) which can have negative consequences on the building's ability to withstand design loads. Steel section fabrication machines have the ability to print onto the steel sections that they roll, which provides a potential for more sophisticated handling of the framing construction process. In this project the use of fiducial markers on the steel framing is investigated as a means of serving the construction process as well as for quality assurance processes. Fiducial markers allow a virtual connection to be established between the BIM design model and the rolled element such that an Augmented Reality (AR) application can be used onsite to support both the construction, and quality assurance, processes. Low cost tablets were investigated as the AR environment to support visualization of framing design on top of the steel framing and to develop a quality assurance application. The impact of accuracy of marker placement, types of fiducial marker, rendering accuracy, field of view of cameras in different tablets, and ease of use were explored for the developed application.

Keywords: Steel framing, augmented reality, quality control

1. Introduction

Mobile devices such as smartphones and tablets are becoming more and more prevalent and have ever increasing processing power as well as various different kinds of location sensors. With these new capabilities, there is an opportunity for these mobile devices to be used on construction sites. By making a connection between the real world and a virtual model of the building, useful real time information can be made available during the construction phase (Koch et al. 2007; Webster et al. 1996). In particular this information could relate to whether the building has been constructed correctly, i.e. provide quality control. This project investigates what problems could be solved in a steel framing application domain by such a mobile application and develops a prototype to demonstrate the feasibility of the solution.

1.1 Steel Framing

Mobile rollforming technology has increased in popularity in recent years with innovative approaches to delivering steel trusses to a building site. In particular, a number of companies manufacture mobile rollforming machinery which can be packed in a container, along with steel coils, and delivered to site for use in remote site construction projects, or in particular for third world settings where the transport infrastructure is not reliable or efficient. In New Zealand the National Association of Steel-framed Housing (NASH) identifies three companies who provide containerised rollforming solutions driven by virtual models developed in BIM-like design tools (i.e., FrameCAD Ltd, Howick Ltd, and Scottsdale Construction Systems Ltd).

While the rollforming machinery is capable of delivering perfectly sized steel framing with highly accurately placed dimples and notches, there is still a manual assembly process for frames and trusses which introduces the potential for human error. This is of greater concern in markets where there is a paucity of a trained workforce and the steel framed construction will be performed by low-skilled workers. This concern is exacerbated by steel frames and trusses appearing quite symmetrical, but in reality having a required installation alignment to ensure that design loads can be withstood.

To help address the assembly concerns the use of information technology to aid in correct assembly, and in the quality control checking of assemblies, is of interest. A vector of support in the context of this project is the fact that the rollforming machinery can print onto the steel sections as they are rolled, enabling a range of (currently low resolution) text or images to be placed on any section of rolled steel.

1.2 Augmented Reality (AR)

Augmented Reality (AR) has been seen as a promising technology for application in many industries, though not reaching its tipping point to date (Carmigniani et al. 2011; Furht 2011). In A/E/C it is mainly expected to benefit on-site processes where the ability to layer virtual model information (e.g., from a BIM) onto the actual site would augment, improve and speed up many current processes. AR can be delivered through many hardware platforms, from smartphones, through tablets, to specialised glasses and helmets. Providing a plethora of platforms upon which an AR platform can be developed. One of the major issues with AR, and of particular concern in A/E/C, is that of alignment between the virtual and real world (Azuma 1993). To support many processes the AR system needs to accurately locate the user of the system and to paint the virtual model accurately into the real world. Accurate location on site is an ongoing research issue with GPS approaches unsatisfactorily inaccurate in many urban environments and inside buildings, and the alternates of wifi, Bluetooth, inertial sensors, fiducial markers, etc all suffering a range of drawbacks along with their successful use scenarios (Watson et al. 2005; Zandbergen and Barbeau 2011). Establishing and maintaining accurate alignment between real world objects and virtual objects in real time also proves problematic in the majority of A/E/C scenarios, though rapid progress is being made to ameliorate these issues.

2. AR Approach

To develop an AR platform for steel framing erection a range of information inputs are required to feed into the on-site application. Figure 1 provides an overview of the information flows necessary for this type of application. Our solution uses a number of different components to generate an augmented reality view of a particular location at a building site. Using markers printed onto the steel framing, the application is able to precisely determine the position of the device in 3D space, which then enables the application to render an overlay of the building model onto a live feed from the device's camera. This allows the user to verify what has been constructed against the model of the building loaded into the application.

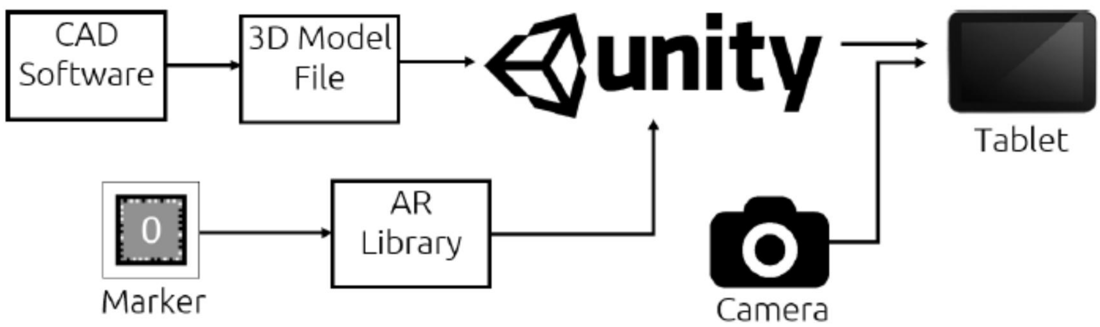

Figure 1: Information flows for an AR application

2.1 Unity

The Unity engine is a cross-platform graphics engine which can be used to visualize models in 3D on both desktop and mobile devices (Unity3D 2014). By using a cross platform engine such as Unity, it is possible to develop an application for both Android and iOS. This will be useful as the application is able to run on whatever type of device is available at the construction site. Unity is able to import 3D models from a range of common building modelling software packages. It also has a scripting engine which was used to develop the interactive components of the application, i.e. the quality assurance process and menu structure.

2.2 Vuforia

Vuforia (2014) is an augmented reality plugin which is compatible with Unity. Using Vuforia, it is possible to define markers and then link them to a position in Unity's 3D model. Through the Vuforia plugin, the application can detect the markers in the physical world using the device's camera, and then adjust the 3D model so it overlays the markers correctly. Vuforia is able to detect the position, rotation and scale of the marker and then adjust the 3D model so that it matches.

2.3 Markers

Developing markers that would be accurately and reliably detected by Vuforia in a range of lighting conditions was one of the major challenges for this project. After trialling a number of different configurations of marker, we found the marker shown in Figure 2 to be most reliable. Because of its large white border and contrasting background, Vuforia is able to detect it reliably at any size greater than 4cm. The black and white binary pattern allows Vuforia to differentiate between 512 different markers, enough for at least a significant portion of a building's framing.

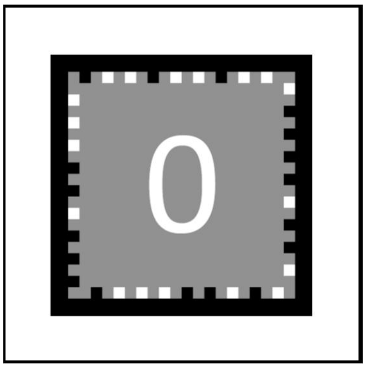

Figure 2: Effective AR marker

Another useful feature of these markers is the central space which is not actually used by the application. This space can be used for human readable text, for instance a joint number. This makes the markers useful even without the AR application.

We carried out an experiment with these markers to determine the relationship between marker size and maximum recognition distance. The larger the recognition distance, the more useful the application, as more of the structure will be visible on the screen.

Our results showed that, as would be expected, the larger the marker size, the better the recognition distance (see Figure 3). In particular, there was a significant jump in detection distance at 4cm, this is the minimum practical limit for marker size. Fortunately, steel framing is typically wide enough to accommodate markers of at least 4cm.

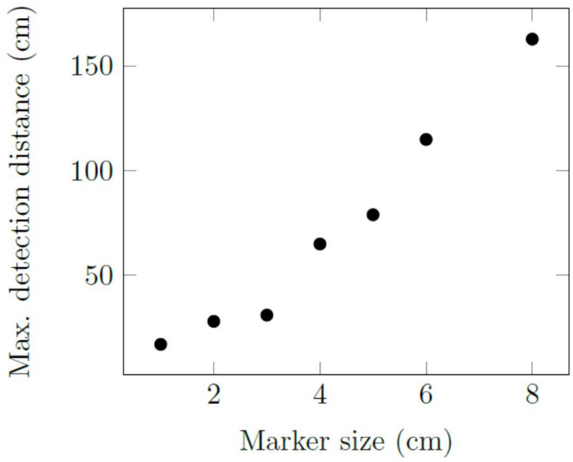

Figure 3: Impact of marker size on detection distance

2.4 Mobile Application

Combining Unity, Vuforia and the markers, we have developed a cohesive mobile application for framing verification. Starting from the home screen the user can select a particular scene they would like to view. Each scene defines a mapping between a set of markers and a 3D model.

Once a scene has been selected, a feed from the device's camera is shown on the screen (Figure 4). When a marker is detected from the camera feed, the corresponding 3D model is overlaid on the screen. The user can then tap on each segment of the model to verify that it is present. In a quality control mode unverified and verified segments are displayed in red and green respectively (see Figure 5). The ID number of the identified marker and the number of unverified segments remaining are displayed in the top left hand corner of the screen.

2.5 Server

To allow an off-site inspector to remotely verify the status of a structure, we have introduced a server component which communicates with the mobile application. The server component tracks the status of each piece of a truss, so that a mobile application can save the status (verified or unverified) of every object to the server. This status can also be loaded from the server by a mobile application, so that multiple devices can be used to verify the same building at the same time.

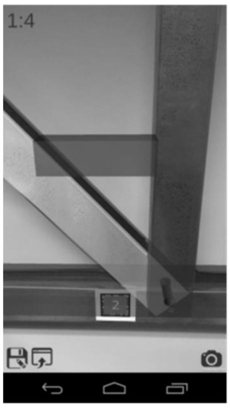

Figure 5: Truss with verified and unverified steel sections

In addition, the camera button in the application allows the user to upload screenshots (as seen in Figure 5) directly to the server. Each screenshot is associated with the marker currently in view. This allows a remotely-based inspector to view photos of each point of interest on the structure and manually verify that it is correct.

To allow information about the current status of the structure to be viewed remotely, there is also a web interface. This allows an expert at a remote location to login, view the overall progress of a building as well as details of every component tracked by the system.

2.6 Limitations

While this project demonstrates the potential usefulness of augmented reality in steel framing quality control, it is very much a proof of concept application. As such, there are a number of limitations in our implementation which would have to be addressed before this project could become practically useful.

Firstly, it would be difficult to print the markers with sufficient clarity for use in this project onto steel framing. Currently, the steel printers are only able to print black ink onto the framing (for labelling different sections), whereas our markers require three high contrast colours (black, white and blue) to be reliably detected. This could be addressed by improving the printing technology, or improving the marker recognition system.

Another interesting problem we encountered was the differing field of view (FoV) of different devices' cameras. When testing on a Nexus 5, for instance, the virtual model and the camera feed lined up perfectly. However, on an ASUS tablet the model did not line up well at all, as shown in Figure 6. This could be fixed by changing Unity's rendering settings depending on the device being used.

A side effect of the intensive image processing performed by the augmented reality engine is the high battery consumption when using the application. A typical mobile device depletes its battery after approximately one or two hours of running the application continuously. This is difficult to mitigate and could become a problem when checking a large building.

Figure 6: Truss with incorrect AR alignment

3. Evaluation

3.1 Quality Control

The main purpose of this application is to streamline the quality control process. We considered the different ways framing could be incorrectly assembled and evaluated how well the mobile application would detect these faults.

Component missing: If there is a component which is in the 3D model but not present at the building site, it would immediately be apparent to the user - when the user comes to check on that particular component, it will not match with any component in the physical world.

Extra component: If there is a component which should not be present, it should be obvious that it does not line up with any part of the 3D model. However this case is not as straightforward as the case of the missing component as the application cannot automatically identify and track these extra components.

Component in incorrect location: One of the specific problems tackled was symmetrical looking pieces of framing being inserted the wrong way around. If there are unique markers at each end of such a piece, it would be obvious when using the application that the framing has been assembled opposite to the expected model.

Component misaligned: Our application is also able to make small errors in alignment obvious to the user. In our testing we found that if a joint was as little as 5° different to the 3D model, it was very apparent that something was misaligned.

3.2 User Testing

To evaluate the ease-of-use of our application, we carried out user tests on Software Engineering students who had never used the application before. The testers were given a simple explanation of what the application does and then were asked to verify our example truss, upload the data to the server and then view their progress on the server. They were encouraged to think out loud and were asked for feedback after the task was completed.

Overall the feedback was positive, with users easily able to determine how the application worked, the meaning of the green and red components and the actions of the various buttons. The testers were all able to identify all the correctly assembled joints as well as a joint with a missing cross-section. However, the testers did highlight some interface issues in the menu system of the application, poor scrolling and confusing menus (which have since been addressed).

All of the testers agreed that this system would be helpful for verifying the correct construction of a building. While this feedback was helpful, more realistic user testing at a real building site with construction workers is needed to determine how useful the application would be in a practical context.

4. Conclusions

Combining architectural visualisation and augmented reality is a powerful way of addressing some of the real world problems experienced in the construction industry. While there are a number of limitations of our implementation, the prototype does demonstrate the feasibility of performing quality control of framing and truss assemblies using augmented reality. The markers developed, in combination with the mobile application, provide easy access to the building model. The checking-off process in the mobile application allows for effective quality control, and the server allows the verification process to be overseen remotely.

Abstract

Text data plays a critical role in construction project management and covers an overall project lifecycle from its beginning to completion. To be specific, project decision makers can take advantage of text data generated from previous projects, in order to solve similar project-related risks occurred while executing different projects. However, text data has usually been in an unstructured form and it was hard to utilize; tacit knowledge presented in documents turned out to be difficult to collect, analyze, evaluate and manage systematically throughout the project lifecycle. Thus, it is important to develop a text data management system not only to discover knowledge but also to keep abreast of accumulated data for a project team. This research developed a prototype system of UNI-Tacit and its modules for preliminary implementation. The primary objective of this study is to investigate text-specific characteristics of the construction industry, such as peculiar term usages or structures of phrases/documents, which can support the extraction of knowledge from text data. The research methodology to support automated knowledge discovery in UNI-Tacit, included (1) data pre-processing and (2) collocation analysis. The research analyzed approximately 30,000 documents on the web such as editorial articles, interviews, official correspondences, and journal papers to demonstrate the usefulness and practicality of the proposed system. Specifically, collocation techniques were uncovered and the most applicable method to overcome technical difficulties, mainly caused by the construction industry's distinct features during collocations, was determined. UNI-Tacit presents two main contributions. One is the automated keywords extraction, which can summarize original documents, and the other is multi-document summary visualization to provide meaningful insights for decision support relevant to keywords.

Keywords: Construction text data, text mining, collocation, knowledge discovery, UNI-Tacit

1. Introduction

A significant amount of text data has been accumulated over time in the construction industry (Hjelt and Björk, 2006; Zhu et al., 2007; Ma et al., 2011). It is so, because construction projects are unique, complex, and of long duration, and the stakeholders face numerous issues from the beginning until the conclusion of the project (e.g. Figure 1). Any problems that arise during the project lifecycle are commonly written in documents as text, which is the most natural form of storing information (Tan, 1999). Construction sites generate documents such as specifications, quality and safety reports, design change documents, and claim documents, as well as construction-related text data on the web such as news, editorials, reports, and journal articles (Rubin et al., 1999; Chun, 2001).

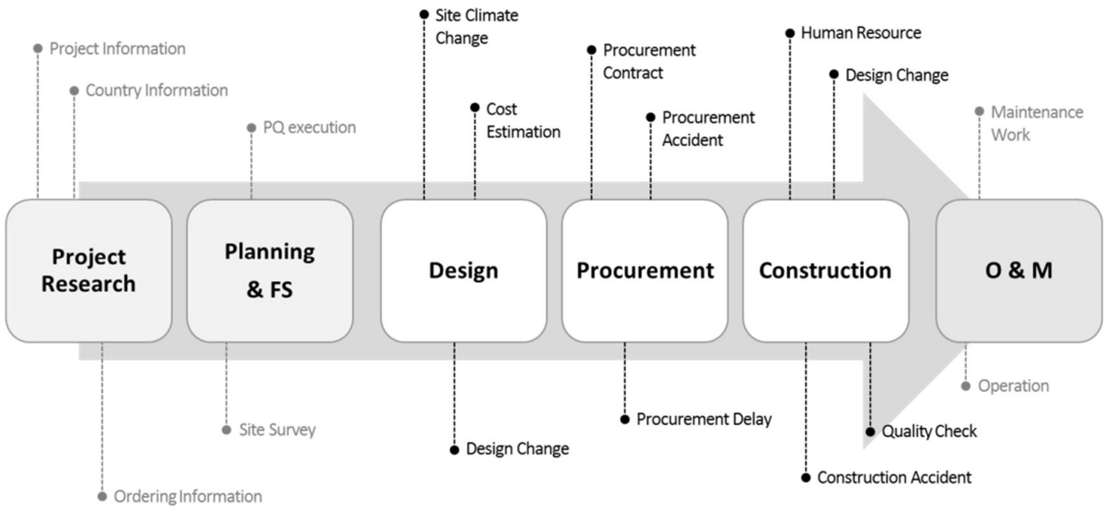

Figure 1: Various issues in a construction project

Text data is very useful to the construction industry, regarding project-related decision making. Nearly 80% of the information generated by companies is in document form (Cleveland, 1995; Gantz and Reinsel, 2012). Furthermore, important information collected from previous projects as experience, is mainly presented through documents (Pathirage et al., 2007; Soibelman et al., 2008). Such information can be reused in upcoming projects, delivering lessons learned for better risk management and project control. Thus, text-based information can play an important role in business strategy development in the highly competitive construction industry (Song et al., 2009; Qady and Kandil, 2010).

However, there are challenges in utilizing text data. Above all, text data needs to be pre-processed before being able to extract useful information from it, as most text data is unstructured (Akilan, 2015). The characteristics of natural language (e.g., non-standard expressions, segmentation issues, and tricky entity names) need to be investigated during the data processing. Complex and distinctive linguistic terms exist in numerous types and forms, in the construction industry (Soibelman, 2008). Moreover, the text data management system infrastructure is scarce in the construction field (Go, 2013). Such text management environments in the construction business, result in plenty of constraints when applying existing text mining techniques, used in other industries, to construction and construction-customized text mining techniques need to be developed.

In addition, problems to keep up with daily updated information and manage piled up construction documents, still exist. They are usually time consuming and require specific manual efforts. To deal with these setbacks, researchers have mainly focused on two fields of study: text analytics and information visualization (Liu et al., 2009). However, few researches that maximize the value of text analytics and information visualization for construction application, were studied (Liu et al., 2009).

To tackle these challenges, this research developed UNI(User Needed Information)-Tacit (Figure 2) prototype. The primary objective of this study is to investigate text-specific characteristics of the construction industry, such as peculiar term usages or structures of phrases/documents, which can support the extraction of knowledge from text data. This was achieved by data pre-processing and collocation analysis. These processes support two main contributions. One is the automatic extraction of the appropriate keywords, which leads to a brief summarization of documents, and the other is a practical visualized output, which provides meaningful insights to keywords in the construction industry.

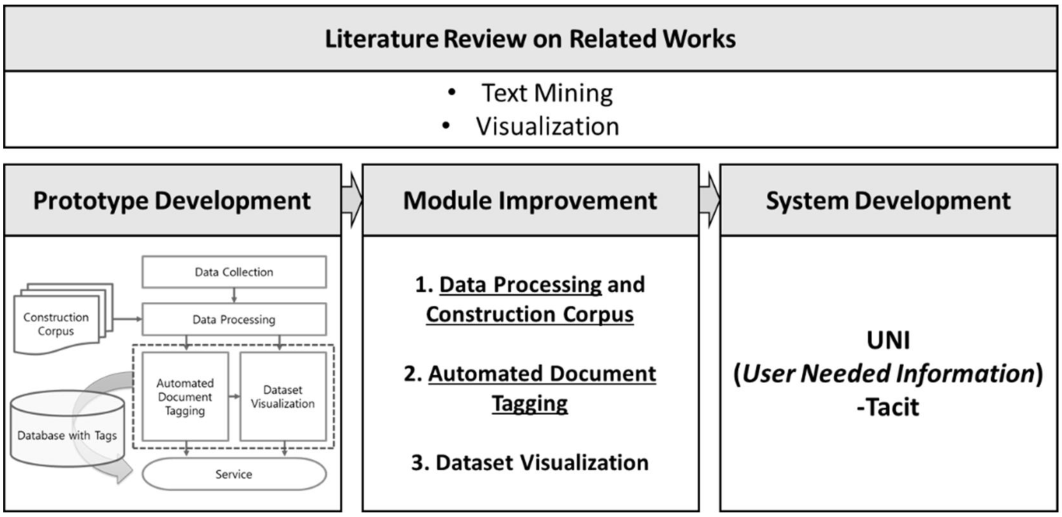

Figure 2: Research framework

In the rest of the paper, UNI-Tacit system framework and user interface are briefly described. Then, the methods of key processes to discover knowledge mechanically are described. The key processes consist of data pre-processing and collocation analysis. The application and discussion of the proposed processes are presented, and the paper concludes with a summary of the research, contributions, and future works.

2. UNI-Tacit System Overview

UNI-Tacit is designed to utilize piled up construction text data effectively and efficiently. With UNI-Tacit, users can view extracted keywords of documents based on automatically processed data and capture essential information easily and quickly through keywords via the visualization function.

2.1 System Framework

UNI-Tacit is constituted by modules, represented by each box (Figure 3). Modules in dashed rectangles are automatic processes (automated document tagging and dataset visualization) and other modules (data collection, data processing, and service) surrounded by a solid line are semi-automatic processes, which include a few manual steps.

The proposed system in this research, mainly focuses on data processing for extracting appropriate keywords from each text data automatically and on dataset visualization for conveying its essential information quickly and efficiently. The construction corpus is used as a data processing module, which reflects the text-related characteristics of the construction industry.

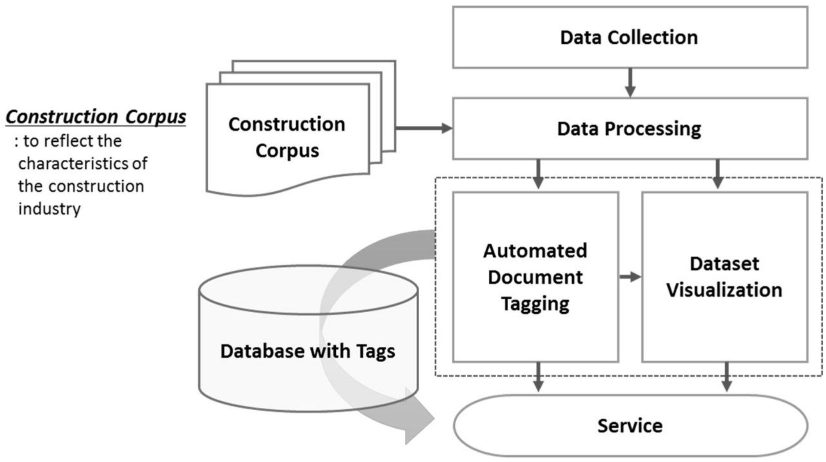

Figure 3: UNI-Tacit system framework

2.2 User Interface

Figure 4 demonstrates the implementation of UNI-Tacit prototype user interface, which employed an opened construction-related online data. The main concept of the user interface is interaction, thus when a user clicks on a tag, the system provides the dataset of documents, including the selected tag, as keywords. To be specific, a global map comes first into view because all countries are tagged, and if a user clicks on a country, a wordcloud is created with the list of the dataset based on its (including the chosen country as a tag) keywords (Figure 4(a), 4(b)). The user can also click on a term he/she is interested in, in the wordcloud and find practical information about that term (Figure 4(b), 4(c)) and the clicking will result in a new wordcloud and a list of dataset for the newly clicked tag.

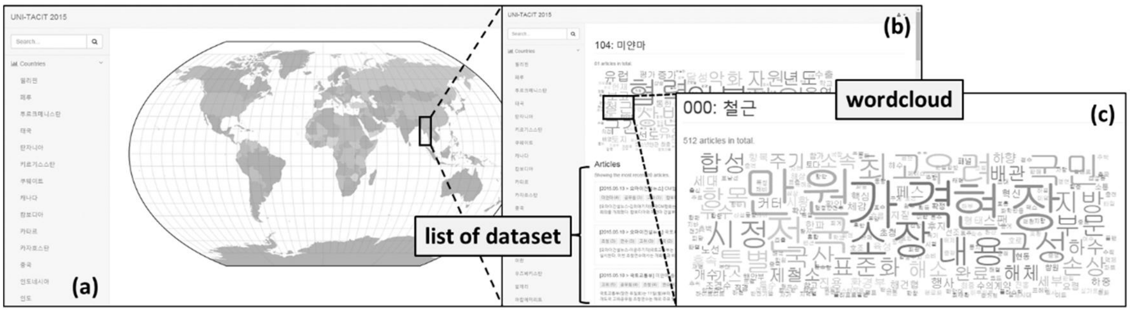

Figure 4: UNI-Tacit user interface

3. Automated Knowledge Discovery

The UNI-Tacit prototype discovered knowledge automatically based on data pre-processing and collocation analysis, which are essential processes to keyword extraction and visualization. The core objective of these processes is to enhance the extraction of exact keywords. To tackle this issue, data pre-processing and collocation analysis methods are proposed.

3.1 Data Pre-processing

Data pre-processing is a necessary step to vectorize text data. Data processing is a semi-automatic process, which includes both automatic and manual steps. Automated steps consist of POS tagging, term frequency calculating, and filtering, and manual steps include dictionary selection, optimum morpheme selection, and filter selection.

In the case of Korean data, the POS tagging process is usually combined with morphological analysis, which identifies the structure of morphemes and other linguistic units in a phrase. Thus, POS tagging is the same as the process of marking-up morphemes in a sentence based on their definitions and context (Park, 2015). Term frequency is calculated based on the POS tagged data, and filtering includes removing unsuitable terms as keywords.

3.2 Collocation Analysis

Collocation is an expression which consists of more than two words that correspond to a customary or habitual manner (Manning and Schutze, 1999). It is common to say ‘strong coffee’, not ‘powerful coffee’. In the same way, one ‘rides a bicycle’, but does not ‘drive a bicycle’. These are collocations in natural language. In this manner, collocations (e.g. strong tea) are more compositional than free constructed phrases (e.g. good boy), but less compositional than idioms (e.g. kick the bucket).

Collocations differ from industry to industry. For instance, tool box meeting(TBM) is a collocation in the construction industry, while it is not a collocation in other industries. To be specific, the phrase *tool box meeting,* in general fields, will be split into *tool, box* and *meeting,* and interpreted just as a tool, a box and a meeting. On the other hand, in the construction industry, *tool box meeting* implies several specific meanings, such as assigning the task of the day, conveying the instructions and contact information to the workers at the beginning of the day. Moreover, there are some collocations which are homonyms, meaning that a phrase can be a critical keyword in the construction industry, but not in other fields, and vice versa.

Thus, collocation analysis and determining an appropriate collocation method, enables the system developer to automatically find some conventional construction phrases out of documents, and to reflect peculiar text-specific characteristics of the construction industry. Collocation discovery also aids data processing by replacing words with the wrong tag, with collocations that are correctly composed phrases, in terms of the construction industry.

Three methods for collocation discovery from construction text data, were analyzed in this study. The hypothesis testing included the t test and Pearson's chi-square test, and mutual information methods, which were selected from among many after carrying out a literature review. Each method was evaluated quantitatively and qualitatively, and the most appropriate method was chosen.

The hypothesis testing detected collocations by assessing whether terms occur together by chance or not. Term occurrences were considered to be independent from each other, which meant that $P(w^1 w^2) = P(w^1)P(w^2)$, and the hypothesis was then tested. Thus, the formulated null hypothesis H_0 implied that there was no relation between the two terms (Manning and Schutze, 1999). The t value for the t test was calculated through the following equation:

$$t = \frac{\bar{x} - \mu}{\sqrt{\left(\frac{s^2}{N}\right)}}. \quad (1)$$

The chi square value for the Pearson's chi square test was calculated by the equation below:

$$\aleph^2 = \sum_{(I,j)} \frac{\left(O_{ij} - E_{ij}\right)^2}{E_{ij}}. \quad (2)$$

These values were used to compute the probability p in relation to a significance level (e.g. 0.05, 0.01, etc.).

The mutual information method also assumed that terms were independent from each other, but it was a measure which was theoretically motivated by information. The pointwise mutual information measured the amount of information (reduction of uncertainty) gained by the occurrence of each term (Manning and Schutze, 1999) through the subsequent equation:

$$I(x', y') = \log_2\left(\frac{P(x'y')}{P(x')P(y')}\right). \quad (3)$$

Both quantitative and qualitative evaluations are required for the appropriate collocation discovery method in the construction industry. Thus, the Jaccard index evaluated the methods quantitatively, as it is commonly used to assess the performance of keywords extraction by the ensuing equation:

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|}. \quad (4)$$

The construction experts' consultations on discovered collocations were taken as qualitative evaluation.

4. Application and Discussion

To demonstrate the performance of the proposed UNI-Tacit prototype system, the system was applied onto a dataset: an opened construction-related online data. In this section, we present the results of the application, followed by a discussion of the results. The application was conducted on a Macbook Pro with Intel Core i7 CPU and 16GB memory on Python programming language.

4.1 Data Overview

The targeted dataset of the proposed system prototype comprised construction-related documents scattered on the Internet. Specifically, construction-related news, editorials, interviews, reports, and official documents on the Internet were deemed to be appropriate for the dataset because these data types are prolific, frequently generated and accumulated in a variety of themes and, above all, treated as being useless at present.

Six construction-oriented websites were selected as the target web pages, which deal mostly with the mentioned data types. Cdaily, Cnews, Fnnews, and Ohmycon sites cover mainly data derived from news, editorials, and interviews. KISCON deals mostly with editorials, reports, and official documents. MOLIT generates primarily official documents and related news. Detailed information on each data sources is ensued in Table 1.

Table 1: Data overview

Korean	***English***	***Number of data***	***Website address***
건설일보	*Cdaily*	*474*	*https://www.kiscon.net/kcn/list.asp*
일간건설	*Cnews*	*4,242*	*https://www.kiscon.net/kcn/list.asp*
파이낸셜	*Fnnews*	*1,561*	*https://www.kiscon.net/kcn/list.asp*
KISCON	*KISCON*	*3,804*	*https://www.kiscon.net/cks/share_bbs/list.asp*
국토교통부	*MOLIT*	*1,492*	*http://www.molit.go.kr/USR/NEWS/m_71/lst.jsp*
	Total	***25,143***	

The dates of the collected data range from the website's inception date to 21/05/2015. The total number of data files for the pilot study was 25,143, which is approximately 279MB as a memory unit.

4.2 Results and Discussion

Raw data firstly went through the data pre-processing step. In this phase, unstructured crawled data was transformed into a structured form. The Twitter dictionary was selected for POS tagging on the dictionary selection step, because the Twitter dictionary requires a relatively short processing time and displays good POS tagging performance on online data. Only Nouns tagged as words frequency, were calculated, since other morphemes are too obscure to represent documents. Lastly, too frequent and too infrequent terms were removed in the stop words removal step, because those terms just lead to the curse of dimensionality with little merit. The terms were sorted by frequency, and the top 30 frequent terms and terms which occurred only once, were deleted. The average number of words per document was 479.97 and the number of unique nouns, excluding stop words, was 21,668.

The selected methods for collocation discovery (the t test, Pearson's chi-square test, and mutual information) were applied to the POS tagged data because collocations are meaningful only when they are discovered as consecutive words. A sentence such as "A dog bites a piece of cookie.", after going through the entire data pre-processing step, would only keep the information of "dog: 1, piece: 1, cookie: 1", which is useless for finding out collocations.

In this study, the focus was on which collocation discovery method was appropriate for the construction industry, therefore collocations were analyzed, regardless of each term's tag. Also, the bigrams (two consecutive words) which occurred more than 30 times, were taken into consideration, because computing all bigrams would just consume time, without any particular discoveries. The number of bigrams with more than 30 times frequency was 49,194.

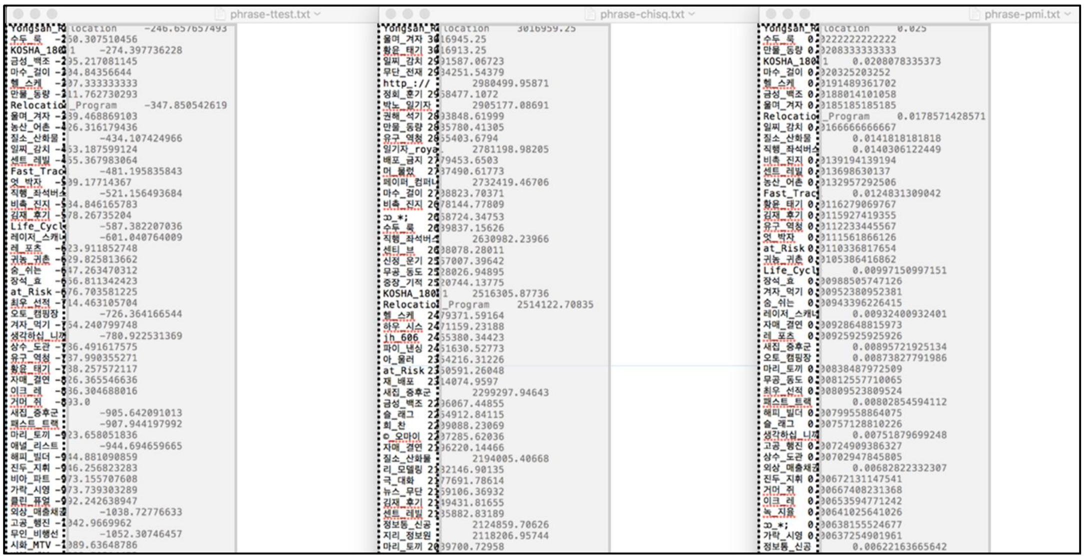

Figure 5: Collocations and calculation results (t test, chi-square test, mutual information)

Figure 5 shows the examples of discovered collocations (in dashed rectangles) and calculated values (in grey rectangles) for each method presented on the list of highest-to-lowest values. The differences between each method can be spotted. Thus, the Jaccard index, which focuses on how many common items two groups have, in their union, evaluated which one would be optimal to the construction industry. The higher the Jaccard index is, the bigger the intersection portion is. Thus, from the qualitative standpoint, the mutual information method showed the best performance, in terms of detecting the most collocations among each method's results for all cases of top 1,000, top 5,000 and top 10,000 collocations.

Table 2: Jaccard index

Jaccard Index	***J(t, chi-square)***	***J(chi-square, mi)***	***J(mi, t)***
Top 1,000	*0.410*	*0.493*	*0.826*
Top 5,000	*0.494*	*0.606*	*0.819*
Top 10,000	*0.559*	*0.670*	*0.840*

The construction experts' consultation guaranteed the usefulness and practicality of collocations. Specifically, there have been considerable errors on the POS tagging process as construction documents do not only include many Sino-Korean words but also follow different word spacing rules respectively. Discovered collocations were of high assistance in the solving of this drawback. An example of this is *레_포츠 (le+ports à leports)* and *최우_선적 (Choi-woo+shipment à the first priority),* which are composed together. There are also collocations, which reflect the characteristics of the construction industry, such as noun phrases, including *Fast Track* and *Life Cycle,* which should be composed together to understand its exact meaning.

The service page of UNI-Tacit prototype system is presented below, in Figure 6. The final output is displayed on the service page, having gone through all modules (data processing, automated document tagging, dataset visualization) in the UNI-Tacit prototype system. When the user clicks on a tag, the keywords of the tag's dataset are drawn in the form of wordcloud, and the dataset list is ensued, below the wordcloud. The extracted keywords are also provided with the document subject and a 100-character preview.

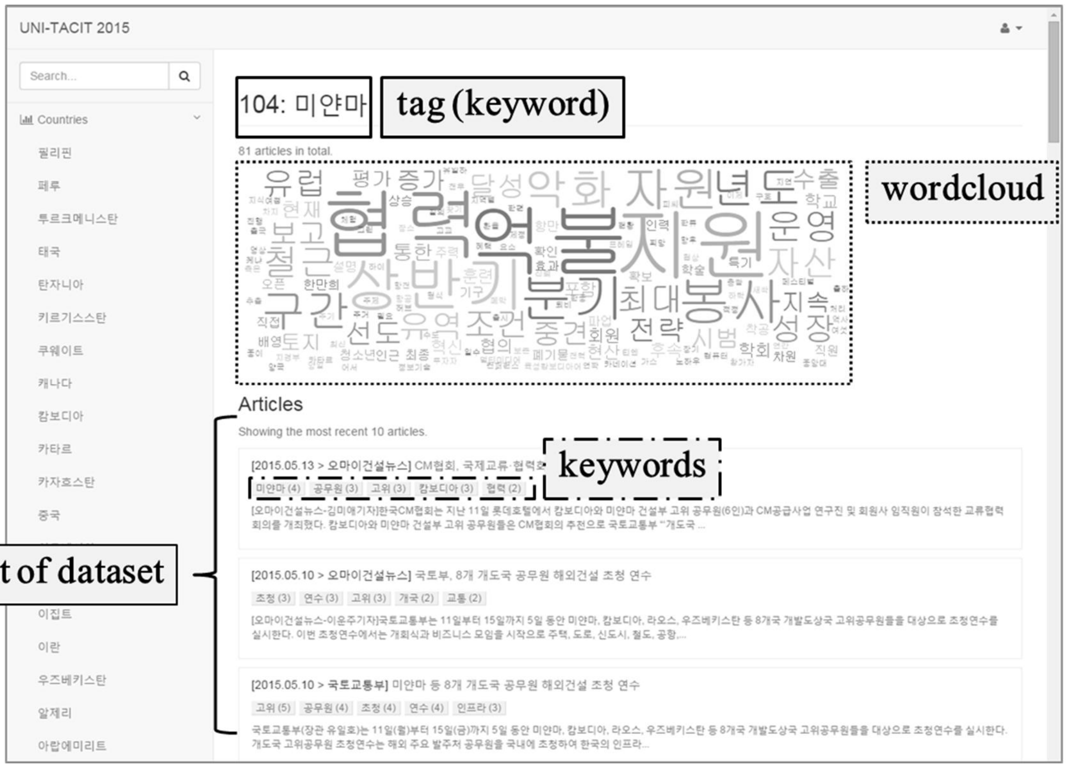

Figure 6: The service page of UNI-Tacit prototype system

5. Conclusion

The UNI-Tacit prototype system extracted correct keywords for a document by data pre-processing and collocation analysis and finally discovered knowledge by document tagging with keywords and dataset visualization based on keywords. Specifically, collocations reflecting the characteristics of the construction industry were discovered and also, the most appropriate method for finding collocations, was determined. Discovered collocations aid text mining in the construction industry overcome technical difficulties, mainly caused by the construction industry's distinct features. From the UNI-Tacit system's point of view, the proposed method of data pre-processing and collocation analysis showed promise, regarding text mining techniques applicable to the construction industry.

In the future, the developed UNI-Tacit prototype system in this study can be improved by developing methods to discover knowledge automatically. Collocation analysis considering trigrams (composed of three consecutive words) would help find more useful collocations. The term-document matrix generated in this study is a base for topic mining, which would lead to better keyword extraction. The dataset visualization improvement is also an attractive subject of research in the construction industry to convey information more effectively and efficiently. The application of the proposed system to English databases is expected to show more novel and promising results, as there are well-developed English text data pre-processing libraries and even more construction related-data in English.

Salman Azhar,
McWhorter School of Building Science, Auburn University
(email: salman@auburn.edu)

Abstract

Virtual Reality (VR), sometimes referred to as immersive environment, is a computer-generated 3D environment that can simulate the real world environment. A user wearing VR headsets can feel the same experience, as he/she would have in the real world. The aim of this pilot study is to investigate the feasibility of 3D VR Headsets in jobsite planning and management, from educational as well as industry implementation perspectives. The specific objectives consist of: (1) to study the current industry workflows for site logistics, layout and planning; (2) to investigate the feasibility of VR Headsets for jobsite planning simulations; and (3) finding ways on how to enhance the effectiveness of jobsite planning process through the use of VR Headsets. A jobsite model during the structural phase of the buildings construction was created using Unity 3D(R) software. Oculus Rift VR headset was chosen for its support and integration with the Unity 3D(R) software. Using the model, three scenarios demonstrating applications of 3D VR Headsets for jobsite management were created. Mixed methods research techniques including a focus group and a questionnaire survey both adopted for feedback and data collection. Presented in this paper are the main findings of this pilot study, which helped us to explore an emerging technology that could be a game changer in the design and construction industry. The results of this research aided in our determination of the best value and applications of VR headsets for jobsite planning and management within design and construction disciplines. We found that VR headsets are indeed very beneficial - allowing the users to immerse into a near-actual environment. The users were able to interact, identify, and gain an in-depth experience pertaining to jobsite management. The application of textures, materials and site development were found to create a life-like feeling. Each participant became physically involved in his/her exploration, exhibiting natural movements outside of the VR environment. This paper also presents some limitations of VR headsets and provides recommendations for future research.

Keywords: Virtual reality headsets, construction, jobsite planning, jobsite management, immersive 3D environment

1. Introduction and Background

1.1 Virtual Reality and Jobsite Organization

Although the term Virtual Reality (VR) has gained popularity recently, its roots can be traced back to the mid-nineteenth century (Wikipedia, 2015). As time evolves, this technology is becoming better, cheaper, and more accessible (Froehlich and Azhar, 2016). The definition of virtual reality is quite straightforward. 'Virtual' means 'near', so the term 'Virtual Reality (VR)' basically implies 'near-reality'. VR refers to "a computer-simulated reality computer technology that replicates an environment, real or imagined, and simulates a user's physical presence that environment in a way that allows the user to interact with it. Virtual realities artificially create sensory experience, which can include sight, touch, hearing, and smell.(Wikipedia, 2015). The term VR was introduced in the 1860s, when the concept of 360-degree art through panoramic murals began to appear. After spanning a period of more than a hundred years for the framework to form, VR came into the public's attention, and the first VR headset was created in 1990s. During the past 10 years, VR has seen a tremendous growth in popularity. Nowadays, it is more often used to describe a wide variety of applications associated with immersive, highly visual, three-dimensional (3D) environments. The 3D environment, which appears to be life-sized from the perspective of the user, can be simulated through computer. It can be interacted with, explored and controlled by a person through a head-mounted display (HMD). HMD is "a pair of goggles or helmet with a screen in front which displays three dimensional images or video". The person who wears a HMD becomes part of this virtual world. With an embedded tracking device, images displayed to the wearer change as he/she moves the head (Wikipedia, 2015).

VR can be extremely useful in the construction industry. Among possible applications, VR technology could significantly aid in jobsite organization, which comprises of a substantial number of tasks spanning from planning to execution stage. Effective jobsite organization is imperative for any construction project as it can provide massive benefits in efficiency that condense the project schedule and productivity that significantly reduces the overall cost of the project (AEC Business, 2015). Yeh (quoted in El-Rayes and Khalafallah, 2005) states that construction jobsite organization during all the construction phases requires the identification of the building footprint, temporary facilities' location including security fences, access roads, parking area and storage areas, stockpiles of excavation, site trailer, fabrication shops, and batch plants. Short and fast transport routes, explicit material flow, efficient use of technology and a safe work environment ensure the success of a construction project (Astour and Franz, 2014). An optimized jobsite organization plan can lead to: (1) optimum usage of available space, (2) less relocation of materials, (3) minimizing travel times of labor, material, and equipment on site, (4) better accessibility to the jobsite, and (5) a safer work environment (Zolfagharian and Irizarry, 2014). As such, effective jobsite organization is significant and critical during all construction phases and should be properly performed and updated as the project goes on.

However, to develop an effective jobsite organization plan, a wide range of factors need to be taken into account. As with the construction of any project, unforeseen complications most likely exist. While preventing all of these issues may not always be possible, having a clear strategy in place to resolve a potential problem can lead to significant cost and time savings. According to Voigtmann and Bargstadt (2008), jobsite logistic processes take up to one third of the total execution time on site, and well-planned and executed construction logistics have the potential to reduce the construction time by 10 percent and the cost by 4 percent in outfitting processes.

Due to the complexity and the number of factors involved, jobsite planners have adopted technologies to improve the efficiency of their tasks. The emerging technology of Virtual Reality provides an effective mean of verifying site operations as well as site logistics. According to Kizil and Joy (2001), people gain 70 percent of information by vision, resulting in systems like HMDs that provide the visual component of immersion to develop virtual environments. The use of high quality three-dimensional graphics, sound and dynamic simulation combine to form a uniquely engaging experience (Kizil and Joy, 2001). By placing users in an immersive environment, it enables the visualization of jobsite arrangements in construction projects at different stages, thus providing the users with a more illustrative site plan and letting them visually see the space utilization. Jobsite organization, including traffic routines for equipment, locations for material stack and manpower availability can also be incorporated into the module to be checked visually as part of the logistics plan (Kymmell, 2008).

1.2 The Virtual Reality Head Gear - Oculus Rift®

This research was conducted using the Oculus Rift Development Kit 2 VR Headset as shown in Figure 1. The Oculus Rift was chosen for its support and integration with Unity 3D® software. The Unity 3D® software was an essential tool for digital model development. Among all of the head mounted VR products which are available in the market, the Oculus Rift, a wearable virtual reality headset which has been labelled as one of the top 10 creations in 2013, has a more tremendous impact on the virtual reality market. It delivers a stereoscopic 3D view with smooth frame rates at high resolutions for immersive virtual reality. A gyroscopic sensor is embedded in the headgear, which can track any tiny rotation the user's head makes so the view can change accordingly, while simultaneously a 3D environment image will be generated on the connected computer (Desai *et al.*, 2014). For now, Oculus Rift has not yet been launched in the construction industry as a commercial product. However, it has the potential to revolutionize the industry in several aspects. With time, the VR headsets will evolve, with applications becoming more apparent and widespread.

Figure 1: Oculus Rift Development Kit 2 (Desai et al., 2014)

2. Research Objectives and Key Questions

To test the feasibility of 3D VR headsets in construction education and practice, this pilot study focused on the area of jobsite organization. The following were objectives of this: (1) to study current industry workflows for site logistics, layout and planning; (2) to investigate the feasibility of VR Headsets for jobsite planning simulations; and (3) finding ways on how to enhance the effectiveness of jobsite management through the use of VR Headsets.

Key questions we seek to answer included the following: (1) Can VR Headsets offer any advantages in jobsite organization as compared to traditional methods?; (2) Should VR Headsets be used alone or in conjunction with the traditional methods?; (3) Are VR Headsets economically viable for commercial usage?; (4) What are the potential benefits and drawbacks of VR Headsets for jobsite organization?; and (5) Are there any potential barriers to widespread adoption within the construction industry?

3. Methodology

The study was conducted utilizing mixed methods research using both qualitative and quantitative research instruments. The study was divided into three phases as shown in Figure 2.

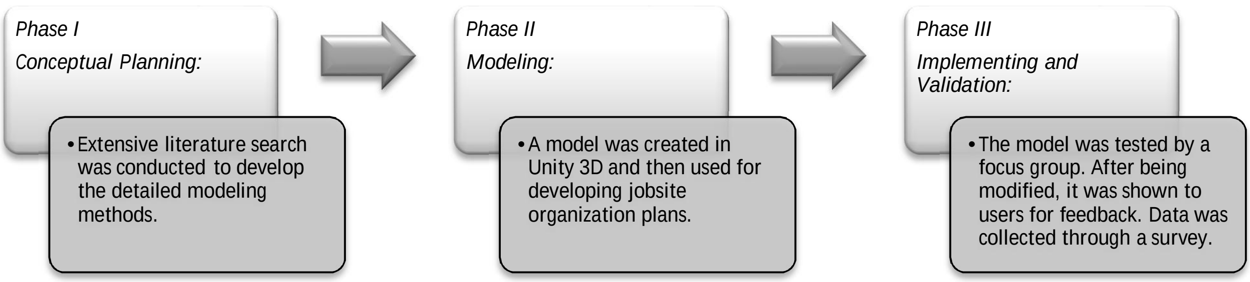

Figure 2: The Research Process

The following sections explain each phase of the research.

3.1 Phase I: Conceptual Planning

The purpose of the conceptual planning phase was to explore existing uses of VR Headsets in construction industry and to develop a detailed plan for creating the jobsite organization models. During an extensive literature review, the following referenced areas of application in construction were identified: (1) Site layout and planning; (2) Rehearsing erection sequences; (3) Progress and monitoring of construction processes; (4) Evaluation of construction scenarios; (5) Inspection and maintenance; and (6) Healthy and safety training. Next step was to review all available hardware (i.e. VR headsets). A number of VR headsets were identified and reviewed such as Oculus Rift DK2, Sony Project Morpheus, Samsung Gear VR, Google Cardboard VR, and LG G3. Among all of the head mounted VR products which are available in the market, Oculus Rift® is found as the best choice. The reason of this has been mentioned in section 1.2. More details of this analysis can be found in Froehlich and Azhar (2016).

3.2 Phase II: Modelling

A model simulating a jobsite was created in this phase. The following software were selected: (1) Autodesk Revit® for creating the 3-story structure, (2) SketchUp® for editing and exporting all the material stack, equipment, characters and related families needed onsite, (3) Unity 3D® for rendering the model, (4) MonoDevelop® for creating the script; and (5) Camtasia Recorder® and Camtasia Studio® for producing the end product videos. Oculus Rift® headset was used to view the model in Unity 3D®. The terrain texture mapping was first created in Unity 3D® software. Unity® is a cross-platform game engine developed by Unity Technologies and is used to develop video games for PC, consoles, mobile devices and websites. A 3-story steel framing structure was created in Autodesk Revit® and then imported into Unity 3D®. All the material, equipment and characters were imported from the SketchUp® warehouse to make the simulated jobsite looks real. Figure 3 shows a screenshot of the model.

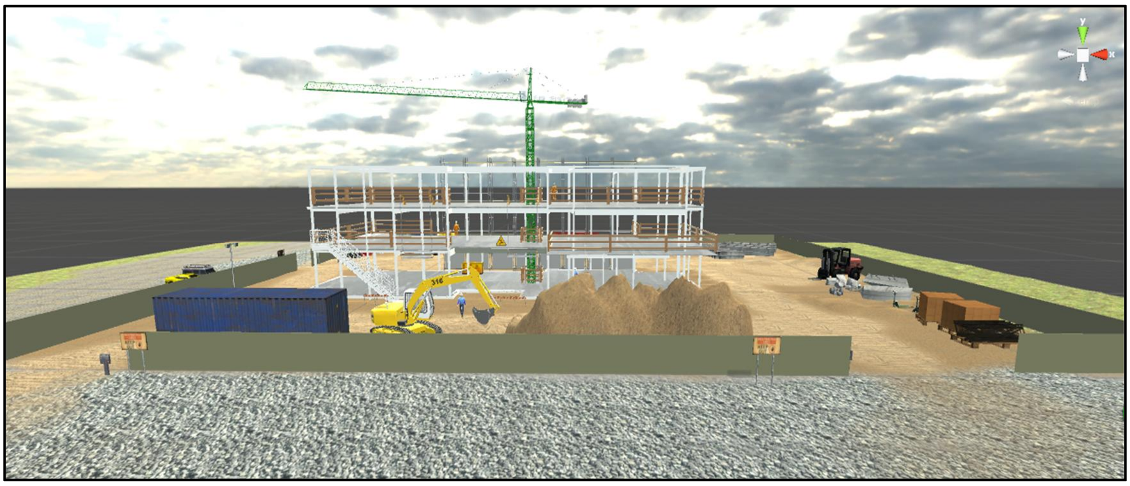

Figure 3: The Jobsite Organization Test Model

After rendering the above model, three scenarios were created, stressing how variation in jobsite organization plans can affect the effectiveness of site utilization. Scenario 1 and 2 were created based on the specific location of this project. Differences of site orientation, site access, crane placement, equipment path, material storage and waste access between these two scenarios. Scenario 3 was created as a vacant jobsite and its purpose was to allow users to create an ideal jobsite. All the material and equipment were placed off-site. By dragging and placing the material and equipment onsite, the end users were able to create their own jobsite layout. The following deliverables were produced: (1) 2D site plan captured from Unity 3D®; (2) 3D site plan (i.e. the 3D rendered model); and (3) 3D site plan with immersive environment using Oculus Rift; and (4) Narrated videos for presentation purposes.

3.3 Phase III: Implementing and Validation

For model testing and relevant data collection the following steps were performed: (1) Opinions were collected from a focus group consisting of eight BIM professionals; (2) After considering the opinions recorded in step 1, modifications were made to the model. Fourteen construction students were then invited to test the model. They were shown how Oculus Rift works in the above-mentioned scenarios. Afterwards, a questionnaire was used to gather their opinions as how they think of trying on Oculus Rift compare to the traditional methods; (3) Responses were analysed using descriptive statistics. Based upon these responses the advantages and disadvantages of Oculus Rift and its use in the construction industry were identified.

4. Model Development, Implementation, and Validation

4.1 Model Development and Implementation

A two-dimensional (2D) site plan is an effective method for implementing a jobsite organizational plan. Providing a simple and concise overview of the jobsite easily communicated to construction personnel. Due to the complexity of the construction projects, the way we organize jobsites is always challenging. Rationalization of the jobsite organization method is essential in catering all the different needs of the personnel as the construction goes on. The M. Miller Gorrie Center, a 3-story steel-framed, brick-clad building, during the structural phase of construction was chose to simulate jobsite organization. Figure 4a and 4b captured from the Unity 3D® model and marked with different colours are the 2D site plans for scenario 1 and 2.

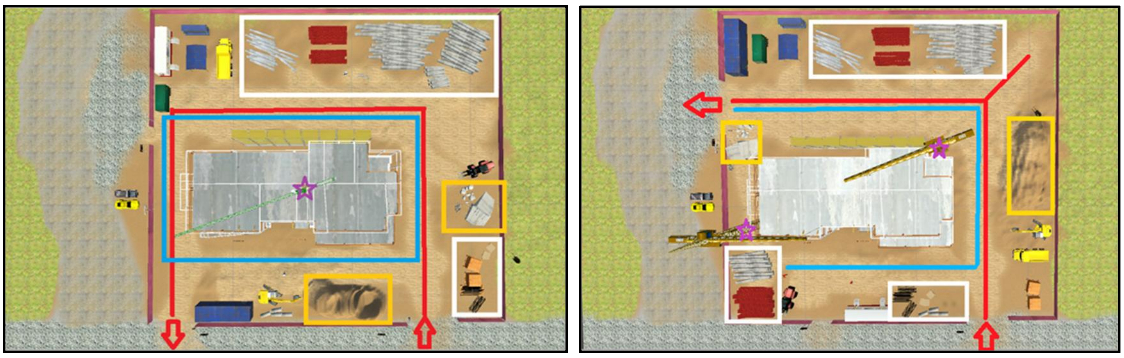

Figure 4: 2D Site Plans (a) for Scenario 1(Left) and (b) Scenario 2 (Right)

Differences can be seen from the following aspects: (1) Site access is marked in red colour. Placement of an entrance and an exit for vehicles in scenario 1 and scenario 2 are next to the jobsite trailer; (2) Crane placement is shown as purple stars. The type of crane, size of the load, crane efficiency, constraints and the associated costs were considered but not shown. In scenario 1 one tower crane was used, while in scenario 2 two tower cranes were employed; (3) Material storage is marked in white colour. Material was staged onsite at each phase of construction. In scenario 1 it was staged on the backside, while in scenario 2 it was staged separately but within the accessible range of the crane and located on the main delivery route; (4) Trash and waste access are marked in orange colour. In scenarios’ 1 and 2, trash and waste stacks were located along the main equipment path; (5) Equipment path is marked in blue colour. Trucks are used and shown on site plans for material delivery and waste removal.

Compared to the 2D site plan, a 3D site plan is a more powerful visual tool providing the viewer a life-like experience**.** It can show a detailed rendering of every component present at the site, including the equipment, materials as well as the site topography. Compared to the 2D plan, the 3D one illustrates how a jobsite may look like in reality, which makes it easier to understand. In addition, a 3D plan could let one see the volume and amount of spaces on site thereby making jobsite layout easier. Figures 5 and 6 depict the 3D site plans for scenario 1 and 2.

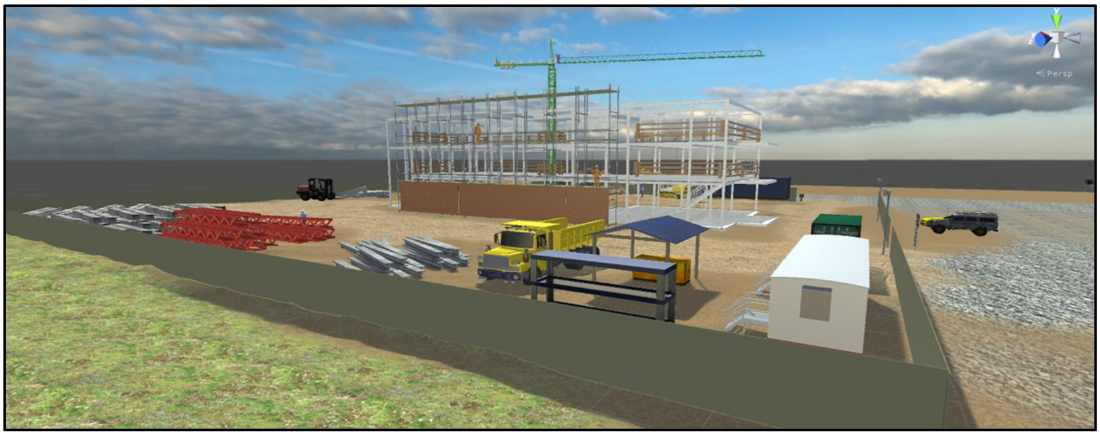

Figure 5: 3D Site for Scenario 1

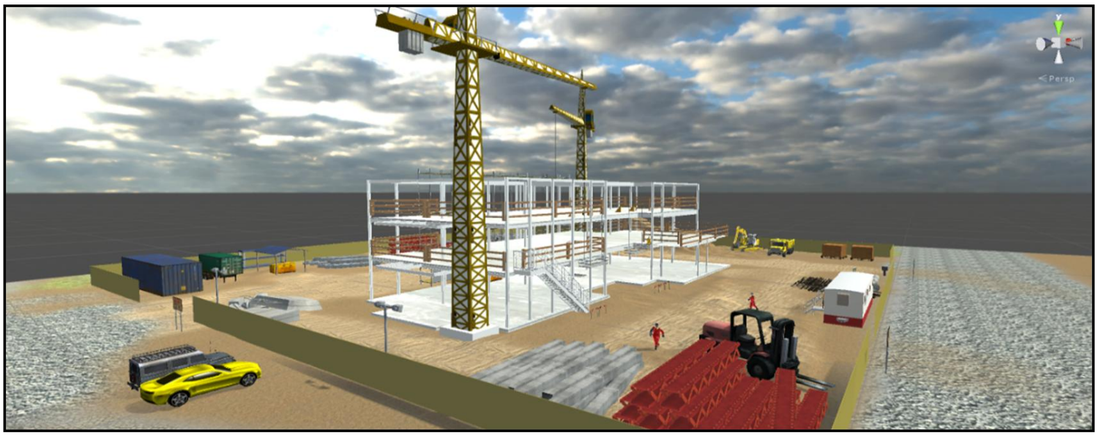

Figure 6: 3D Site for Scenario 2

For both scenarios, immersive environments of the 3D site plans were also developed providing a full VR experience to the users. Utilizing the Oculus Rift®, a 360-degree virtual view could be experienced by the user, sparking his/her early engagement in jobsite organization. Figure 7 shows a user's view through Oculus Rift® headset. The whole walk-through process via Oculus Rift® was recorded and shown to focus group participants for discussion.

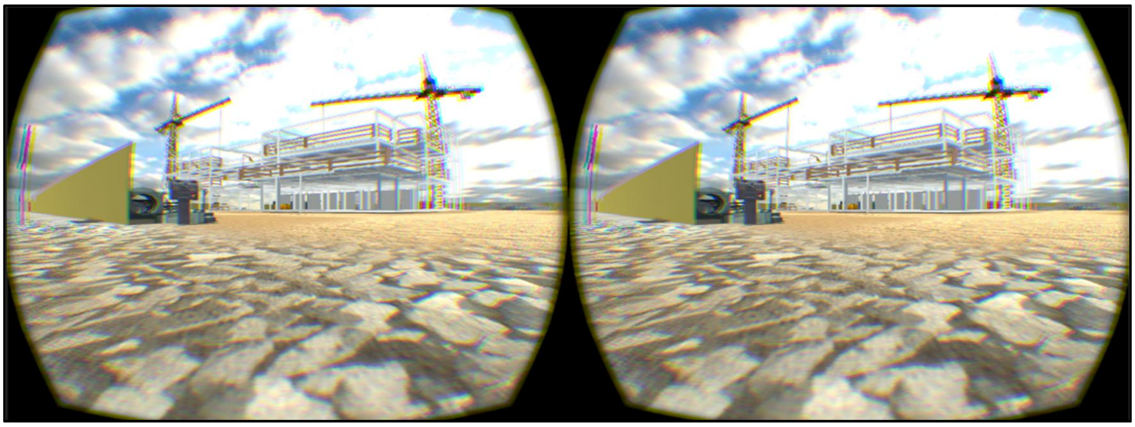

Figure 7: Users View through Oculus Rift® Headset (for Scenario 2)

Scenario 3 was developed assuming a vacant jobsite. All the material and equipment were placed off-site. The embedded script allowed users to interact with the 3D environment by dragging and placing materials and equipment on the site, thus creating their own ideal jobsite layout. Figure 8 shows the equipment and material available to the users in front of the jobsite.

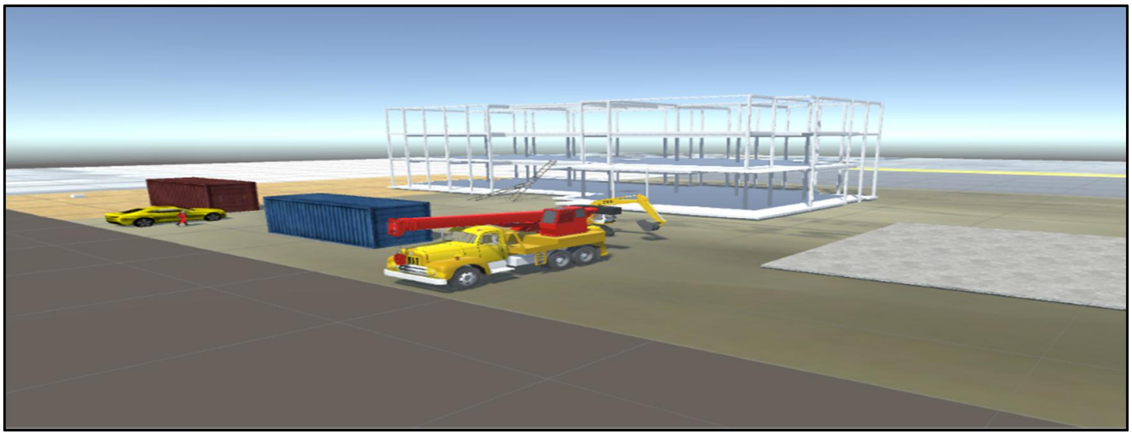

Figure 8: 3D View of Scenario 3

4.2 Validation: Analysis of Responses of the Focus Group

A focus group of eight BIM professionals was formed. The three scenarios and accompanying narrated videos were shown to them and their opinions were recorded. The participants were first shown the 2D site plan, then the traditional 3D site plans, and finally the 3D site plans in immersive environment. They were asked to identify strengths and weaknesses in all the models. They were also asked to identify any advantages of utilizing the Oculus Rift®. Participants considered 'Jobsite Virtual Tour' as best candidate for VR applications. Some specific comments were as follow: (1) "Very promising way to assess potential danger without being put in the actual situation." (2) "It reminds me of a game. It's very interactive and effective. I think it's an interactive idea for safety training and the immersive environment is definitely useful." (3) "It shows actual situation, real life experience rather than Revit model".

The following comments were collected for the application of VR in jobsite management: (1) “Crane placement has a great deal to gain from a VR interface. This would allow workers to see where a jobsite is in relation to the crane. The improved awareness would be beneficial for jobsite safety and planning.”; (2) “Was a good tool for identification and orientation of the jobsite, which provided a better understanding of what to expect on the site.”; (3) “Slower assessment but you get a real life hands on idea of the site layout.”; and (4) “Very beneficial when determining jobsite area and organization as well as safety.”

At the end of the focus group session, the participants were asked ‘Is your company currently using or plan to use the Oculus Rift®?’ Among the eight BIM professionals, five said ‘No’, two of them were ‘in testing and researching stage’, and one company currently utilizing it. One BIM professional revealed potential barriers for the headgear to be accepted by the construction industry: “It’s hard for the construction industry to accept technology that is unproven or still doesn’t work well. It will be a very long time before VR is accepted.” In addition, cost, inability to adapt to the quick changes and motion sickness were some other concerns expressed by the focus group members.

4.3 Validation: Analysis of Responses of the Questionnaire Survey

Fourteen graduate students with some construction experience were invited to participate in the testing process. Each participant was given 30 minutes to test all models (i.e. the 2D site plan, the 3D site plans and 3D walk-through model using Oculus Rift®) and then asked to complete a short questionnaire. Key words identified from the focus group discussion were used for opinions’ measurements in the questionnaire.

In question 1, respondents were asked to rate the effectiveness level of each of the three site plans on a 1 to 5 scale. Table 1 shows the results.

Table 1: Effectiveness of the 3 Site Plans

Measure	*Mean*	*Median*	*Mode*	*S.D.*
2D site plan	*1.23*	*1*	*1*	*0.58*
3D site plans	*1.62*	*2*	*2*	*0.62*
3D site plan with immersive environment	*1.85*	*2*	*2*	*0.36*

2: Highly effective; 1: Moderately effective; 0: No differences; -1: Moderately ineffective; -2: Highly ineffective

The 3D site plan with an immersive environment had the highest mean value with the lowest Standard Deviation (SD). The mean value of 1.85 indicates a moderately to highly effectiveness in jobsite organization. The traditional 3D site plans have the second highest mean value, but a SD of 0.62 indicates some mixed responses. By looking at the median scores, it is apparent that a considerable amount of respondents think that a traditional 3D site plan is as effective as the one with immersive environment. One respondent indicated that both the 3D plan and the 3D plan with immersive environment result in a ‘slower observation process than a 2D drawing’. Some respondents indicated that the amount of effort needed in developing 3D site plans outweighs their benefits over the 2D plans.

Next respondents were asked to indicate the level of possible advantages that Oculus Rift® offers in jobsite organization. Results are shown in Table 2 and Figure 9.

Table 2: Level of Possible Advantages that Oculus Rift® offers in Jobsite Organization

Measure	*Cumulative Mean*	*S.D.*
Site orientation	*1.62*	*0.62*
Site access	*1.23*	*0.89*
Crane placement	*1.08*	*1.00*
Equipment location/path	*1.46*	*0.84*
Material storage	*1.46*	*0.84*

Degree of certainty: 2: Definitely; 1: Probably; 0: Neutral; -1: Probably not; -2: Definitely not

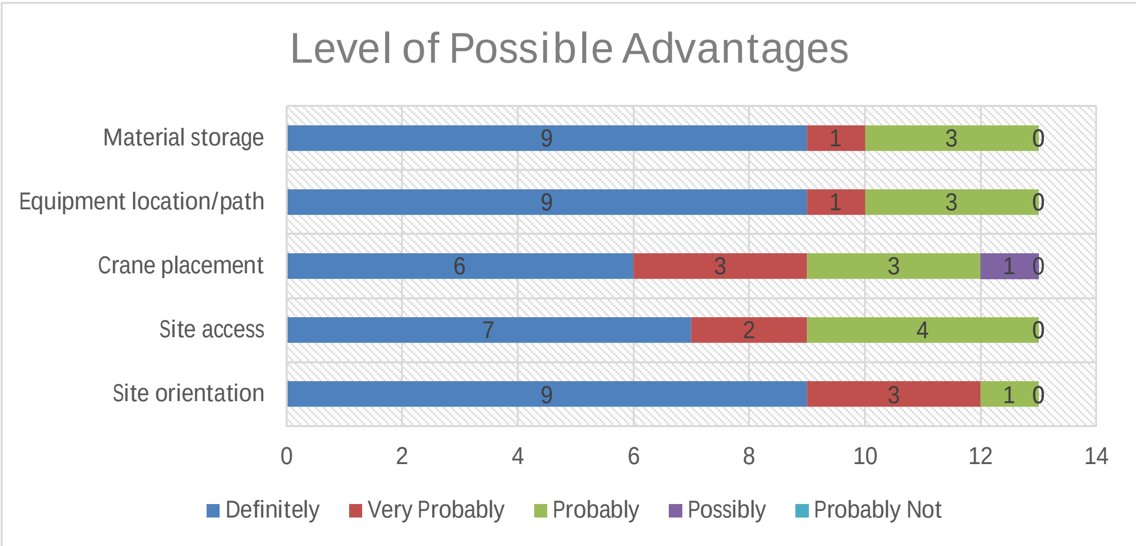

Figure 9: Distribution of the Responses

Of the five measurements indicated that Oculus Rift® offers ‘Definitely Probable’ to ‘Very Probable’ offer advantages in jobsite organization. Following are some specific comments from the survey respondents:

- ‘Crane placement has a great deal to gain from a VR interface. This would allow workers to see where a jobsite is in relation to the crane. The improved awareness would be beneficial for jobsite safety and planning.’
- ‘Was a good tool for identification and orientation of the jobsite, which provided a better understanding of what to expect on the site.’
- ‘Slower assessment but you get a real life hands on idea of the site layout.’
- ‘Very beneficial when determining jobsite organization.’

The following are some of the respondents’ overall impressions either toward the VR headsets or the 3D immersive models:

- 'Proven VR system. Certainly some possible applications but cost/benefit may not be sufficient to justify purchase of the system for some companies.'
- 'Very good organizational tool to use. However, I felt sort of lightheaded afterwards.'
- 'Very neat concept that can certainly benefit the industry.'
- 'It's a neat, interesting software but I mainly see it used for visual presentations of spaces compared to organizations of spaces.'
- The immersive is beneficial. However only if the frame rate and motion can be calibrated.
- 'Wearing it for an extended period of time gave me motion sick.'

Some users complained about motion sickness, which could be directly related to the amount of time spent in the VR environment. Participants stated, "using the Xbox game controller instead of the built-in head tracking eased the blurring associated with the movement". Collective feedback from participants indicated there is a strong interest in learning more about VR headsets in the construction industry. The participants interacting with the built scenarios and being able to identify key aspects as well as conflicts confirms VR as a viable option for jobsite management. Many participants wanted to explore beyond the built scenarios such as visiting the surrounding site and testing various site logistics options to obtain the best combinations (e.g. best location for tower crane placement).

5. Concluding Remarks and Recommendations

This pilot study aimed to test the feasibility of 3D VR headset applications in construction practice and education with focus on jobsite management. The results showed positive responses from both industry professionals and students. VR headsets and their applications in the construction industry have endless potential. Overall, we found that VR headsets are indeed very beneficial - allowing the users to immerse into a near-actual environment. The users were able to interact, identify, and gain an in-depth experience pertaining to jobsite management. The application of textures, materials and site development were found to create a life-like feeling. Each participant became physically involved in his/her exploration, exhibiting natural movements outside of the VR environment. This observation confirms the immersive viability of the VR environment, creating a lifelike reality. The workflow outlined in this paper allows for gaming like scenarios to be developed. There are many other options for creating a VRE, depending on the amount of control and detail. Some simple click and go options are, *insiteVR*, *irisVR*, and *Revizto*. The respondents made some recommendations during the data collection stage. One was the use of mobile controller. As the respondent sometimes needed to turn around in the model and it was inconvenient to use the keyboard to navigate, a mobile controller would allow for easier movement in the environment, i.e. Xbox controller. Another one was to provide more background information and instructions. The VR headset cuts off the user from the outside world. The end users focused more on what they can see instead of what they can hear. Adequate interpretation on what they will experience in the VR environment and what you expect them to see will enhance a better understanding among the end users. From this research, we have also uncovered a number of limitations concerning the effective use of the VR Headset such as: (1) Single user limitation. While conducting focus group, other people have no visibility of what the tester could see in the virtual world. To enhance communication and interactivity, a projector connected to that computer could be used to show the inherent movement of the user to other participants; and (2) Improvement in model quality. Some further improvements to the 3D immersive model could be made. Specifically reducing the size of the model to eliminate the lag while moving in the model and using more real information to rationalize the model.

Improved Construction Safety: An Analysis of Real-Time Physiological Data through Innovative 'Smart' Safety Vests

Ruwini Edirisinghe,
School of Property, Construction and Project Management, RMIT University
(email: ruwini.edirisinghe@rmit.edu.au)

Abstract

The development of systems to monitor the physiological parameters of construction workers to generate early warnings has the potential to improve health and safety significantly in the globally dangerous construction industry. The aims of the recently-formed CIB task group on wearable sensor technology evidence the need for research and innovation in wearable technologies in construction, which lags in technology adoption compared to other industries.

An innovative approach using wearable technology and e-textiles to monitor the physiological parameters of construction workers in real time is proposed to improve health and safety. The technological feasibility of the proposed system was validated using a system implementation.

This paper reports the fully functioning system and its components. The proposed systematic mechanism to validate the usability of the system on a real construction site is also discussed. It reports the planned process to test the smart vest system on a construction site and to capture real-time physiological parameters.

An anticipated outcome of the research project is a significant contribution to the use of wearable sensor technology in the inherently dangerous construction industry to achieve improved safety performance.

Keywords: Construction safety, smart technologies, smart vest, wearable, real-time data

1. Introduction

1.1 Construction industry's poor safety record

Globally, the construction industry is one of the poorest performing industries in terms of its safety record. In the USA, out of 4,251 worker fatalities in private industry in calendar year 2014, 874 or 20.5% were in construction: that is, one in five worker deaths in 2014 were in construction (OSHA, 2015). In the UK the construction industry is the second-worst industry in terms of worker fatalities (HSE, 2015).

In Australia in 2014, the mining sector, the fourth worst performing industry, recorded 13 fatalities, whereas the construction industry, the third worst performing industry recorded 29 fatalities. Due to industry's poor safety record, the Australian Work Health and Safety Strategy 2012-2022 identified the construction industry as a priority industry for work health and safety improvement (Safe Work Australia 2012).

1.2 Health risks due to heat-related illness

Workers exposed to extreme temperature conditions are at risk of heat-related illness (also termed heat stress). Heat-related illness covers a spectrum of disorders (Lugo-Amador et al, 2004) such as heat stroke, heat exhaustion and heat rash. Heat stroke occurs when the core body temperature rises above 40.5°C. It can cause liver, kidney, heart and muscle damage. Often, the nervous system is affected, resulting in delirium, coma, and seizures. Permanent disability, even death, can result. It is evident that workers are unable to recognise early warning symptoms of heat-related illness. Construction fatalities from heat stroke have been reported globally.

Accident statistics report fatalities and serious injuries due to exposure to extreme temperatures. For example, in 2006, 3,100 U.S. workers had a heat-related illness that caused them to miss work (Office of Compliance, 2009). According to recent statistics from Occupational Safety and Health Administration (OSHA), construction worker fatalities were reported in occupation categories such as concreters, carpenters and construction labourers. In Australia, worker fatalities, lost time injuries and serious compensation claims were recorded due to heat stress (Government of Western Australia Department of Commerce, 2014), including in the construction industry (Mining Australia, 2013). From 2001 to 2010, relatively high incidence rates (6.8%) and compensation claims (4.6%) were reported in the construction industry in South Australia (Xiang et al., 2015). This study investigated the association between ambient temperature and occupational heat illnesses, and estimated that claims are associated with the 35.5°C threshold, above which claims increase.

Indoor and outdoor environmental factors or job-specific factors can expose construction workers to health risks due to heat stress. Outdoor environmental factors include high/extreme temperatures and/or humidity, radiant heat from direct sunlight, and areas with limited air movement (no wind or ventilation). Indoors, hot air conditions can be caused by nearby radiant heat sources such as boilers, steam pipes, ovens and heated tanks. Job-specific factors such as physical exertion and the use of bulky or non-breathable protective clothing and equipment can also contribute to the problem (US Department of Labour, 2015). Workers in operations involving high air temperatures, radiant heat sources (such as arc welding), heat-treatment operations, plating, and those working in confined spaces are also vulnerable to risks.

2. Background and Related Work

Regulatory bodies such as SafeWork in Australia, Occupational Safety and Health Administration (OSHA) in the USA and the Health and Safety Executive (HSE) in the UK are increasingly recognising heat stress hazards.

For example, in the USA, OSHA has introduced a practical guide to workers and employers in the form of a tool called the heat index. The heat index indicates the risk level associated with a range of temperatures and suggests protective measures against each risk level. In the UK, the HSE recommends carrying out a heat stress risk assessment in the workplace and a heat stress check list is provided to control the risks.

Researchers predict productivity decreases in other regions of 11–27% by 2080 in hot regions such as Asia and the Caribbean (Kjellstrom et al., 2009), and globally up to 20% in hot months by 2050 (Dunne et al., 2013).

In Australia, heat stress has been recognised as an occupational risk by many state level regulatory bodies. WorkSafe Victoria (2012) and SafeWork South Australia (2012) have developed practical guidance notes that advise how to prevent heat illness from working outdoors in hot weather or where heat is generated as part of work. WorkCover Queensland (2015) outlines a preventive strategy for heat-related health problems at work. However, a recent study in Hong Kong on the institutional analysis of construction accident causality based on the investigation of heat illness cases on construction sites recommends revisiting the guidelines, in recognition of the existence of the system and the institutional environment associated with it (Rowlinson, et al. 2015).

A recent Australian study reports that heat stress in the workplace is not only an occupational health hazard but also significantly reduces labour productivity, based on the self-reported estimates of work absenteeism and reductions in work performance caused by heat during 2013-2014 (Zander et al., 2015). These researchers reported an annual cost of US$655 per person across a representative sample of 1,726 employed Australians. This represents an annual economic burden of around US$6.2 billion for the Australian workforce. This amounts to 0.33 to 0.47% of Australia’s GDP. Similarly, a study done in Australia which included the construction industry on heat-related occupational illness reports that excessive heat exposure presents a significant challenge for the industry or activity (Singh et al., 2015). This study also reports that heat exposure during Australian summers commonly results in adverse health effects and productivity losses.

Edirisinghe and Blismas (2015) propose a technological solution to the problem based on the innovative approach of using wearable technology and e-textile to monitor the physiological parameters of construction workers in real time and to generate early warnings of hazardous conditions for improved health and safety. The technological feasibility of the proposed system has been validated through a prototype system (Edirisinghe and Blismas, 2015). This paper reports the further development of the system and the plan for usability validation of the technology in the construction industry.

2.1 Wearable technologies

Next-generation wearable technologies and e-textiles to monitor physiological conditions have been successfully used in industry sectors such as therapy and rehabilitation (Dunne, 2010), health and fitness (Coyle et al., 2009; Senol et al., 2011) and healthcare & tele-medicine (Lee and Chung, 2009; Pandian et al., 2008). For example, Lee and Chung (2009) developed a wireless sensor network-based wearable smart shirt for health and activity monitoring. In this smart shirt, ECG and acceleration data are transmitted via Zigbee. Another example is the wearable physiological remote monitoring system developed by Pandian et al. (2008). It is a washable shirt, which uses an array of sensors connected to a central processing unit with firmware for continuously monitoring physiological signals. The sensors measure electrocardiogram (ECG), photoplethysmogram (PPG), body temperature, blood pressure, galvanic skin response (GSR) and heart rate.

However, little research has been done on safety, particularly in the construction industry, where technology adoption is slow compared to other industries (Hosseini et al. 2012), with the exception of work on nano-material-based anti-heat stress uniforms (Chan et al., 2012; PolyU, 2014). However, this uniform is not capable of monitoring the parameters and providing real-time feedback/warnings.

The International Council for Building (CIB) formed a task group on wearable sensor technology (TG 92) to encourage research and innovation in wearable technologies in construction in 2015. The smart safety vest system (Edirisinghe and Blismas, 2015), while addressing a significant health problem in the industry, also strategically aligns with the research and innovation requirements in the building and construction industry.

3. Smart Safety Vest

The smart vest measures the body temperature and heart rate of construction workers using the LilyPad Arduino embedded platform, which is a micro-controller board designed for wearables and e-textiles. The data is transmitted to a mobile phone in real time. The system has an alerting mechanism to alert about unacceptable variations of measured parameters. For example, warnings for extreme temperature ranges are generated by flashing LED lights in the vest or by playing audio/video on the smart phone/device. Given the increasing popularity of smart phones, visualisation and alert generation is facilitated through a smart phone. In situations where the national and/or organisational policy does not encourage a smart phone on site (for example, anecdotal evidence suggests that in the UK construction industry the use of mobile phones on site is discouraged) the same functionality will be provided at the central computer.

Figure 1 illustrates the smart safety vest system. The system is composed of three components: smart safety vest, mobile app and smart safety glasses. The functionality of each of the components is described below.

Figure 1: Smart Safety Vest System

- Smart safety vest
  The vest has temperature and pulse sensors sewn into the vest. These sensors monitor the body temperature and heart rate of the wearer. The vest has flashing LEDs to facilitate the alert mechanism.

- Mobile app
  The sensor data is sent to the mobile app via Bluetooth connectivity. The mobile app visualises the data graphically. The mobile app has two functional components to visualise the temperature data and the heart rate data separately. As described above, the mobile app facilitates the alert by generating audio/visual warnings.

- Smart safety glasses

  Smart safety glass is included in the system to demonstrate the feasibility of projecting the sensor in smart glasses. This is particularly useful if the workers are not allowed a mobile phone on-site for them to self-assess their own health conditions.

Figure 2 illustrates the graphical use interface of the mobile app which visualises the temperature data. The current temperature values and the variation of temperature values over the period are displayed.

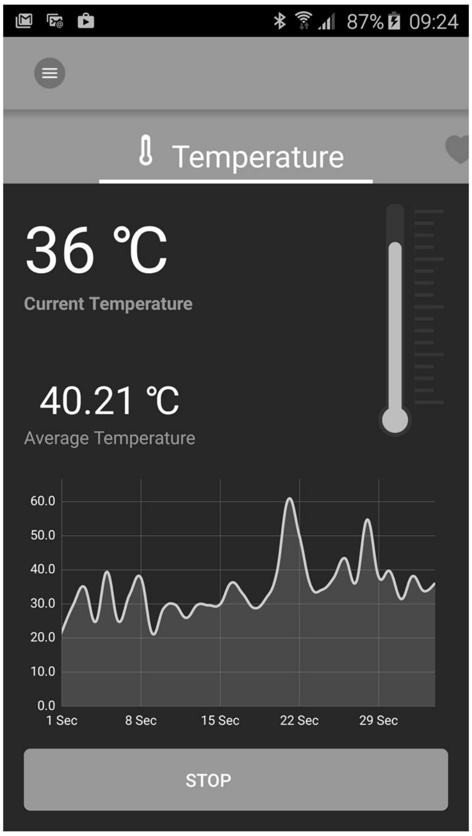

Figure 2: Data visualisation on the mobile app

4. Technology Usability and Extendibility

4.1 Technology Usability Validation

As the technological feasibility of the system has been validated, the next step is to validate the usability of the technology in industry. With recent funding support from an industry award, the system will be tested in the construction industry. Calibrating the sensors to various climates, seasons, and organisational and work procedures will be done during site testing. Workers from a range of work groups at multiple sites including concreters, brick-layers, plasters and carpenters will trial wearing the smart vest during normal duties. The workers will be provided with the mobile app subject to organisational policy. Management personnel will be given access to a central computer to monitor the worker data.

The technology evaluation together with the users' perceptions of using the technology will be evaluated after the trial period. The smart vest usability for the workers will be tested using the widely used system usability scale (SUS) developed by Brooke (1996) and validated by Bangor et al. (2008 & 2009). The widely-used SUS is an inexpensive, yet effective, tool for assessing the usability of a system. The effectiveness, efficiency and user satisfaction of the smart vest system will be evaluated using SUS by surveying the workers at the end of the trial period. Management feedback will also be sought at the end of the trial period to evaluate the usability of the system for organizational needs.

Management feedback will also be sought at the end of the trial period to evaluate the usability of the technology for organizational needs. In-depth interviews will be conducted to understand management perceptions of using the technology. Interviews will be designed based on the Technology Acceptance Model (TAM) by Davis (1989). TAM is widely accepted, used and tested in research to help understand management behaviours in technology acceptance. The interviews will cover the participants' perceptions of using the technology in terms of benefits/advantages, ease of use, trialability, result demonstrability, compatibility of the technology, motivators for using the system (change of image and relative advantage due to technology use), challenges experienced, and willingness to use the technology in future.

4.2 Extendibility

The smart safety vest system has potential for extension into two areas in future. Figure 3 illustrates the future smart safety vest system.

Firstly, the sensors are extendable beyond the temperature and pulse sensors. Depending on the physiological parameters to be monitored, the vest can be extended. For example, muscle sensors can be included to monitor ergonomic hazards. Motion sensors can be included as proximity detectors of exposure to hazardous environments/equipment. ECGs or other biomedical sensors/pads can be included to monitor other health conditions.

Secondly, the alerting mechanism can be linked with healthcare support systems such as emergency services. The alerting mechanism can also be included in a web application for remote telemedicine support systems. These are essential and integral parts of future mHealth applications.

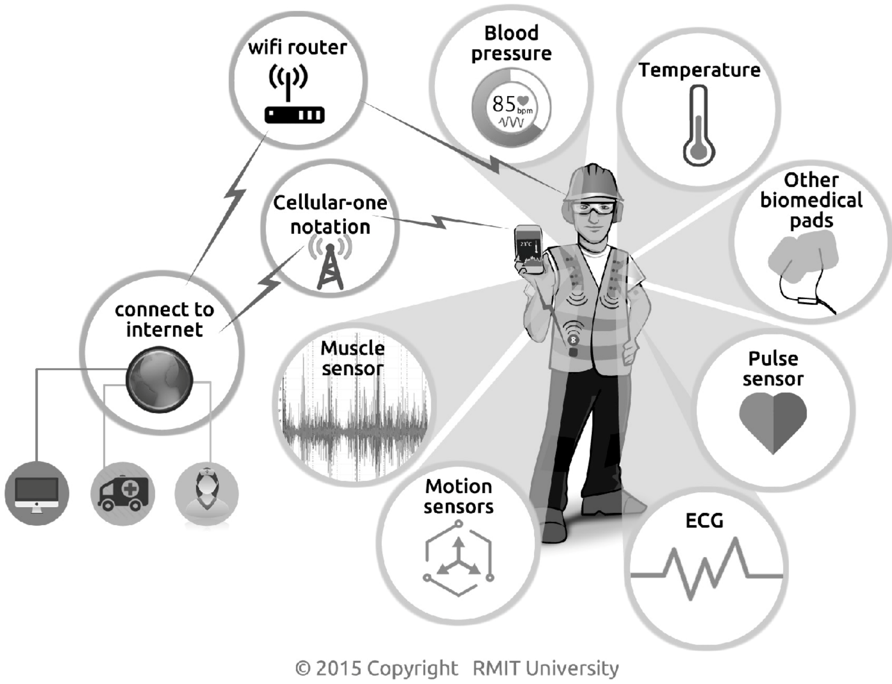

Figure 3: Extendibility of the system

5. Conclusions

This paper presents the innovative smart vest system developed to improve safety related to heat stress conditions in the construction industry. The safety vest system captures real-time physiological conditions of the workers and communicates the data with a mobile app and/or a central computer for management personnel to review. The data in these systems will be visualised in graphical format and early warnings will be generated if abnormalities occur. The plan to validate the technology's usability in industry was discussed.

The feasibility for the workers to use the mobile phones on site can be influenced by the organisational and/or national regulations and policies. For example, anecdotal evidence suggests that the use of mobile phones on construction sites is becoming restricted in the UK. In future the system will provide a central application for the site management to visualise the risk profiles of workers to overcome this limitation. The future work also includes extending the system to other physiological parameters and to link with remote heath care systems.

It is expected that the proposed technology addresses a significant problem in the industry and contributes to the zero harm vision in the industry. At the same time, the smart vest system contributes strategically and in a timely fashion to the research needs of the building and construction industry and is expected to enable step change in industry practice in technology adoption.

Abstract

Planning and control of project execution is the core of project management. One key success factor is an adequate implementation strategy. The Architecture, Engineering and Construction industry (AEC) is portrayed as an industry with serious challenges ahead. Among observed problems that often happen in AEC project are the decisions, which are made in wrong time or at the wrong level of organization, as well as solutions executed in the project without being aligned with corporate strategies. This conceptual paper presents a new systematic approach introduced in Norway to fight the many difficult challenges in the AEC industry. The systematic approach is called "Next Step" and is a framework inspired by the RIBA plan of Work. The new framework presented in this paper identifies the key steps and tasks in a project lifecycle from the definition to the termination of the building. The framework focuses on project execution as well on the critical decisions on a corporate level, involvement of the proper stakeholder perspective, and a sustainable development of the AEC industry. The main purpose is to help the actors of the AEC industry. The intention is not to define a constraining recipe, but to give the industry a common language and collective reference for AEC projects. The framework also highlights important issues in the front end of projects concerning strategic alignment and project planning. This paper also reports on the adaptability of the new framework with different procurement forms. The new framework suggests examining the different phases in this systematic approach through different perspectives: by introducing the perspective of the owner, user, supplier and public, the project is driven to achieve strategic goals and leads to a more efficient process and sustainable outcome.

Keywords: Project execution framework, perspectives, stage gates, project delivery methods, contracts

1. Introduction

Planning and control of project execution is the core of project management. One key success factor is an adequate implementation strategy. This is specifically true in the architecture, engineering and construction (AEC) industry. Implementation strategies refer to the systematic approach to planning and execution of a specific project within a corporation. Reasons for wanting systematic approaches are obviously the constant need for continuous improvement and learning from past experiences. These are difficult challenges, and given the wide array of different contexts (national-, financial-, industry etc.) and individual strategies of corporations (business models, markets, growth etc.) and technical solutions (elements, products, materials etc.) it is no surprise the approaches vary a lot. Focusing the AEC industry, the specific challenges are often identified as being increasingly fragmented and complex on one side (Pennanen et al., 2010) and reluctant to change and innovate on the other (Dale, 2007). These characteristics combined portray an industry with serious challenges ahead.

To summarize some observed problems that frequently occur in construction projects: strategic decision-making often rely on documents (Business Case, Project Plans etc.) that are incomplete, inconsistent and in some cases simply wrong by purpose or incident (Flyvbjerg et al., 2002). Decisions are not made in time, sometimes made on the wrong level of the organization (Berg, 1999) or by the wrong individuals. This may be indication of unclear roles in connection to the decision-making process, or ineffective organizations. It may also indicate errors and flaws in decision making on individual or group level as pointed out by many authors (e.g. (Kahneman, 2011; Lovallo & Kahneman, 2003; Raiffa et al., 2006). Another recurring problem is solutions planned and executed in projects, without being aligned with corporate strategies. Projects are often viewed as pure execution without responsibility for delivering the right product, the right result for users and owners. This is evident in the traditional definition of a project as a unique task (PMBOK, 2004). It is also well known that construction projects are tormented with errors and mistakes in planning, design and execution, costing unnecessary money and reputation (Love et al., 2003).

In sum all these challenges form a problem-complex that is too much to handle for each individual project owner, project sponsor or project manager. Allowing completely individual implementation strategies to be developed for each single project will not only be costly in terms of making the same development many times, but will also miss out the opportunity to improve and learn. This conceptual paper presents a new systematic approach introduced in Norway to fight the many difficult challenges identified above. The framework is presented in chapter 3. The main issues in this paper are addressed through three axes, each represented in a research question:

- How can the framework help to achieve the right result for owners and users?
- How can the framework help to secure that the right perspectives are considered?
- How can the framework deal with different procurement forms?

2. Theoretical Framework

2.1 Success and stakeholders

In project management literature there are many definitions of success, yet Oxford dictionary of English simply states, “Success is the accomplishment of an aim or purpose” and failure as “lack of success”. Samset (2010) states “Projects are initiated to solve problems or satisfy needs”. Thus, we can assume that a project success is actually connected to its ability to solve those problems or needs.

The identification of problems and needs and the process of solving them is an important step to be able to define the project, and to define the aim or purposes in order to achieve success. Samset (2010) also argues to look at AEC projects in a larger context than only to solve the immediate problem. He claims that monitoring of a project should be both on tactical and strategic level. The tactical level deal with what most regards as the important success indicators in a project; cost, time and quality. Tactical success in projects is associated with the term “project management success” (Cooke-Davies, 2002). The strategic level looks at indicators as effect, relevance and sustainability. Strategic success is associated with “project success” (Cooke-Davies, 2002).

The AEC industry is a fragmented industry and relies on many different stakeholders to complete a project (Kerosuo, 2015). Each stakeholder have a different perception of the aim and the success of the project and these stakeholders will most certainly try to optimize their own operation (Aapaoja et al., 2012). This leads to sub-optimization of projects (Zidane et al., 2015). The right stakeholder involvement is important to create value in projects. By displaying key stakeholders and together aligning their aims, can help to conquer some of the differences (Yang et al., 2009). Keeping the most important stakeholders in mind, it is important to look at the three major groups of stakeholders and their views. Samset (2010) refers to this as perspectives and list them as the owner perspective, the user perspective and the executing perspective.

The owner is the initiating and financing party, the one who normally has a long-term interest in the investment that the project represents. The user is the party who is going to utilize the result of the project for operating their business. The executing party (-parties) is the architects, engineers and contractors who are executing the project on behalf of the owner – the project organization. The owner typically has, or at least should have, interest in the strategically performance of the project, while the executing parties typically limit their interest to the tactical performance (Slevin & Pinto, 1987). Bertelsen and Emmitt (2005) identify the owner, user and society as important groups that a “client” should represent: “These three groups of interest each value different things at different times in the life of the building.” Identifying the perspectives early might help to change and understand the focus of the stakeholders.

2.2 Project delivery methods

Project Delivery Method (PDM) - a system for organizing and financing design, construction, operations and maintenance activities that facilitates the delivery of a goods or service (Miller et al., 2000). Choosing different PDM will affect the project cost, schedule, success and influence the efficiency of running the project. This makes it a challenging issue for stakeholders and decision makers (Al Khalil, 2002; Chan et al., 2001; Kumaraswamy & Dissanayaka, 2001). The suitability of the selected PDM can improve the project performance to a great extent (Al Khalil, 2002; Han□Kuk et al., 2008; Kumaraswamy & Dissanayaka, 2001; Oyetunji & Anderson, 2006; Udechukwu et al., 2008).

There are large numbers of different PDMs available in AEC industry to overcome the shortcomings of traditional procurement (Alhazmi & McCaffer, 2000). Numerous authors have categorized the range of procurements forms in the literature. However, in this paper we try a new classification of procurement forms, to make it more practical for alignment with the framework. This classification is inspired by a very recent PMI book (Walker & Lloyd-Walker, 2015).The procurement forms could be fitted in three groups:

Segregated procurement forms: A key feature of procurement forms in this group is a trend to separate design and construction/delivery. Segregated forms include well-known traditional approaches. The dominant segregated form of procurement, which is operating in most countries, is Design Bid Build (DBB). In DBB the owner will receive the bid and award construction contract based on the finished designer's construction document. In this procurement approach, it is assumed that the project design is complete enough to enable a bidding process to establish the cheapest and/or the quickest tender cost. It also assumes that the price of design variations encountered throughout the delivery process will not be excessive (Masterman, 1992; T. Rizk & Fouad, 2007; Sanvido & Konchar, 1998).

The advantage of segregated forms, which is the key cause to select this procurement form in many organizations, theoretically lies with market contestability for the lowest cost (bid) in combination with shortest time. Other example of forms in this group is Cost reimbursement (Cost-Plus).

Integrated procurement forms: Integrated procurement forms are to some extent either physically or contractually integrated design and delivery process. A key character of this collection of procurement forms is that there is a planning and control logic driving the project and a confidence that integration is mainly accomplished through planning and control systems. Some of the procurement forms in this group are: Design and Construct (D&C), Management contracting (MC/CM), Joint venture consortia, and BOOT family procurement approaches (PFI, PPP). The most recognized procurement form in this cluster is Design and Construct (D&C) where one entity is contractually responsible to produce design and perform the construction service, typically called design-builder. It integrates the design and delivery functions either through an integrated firm mechanism, which has an in-house design team, as well as a delivery team or by the delivery organization outsourcing the design to another team that becomes its design services provider (Molenaar & Songer, 1998; Molenaar et al., 1999; T. F. Rizk, Nancy, 2007).

In all integrated procurement forms the main focus is on integrating design and delivery processes by emphasizing on planning and control, however, this does not eradicate the importance of collaboration aspect and the people management but it indicates the weight on systems integration through planning and control.

Collective procurement forms: In this cluster the focus is on integrating the project design and delivery teams rather than the process by highlighting collaboration and coordination. Some might claim that this group of procurement forms could be the most mature forms for best outcome and value for money. Collaborative procurement forms like *Partnering, Integrated Project Delivery (IPD), Delivery Consortia/Partner (DC/P), Competitive Dialogue (CD)* and *Alliancing* are fitted in this collection. However, the authors believe that some of the forms in this cluster (partnering, competitive dialog, etc.) are naturally represented as a cultural state or formal/informal contract arrangements rather than procurement choice. They have characteristics, features, and cultural elements that can be applied to other forms.

Collective procurement forms provide a framework for establishing mutual objectives among all parties involved. This normally also lead to developing an agreed dispute resolution system. Collective forms need strong team building skills among participant. Compared to other traditional forms it also needs a different paradigm from highly commercial winner-gets-all and adversarial relation between parties involved. In collective forms, the project owner does not only engage/collaborate with the designers but also collaborate from the very initiate stage of the project with contractors and possibly with significant subcontractors. Collective forms mainly characterized by covering collaboration, transparency, innovation and accountability.

2.3 Phases and decision gates

The governing of projects is a major challenge for project management. With the increased focus on governance over the last decade, phases and decision gates became more in focus and hence have received increasing attention (O.J. Klakegg et al., 2009; Müller, 2009). A fundamental logic in this perspective is that for each step of the development, one should stop and check the status before moving on, that is; one should proceed only if everything is in order. This approach is maybe best summarized in the concept of gateways: a formal control of documents and assumptions before making a decision to accept a project, or to close one phase and enter into the next. The source of this thinking seems to stem back to the term “stage gate” introduced by Cooper (1993). We choose to use the term “decision gate” as a reminder that in a governance perspective, we hold the decision to be the main issue connected with these gates.

The gateway is a key element in an adequate implementation strategy: Seen from an owner’s perspective a decision point (a point for looking forward), whereas seen from the constructor´s perspective it may be a milestone (a point for celebration, following accumulated results), as pointed out by Lereim (2009). The purpose of a decision gate, as seen from a project owner’s perspective, is to make sure the formal decision-making is successful in supporting the success of the organization, business-corporation or public entity. Broadly speaking, this depends on making the right decisions. The logical way of making sure the right decisions may be achieved is to choose the right people to make the decisions, and make sure they have the best possible basis for making the decisions.

Having the best possible basis for making key decisions is a question of extracting the right information. The right information is a question of what is available (known at the time of decision) balanced against the cost of obtaining more/better information and the risk associated with making the decision on less than perfect basis. Decision gates are often characterized by having defined procedures for assessments/control and decision making, defined roles and responsibilities, criteria for acceptance, and a gatekeeper (owner of the gateway process) who decides whether the project is allowed to enter the gateway or not.

The cost of attaining perfect information means it is rational to divide the development in steps and not produce more than needed at each step. Making sure the relevant information is available at the right time and in adequate detail is paramount. Consequently, phases and decision gates are key elements of an information flow framework. Examples from phases given below are meant to illustrate some selected decisive moments in this development:

The first phase is the initial process where the problem or need is acknowledged. This could be due to an owner having a site he wants to realize, or a company looking for other facilities to do their business. This indicates a reason to invest and is often referred to as the business case. Acknowledging that a reason to invest exists is a decisive moment because it drives the decision-making and planning process forward and raises expectations among users.

The next logic step is to view the feasibility of the business case; can it be developed, what are the best alternative concepts, what should the project include. This should now end up in a brief, specifying the contents of a project. Particularly the brief is viewed as a crucial document to achieve a successful project (El. Reifi et al., 2013). The brief is the foundation for a good design and production process. Approving the brief is another decisive moment because this is the point in time where you decide what the users are going to get in the end.

Another key milestone is the handover from the contractors to the owner. This decisive moment represents responsibility shifting from executing party to owner. At this point it is crucial to compare the actual delivery against what was decided in the final brief. For some projects this is when the owners and users for the first time are able to consider to what degree the project fits his or her needs. Traditionally this was where the focus of the project organization ended, but today there is strong focus in the use of the project, looking at how the users of the project succeed in their business and in the management of the facility.

Having a long-term perspective that includes sustainability of the investment is today required, even expected for all parties, despite traditional short-sighted execution perspective. Sustainability has to be considered in in terms of the investment's economical-, social- and environmental consequences. Only when the truth is known about the investment's long-term consequences can its true value be assessed. This makes the decision to terminate, decommission or sell the facility into another decisive moment. This is where the initial intention meets the hard reality of the end and the circle is completed.

3. Result

In January 2015 Bygg21 and The Norwegian Property Federation took an initiative to make a common phase model for the Norwegian AEC industry. The project was undertaken by a research group from the Norwegian University of Technology and Science (Ole Jonny Klakegg et al., 2015). Figure 1 presents an outline of the resulting framework, which was released in December 2015 (www.bygg21.no).

Step	1 Strategic definition	2 Brief development	3 Concept development	4 Detailed designing	5 Production	6 Handover	7 In use	8 Termination
Core process	Owner perspective							
	User perspective							
	Supplier perspective							
	Public perspective							
Management process	Planning							
	Procurement							
	Communication							
	Sustainability - economics							
	Sustainability - environment							
	Sustainability - scocial							

Figure 1: Outline of the framework called "Neste Steg" (Next Step)

The framework “Next Step” is generic and based on a similar set-up as the RIBA Plan of Work (RIBA, 2013). The AEC industry can use the framework with any form of contracts and is open for future development of new PDMs as well. The main purpose is to help the actors of the AEC industry with defining key tasks that need to be fulfilled in the different stages of a project, and to help coordinate their involvement. The intention with this framework is not to define a recipe that needs to be followed to the letter, but to give the industry a common language and collective reference to execute projects.

The different steps of the project are indicated on the top of Figure 1. Each step has a clear purpose and together they all the different phases of a project. In this framework there are 8 steps, including the last important step of termination. Termination can refer to the termination of ownership; i.e. the owner sells the property or the demolishment of the building in order to utilize the site in a different way. The logic of the steps is based on a systems thinking approach with input, process, and output logic, creating decisions gates after each step. The output can be input to the next step or leading to a termination of the project. The process is the actual tasks that need to be completed in order advance the project (Ole Jonny Klakegg et al., 2010).

Inspired by Eikeland (2001) the framework divides the processes into two major categories: Core processes and Management processes. Core processes are main tasks and supporting tasks that develop the professional contents of the project. Management processes are planning, coordination and control tasks that need to be performed professionally to make the core processes work well.

In the core processes, the activities are separated into four different perspectives, allowing the stakeholders to easier identify their major activities and tasks and understand the purpose of the tasks at hand. The fundamental perspectives are described by Samset (2010), consisting of owner- user- and executing perspectives. In addition, the new framework includes a public perspective to put focus on how projects need to work actively with their context. The core processes are described with recommended activities that needs to be addressed, in what perspective they need to be performed, and summarizes necessary start-up conditions (input) and deliveries (output) from each step. The idea is that all parties in the project need to know that these are the main activities and issues to be addressed. The framework does not prescribe who should address each task – it is up to the project management to organize the project. The framework prescribes what perspective, or mindset, each task should be performed in.

The management processes includes several categories of tasks that are of the utmost importance for the project process. Planning, procurement and communication are three vital examples. These processes run continuously over time across all steps, but also include separate tasks for each step. Another category of management processes deals with the sustainability of the projects. To secure a wide perspective all three dimensions of the triple bottom line is explicitly addressed. To secure a long time perspective the 8th step focus termination of the project result (the infrastructure, building etc.). There shall be no excuse for not making sustainability considerations in construction projects.

The planning tasks are linked to making plans for the execution of the tasks, adding details to the plan through each step. Examples of important planning tasks include planning the handover strategies from the contractor to the owner and for the user. The procurement tasks will vary along the steps and have to be adjusted to the execution strategies of the project. A typical question is at what step you procure consultants and contractors: This can vary from step three to step five depending on how early involvement is optimal for the development of the project. Some execution strategies require involvement of all parties on an early stage; other strategies develop a detailed design before procuring the construction companies and suppliers. The framework holds that it is important not only to plan but also to control that the plans are followed. The framework is a powerful tool for project management.

Communication in a project is important and challenging; given that the construction industry tends to be fragmented with many different parties specialized in different areas. The framework explicitly addresses the digitalization of the project process, especially the use of integrated communication tools, such as building information models (BIM) as a communication platform. Developing digital project execution strategies early in the project is important to make sure the parties are all “on the same page”.

Sustainability is necessary for future projects – both in execution and with regards to the result. The AEC industry will not be allowed to continue using energy and producing waste like they used to. The framework differentiates the sustainability in three dimensions: economic, environmental and social. The economic sustainability includes securing the right choices in investment and for the full lifecycle cost of the project result. The environmental sustainability is regarding the use of materials, emission, heating, cooling etc. – both the climate effect and the energy use. The social sustainability is how the project affects the life of the team members, users of the result and people around the project, including ethical dimensions and fairness in distribution of effects.

4. Discussion

Planning and control of project activities is still a challenge in the AEC-industry. As seen in the introduction, this is a serious threat to tactical or project management success (doing it right). However, as argued in the introduction, there is a bigger issue – the strategic or project success (doing the right thing). More systematic planning and execution in every step of the development, from problem to solution to effect to termination, can improve both. Doing this one by one (each company by themselves) will necessarily create non-conformance and miscommunication. It will also require a lot of unnecessary effort in repeatedly inventing the wheel. It will waste time and resources and at the same time create limited results.

Trying to change this situation require major steps. Designing a new framework like described above is only a first step. Whether it is good or bad, suggesting it as a general standard will inevitably spark resistance in a traditional industry. To have effect many actors will have to adapt their systems and management practice to the new framework.

First of all, the time is right. There is a growing attention to the importance of good governance in solving major challenges in the industry, companies and projects. All leading actors in the industry accept sustainability as the standard – at least on paper and in speeches. There is a highly developed understanding that projects are about value creation and that everything that represents wasting time and money or “gold plating” is improper. This is helped by the current slow-down in the economy due to reduced activity in the oil and gas sector. Finally there is a wide range of different new standards being developed for PDMs and information exchange that paves the way for integrated delivery strategies. These strategies obviously need some sort of common framework.

The new framework itself is made as flexible and future oriented as possible. The generic framework is valid for different projects delivery methods (PDM) including future innovations. The framework is scalable in the sense that roles and activities can be adapted to small and big, simple and complex projects. Finally the framework is not a strait jacket that requires everyone to become the same or use the same words. On the contrary, it is designed acknowledging the need for companies to be able to develop their profile and competitive edge. The framework is supposed to be a common reference and “language” that all parties refer to in order to clarify concepts and better coordination. In order to achieve this, the framework should highlight the most important issues in each step, and help to create a platform for timing the right decisions and securing relevant basis for these decisions.

The framework is constructed from well-known principles and international best practice. It has a solid basis. For most actors the changes needed to implement it will be small to moderate. A comparison between the project-models of major companies in the industry reveals that most of the major decision making points are identified in most models(Ole Jonny Klakegg et al., 2015). The level of detail in models varies and the choice of words and graphic presentation is different, but the fundamental structures are remarkably compatible.

Leading organizations in the Norwegian AEC-industry are behind the new framework, including major public clients. The response from the industry has been positive. Other major actors are ready to start using it, and this is the main force that will be able to influence the industry. By January 2016 it is already clear that three different committees in Standards Norway are using Next step as a part of their working basis in developing new standards for the AEC industry. When major clients require it used as a reference, and major executing parties also say they will comply, this has the potential to grow into a strong wave with the force to change a conservative industry. In the long run, the observed improvements will be the best selling points for the model. This of course still remains to be seen.

5. Conclusions

This paper presents a new Norwegian framework for the AEC industry. The framework is not a detailed recipe for project execution, but tries to define the key tasks and steps in a project from the definition to the termination of a building. To sum up we conclude the proposed research questions:

How can the framework help to achieve the right result for owners and users? By defining the decisive moments and the necessary steps on the way from problem to solution until the investment is terminated. By forcing the parties to consider the long-term issues, and assess holistically the relevance and sustainability of alternative concepts, the right choice comes forward and becomes the natural decision.

How can the framework help to secure that the right perspectives are considered? A key feature of this framework is the focus on the key stakeholders and their perspectives. To help the owner make good business decisions, the actors need to think like an owner when they perform their tasks in planning and execution. To create the right solution for the users, the actors need to think like a user and consider how the project can best support the user’s business and facility management. To perform an efficient execution process the actors need to think about project delivery models early and make conscious choices about constructability. To secure that society’s perspective is considered, the model puts emphasis on requirements, approvals and other aspects of context that the project has to work with.

How can the framework deal with different procurement forms? One challenge in delivering a project is at what stage you procure consultants and contractors. The framework helps to deal with this challenge by explicitly state on what stages different procurement strategies has to be considered to be valid alternatives. Collective and integrated procurement forms needs to be considered early – from step three to five – depending on how early involvement of parties is optimal for the development of the project. Segregated procurement forms could be fitted in step five. A typical problem today is that some strategies are constantly considered too late in the process and thus remain unexploited. Other actors choose strategy from tradition and lack of awareness more than a conscious choice. If they are confronted with the new framework there will be no room for such neglect anymore.

Towards Quantification of the Economic Efficiency Advantage of Alliancing in Complex Infrastructure Projects

Pertti Lahdenperä,
VTT Technical Research Centre of Finland Ltd
(email: pertti.lahdenpera@vtt.fi)

Abstract

Project Alliance is a construction project delivery system where the owner and service providers form a joint organisation as well as share project risks. Challenging projects are expected to benefit from alliancing although existing proof is somewhat ambiguous. Thus, the study aimed to improve the understanding of whether project alliancing can be used to implement a challenging construction project economically compared to traditional delivery systems such as Design-Bid-Build, Design-Build and Construction Management at Fee.

The subjects of study were ideas born in the development phase of an actual alliance project and their refinement into innovations that bring cost savings and added value as data on related savings and other impacts were available. The comparison of the alliance contract and traditional delivery systems was based on expert assessments. Experts assessed first and foremost the capacity of traditional delivery systems to promote the creation, demonstration and introduction of new ideas, and the beneficial effects they can have at best. That allowed comparing the relative performance of different delivery systems.

The alliance model seems to have several features that stimulate birth of ideas and innovations, such as multidisciplinary expertise, contract and risk sharing procedures that motivate innovation, as well as a fairly long development phase that allows developing innovations and putting them into practice. On the other hand, traditional delivery systems feature many identifiable factors that cause fewer ideas to be born, demonstrated and introduced than the alliance model. Moreover, introduction may be delayed due to factors like contract negotiations which often reduce the benefits derived from innovations in the case of traditional systems. Alternative delivery systems are not expected to result in similar cost savings as alliancing, but in a price level clearly above that attainable by alliancing without any actual value creation benefit.

Keywords: Alliancing, project delivery systems, comparison, economic efficiency, transport infrastructure

1. Introduction

Demanding road and rail projects, their conditions and input data are fraught with great uncertainty. The numerous designers and implementers, many interest groups and linkages to existing infrastructure increase the complexity of the projects. Traditional project delivery methods based on a certain distribution of responsibilities have been found to be poorly suited for projects of this type. The uncertainty is reflected in large risk contingencies while the primary interest of the parties is to safeguard their own interests.

In Project Alliance (alliance contracting) designers, contractors and the project owner form a joint project organisation and work in open collaboration. All benefit from the success of the project entity and there is neither need nor opportunity for company-specific sub-optimisation. Moreover, alliance contracting makes good use of the early cooperation of the actors. Thereby it is believed to enable better innovative development and more effective project implementation than traditional delivery methods. Yet, systematic comparison data are scarce.

The aim of this study was to increase understanding of the ability to implement construction projects at a lower cost than normally through alliancing. Its economic efficiency is compared to results achievable by alternative delivery methods. The work concretises in the development possibilities of a project solution, and other possible factors causing differences in relative economic efficiency are not analysed meaning that e.g. possible differences in transaction costs and pricing are excluded. The study was also limited to the alliance's development phase, i.e. the planning period between the selection of the alliance consortium and agreement on the project's commercial terms when conditions for launching construction exist.

2. Compared delivery methods

The most common delivery methods used to implement infrastructure projects in Finland, limited to the investment phase, are Design-Bid-Build, Design-Build, and Construction Management at Fee. Thus, they are also the logical benchmarks of comparison for the economic efficiency of Project Alliance. The project is generally organised as follows when using them:

- *Design-Build* (DB), where a contractor under contract to the owner is responsible for the project's design and construction as an entity.
- *Design-Bid-Build* (DBB), where the owner assumes responsibility for design and the project is constructed on the basis of a separate contract.
- *Construction Management* (CM), where a separate organisation manages the overall project and implementation is realised through numerous partial contracts.

In alliancing, the traditional roles are abandoned on the contract level, and in its purest form all the key parties – owner(s), designer(s) and contractor(s) – form an alliance through which they assume joint responsibility for the project's design and implementation. The alliance organisation comprises people from all partner organisations, including the owner's. Decisions on project implementation are made jointly and unanimously by the parties. Alliance partners also share the risk of project implementation. Thus, the reward of service providers is based on the success of overall project implementation, not on their performance of their individual tasks (Lahdenperä, 2009, DTF, 2006, DIT, 2011).

In alliancing, the key actors are brought together and the alliance is typically formed at an early phase with respect to design. Service providers are often selected as a consortium with an emphasis on competence. Then, actual collaboration begins with a development phase during which the project solution is developed and the project's target cost is set and other central goals are concretised. The implementation phase starts only after agreement is reached between the parties on the above. The case study project also followed the presented procedures (Alliance Executive Team, 2014) although the alliance contract can be applied in many different ways.

3. Present knowledge

The alliance contract has been the subject of active research since the first projects that used it (e.g. Ross, 2003; Walker & Hampson, 2003; Hauck et al., 2004). These and many later project-specific case studies (e.g. Jefferies et al., 2014; Walker & Jacobsson, 2014; Morwood et al., 2008) focus on principles of operation while also trying to assess the results achievable by alliancing. Belief in the excellence of the model is strong in general. However, also as concerns assessment of performance, the study is mainly qualitative with the exception of occasional cost savings estimates. Walker et al. (2015) and Sweeney (2009) are among the rare studies based on a broad stock of projects and exact data. The results speak for the excellence of alliancing as earlier studies. DTF (2009) also examines project outcome data but mars the otherwise positive picture by questioning alliancing based on non-price selection. The significance of project-specific challenges and conditions, however, remains unclear (cf. Rooney, 2009).

Despite their merits, quantitative studies (Sweeney, 2009; DTF, 2009; Walker et al., 2015) are also deficient due to the lack of an unambiguous benchmark. For instance, actual cost is compared to the previously agreed contract price, the target cost or the owner's budget estimate since genuine comparison of projects in a world of individual projects is nearly impossible. This raises many questions because the contract price level is determined differently in different delivery methods, and the owner's budget is a highly unreliable and most often too optimistic standard of comparison (e.g. Flyvbjerg et al., 2002; Cantarelli et al., 2012; Andersen et al., 2016). Thus, it is clear that assessment of alliancing requires further study, especially in terms of quantification of the economic efficiency of alliancing in relation to other delivery methods.

4. Study method

Comparison of the economic efficiency of different delivery methods is not very simple. Statistical comparison of large amounts of data produces exact results, but in the case of individual projects it is problematic since different projects use different delivery methods, and all influencing factors cannot be taken into consideration explicitly. On the other hand, that would not even have been possible in Finland in the case of alliancing since there is only little experience of its use. Therefore, it is best to use the case study method with alliancing whereby in-depth focus on the performance of the model and the ensuing understanding achieved facilitate implementation of the comparison (cf. Yin, 2014; Eisenhardt, 1989).

As to alternative delivery methods, the study uses expert opinions which allows closing the gap between evaluation of the different operational preconditions and impacts of alliancing and other delivery methods. The case study generates data on the new procedure – alliancing – and it is the task of experts to use that data to evaluate the capacity of so-called traditional delivery methods to meet the challenge of alliancing. There is a lot of experience from so-called alternative delivery methods. Consequently, if the experts first familiarise themselves with the results of the case study on alliancing, their evaluations become more reliable.

The starting point of the case study were the innovations of an alliance project, of which the five most significant were selected for examination. First the birth mechanisms of innovations were investigated including influencing factors and boundary conditions. These were then presented to infrastructure experts participating in a focus group workshop: the 17 persons represented owners (7), designers (4), contractors (4) and construction management consultants (2). Then the experts of the workshop divided into five groups. An attempt was made to include members of all actor types in each group. Each group also included a case study project participant to specify knowledge about innovations and their backgrounds.

Each team concentrated on assessing one of the five major innovations. Guided by a list of questions, they were to consider the possibility of the innovation becoming reality if one of the alternative delivery methods had been used to implement the project. Each team also reported the results of its work to the entire group of participants and time was reserved for discussion afterwards. The reporting at this phase formed the framework for the qualitative analysis of the study (Ch. 6.1). After discussion, workshop participants were asked to complete a personal questionnaire, the results of which were used as input data for the quantitative part of the study (Ch. 6.2). The focus group was used to get expert views as well as to give the participants an opportunity to exchange information and views with each other before presenting their evaluations in order to ensure transfer of sufficient background information and comprehensive understanding as a basis of assessments concerning a complex issue (cf. Morgan, 1996; Cyr, 2015). Personal questionnaires were, again, used to avoid the dynamics of randomness related to team work and the related possible bias in results. They also enable more detailed analysis.

In the questionnaire respondents were asked to estimate the *probability* of a certain innovation of the case study project being adopted by alternative delivery methods and what the *benefit/cost saving* compared to alliancing would have been if adopted. The response alternatives (see Fig. 1 below) cover all possible paths forward meaning that the sum of their probabilities would always be 100 per cent by delivery method. The savings in euros achieved by alliancing were made known at the workshop in relation to all innovations dealt with, but in the questionnaire it was 100 per cent for the sake of simplicity. The net gain to the owner was the primary target of estimation when all possible other additional costs or, for instance, the share of the implementer are considered besides savings. In order that the formulation of the question would not lead people to regard the gain from alliancing as the absolute maximum, it was stressed to respondents that the gain could well exceed 100 per cent. Responses to all questions were otherwise complete except that four respondents did not evaluate the expected innovation benefit of Construction Management at Fee. The procedures are explained as to calculation of comparative prices in the results section (Ch.6.2). They are based on the results of the questionnaire as well as the costs of the case project (Ch. 5).

5. The case project

The case project of the study was the Tampere Road Tunnel to be implemented by an alliance. As the project proceeds, Highway 12 (which presently runs along the shore of Lake Näsijärvi above ground) will be put in a tunnel in the centre of Tampere [Alliance Executive Team, 2013]. The tunnel section is 2.3 km long. Moreover, the road and street arrangements, the relocation of utilities/services networks, and the interchanges at both ends of the tunnel are part of the project. Both directions of travel have their separate tunnels with three lanes including a safety lane. Several passageways with fire and smoke compartmentation will be built between the tunnels, and traffic control and guidance systems will play a significant role in the project. All in all, we are speaking of a demanding project fraught with much uncertainty.

Alliance procurement started in December 2011, and the parties signed the development agreement in July 2012. Development-phase planning led to the alliance implementation contract which was signed in October 2013. The road section is expected to be ready for use in late spring 2017 and the finishing work will end about a year later. This is the third alliance project launched in Finland (cf. Amaral Fernandes et al., 2014); the owner had experience from one rail project launched a year earlier (Lielahti–Kokemäki allianssihanke, 2015).

A total of 76 recorded development ideas were born during the alliance's development phase (Alliance Executive Team, 2013), about half of which (39) were accepted for use while a quarter (20) were relegated for assessment at the alliance project implementation phase. The cost-benefit impacts of 28 adopted ideas were reported in the project's first value-for-money report (Alliance Executive Team, 2014) while the other innovations were implemented mainly due to their positive value effects. The total saving was reported to be about M€17.0. The share of the five most significant innovations was M€9.2, and the combined benefit of the achieved shorter schedule M€2.5. According to the owners, the building plans including the innovations are in all respects such that the quality level of the road plan will be met: quality or life-cycle requirements have not been sacrificed to achieve savings.

The target cost based on the alliance implementation agreement is M€180.3 (at May 2013 cost level) which puts the logical estimate of the so-called baseline price at M€197.3 (i.e. 180.3 + 17.0). On the other hand, the road-plan phase cost estimate (ELY, 2011; March 2011 price level), corrected to the index value of the target cost (OSF, 2013), is M€203.6 when the cost items (ab. M€4) missing from the (original) estimate but included in the project are considered.

6. The results

6.1 Factors affecting economic efficiency

With regard to alliancing, experts emphasised its great ability to generate innovations which was the key to high economic efficiency. The joint interest of alliance members is to implement the project in an overall efficient fashion which eliminates obstacles to the expression of ideas as the participants have no need to sub-optimise their performance. Should the implementation of an idea require re-design, the designer is compensated for it. Since the owner is also part of the alliance, alteration of earlier designs is easier when it is also in the interest of the owner. Confrontation does not occur and distrust and risk avoidance do not guide decision making.

Ideas are born mainly during development-phase planning when conservative application of competition regulations no longer prevents new alternatives from emerging. Multidisciplinary expertise becomes integrated in planning and creates good conditions for development. Since ample time can be reserved for the development-phase, ideation, development of ideas, dealing with permits and re-design are possible. All in all, the assessments of the performance of alliancing correspond to those of a parallel survey related to the project, but implemented from a different perspective and using different experts (Lahdenperä, 2015).

Project development is more difficult when using the alternative delivery methods instead of alliancing. In delivery methods based on apportioned responsibility and risks, the actors lack the motive and overall competence required to improve economic efficiency. Even the business logic does not support the presentation of ideas. The distribution of the risks, responsibilities and benefits related to new solutions is unclear without negotiations. Thus, even good ideas are not always brought forward since it does not benefit the inventor of the idea – even the opposite may happen. If a suggestion for improvement is made, however, the other parties may try to prevent its introduction. The parties optimise first and foremost their own share and the best of the project is not the driver of development.

The possibilities and problems of different delivery methods are naturally slightly different. As it is not possible here to delve into these details, reported in Koski and Lahdenperä (2015), a joint summary is presented only. Accordingly, obstacles to birth and presenting of ideas in traditional delivery methods, in accordance with the sequential phases used in the survey (i.e. A–C in Figs. 1–3), are the following:

A. Before contractor selection during design

- The designer does not present an improvement idea as it may involve extra work or re-design. The party fears that the owner considers the idea part of the already purchased expert service package. Thus, the idea should be made part of the design solution without extra compensation which is not reasonable from the designer's viewpoint. Alternatively, the presented idea does not move forward should the owner have to commission re-design by separate parallel orders. Another obstacle can be if the designer has to obtain permits related to the idea.

- Design commissions are generally lump-sum and put out to competitive tender. Therefore, there is no time for ideation and alternatives are rarely analysed. The main aim of design is to produce the necessary design documents. Constructability and cost awareness is also poor, and lack of overall competence minimises improvement ideas especially in DBB where design and construction are differentiated. To be sure, in DB the competence of designers and contractors is utilised synergistically already at the tender phase, but the preconditions for promoting ideas remain inadequate especially due to the challenges posed by public procurement.

B. At competition phase of contractor selection

- Requests for proposal plans can be too detailed and the owner may limit the contractors' alternative proposals. The primary reason is that degrees of freedom and alternatives leave too much room for interpretation which may lead to Market Court appeals and subsequent project delays and extra costs in case of public procurements. Should the owner nevertheless accept an idea suggested by tenderers, the needed requirement changes or even the idea itself, should be made known to all to ensure fair competition. That would eliminate the competitive advantage offered by the idea and only make competition more complicated which prevents effectively the publication of improvement ideas.
- Often the owner also has quite limited resources for processing proposed changes. There is no time to determine the compliance of alternatives with requirements and regulations. That is necessary especially since there can be fear that the presenter of an idea tries to reap all the benefits from it, and the idea does not necessarily benefit the owner, or may even be harmful. The attitude is the result of the experiences from confrontation and sub-optimisation in traditional projects. A short competition phase is also a hindrance since new solutions require redesign or decisions by authorities and affect the tasks of other parties which can be critical especially when using parallel agreements.

C. After contractor selection during implementation

- A proposal for improvement made during the construction phase requires agreeing separately about who pays for design, who assumes responsibility for the design solution's functionality, and how the benefits are shared since lump-sum contracts do not deal with these issues. On the other hand, the negotiations are expected to be so cumbersome and long that people do not wish to go to that trouble, especially if the preconditions for profitable introduction of the ideas have already weakened crucially at the implementation phase. The project has advanced so far that there is no time to introduce the idea, or it will no longer bring sufficient benefits.

- The activity takes place in a climate of general lack of confidence. The parties to the project suspect that anyone who presents any idea only seeks to benefit from it himself, and therefore do not support or approve its introduction. An individual party can also prevent the introduction of an idea in the parallel agreement model if only seeking its own advantage. Agreeing about changes is impossible in the shared responsibilities model. The parties want to save their labour and avoid takings risks by sticking to previously used solutions and operational models and existing building and implementation plans.

6.2 Comparison of economic efficiency

The respondents to an expert survey estimated first the probabilities of the occurrence of the ideas behind the alliance's innovations in alternate delivery methods (Fig. 1). The responses indicated that the failure of innovations to materialise is most probable in DBB (alternatives D–E), but there is not much difference between DB and CM-at-Fee. Often the idea would have been assessed (D) by the actors also in the case of the alternative delivery methods, but it would not have put into practice. Yet, it is clearly more probable that the idea would not even have been presented to other project partners (E) as was stressed especially by contractors.

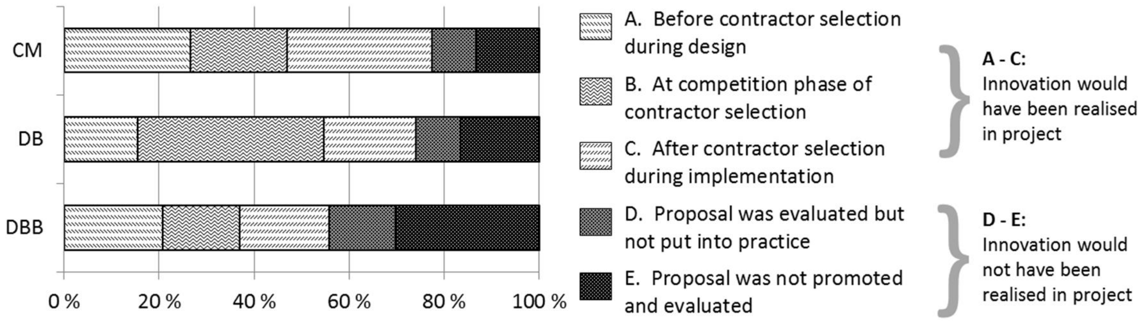

Figure 1: Estimated probabilities of occurrence alternatives (average values).

Yet, the introduction of the idea is not the only crucial factor since its net benefit may differ between delivery methods. Figure 2 shows the probabilities of the described phases combined with estimated net benefits (response averages). Accordingly, the strength of DB is the competitive tendering phase (B) where high probability of occurrence and owner benefit are combined. There DB beats clearly the other methods, but in design prior to competition (A), it fares worse than the alternatives because it involves mainly definition of requirements. After selection of contractor(s) (C), innovation expectancy is generally lower than at earlier phases. This is shown best by Figure 3 where the impact of the estimated probability and net benefit are combined (by multiplication), and the estimated savings potential is described as accumulating in phases. At the same time, the final situation of Figure 3 (C) shows the relative total development potential of different delivery methods. According to the results, DB would be the best alternative for an alliance although CM-at-Fee is nearly as good. Yet, it is estimated that these methods only provide about half of the development benefits of an alliance while DBB's share was only a good third.

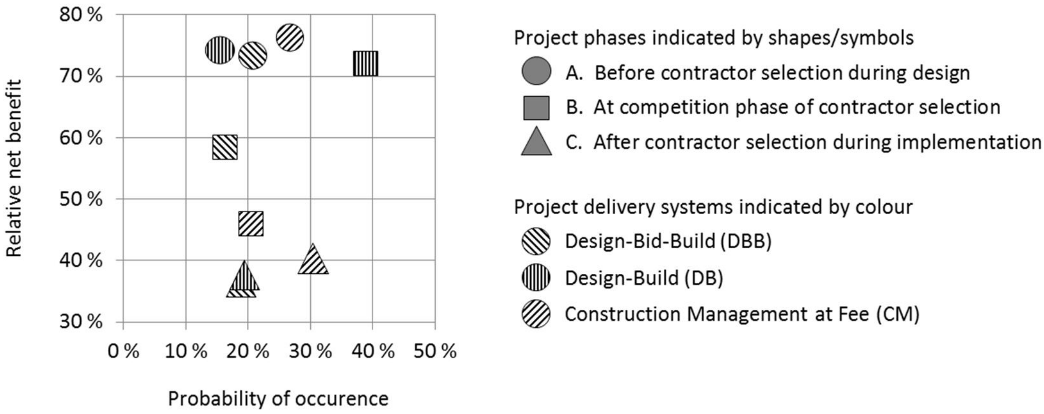

Figure 2: Probability and relative net benefit of occurrence alternatives.

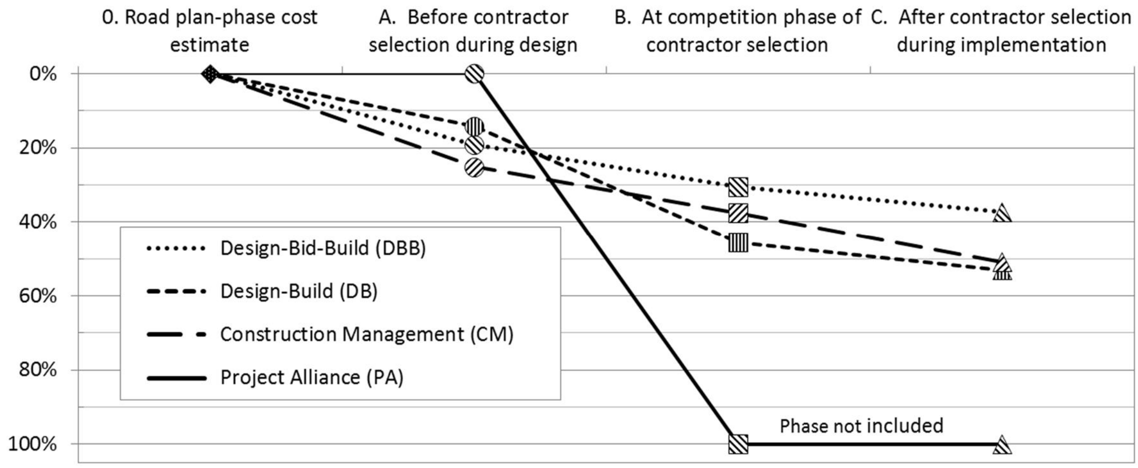

Figure 3: Estimated relative reduction of cost level by phases.

Figure 4, again, presents the comparison costs of delivery methods when this relative total development potential is applied to the cost data of the case study (see Chs. 3 and 5). Calculations were made for the part of owners and other respondents separately although Figure 3 shows their joint estimates only. The comparison cost of a delivery method is the so-called baseline price minus related cost improvement. Two alternative baseline prices are used in calculations. In *Calculation I* (solid colouring) the baseline price is the target cost of the alliance implementation agreement plus the cost savings from innovations (taking into account the 100% saving gives the alliance a comparison price in line with its actual target cost, i.e. 180.3 + 17.0 – 100% * 17.0, etc.). The development potentials of other delivery methods are smaller and the comparison costs correspondingly higher. In *Calculation II* (non-solid colouring) the baseline price is the cost level of the owner's estimate composed before the launching of the project, but index-adjusted for the time the target cost was set (including missing items; 100% development potential equals the difference between the owner's cost estimate and agreed target cost, i.e. 203.6 – 180.3). Baseline cost II is higher than cost I which means that the comparison costs of alternative delivery methods are also higher, respectively.

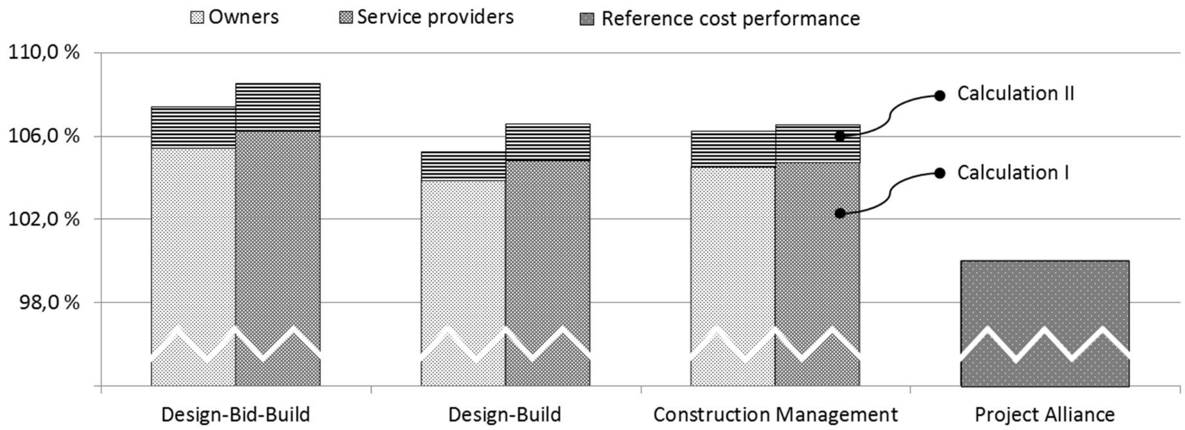

Figure 4: Relative comparison prices of different delivery methods.

Owners assessed the development potential in alternative delivery methods slightly better than other respondents. Yet, the views were quite similar since the differences in overall costs between owners and other respondents were at the most one percentage unit while the difference is mostly smaller than the difference between delivery methods. The difference with the alliance is in any case fully clear in every respect. Thus, it can be said that the use of alternative delivery methods is not expected to provide cost efficiency corresponding to that of an alliance contract, but that they would lead to a price level typically 4–6 per cent higher than that achievable by alliancing (I). An alternative survey (II) indicated even bigger differences (5–8%).

7. Discussion

The study aimed to increase understanding of the value creation capacity of project alliance compared to so-called traditional delivery methods. As to the alliance, the study was, however, limited to development phase innovations while the implementation phase was left out of the comparison. Alliancing can, yet, be assumed to be at least as capable of effective implementation as the other methods. Functioning cooperation boosts effectiveness, and the alliance already had a stock of development ideas to be evaluated only at the development phase while the owner also had the possibility of benefiting from implementation phase improvements due to the target cost procedure. On account of the incompleteness of the case study project, the implementation phase of the alliance was, however, not examined in the study.

As a result of the multidimensional nature of value creation, the cost side received emphasis in this study aiming at quantitative assessment. Yet, the owner did consider that value creation was not sacrificed to reduce costs. Instead, part of the innovations were introduced precisely because they generated added value. Thus, all improvements were not aimed at cutting costs. Inclusion of many qualitative key result areas as payment bases should also enhance value creation. Traditional delivery methods have not incorporated corresponding systems. Moreover, the fast implementation of an alliance project can have positive societal impacts that were not dealt with in the comparison. Thus, alliancing would appear to be even more advantageous than indicated by the calculations.

Although the result suggests that alliancing is superior, its generalisability can be questioned. After all, we are only dealing with a single project. Moreover, the development was also strongly driven by the uncertainty of project implementation as a low target cost was an apparent precondition for a favourable political decision to implement the project since the entire project was questioned anew on the political level while the development phase was underway (cf. Vainio, 2015). On the other hand, the uncertainty has also reduced potential subcontractors' willingness to submit serious tenders which has weakened the ability of the alliance to improve economic efficiency. Assessment of the influence of these factors is naturally impossible.

Determination of the innovation potential and cost savings of alternative delivery methods was based on expert opinions. They were experienced infrastructure construction professionals who were familiarised with the case study project and the innovations to be evaluated in advance. Part of the experts knew the project very well beforehand. The reliability of the responses is also increased by the fact that the experts did not assess alliancing, but specifically its alternative delivery methods, of which they had years of practical experience. Their views on the functioning of alliancing were also quite similar, and no special bias was identified in the responses. On the part of the alliance, again, the data are based on actual performance.

A key point is also that the study not only sought out differences between the economic efficiency of delivery methods, but also focused strongly on determining what is required to come up with and implement improvement ideas. As a result, several factors were found in the processes of traditional delivery methods that hindered introduction of proposed improvements. The emphasis on these hindrances is also fully in line with the estimates of economic efficiency which supports the perceived correctness of the quantitative overall assessment. Moreover, the overall view seems to be in line with literature (cf. Ch. 3) while also providing wider understanding.

8. Conclusions

The study assessed the economic efficiency of different delivery methods – Project Alliance, Design-Bid-Build, Design-Build and Construction Management at Fee – in transport infrastructure construction. The result was that an alliance creates the preconditions for achieving the highest economic efficiency particularly in demanding projects. The indicative comparison suggested at least 5 per cent higher costs for alternative delivery methods than alliancing without any added value. It is obvious, of course, that the relative performance of alternative delivery methods improves in the case of simpler projects, and that mere formal use of alliance contracting does not always guarantee a good result either. Yet, alliancing creates excellent conditions for benefiting from the integration of different competencies. Development in traditional delivery methods, on the other hand, is hindered by inadequate incentives, stringent boundary conditions for designs, tight schedules, rigid attitudes and many challenges related to the functioning of competition.

The Development of UK PFI from an Organisational Economics Perspective

Alex Murray,
The Bartlett School of Construction and Project Management, University College London.
alex.m.murray@ucl.ac.uk

Abstract

The increased use of integrated forms of procurement, specifically PFI, for provision of new UK public service assets is a defining feature of tax funded fixed capital investment since 1992. The value for money proposition of PFI relies on the notion that through integrating construction and operations via a single contract, whole life cost efficiency gains are made possible, indeed incentivised. Discussion focuses on improvements in our understanding of PFI, whole life cost and value for money issues over recent years, through reference to key literature including academic papers, empirical analyses, audit reports and industry publications. A range of organisational economic concepts is applied in reflection of recent policy developments, with an underlying theme of potential for *investment in operations*. Review of the healthcare sector's outsourcing practises, as well as the scope and scale of PFI healthcare investment in recent years allows for in depth discussion on issues of asset ownership and control, as fundamental concepts in procurement theory. To conclude, findings of recent studies are considered in light of reforms to the standard PFI model, including the insistence that future PF2 contracts should exclude soft FM services from their scope, as well as increase equity investment in the SPV. The need for greater transparency on the cost and performance of public service assets is posited to support better comparison of the efficacy of alternative procurements methods.

Keywords: PPP, public investment, value for money, whole-life costing, healthcare

1. Introduction – a brief PFI history

1992 saw a fundamental change in UK public procurement. This change would spread to become a feature of many developed nations publicly funded long-term investment. This change concerns the approval to use private financial capital in the delivery of public service assets (Norman Lamont, 1992). When in 1997, New Labour came to power, despite what might have been expected (though their abandonment of Clause 4 may have indicated their accommodation of the private finance initiative (PFI) in principle), they greatly expanded the policies' use with the vast bulk of all projects today reaching financial close under their reigns (2002-2008). In the year New Labour came to power, the first of the Bates Reviews of PFI reported advising government should establish an internal unit to co-ordinate its use (Bates, 1997). This led to the creation of the Treasury Taskforce within HM Treasury. The second Bates review (Bates, 1999) encouraged a more outward facing centralised unit (a proxy regulator) that could engage with the private sector more effectively. The incorporation of Partnerships UK (P UK) aimed to fulfil this ambition. This unit was also intended to better support local public clients of the growing number of PFI projects in the pipeline.

PFI was radically different forms of procurement than most public sector estate management functions had ever been required to use. One complexity of early PFI was a lack of standardized contracts. Local clients and private sector bidders duplicated much of the work to establish similar output based service contracts, these being a defining feature of PFI. This problem led to P UK's development of the Standardisation of Procurement Contracts (SOPC), with the fourth and final iteration in 2007. P UK also published guidance notes and provided assistance to local, decentralised procurement teams. One emerging issue was the lack of public procurement skill in terms of negotiating with an often more informed private sector team (Armstrong, 2005).

P UK facilitated government direct investment in PFI projects via equity stakes. Typically, this included a *pinpoint* equity stake of 1% (one tenth of issued equity given typical gearing at 90%). Shareholdings in special purpose vehicles (SPVs) often took the form of mezzanine type shareholder loans, a hybrid between debt and equity. Public sector investment was intended as a means of monitoring these projects allowing access to useful information as shareholders. New Labour's commitment to private involvement in public services was in no doubt and the establishment of large programmes of capital investment ensued post 2000. Building Schools for the Future (BSF) was the most significant. A part PFI, part conventional procurement programme set to renew all secondary comprehensive schools in England (budgeted at $45bn).

In the aftermath of the GFC, the incoming coalition government stopped the pipeline of PFI projects in 2010 to conduct a review of the policy, as well as scrapping BSF. P UK was brought back into HM Treasury, transferred under the remit of the lager-scoped unit of Infrastructure UK (I UK), itself only recently merging with the Major Projects Authority to form the Infrastructure and Projects Authority going into 2016. The 2010 review finally led to the announcement of PF2 in late 2012 as an adapted form of PFI. Given on-going fiscal austerities, government also took the decision to sell off many of the equity stakes in operational projects. August 2011 saw the sale of BSF Investments to the equity fund International Public Partnerships Ltd. Ironically there is a return by government to consider investing directly into PF2 projects. PF2's application looks likely to pick up to re-establish the longer-term use of private capital in the procurement of public service assets.

PFI is presently being used to deliver over 720 contracts. These have already delivered projects with combined capital values around £54bn (un-indexed, HM T, 2013). The weighted average contract length by capital value is 27.8 years. The longer-term liabilities on the public purse in PV terms for this portfolio of projects is approximately £177bn (discounted at 2.5% RPIX). The following paper attempts to consider the impact of the above developments in the PFI policy from an organisational economics point of view (Coase, 1937). Considerations of the implications for risk transfer, financial and value for money aspects are critiqued.

2. Value for money and whole life cost

One underlying principle of PFI is its incentivisation of investment in operations (Hart and Moore, 1990). The SPV is the legal entity contractually liable to deliver PFI serviced assets. The use of a SPV is crucial in providing off-balance treatment and limited recourse to sponsor corporate assets should the contract go badly. The construction and operational costs are at the discretion of a single agent, the SPV. They are thus, in theory, able to internalise the interdependencies between construction and operations via one contract (Hart et al., 1997; Iossa and Martimort, 2008). The incentivisation comes in the form of higher residual profits on the unitary charge payments (UCPs) revenue if they are able to reduce whole life cost (WLC). The UCP is the predetermined price for the contract paid in periodic instalments subject to adequate service provision. A key feature of the UCP in UK PFI is that a *significant* proportion of the payment must be *at risk* subject to provision of predefined serviced assets. This feature is important given that this allowed PFI's classification as *operational leases* (in the early days), rather than *financial leases*, the latter prohibited by public procurement rules (ONS, 2006).

The value for money achieved on the contract in excess of alternative procurement options will depend on the extent to which *investment in operations* is pursued, how well competitive procurement processes did in capturing these returns for clients, as well as the cost of capital used to deliver projects. There will be other project performance and time value of money considerations that will impact on the value for money (VfM) achieved through the project life cycle (Nasir, 2007). These will include the actual level of risk transfer achieved in light of some high profile failed contracts (NAO, 2009a, 2003a, Whitfield, 2012).

In light of incentives for investment in operations, its expected SPVs to pursue design and build solutions that seek to minimise WLC. This is especially the case for soft FM services[1], where the alternative is to pursue profitable contracts that may fail benchmarking and market testing (BM&MT, NAO, 2007a). Any gain in equity returns resulting from inflated operational contract prices from the client will only partly benefit the equity-owning sponsor, being shared with other equity owners in the SPV. An equity owning delivery contractor will wholly appropriate any gains in terms of higher revenues for operational contracts. This creates a moral hazard for the contractor to extract profits from operational contracts, rather than wait for future financial return on equity. The relevance of this point is limited by the extent to which equity-owning sponsors deliver these services. These are often sub-contracted to other providers, bringing with it further complexity in co-ordinating optimal service delivery (Rintala, 2005).

The higher cost of private capital used to deliver PFI projects is a major impediment for the net value of these returns from *investment in operations* (Public Accounts Committee, 2011), which could be achieved in publicly financed projects if adequate incentivisation of their delivery could be instilled (Mumford, 1998; Palmer, 2000). The nominal values of capital expenses over the project's life (put, arguably too simply, as a function of discounted factor price (r) and quantity (C_i)) will be subject to far less discounting, given the bulk are incurred at the front-end during construction. Their present value thus will be markedly greater, compared to future operational expenses (function of discounted factor price (w) and quantity (O_i)). This limits the extent to which present value reductions of WLC can be achieved via investment in operations. That is, the future potential savings from investment in operations translated into present value

---

[1] Soft FM services are services, usually labour intensive, which operate within the facility to support front line service delivery e.g. cleaning, catering, laundry, portering, security etc. They typically account for around 25% of the UCP in a full scope hospital PFI contract, but this will vary between projects. Consider one type of project that has proved popular in recent years, that of public street lighting, which will involve little or no soft FM services.

will have been subject to considerable discounting. This issue is compounded by the higher discount rate applied resulting from recourse to private capital. Here, *w* is used to convey the higher proportion of future operational expenses incurred on labour intensive (waged) factors of production in the form of cleaning, catering, security and other operational service staff. These estimated costs are at risk with potential increases in labour cost, the impending introduction of a UK living wage serves as a case in point. Operational costs are commonly indexed against RPIX variable or fixed 2.5% to account for these anticipated cost increases. Considering the long-term nature of these contracts, it is likely they may witness periods of above long-term average inflation cost increases, though not in recent years in the UK following the GFC.

The downward constraint to this minimisation of WLC is the provision required under the contract (P_i)[2], and the ability of capital and operational resources to deliver these (Murray, A. et al., 2013). Another constraint on PFI's ability to achieve returns from investment in operations, at least in a healthcare context, concerns the labour intensity of required services. While there may be instances of innovations in the way operational services are delivered under PFI, the prevalence is for services that closely resemble forms of delivery seen in non-integrated outsourcing contracts. This suggests a lack of major innovations in operational service delivery resulting from investment in operations. A further finding on the novelty of innovations in pursuit of lower WLCs concerns the risk aversion of debt providers to back new, untested, perceivably risky design solutions (Ive, 2004; National Audit Office, 2010; Rintala, 2005).

The constrained optimisation of whole life asset provision (Murray et al, 2013)

Min WLC: $r_i C_i + w_i O_i$

Subject to: $f(C_i, O_i) = P_i$

The ability of the operator to reduce WLC is arguably higher concerning elements of hard FM, given the functional on-going fixed cost of building performance is determined to a much greater extent during construction. This may be, in part, why these services are not subject to such strict tests of continuing competitive provision. Nevertheless, there will be knowledge held by any incumbent soft FM provider about the interaction of the specific asset's characteristics and optimal service delivery and management. An example of this may include the benefits of site planning design in reducing the need for security personnel.

3. Healthcare sector insight

For a sectorial insight into the diverse PFI programme, we focus on contracts procured by the Department for Health (DoH) in England. To place healthcare PFI into context, the analysis below (Fig. 1) presents two concepts plotted over time. These include the capital values of projects agreed at financial close (left hand axis) and the UCPs liable to pay for the contracts (right hand axis). It includes all UK PFI contracts and those pertaining to DoH and local

[2] In reality it may prove more profitable for an SPV to run riskier lower cost asset management regimes, that incur infrequent penalties and do not meet P_i completely (sweating the asset and holding back *some* life cycle funds).

authority Trusts[3]. As is evident, healthcare contracts represent between 20 - 30% of both capital values and of the on-going UCPs. The present view that seemingly all UCPs liable beyond approximately 2041 are liable against healthcare contracts suggest they represent the entirety of longer-term contracts procured most recently.

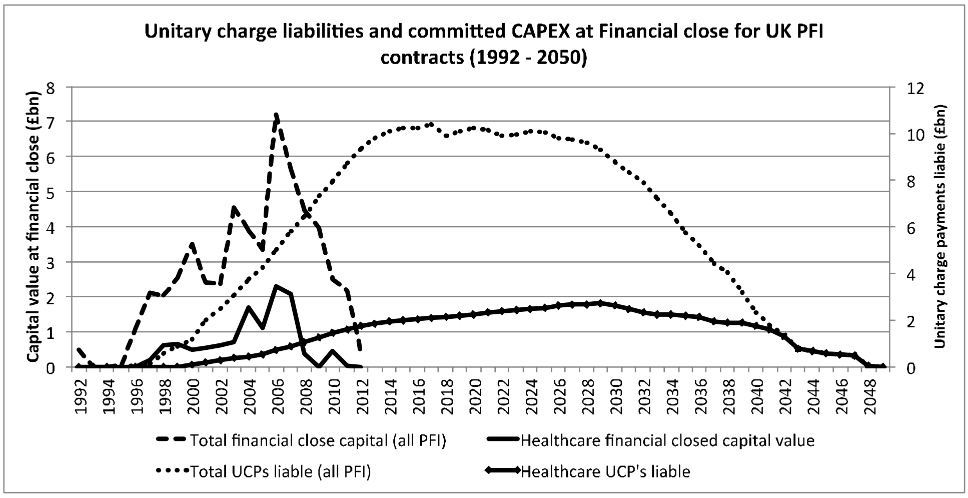

Figure 1. PFI programme and healthcare sector: capital values and unitary charge payments (1992 – 2050, nominal) Source: PFI signed projects list March 2013, HM Treasury

3.1 Contract scope

The scope of operational services in PFI contracts is important in defining the SPV's exposure to potential for investment in operations, as well as the inherent risks attached to levels of service. There is significant variance in the scope of PFI contracts, especially with regard to Soft FM services. A survey of hospital contracts undertaken by the NAO (2010) found that around one third of hospital contracts did not include core Soft FM services such as cleaning and catering. With reduced scope of Soft FM services, the contracts resemble more DBFM (maintenance) rather than DBFO (operation) status. The negative impact on value for money from the higher cost of capital of PFI projects arguably increases here by reducing scope of operations. The higher cost of capital incurred must be at least compensated for by future returns from investments in operations and reduced WC, if VfM is to be more favourable to conventional D&B and separate O contracts. In the DBFM case, the client will fund relatively expensive private finance for a facility in which a separately outsourced operational contractor (for catering say) has not been given the opportunity, or incentive, to *invest in operations*.

3.2 Non-PFI outsourcing

The contract period will of course be important, in part determining the incentive for investment in operations. If the contract is short (say 2 – 5 years) there will be limited scope for the contractor to realise returns from investments in the asset to be operated, hence one of the

[3] A small numbers of additional healthcare projects will have been commissioned by devolved administrations in Wales, Scotland and Northern Ireland. These are not included here due to the devolved and variable coverage of data.

fundamental reasons why PFI contracts are of such considerable length. Considering some specific potential scenarios of asset ownership, the provision of catering serves as a case in which there is variability, in both form of provision and extent of asset ownership. These two aspects will have bearing upon one another in line with transaction cost economics (TCE) theory (Mumford, 1998; Williamson, 1981), in the sense that asset ownership frames the potential risk transfer as asset owners are the bearers of residual risks (beyond those specifiable within the contract). The provision of pre-prepared catering services lends itself to outsourcing as an activity considered less and less as a core (in-house) function of public clients. Insight on the extent of in-house catering within the NHS is covered in data from Patient Environment Action Teams, compiled previously by the then National Patient Safety Agency (disbanded in the 2010 *'bonfire of the QUANGOs'*). Using 2010 data, of the 1232 facilities surveyed approximately 57% of facilities recorded catering as provided in-house (Table 1 below). This vastly underestimates the extent of private catering in the NHS as many of the newest PFI facilities are very large General Acute hospitals with many times more beds than other smaller facilities. Using another dataset from 2008[4], and just looking at NHS hospitals that are completely new as of 1995 (Table 2 below), we see that where as there are over twice as many new non-PFI hospitals, (95 to 37), the combined gross internal floor area of these PFI facilities is over 4 times that of non-PFI conventionally procured facilities.

One can also see from the Table 1 above, there is a higher prevalence of the catering services being provided as *delivered meals* when it is contracted (47%) compared to when it is in-house (30%). This might imply the quality of contracted catering services is inferior, though recent analysis suggests catering is an area where private provision is able to reduce costs considerably, without anticipated lower indicators of service quality (Mohammadi et al., 2013).

3.3 Procurement lead times

One on-going criticism of PFI concerns the long procurement periods witnessed securing preferred bidders, and further towards financial close of the contracts. The typical period between OJEU and financial close, where data is available is between 2.25 and 3.25 years (n=372, Fig. 2, HM Treasury, 2013). This is a considerable period of time incurring comparatively larger transaction costs than other public procurement options. One of the factors here concerns the due diligence processes required by lenders before approving debt finance pre financial close. Another major source of transaction costs come from the prescriptive output specifications of contracts. These costs, at least in the UK, will have benefitted from the introduction and development of SoPC. One constraint on reducing procurement costs for other types of projects, especially Schools and Hospitals, will have been the decentralized nature of these clients, where an NHS Trust will commonly only procure one PFI hospital. This limits the potential for learning and efficiency in future procurements using such new forms of procurement. Considering the period between financial close and commissioning is typically between 1.25 to 2.25 years (50% - 70% of the period from OJEU to FC, and of course including the construction period), it would seem the main impediment to more prompt delivery of these projects is the competitive processes required to secure a preferred bidder. The lack of clients having properly thought through project requirements before commencing procurement is cited as a major cause of delayed procurements (NAO, 2003b).

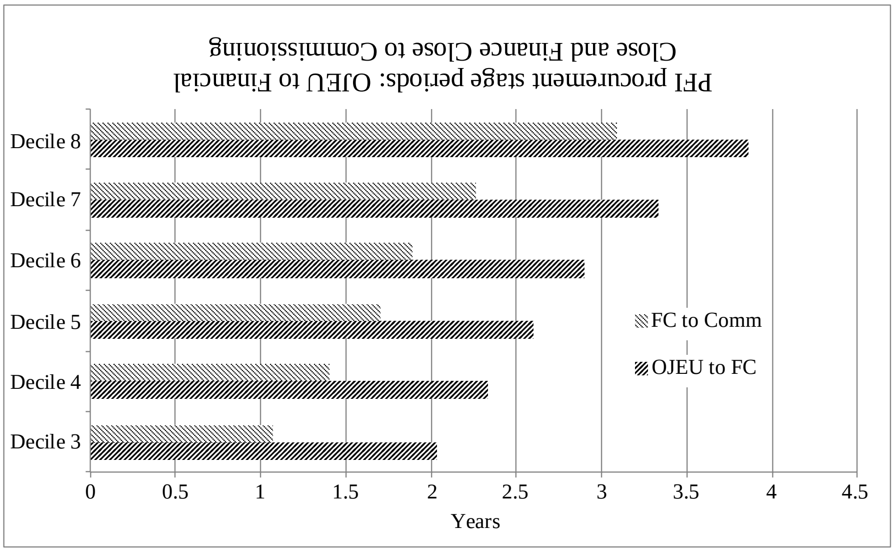

Figure 2. Procurement lead times for PFI projects.
Source: PFI signed projects list March 2013, HM Treasury

3.4 Competition during procurement

Depending on the specific project, typically 7-9 consortiums will respond to the invite to tender, reducing to 3-5 for the actual fully developed bid. Actual competition is limited somewhat given the considerable bid costs involved in PFI (Construction Industry Council, 2000, 1998), leading to the common strategy that any repeat bidder needs to win at least 1 in 4 projects to cover the considerable sunk cost, as a form of transaction cost, of failed bids. Social infrastructure projects (specifically schools and hospitals) have witnessed considerable price creep during preferred bidder stage (Armstrong, 2005). This is not surprising given the prevalence of decentralised public clients, a factor in determining the commercial expertise of clients, and thus their ability to negotiate with consortium bidders (Assenova et al., 2002). Relatively few Local Authorities will have experience with more than one PFI schools project. Contrast this with, for example, the Highways Agency (now Highways England, a more devolved agent of government) who would have been able to build experience and develop expertise in managing the procurement process of a clear project pipeline. That will have contributed to maintaining competitive tension through to financial close.

3.5 Balance sheet treatment

Another source for early scepticism about PFI concerned it's treatment of the facility asset with regard to who is acknowledging the future financial liabilities. Under public procurement rules, liability for the asset should be determined by who owns the *operational risk* for the service, and as such can be considered an *operational lease*, rather than a *financial lease* (ONS, 2006). Pure finance leases are not available as a form of capital investment for UK public clients. The acceptance of PFI in the 1990s relied on the assurance there was significant operational risk transfer to justify operational lease status (HM Treasury, 1997). This operational risk comes in many forms, dependent on the terms of contracts. It was required to be *significant,* represented by a minimum 20% of the UCP that must have some deductible element based on contractual performance. This risk transfer allowed government to classify liabilities on such contracts not as determined financial risks but rather contingent on contractual performance, avoiding the requirement to place significant sums of *committed* liabilities on the government's balance sheet. In more recent years, criticism of this approach has led government to acknowledge the significant liabilities under PFI contracts (House of Commons Treasury Committee, 2011). Now, of the near whole portfolio of projects (n=696, HM Treasury, 2013) 95% are recorded as on *balance sheet* under International Financial reporting Standards (IFRS).

3.6 Life cycle allocations

Lifecycle allocations exist to provide for on-going capital replacement and maintenance. They are built into UCPs the SPV receives for the contract. The relative size of life cycle allocations will be of considerable importance to lower WLC. A more intensively used facility, say a waste to energy disposal plant (in more recent PFIs) undergoing significant wear and tear, might reasonably require a higher proportion of WLC allocated to the life cycle fund. This will ensure the asset is maintained adequately and does not lead to increased risk of unavailability due to asset failure. Specifically when those life cycle expenditures are intended to be incurred will bear on the project's NPV as the anticipated return to the SPV investing in the asset. Further, when in reality those expenditures are incurred will bear on the on-going profitability of the SPV. If the SPV wants to take the risk of not expending life cycle funds, and accept the resulting chance of non-availability if the asset deteriorates and becomes unavailable (incurring financial deductions from the UCP), they may make additional returns. There is increasing pressure for public clients to share in these savings, as many early projects were considered to have over allocated resources to these life cycle funds (HM Treasury, 2012). Analyses comparing the annual comparative total cost of a wide range of FM expenditures seem to suggest there is little difference between PFI and non-PFI renewed schools (Edkins et al., 2011). Further, this study highlighted the vast differences in specifically hard FM expenditures between conventionally procured (and operated) schools and PFI schools. PFI schools were shown to incur typical life cycle expenditure profiles compared with flat line expenditures in non-PFI schools up to 9 years into operation. This raises concerns about the accumulation of backlog maintenance in non-PFI schools, an issue that PFI was designed to resolve.

3.7 Financing PF2

Following the latest review of PFI (2010-2012) and announcement of the PF2 reformed policy, there is now a requirement for larger allocations of shareholder finance within future projects (increased to 15% from 10%). There are many relevant implications of this. One might be to reduce the likelihood that sponsors will *walk-away* from contracts[6] given the higher sums of their own money[7] tied up in the SPV. Another implication is the strengthening of the incentive for investment in operations. Mandating that more SPV capital is equity increases the proportion on which the financial returns from investment in operations can be earned.

An undesirable implication of increasing proportions of equity will be a positive pressure on the weighted average cost of capital, a core concern for PFI projects generally. Theory (Grout, 1997) and practice (NAO, 2012; Vecchi et al., 2013) tells us that as PFI resorts to privately sourced finance (as opposed to the government raising public debt via gilts), it will incur a higher overall WACC. The highly geared nature of PFI Co's helps reduce this differential. The cost of debt and equity do relate to the proportions of each capital source applied, with higher gearing typically increasing the cost of debt as anticipated interest cover ratios tighten[8]. Further, it is reasonable to expect the returns of PFI equities to reduce in time given the established nature of this procurement route, as well as the increasingly active secondary market for PFI

---

[6] The incidence of this is quite rare in UK PFI by any reasonable benchmarks. Considered from an option theory perspective, discounting the significant sunk costs incurred by the SPV in building the facility, the present value of expected future losses would assumingly have to be *significant* to absorb the reputational cost of walking away. Additionally, the expected loss would have to counter front loaded procurement costs and potential refinancing gains.

[7] The vast majority of initial sponsor equity stakes in PFI Co's is typically held by the main build and/or operational contractor involved in delivering the project, though there is frequent subcontracting of services.

[8] The extent of this is tempered by the low levels of client and market (demand) risk in availability assessed PFIs.

equities (De Biasio and Murray, 2015). This is an area the government could help assist, promoting transparency in this unlisted market (Whitfield, 2014), if they intend to continue the use of private capital in this way.

Following the GFC, the debt margins on project finance (inc. PFI) increased significantly, if only temporarily. With debt's larger proportion in the SPV's financial capital employed, this will have increased the WACC of SPVs established during those periods' higher debt costs, as well as some of those that had little choice but to refinance in that period. It seems reasonable to assume a minority of PFI Co's operating in 2016 will not have had, or chosen, to go through a refinancing following the GFC, given initial debt tenors are typically around 7 years. Quantitative easing no doubt helped SPVs access cheaper debt finance in the GFC aftermath. There will have been instances of SPVs who had neared construction completion during the GFC that will have required refinancing (e.g. a bridge loan). This will have lead to at least a temporary and significant increase in the SPV's WACC.

For those sponsors that have sold off their equity stakes in recent years, they cease to be incentivised in minimising WLCs in future operations. Their remaining revenue stream from the project will be the payment for any on-going operational services, and not the residual financial returns above on-going cost of service provision. This issue could also cause conflict with the wider SPV shareholder, as the contractor is left chasing higher margins on delivery of operational services, rather than waiting for equity returns via the SPV. This may lead to SPVs seeking to replace incumbent providers, if they believe new providers can provide better value services. Whether they would offer equity to incentivise this new supplier is unlikely given the standard model for commercial service outsourcing. If not, the new supplier would do well to encourage spending of unspent life cycle funds to renew the asset they are responsible for future maintenance and/or operation of. Observing these actualities through PFI Co's life cycles is an imperative to develop evidence based, incentivised forms of private finance procurement.

3.8 Soft FM services in PF2

The decision of the coalition government to remove soft FM services in PF2 is questionable, given the emphasis placed on operational innovations PFI projects are supposed to deliver. This is in spite of evidence to suggest the performance of such services within operational PFI contracts are at least as good, often better, than those seen in conventionally procured facilities (Edkins et al., 2011; NAO, 2010). The reduction in the operational scope of future PF2 projects will mean that the potential returns from *investment in operations* are materially reduced, given the sizable proportion of the UCP payment that go to pay for soft FM services in present contracts (NAO, 2007b, pg 5). This will have a negative effect on the potential for, and pursuit of, whole life cost reducing innovations. Presumably, these services will now be kept in-house or separately outsourced, incurring separate and additional procurement transaction costs.

4. Conclusions

The development of PFI in the UK has been something of a learning curve, especially in aspects of their procurement. The typically much lower period from financial close to commissioning suggests projects are reaching operations promptly, as acknowledged by the NAO in numerous studies (NAO, 2009b, 2003b). Key issues such as balance sheet treatment, as well as fairer distribution of considerable re-financing savings via gain share mechanisms serve as good examples of how this policy has adapted to be more acceptable for continued use.

The considerable proportion, and variety, of PFI projects in the Healthcare sector demonstrates it's ability to deliver medium to large projects, some very complex, that may have not been deliverable under alternative procurement methods without cost overruns and a lack of integration between build and operations. One finding concerns the observation that the entirety of recent longer-term PFI contracts is solely within the healthcare sector (Fig. 1). Given the continued high profile nature of NHS reforms, especially the role of community based primary care, it is hard to conceive private finance will not have a role in many of these future projects.

Equity incentives within SPVs will impact on the pursuit of investment in operations. The requirement for increased equity investment in future PF2 projects should serve to increase these incentives and strengthen to case for using such forms of procurement. Procuring authorities might benefit in future by appreciating this, especially if they intend to consider the pursuit of WLC savings as a viable defence against the higher costs of capital involved.

Further research should focus on developing fair benchmarks of both build and operational cost and performance if government is to support the use of this controversial policy. One area for work concerns the collation and analysis of SPV accounting data that should give insights into the levels of risk transfer against the UCP liable on the government. Greater transparency is needed to compare the efficacy of alternative procurement routes, an area where government as the client could do more, as consistently reiterated by the NAO.

Abstract

Public-private partnership is one of the recent co-operation models, which has been widely and successfully applied in Western Europe and over the world. PPP programming is boosting in Lithuania recently: 22 new PPP projects are on the way at the different preparation and development stages. There is a need for the system of PPP project prioritization from the public sector perspective. In order to make PPP projects successful, the appropriate evaluation procedures have to be applied and adequate criteria used for the project assessment.

The objective of this research paper is to analyse the model of PPP project development in Lithuania and to suggest the new criteria for the certain stage of the PPP project assessment procedure which would help to justify distribution of limited public sector financial resources for the most sustainable projects within the area of any specific sector. In order to achieve the objective, the legal basis for the implementation of the partnership between the public and private sectors as well as the PPP project development methodology in Lithuania was analysed. The criteria set for PPP projects evaluation was developed by the authors and according to results of the expert evaluation survey their relative weights were established. The new approach was applied in the case study for PPP projects evaluation by using SAW, COPRAS and TOPSIS multi-criteria assessment methods. All three selected methods revealed the same effectiveness priority results of the considered PPP projects.

Keywords: Public and private partnership, project, multi-criteria evaluation

1. Introduction

Lithuania, like many other Eastern European countries is searching for the new ways to improve the existing public infrastructure and services as well as to create the new ones. Public-private partnership is one of the recent co-operation models, which has been widely and successfully applied in Western Europe and over the world to stimulate the economy and attract the investments into the local infrastructure development.

According to the European PPP Expertise centre (EPEC) Review of the European PPP Market in 2014, 82 contracts with the total budget of 18,7 billion EUR were signed in Europe and in Turkey in 2014 (EPEC, 2015). “In countries which are commonly considered to have a mature PPP environment and favourable conditions for project implementation (e.g. United Kingdom, France), investment projects implemented under the PPP model amount to 10%–15% of the annual state investment programme” (Aleška, 2013).

Statistical data provided by Ministry of Finance of the Republic of Lithuania proves that implementation of PPP model and its impact on the economic development of the country has been growing in Lithuania. 34 PPP contracts have been implemented in 2014, of which 32 were concessions contracts, and only 2 Private Finance Initiative (PFI) projects: Vilnius Balsiai school construction project was finished in 2011 and Palanga seaside resort bypass construction in 2015. In total 47 PPP contracts were concluded and 139 million EUR were invested until January 1, 2015. Most of the PPP contracts were implemented in utilisation, recycling and waste management sector (10 cases), in the area of culture, sports, leisure facilities, equipment and other infrastructure (9 agreements) and energy sector, including heat and electricity, petroleum and natural gas (8 contracts). According to PPP accounting data investment reached 15,84 million EUR in 2014, payments for private entities amounted to 10,72 million EUR, and public sector entities received income of 4,34 million EUR.

PPP programming is boosting in Lithuania recently and becomes a part of EU SF programming for 2014-2020, which also promotes the partnerships between the public sector and business. 22 new PPP projects are on the way at the different preparation and development stages. In order to make PPP projects successful, the appropriate evaluation procedures have to be applied and adequate criteria used for the project assessment from the private as well as public partner perspective.

The objective of this research paper is to analyse the model of PPP project development in Lithuania and to suggest the new criteria for the certain stage of the PPP project assessment procedure which would help to justify distribution of limited public sector financial resources for the most sustainable projects within the area of any specific sector.

2. Lithuanian Model of Public and Private Partnership project development

“Public-private partnerships” means the ways of co-operation between a state or municipal authority and a private entity as specified by laws, whereby the state or municipal authority transfers to the private entity the activity assigned to its functions, while the private entity invests into this activity and the assets required for carrying it out and receives a remuneration therefore as specified by the laws. The forms of partnerships between the public and private sectors shall be specified by this Law, the Law of the Republic of Lithuania on Concessions and other laws” (Republic of Lithuania Law on Investments, 1999, as last amended on 16 June 2009).

PPPs in Lithuania are regulated by the Law on Concessions, adapted in 1996 (amended 2011), Law on Investments(1999), Law on Public Procurement (1996), Resolution on Public-Private Partnership of the Government of Lithuania (2009), Law on Management, Usage and Disposal of State and Municipal Property, Civil Code, and other documents. Lithuanian legislation describes available schemes for PPP implementation: contractual and institutional Public-private partnership. The contractual partnership is carried out exclusively on a contractual basis without the establishment of a mixed investment project realization company (concessions, PFI). Institutional partnership is carried out by establishing a special purpose company - mixed capital (public and private) company. PPP projects can be implemented both at the central and municipal level (Manual for the Public–Private Partnership Projects, 2014). Legislation allows private entities to initiate PPP projects.

In 2009 there was a programme introduced by the Government to enhance PPP in priority sectors: transport, education, social housing, public order and safety. In 2009 Lithuanian Government authorized the public institution Central Project Management Agency (CPMA) to provide methodological and advisory assistance to the issues of the development and implementation of public and private partnership projects. PPP Competence Centre was set up by CPMA in 2010. PPP project development and implementation methodology was officially approved on 16 April 2013. According to the survey conducted by the European Bank for Reconstruction and Development Lithuania was ranked very high among other Eastern Europe countries for the comprehensiveness of PPP regulatory framework (1st place), PPP environment in general (2nd place) and for clearly defined institutional framework (3rd place) (The Economist Intelligence Unit, 2013).

The PPP development process of the state level projects in Lithuania, acting institutions and their functions are described in Figure 1. The PPP development process of the local level essentially corresponds to the state level procedures with the exception that PPP Commission is substituted by the Municipal Inspector and the Government – by the Municipal Council.

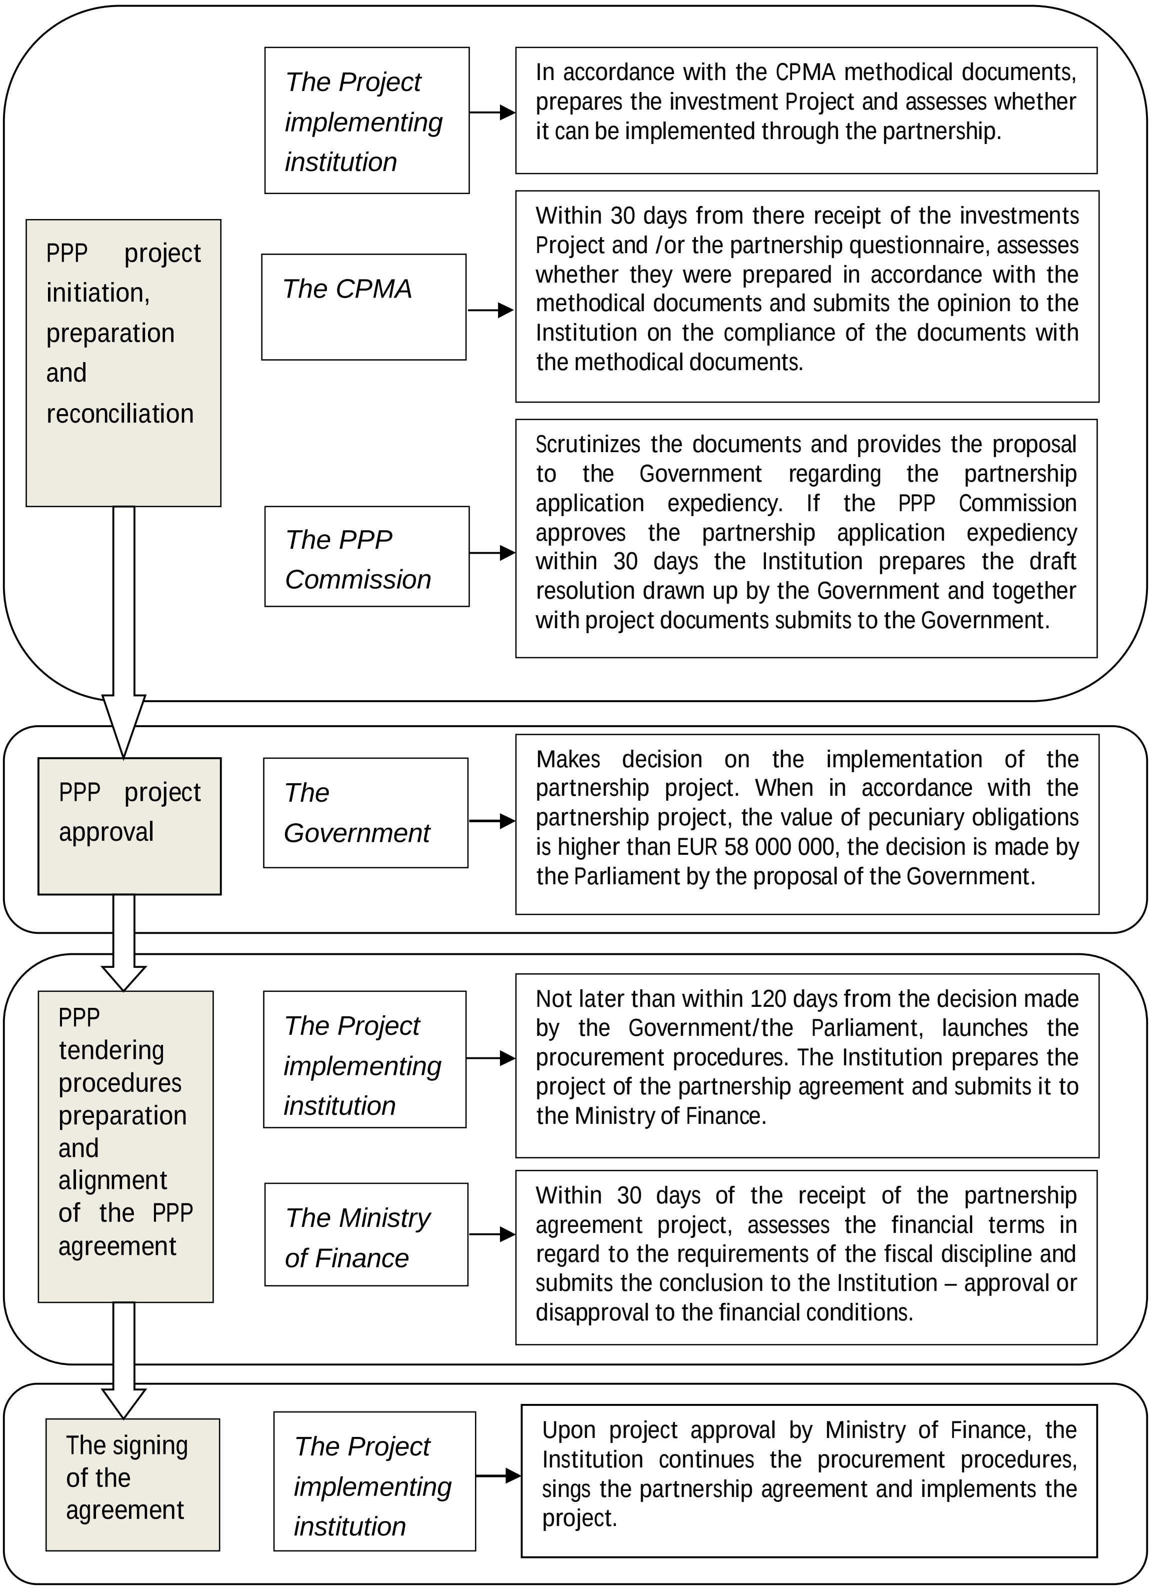

Figure 1: PPP project development model (adopted from PPP Competence Centre. Viešojo ir privataus sektorių partnerystė: Lietuvos patirtis ir ateities perspektyvos [Public and Private Partnership: Lithuanian experience and future perspectives], 2014)

3. Public and Private Partnership Project Evaluation

As a result of recent scientific literature review, the main research areas were identified related to the PPP projects development (Table 1). While the foreign authors investigate financing and management problems, analyse different PPP application areas, share the best practise of the PPP coordinating institutions, European Commission Directorate - General for Regional Policy (2006) and most of the Lithuanian authors emphasize the significance of the criteria used to assess the PPP project effectiveness at the stage of feasibility study: political, administrative and legal environment, communication between the public and private sectors, etc. (Table 2).

The existing PPP project evaluation stages and criteria from the perspective of the public sector in Lithuania are presented in the Figure 2. According to the Republic of Lithuania Government Decree No.1480, November 1, 2009 (last amended in 2015) PPP Commission approves/rejects the projects based on the CPMA recommendations and institution's financial capability. However, the National Audit Office Report (2013) states: "the areas to be improved include initiation and development of partnership projects. Prior to the preparation of feasibility studies, none of the analysed projects had been subject to detailed assessment in order to find out whether it is appropriate to carry out these projects in the form of PPP. Also, none of the feasibility studies evaluated the financial capacity of the institutions, although this is a very important criterion". In authors' opinion, public PPP commitments should have the financial limits, and clear and transparent criteria need to be established for project prioritization within the certain area. Thus, the set of the criteria (shaded area of Figure 2) was developed by the authors and is recommended to be used for the PPP project evaluation by PPP Commission from the public sector perspectives:

- **C1 - Impact on the regional labour market.** This criterion refers to the number of new job places created due to the project implementation and the number of unemployed people in the region, measured as a percentage.
- **C2 - Share of the project value per single consumer of project target group**. The ratio is calculated dividing the value of public sector capital investments and operation expenses by the number of targeted users (recipients) for whom the infrastructure and public services/ social economic benefits supposed to be created, calculated in EUR.
- **C3 - Complexity of the public services.** It reflects the responsibilities and risk acceptable by the private sector. Criterion is calculated taking into account different tasks/ services or groups of services to be transferred to the private sector during the project implementation and operation period.
- **C4 - Expansion of the provided services within the region.** It refers to the increased percentage of customers after the PPP project implementation in regard to the total number of people residing within the public institution's service territory.
- **C5 - Size of the target group within the region.** The criterion represents the proportion of the population in the region which receives the benefits of the implemented PPP Project, measured as a percentage.
- **C6 -Project priority in regards to regional strategic development plan**. It defines the priority of the project implementation area within the municipal/state strategic development plan. The criterion is measured on a scale from 1 to 10 points. Scores are calculated by dividing the project area priority number by the total number of priority areas and multiplying it by 10 - the number of max points. The project is of the highest priority when it's score is equal to 1.

The authors define the following advantages of the suggested methodology:

ü accurate and clear criteria are used to prioritize the PPP projects of the same area;

ü less projects are presented for Government, Parliament or the municipal council consideration;

ü the most rational and sustainable PPP projects within the certain field are selected for funding by the end of the financial period.

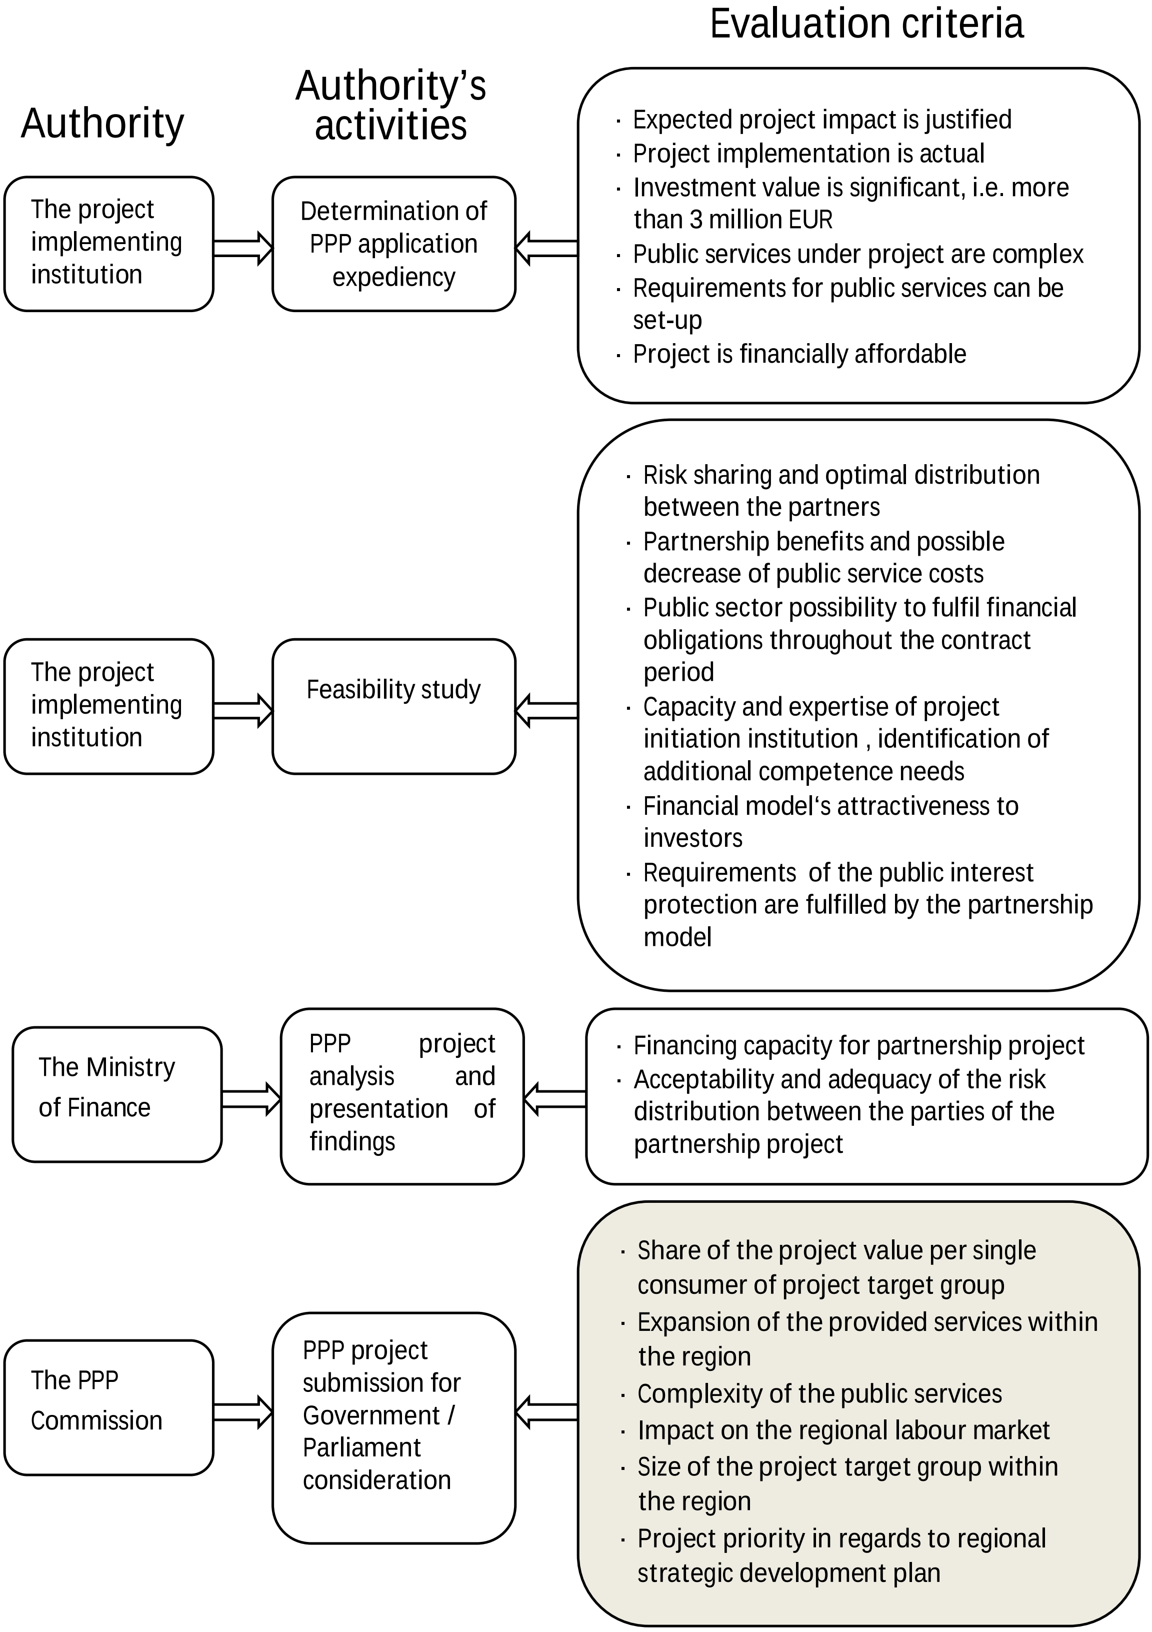

Figure 2: PPP project evaluation criteria

4. Effectiveness of PPP Projects: Case Study

Three Lithuanian public-private partnership projects were selected for analysis and priority identification. Information about all of these projects is presented on the PPP Competence Centre website (www.pppLietuva.lt) as well as the documents of public procurement. New construction or reconstruction of the existing buildings in all of the projects is planned to be carried out as well as building maintenance and operation services provided for the period of 25 years. In fact, two of these projects belong to the public security sector within the central government level, and the third one to the sports and leisure sector within the local (municipal) level. It is conditionally assumed that all projects are classified in the same area and are funded from the same source of the public sector, taking into consideration the limited availability of financial resources. The selected projects are:

A1 - Project of Vilnius County Police Headquarters. Project goal - to create the conditions for the proper performance of the police functions in Vilnius city by building and operating appropriate facilities for Vilnius Regional Chief Police Station Custody and Vilnius City 1st Police station. Project Owner - Police Department under the Ministry of Internal Affairs. Total area 8,155 m^2. Max Project value 57 million EUR. PPP Contract: Design-Build-Finance-Operate (DBFO). Project term - 25 years. Current status- Private partner selection.

A2- Sports palace renovation and wellness complex development project in Naujoji Akmenė city. The aim of the project - to ensure the sports and leisure facilities accessibility and attractiveness for community and tourists of Naujoji Akmenė municipality. Project owner - municipality of Naujoji Akmenė. Total area 3,625 m^2. Max project value 8 million EUR. PPP Contract: Design-Build-Finance-Operate (DBFO). Project term - 25 years. Current status – Preparation for tender.

A3 - Project of abandoned buildings reconstruction into the prison in Pravieniškės 1st prison territory. Project goal - to relocate the existing prison from the current Lukiškės remand prison in the central part of Vilnius to Pravieniškės. Project Owner - Prison Department of Lithuania. Project term - 25 years. Max Project value 30 million EUR. Total area 4,883 m^2. Number of prison places 320. PPP Contract: Design-Build-Finance-Operate (DBFO). Current status - Private partner selection.

The significance of PPP projects evaluation criteria was determined by using pair-wise expert evaluation method. The questionnaire was developed and electronic survey (www.manoapklausa.lt) was filled out by 28 experts who directly participate in public and private partnership projects initiation or development and work for the agency „Invest in Lithuania“, CPMA, Ministries of the Republic of Lithuania and local governments. In regards the results of expert evaluation the priority row of criteria was developed (Table 3).

The case study projects were analysed by applying multi-criteria evaluation methods: Simple Additive Weighting (SAW), Complex Proportional Assessment (COPRAS) and Technique for Order Preference by Similarity to Ideal Solution (TOPSIS).

Table 3. The weights of PPP criteria

No.	*Criteria*	*Weights of significance*
C2	*Share of the project value per single consumer of project target group*	*0,23*
C4	*Expansion of the provided services within the region*	*0,19*
C3	*Complexity of the public services*	*0,18*
C1	*Impact on the regional labour market*	*0,15*
C5	*Size of the project target group within the region*	*0,15*
C6	*Project priority in regards to regional strategic development plan*	*0,10*
	Total:	*1,00*

The matrix of initial data for the alternatives *A1*, *A2* and *A3* was created with the criteria values which were calculated by using data from PPP Competence Centre, public procurement documents, Lithuanian Statistical Department, also information received from project initiating institutions (Table 4).

Table 4. Matrix of initial data

	C1	*C2*	*C3*	*C4*	*C5*	*C6*
A1	*0,34*	*799*	*9*	*12*	*22*	*6,67*
A2	*0,26*	*7404*	*13*	*13*	*14*	*6,00*
A3	*3,90*	*324566*	*9*	*105*	*0,0005*	*3,68*
Optimality	*Max*	*Min*	*Max*	*Max*	*Max*	*Min*

By applying multi-criteria evaluation methods of SAW, COPRAS and TOPSIS, Project of Vilnius County Police Headquarters was identified as the most rational and sustainable from the public sector perspective. Sports palace renovation and wellness complex development project in Naujoji Akmenė city was selected as the second one in priority. The Project of abandoned buildings reconstruction into the prison in Pravieniškės 1st prison territory was assigned to the third place (Table 5).

Table 5. The summary results of multi-criteria evaluation

	SAW		*COPRAS*		*TOPSIS*		*Final ranking*
	Priority	*Value*	*Priority*	*Value*	*Priority*	*Value*	*Priority*
A1	*1*	*0,59*	*1*	*0,33*	*1*	*0,49*	*1*
A2	*3*	*0,40*	*2*	*0,32*	*2*	*0,48*	*2*
A3	*2*	*0,56*	*3*	*0,31*	*3*	*0,46*	*3*

5. Conclusions

Legal basis for PPP projects development in Lithuania was significantly improved during the period of 2010-2015. Up to date only two institutional PPP projects have been successfully implemented under the partnership scheme, but the number of new PPP projects is growing and the responsible institutions have to justify the public sector participation in the light of limited state/municipal budget resources. There is a need for the system of PPP project prioritization from the public sector perspective.

Analysis of Lithuanian PPP project development model was carried out and the conclusion was made that PPP model requires improvement, especially at the stage of feasibility study. By evaluating the projects in the early development stage it would be possible to identify the most efficient projects, thereby reducing the number of further activities and saving the costs.

The criteria set for PPP projects evaluation by PPP Commission was developed by the authors and according to the results of expert evaluation survey their relative weights were established. The following priority of criteria based on their importance was identified:

- Share of the project value per single consumer of project target group
- Expansion of the provided services within the region
- Complexity of the public services
- Impact on the regional labour market
- Size of the project target group within the region
- Project priority in regards to regional strategic development plan

Case study of the three selected PPP projects revealed the same priority line of projects' effectiveness by applying SAW, COPRAS and TOPSIS multi-criteria evaluation methods. This demonstrates the validity of the proposed evaluation methodology, thus it is recommended for practical application of PPP project assessment from the perspectives of Lithuanian public sector.

(email: aakintoye@ucaln.ac.uk)

Abstract

The Bangladeshi government is considering Public Private Partnership (PPP) procurement options in the road sector by encouraging the involvement of local and foreign investors. However, there is ongoing evidence of poor success rating in implementing road projects in Bangladesh. Although the policy makers, public sector clients, private investors and the lenders are aware of the benefits of road projects procurement under PPP arrangement, there is little information on the likely risks and their impacts on PPP road projects. This paper therefore identifies and prioritises the risks associated with PPP road projects in the context of Bangladesh through a questionnaire survey of public clients, contractors and consultants that are involved in road sector projects development. In order to prioritise the 36 previously identified risk factors associated with PPP road projects, a questionnaire survey was conducted among the three groups of respondents: public clients, contractors and consultants. The survey results show that availability of land is the most significant risk factor for PPP road projects in Bangladesh. The other top ranked risk factors are improper planning for PPPs, risk in financing in PPP road projects, delay in land acquisition, corruption in government sector and toll road acceptance by the public majority. It is concluded that these risk factors need to be prioritised and addressed through government initiatives in order to encourage local and foreign investors' participation in the PPP road projects in Bangladesh.

Keywords: Risk management, public private partnership, Bangladesh, road construction, project procurement

1. Introduction

Project implementation through Public Private Partnerships (PPPs) is now an accepted alternative to traditional procurement methods in delivering public service infrastructure facilities. The private partners can be engaged in delivering public services through different models of PPP procurement (Akintoye and Chinyio, 2005). It is widely used because of its special characteristics such as ease of pressure on public fund, proper allocation of project risks and efficiency in project completion with innovative design and construction methods, which encourage the public clients to initiate PPP-based infrastructure projects worldwide (Li and Akintoye, 2003).

Over the past two decades, private sector financing through PPPs has become increasingly popular as a way of procuring and maintaining public sector infrastructures, in the sectors such as transportation (roads, bridges, railways, ports, airports etc.), social infra-structures (schools, hospitals, prisons, social housing etc.), public utilities (water supply, waste disposal and treatment, water treatment etc.), power sector, government offices and accommodations and other special services such as communication networks, defence equipment. However, PPP project implement process comes across a number of risks in different forms such as political, cultural, technological, social, legal, environmental, financial, macroeconomic, project default risks etc. In addition, owing to its complex nature, large volume of capital investment, long- term concession period and involvement of diversified parties, project implementation through PPP models has been adjudged to be full of risks (Li and Zou, 2011). Moreover, in PPP road project, traffic revenue or demand risk, toll pricing and collection risks are other important factors that can create uncertainty in getting back the cost of capital and profit to the private entity by the end users throughout the long range concession period (Singh and Kalidindi, 2006).

Impact of risks in completing a PPP project is usually significant. Failure to manage the risks has direct or indirect impact on goals and objectives of the organisation. Thus, all the parties involved in PPP procurement need to know the nature and complexity of project risks. The public sector clients need to address the project risks for assessing financial and economic viability before embarking on any project (Singh and Kalidindi, 2006), preparing a successful concession agreement and transferring the major risks to the private sectors as they are best able to manage them (Ibrahim et al., 2006).

The Bangladeshi government is embarking on PPP options in the road sector by encouraging the involvement of local and foreign investors. However, there is evidence of poor success rating in implementing road projects in Bangladesh. Project procurement through PPP models in Bangladesh is new and at the embryonic stage; a few PPP projects have been started recently including two PPP projects in the road sector. The client organisations are being encouraged to procure PPP road projects. However, the policy makers, public sector clients, private investors and the lenders do not have enough information about the likely risks and their impacts on road projects procurement under PPP arrangement, Not too many private investors are expressing interests to take part in bidding competition for PPP projects because of risks that could be attributable to the procurement arrangement including lack of confidence on their return on investment. This paper therefore identifies and prioritises the risks associated with PPP road projects in the context of Bangladesh

2. Risks associated with PPP road projects

Several studies (Xu et al., 2010; Chung et al., 2010; Singh and Kalidindi, 2006; Thomas et al., 2003) have identified the significant risks associated with PPP road projects, their impacts and development of risk management tools for different countries.

Wang et al. (2000) identified a list of risks in PPP road projects in the context of China. This comprises political risk factors such as change in law and policy, delay in approval, corruption in government, government's reliability and creditworthiness; and force majeure risks, which are regarded as the most critical risk factors affecting the BOT projects in China.

Thomas et al. (2003) identified the major risks in Indian BOT toll road projects and classify them into four different phases of a project. The first phase is the development phase which comprises of land acquisition/resettlement risk, permission/approval risk and delay in financial closure. This is followed by the construction phase risks comprising technological risk, design risk, project delay and cost overruns risk. The operation phase risks are traffic revenue risk, operation risk, demand risk, debt servicing risk. Lastly, the project life cycle risks comprise legal risk, political risk, partnering risk, regulatory risk, environmental risk and force majeure. In addition, Singh and Kalidindi (2006) emphasised risk in traffic revenue (i.e. demand risk) affecting the commercial success of PPP toll road projects in India.

Wibowo and Kochendorfer (2005) work on PPP toll road project in Indonesia shows that construction cost overruns, delay in land acquisition and total delay in project complementation, pricing of toll rate, estimation of future traffic volume, change in regulation and some macroeconomic factors such as inflation, interest rate are the most significant risks affecting the success of PPP toll road projects in Indonesia.

Ogunlana and Abednego (2009) listed risk factors for PPP road way and conducted a case study research on Cipularang Toll-way Project in Indonesia to identify the major risk factors on the project. The study shows that project financing, lack of government support, delay in decision/approval, problem with land acquisition and change in design affected mostly the success of the project.

Xu et al. (2010) identified 17 major risks associated with PPP road project; these are ranked in accordance with their importance on PPP Highway projects in China through Delphi questionnaire survey technique and identify the most critical risk groups using factor analysis. They concluded that government intervention (political interference on project procurement) and government maturity (corruption and poor decision making and inadequate law and order situation) are the two most critical risk groups affecting the success of PPP Highway projects.

Rajan et al. (2010) conducted a case study on East Coast Road project, a PPP road project in Chennai, India. The most critical risk factors identified on the project are project finance risk, poor decision making by the government, delay in land acquisition, cost overruns, risk associated with traffic revenue and collection of tolls.

In the Australian PPP road project, Chung et al. (2010) identified the most critical risk factors as fluctuating traffic volume, design and construction risk, operation and maintenance risk, risk for change in country's legislation and policy, pricing of toll, debt coverage risk and low level acceptance of toll road by users.

Li and Zou (2011) developed a fuzzy analytical hierarchy process (AHP) to assess the risks in PPP projects. They identified the risks associated with PPP roadway project in China which are verified by the PPP experts and assessed them using fuzzy technique. From this study, planning deficiency, low residual value, lack of enough competition, design risk, delay in approval, change in legislation and traffic volume risk were identified as the most critical risk factors for PPP highway projects in China.

Based on the literature above, Table 1 is produced which shows that fluctuating traffic (or demand risk) is the mostly cited risk factors associated with PPP road projects. The commercial success of PPP road projects depends in some ways on the toll collected from the traffic use of the assets if investors are otherwise not compensated by the public sector clients. Private investors perceive the returns on investment from PPP road projects is risky despite the assumption of any traffic revenue presented in the PPP business case by the client organisations (Singh and Kalidindi, 2006).

Delay in construction is another most cited important factor. Construction time overrun is a general factor for any type of project which could result from insufficient experience of the contractors, use of inappropriate construction methods, inaccurate time and cost estimating, improper project planning and scheduling, incompetent project team, unreliable subcontractor, obsolete technology etc. (Long et al., 2004).

Delay in land acquisition, frequent change in laws/policies and risk in operation and maintenance are the third most cited risk factors. Road project requires acquisition of public land. The acquisition process involves several steps such as estimation of land and other assets, supply of necessary documents; followed by a number of steps to get the final approval, which often consumes significant time and cost for the road projects (Wang et al., 2000). Risks associated with frequent change in law includes changes in government policies, laws and regulations related to public procurement, methods of handling inflation, fixation of currency conversion rate and methods of setting taxation rate by the different organisations of the government: these can hinder the success of a PPP road project (Wang et al., 2000).

Factors such as residual value risk, availability of land risk, unstable law and order situation, risks in evaluation of PPP procurement and delay in annuity payment are the least cited risk factors.

Table 1: Risk associated with PPP road projects (Content analysis)

Inflation	*x*		*x*		*x*		*x*		*x*	*5*

3. Research Method

The principal objective of the study was identification of significant risks in PPP road projects in the context of Bangladesh. To identify the risk associated with PPP road projects, the available literature on risk associated with PPP road projects have been analysed and the risk factors have been listed in a tabular form through content analysis (after Bryman, 2008). A total of nine research papers on risk in PPP road projects have been reviewed to identify the risks associated with PPP road projects. Based on the nine research papers, 36 risk factors were identified (after Xu et al., 2010) as shown in Table 1.

A questionnaire survey which contains all 36 identified PPP road risk factors have been used to gain a wider spread of opinion on risk factors in the context of Bangladesh PPP road projects based on a 5-point Likert scale (5=Very important; 4= Important; 3=Moderately important; 2=Less important, and 1= Unimportant). The questionnaire was piloted with 5 road procurement experts. Construction professionals both in government and private sectors as well as consulting firms, who have vast experience in procurement of road projects in Bangladesh were targeted.

The respondents are (i) public sector client respondents drawn from Roads and Highways Department (RHD), Local Government Engineering Department (LGED), Bangladesh Bridge Authority (BBA) and City Corporations; (ii) private sector contractors who are road project construction experts from national level construction firms (enlisted by the public procurers) in Bangladesh; and (iii) consultants who are public procurement consultants working in consulting firms, donor aided public procurement project and as freelance consultants.

As there was no systematic database for the road construction professionals in Bangladesh, non-probabilistic quota sampling technique instead of random sampling was used with a view to comparing the perceptions on PPP road risks from the three groups of respondents. A total of 120 respondents (40 from each group) was asked to rate the factors based on their experience in road project procurement. The questionnaires were self-administered in Bangladesh over a period of two months. A total of 82 completely completed questionnaires was returned, representing a response rate is 68.33% (public clients 80%, contractors 75.5% and consultants 52.5%).

These risk factors are presented to Bangladeshi respondents. Mean score (MS) for each risk factor from the 5-point Likert scale was calculated (after Chan and Kumaraswamy, 1996) as follows:

$$\text{MS} = \frac{\sum_1^5 (f.s)}{\text{N}}$$

Where f = frequency of each rating for each risk factor; s = score given to each risk factor by the respondents (ranging from 1 to 5); and N= total number of responses for each risk factor. In addition, the standard deviation of the MS for each factor is provided to show the variability.

4. Results of the Survey

Table 2 shows that 61% of the respondents had over 10 years of experience in road projects construction and procurement; suggesting that the majority of the respondents were operating at senior level of construction professional experience.

Table 2: Experience level of the respondents

Years of experience	*Overall*		*Public Clients*		*Private Contractors*		*Consultants*	
	No.	*(%)*	*No.*	*(%)*	*No.*	*(%)*	*No.*	*(%)*
Less than 5 years	*9*	*11%*	*8*	*25%*	*1*	*3%*	*0*	*0%*
5^+ to 10 years	*23*	*28%*	*12*	*37.5%*	*9*	*31%*	*2*	*10%*

More than 20 years	*12*	*15%*	*4*	*12.5%*	*6*	*21%*	*2*	*10%*
Total	*82*	*100%*	*32*	*100%*	*29*	*100%*	*21*	*100%*

4.1 Ranking of risks in PPP road projects

The responses of clients, contractors and consultants are ranked based on their mean score (MS) and standard deviation of a list of 36 identified risk factors involved in PPP road projects. Also, an overall ranking of the risk factors is presented by combining the data from all respondents.

Table 3 shows ranking of the risk factors by the three respondent groups and the overall ranking from all the three groups of respondents. The mean scores ranged from 4.43 to 2.13. Availability of land (MS = 4.43), improper planning for PPP project procurement (MS = 4.33), financing in PPP road projects (MS = 4.27), delay in land acquisition (MS = 4.24) corruption in government sector (MS = 4.09), acceptance of toll roads (MS = 4.02) are considered the top most risk factors by the respondents.

The top most significant risk factors for clients are: delay in acquisition of land for the projects (MS = 4.50), initiating PPP projects without proper planning by the client organisations (MS = 4.41), availability of sufficient land for construction of road projects (MS = 4.38), lack of qualified bidders to invest in large scale road projects (MS = 4.13), financing in PPP road projects (MS = 4.06), resettlement and relocation of utilities (MS = 4.03), frequent changes of laws, rules and regulations related to public procurement of Bangladesh (MS = 4.00).

The most significant risk factors by contractors are: availability of land (MS = 4.55), financing in PPP road projects (MS = 4.48), corruption in government sectors (MS = 4.41), improper planning for PPP road projects (MS = 4.34), government intervention in large scale project procurement (MS = 4.28), and delay in land acquisition (MS = 4.14).

The most important risk factors associated with PPP road projects in Bangladesh identified by the consultants group are availability of land for road project (MS = 4.33), financing in PPP road projects (MS = 4.29), improper planning for PPP road projects (MS = 4.19), acceptance of toll road by the users (MS = 4.14), corruption in government sector (MS = 4.05), delay in land acquisition (MS = 4.00), government intervention in project procurement (MS = 3.90), unstable law and order situation (MS = 3.86) and lack of qualified bidders (MS = 3.76).

Table 3: Rankings of risks in PPP road projects in Bangladesh from different perspectives

Risk Factors	*Overall*			*Clients*		*Contractors*		*Consultants*	
	R	*MS*	*SD*	*R*	*MS*	*R*	*MS*	*R*	*MS*
Risk of availability of land	*1*	*4.43*	*0.817*	*3*	*4.38*	*1*	*4.55*	*1*	*4.33*

*R = Ranking, MS = Mean score, SD = Standard deviation

Spearman correlation analysis results for the 10 most important risk factors to test for any agreement between various groups of respondents is presented in Table 4. This shows that there is general agreement between the consultants and contractors in respect of the ranking of the top ten risk factors, whereas there are significant disagreements between clients and contractors, as well as clients and consultants. This test reinforces the concordance of perception between the two private sector groups (contractors and consultants).

Table 4: Test for agreement on the overall ranking of the 10 most important risk factors as perceived by different group of respondents

Groups of respondents	r_s	*t*	*Reject H_0?*	*p-value*
Clients and Contractors	*-0.297*	*-0.880*	*No*	*Not significant*
Clients and Consultants	*-0.103*	*-0.293*	*No*	*Not significant*
Contractors and Consultants	*0.867*	*4.914*	*Yes*	*Significant, <0.05*

*r_s = Spearman's rank correlation coefficient; t = t-statistics; H_o = null hypothesis; p = probability that rejects the null hypothesis.

5. Discussion of the results

Overall, the survey results show that risk in availability of land for road projects, improper planning for PPP procurement, risk in financing, delay in land acquisition, corruption in government sector and risk in acceptance of toll roads are the top ranked factors in the context of Bangladesh. However, the prioritisation based on the Table 1 (undertaken through content analysis of literature review) is quite different from this survey result. For example, availability of land is mentioned as a significant risk factor in only one of the literature, whereas, it is ranked first in this study. On the other hand, fluctuating traffic revenue is cited in all the research papers; however, this factor is ranked 25th important factor in Bangladesh.

It is noted that the three respondent groups (clients, contractors and consultants) ranked the risk factors associated with PPP road projects according to their objectives and interest in road sector project development. However, the consistently least important risk factors overall and within the groups for PPP road projects in Bangladesh are the risks associated with residual value of the asset, commissioning of the asset, health and safety, payment of debt to the financial institutions and changes in design of works. The top ranked risk factors and how they could impact the success of PPP road projects in Bangladesh are discussed as follows:

Availability of land for PPP road projects: The risk of availability of land for PPP road projects is ranked 1st overall. This is not surprising given that availability of land is a common problem for road project for the countries with high population density like Bangladesh; availability of land is regarded as one of the significant risk factors for PPP road projects in India (Thomas et al., 2003). Bangladesh is an agriculture-based country with high density of population. Road construction projects need considerable land and in Bangladesh it is associated with high market price. In addition, a PPP new road project development might lead to a need to demolish high-rise buildings, markets and other structures which are located adjacent to the existing roads. Thus scarcity of land creates high barrier to the implementation of road projects in Bangladesh. For example, it was speculated that one of the large PPP road projects in Bangladesh, Dhaka Elevated Expressway (with the estimated cost of over US$ 1 billion), would fail at its initial phase because of insufficient and costly land in Dhaka city (GOB, 2011).

Improper planning for PPP procurement: Although 'improper planning for PPP procurement' is identified as one of the least cited factors in the literature reviewed, this factor is ranked 2nd in the context of PPP road projects in Bangladesh. This is a critical risk factors for Bangladesh as development of most road projects in Bangladesh is considered on the basis of political imperatives. The financial and economic needs are often ignored while initiating projects. As a result, many road projects in Bangladesh have been known to experience time and cost overruns and in some cases abandoned due to improper procurement choices and planning.

Financing of PPP road projects: The risk factor ranked 3rd overall is ranked 5th by clients and 2th by both contractors and consultants. This is an important factor to contractors and lenders as it may affect the project revenue and cash flow regime, which has a direct impact on payment for the services provided by the asset and consequently the recovery of capital invested by the lender. Lenders perhaps perceive PPP investment risk as a 'business' risk and are rightly concerned if this is inappropriately passed to the project consortium. Increase in project cost, government intervention, corruption, fluctuating traffic volume, change in laws/policies by the government etc. are some of the factors which could create risk and uncertainty of the investment in PPP road projects for investors.

Delay in land acquisition: Delay in land acquisition is ranked fourth overall. While clients ranked it as first, the contractors and consultants have ranked the factor as sixth. For road projects construction in Bangladesh, the public clients have had acrimonious experiences with land acquisition. Land acquisition requires a number of steps to get the approval needed coupled with associated complexities, which could lead to considerable time and cost overruns. The impact could mean that the contractor is not able to start the physical work on site or the work is delayed during the construction stage until the problem is resolved. There are evidence of poor performance of road project developments in Bangladesh due to land acquisition problems.

Corruption in government sector: Overall, the risk factor is ranked fifth (third by contractors, fifth by consultant and eleventh by clients). Corruption is prevalent in Bangladesh public sector (Zafarullah and Siddiquee (2001). Bangladesh is ranked among the top corrupt countries based on corruption index by Transparency International. As a result, contractors and consultants often give corruption in public sector as a reason for delays in project execution. The corruption activities could be found in every aspect of construction including tendering process, necessary documents approval, interim payment, utility connections etc. A high level of corruption in the public sector of a country could demotivate local and foreign investment in PPP projects.

Acceptance of toll roads by the end users: This risk is ranked sixth by all the respondents. This is not surprising given that the road users in Bangladesh are not used to paying tolls for the use of roads and bridges; road assets are traditionally constructed and maintained by the public sector. There is a risk that the end users may divert to non-tolled routes to avoid paying tolls on PPP roads, which may hinder generation of revenue needed to cover the investment and profit margin of PPP road investors.

6. Conclusion

Given some benefits acclaimed to project procurement through PPP models over the traditional procurement methods, governments in both the developed and developing countries, are encouraging the private investors in the delivery of public facilities and services through PPP procurement. However, PPP procurement involves a complex procurement process, multi-party involvement and high capital investment along with long-term concession period, which sometimes discourage the private contractors to invest in the uncertain business environment. PPP has been used to deliver infrastructure in many countries where there is not enough public sector funding.

Hence, PPP procurement method could become one significant option for the government of Bangladesh to develop its road sector projects. This has the potential to reduce pressure on the government associated with: huge public sector funding, need for foreign loans, timely completion of road projects; attracting local and foreign investors; etc. However, PPP road projects procurement is adjudged to have many risks that must be mitigated or properly allocated to parties involved in the development.

In PPP projects, the private investors normally assume the revenue/demand risk for the use of the asset including the risk in design, finance, construction and maintenance, although sometimes demand risk may be shared by the public sector assuring the guarantee of a minimum level of use. The results of the survey of Bangladesh respondents show other risks that should be considered. These are availability of land and delay in land acquisition, improper planning for PPP procurement by the government, risk in financing in PPP road projects, corruption in public sector, government intervention and risk in acceptance of toll roads. These are the top risk factors that might affect the success of PPP road projects in Bangladesh.

In order to encourage the private sector (financial institutions, private investors, contractors, etc.) involvement in PPP road project, the government of Bangladesh should initiate processes and guidelines to minimising the impact of the above mentioned risk factors. Land for road projects seems to be a major risk factor that should be addressed in terms of on how to make this available or work with the community in order to gain the trust of investors and to achieve successful road projects development through PPP. The policy makers should also engage pressure groups and stakeholders in a constructive dialogue and involvement very early in a PPP road project development on the requirements of PPP road projects and associated tangible and intangible benefits. Creation of a sound business environment through development of policy and legal framework and guidelines for PPP should be considered a priority by the government in order to gain the trust of both the local and foreign investors. In addition, the planning and procurement processes should be given very care consideration coupled with the engagement of the right professionals from both the public and private sectors very early in the process.

Abstract

In recent years, Colombia has had strong economic growth. The constant need to expand infrastructure have led to the development of road projects in the form of public-private partnerships (PPP). However, draft social infrastructure has been stalled by the lack of legislation to help correct equitable allocation and quantification of risks between the private and the public sectors. Therefore, this paper seeks to make a methodological proposal of an equitable allocation and quantification of risks for the public and private sectors in Colombia for the development of social infrastructure projects under the framework of PPPs. This work is done through the verification of international experiences and previous local studies on the determination of the factors that affect the decision of the existing risk situation, and with this basis, we seek to find the feasibility of establishing a methodology capable of quantifying and allocating risks through a fuzzy logic approach and mathematical models for the modeling and parameterization of the risks associated with the awarding of contracts and delivery of such projects.

Keywords: Public-Private Partnerships, Fuzzy logic, social infrastructure, Economy

1. Introduction

Following the steady economic growth that has taken Colombia over the past two decades, the state has been forced to consolidate government plans based on building national infrastructure to boost a developing economy. Thanks to the consolidation of economic treaties and projects that enable or facilitate the dynamic economic policy, the C.E in the country during the past three years has averaged the third highest in Latin America with an average of 4.9 percent annually. From this, one of the main needs of the country is the construction and maintenance of transport infrastructure; the so called 4^{th} generation (4G) projects have been promoted through joint (public and private) resources in order to expedite construction and to distribute the associated risk. However, with the enhancement of private public associations in the country, given already years ago, different challenges arise even today, after having consolidated a law focused on this issue are pending.

So far, efforts have been focused on PPPs for road infrastructure as Colombian law scheme is specifically suited for road concessions without going into much detail about other schemes. However the demand for other type of services in the country requires this model to also be applied to other projects like social infrastructure development. However, even when the risks and financial income are different, law conditions are equally enforced; therefore, the private investor bears some suspicion when proposing or seeking social infrastructure PPPs. This is evident in projects declared void because no private was presented.

To partially solve to this problem, the authors propose a methodological approach for the correct risk allocation and quantification in social infrastructure projects based on a fuzzy logic approach. This mathematical models allow the modeling and parameterization of the risks associated with the procurement, contracting, and implementation of such projects. This article seeks to stablish the feasibility of the implementation of such a methodology in the Colombian context under the current conditions.

The remain of this article is as follows: First, we contextualize the reader on Social Infrastructure PPPs and their current state of risk quantification and allocation. Then we state a theoretical and conceptual framework on fuzzy logic and risk in PPPs. Later, we develop a methodological approach for the implementation of this concepts in risk allocation and quantification in PPPs and, finally, we state some recommendations about it applicability in the Colombian context.

2. Public-private partnerships in social infrastructure projects.

Social infrastructure projects are developments identified by the government or the private sector in search of promoting development and investment in urban and rural areas nationwide. Projects of this type seek to satisfy basic and complementary needs of a population in terms of the development of basic rights and government plans. Examples of such projects are schools, in search of the right to education; hospitals, searching for the right to health and life; prisons, with a view to safety plans; service networks or road axes, allowing the development of the country.

However many of these projects cannot be realized due to the lack of public resources. On other occasions, the project life cycle requires maintenance and strict control that is out of the functions of a public body. For these cases, a figure, which allows a partnership between the public sector and the private sector, is often encouraged. The private sector contributes a certain amount of resources that allow the state to carry out such projects. The private meanwhile, expects an economic return for the execution of the project and/or its operation and maintenance, where the investment will be paid.

Additionally, these projects carry great uncertainty and risk for both parties. Therefore you should always pre-assess the suitability of each project using this form or simply make a project through public procurement if the private cannot take the risk assigned. Basically the study currently undertaken by public organizations to establish the viability of these projects is based on a quantitative analysis intended to estimate revenues, costs and project risks.

When there is doubt about the most convenient way, financially speaking, a project (CP or PPP) is performed what is known as value for money. This concept defines Grove (Grove, 2012) as:

> "The result of the comparison of the present value of risk-adjusted costs to develop a public project (Project Public Reference) with the present value of risk-adjusted cost of the same project developed under a PPP scheme."

This analysis should ensure that with the proper development of the project, if realized in the form of a PPP, it will be economically sustainable from a level of initial investment, operating cost, and worthiness of assuming the risk associated. For this, the risks should be allocated between the private and the public parties so that each sector assumes those factors that it is able to efficiently manage (Loosemore & McCarthy, 2008). In this sense, there are two kinds of risks: the risk transferred, which assumes the private; and the risk retained, which assumes the public.

In this order of ideas, the cost of risk of the project refers to monetary impact on the initial budget due to the occurrence of the risk. Although current analysis to define this type of project is done in a quantitative way, this method has serious shortcomings because it does not consider elements of decision. For this reason, countries such as Peru, Chile and Mexico, more developed in the implementation of PPPs, have sought to incorporate in their quantitative analysis the relevant dimensions of subjective nature. However, these efforts have been corrected by the inclusion of the probabilities in the analysis.

Some other experiences (citas...) have proposed the implementation of a system based on fuzzy logic to develop the quantitative analysis of income, cost and risk in PPP projects. These authors have identified that this method is preferable because...

Accordingly, the authors propose a fuzzy logic mathematical approach to apply it in the allocation and quantification of infrastructure projects in Colombia for PPP project development. For this, we have identified four steps in the application of quantitative methods of analysis for the implementation of projects financed in Colombia, Chile and Peru: Identification, Assignment, Measurement, and Mitigation. However, the opinions of experts vary depending on particular interests, and thereforeit is difficult to have a unanimous opinion that allows the correct setting of the parameters for these 4 steps. That's why, as part of the validation of information, and in order to find a balanced response should be performed fuzzy analysis of subjective responses for both the public and private sectors.

3. Theoretical and conceptual framework

Classical logic holds that an event may or may not belong to a certain universe as if it contains conditions of ownership within this set. As before, a car can be considered if tin full commercial value is high, if your engine is powerful, if the finishes are unique and if production is restricted. In this sense a Ferrari belongs to high-end set while a Renault does not. Classical logic is clear in the separation by placing barriers between each set of elements.

However, because the division between sets depends on subjective or undefined conditions, this membership is not always so simple. Therefore, it is not clear to say that an event belongs entirely to a set. This concept is more clearly belonged-law one meets most conditions but not all event; in these cases could not make the event one party or another set di, then what happens? Fuzzy logic postulates the determined degree of membership for which an event may partially belong to one or more sets as the case requires. Alfa Romeo trucks, following the example of cars, belong to the set of high-end and mid-range set with a degree of partial belonged; It is not fully acknowledged within a set.

The same happens with millions of things based on linguistics. What is the limit that marks whether something is high, medium or low? How to know if a temperature is cold or hot? How to tell if something is white or black? These are all vague concepts that classical logic fails to establish clearly, just remember that an object can not only be white or black -that known that Eskimos recognized more than 20 shades of white. Fuzzy logic is a more flexible and complete logic in these situations. A level of 100% owned within a set put us in a particular case of fuzzy logic that corresponds to the classical logic.

A basic definition of risk according to the RAE is "Contingency or proximity of damage ". This risk must be understood on two parameters: the threat and vulnerability (Davis, 2007). These are listed in the following equation.

Risk = Hazard x Vulnerability

The threat understood as a magnitude of harm and vulnerability as a possibility of such magnitude occurs. The vulnerability can be expressed by the following relationship:

Vulnerability = exposure x susceptibility / resilience

In mathematical modeling the risk is understood as a stochastic parameter. This leads to the risk is subject to random events. These random events are what are called environment of uncertainty within a mathematical model. These mathematical models with uncertainty are represented by fuzzy variables. For practical purposes, the risk is modeled through these variables.

These fuzzy variables have a "probability space", which is expressed by the degree of membership, or occurrence, within an event. For example, a variable called earthquake that represents the risk of an event of occurrence of an earthquake in the construction of a building project, is composed of a threat and vulnerability. Threat is understood as the involvement of the structure, and a vulnerability that the probability of this natural event will actually occur during project implementation. Therefore, as denoted expression before, if the threat is high but very low probability, the risk is low. Similarly, although the threat is low, if the probability is high, the risk will remain high because the occurrence of the event is high.

There are two types of uncertainty: stochastic and also known as lexical or inaccuracy. The stochastic uncertainty focuses on the occurrence of an event, it is a question with two possible solutions. (Akbiyikli & Eaton, 2004) We base the lexical uncertainty on the vagueness of the events and the way of perception of events. It is related to how to evaluate concepts and draw conclusions. In this case, complex situations are evaluated using abstraction and referring to analogies. An example is, will it or not be white? Or will it cost more than planned?

Assuming that not all events can be simulated within the parameters of the theory of probability, it is difficult to define the perceived events. That is, the theory of probability to define both an A or B event can occur; however it cannot stipulate the behavior of A or B, or rather cannot define what is A, B or AB. An example of this is seen in the following sentence:

> "The projects in the form of public-private partnership, the risk of over-construction costs is taken by the private and vulnerability to the risk of occurrence is high." (J.Cala, 2015)

The probability theory can model whether or not the risk will occur, however cannot be implemented due to the combination of subjective categories in the process. In other words, it cannot be said to be high or low (Figure 1 and Figure 2).

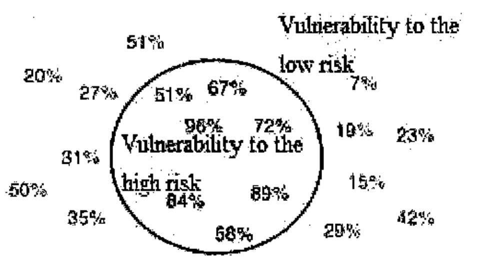

Figure 1. Representation of a set. Classical logic.

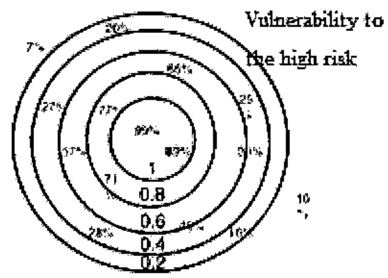

Figure 2. Representation of set b. fuzzy logic.

In the assembly (Figure 1), we have the traditional logic, which is necessary to group the myriad of events in two categories. The events occurring must belong to the set high or not high, that is, in a mathematical reasoning take the values [0, 1].

In Figure 2, a fuzzy set is observed. This type of assembly does not categorize the countless events such as high or higher; but sets limits or levels not clearly defined, the high set membership. That is, to mathematically model a situation an event rather than "0" or "1" can take values between [0,1]. In this vein, the value of the events within the group can be represented by the function uA (x) in which x is the variable represented within a range between 0 and 1. (Ponz Tienda, Pellicer, & Yepes, 2011)

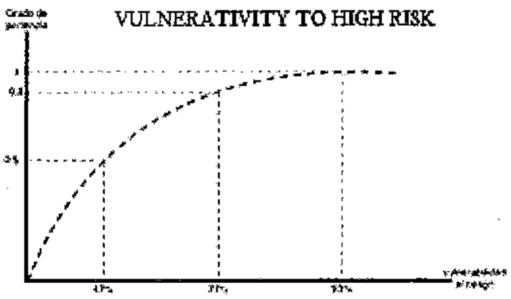

Figure 3. Function belonged Simple variable high risk vulnerability

In the example in Figure 3 it shows that for an event which should be considered if the vulnerability to risk is high, when we have 47% of vulnerability we no longer say it is on the whole not high, but It is set high in a degree of membership of 0.5. That is 0.5 would be correct to say that you have a high vulnerability. As can be seen, the function defines a set belonging Fuzzy. This comes to be understood as an input to the system established with a domain generating a specific grade of membership.

However, the perception of the variable fuzzy logic allows us to combine multiple subject categories. So, for the variable risk vulnerability there will be low, medium, high categories. For each category there will be a membership function. An example of this will be below.

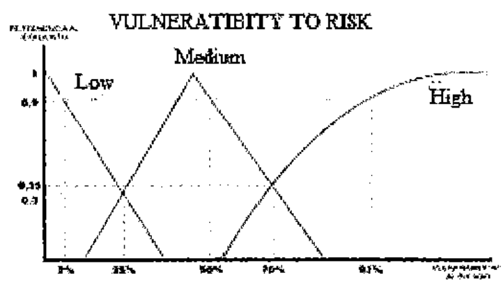

Figure 4. Function Vulnerability categorized variable irrigation.

In Figure 4, the function categorized, in which a specific event may be included within two categories exemplified. Vulnerability of 25% can be understood in two sets with a 0.3 belonged: the low set and the environment. Vulnerability 70% can be understood as high or medium with a membership of 0.35. Because of this we can create new scenarios of reasoning.

This leads us to believe if necessary and / or desirable to categorize the variables so as to obtain a function categorized rather than a simple? What variables can be categorical? How to define these categories? And even more importantly, how to define functions belonged depending on the variable?

On the issue of risk it is very important to understand that both affect a decision. Moreover, in areas where public-private partnerships, apart from having to see who takes the risk and the percentage, the quantification of this and belonged in the allocation. Therefore, each process variable is intended to model under fuzzy logic has to first go through a process of "fuzzification" that will allow us to develop operations and parameters analysis under the same logic. That is, a normal variable you want to reach fuzzy variable characteristics.

3.1 Fuzzy number and fuzzy set

First, a set of elements in which the degree of membership is continuous and abrupt, is called fuzzy set. Similarly, a fuzzy number is set. This, however, must be convex and regular; you must have a continuous function and sectioned membership. Fuzzy numbers are generally triangular, as seen in the example above: A triangular fuzzy set can be the means allocation in the example of vulnerability to risk. His fuzzy number is given by [10/45/80] all in percent.

Other concepts to consider are the core, the lower support and the upper support. For this case, the core corresponds to the value 45% and has a membership of 1, and supports the values 10% and 80% respectively belonging 0. Another common way to find these kinds of numbers is the keystone; these are not already defined by three but by four values. These will define the larger base with a zero belonged and belonged with a smaller base 1.

3.2 Fuzzy Order

The ordering of fuzzy numbers is the greatest difficulty when performing arithmetic operations or generate conclusions. Clearly with the naked eye, two triangular numbers are impossible to compare if they share a range of values. In the following chart, we show an example of a quantitative analysis of risk quantification, we have two triangular fuzzy numbers and we want to know which of these two numbers is greater.

To accomplish this, there is a method of the centers of gravity, which is to determine the centroid of each of the triangles and compare them. This centroid corresponds to the center of mass number, which can be applied to any type of fuzzy number and it is not triangular.

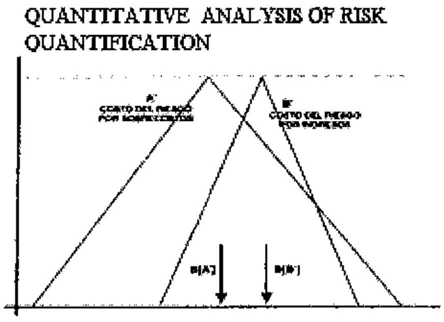

Figure 5. Example diffuse management

Supporting the idea above, normal or sharp numbers are a special case of fuzzy logic, as was mentioned previously. In these numbers the core and the supports coincide.

For the example, although the number A 'has a higher top bracket, the centers of gravity of the triangular numbers do not lead to the conclusion that the cost of risk is greater than the cost income over costs.

3.3 Steps to risk management using the concept of fuzzy variables for the validation of information

Below will be shown as each of the previously mentioned steps for the proper use of risk can be seen from a fuzzy plane.

3.4 Identification: Typology of assessed risks in quantitative analysis.

Within the current methodology of analysis, risks are divided into two groups: on one side are the costs of risk of cost overruns, corresponding to the deviation of the investment costs; and secondly the risk of hospitalization costs corresponding to the deviation in the expected revenue. (Ministry of Economy and Finance of Peru, 2014)

These two kinds of risk are what we call as direct financial cost risk of diversion. This is the first approach to identifying risks public-private partnerships. Generally the costs associated with income risk are taken by the public body; And for purposes of the methodology that should always be made and supported by the public sector. An example of this is the fact that the public sector ensures a minimum rate of vehicles per year traveling on a road made in the form of PPP. Therefore, it is stricter than the rules established by income customers must be made and secured to the private sector from the public.

For the risks of cost overruns must first perform a literature review that includes the study of projects in other countries, which have already been detected, analyzed and categorized into different kinds of risk.

From this shortlist of good risks reported in past studies must make a selection to identify which of all these risks, literature, are more relevant to the national level, for social infrastructure and for future allocation and quantification. In this order of ideas, the dispute moves to identifying the risks of cost overruns, in which engineering risk, bad weather, public policy and others are included.

It is important to emphasize "systematic risk management enables early detection of risks and encourages PPP stakeholders to identify, analyze, quantify and respond to the risks and take measures to introduce risk mitigation policies". (Akbiyikli & Eaton, 2004) An approach to the screening of the risks presented by a project under the PPP mode evidence is presented in Table 2. This identification work is summarized from a literature search to a selection process through a multi-criteria selection or MAUT.

For this selection we should identify the different risk categories that mainly influence the risks associated with operating, legal risks, risks from natural events, risks of social and cultural factors and uncontrollable risks from macroeconomics. All these groups are going to have in all events associated with cost overruns.

To establish the risks to be assessed, quantified and assigned, a project must recognize the principles and factors that influence the equitable allocation of risks APP Projects (Xu, Yeung, Chan Chan, & Wang, 2010). It must be taken into consideration that this identification affect either medium or long-term economic stability of the project, the strength and the tax base and the scope and impact of the project.

Once the pre selection has been made based on "best practices" and review of the literature, a technical level review must be conducted by a panel of experts to verify the validity of these risks on projects associated with the national situation. For which they should introduce a series of questions in order to verify which of the identified groups has greater influence on each project to be assessed. The experts will give a quantitative value from 1 to 5, where 1 corresponds to a group that does not have any influence and 5 to a group that strongly affects the project. Following this evaluate each event affects both identified belonging to the group using the same quantitative criterion.

Once these subjective values have been stablished, because they come from a personal opinion a fuzzy logic validation should be performed. This will lead us to find the value associated with the vulnerability of the project to each event and risk group using the methodology of "defuzzification" of barycenter's. With the previous result we will know what are the real risks to be considered for allocation. This identification process should be a part of a database that both the public sector and the private sector have for any project, whether it is a school, a hospital, a highway, or a government building.

3.5 Assignment: Application of fuzzy logic in the current model

The mapping process should be run from an academic background in order to ensure the validity and transparency of the risk equitably. Therefore the first thing to be done is to find patterns and mapping projects in other countries, such as assuming a theoretical panel of experts. It will assess and identify at least 10 times the allocation of a specific risk for other projects in order to have a representative base dice.

This process should be performed observing projects corresponding to the same type of infrastructure. Once you have this review, the result of this will be taken into account as part of the real expert panel, consisting of engineers, economist, and administrators. This new panel of experts should, in its sole discretion, assign to 1-5 risk to each party; 1 corresponds to a whole risk associated with the public sector, the value 5 corresponds to an assumed entirely by the private risk and a value of 3 corresponds to a risk assumed alike. (Chang, Jimenez, McAleer, & Pérez, 2011)

The validation of these opinions will be performed using fuzzy logic. Using the centroid again reach a value assignment for each of the associated risks. Based on these opinions we will get the fuzzy number vertices. From there all alpha cuts are calculated.

The center of gravity, which in this case corresponds to the value 1.87, is calculated. Corresponding rule 3 to approximately 80% allocation for the public sector and 20% private. Once the academy has reached a value of allocation should be socialized with stakeholders. Each party must be able to assume the risk percentage by value of quantification.

3.6 Measurement: Application of fuzzy logic in the current model.

Once the assignment has been made, you begin to speak of retained risk (public sector) and transferred risk (private sector). At this time, the current methodology introduces the concept of public private CPP or comparator. This is an element of analysis of revenues and costs required by law and regulated by the National Planning Department in 2014.

Measurement, attempts to quantify the impact that affects the cost of the project investment. For this you must keep in mind two scenarios: the first one is where it is assumed that the risk does not occur and where the expected value of the project cost is about zero. In the second scenario, the risk occurs with an estimated probability and the associated loss is a factor (fraction) between zero and one of the investment cost (CI). Therefore, the value associated with the project cost overrun in a given risk, taking into account the two scenarios is equal to the product of the probability factor and together with IQ. (Ministry of Economy and Finance of Peru, 2014)

E (on cost) = β * P * CI (occurrence of risk)

However there will always be controversy about the factor to use for each risk and the likelihood of risk. These values, according to the methodology proposed must be extracted through two processes. The first is the review of projects, previously selected and classified according to their type, which will form a guide of good practices that will be the starting point of our analysis. First you should evaluate projects from different countries to Colombia with great power in the field of infrastructure projects PPP mode. These countries are Chile, Mexico, Peru, United Kingdom, Australia and China, as they have found in this investigation.

Analyzing these projects should find the rate of occurrence of each risk assigned. Likewise you have to keep track of the percentage cost overruns on each CI I entail. Once the data is available, and the sample is representative for the type of project to be analyzed we should perform a statistical analysis to see the spread of the data and to validate them. Once this analysis is obtained and data validity checks, these are modeled on fuzzy numbers, following the model presented in the allocation. Subsequent to this review, you should check for similar projects already undertaken at the national level. If there is need to perform the same analysis with external projects.

Now the second process for risk measurement is performed through a panel of experts. Which must establish a professional approach and an analysis of the project it is the probability of occurrence of risk and budgetary factor involvement. These subjective values of each expert be validated by fuzzy numbers. They also correlate with those found in the literature search. In order to reach a unified consensus value range of each parameter.

Now this expected value should bring this value to perform the proper analysis taking into account the value of money over time. However, this discount rate with which it is done must be projected inflation. This process must also find the factors of each risk analyzed in order to determine patterns of error. These error patterns form the guide of good practices for projects in Colombia.

4 Conclusions

A base for future development of the country lies in the development of its infrastructure. There is currently a strong impetus to the construction of road infrastructure; however it is necessary to encourage private and public initiative towards the implementation of social infrastructure projects. A fundamental part of this is the regulation of identification standards, allocation and measurement of the risks associated with such projects. Colombia currently has no specific and clear rules to regulate the methodology of these three concepts. Therefore an approach to a new equitable and transparent methodology for risk management does believe that Colombia could become one of the most developed region in terms of social infrastructure countries.

Finally, it is up to the academic to be the mediator in all the interests of both parties (public and private). Fuzzy logic, like many academic data validation tools can handle capturing subjective data, which is necessary for these cases. To achieve a correct and complete risk management public-private partnerships would be the main engine of social development in the country for the coming years, as seen from the construction sector.

Abstract

The implementation of Public-Private Partnerships (PPP) has provided an opportunity to cover the need for investment on social and economic infrastructure. The success achieved with the development of PPP projects on countries such as Australia and the United Kingdom, has established a significant start point for countries like Singapore, China and Mexico. International experience and many studies have identified that the viability and success of PPP projects in social infrastructure depend on two main factors: a strong public policy and adequate risk management among participating parties. This research presents a methodological proposal for risk allocation in social infrastructure projects in developing countries, adapted to the especial characteristics of the Colombian context, partially filling the existing gap in scientific literature. This paper is divided in two parts. First, the authors argues the benefits of creating, and establishing a national public policy based on the legal implementation and development of PPP projects in the pursuit of economic, social and environmental prosperity. Finally, this study presents a proposal for the creation of a reliable and practical model to achieve an adequate risk allocation for social infrastructure, based on the selection of 17 critical risks using the multi-criteria decision method and the design of a structured interview for experts in different contexts.

Keywords: Public-private partnerships, social infrastructure, risk management, national strategy

1. Introduction

The scheme of Public Private Partnerships (PPP) has been presented as an opportunity to bridge the gap of infrastructure deficiency without compromising national resources, obtaining more efficient and higher quality projects. Especially, PPP is the provision of a public service by a distribution of responsibilities and risks between a public actor and a private actor. Since its implementation in 1992 in the UK, 193 countries around the world have implemented and accomplished projects under this scheme (Chou & Pramudawardhani, 2015). This worldwide application of PPPs has been used in a variety of projects ranging from energy supply projects (Pongsiri, 2004), to telecommunications and subsidized housing (Efficiency Unit, 2003). However, given its complexity and nature, its implementation has not always been successful.

One of the main causes of failure is the improper risk allocation management. (Efficiency Unit, 2003).

The implementation of PPP schemes in emerging economies has been slow due to diverse political, social and economic factors. In Latin America it has been specially difficult as a result of: (a) political instability in the region, (b) the challenging assimilation process of changes to the traditional status-quo, especially given to the presence of private operators in the provision of public services, and (c) the high risk premiums demanded by private participants in the development of projects due to high initial investments, distant cash flow incomes and the country economic risk (Engel, Fischer, & Galetovic, 2008).

Although there are many studies in risk management for PPP, in the analyzed literature, no studies were found which evaluated the risk allocation for social infrastructure in developing countries. Therefore, to partially fill this gap, the authors propose a risk allocation methodology for social infrastructure projects in developing countries, adapted to the Colombian context.

This exploratory research is divided in two stages. The first one follows a PPP qualitative approach which is based in a comprehensive review of related literature and the identification of the most relevant risks in the PPP projects. Stage two follows a quantitative approach for risk identification thoroughly an analysis of the Colombian context. The risk selection process was conducted through two steps. (1) Pre-selection of most relevant risks in literature choosing those that appeared in 5 or more studies. (2) A final selection was made by the method of Multi-Attribute Utility Theory MAUT. For each risk, 5 criterions were analyzed and objectively quantified when possible and subjectively qualified by experts on a scale of 1-9: (A) Scientific literature relevance. (B) National impact, (C) Applicability to social infrastructure (schools, hospitals, government buildings, plant sewage treatment, etc.), (D) Public-private relationship and allocation, and (E) Value For Money (VFM) impact (Economic viability for the public sector). Finally, a proposal for risk assessment is made to allocate the identified and qualified risks.

To introduce this proposal properly, section 2 deals with the advantages of PPP as a strategy for growth and improved competitiveness and the specific issue of social infrastructure development. Section 3 illustrates the state of the art for risk management in PPP. Section 4 gives an introduction to the Colombian context. Section 5 exposes the proposal of risk allocation and finally conclusions, limitations and future extensions of the research are drawn.

2. Public Private Partnerships

The collaboration between public and private sector has been materialized in the concept of Public-Private Partnerships (PPP) that are related to the contractual cooperation between public authorities and various private agents to achieve objectives for the public goods provision and its corresponding services. According to the World Bank (2012), PPP have four characteristics and relevant principles: a) Projects with a long-term development, b) Private investors participates in the financing of the project, c) The private investors is responsible for the infrastructure maintenance and operation, d) The relationship between the public and private parties must establish an appropriate risks distribution.

There are three advantages in PPP contracts implementation (CAF, et al., 2010): a) Technical innovation due to the competition between proponents and the inclusion of the private agent in the design, construction, financing, maintenance and operation of the project, b) The private sector investment in social infrastructure set free the public budget for other types of investments, c) Improvement in the project quality due to strong monitoring and evaluation from public institutions.

However, the main opponents of the PPP procurement system identifies two disadvantages for its execution (CAF, et al., 2010): a) PPP transaction costs are higher than transaction costs generated by traditional public project, b) The PPP require greater financial cost compared to a public project financing through public project.

National infrastructure, both physical and digital, is an important instrument of social interconnection (CAF, et al., 2010). It has the ability to integrate space, improve accessibility and make certain the equality on populations. A good infrastructure guarantee of international competitiveness, job creation and economic stability. Yescombe (2007) Identified two infrastructure types: a) Economic: Describe all assets or property that aims to provide a function and economic activity. E.g. road, canals, and railroads, b) Social: Infrastructure dedicated to provide a public service with social purposes. This projects are usually smaller in scale and, therefore, tend to be complex, given the close and ongoing involvement with the community (Jefferies & McGeorge, 2009).

There is a confrontation of opinions on the purpose of carrying out projects under the scheme PPP. For example, Leone (1999) establishes that PPP projects are a "words game" created by the leaders to hide the privatization of assets and present an "attractive idea to the voter's minds". On the other hand, McGeorge (2009) establishes that PPPs are a funding mechanism for the public sector where the private sector assumes responsibilities and risks. Although the discussion is also presented in economic infrastructure, the development of PPP projects in social infrastructure increases and amplifies the discussion. This is mainly due to the presence of a private operator in the provision of public services which are directly related to the person, because it makes it particularly difficult to accept by the user and citizen. Jefferies & McGeorge (2009) identify this discussion as one of the primary constraints to the development of PPP projects in social infrastructure as "private-sector bidders are often presented with a situation where the financial rewards are less and the operational demands are more complex than for hard economic PPP projects".

3. Risk management in PPPs

As mentioned by Seldon Global SC (2014) , "the key to understanding the role of risk in a PPP is the link between the way in which the risks are managed and the degree of efficiency achieved in the projects". The development of a public-service project whit private participation requires it to assume certain responsibilities to ensure the quality and continuity of the service. The transfer of risk to the private agent is the most appropriate way that it assumes responsibility for the project development. However, this also means that the private sector have to effectively minimize their risks, get a maximization of economic benefit, considering that the materialization of risks results in high costs and potential economic losses. Accordingly, risk quantification and allocation determined the economic viability of the project and the benefits obtained by the government for developed the project through the PPP scheme. Therefore, as shown, risk management plays a key role in all stages of project development, from planning to operation and maintenance.

Cases such as Indonesia and Thailand, reflect the importance of proper risk management. In those, the increase in economic rates, regulatory changes and land acquisition did not allow the private party development the project properly and the project had high economic costs and created absolute mistrust between participating sectors (Ogunlana, 1997). On the other hand, cases such as Hong Kong and the United Kingdom are a clear example of successful implementation of the PPP scheme, Bing, et al (2005) argued that the high success rate of PPP in the UK was due to effective risk allocation caused by the properly communication between the parties involved on.

Finally, risk management defines competitive advantage of a private proponent within the local market. Basically, experience, innovation for cost reduction and the perception of risk assumed by the private agent are the factors that will define the competition for the development of a proposal for allocation risk in social infrastructure PPPs.

4. Colombian context

Latin America and the Caribbean have shown an increasing economic growth since the beginning of the millennium, demonstrating its solid growing potential. This is often encouraged by the development of infrastructure projects as it provides the means for increasing national competitiveness and directly improves employment rates. The growth rates of these emerging economies reached 10.5% and 9.0% respectively (Inter-American Development Bank, IDB, 2008).

In the Colombian context, the National Competitiveness Report (Private Council on Competitiveness, 2014) shows a current worrying situation in the country weakening from 68th place among 139 countries to 66th place among 144 countries. Despite the successful growth of the Colombian economy in the last decade and the implementation of programs of social and economic development (seventh place in Latin America), Colombia is so far away from the goal set for 2032, in which it was intended to be the third most competitive economy in Latin America. This may be the evidence that the country is in a development stage and that the infrastructure development instruments have not been appropriate to achieve a more competitive economy.

The most concerning issues the country should focus on, obtained from the Private Council on Competitiveness (2014) are: a) Health and elementary education: In this issue Colombia has fallen 26 places since 2010 and is currently ranked 105th worldwide and 14th in the region. As mentioned above, human capital is one of the bottlenecks in productivity in Latin America, especially in Colombia. For example, the coverage of elementary education is a great concern. That is to say, it is not just a quality problem regarding teachers training, it is also educational infrastructure coverage, access to it and therefore, financing of it. The main issue with the health system is it is difficult to access and of low quality. b) Efficiency of the employment market: The country is currently ranked 84th worldwide (15 places down from 2010), this element is directly related to regulatory and legal subjects around minimum wage laws and tax issues. c) Infrastructure: The country is currently ranked 84th in the world in reference to this issue, with more than 30 stalls difference with Uruguay, the country with the third most competitive infrastructure in Latin America. Beyond the lack of road, rail, port and airport infrastructure, Colombia has deficiencies in sectors such as energy supply, where it is identified that the main constraints are the efficiency of the industry and regulation of the sector. Nowadays it is developing the structure of the fourth generation of road concessions, where it is expected to reduce the deficit of road infrastructure. d) Innovation: This pillar has lost 12 positions, reaching 77th place in the world and ninth out of 13 Latin American countries in 2014, this is worrisome because the country has 346 investigators per million of citizens. According to the World Management Survey (World Bank, 2014), the country is the worse qualified in terms of quality management in Latin America, the central problem of this issue is the absence of a medium and long-term public policy. According to the Private Council on Competitiveness, "the country still lacks an effective structure that allows to align the different public and private stakeholders in initiatives that generate productivity and sophistication of national production through the use of local competitive advantages” (Private Council on Competitiveness, 2014).

Devlin and Moguillansky (2009) identified different countries that achieved during 2003 to 2012, closing the income gap compared to richer countries in more than ten points. This was the case of Spain, Finland, Ireland, Korea, Singapore, Australia and New Zealand. Despite their difference, several important similarities for obtaining these national achievements in economic progress were identified. Mainly, the remarkable development of these countries has its basis in the formulation and implementation of a strategy in the medium and long term to promote accelerated production change. That means, establishing lines of action with specific objectives to determine and achieve international integration of the country, reduction of poverty and increased productivity, and therefore increased competitiveness. These strategies can be based on the development of multi-year plans that should have the following priorities: a) Economic stability, b) Robust tax policy, c) Solid investment rates, d) International dynamic, e) Innovation and human development, f) Conservation of national practices.

Hausmann, Rodrik and Velasco (2006) identified that due to market failures, these strategies tend to be selective because governments have limited resources to carry out projects, programs and promote resources for development. Moreover, unlike the nineteenth century where the public sector were the main sponsor of the market, nowadays the private investments dominates the production sector. Therefore, the development of countries requires cooperation between the public sector and the private sector, which allows them to "get the opportunities of social benefits and resolve the primary constraints of new productive activities" (Devlin & Moguillansky, 2009). Through a PPP scheme, the public sectors could get involved in a partnership with private sectors for the development of infrastructure.

5. Proposal for risk assessment for social infrastructure PPPs in Colombia

The proposal for risk assessment is divided into two stages. The first one stage is the risk identification and selection for the assessment process. The second stage is the proposal for risk assessment.

5.1 Risk identification and selection

Multiple previously studies have concentrated its efforts in identifying, measuring and mitigating risks process involved in developing projects through PPP. For example, Bajaj, Oluwoye, & Lenard (1997) focused on analyzing the methodologies used for identifying risks. They found the most commonly method used was the top-down strategy. This analysis makes a hierarchical list based on stages, each stage more detailed than the previous one. Another frequent method is the brainstorming process as a system for the risks identification and quantification, in which staff involved experienced engineering and senior officer’s judgment (Baker, et al., 1999). Similarly, other authors such as Bing, Akintoye, & Edwards (2005) , and Heravi & Hajihosseini (2013) have focused on summarizing the positive and extensive experience of countries like Australia, India and the United Kingdom respectively. Recent studies as those conducted by Chan, et al (2011), Hwang, et al (2012), and Wang, et al (2004) based the development of their research in countries that are just implementing the PPP scheme as China, Singapore, and developing countries such as Chile and Mexico. These researches reach similar conclusions about the need for a risk allocation model on PPP projects implementation. To achieve a risk allocation model, they run the methodology used by Bing, et al (2005) . This development is based on a questionnaire of three sections. In the first part is evaluated the personal knowledge about the PPP subject and its influence and membership within the construction industry. In the second section it is established the risk assessment asked. This is done through an evaluation system 1 to 5, wherein the scale represents: 1 = totally assumes the public sector, 2 = mostly assumes by the public sector, 3 = equally shared by public- private, 4 = mostly assumed by the private sector and 5 = fully assumes by the private sector. As a result from the preview studies, 72 risks in PPP projects were initially identified.

After the risk identification from literature review, a specific selection process was conducted through two steps:

Pre-selection from repetition in previous studies: the type of risks that had been previously studied in different countries was analyzed and summarized by recording the frequency in which each risk appeared in one of the studies identified. The risk that appeared in more than 5 studies was pre-selected. Thus, 27 definitive risks where selected to be quantitatively categorized.

Table 1: 72 Risks identified on the literature review

RA1	*Unstable government*	*RA19*	*legal/regulatory framework*	*RA37*	*High finance costs*	*RA55*	*Technological risk*
RA2	*Expropriation of assets*	*RA20*	*contract variation*	*RA38*	*Residual risk*	*RA56*	*Operation default*
RA3	*Poor public decision-making*	*RA21*	*Immature juristic system*	*RA39*	*Delay in project approvals*	*RA57*	*Organization and co-ordination risk*
RA4	*Strong political opposition/hostility*	*RA22*	*Improper of contract*	*RA40*	*Design deficiency*	*RA58*	*Inadequate distribution of risks*
RA5	*support from government*	*RA23*	*standard model for agreement*	*RA41*	*engineering techniques*	*RA59*	*distribution of authority*
RA6	*Corruption and bribery*	*RA24*	*Inability of concessionaire*	*RA42*	*Scope variation*	*RA60*	*Differences in working method*
RA7	*Government's intervention*	*RA25*	*private provision of public services*	*RA43*	*Workmanship*	*RA61*	*Lack of commitment from either partner*
RA8	*Government's reliability*	*RA26*	*Level of public opposition*	*RA44*	*Construction cost overrun*	*RA62*	*Private investor change*
RA9	*government support network*	*RA27*	*Market demand change*	*RA45*	*Construction time delay*	*RA63*	*Third Party Tort Liability*
RA10	*Termination of concession*	*RA28*	*Force majeure*	*RA46*	*Material/labor availability*	*RA64*	*Staff Crises*
RA11	*Inflation rate volatility*	*RA29*	*Geotechnical conditions*	*RA47*	*Poor quality workmanship*	*RA65*	*Competition (exclusive right)*
RA12	*Interest rate volatility*	*RA30*	*Weather*	*RA48*	*Insolvency of sub-contractors*	*RA66*	*Tarif change*
RA13	*Influential economic events*	*RA31*	*Environment*	*RA49*	*Site safety and security*	*RA67*	*Payment risk*
RA14	*Foreign exchange and convertibility*	*RA32*	*Land acquisition)*	*RA50*	*Operation cost overrun*	*RA68*	*Lack of consortium expertise*
RA15	*Financial risk*	*RA33*	*Uncompetitive tender*	*RA51*	*Operational revenues*	*RA69*	*Subjective evaluation*
RA16	*Legislation change*	*RA34*	*experience in PPP projects*	*RA52*	*Low operating productivity*	*RA70*	*Insufficient financial audit*
RA17	*Change in tax regulation*	*RA35*	*Availability in finance*	*RA53*	*Maintenance costs higher*	*RA71*	*Construction/operation change*
RA18	*Industrial regulatory change*	*RA36*	*Financial attraction*	*RA54*	*Maintenance more frequent*	*RA72*	*Intellection property*

Final selection, Multi-Attribute Utility Theory MAUT: Each risk was analyzed on the basis of 5 criterions, objectively quantifying them when possible and subjectively qualifying them by a pool of 6 experts in a focus group session. A percentage weight was assigned to each criteria and each risk was evaluate against every criteria through a scale of relevancy 1 to 9.

A. Scientific literature relevance: frequency of appearance previously outlined was taken into account. For this criteria was defined a weight of 25%.
B. National impact: each risk is placed within the national context. That is, the applicability to the reality of the Colombian construction industry is sought. For this criteria was defined a weight of 10%.

C. Applicability to social infrastructure: In this criterion is evaluated the degree of risk for the development of social infrastructure projects such as schools, hospitals, government buildings, plant sewage treatment, etc. For this criteria was defined a weight of 20%.
D. Public-private relationship and allocation: This criterion aims to capture the concerns about risk allocation. That is to say, questions whether the risk has a tendency to be adopted by default to any of the (public or private) agents or risk allocation is a real unknown quantity. This section was given a special importance because these are the risks that the study aims to concentrate. For this criteria was defined a weight of 20%.
E. Value For Money (VFM) impact (Economic viability for the public sector): Since the risks are significant in the economic analysis of the project and the VFM, it is taking the economic risk into the account associated with each risk. For this criteria was defined a weight of 25%.

After this evaluation, the importance of each risk was calculated as the sum of the multiplication of the percentage weight by the scale of relevancy. Thereafter, the average of the all risks weight was determined. Finally, 17 risks were located over the average and these were selected as the most relevant risks that affect the successful implementation of PPP on the issue of social infrastructure projects these risks are presented in Table 2.

5.2 Risk assessment proposal

Most of the studies reviewed based on the generation of a questionnaire which is directed at people with experience in the construction industry, in the public sector, private sector and academy. However, the main problem of these questionnaires is the low response rate. Roughly, the response rate is around 20% and 40% (Akintoye, 2000). Consequently, the amount of sent questionnaires needed for effective data analysis represents a serious problem. Additionally, it is not always possible to guaranty the reliability and quality of responses. Therefore, it is often proposed to conduct a number of structured interviews to characters with high experience and knowledge on PPP in the specific context where the risk management process is taking place.

The interviews have to be made to PPP experts from the academia, public sector and private sector. The involvement of academia is essential. As manifested Osipova & Erikson (2013), the best method to achieve agreement on the management of risk is with the incursion of the academic world to determine an optimal method where several opinions about risk management, are combined. Likewise, it is important to involve some private sector agents and governmental organizations who have exercised the function of regulatory body of the PPP's. Within the national framework, it is suggested the involvement of the National Planning Department, the Ministry of Finance and the Ministry of Education.

The interview will be divided into three stages, such as the questionnaire division given by Chou, et al. (2012):

The first stage involves a socialization and context with the interviewee. Initially, it will be explained to the person to conduct the study, the objectives, the methodology followed in the interview and the importance of the study. Similarly, in this part some specific data will be asked to the interviewee to evaluate the credibility of his answers in the following stages. The necessary data to request are: Sector in which works (public, private or academic), and years of work experience in construction projects and projects under PPP mode.

Table 2: Selected risks

Risk	***Group membership***	***Definition***
Expropriation of assets	*Governmental*	*Given political, social or economic pressures, the government take ownership of the project without proper compensation to private.*
Corruption	*Governmental*	*Selection and development of projects under illicit schemes and decisions to promote other interests.*
Inflation rate	*Macroeconomic*	*Unexpected and significant changes in interest rates and inflation, due to immature economy and a local non-consolidated market.*
Interest rates	*Macroeconomic*	
Legislative changes	*Legal*	*Vulnerability to a change in government regulations, including tax policies, which affect income or established project costs from the viability stage.*
Tax regulation changes	*Legal*	
Demanding market	*Social*	*Inadequate methods for determining demand stage project operation and maintenance requirement.*
Environment	*Environment*	*Public regulation with high requests on the environmental impact of the project.*
Land acquisition (availability)	*Project selection*	*Difficulty in time and / or costs to acquire the land needed for the project.*
Residual risk	*Residual*	*It reflects the probability of finding unexpected adverse situations.*
Delay in project approval and permits	*Residual*	*Difficulty in obtaining documents required for a legal framework for the proper development of the project.*
Operation cost overrun	*Operation*	*Higher costs than expected in the operation stage.*
Public private coordination	*Operation*	*Lack of coordination and coherence between public and private.*
Low experience in PPP projects	*Project selection*	*Low national experience in the development of social infrastructure projects under PPP scheme.*
Absence of a legal framework.	*Legal*	*Inappropriate or contradictory legal framework to the development of projects under PPP scheme.*
maintenance costs	*Operation*	*Higher than expected costs in maintenance of assets.*
Technological risk	*Operation*	*Project vulnerability to technological disadvantages and therefore the presence of a constant need to update.*

The second stage involves the assessment of previously identified risks. To perform this method, three important aspects must be considered. First, a dictionary of risks to ask must be prepared if the respondent does not easily recognize the applicability of risk in a PPP project. Second, it is recommended that the respondent, with the aim of further analysis, give an opinion about the role of these risks in social infrastructure and economic infrastructure. To facilitate this discussion, the risks should be asked in the context of an important project (hypothetical or real) in public politics. That is an important current project is introduced like a complex of schools or hospitals and it is compared against the development of a concessioner highway. Finally, assess their responses on a scale of 1-5, where the scale represents 1 = totally assume for the public sector, 2

= most assumes for public sector, 3 = equally shared by the public and private sector, 4 = assumed mostly by the private sector and 5 = fully assumes the private sector.

The last step is a final stage of completion where it is located different questions related to the future of PPPs in social infrastructure. For example, you can ask:

· What is the next step for PPPs in social infrastructure evolve?
· Do you believe that PPPs in social infrastructure will become of the magnitude and importance of the concession highways?
· How important is the PPP scheme to satisfy social public policies?

6. Conclusions

This study is divided into two parts. In the first part, the benefits of the implementation, develop and evolve of PPP contract scheme is exposed. Beyond the typical discussion of PPP efficiency gains and cost reduction, this study defines PPP as a government instrument to carry out projects of national importance. Given the nature and characteristics of the projects, PPP acts as a central hub for the establishment of a national policy in the medium and long term, which seeks an economic, social and environmental well-being and, ultimately, an axis of development and productive transformation.

The last part analyses the importance of risk management and the role of risk allocation through international experiences of private investment in social infrastructure. Formerly a proposal for the process of risk allocation for social infrastructure projects in Colombia is developed. In order to do so, an extensive literature review about the risks involved in the development of PPP projects was made. In this research, a list of 72 risk was obtained on the basis of their relevance in reviewed literature and subsequently narrowed down to 17 critical risks using multi-criteria analysis. Five evaluation criteria were used: frequency of appearance in reviewed literature, national impact, criticality in social infrastructure, public-private definition and economic impact.

Lastly, an expert opinion evaluation to effectively allocate risks is suggested. Given the low response rate of questionnaires, the development of semi-structured interviews to a selected group of experts from the industry, the public sector and the academy is proposed as an alternative.

For the purposes of validating and enhancing this model, it is suggested that further research focuses on the selection of a representative project sample in Colombia to implement the risk allocation process proposed in this research and evaluate the feasibility of the development of this type of projects under the PPP scheme on the basis of the concept of Value For Money. The resultant adjusted proposal should be implemented in Colombian social infrastructure policies.

Clients' Perception on Risk Sharing in Construction Projects

Md Motiar Rahman,
Universiti Teknologi Brunei
(Email: motiar.rahman@utb.edu.bn)

Noor Hadijah Hj Abd Hadi,
Universiti Teknologi Brunei
(Email: hadijah.hadi@utb.edu.bn)

Abstract

Risk Sharing is a concept of equitable allocation of identifiable and quantifiable risks at pre-contract stage, followed by their dynamic management at post contract stage, for which general/flexibility provisions should be made in the contract conditions, because not all risks are foreseeable/predictable and/or quantifiable at the planning stage. Moreover, risks may change with project progress: some risks may become more critical, some other risks may disappear, while some other risks may need some degree of joint efforts of contracting parties for their effective management. The objective is to minimize the risk and total cost of risk to a project, not necessarily the costs to each party separately. On the basis of such conceptualization, the present paper summarizes the outcomes of a questionnaire survey that examined the perceptions of 48 respondents from construction clients in Brunei on present and preferred sharing of 28 common risk items, as well as the criticality (or severity index) of those risk items in terms of their importance and frequency of occurrences. The respondents have considerably differing perceptions of risk allocation, with extreme divergence in most of the risk items. Despite such divergence, respondents have demonstrated a general enthusiasm towards shared or joint management of risks as they opted for about 18-53% of expected shared risks. Three risk items were identified as 'most important' in terms of their importance index, with the most of the remaining risk items are 'more important'. No risk item was verified as 'most critical', but most of the items were 'more critical'. Moreover, there seem to be no clearly identifiable relationship between the degree of risk sharing and critical index of the risk items. The outcomes are expected to allow the clients to better formulate construction contracts to effectively manage construction risks. It is also expected to further allow a better understanding of dynamic risk management and the need for proactive contracting in construction.

Keywords: Construction industry, proactive contracting, risk allocation, risk sharing, risk importance

1. Introduction

One of the principles of risk allocation is that the party best able to manage a risk should bear the risk. However, clients are seen to exculpate risks to contractors, especially in the traditional procurement regimes, without considering if contractors can manage those risks. Contractors too assume those risks, without considering if they can manage those risks, in order to do business, and survive (Ahmed *et al.* 1999). Obviously, contractors may better manage some of the risks, but clients may better manage some other risks, and some other risks may better be shared or managed jointly by clients and contractors. The goal of optimal risk management should be to (a) "minimize risk – whomever risk it may be" (ASCE 1979), and (b) minimize the total cost of risks to a project, not necessarily the costs to each party separately (CII 1993).

Construction risks are often project specific, and allocated to different parties through definitive contract conditions, on the basis of information available at the time of contracting. However, the nature and extent of such project-specific risks can only be realistically appreciated at later stages during the project execution. The nature and extent of risks may change along with project progress. New risks may emerge and existing risks may disappear or change in importance or be re-allocated. Any such changes may also ease or aggravate some other risks. Moreover, some of the risks may occur more frequently than some others, and some of the risks may have more impact on project objectives than some others. Some of these risks may also need to be shared between contracting parties or managed using the combined efforts of contracting parties for their effective management. Therefore, proper and exhaustive allocation of risks cannot be achieved through contract conditions alone. Instead, what needs to be done, is to equitably allocate all identifiable and quantifiable risks at pre-contract stage, on the basis of available information. This needs to be coupled with some flexibility crafted in the contract documents, in order to allow proactive appreciation of any changes to those allocated risks, identify any new risks, assess or re-assess them, re-allocate and/or share those risks and jointly manage them with the collaborative efforts of major contract parties at post contract stage, using a joint risk management (JRM) strategy, and as the situation requires (Rahman and Kumaraswamy 2002).

Two previous studies in this area were conducted by Hartman et al. (1997) in Canada, and Rahman and his collaborators in Hong Kong (Rahman 2003, Rahman and Kumaraswamy 2002, 2004). The Canadian investigation compared perceptions on present and preferred allocation of risk. In addition to that, the Hong Kong study addressed attitudinal aspects of contract parties towards the suitability of any shared parts of any risks leading to a probable JRM model. The present study goes further from these two studies and investigates both present and preferred risk sharing arrangements between client and contractor, as well as attempts to assess criticality of various risk items in terms of their frequency and impact on project objectives.

2. Methodology

The overall research project was designed with literature review, and two surveys. The present paper summarises the interim outcomes of the study, on the basis of first questionnaire survey, which was focused on respondents from cliental organisations only. The objectives of this paper are twofold:

- To compare the perceptions on present and preferred risk allocation between clients, contractors, and ‘shared’ between them; and
- To assess criticality of various risk items in terms of their frequency and impact on project objectives.

Data was collected using a structured questionnaire survey. The questionnaire was carefully designed to meet the above objectives, pilot-tested by two industry experts, and improved based on the opinions obtained from the experts. There were four sections in the questionnaire. Section One included an ‘introduction’ clarifying the risk sharing concept and solicited experience based opinions of the respondents. Section Two was designed to collect respondents’ information for the survey sample composition. Section three contained an inventory of 28 risk items. All the 28 risk items have been shown in their entirety in Tables 2 – 5. The risk items were mainly sourced from Rahman and Kumaraswamy (2002), but adjusted to suit local situations and to meet the opinions obtained from two experts during the pilot test. Most of the risk items that were identified and verified in this manner, are also commonly reflected in standard forms of construction contracts, since risks are allegedly allocated through the conditions of contract. The respondents were requested to reflect their opinions on the above mentioned 28 risks in terms of their perceptions of present and preferred risk allocation in conventional construction contracts, i.e. what percentage of a particular risk presently lies or they prefer to be:

1. with the client (X, from 0 to 100);
2. with the contractor (Y, from 0 to 100); and
3. shared between the client and the contractor (Z, from 0 to 100); in such a way that the sum of X, Y and Z equals to 100.

Section four contained the same 28 risk items and was designed to collect information on their frequency of occurrence and importance or impact, if they occur. Respondents were asked to assess and write scores on a scale from 1 to 5: 1 being the ‘least frequent/important’ and 5 being the most frequent/important. Additional spaces, to both the inventory of risk items in sections 3-4, were provided requesting respondents to add any risk items if they think important, and to assess the same. Moreover, blank space was also kept at the end of the questionnaire to allow the respondents to provide any comments / suggestion on effective risk management in general.

Public Works Department (PWD) of the government of Brunei Darussalam assisted in distributing the questionnaire to its officers and collecting the responses from them. As such, 48 responsive responses were received, with an average total work experience of 10.13 years, and average experience directly in construction of 9.38 years, as shown in table 1. This may relate to the quality of the data, as they are considered to reflect the experiential knowledge of the respondents. During the time of the survey, respondents were working on an array of positions, and with various kinds of managerial (e.g. project manager, assistant project manager, quantity surveyor, site supervision, and contract manager) and engineering type of responsibilities (e.g.

structural designer/ engineer, architects, architectural designer, and quantity surveyor). There were 17 engineering, and 29 managerial respondents. Two respondents did not mention their designation and/or nature of job. The data may therefore be considered to represent the public sector of Brunei, both in terms of coverage of works related to public services, and types of job, i.e. nature of experience of the responses.

Table 1: Summary of respondents' profile

Description of information	*Total sample*	*Engineering*	*Managerial*
Responses received	*48*	*17*	*29*
Average Total work Experience (years)	*10.13*	*9.38*	*10.57*
Minimum work experience (years)	*1*	*1*	*1.4*
Maximum work experience (years)	*27*	*25*	*27*
Average experience in construction (years)	*8.33*	*8.06*	*8.5*
Minimum experience in construction (years)	*1*	*1*	*1*
Maximum experience in construction (years)	*27*	*25*	*27*

3. Perception of risk allocation

Responses on risk allocation directly indicated the percentages of risk related to each risk item that is perceived to lie with the client, contractor and shared between them. The analysis was done by arithmetically averaging these figures for each risk item, separately within the total sample of 48 responses, as well as within each group based on nature of job (e.g. engineering and managerial). However, this paper presents summary results only, hence only the outcomes from the total sample are presented.

Table 2 shows perceptions of risk in percentage terms that presently lies with clients for the total sample of 48 responses, along with the respective standard deviations (SDs), minimum scores and maximum scores. It is seen that, except for the two risk items, minimum scores for all the risk items are zero, meaning clients are not allocated any risk on these items. On the other hand, 17 risk items have 100% scores, meaning clients have the entire amount of risks of those items. The maximum score of the remaining 11 risk items vary from 50% to 90%. On the whole 16 items have extreme divergence (i.e. minimum zero and maximum 100). Such diverse minimum and maximum scores produced averages from 19.0% to 52.1%, along with high standard deviations (SDs), which in turn also indicate a wide spectrum of responses. Although not shown here, similar pattern of responses (i.e. general diversity with extreme divergence on most of the risk items) was observed for the rest of the options on risk allocation, both for present allocation and preferred allocation. Such a widespread divergence within the same contract party (i.e. client) may relate to their superficial involvement in preparing and managing contracts, and resulting in to a kind of subconscious demotivation or disinterest, as consultants prepare and manage contracts for them. Such divergence may well arise from varied personal experiences and therefore highlight a need for cooperative learning as well.

Table 2: Average perceptions of present allocation of risks with clients (in % terms)

Risk ID	*Risk description*	*Average*	*SD*	*Minimum*	*Maximum*
F-01	*Acts of God/nature*	*39.7*	*35.2*	*0*	*100*
F-02	*Change in scope of work*	*43.9*	*23.2*	*10*	*100*

F-12	*Environmental hazards (project area)*	*39.7*	*28.5*	*0*	*100*
F-13	*Financial failure of client (Owner)*	*40.3*	*30.5*	*0*	*100*
F-14	*Financial failure of contractor*	*41.1*	*30.6*	*0*	*90*
F-15	*Indemnification and hold harmless*	*33.5*	*26.6*	*0*	*100*
F-16	*Inflation and exchange rates*	*25.3*	*27.4*	*0*	*90*
F-17	*Labor quota / problems*	*19.0*	*15.8*	*0*	*50*
F-18	*Availability of equipment*	*25.0*	*21.5*	*0*	*80*
F-19	*Labor and equipment productivity*	*17.9*	*17.8*	*0*	*70*
F-20	*Material and equipment quality*	*30.8*	*24.6*	*0*	*90*
F-21	*Permit and ordinance*	*26.2*	*21.5*	*0*	*100*
F-22	*Quality of work / Workmanship*	*49.7*	*32.8*	*0*	*100*
F-23	*Safety at site / Health & Safety*	*21.1*	*16.5*	*0*	*80*
F-24	*Site access upon contract award*	*36.5*	*32.6*	*0*	*100*
F-25	*Subcontractor failure*	*23.4*	*21.4*	*0*	*100*
F-26	*Third party delays*	*32.8*	*29.1*	*0*	*100*
F-27	*Unforeseen site/ ground conditions*	*37.1*	*19.6*	*0*	*100*
F-28	*Availability of materials*	*31.3*	*28.6*	*0*	*95*

Table 3 shows the difference between average ‘present shared’ allocation with that of ‘expected shared’ allocation, along with the ranks for differences in shared allocation. Negative sign indicates increase in allocation. All the risk items are seen to have increased in ‘shared allocation’ of varying degrees. Nine items (ranks 20-28) are seen to have increased shared allocation of risks by less than 10% only. However, 13 (ranks 7-19) items increased by 10-20%, and remaining six items (ranks 1-6) increased by 21-30%. These increases occurred from reduced expected allocation either to both parties; or to one party but with resulting reduced expected allocation.

Table 3: Comparison of present and expected risk allocation

Risk items	*Expected allocation*		*Difference between present and expected allocation*	
	Shared	*Rank*	*Shared*	*Rank*
F16: Inflation and exchange rates	*51.1*	*2*	*-24.5*	*1*
F15: Indemnification and hold harmless	*53.0*	*1*	*-24.2*	*2*
F02: Change in scope of work	*37.0*	*8*	*-23.8*	*3*
F05: Discrepancies / Conflicts in documents	*46.3*	*4*	*-23.8*	*4*
F27: Unforeseen site/ ground conditions	*39.6*	*5*	*-21.6*	*5*
F21: Permit and ordinance	*38.8*	*6*	*-21.1*	*6*
F13: Financial failure of client (Owner)	*35.5*	*9*	*-19.6*	*7*
F20: Material and equipment quality	*33.6*	*13*	*-19.5*	*8*
F28: Availability of materials	*33.4*	*15*	*-18.0*	*9*
F17: Labor quota / problems	*30.2*	*17*	*-17.6*	*10*
F03: Change order evaluation & negotiation	*34.7*	*10*	*-17.1*	*11*
F04: Changes in codes and regulations	*49.6*	*3*	*-16.0*	*12*
F22: Quality of work / Workmanship	*27.4*	*21*	*-15.0*	*13*
F09: Long lead time / Delay in payments	*30.6*	*16*	*-15.0*	*14*
F18: Availability of equipment	*27.3*	*22*	*-14.3*	*15*
F19: Labor and equipment productivity	*26.9*	*23*	*-13.9*	*16*
F24: Site access upon contract award	*28.7*	*19*	*-13.0*	*17*
F23: Safety at site / Health & Safety	*25.6*	*24*	*-12.1*	*18*
F25: Subcontractor failure	*24.0*	*25*	*-11.5*	*19*
F26: Third party delays	*34.7*	*12*	*-8.7*	*20*
F08: Defective design	*27.8*	*20*	*-8.4*	*21*
F06: Contractor competency	*28.8*	*18*	*-6.6*	*22*
F01: Acts of God/nature	*37.1*	*7*	*-6.3*	*23*
F12: Environmental hazards (project area)	*33.5*	*14*	*-5.8*	*24*
F14: Financial failure of contractor	*18.3*	*27*	*-5.1*	*25*
F11: Delays in resolving disputes	*17.9*	*28*	*-4.1*	*26*
F10: Delays in resolving contractual issues	*19.7*	*26*	*-2.9*	*27*
F07: Cost of legal processes	*34.7*	*10*	*-0.1*	*28*

‘Expected shared’ allocation of risks are seen to range from 17.9% to as high as 53%. On the whole, two risk items are seen to be shared by above 50%, two risk items by 40-50%, 13 risk items (ranks 5-17) by 30-40%, eight risk items (ranks 18-25) by 20-30% and three risk items are by less than 20% with the least one of 17.9%. Such a higher degree of expected sharing of risks may indicate respondents’ general enthusiasm towards joint management of risks in general, which might have been influenced by elsewhere, or simply form their consciousness. This may be indicative of attitudinal changes of the public sector towards embracing ‘modern’ contracts.

4. Criticality of risk items

Table 4 summarises the count of responses on ‘frequency of occurrences’ of the risk items that was asked in section four of the questionnaire.

Table 4: Count of responses on frequency of occurrence

Risk Items	*Count 1*	*Count 2*	*Count 3*	*Count 4*	*Count 5*
F01: Acts of God/nature	*13*	*14*	*9*	*10*	*2*
F02: Change in scope of work	*1*	*5*	*17*	*13*	*12*
F03: Change order evaluation & negotiation	*6*	*8*	*22*	*7*	*4*
F04: Changes in codes and regulations	*19*	*16*	*11*	*1*	*1*
F05: Discrepancies / Conflicts in documents	*3*	*13*	*15*	*14*	*3*
F06: Contractor competency	*3*	*7*	*20*	*14*	*4*
F07: Cost of legal processes	*12*	*18*	*13*	*3*	*1*
F08: Defective design	*7*	*15*	*18*	*8*	*0*
F09: Long lead time / Delay in payments	*1*	*2*	*20*	*19*	*6*
F10: Delays in resolving contractual issues	*1*	*12*	*21*	*11*	*3*
F11: Delays in resolving disputes	*3*	*11*	*22*	*11*	*0*
F12: Environmental hazards (project area)	*11*	*14*	*17*	*6*	*0*
F13: failure of client (Owner)	*22*	*8*	*13*	*3*	*2*
F14: Financial failure of contractor	*4*	*4*	*23*	*15*	*2*

Respondents gave their opinion on frequency of occurrences, and importance or impact on project objectives, of the 28 risk items on a scale from 1 to 5: 1 being the 'least frequent/important' and 5 being the 'most frequent/important'. As such, the column labelled with 'Count 1' shows the number of respondents who scored 1. Similarly, the column 'Count 2' shows the number of respondents who scored 2, and so on. As seen from the table, all the risk items have scores from 1 to 5, except a few. Similar pattern of responses was also received for 'importance or impact' of various risk items on project objectives, using the same scale of 1 to 5. For comparison purposes, all such responses were calculated in to a single representative score of 'frequency index' (FI) and 'importance index" (II) (Lim and Alum 1995) as:

Frequency (or Importance) Index = $(5n_5 + 4n_4 + 3n_3 + 2n_2 + n_1) / \{5(n_1 + n_2 + n_3 + n_4 + n_5)\}$

where,

- n_1 the number of respondents who scored 1 or "least frequent / important",
- n_2 the number of respondents who scored 2 or "less frequent / important",
- n_3 the number of respondents who scored 3 or "frequent / important",
- n_4 the number of respondents who scored "more frequent / important", and
- n_5 the number of respondents who scored 1 or "most frequent / important".

The above two indices were then converted in to an overall index called "Severity Index" (SI), by multiplying the frequency index and importance index. The severity index was used to rank the overall implication of each risk item on project objectives.

Severity Index = Frequency Index X Importance Index.

As used in this study, FI and II $\geq$ 0.8 was considered 'most frequent / important', between 0.60-.80 'more frequent/important', between 0.4-0.6 'frequent / important', between 0.2-0.4 'less frequent/important', and $\leq$ 0.2 'least frequent / important' or negligible. For SI $\geq$ 0.64 most critical, between 0.36-.64 more critical, between 0.16-0.36 critical, and $\leq$0.16 less critical.

Table 5 shows the above three indices of 28 risk items, along with their respective ranks, arranged in order of the rank of severity index. Health and safety, change in scope of work, workmanship and delay in payments are seen as the most frequent risk items with ranks from 1-4. These are also seen as the top-ranked risk items in terms of importance indices. At the bottom of the table, ranks of different risk items in the two category are seen closer, but not exactly of same rank. For example, 'cost of legal processes' ranks 25 as per its frequency index, compared to rank 26 as per importance index. 'Inflation and exchange rates' ranks 28 in both category, but 'permit and ordinance' ranks 22 and 25 respectively. Similar pattern is also seen around the middle of the table. Thus, both the indices may be taken to be considered to form similar pattern in terms of their ranks. However, their ranges are different.

For example, the range of frequency indices is 0.729 to 0.383, compared to importance indices of 0.854 to 0.525. However, 10 risk items are seen more frequent, 16 risk items are frequent, and only two risk items are less frequent. On the other hand, three risk items are seen as most important, 21 risk items are more important and four risk items are important. These resulted in to no risk item in the category of 'most critical', but 18 risk items as 'more critical' and 10 risk items are critical.

Table 5: Comparison of criticality of different risk items

Risk item	*Frequency*		*Impact*		*Severity*	
	Index	*Rank*	*Index*	*Rank*	*Index*	*Rank*
